Background: Immune checkpoint inhibitors (ICIs), as an emerging immunotherapy, have shown great potential in improving the prognosis of patients. Peripheral blood follicular helper T cells (Tfh), As a specialized T cell subset, Tfh cells play a pivotal role in humoral immunity. In the context of ICIs therapy, Tfh cells may have an important impact on the short-term prognosis of HCC patients by affecting the function of B cells and then regulating humoral immune response. However, the specific role of Tfh cells in predicting the efficacy of ICIs in HCC patients remains to be fully elucidated. **Methods:** This study aims to assess the prognostic potential of peripheral Tfh cells in HCC patients undergoing ICIs treatment.200 patients treated with ICIs for HCC in The First Affiliated Hospital of Fujian Medical University from Jan 2020 to 2023 were retrospectively selected as the study subjects. This study used flow cytometry to analyze peripheral blood lymphocyte subsets and cytokines.All treatment protocols in this study were conducted in accordance with the “Chinese Guidelines for the Diagnosis and Treatment of Primary Liver Cancer (2022 Edition)”. In clinical trials, the research team used lenvatinib and triplimumab targets specific diseases. Patients were followed up regularly every three months after starting treatment. During each follow-up visit, physical examinations, blood tests (including liver function, tumor markers, etc.), and imaging examinations (such as ultrasound, CT, or MRI) were performed to assess treatment response, disease progression, and any treatment-related

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

adverse events. **Results:** Patients were retrospectively analyzed, and those with improved conditions within six months post-treatment were classified as having a favorable prognosis (n = 86), while those with no remission, worsening, or death were grouped as having a poor prognosis (n = 114). C-reactive protein (CRP), interleukin-6 (IL-6), Tfh cell counts, and combination therapy were significantly associated with prognosis ($P < .05$). Multivariate analysis confirmed CRP, IL-6, Tfh cells, and combination therapy as independent predictors of short-term prognosis ($P < .05$), explaining 78.3% of the variation. The area under the curve (AUC) for Tfh cells in predicting prognosis was 0.902 (95% CI: 0.8567-0.9477), with 100% sensitivity and 80.70% specificity at an optimal cut-off of 1.995. Patients with high Tfh cell levels (≥ 1.995, n = 93) had a median overall survival (OS) of 5 months, significantly better than those with low levels (< 1.995, n = 107) whose median OS was not reached ($P < .05$). **Conclusion:** Tfh cells are an independent predictor of short-term prognosis in HCC patients receiving ICIs. High Tfh cell levels indicate a better short-term prognosis, offering valuable insights for clinical decision-making.

3253 | CHARACTERISTICS AND CLINICAL COURSE OF FONTAN-ASSOCIATED LIVER DISEASE (FALD)

Sumire Takano[1] Tomomi Kogiso[1] Motoyuki Otsuka[2] Makiko Taniai[1] Yousuke Nakai[1], [1]Tokyo Women's Medical University, [2]Okayama University Hospital

Background: In Fontan-associated liver disease (FALD), fibrosis progression and hepatocellular carcinoma (HCC) development in young patients are major concerns. Connective tissue growth factor (CTGF), produced by endothelial cells and platelets, plays a key role in fibrosis across various organs. We retrospectively analyzed the clinical features and progression of FALD and FALD-HCC, as well as the significance of CTGF in FALD. **Methods:** 1) Among FALD patients who visited our department between 2003 and 2025, 282 cases (140 males, 49.6%) were analyzed. Of these, 27 (9.6%) developed FALD-HCC (14 males, 51.9%). We examined their characteristics and clinical course. 2) Serum levels of full-length CTGF and its N-terminal fragment were measured using two detection antibodies targeting the N- and C-terminal regions. We assessed CTGF levels (via enzyme-linked immunosorbent assay) and liver fibrosis stage in 38 FALD patients. **Results:** 1) The median age at Fontan surgery was 4.7 years (range: 0.0–37.4), and at referral, 27.0 years (range: 6.4–61.4). HCC developed at a median age of 32.6 years, occurring 26.1 years postoperatively. The median laboratory values for FALD-HCC were: albumin 4.3 g/dL, total bilirubin 1.4 mg/dL, ALT 21 U/L, GGT 73 U/L, platelet count 13.8 $\times 10^4$/μL, AFP 39 ng/mL, and MELD-XI 11.51. Tumors were located in the left/right/caudate lobe (n = 8/12/1), and both lobes (n = 6), predominantly in the liver periphery. Tumor counts were single (n = 19), two (n = 3), and multiple (≥ 3, n = 5). Staging included stage I (n = 11), II (n = 9), III (n = 2), and IV (n = 5). HCC differentiation was well/moderate/poor in 3/1/4 cases, and fibrosis in non-cancerous liver tissue was F1/2/3/4 in 0/1/1/2 cases. Treatment included liver resection (n = 4), transarterial embolization (n = 6), radiotherapy (n = 6), proton beam therapy (n = 6), and systemic therapy (n = 2). Three patients received only palliative care due to liver failure. The 5-year survival rate for FALD-HCC was 55%, with six of seven deaths attributed to liver-related causes. 2) Full-length CTGF was significantly inversely correlated with liver fibrosis in FALD, while the N-terminal fragment increased with fibrosis progression. **Conclusion:** CTGF may be involved in fibrosis progression in FALD. FALD-HCC develops approximately 26 years after Fontan surgery and is associated with poor survival. HCC significantly affects prognosis, underscoring the need for surveillance strategies and preventive measures.

3254 | HISTOTRIPSY TO ACHIEVE LOCAL TUMOR CONTROL FOR LIVER TUMORS: A NATIONAL MULTI-CENTER STUDY

Chase Wehrle[1] Kevin Burns[2] Tarub Mabud[3] Ahmed Sayed Ahmed[1] Ahmed Sayed Ahmed[1] Mohamed Alassas[4] Tiffany Juarez[2] Jimmy Ton[2] Andrea Schlegel[1] Jaekeun Kim[1] Federico Aucejo[1] Evan Ong[4] Mikhail Silk[3] Brock Hewitt[3] David Kwon[1], [1]Cleveland Clinic, [2]Mission Hospital, [3]NYU Langone, [4]Swedish Hospital

Background: Histotripsy is a non-invasive, non-ionizing, non-thermal, ultrasound-based modality for treatment of liver tumors that received FDA clearance in October 2023. National studies have demonstrated favorable safety profiles, yet only isolated case reports have been published regarding oncologic outcomes after treatment. We aim to describe the ability of histotripsy to achieve local tumor control (LTC) for primary and secondary liver tumors. **Methods:** All patients receiving histotripsy since FDA clearance (Edison system, HistoSonics Inc) four institutions (two academic; two private practice) performing histotripsy who achieved at least 30 days active-follow-up were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

included. Cases were divided into palliative-intent and complete control, in which the treatment was intended to yield no-evidence of disease (NED) on radiographic imaging. 30- and 90-day follow-up are reported. Outcomes are reported according to the standardized imaging-guided tumor ablation criteria. **Results:** In total, 161 patients received treatment to 285 individual liver tumors. The most common treated tumor types were colorectal metastasis (CRLM, n = 84), cholangiocarcinoma (CCA, n = 52), neuroendocrine (NET, n = 48), breast (n = 34), pancreatic (PDAC, n = 32), and hepatocellular (HCC, n = 21). Treatment intent by liver tumor was palliative (n = 194, 68%) or complete (n = 91, 32%) intent.

Patients (n = 47) and tumors (n = 91) intended for complete treatment were assessed for complete tumor response, or radiologic non-viability. At 30-days, 95% (n = 86/91) of treated liver tumors were radiographically non-viable. Two patients received repeat treatment between POD30 and POD90, both converted to complete response after the second treatment. Thirty-two patients receiving treatment for 62 tumors achieved 90-day follow-up. Of these, 30 patients (94%) and 60 tumors (97%) achieved complete tumor response in the liver. The two patients with viable disease had NET (n = 1) and CRLM (n = 1) respectively. We thus report a primary efficacy rate of 94% and a secondary efficacy rate of 97% at 90-days with no serious safety events reported. **Conclusion:** This preliminary data suggests histotripsy can achieve local control of liver tumors. Longer-term follow-up is needed to evaluate treatment durability.

3255 | CLINICALLY SIGNIFICANT PORTAL HYPERTENSION AS A PROGNOSTIC FACTOR IN CHOLANGIOCARCINOMA: A COHORT STUDY

Yingfan Chen[1] Yu-Jen Chen[1], [1]Division of Gastroenterology and Hepatology, Taipei Veterans General Hospital, Taiwan

Background: The clinical significance of cholangiocarcinoma (CCA) has grown in recent decades due to a notable rise in global incidence and mortality, especially for iCCA. While survival is influenced by various factors such as tumor stage and location, the prognostic impact of clinically significant portal hypertension (CSPH) remains under investigation. CSPH is associated with an elevated risk of cirrhosis-related complications, but its impact on cancer prognosis remains inconclusive. This study seeks to determine whether CSPH functions as an independent prognostic factor in patients with CCA. **Methods:** We conducted a retrospective cohort study of 841 patients with histologically confirmed CCA at Taipei Veteran General Hospital, Taiwan, from 2013 to 2024. CSPH was defined by the presence of at least one of the following: moderate ascites, esophageal varices, or splenomegaly with thrombocytopenia. Overall survival (OS) was analyzed using Kaplan-Meier curves and Cox proportional hazards models. Subgroup analyses were performed based on surgical treatment, tumor stage, and tumor location. **Results:** Among 841 patients, 194 (23%) met criteria for CSPH. Compared to patients without CSPH, those with CSPH were more likely to be male (64.9% vs. 57.0%, $p = 0.049$) and had significantly worse platelet counts (184000 vs. 224000/uL, $p < 0.001$), INR(1.14 vs. 1.08, $p < 0.001$), albumin (3.65 vs. 3.8g/dL, $p = 0.001$), total bilirubin (1.04 vs. 0.75mg/dL, $p = 0.001$), and higher FIB-4 scores (3.08 vs. 2.08, $p < 0.001$). Fewer patients with CSPH underwent surgery (26.8% vs. 38.3%, $p = 0.03$). After a median follow-up of 374 days, 293 patients died. Median OS was significantly shorter in the CSPH group (260 vs. 412 days, $p < 0.001$). Subgroup analysis revealed that CSPH predicted worse survival in both iCCA and non-surgical patients. **Conclusion:** CSPH is an independent predictor of poor survival in patients with CCA. It reflects compromised hepatic reserve and correlates with decreased likelihood of curative surgery. Incorporating CSPH into routine prognostic assessment may improve treatment planning. Further prospective studies are needed to validate these findings and explore therapeutic strategies targeting this high-risk subgroup.

3256 | BARRIERS AND FACILITATORS TO HEPATOCELLULAR CARCINOMA CARE COORDINATION AMONG HISPANIC PATIENTS AT A MULTIDISCIPLINARY CLINIC

JANAN LEPPO[2], MD; MARYAM ZAFER[1], MD; KELLI LIU[2], MD; EDMUNDO ESPARZA, MD[2]; JESSE NODORA[3], DRPH; ADAM BURGOYNE[4], MD, PHD; ZACHARY BERMAN[5], MD; YUKO KONO, MD, PHD[1], [1]UC SAN DIEGO DEPARTMENT OF HEPATOLOGY, [2]DEPARTMENT OF INTERNAL MEDICINE, [3]DEPARTMENT OF FAMILY MEDICINE AND PUBLIC HEALTH, [4]DEPARTMENT OF HEMATOLOGY AND ONCOLOGY, AND [5]DEPARTMENT OF INTERVENTIONAL RADIOLOGY. Janan Leppo[1] Maryam Zafer[1] Kelli Liu[1] Edmundo Esparza[1] Jesse Nodora[1] Adam Burgoyne[1] Zachary Berman[1] Yuko Kono[1] [1]UCSD

Background: Hepatocellular carcinoma (HCC) is among the fastest rising causes of cancer-related death in the U.S., with Hispanic patients disproportionately affected by late-stage diagnosis, fragmented care, and referral delays. A retrospective study at UC San Diego (UCSD) found that multidisciplinary clinic care improved treatment timelines, but Hispanic patients still entered care late and often with advanced disease. This study underpinned future efforts to explore barriers to and facilitators of cancer care coordination, particularly as they apply to timely referrals to specialty cancer care. To date, no qualitative study has explored experiences with cancer care coordination among Hispanic patients with HCC. **Methods:** We conducted 19 interviews with 14 Hispanic patients with imaging-or-biopsy confirmed HCC and 5 key informants. Participants also completed a brief survey in which questions were crafted to discuss barriers and facilitators in the referral process. Four additional key informants completed surveys only. All patients were seen at UCSD's Moores Cancer Center. Interviews explored referral experiences and systemic, cultural, and linguistic barriers. Certified interpreters supported interviews. Transcripts were coded line-by-line in Taguette, and themes and subthemes were developed using an inductive approach informed by grounded theory. Clinical and demographic data were collected by chart review. **Results:** The median age of patients was 69.5 years. Ten were referred from providers outside of UCSD. BCLC stages were as follows: 0 (n = 1), A (n = 7), B (n = 1), C (n = 5, D (n = 0). Five had decompensated cirrhosis. Twelve patients were treatment naive. Referral-to-appointment time averaged 35 days. Eleven patients primarily spoke Spanish. Ten had public insurance. From patient interviews, analysis revealed key themes including logistical barriers (transport, insurance), communication gaps (language, literacy), emotional responses (guilt, anxiety), and trust. From provider interviews, themes included system inefficiencies, administrative delays, provider-level knowledge gaps about when to refer, and patient disengagement linked to unclear communication. **Conclusion:** Patient and provider perspectives highlight key breakdowns in care coordination, ranging from incomplete referrals and missing imaging to limited comprehension and logistical barriers like language and transportation. Interventions should include standardized electronic medical record referral templates, streamlined record retrieval, bilingual navigation from the point of referral, and targeted outreach to enhance provider awareness of when and how to refer patients. Culturally responsive education and interpreter-supported scheduling should also be expanded upon. These strategies are critical to improving care coordination and referral efficiency, ultimately advancing equity in HCC care for Hispanic patients.

3257 | EFFICACY AND SAFETY OF BINTRAFUSP ALFA IN BILIARY TRACT CANCER: A REVIEW OF THE CLINICAL TRIALS

MANASA SINDHURA NAGINENI[1] Sunil Bogati[1] Bheshraj Karki[2] Qi Yu[3], [1]New York Medical College, St. Clare's Health, [2]SUNY DOWNSTATE MEDICAL CENTER, [3]SUNY DOWNSTATE MEDICAL CENTER

Background: Biliary tract cancers (BTCs) are rare and aggressive with limited treatment options. Bintrafusp alfa (BA), a bifunctional fusion protein targeting Programmed Cell Death Ligand 1 (PD-L1) and Transforming Growth Factor-β (TGF-β), has been investigated in clinical trials. **Methods:** A detailed search was done on Pubmed, Scopus and Embase for the articles, using the search terms ("bintrafusp alfa" OR "M7824") AND ("biliary tract cancer" OR "biliary tract neoplasm*" OR "cholangiocarcinoma" OR "gallbladder cancer" OR "extrahepatic cholangiocarcinoma" OR "intrahepatic cholangiocarcinoma") AND ("locally advanced" OR "metastatic" OR "advanced stage" OR "unresectable"). Upon analysis, descriptive synthesis was conducted from two trials: a randomized phase 2/3 trial assessing BA plus GemCis versus GemCis alone in first-line BTC, and a phase 2 single-arm trial evaluating BA monotherapy in chemorefractory BTC.

We reviewed findings from two multinational clinical trials:

(1) An open-label, single-arm Phase 2 trial (n = 159) assessing BA monotherapy, and

(2) A randomized, double-blind, placebo-controlled Phase 2/3 trial (n = 297) evaluating BA + Gemcitabine and Cisplatin (GemCis) versus placebo + GemCis.

Key endpoints were objective response rate (ORR), progression-free survival (PFS), overall survival (OS) and safety. **Results:** In the single-arm phase 2 trial (N = 159), BA monotherapy showed a modest ORR of 10.7% with a median OS of 7.6 months and a manageable safety profile. In the phase 2/3 trial (N = 297), BA+GemCis did not show improvement of OS compared to GemCis alone (11.5 vs 11.5 months; HR: 1.23; p = 0.7394), with higher early death and bleeding rates.

In the monotherapy trial, BA showed an ORR of 10.7%, including 3 complete responses, 10.0 months median duration of response. Response was present irrespective of PD-L1 expression. Of note, ORR was higher in those who had low tumor mutational burden (15.5%) and Isocitrate Dehydrogenase 1 (IDH1) mutations (21.4%). Immune-related adverse events (irAEs) occurred in 28.9%, with steroid management required in the majority of the cases.

In the Phase 2/3 trial, bintrafusp alfa + GemCis did not improve OS (11.5 vs 11.5 months; HR 1.23) or PFS (5.5 vs 5.6 months) compared to GemCis alone. Though ORR was higher (31.5% vs 19.5%) in numbers, the combination arm patients showed a higher incidence of irAEs (20.5%), bleeding events (28.8% vs 7.4%), and early deaths. Biomarker analyses got limited due to early trial termination but there was no suggestion of strong benefit. **Conclusion:** Comparatively, BA monotherapy showed a bit better response than combination therapy, as the latter had more toxicity without clear additional benefits. BA is not effective for unselected patient population, with limited Results: in only certain molecular subgroups.

3258 | TARGETING PAK1 ON TUMOUR-ASSOCIATED MACROPHAGES ENHANCES THE EFFICACY OF IMMUNOTHERAPY IN HEPATOCELLULAR CARCINOMA

Tongguo Miao[1] ying zhang[2] Yuemin Nan[2], [1]Tianjin First Central Hospital, [2]Hebei Medical University Third Hospital

Background: The tumour microenvironment (TME) is an important mediator of tumour immunotherapy resistance. Unfortunately, hepatocellular carcinoma (HCC) does not respond to immunotherapy due to a lack of enhancing inflammation in tumor microenvironment (TME), a contributing factor is P21 (RAC1) Activated Kinase 1 (PAK1). PAK1 is selectively highly expressed in tumour-associated macrophages (TAMs). How PAK1 impacts the TME remains understudy. **Methods:** We investigated the role of the PAK1/mTORC1/TFEB pathway in HCC development by conducting metabolomic analysis, gene expression profiling and immunohistochemistry analyses in RAW264.7 cells, oncogene-induced HCC mouse models and human HCC samples, and further explored the molecular mechanism by which PAK1 promoted macrophages M2 polarization. **Results:** PAK1 is selectively expressed in different types of tumours, and was associated with adverse clinical outcome in patients with cancer. We show that targeting PAK1 is a novel and tolerable approach to significantly reverse M2 transition to inhibit tumor development in vitro experiment. This approach reshaped the tumour immune microenvironment, reduced IL-10 and TGF-β expression of macrophages, together with increasing expression and nuclear localization of TFEB. Mechanistically, PAK1 promoted M2 polarisation of macrophages by activating mTORC1/TFEB pathway. **Conclusion:** The PAK1/mTORC1/TFEB pathway plays an important role in HCC, targeting PAK1 represents a potential strategy to enhance the efficacy of immunotherapy in HCC patients.

3259 | BASELINE VON WILLEBRAND FACTOR AS A PREDICTIVE BIOMARKER FOR RESPONSE TO ATEZOLIZUMAB PLUS BEVACIZUMAB IN ADVANCED HEPATOCELLULAR CARCINOMA

Tadashi Namisaki Shinya Sato[1] NORIHISA NISHIMURA[2] Kosuke Kaji[2] Hiroaki Takaya[2] Naoki Nishimura[2] Hitoshi Yoshiji[1], [1]Nara Medical University, [2]奈良医大　消化器代謝・内科

Background: We have previously reported that von Willebrand factor antigen (VWF), a blood coagulation factor, is a potential predictor of response to molecularly targeted drugs and hepatic infusion chemotherapy in patients with advanced hepatocellular carcinoma (HCC). In this study, we investigated the usefulness of VWF as a predictor of response to atezolizumab plus bevacizumab (AB) therapy for HCC. **Methods:** This study included 58 patients with advanced HCC treated with AB therapy. Serum vWF levels were measured by ELISA prior to treatment. Treatment response was assessed using RECIST v1.1 and modified RECIST (mRECIST). Multivariate logistic regression was performed to identify independent predictors of response. Associations between vWF and progression-free survival (PFS), overall survival (OS), liver function, and tumor characteristics were also analyzed. **Results:** Median age: 74 years, HBV/HCV/alcohol/MASLD/PBC/other: 11/13/13/12/1/8, median maximum tumor diameter: 3.7 cm, median number of tumors: 4. VWF was positively correlated with Child-Pugh score, ALBI score, PIVKA2, and number of tumors, and negatively correlated with Alb. VWF, ALBI score, and Child-Pugh score were significantly lower in the response group [CR/PR] than in the non-response group [SD/PD] in the RECIST study. In multivariate analysis, only low VWF (<135) was identified as a predictor of therapeutic response based on RECIST. Progression-free survival (PFS) was prolonged in the low VWF group (<135) compared to the high VWF group ($135\leq$). mRECIST showed that VWF was significantly lower in the response group than in the non-response group. Only

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

low VWF (< 135) was also identified as a predictor of therapeutic response based on mRECIST in multivariate analyses. PFS in the low VWF group was prolonged compared to the high VWF group. The area under the ROC curve (AUC) was 0.807 (RECIST v1.1) and 0.760 (mRECIST). vWF levels correlated positively with T-Bil, AST, ALT, tumor number, and VEGF, and negatively with albumin. Positive correlations were also observed with Child-Pugh and ALBI scores. **Conclusion:** Low baseline vWF levels are associated with favorable response and prognosis in AB therapy for advanced HCC. vWF may serve as a useful non-invasive biomarker to guide treatment selection in clinical practice.

3260 | THERAPEUTIC EFFICACY AND SAFETY OF LENVATINIB AS A SECOND-LINE THERAPY AFTER FIRST-LINE THERAPY OF ATEZOLIZUMAB PLUS BEVACIZUMAB IN PATIENTS WITH UNRESECTABLE HEPATOCELLULAR CARCINOMA

Chinatsu Nishioka[1] Kazuki Maesaka[1] Machiko Kai[1] Kumiko Shirai[1] Kazuhiro Murai[1] Yuki Makino[1] Yuki Tahata[1] Kazuyoshi Ohkawa[2] Masanori Miyazaki[3] Nobuyuki Tatsumi[4] Kengo Matsumoto[5] Yasutoshi Nozaki[6] Takayuki Yakushijin[7] Ryotaro Sakamori[8] Takahiro Kodama[1] Hayato Hikita[1] Tetsuo Takehara[6], [1]The University of Osaka, [2]Osaka International Cancer Institute, [3]Osaka Police Hospital, [4]Japan Community Health Care Organization Osaka Hospital, [5]Toyonaka Municipal Hospital, [6]Kansai Rosai Hospital, [7]Osaka General Medical Center, [8]Osaka National Hospital

Background: Atezolizumab plus bevacizumab is approved as a first-line treatment for unresectable hepatocellular carcinoma (uHCC). Most patients experience disease progression during this therapy, but optimal subsequent therapies remain unclear. In Japan, re-administration of immune checkpoint inhibitors is permitted for uHCC, and durvalumab plus tremelimumab or lenvatinib is often used as second-line therapy following first-line treatment with atezolizumab plus bevacizumab. This study aimed to compare the therapeutic efficacy and safety in patients who received durvalumab plus tremelimumab or lenvatinib as a second-line therapy, all following prior first-line therapy of atezolizumab plus bevacizumab. **Methods:** We retrospectively analyzed the therapeutic efficacy and safety in 85 patients with unresectable HCC who received durvalumab plus tremelimumab (18) or lenvatinib (67) as a second-line therapy after first-line therapy of atezolizumab plus bevacizumab using a prospectively registered cohort. Tumor response was assessed using RECIST version 1.1. Progression-free survival (PFS), overall survival (OS), and adverse events (AEs) were compared. **Results:** In the durvalumab plus tremelimumab group, the background etiology was viral/non-viral in 6/12 patients, modified ALBI (mALBI) grade 1–2a/2b–3 in 9/9, and BCLC stage A/B or C in 8/10. In the lenvatinib group, etiology was viral/non-viral in 32/35, mALBI grade 1–2a/2b–3 in 38/29, and BCLC stage A/B or C in 24/43. Following atezolizumab plus bevacizumab, the ORRs were 11.1% in the durvalumab plus tremelimumab group and 20.9% in the lenvatinib group ($p = 0.616$); the DCRs were 33.3% and 68.7%, respectively ($p = 0.005$). The median PFS was 1.9 months vs. 4.2 months, favoring lenvatinib ($p < 0.001$), and median OS was 10.6 vs. 14.0 months ($p = 0.323$). In the analysis of PFS, the treatment regimen (durvalumab plus tremelimumab) was a significant factor ($p = 0.002$). For OS, BCLC stage C ($p = 0.015$) and neutrophil-to-lymphocyte ratio ≥ 3 ($p = 0.020$) were significant; treatment regimen was not ($p = 0.137$). **Conclusion:** Following first-line therapy with atezolizumab plus bevacizumab, lenvatinib showed better PFS than durvalumab plus tremelimumab and may be considered an effective second-line treatment option.

Background: A subset of primary liver cancer patients lacks identifiable etiologies at diagnosis, termed cryptogenic hepatocellular carcinoma (HCC). Increasing evidence suggests metabolic dysfunction-associated steatotic liver disease (MASLD) as a key contributor to cryptogenic HCC. Genetic factors play a critical role in MASLD-associated HCC pathogenesis. This study aims to compare the clinical and genetic profiles of cryptogenic HCC and hepatitis B virus (HBV)-related HCC (HBV-HCC), providing novel insights for early diagnosis and targeted treatment. **Methods:** From January 2017 to December 2023, 41 cryptogenic HCC patients diagnosed at the Department of Hepatology, First Hospital of Jilin University, were enrolled. 212 patients with HBV-HCC diagnosed during the same period were randomly selected. 233 healthy controls (NC group) from the health examination center were included. Demographic characteristics, laboratory parameters, and genetic polymorphisms (PNPLA3 rs738409, TM6SF2 rs58542926, GCKR rs1260326, MBOAT7 rs641738, HSD17B13 rs72613567, ALDH2 rs671) were analyzed to compare NC, cryptogenic HCC and HBV-HCC groups and explore disease-specific features. **Results:** Among 4,545 HCC patients, 85 (1.87%) met cryptogenic HCC criteria. Compared to HBV-HCC patients, cryptogenic HCC patients exhibited older age at diagnosis, higher BMI, increased female predominance, higher rates of non-cirrhotic background and diabetes, and elevated GGT, ALP, and TG levels (all $P < 0.05$). Statistic analysis revealed significant differences in genotype and allele frequencies of PNPLA3 rs738409 and GCKR rs1260326 among cryptogenic HCC, HBV-HCC, and NC groups (all P **Conclusion:** Patients with cryptogenic HCC exhibit older age at diagnosis, higher BMI, and a higher prevalence of female, diabetes, non-cirrhotic background, distant/lymph node metastasis. Notably, this group demonstrated lower rates of AFP elevation but significantly elevated serum levels of GGT, ALP, and TG compared to HBV-HCC patients. PNPLA3 rs738409 (GG genotype and G allele) and GCKR rs1260326 (TT genotype and T allele) polymorphisms may serve as genetic risk factors for cryptogenic HCC, highlighting their potential involvement in disease development.

3262 | PERFORMANCE OF HCC RISK SCORES IN PATIENTS WITH ADVANCED CHRONIC LIVER DISEASE IN THE NETHERLANDS

Mohamed Moussa[1] Koos de Wit[2] Bert Baak[3] Dave Sprengers[1] Stan van Wijk[1] Emma Kleij[1] Roy Dwarkasing[4] Willem Pieter Brouwer[4] Femme Dirksmeier-Harinck[5] Jordan Feld[6] Harry Janssen[7] Bart Takkenberg[8] Milan Sonneveld[9], [1]Erasmus University Medical Centre, Rotterdam, The Netherlands, [2]Amsterdam University medical center, Amsterdam, The Netherlands., [3]OLVG Hospital, Amsterdam, The Netherlands., [4]Erasmus University Medical Center, Rotterdam, The Netherlands., [5]St. Franciscus hospital, Rotterdam, Netherlands., [6]Toronto Centre for Liver Disease, University Health Network, University of Toronto, Toronto, Ontario, [7]Erasmus University Medical Centre, Toronto Centre for Liver Disease, Toronto General Hospital, [8]Amsterdam University Medical Centers, location AMC, Amsterdam, The Netherlands, [9]Erasmus University Medical Center, Rotterdam, The Netherlands

Background: Patients with advanced chronic liver disease (ACLD) are at high risk of developing HCC and are therefore recommended to undergo bi-annual HCC surveillance. Given the increasing prevalence of ACLD, individualised risk prediction would be helpful to identify patients in whom surveillance could be safely deferred. This study aimed to assess the performance of three HCC risk scores—PAGE-B, THRI, and aMAP in patients with ACLD in the Netherlands. **Methods:** In this retrospective multicentre study, adults (≥ 18 years) with ACLD (diagnosed by liver stiffness ≥ 10 kPa, liver biopsy, or compatible imaging findings) were included. Exclusion criteria were follow-up < 6 months, missing data for any of the three risk scores, prior HCC, other baseline malignancies, or other life-limiting conditions (e.g. heart or kidney failure). PAGE-B (age, gender, platelet count), THRI (age, gender, platelet count, etiology) and aMAP (age, male, albumin-bilirubin and platelets) scores were calculated as previously reported, and patients were allocated to low, intermediate and high-risk groups according to established cut-offs (PAGE-B: 0-9, 10-18, > 18; THRI < 120, 120-240, > 240; aMAP < 50, 50-60, > 60). Kaplan–Meier analysis was used to estimate cumulative HCC incidence according to risk score categories. **Results:** A total of 1,698 patients were included in this cohort, with the most common etiologies being steatotic liver disease 494 (29%), HCV 307 (18%), and HBV 294 (18%). The majority were male (64%), and the median age was

52 years (IQR: 43–60). Median baseline CTP was 5 (IQR: 5–6), and 316 (19%) had a history of decompensation. A total of 201 (11.8%) patients developed HCC during a median follow-up time of 5.7 years (IQR: 3.3–9.7 years). The 5-year and 10-year cumulative HCC incidence was 6.34% (95% CI: 5.02–7.64) and 16.20% (95% CI: 13.63–18.68), respectively. For PAGE-B, the numbers of patients identified as low/intermediate/high risk were 305 (18%)/ 846 (50%)/ 547 (32%). The 5-year cumulative incidences of HCC in the low, intermediate, and high-risk groups were 0.78%, 4.26%, and 12.97%, respectively. For THRI, the numbers of patients identified as low, intermediate, and high risk were 371 (22%), 780 (46%), and 547 (32%). The 5-year cumulative incidences of HCC in the low, intermediate, and high-risk groups were 1.40%, 5.19%, and 11.30%, respectively. For aMAP, the numbers of patients identified as low, intermediate, and high risk were 567 (33%), 680 (40%), and 451 (27%). The 5-year cumulative incidences of HCC in the low, intermediate, and high-risk groups were 1.92%, 5.96%, and 13.71%, respectively. **Conclusion:** Patients with ACLD at low predicted risk of HCC according to PAGE-B, THRI and/or aMAP scores had a very limited 5-year risk of HCC. Application of these scores could allow for safe deferral of HCC surveillance in 20-30% of patients with ACLD.

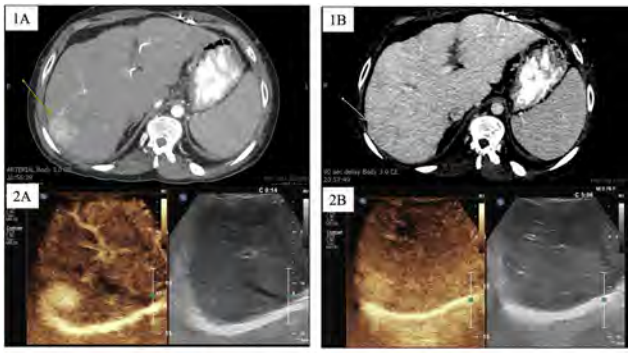
3263 | UTILITY OF CONTRAST-ENHANCED ULTRASOUND IN HCC SURVEILLANCE IN FONTAN ASSOCIATED LIVER DISEASE

Rachel Orbuch[1] Amanda Pirola[1] Daniel Ganger[2] Amir Borhani[2] Maryam Haghshomar[2] Camila Lopes Vendrami[2] Frank Miller[2] Helena Gabriel[2],
[1]Northwestern McGaw Medical Center, [2]Northwestern Memorial Hospital

Background: The Fontan procedure for patients with congenital heart disease and univentricular physiology involves diversion of systemic venous return to the pulmonary artery. This results in chronic hepatic venous congestion and decreased cardiac output, leading to progressive hepatic fibrosis known as Fontan-associated liver disease (FALD). FALD is associated with an increased risk of hepatocellular carcinoma (HCC). Additionally, these patients may have lesions associated with Fontan physiology, such as nodular regenerative hyperplasia (NRH) and focal nodular hyperplasia (FNH). These benign focal lesions can erroneously demonstrate suspicious features on CT and MR imaging. Society guidelines recommend HCC surveillance and screening. No universal guidelines exist as to the correct screening method or interval in Fontan

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients. CT and MR are problematic in this patient population due to the cumulative radiation risk and difficulty with MRI due to pacemakers and postsurgical changes. Ultrasound is often used as the surveillance method; however, gray scale ultrasound may not visualize focal lesions seen with FALD. Contrast-enhanced ultrasound (CEUS) is typically used as a diagnostic tool once a focal lesion is identified, however, in this specific patient population it may also be helpful as a screening/surveillance tool. This is a novel use of CEUS. The purpose of this study is to introduce CEUS as a means of screening, surveillance, and diagnostic characterization of focal lesions in FALD. **Methods:** We conducted a retrospective case series of 10 post-Fontan patients receiving care at a tertiary academic medical center. Patients who underwent both non-contrast liver ultrasound and CEUS between 2020 and 2024 were identified. We gathered the data from previous imaging studies, including MRI and CT scans. The stability at 2 years was utilized as a reference standard for benign lesions in accordance with AASLD criteria. We assessed the impact and accuracy of CEUS on lesion characterization and clinical decision-making. **Results:** 10 post-Fontan patients underwent HCC surveillance with both standard US and CEUS to screen for HCC. The median age of the Fontan procedure for patients was 3 years old. Patients were aged between 22 to 38 years old at the time of CEUS scan (mean age: 29.8). CEUS classified hepatic lesions as benign in 8 of 10 patients (6 FNH and 2 NRH). In one patient case, CEUS was unable to localize the lesion, and in another, lesion characterization was incomplete. In all 8 visualized cases, the lesions were stable on subsequent imaging. **Conclusion:** CEUS is a novel diagnostic imaging method that can problem-solve and confirm benign lesions with suspicious characteristics. CEUS can potentially be used as a surveillance method in FALD patients in whom CT and MR imaging is limitated. Although small in scope, this study introduces a method that can have utility in surveillance and management of post-Fontan patients.



Surveillance imaging of post-Fontan patient comparing CT triple-phase imaging demonstrating enhancing lobulated mass in the right hepatic lobe (1A). The mass is hyperdense on 60 second image and is isodense to slightly hypodense on CT washout image (1B). Contrast-enhanced ultrasound (CEUS) performed demonstrating arterially hyperenhancing lesion (2A) without washout at 4 minutes (2B). CEUS is able to further classify the lesion as a benign Fontan-related FNH-like lesion.

3264 | TP53 ALTERATIONS PREDICT POOR RESPONSE TO IMMUNE CHECKPOINT INHIBITOR-BASED CHEMOTHERAPY IN INTRAHEPATIC CHOLANGIOCARCINOMA.

Hiroki Inada[1] Satoshi Narahara[1] Daiki Maeda[1] Hideaki Miyamoto[1] Katsuya Nagaoka[1] Hiromitsu Hayashi[1] Yasuhito Tanaka[1], [1]Kumamoto University

Background: Comprehensive genome profile (CGP) has shown promise in improving outcomes for biliary tract cancer, particularly intrahepatic cholangiocarcinoma (ICC). However, there are no reports linking genetic mutations identified through CGP to the efficacy of immune checkpoint inhibitors (ICIs) for ICC. This study aimed to clarify the association between genetic alterations and clinical outcomes of ICI-combined chemotherapy. **Methods:** We retrospectively analyzed 25 patients with ICC who initiated Gemcitabine + Cisplatin + Durvalumab (GCD) therapy between December 2022 and August 2024 at our institution and affiliated facilities. **Results:** The median patient age was 73 years (range: 47–81), with 18 males (72%). Disease stage distribution was I/II/III/IV (2/3/0/20), and distant metastases were present in 14 patients (56%). GCD was used as first-line therapy in 16 patients (64%), and CGP was performed in 19 patients (76%). The best overall response included partial response in 6 (24%), stable disease in 13 (52%), and progressive disease in 2 (8%); one patient underwent conversion surgery. Median overall survival (OS) was 11.1 months (95% CI: 6.9–not reached), and median progression-free survival (PFS) was 7.8 months (95% CI: 3.6–10.6). Actionable gene mutations were identified in 16 of 19 patients (84%) who underwent CGP, and 6 of 8 patients whose GCD therapy was discontinued due to progression received genomically matched therapies. Multivariate analysis identified TP53 mutation as a significant factor associated with shorter PFS ($P = 0.036$, HR: 4.2, 95% CI: 1.10–16.1). The disease control rate (DCR) was significantly higher in the TP53 wild-type group (100%, 11/11) compared to the TP53-mutant group (62.5%, 5/8) ($P = 0.047$). Median PFS was also significantly shorter in the TP53-mutant group (4.0 months, 95% CI: 1.8–5.2) than in the TP53 wild-type group (9.6 months, 95% CI: 3.4–14.0) ($P = 0.011$). Spatial transcriptomic analysis further revealed a reduced density of CD8+ T cells at the tumor–non-tumor interface in TP53-

mutated ICC, suggesting a potential immune evasion mechanism. **Conclusion:** Our findings indicate that TP53-mutated ICC is characterized by an immune-cold tumor microenvironment, potentially contributing to resistance to immune checkpoint inhibitors. CGP may play a critical role in identifying predictive biomarkers and guiding personalized treatment strategies for ICC.

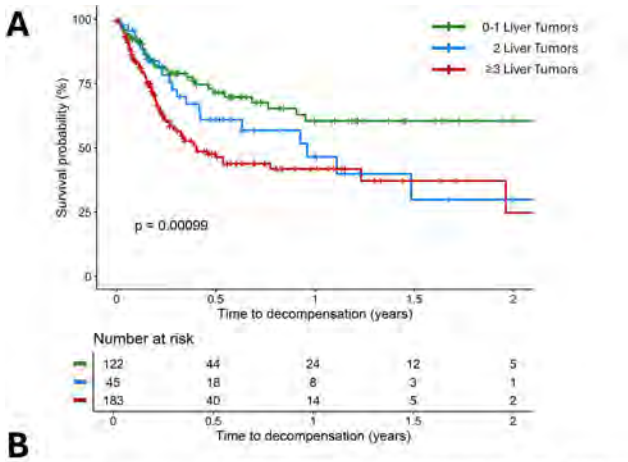
3265 | LIVER TUMOR BURDEN INDEPENDENTLY PREDICTS RISK OF HEPATIC DECOMPENSATION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA RECEIVING IMMUNOTHERAPY.

Erica Storm[1] Yoo Jin Lee[1] Willis Tang[1] Francis Yao[1] Neil Mehta[1] Robin Kelley[1] Jennifer Lai[1] Michael Li[1], [1]University of California, San Francisco

Background: Hepatic decompensation is a major driver of mortality in patients with advanced hepatocellular carcinoma (HCC). We hypothesized that liver tumor burden contributes to decompensation risk. **Methods:** We conducted a single center retrospective cohort study of all patients who received immune checkpoint inhibitors (ICI) for HCC from 2016-2024. The primary outcome was time to first decompensation or further decompensation. First decompensation was defined as new ascites, hepatic encephalopathy (HE), and/or variceal bleeding (VB). In patients with decompensated liver disease, further decompensation was defined as per Baveno VII criteria. Competing risks regression was utilized to investigate the impact of number of liver tumors (as a surrogate for hepatic tumor burden) on time to hepatic decompensation, with mortality as a competing risk. **Results:** Of 350 study patients with a median follow-up of 288 days, 134 (38%) decompensated after starting ICI therapy. The median time to decompensation was 63 days (IQR 27-199); ascites (29%) was the most common event followed by HE (15%) and VB (5%). Patients with 3+ liver tumors had significantly shorter time to decompensation compared to those with 2 tumors and to those with 0-1 tumors (median 0.4 vs 1.0 vs 2.4 years, $p < 0.001$; Figure 1A). On competing risks regression, number of hepatic tumors was significantly associated with hepatic decompensation (HR: 1.28 for each additional tumor up to 4, 95% CI 1.11-1.48, $p < 0.001$) after adjusting for key confounders including MELD 3.0, ICI regimen, prior locoregional therapy, line of systemic therapy, macrovascular invasion, extrahepatic metastases, and alpha-fetoprotein (Figure 1B). This effect was maintained in subgroup analyses of patients without cirrhosis ($n = 79$) (HR 1.89 per tumor, $p = 0.008$) and previously compensated cirrhosis ($n = 245$) (HR 1.43 per tumor, $p < 0.001$). However, in patients with prior decompensation ($n = 105$), liver tumor number was not associated with further decompensation (HR 1.07, $p = 0.541$). Patients who decompensated ≤ 90 days of ICI initiation had shorter overall survival compared to those who remained compensated (median 0.2 vs 1.7 years, $p < 0.001$). **Conclusion:** Number of liver tumors is positively associated with time to hepatic decompensation, even after adjusting for liver function and cancer stage. Compensated patients with high tumor burden may be at higher risk for decompensation than their MELD score would suggest and may benefit from co-management with hepatology.



B

Parameter	Hazard Ratio (HR)	95% Confidence Interval	P-Value
# Hepatic Tumors	1.280	1.107-1.480	0.0009
Atezolizumab plus Bevacizumab	1.050	0.642-1.718	0.8461
STRIDE†	0.907	0.547-1.504	0.7045
Prior Systemic therapy	0.898	0.557-1.447	0.6585
Prior Locoregional Therapy	1.282	0.859-1.913	0.2248
Macrovascular Invasion	1.367	0.922-2.027	0.1201
Distant metastasis	1.014	0.680-1.512	0.9461

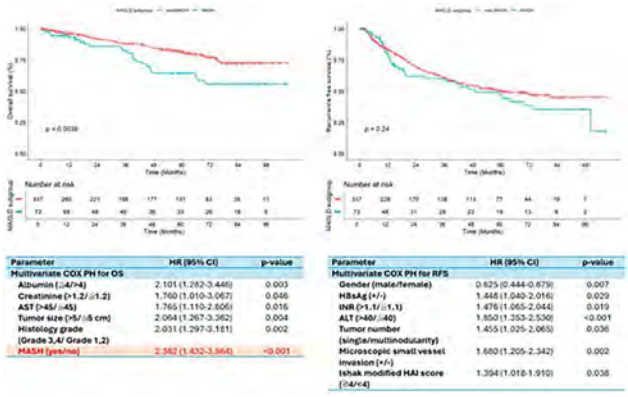
3266 | METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS PREDICTED POOR PROGNOSIS IN HEPATOCELLULAR CARCINOMA PATIENTS WITH CONCURRENT MASLD

Chien-Wei Su[1] Chun-Ting Ho[1] Chia-Jung Ho[1] Wei-Yu Kao[2] Ying-Ying Yang[1] Yi-Hsiang Huang[1] Ming-Chih Hou[1] Jaw-Ching Wu[3], [1]Taipei Veterans General Hospital, [2]Taipei Medical University Hospital, [3]National Yang Ming Chiao Tung University, Taipei, Taiwan

Background: The prognostic significance of metabolic dysfunction-associated steatotic liver disease (MASLD) in patients with hepatocellular carcinoma (HCC) remains unclear. Furthermore, the impact of metabolic dysfunction-associated steatohepatitis (MASH), on clinical outcomes in patients with MASLD-related HCC has not been well defined. This study aimed to evaluate the prognostic role of MASH in HCC patients with concurrent MASLD and to identify risk factors associated with poor overall survival (OS) and recurrence-free survival (RFS). **Methods:** We retrospectively analyzed 410 HCC patients with histologically confirmed MASLD who underwent curative surgical resection at Taipei Veterans General Hospital between 2016 and 2022. MASLD was defined as $>5\%$ steatosis in non-tumor liver tissue with at least one cardiometabolic risk factor. Patients with histopathological features of steatohepatitis were categorized as MASH. The primary and secondary endpoints were OS and RFS, respectively. Clinical, laboratory, imaging, and histopathological data were collected. Survival outcomes were estimated using the Kaplan–Meier method and compared by the log-rank test. Independent prognostic factors were identified through Cox proportional hazards models. **Results:** Among the 410 MASLD-HCC patients, 73 were classified as MASH and 337 as non-MASH. Compared to the non-MASH group, MASH patients were older, had smaller tumors, higher serum aspartate aminotransferase (AST) and fibrosis-4 (FIB-4) scores, and lower platelet counts (all $p < 0.05$). After a median follow-up of 59.2 months, 79 patients died and 168 experienced HCC recurrence. The 5-year OS rate was significantly lower in the MASH group (64.4%) than in the non-MASH group (81.7%; $p = 0.006$), while RFS was comparable between the two groups. Multivariate analysis identified lower serum albumin, higher serum creatinine and AST levels, larger tumor size, higher histological grade, and presence of MASH as independent predictors of poor OS. **Conclusion:** MASH was associated with poor OS in HCC patients with concurrent MASLD following surgical resection.



Parameter	HR (95% CI)	p-value
Multivariate COX PH for OS		
Albumin (≦4/>4)	2.101 (1.282-3.446)	0.003
Creatinine (>1.2/≦1.2)	1.760 (1.010-3.067)	0.046
AST (>45/≦45)	1.765 (1.110-2.806)	0.016
Tumor size (>5/≦5 cm)	2.064 (1.267-3.362)	0.004

3267 | A NOVEL MOUSE MODEL OF INTRAHEPATIC CHOLANGIOCARCINOMA AND EFFECTS OF SGLT2 INHIBITORS ON THE MALIGNANCY

Yohei Shirakami[1] Masahito Shimizu[1] Hiroyasu Sakai[1], [1]Gifu University

Background: Cholangiocarcinoma (CCA) is the second most common primary cancer of the liver and has a poor prognosis. Although animal models for various human cancers have been established, an appropriate model for CCA has not been established yet. Sodium-glucose cotransporter 2 (SGLT2) inhibitors have been reported to possess anti-tumor effects against several types of cancers; however, studies examining their potential impact on CCA are lacking. This study was conducted to establish a novel mouse model for CCA induced by administration of a carcinogen to obese mice. This study also investigated anti-tumor effects of SGLT2 inhibitors on CCA. **Methods:** C57BLKS/J-db/db (db/db) mice, which displayed obesity and steatohepatitis, and a colonic carcinogen azoxymethane (AOM) were used. CCA cell lines were also used to investigate the mechanism of action of an SGLT2 inhibitor canagliflozin (CANA) on CCA, evaluating cell proliferation, cell cycle, and epithelial-mesenchymal transition (EMT). **Results:** Histopathological analysis revealed that biliary tract lesions in the liver appeared to be intrahepatic CCA with higher tumor incidence, shorter experimental duration, and a markedly increased incidence in obese mice. Molecular markers analyzed by microarray and qPCR indicated that cancerous lesions originated from cholangiocytes and developed in inflamed livers. These findings indicated that

this might be a novel mouse model of intrahepatic CCA in the context of steatohepatitis. SGLT2 gene expression was confirmed in human CCA tissue and cell lines. CANA treatment decreased CCA cell viability, while growth promotion was also observed in a relatively low dose treatment. CANA treatment arrested the cell cycle and suppressed EMT in CCA cells. CANA reduced the expressions of histone deacetylase 6 (HDAC6), increased NAMPT and SIRT1, and activated the NAD+ salvage pathway. Combination of CANA with an NAMPT inhibitor significantly decreased cell viability. In addition, administration of an SGLT2 inhibitor suppressed the development of bile duct lesions in a novel mouse CCA model. **Conclusion:** We established a novel mouse model of intrahepatic CCA using obese db/db mice administered AOM. This novel CCA model may provide insights into the pathogenesis of intrahepatic CCA and contribute to the establishment of new therapies for this disease. An SGLT2 inhibitor CANA inhibited cell proliferation and EMT by inducing cell cycle arrest in CCA cells, while CANA may also have tumor-promoting effects. Further studies are required to investigate the dual effects of CANA on CCA.

3268 | DIFFERENTIAL IMPACT OF ANTIBIOTICS ON ANTI-PD-1 VERSUS ANTI-PD-L1 THERAPY IN HEPATOCELLULAR CARCINOMA

Cheng-Hao Kuo[1] Chun-Ying Wu[1], [1]National Yang MIng Chiao Tung University, Taiwan

Background: Immune check point inhibitors (ICIs) targeting the PD-1/PD-L1 axis have improved clinical outcomes in advanced hepatocellular carcinoma (HCC), yet response rates remain suboptimal. Recent findings have demonstrated an association between ICI responsiveness and the gut microbiota, suggesting that the microbiome may modulate ICI efficacy. Mechanistic distinctions between anti-PD-1 and anti-PD-L1 antibodies imply that the microbiome and its perturbations may differentially affect treatment outcomes. We therefore evaluated the impact of antibiotic-induced dysbiosis on anti-PD-1/PD-L1 therapy in real-world HCC patients. **Methods:** We conducted a multicenter, retrospective cohort study using the TriNetX Global Collaborative Network. HCC patients initiating anti-PD-1 or anti-PD-L1 therapy between 2006 and 2023 were identified. Antibiotic (ABX) exposure was defined as ≥ 1 ABX prescription within 3 months before to 3 months after ICI initiation, with a 3-month wash-out to minimize confounding by active infection. Propensity score matching (PSM) was performed to adjust for 78 covariates, including demographics, liver function and decompensation status, etiology, tumor burden, comorbidities, and concurrent medications. The primary outcome was 1-year overall mortality; secondary outcomes included liver decompensation and metastasis. Exploratory analyses extended follow-ups for all outcomes up to 3 years. Cox proportional hazard regression was performed, and all outcomes were assessed using landmark analysis at 6, 12, and 36 months. **Results:** After PSM, the anti-PD-1 cohort comprised 698 matched pairs of ABX-exposed and non-exposed patients, and the anti-PD-L1 cohort 627 pairs. In patients initiating anti-PD-L1, ABX exposure was associated with a higher 1-year mortality risk (HR, 1.47; 95% CI, 1.13-1.91), with survival curves diverging through 36 months. In contrast, the anti-PD-1 cohort showed no significant difference in overall mortality between ABX-exposed and non-exposed patients. Both ICI classes exhibited an increased risk of liver decompensation with ABX use, while metastasis risk did not differ by ABX exposure in either cohort. **Conclusion:** Recent ABX exposure significantly impairs 1-year survival in HCC patients receiving anti-PD-L1 therapy, but not in anti-PD-1 therapy. These findings highlight a microbiome-dependent modulation of the PD-L1 axis, whereas PD-1 blockade appears less sensitive to antibiotic-induced dysbiosis.

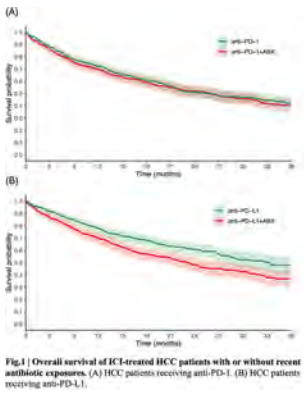

Fig.1 | Overall survival of ICI-treated HCC patients with or without recent antibiotic exposures. (A) HCC patients receiving anti-PD-1. (B) HCC patients receiving anti-PD-L1.

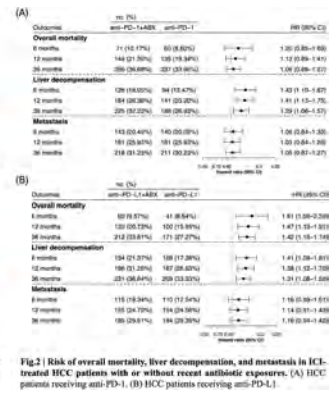

Fig.2 | Risk of overall mortality, liver decompensation, and metastasis in ICI-treated HCC patients with or without recent antibiotic exposures. (A) HCC patients receiving anti-PD-1. (B) HCC patients receiving anti-PD-L1.

3269 | ASSESSMENT OF QUALITY OF LIFE IN PATIENTS WITH ADVANCED HEPATOCELLULAR CARCINOMA RECEIVING ATEZOLIZUMAB PLUS BEVACIZUMAB

Rania Lithy[1] Mohamed Samy[2] Menna Rashwan[2] Tamer Elbaz[3] Ashraf Omar[4] Hend Shousha[2] Yasser Hamada[2] Yasser Elesnawy[5] Marwa Abdelghany[5] Mohamed Abdelwahed[5] Hany William[5] Nouran Roby[5] Ahmed Abdelmaksoud[2] Moahmed Nabil[2], [1]Faculty of Medicine, Cairo University, ESLC member, Cairo, Egypt, [2]faculty of medicine, Cairo University, Cairo, Egypt, [3]Faculty of medicine, Cairo Univeristy, NGU, Cairo, Egypt, [4]Faculty of medicine, Cairo university, ESLC founder, Cairo, Egypt, [5]Ahmed Maher teaching hospital, Cairo, Egypt

Background: Patients with hepatocellular carcinoma (HCC) experience significantly lower health-related quality of life (HRQOL) compared to the general population. This study aimed to evaluate changes in HRQOL and its correlation with treatment response and overall survival in patients with advanced HCC receiving Atezolizumab plus Bevacizumab. **Methods:** This prospective study included 25 patients with advanced HCC treated with Atezolizumab and Bevacizumab. HRQOL was assessed every three months using the FACT-G, EORTC HCC-18, and EORTC QLQ-C15-PAL questionnaires. Over a 12-month period, we evaluated the association between HRQOL, and tumor characteristics, and treatment response according to modified RECIST. Overall survival was determined at the end of the study. **Results:** Among 25 participants (88% male, median age 63), all had ECOG 0 and Child-Pugh A. 24 of the patients were BCLC stage C; one was stage B. Overall survival was 92%. Per mRECIST, 8% achieved complete response, 44% partial response, 21.7% stable disease, and 22.7% progression. At 12 months, QOL was assessed based on mRECIST-defined treatment response (regression, stable disease, progression). The regression group reported the highest overall FACT-G score (59.38 ± 8.26), followed by the stable disease group (56.80 ± 1.10) and the progression group (55.80 ± 0.45), although these differences were not statistically significant. Notably, the regression group also had the highest scores in both emotional and physical well-being domains. The EORTC HCC-18 scores suggested a tendency toward a higher symptom burden in the regression group across several domains, including nutrition (5.38 ± 0.87) and fatigue (3.85 ± 1.77). Similar patterns were noted in the subscales for body image, jaundice, fever, and pain, all showing numerically elevated scores in the regression group. Similarly, EORTC QLQ-C15-PAL scores showed a slightly higher symptom burden in the regression group (22.85 ± 6.14). Tumor size negatively correlated with FACT-G pain ($r = –0.476$, $p = 0.025$) and physical well-being ($r = –0.409$, $p = 0.059$), and was significantly linked to greater symptom burden on the HCC-18 physical subscale ($r = –0.425$, $p = 0.049$). **Conclusion:** HRQOL was not significantly compromised in patients who completed a one-year course of Atezolizumab plus Bevacizumab. This suggests HRQOL may be a useful prognostic marker in advanced hepatocellular carcinoma, with potential importance comparable to survival. **Disclosures:** Rania Lithy: Nothing to Disclose, Mohamed Samy: Nothing to Disclose, Menna Rashwan: Nothing to Disclose, Tamer Elbaz: Nothing to Disclose, Ashraf Omar: Nothing to Disclose, Hend Shousha: Nothing to Disclose, Yasser Hamada: Nothing to Disclose, Yasser Elesnawy: Nothing to Disclose, Marwa Abdelghany: Nothing to Disclose, Mohamed Abdelwahed: Nothing to Disclose, Nothing to Disclose, Hany William: Nothing to Disclose, Nouran Roby: Nothing to Disclose, Ahmed Abdelmaksoud: Nothing to Disclose, Moahmed Nabil: Nothing to Disclose

3270 | MALIGNANT LIVER NEOPLASM RELATED MORTALITY TRENDS DUE TO INFECTIVE VS NON-INFECTIVE ASSOCIATION: CDC WONDER ANALYSIS (1999–2020)

Jay Kakadiya[1] Jayasree Rajapandian[2] Kush Varsadiya[3] Areeba Fatima[4] [1]Kansas University Medical Center, [2]University of Alabama Birmingham, Montgomery, [3]Shri MP Shah Government Medical College, Jamnagar, India., [4]Civil Hospital Karachi

Background: Hepatocellular carcinoma (HCC), including intrahepatic bile duct cancer, remains the sixth leading cause of cancer-related mortality in the United States. Despite an overall decline in cancer mortality, deaths from liver cancer continue to rise. Recent surge in metabolic abnormalities plays a significant role in developing liver disorders. This study evaluates trends in age-adjusted mortality rates (AAMRs) for malignant liver cancers, distinguishing between infective causes (hepatitis B and C) and non-infective causes. These insights can guide future public health strategies and policy interventions. **Methods:** We conducted a cross-sectional analysis using CDC WONDER data from 1999 to 2020, focusing on malignant liver neoplasms, including intrahepatic bile duct cancer. Data were extracted using ICD-10 codes and stratified by age, sex, race, and region. Mortality trends were categorized by infective (hepatitis B or C) and non-infective (e.g., alcohol-related or metabolic liver disease) causes. Joinpoint regression was utilized to determine annual percent changes (APCs) and to identify trend inflection points across all the groups. **Results:** As shown in Figure 1A, AAMR from non-infective causes of liver

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cancer significantly increased from 2.8 in 1999 to 4.5 in 2020, with APCs were 3.26% for males and 2.97% for females. In contrast, infective causes showed a more modest rise in AAMR—from 0.6 to 1.2 during the same period. Non-infective cause is associated with 80% of total death count attributable to liver cancer. Table 1 highlights racial disparities: Non-Hispanic (NH) Asians had the highest AAMR among the infective cohort (2.6), driven primarily by hepatitis B (1.0). NH African Americans showed the highest hepatitis C-related AAMR (1.3). Among non-infective causes, Hispanic Whites had the highest AAMR (6.5). Age-group wise disparities: non-infective AAMR rose steadily with age, peaking in those 85+, while infective AAMRs peaked in the 55–64 age group. Regional variation is depicted in Figure 1C, with the Western U.S. consistently showing the highest AAMRs across all groups. Detailed result is shown in Figure 1. **Conclusion:** With advances in viral hepatitis management, the mortality burden from HCC has shifted toward non-infective etiologies, likely driven by alcohol use, obesity, and metabolic syndrome. Targeted public health interventions addressing these modifiable risk factors are essential to curb the rising trend of liver cancer mortality in the U.S.

3271 | IDENTIFICATION OF URIC ACID-RELATED GENES AS POTENTIAL BIOMARKERS IN HEPATOCELLULAR CARCINOMA

Yuqin Xie[1] Fengsheng Dai[1] sheng wang[1] Cheng Zhang[1] MaoYun Liu[1] Yi Wang[1] Jiale Lu[1] Hui Li[1] DeWei Li[1], [1]Chongqing University Cancer Hospital

Background: The potential role of abnormal uric acid metabolism in the pathogenesis and progression of hepatocellular carcinoma (HCC) has attracted increasing attention. Recent studies have shown that serum uric acid levels are closely related to the development of HCC. However, the role of uric acid in the occurrence and recurrence of HCC remains unclear. In this study, our goal was to explore the role of uric acid-related genes in HCC comprehensively. **Methods:** We analyzed RNA sequencing and clinical data from 374 HCC patients to develop a prognostic model of UARGs via 10 machine learning algorithms and 117 unique combinations. Survival and time-dependent receiver operating characteristic (ROC) analyses were performed to assess the efficacy of the model. Differences in clinical characteristics, the tumor immune microenvironment and drug sensitivity between the high- and low-risk groups were also analyzed. The function of the target gene PSRC1 was evaluated through in vitro and in vivo experiments, including CCK-8, colony formation, flow cytometry, Transwell assays, and xenograft mouse models. **Results:** UARGs have strong predictive performance for the prognosis and predictive performance of HCC patients. In addition, prediction models based on UARGs can effectively predict the outcomes of HCC immunotherapy and chemotherapy and are related to the immune characteristics of different risk groups. PSRC1 is a key gene whose high expression is associated with poor prognosis in HCC patients. Knockdown of PSRC1 significantly inhibits HCC cell proliferation, induces apoptosis, promotes cell cycle arrest, and inhibits HCC cell migration and invasion. **Conclusion:** This integrative strategy not only bridges the gap between uric acid metabolism and HCC pathobiology but also paves the way for identifying novel diagnostic biomarkers and therapeutic targets. Our work is anticipated to contribute to a deeper understanding of the molecular mechanisms linking metabolic dysregulation to HCC, ultimately guiding the development of more effective precision medicine approaches for HCC patients.

great promises for hepatocellular carcinoma (HCC) treatment, but several factors limit the delivery of NPs: tumor microenvironment, vasculature, reticulo-endothelial clearance, and immune responses. This study aims to investigate the specific vasculature and angiogenesis of HCC which hinders the NP distribution. **Methods:** HCC was induced with western diet and high-sugar water in combination with CCl_4 injection for 28 weeks. 200nm-sized NPs were injected 24hrs before sacrifice. Gross examination and histopathological analysis, serum biochemistry, immunofluorescence (IF), and immunohistochemistry (IHC) were performed to assess the microenvironment and vasculature of the disease related to NP distribution. **Results:** In tumor-induced mouse livers, hepatic NPs showed excess distribution in the pericentral areas of cirrhotic liver and fibrotic capsule surrounding the tumor. Majority of NPs were co-localized with CD68-positive Kupffer cells surrounded by collagen matrix. Also, nanoparticles were mainly distributed in the borderline of tumor region, showing limited entrance into the tumor tissue. In contrast to high distribution in cirrhotic tissue, NPs were significantly decreased in tumor tissues. Lyve-1 expression was significantly diminished in tumor tissues, and dilated lymphatic vessels were observed in the borderline of tumor region. **Conclusion:** Previously, the studies on limitations for nanoparticle therapy were focused on the penetration of nanoparticles into the tumor region. However, nanoparticle distribution in the tumor region was extensively low despite the nanoparticle influx through arterial blood supply. Absence of Lyve-1 expression in the tumor region suggests the loss of LSEC fenestration and dilated lymphatic vessels in the borderline of tumor showed retention of lymphatic outflow. Conclusively, the defenestration of LSEC and elevated blood pressure in the tumor region explains the absence of nanoparticles, suggesting the need for extensive study on tumor microvasculature for efficient delivery of therapeutic nanoparticles.

3273 | IMPACT OF CARDIOMETABOLIC RISK ON HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC HEPATITIS B: A RETROSPECTIVE STUDY

Chanavee Toh[1] Kedsiree Sanit[2] Pimsiri Sripongpun[2] Naichaya Chamroonkul[2] Suthat Liangpunsakul[3] Teerha Piratvisuth[4] Apichat Kaewdech[2], [1]Faculty of Medicine, Prince of Songkla University, Thailand, [2]Division of Internal Medicine, Faculty of Medicine, Prince of Songkla University, Thailand, [3]Department of Medicine, Indiana University School of Medicine, Indianapolis, Indiana, USA, [4]NKC Institute of Gastroenterology and Hepatology, Faculty of Medicine, Prince of Songkla University

Background: Chronic hepatitis B virus (HBV) infection remains a major global health concern and a leading cause of hepatocellular carcinoma (HCC). While cirrhosis is a well-established risk factor for HCC, the role of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) and cardiometabolic risk (CMR) factors —such as obesity, diabetes mellitus, hypertension, and dyslipidemia—remains unclear. This study aimed to evaluate the impact of MASLD and CMR factors on HCC risk in patients with chronic hepatitis B (CHB). **Methods:** We conducted a retrospective cohort study at Songklanagarind Hospital from January 2011 to December 2021. Adults with CHB and no evidence of HCC within six months of diagnosis were included. Data collected included demographics, liver biochemistry, metabolic comorbidities, HBV viral load, antiviral treatment, and imaging findings. HCC diagnoses were confirmed through the hospital cancer registry. Cumulative HCC incidence was estimated using Nelson-Aalen plots, and multivariable Cox proportional hazards models identified predictors of HCC. The aMAP score was assessed in subgroups with obesity, CMR factors, and MASLD. **Results:** Among 4,944 patients with CHB, 151 (3.1%) developed HCC. HCC occurred more frequently in older, male patients. Cirrhosis was the strongest predictor (adjusted hazard ratio [aHR] = 7.22; 95% CI: 4.46–11.70), followed by obesity (aHR = 1.85; 95% CI: 1.28–2.67) and male sex (aHR = 1.78; 95% CI: 1.25–2.53). Hypertension (aHR = 1.34; 95% CI: 0.91–1.97) and diabetes (aHR = 1.08; 95% CI: 0.70–1.65) showed nonsignificant trends toward increased risk. Statin use (aHR = 0.43; 95% CI: 0.22–0.85), higher platelet count (aHR = 0.62; 95% CI: 0.47–0.82), and higher serum albumin (aHR = 0.64; 95% CI: 0.48–0.86) were associated with lower HCC risk. Dyslipidemia without statin therapy (aHR = 1.10; 95% CI: 0.70–1.72) and hepatic steatosis (aHR = 0.85; 95% CI: 0.49–1.48) were not significantly associated with HCC. HCC incidence increased with the number of

CMR factors. The aMAP score demonstrated good discriminatory performance in patients with obesity (C-index = 0.82), CMR factors (0.79), and MASLD (0.74). **Conclusion:** In this CHB cohort, cirrhosis, male sex, and obesity independently increased the risk of HCC, while statin use, higher platelet count, and higher albumin were protective. An increasing number of CMR factors was associated with higher HCC risk. The aMAP score effectively stratified HCC risk among patients with obesity, CMR, and MASLD.

3274 | PUS7-MEDIATED RNA PSEUDOURIDYLATION DRIVES PROLIFERATION AND METASTASIS IN INTRAHEPATIC CHOLANGIOCARCINOMA

liu maoyun[1] Fengsheng Dai[1] sheng wang[1] Yi wang[1] Jiale Lu[1] YuQin Xie[2] Ai Shen[1] DeWei Li[1] Hui Li[1],

[1]Chongqing University Cancer Hospital, [2]Chongqing university cancer h

Background: Intrahepatic cholangiocarcinoma (ICC), the second most common subtype of primary liver cancer, is a highly aggressive and metastatic malignancy with limited therapeutic options. Despite progress in surgical and systemic treatments, clinical outcomes for ICC remain dismal. Post-transcriptional RNA modifications have emerged as key regulators of tumor biology. Among these, pseudouridine (Ψ) is one of the most abundant RNA modifications, broadly distributed across RNA species and implicated in various pathological processes. This study aims to investigate the biological role and mechanistic contribution of PUS7-mediated pseudouridylation in ICC progression. **Methods:** Three pairs of matched primary and recurrent ICC tissues were collected. RNA modification levels were quantified using LC-MS/MS and dot blot analysis, and differentially expressed genes were identified by RNA sequencing. Immunohistochemistry (IHC) was performed on a tissue microarray containing 136 ICC samples to evaluate PUS7 expression and its association with clinicopathological features and patient prognosis. Pus7 knockout ($Pus7^{-/-}$) mice and a hydrodynamic tail vein injection–induced ICC model was used to investigate the role of PUS7 in ICC development. Functional assays were conducted to assess the proliferative, migratory, and invasive capacities of ICC cells. Nascent protein synthesis was measured using the SUnSET assay and HPG pulse-labeling assay. **Results:** LC-MS/MS analysis revealed that the Ψ modification level was significantly elevated in recurrent ICC tissues compared to primary tumors. This increase in Ψ modification was primarily mediated by PUS7, a pseudouridine synthase which was also found to be highly expressed in recurrent tumors. High PUS7 expression was significantly associated with vascular invasion, lymph node metastasis, and poor patient prognosis. In vitro functional assays demonstrated that PUS7 promotes ICC cell proliferation, migration, and invasion. In vivo, hydrodynamic tail vein injection–based ICC models showed that Pus7 knockout markedly suppressed tumor initiation and progression, whereas PUS7 overexpression significantly enhanced tumor development. Mechanistically, PUS7 was shown to regulate nascent protein synthesis in ICC cells, suggesting a critical role of PUS7-mediated pseudouridylation in driving ICC progression. **Conclusion:** Our study revealed that PUS7-mediated pseudouridylation plays a critical regulatory role in the progression of ICC, providing a theoretical foundation for the development of novel PUS7-targeted therapeutic strategies.

3275 | ADVERSE EVENT PROFILE OF SECOND-LINE TYROSINE KINASE INHIBITORS AFTER ATEZOLIZUMAB/BEVACIZUMAB IN ADVANCED HCC: A META-ANALYSIS OF TREATMENT-RELATED TOXICITY

Ronald Blanco Montecino[1] Nehemias Guevara Rodriguez[2] Noemy Coreas[3] Yassine Kilani[4] Syeda Fatima Kamal[5] Daniel Mendoza Quispe[1] Iqra Arshad[4] Kamran Qureshi[6] John Richart[2], [1]Department of Internal Medicine, St Barnabas Hospital, Bronx, NY., [2]Division of Hematology-Oncology and BMT, Saint Louis University, St. Louis, MO, [3]National University of El Salvador, Social Security System, Division of OBGYN-Oncology, [4]Division of General Internal Medicine, Saint Louis University School of Medicine, St. Louis, MO, [5]Division of Hospice and Palliative Medicine, Saint Louis University School of Medicine, [6]Division of Gastroenterology and Hepatology, Saint Louis University School of Medicine, St. Louis,MO

Background: The tolerability of tyrosine kinase inhibitors (TKIs) in the post-immunotherapy setting has gained increasing relevance as treatment sequencing in HCC evolves. Comparative safety data are critical for optimizing therapeutic decisions with multiple agents available as second-line options after Atezolizumab/Bevacizumab failure. We conducted a proportional meta-analysis to quantify the incidence of treatment-related adverse events (AEs) associated with second-line TKIs in advanced HCC. **Methods:** We reviewed retrospective studies reporting any-grade and grade ≥ 3 AEs in patients receiving Lenvatinib, Regorafenib, Sorafenib, or Cabozantinib as second-line therapy following progression on first-line treatment. Data on nausea, vomiting, hypothyroidism, and other key toxicities were extracted. Pooled proportions were calculated using a random-effects model, and heterogeneity was assessed using I² statistics. All statistical analyses, including pooled proportions and heterogeneity estimates, were performed using Stata version 18 (Stata Corp, College Station, TX). **Results:** We included 9 studies comprising 907 patients treated with second-line tyrosine kinase inhibitors (TKIs) for advanced hepatocellular carcinoma (HCC). The overall safety profile was favorable, with most adverse events (AEs) being low grade. Pooled incidence rates for any-grade vomiting, and hypothyroidism were 4%, and 29%, respectively. Hypothyroidism was common with cabozantinib (32%) and lenvatinib (28%). Grade ≥ 3 AEs were infrequently reported due to inconsistent data across studies.

In lenvatinib-treated patients, elevated liver enzymes (AST/ALT) were the most frequent AE (any-grade: 61%; grade ≥ 3: 11%), followed by thrombocytopenia (33%/3%), bilirubin elevation (43%/5%), and hypothyroidism (28%/2%). Other notable AEs included proteinuria (37%/18%), fatigue (43%/5%), and hypertension (27%/3%).

Across TKIs, fatigue was the most common AE overall (48%, 95% CI: 34–61%), followed by hand-foot syndrome (30%, 95% CI: 17–43%), diarrhea (14–30%), and hypertension (21%, 95% CI: 10–33%). Severe events such as liver failure (overall: 6%/1%) and rash, vomiting, or elevated bilirubin $\geq$ G3 were rare. Anorexia and proteinuria were reported with similar frequency in lenvatinib and cabozantinib, with anorexia reaching up to 53% in cabozantinib-treated patients.

Heterogeneity was moderate (I² 43–70%) for most endpoints, reflecting variability in reporting and patient populations. **Conclusion:** Overall, our findings suggest that second-line TKIs exhibit a manageable safety profile, with low rates of high-grade toxicity. These results support their continued use in appropriately selected patients and highlight the need for uniform AE reporting in future head-to-head trials.

Table 1. Adverse events

Adverse Event	Lenvatinib (Any/ ≥G3)	Cabozantinib (Any / ≥G3)	Regorafenib(Any/ ≥G3)	Sorafenib (Any/ ≥G3)	Overall (Any/≥G3)

3276 | RISK STRATIFICATION FOR HEPATOCELLULAR CARCINOMA IN AUTOIMMUNE LIVER DISEASES USING THE ADRESS-HCC MODEL: U.S. SINGLE-CENTER VALIDATION

Ana Marenco-Flores[1] Ximena Parraga[2] Esteban Garita[3] Natalia Rojas-Amaris[2] Kim Ruiz-Arellanos[1] Romelia Barba[4] Vilas Patwardhan[1] Behnam Saberi[2] Alan Bonder[2], [1]Beth Israel Deaconess Medical Center, [2]Beth Israel Deaconess Medical Center, Harvard Medical School, [3]Montefiore Medical Center, Albert Einstein College of Medicine, [4]Texas Tech University

Background: Hepatocellular carcinoma (HCC) is the most common primary liver cancer and is typically fatal without early detection, with >90% of cases occurring in patients with cirrhosis. The incidence of autoimmune liver diseases, including autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC), is rising, though reported 1-year HCC risk varies widely. Risk is further shaped by age, sex, cirrhosis, comorbidities, and lifestyle factors. The ADRESS-HCC model provides personalized HCC risk estimates based on these variables. This study aims to externally validate the ADRESS-HCC score in autoimmune liver disease to estimate 1-year HCC risk and guide surveillance strategies. **Methods:** We conducted a prospective cohort study of adults with autoimmune liver disease (AIH, PBC, or PSC) evaluated at a U.S. tertiary care center between January 2018 and May 2025. Patients with complete data for ADRESS-HCC scoring and at least 12 months of follow-up or a 1-year HCC event were included. Exclusion criteria included prior HCC, liver transplantation, viral hepatitis, non-hepatic malignancy, or insufficient baseline data. The primary outcome was 1-year HCC. Predicted risk was compared by outcome and subtype using Mann–Whitney U tests with Bonferroni correction. Analyses were conducted in Stata; visualizations in Python. **Results:** Among 402 patients with autoimmune liver disease, 1.5% developed HCC within 1 year. Predicted 1-year HCC risk varied by disease subtype and cirrhosis status. Cirrhosis was more frequent among those who developed HCC compared to those who did not (50% vs. 12%, $p = 0.005$). The median predicted risk was higher in patients who developed HCC (7.9%) than in those who did not (0.069%; $p < 0.001$). Among patients with cirrhosis, predicted risk was significantly higher in AIH and PBC ($p = 0.015$ and $p = 0.006$, respectively), but not in PSC ($p = 0.826$). In pairwise comparisons, risk was significantly greater in PBC than PSC ($p = 0.003$, Bonferroni-adjusted), while no significant differences were observed among patients without cirrhosis. The ADRESS-HCC model demonstrated strong discriminatory performance, with an AUROC of 0.858 for predicting 1-year HCC. **Conclusion:** The ADRESS-HCC model accurately stratified 1-year HCC risk in patients with autoimmune liver disease, particularly those with cirrhosis. These findings support its use to guide individualized HCC surveillance strategies in this population.

3277 | TUMOR-DERIVED CXCL2 SUPPRESSES HEPATOCELLULAR CARCINOMA THROUGH PROMOTING NEUTROPHIL N1 POLARIZATION VIA THE YBX1/SREBP2 AXIS

Xin Liu[1] Danli Yang[1] Ting Zhang[1] Lin Wang[1] Fengmin Lu[1] Xiangmei Chen[1], [1]Peking University Health Science Center

Background: While anti-tumor neutrophils (N1) play pivotal roles in immune regulation and tumor control, hepatocellular carcinoma (HCC) frequently reprograms them into a pro-tumor (N2) phenotypes to facilitate tumor immune escape. Identifying key modulators of neutrophil polarization toward the anti-tumor state is thus critically needed. **Methods:** We integrated comparative genomic hybridization and the RNA expression profile to identify pivotal neutrophil associated genes with copy number variations in HCC. Clinical specimens and *in vitro* and *in vivo* experiments, including gain-function assays, flow cytometry and subcutaneous

tumor xenograft model, were conducted to validate the roles and molecular mechanisms by which C-X-C Motif ligand 2 (CXCL2) modulating HCC immune microenvironment and its synergistic therapeutic efficacy of anti-PD-1 antibody. **Results:** CXCL2, a well-documented chemokine for neutrophil recruitment, was significantly downregulated in HCC tissues. Low CXCL2 expression was associated with poor prognosis and increased pro-tumor neutrophils. Surprisingly, subsequent experiments results identified that the overexpression of CXCL2 not only recruited neutrophils but also polarized them toward the N1 phenotype, thereby inhibiting HCC progression. Mechanistically, deviating from its canonical extracellular role, intracellular CXCL2 could bind to YBX1 and block its nuclear translocation. This reduced SREBP2-mediated transcriptional activation of the genes in regulating cholesterol biosynthesis, thereby remodeling the tumor microenvironment and impeding HCC development. More importantly, the combination of CXCL2 overexpression with anti-PD1 therapy synergistically suppressed HCC progression. **Conclusion:** We demonstrate an unconventional, tumor-suppressive role of CXCL2 in driving neutrophil N1 polarization and anti-tumor immune responses in HCC, positioning it as a promising therapeutic target for HCC.

3278 | EFFICACY OF TACE WITH TKIS ALONE VERSUS TACE COMBINED WITH TKIS AND ICIS IN UNRESECTABLE HEPATOCELLULAR CARCINOMA: A RETROSPECTIVE COHORT STUDY

ABOUBACAR HAROUNA ABOUBACAR[1] Xin Zheng[2] Yujing Zhang[1] Yuhan Zhou[1] Haonan Liu[1] Tianli Liu[1], [1]Xi'an Jiaotong University, [2]First Affiliated Hospital of Xi'an Jiaotong University

Background: Unresectable hepatocellular carcinoma (uHCC) remains a major treatment challenge worldwide. Trans-arterial chemoembolization (TACE) combined with tyrosine kinase inhibitors (TKIs) is commonly used as first-line treatment for uHHC patients. However, survival outcomes remain limited, with overall survival (OS) of 13-20 months. Recent interest has focused on whether adding immune checkpoint inhibitors (ICIs) to this combination can improve outcomes. This study aimed to compare OS, progression-free survival (PFS), tumor response, and safety between TACE plus TKIs and TACE plus TKIs with ICIs in uHCC patients, and to identify subgroups that derive the greatest benefit. **Methods:** This retrospective cohort study included 229 uHCC patients treated at the First Affiliated Hospital of Xi'an Jiaotong University between 2019 and 2022. The patients received either TACE plus TKIs (n = 169) or TACE plus TKIs with ICIs (n = 60). The primary endpoint was OS, while the secondary endpoints included PFS, tumor response (ORR, DCR), and adverse events (AEs). Kaplan-Meier and Cox regression were used for survival analysis. Tumor response was evaluated using modified RECIST. AEs were classified using NCI-CTCAE version 5.0. **Results:** The TACE plus TKI with ICI group showed improved OS, which was not reached at the final follow-up cut-off date, compared to 19.23 months in the TACE plus TKI group (HR: 0.582; 95% CI: 0.365–0.929; P = 0.047). Subgroup analysis showed significant OS benefit in patients with BCLC 0&A (HR: 0.336, P = 0.016), AFP > 400 ng/mL (HR: 0.422, P = 0.028), Child-Pugh A (HR: 0.541, P = 0.035), and tumors > 3 cm (HR: 0.451, P = 0.013). Objective Response Rate (ORR) and Disease Control Rate (DCR) were higher in the TACE plus TKI with ICI group (56.1% vs. 30.4%, P < 0.001; 96.5% vs. 86.9%, P = 0.044). Median PFS was similar between the two groups (7.23 vs. 7.37 months; HR: 0.981, P = 0.423). Most AEs were mild to moderate, with more vomiting (P = 0.006) and elevated ALT (P = 0.047) in the TACE plus TKI with ICI group, but fewer serious complications overall. **Conclusion:** TACE combined with TKIs and ICIs significantly improved survival and tumor response in patients with uHCC while maintaining an acceptable safety profile. These findings support further investigation of TACE plus TKIs with ICIs therapy as a potential new standard of care for patients with uHCC.

3279 | CLINICAL CHARACTERISTICS AND ONE-YEAR SURVIVAL OF PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)-RELATED HEPATOCELLULAR CARCINOMA (HCC): INSIGHTS FROM A LARGE INSTITUTIONAL REGISTRY

Saleh Alqahtani[1] Saleh Alessy[1] Faisal Abaalkhail[1] Waleed Al-Hamoudi[1] Abeer Alabdullah[1] Amwaj Alanazi[1] Heba Alharith[1] Mussadique Ali Jhatial[1] Mehwish Shahzadi Sajjad Hussain[1] Fahad AlMugbel[1] Ali Alqahtani[1] Ali Albenmousa[1] Dimitri Raptis[1] Dieter Broering[1] Waleed Alomaim[1] Bandar Aljudaibi[1] Saad Alghamdi[1], [1]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia

Background: HCC, the most common type of primary liver cancer globally, remains a leading cause of cancer-related mortality in Saudi Arabia. With the declining prevalence of viral hepatitis, there is a global shift in HCC etiology toward MASLD. Data on the clinical presentation and outcomes of MASLD-related HCC in Saudi Arabia are still evolving. We aimed to assess and compare patient characteristics, disease presentation, and clinical outcomes between individuals with MASLD-related HCC and those with HCC of other etiologies (non-MASLD-related HCC). **Methods:** We retrospectively analyzed a prospectively maintained HCC registry at King Faisal Specialist Hospital and Research Center, Riyadh, which included patients diagnosed with HCC (histologically or radiologically) between August 2020 and May 2025. Demographic, clinical, and tumor characteristics, as well as treatment modalities, were assessed and compared between patients with MASLD-related and non-MASLD-related HCC. One-year survival was estimated using Kaplan-Meier analysis, with censoring at the date of last follow-up for patients who did not die within the first year. All patients, including those with less than one year of follow-up, were included in the analysis. **Results:** Of the 427 patients with HCC, 152 (35.6%) had MASLD-related HCC. Most patients were male (69.5%), with no significant difference in sex distribution between MASLD-related and non-MASLD-related HCC groups ($p = 0.971$). Patients with MASLD were older at diagnosis (median age 66 vs. 63 years, $p < 0.001$) and more likely to have diabetes (67.8% vs. 46.9%, $p < 0.001$). There were no significant differences between the groups in ECOG performance status, BCLC stage, Milan criteria, or Child-Pugh class at the time of diagnosis. Locoregional therapies were the most common first-line treatments in both groups (53.3% in MASLD vs. 57.1% in others, $p = 0.913$). One-year survival was similar across groups (log-rank $p = 0.44$), with comparable Kaplan-Meier survival estimates. **Conclusion:** MASLD has become the predominant etiology of HCC in Saudi Arabia, accounting for over one-third of the cases. Despite presenting at an older age and having a higher diabetes prevalence, patients with MASLD-related HCC had similar tumor burden, treatment approaches, and one-year survival outcomes compared to non-MASLD-related HCC. The findings underscore the need for increased surveillance efforts and earlier risk stratification for MASLD. Future research should focus on long-term outcomes and tailoring therapies to the distinct metabolic profile of MASLD-related HCC.

3280 | A NOVEL INDEX TO PREDICT TREATMENT RESPONSE TO ATEZOLIZUMAB AND BEVACIZUMAB THERAPY IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

Satoshi Narahara[1] Takahiro Mizuta[1] Toshinori Toyota[1] Daiki Maeda[1] Kentaro Tanaka[1] Hiroki Inada[1] Sotaro Kurano[1] Estuko Iio[1] Yoko Yoshimaru[1] Takehisa Watanabe[1] Katsuya Nagaoka[1] Hiroko Setoyama[1] Masaya Onishi[2] Yasuhito Tanaka[1], [1]Department of Gastroenterology and Hepatology, Faculty of Life

Sciences, Kumamoto University, [2]Graduate School of Frontier Sciences, The University of Tokyo

Background: Atezolizumab plus bevacizumab therapy (Atezo+Bev) is widely used for the treatment of advanced hepatocellular carcinoma (HCC); however, no reliable biomarker is currently available to predict treatment response before or in the early phase of therapy. Previously, we reported that elevated AGRP1 (tentatively named) levels were associated with poor response to lenvatinib (AASLD The Liver Meeting 2023). Furthermore, using VISIUM, a spatial transcriptome analysis of HCC tissue and serum, we identified cytokine X as a contributor to resistance against Atezo+Bev (AASLD The Liver Meeting 2024). In this study, we aimed to develop a novel composite index by combining these two serum proteins to predict resistance to Atezo+Bev therapy. **Methods:** We retrospectively analyzed 155 patients who started Atezo +Bev therapy between November 2018 and December 2024. Inclusion criteria included availability of stored serum samples collected before treatment and at week 3, and sufficient clinical follow-up to assess response. Tumor response was evaluated using mRECIST. Serum AGRP1 and Cytokine X levels were measured by ELISA, and cutoff values were established via ROC analysis. **Results:** Median age was 67 years (range: 41-87), 30 men and 4 women, 28 in primary treatment and 6 in secondary or later treatment. Pretreatment AGRP1 and cytokine X were 351.3 (177.9-736.4) pg/mL and 138.9 (31.3-900.2) pg/mL, respectively; second course AGRP1 and cytokine X were 308.2 (93.1-643.7) pg/mL and 90.4 (14.0-547.7) pg/mL. Dichotomized by median value, high AGRP level at 3 weeks and high cytokine X level before treatment had significantly shorter PFS ($p = 0.046$ and 0.036, respectively). Next, using ROC analysis to set cutoff values, high AGRP level at 3 weeks and high cytokine X level before treatment were identified as contributing to PD significantly ($p = 0.049$ and 0.041, respectively). Finally, we developed a novel index, the Atezo+Bev Resistance Index (ABRI), calculated by assigning +1 point for each parameter exceeding the defined cutoff. A total score of 2 points was significantly associated with progressive disease ($p = 0.042$), demonstrating a high AUC of 0.826 and significantly shorter progression-free survival (PFS) ($p = 0.002$). **Conclusion:** We developed a novel predictive index, the ABRI, based on serum AGRP1 and cytokine X levels before and early after initiation of therapy. ABRI may serve as a useful index for predicting resistance to Atezo+Bev in patients with HCC.

3281 | INVESTIGATION INTO THE DIFFERENCES BETWEEN HBV-RELATED HCC AND MAFLD-RELATED HCC BASED ON SINGLE-CELL SEQUENCING

Jiashuo Li[1] Ying Cao[1] Wen Xie[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Hepatocellular carcinoma (HCC) remains a critical global public health issue, posing persistent challenges in management and treatment. The etiology of HCC is diverse, primarily involving hepatitis B virus (HBV) infection, and metabolic dysfunction-associated fatty liver disease (MAFLD). HCC patients exhibit distinct characteristics depending on its underlying etiology. Unlike virus-related HCC, MAFLD-associated HCC is diagnosed at later stages constantly, as well as exhibits distinct immunological features and treatment responses. Therefore, a deeper understanding of the tumor microenvironment differences under varying etiological backgrounds has become a crucial research direction for improving therapeutic precision, optimizing immunotherapy efficacy, and enhancing patient survival. **Methods:** This study enrolled patients who were treated at Beijing Ditan Hospital between June 2023 and June 2024. Based on etiology, patients were divided into two groups, with 5 patients per group, and one tumor tissue sample was collected from each patient. Additionally, 2 paired adjacent tissues from MAFLD-related HCC patients and 1 adjacent tissue from a HBV-related HCC patient were included as controls. Firstly, differentially expressed genes (DEGs) between the two groups were identified following dimensionality reduction, and cell annotation. Subsequently, functional enrichment analysis was performed to annotate the biological processes and signaling pathways associated with the DEGs. Finally, ligand-receptor interaction analysis was conducted to investigate intercellular communication networks among different cell types. **Results:** The results of this study revealed significant disparities in the proportions of macrophage, T cell, and NK cell subsets between HBV-related HCC and MAFLD-related HCC. Specifically, $GZMK^+CD8^+$ T cells were markedly enriched in MAFLD-associated HCC, whereas $ACP5^+$ macrophage subsets were more prevalent in HBV-related HCC. Additionally, the study identified distinct signaling pathway enrichment patterns and immune checkpoint

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

interaction networks. **Conclusion:** The results of single-cell RNA sequencing revealed distinct immune microenvironment between HBV-related HCC and MAFLD-related HCC, indicating potential immunological heterogeneity.

3282 | TEAD INHIBITION BY IAG933 AS A NOVEL THERAPEUTIC STRATEGY FOR CHOLANGIOCARCINOMA

Hidemi Nishi[1] Erik Jessen[1] Enis Hikmet Ozmert[1] Danielle Carlson[1] Jack Sample[1] Amro Abdelrahman[1] Nathan Werneburg[1] Rory Smoot[1], [1]Mayo Clinic Rochester

Background: Cholangiocarcinoma (CCA) is an aggressive and heterogeneous malignancy of the biliary epithelium and remains one of the most challenging hepatobiliary cancers, with limited systemic treatment options and poor prognosis. Dysregulation of the Hippo signaling pathway, particularly hyperactivation of YAP/TAZ and their interaction with TEAD transcription factors, is increasingly recognized as a key driver of CCA progression, proliferation, and treatment resistance. Targeting the YAP/TAZ–TEAD axis represents a promising strategy to overcome these limitations. IAG933 is a novel oral pan-TEAD inhibitor specifically designed to disrupt YAP/TAZ–TEAD interactions and suppress oncogenic transcriptional programs in CCA. **Methods:** We investigated the effects of IAG933 in human (HuCCT1, RBE) and murine (SB1, FAC) CCA cell lines. Cells were treated with IAG933 alone or in combination with either standard chemotherapy (gemcitabine/cisplatin; GemCis) or a pan-KRAS inhibitor (RMC-6236). Cell viability assays were performed to determine IC_{50} values and calculate combination indices (CI) for synergy. TEAD transcriptional activity was quantified using luciferase reporter assays and qRT-PCR of target genes (CTGF, CYR61, NUAK2). RNA sequencing was performed to assess transcriptomic changes. In vivo efficacy was evaluated using a syngeneic orthotopic liver tumor model. **Results:** IAG933 significantly suppressed TEAD-dependent transcription ($IC_{50} \approx 500$ nM) and downregulated key TEAD target genes. Combination with GemCis or RMC-6236 showed synergistic anti-tumor effects (CI < 1) in all tested cell lines. In vivo, IAG933 reduced tumor growth to a similar extent as GemCis. qRT-PCR confirmed downregulation of CYR61 and NUAK2. Transcriptomic analysis revealed upregulation of oxidative stress response genes, most notably SOD2. MitoSOX staining demonstrated increased mitochondrial ROS levels 8 hours post-treatment, suggesting a compensatory transcriptional stress response associated with TEAD inhibition. **Conclusion:** IAG933 robustly inhibits TEAD-driven transcription and suppresses CCA growth in vitro and in vivo. Its synergy with GemCis and RMC-6236 supports its potential as a therapeutic candidate for CCA, including KRAS-mutated subtypes. Notably, SOD2 upregulation as a response to TEAD inhibition may represent a general resistance mechanism in CCA. These findings support further translational development of IAG933 and highlight the Hippo–TEAD axis as a targetable vulnerability in aggressive hepatobiliary cancers.

3283 | THE PROGNOSTIC SIGNIFICANCE OF AAA SCORING SYSTEM IN BCLC STAGE 0/A RUPTURED HEPATOCELLULAR CARCINOMA

Chao Wang[1] Zhiyuan Huang[1] Peng Zhu[1] Hongping Luo[1] Yifa Chen[1], [1]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology

Background: Ruptured hepatocellular carcinoma (rHCC) is a rare yet life-threatening disease with a poor prognosis. Accurate evaluation of liver function and survival outcomes is critical in managing patients with rHCC. Traditional methods including the Child-Pugh classification have limitations due to subjective parameters. The Albumin-Bilirubin (ALBI) grade offers a more objective assessment, while the AAA (ALBI + AST + AFP) scoring system has emerged as a comprehensive prognostic tool. This study evaluates the predictive performance of various prognostic systems, including ALBI, Child-Pugh, AFP, AST, and AAA scoring, among BCLC Stage 0/A rHCC patients. **Methods:** A total of 249 patients with rHCC were retrospectively analyzed. Kaplan-Meier survival analysis assessed overall survival (OS) differences based on AFP (>100 ng/ml vs. ≤ 100 ng/ml) and AST (>45 U/L vs. ≤ 45 U/L).

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Predictive accuracy of ALBI grade, AAA score, Child-Pugh class, AFP, and AST levels was compared using time-dependent ROC curve analysis for 1-, 3-, and 5-year OS. Subgroup analysis was conducted to evaluate gender-specific predictive capacities of the AAA score. Statistical significance was set at $P < 0.05$. **Results:** Elevated AFP and AST levels were significantly associated with reduced OS ($P < 0.001$ and $P < 0.01$, respectively). The AAA scoring system showed superior predictive performance for 1-, 3-, and 5-year OS (AUCs: 0.672, 0.705, and 0.739, respectively) compared to other indicators. Subgroup analysis revealed that AAA scoring had strong prognostic significance in male patients ($P < 0.001$), whereas the association was not statistically significant in females ($P = 0.230$). AAA scoring demonstrated consistent stratification of survival outcomes and outperformed single-parameter models. **Conclusion:** The AAA scoring system offers superior prognostic accuracy over conventional methods for predicting survival in BCLC Stage 0/A rHCC patients, particularly in males. Its integrative approach makes it a valuable tool for individualized prognosis and therapeutic planning. Further investigation is warranted to clarify observed gender disparities in predictive performance.

3284 | SEX DISPARITIES IN HEPATOCELLULAR CARCINOMA: AGE, ETIOLOGY, AND TREATMENT GAPS IN A KOREAN NATIONWIDE COHORT

Do Seon Song Su Jong Yu[1] Ji Won Han[2] Gwang Hyeon Choi[3], [1]Seoul National University Hospital, [2]The Catholic University of Korea, [3]Seoul University

Background: Hepatocellular carcinoma (HCC) is a malignancy with a well-established male predominance, with incidence rates two to three times higher in men than in women. However, sex-related disparities in HCC have not been well characterized in Asian populations. **Methods:** This study included patients newly diagnosed with HCC between 2008 and 2020 from the Korea Central Cancer Registry. Exclusion criteria were age < 18 years, missing data, and combined HCC and cholangiocarcinoma. Tumor stage was classified according to the modified Union for International Cancer Control (mUICC) staging system. **Results:** A total of 19,729 patients with HCC were included, of whom 15,595 (79.0%) were men. HCC in men peaked in their 50s and declined thereafter, whereas in women, the number of cases increased with age. The male-to-female (M:F) ratio was highest in patients aged 40–59 years (6.0:1), followed by 60s (3.7:1) and ≥ 70 years (2.4:1), indicating a decreasing male predominance with age.

By etiology, the M:F ratio was 2.7 for HBV, 1.4 for HCV, 22.0 for alcohol-related HCC, and 2.2 for other causes, with the most pronounced male predominance in alcohol-related cases. From 2008 to 2020, the proportion of women with alcohol-related HCC increased from 3.6% to 5.6% ($P < 0.05$), while no significant sex-based changes were observed in other etiologies ($P > 0.05$).

At diagnosis, the proportion of women decreased with advancing stage: 28.2% in stage I, 23.2% in stage II, 18.2% in stage III, and 14.9% in stage IV ($P < 0.001$), suggesting later-stage diagnosis in men.

In stage I, treatment patterns did not differ by sex. However, in stage II, men were more likely to undergo surgical resection (35.2% vs. 28.2%). In stage IVa, systemic therapy was more common in men (17.4% vs. 12.6%), whereas more women remained untreated (43.2% vs. 36.1%). In stage IVb, men more frequently received transarterial therapy (24.4% vs. 17.7%) and systemic therapy (26.4% vs. 22.6%), while untreated rates were higher among women (50.9% vs. 41.0%). These findings indicate that men were more likely to receive active treatment, especially in advanced stages. **Conclusion:** The incidence of HCC differs by sex across age groups and underlying etiologies, with the most pronounced disparity observed in alcohol-related liver disease. Notably, the proportion of women developing alcohol-related HCC has been gradually

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

increasing. Following diagnosis, men tend to receive more active treatment compared to women. Recognizing these sex-based differences in HCC is essential to guide strategies aimed at improving outcomes

3285 | ONCOLOGIC OUTCOMES FOLLOWING LIVER TRANSPLANTATION FOR CHOLANGIOCARCINOMA: A NATIONAL COHORT ANALYSIS (2009–2022)

Andrew Caddell[1] Minzhi Xing[1] Andrew Moon[1] Neil Shah[1] Jinquan Jia[1] Hanna Sanoff[1] Sandra Gad[1] Jonathan Sorah[1] Ted Yanagihara[1] David Mauro[1] Alexander Villalobos[1] Nima Kokabi[1], [1]University of North Carolina at Chapel Hill

Background: Purpose: To evaluate oncologic outcomes of adult patients undergoing liver transplantation (LT) for the indication of Cholangiocarcinoma (CCA) since its adoption as a structured, protocol-driven treatment in 2009. **Methods:** Materials and Methods: Using the United Network for organ Sharing (UNOS) database, adult patients undergoing whole-organ LT for CCA between 2009 and 2022 were identified. Exclusion criteria included prior LT, prior hepatocellular carcinoma diagnosis, retransplantaion, and follow up less than 1 year. Kaplan-Meier analysis was used to estimate post-transplant recurrence and survival at 1,2,3 and 5 years. Waitlist time difference by recurrence status was evaluated using the Wilcoxon test. Multivariable Cox proportional hazards models were used to assess predictors of recurrence and survival, adjusted for sex, MELD at listing, and MELD prior to transplant. Association comparing additional tranplantation indictations and recurrence were evaluated using Fisher's Exact test. **Results:** Results: A total of 402 patients met inclusion criteria. The cumulative recurrence rates were 7.7%, 16.3%, 21.2% and 24.8% at 1, 2, 3 and 5-years post LT. Corresponding overall survival rates were 90.3%, 78.7%, 69.7%, and 61.1%. Median waitlist time did not differ significantly by recurrence status ($p = 0.92$). Multivariable analysis showed MELD at listing (HR 0.98; $p = 0.50$) and MELD prior to LT (HR 1.01; $p = 0.54$) were not associated with recurrence. Female sex showed a non-significant trend toward increased recurrence (HR 1.45; $p = 0.13$). The recurrence model did not reach significance ($p = 0.25$).
During follow up, 165 patients (41.0%) died. MELD at listing (HR 1.01; $p = 0.49$) and MELD prior to LT (HR 1.07; $p = 0.10$) were not predictive of survival. MELD categorized into three groups (< 15, 15-24, ≥ 25) also showed no significant association (HR 1.47; $p = 0.19$). There was a non-significant trend toward worse survival in female patients (HR 1.37; $p = 0.07$). The survival model did not reach statistical significance ($p = 0.14$). CCA recurrence was more common in patients listed with transplantation diagnosis of cirrhosis compared to primary sclerosing cholangitis (33.3% vs 9.2%; $p = 0.0014$). **Conclusion:** Conclusions: LT for CCA is associated with encouraging long-term survival outcomes, with a 5-year survival rate exceeding 61% and recurrence in approximately 25% of patients. No clinical variable evaluated significantly predicted outcomes. Further prospective national cohort studies are needed to refine selection criteria and improve prediction of patient prognosis.

Variable	All Patients (n = 402)	With Recurrence (n = 84)	Without Recurrence (n = 318)

of Hepato-Pancreato-Biliary (HPB) Surgery, Cleveland, OH

Background: Histotripsy, a non-invasive and non-thermal focused ultrasound method, is being studied for its potential in treating liver tumors. This research examines the radiologic and molecular impacts of histotripsy, with a focus on circulating tumor DNA (ctDNA) positivity, tumor mutational burden (TMB), and the viability of lesions. **Methods:** A retrospective study was conducted on 16 patients with liver tumors who underwent histotripsy. ctDNA and TMB (mut/Mb) were evaluated at a median of 91 days before and 50 days after the treatment (average interval: 141 days). Changes in ctDNA were classified as stable, cleared, or newly positive. Associations with diagnosis, systemic therapy, number of treatments, tumor viability on post-operative day (POD) 1 and 30, and off-target effects were analyzed using Chi-square and Fisher's exact tests. **Results:** The study included patients with colorectal cancer (37.5%), neuroendocrine tumors (12.5%), breast cancer (19%), and other cancer types (31%). They had a total of 25 liver lesions, averaging 3.27 cm in size, primarily located in segments III and IV. Most treatments (97%) were palliative, and 62.5% of the patients received systemic chemotherapy. The average TMB was 10 mut/Mb before treatment and 21.14 mut/Mb after treatment. The highest variant allele fraction recorded was 15.71% before treatment and 16% after. TMB was categorized into low, intermediate, and high levels, with 7 patients having pre-treatment TMB of 29%, 57%, and 14%, and post-treatment, 13 patients had TMB of 38.5%, 38.5%, and 23%, respectively. Eleven patients experienced an increase in TMB after treatment, most of whom had prior disease progression and systemic therapy. Among these, 6 out of 15 lesions were non-viable on POD-1, and 4 remained non-viable by POD-30. Off-target effects were noted in 4 lesions. Only one patient showed a decrease in TMB, who had not undergone primary tumor resections and had progressive disease before histotripsy. This patient had 2 lesions treated twice with histotripsy, and the lesions were viable on POD-1 and POD-30, with off-target effects observed. Of the remaining four patients, 2 out of 4 had negative ct-DNA tests, and 2/4 patients lacked pre-histotripsy TMB data, with one of these 2 patients having a positive intermediate TMB post-histotripsy; their lesions were viable on POD-1 and POD-30, with off-target effects seen in the patient with intermediate TMB post-histotripsy. Trends in ctDNA positivity, although not statistically significant, were associated with disease burden ($p = 0.079$) and tumor viability at POD-1 ($p = 0.079$) and POD-30 ($p = 0.098$). **Conclusion:** Histotripsy appears promising in inducing local tumor non-viability, particularly in smaller, palliatively treated lesions. ctDNA dynamics and TMB changes seem to reflect prior disease progression and treatment context. Further prospective studies are needed to clarify their predictive roles in histotripsy outcomes.

Background: Recurrence after curative radiofrequency ablation (RFA) in hepatocellular carcinoma (HCC) patients is high. Currently there are limited predictive biomarkers. This study combined deep learning with machine learning to develop radiomic models predicting time-to-recurrence (TTR) and disease-free survival (DFS) after RFA. **Methods:** 156 consecutive HCC patients from two prospective randomised control clinical trials were included in the study. Patients undergoing RFA from the SORAMIC trial (n = 93) were used for training. A deep learning U-Net model automatically segmented tumour lesions from pre-treatment dynamic contrast-enhanced MRI, with subsequent radiologist verification. A total of 12,393 radiomic features were extracted from arterial, portal venous and delayed phases. Radiomic models predicting 12-month recurrence were trained using seven supervised machine learning algorithms with thirteen feature selection techniques for each phase. Ensemble learning selected the best performing machine learning and feature selection combinations. Radiomic models were benchmarked against established clinical predictors. Using unsupervised K-means clustering and threshold optimisation, high- and low-risk radiomic risk groups were identified. The model performance was evaluated on an external independent patient cohort from a prospective randomised control trial (CHUV, n = 63). **Results:** The arterial phase based radiomic model had the highest AUC when predicting 12-month post-RFA recurrence in the training (AUC: 0.90, 95% CI 0.80-0.98) cohort, significantly outperforming Barcelona Clinic Liver Cancer (BCLC) stage (AUC: 0.58, 95% CI 0.39-0.77, $p = 0.003$) and Child-Pugh (CP) class (AUC: 0.47, 95% CI 0.30-0.65, $p < 0.001$). The arterial phase radiomic model maintained predictive performed in the independent external validation cohort (AUC: 0.74, 95% CI 0.61-0.87) cohorts, significantly outperforming BCLC (AUC: 0.58, 95% CI 0.51-0.67, $p = 0.03$) and CP class (AUC: 0.45, 95% CI 0.34-0.56, $p < 0.001$). Threshold optimisation identified a high-risk arterial-phase radiomic group, with a significantly shorter TTR compared to the low-risk radiomic group in both the training (median TTR: 4.2 months, 95% CI 1.9-9.9 vs. 29.0 months, 95% CI 15.8-inf; $p < 0.001$) and external validation (4.5 months, 95% CI 9.6-22.9 vs. 12.5 months, 95% CI 1.2-9.4, $p = 0.007$) cohorts. The high-risk group had significantly shorter DFS compared to the low-risk group in both training and validation (4.5 months, 95% CI 1.2-9.4 vs. 12.2 months, 95% CI 5.9-19.7, $p = 0.023$). In a multivariable Cox regression model with BCLC stage, CP class, tumour size and multinodularity, radiomic risk group was the strongest predictor of TTR and DFS. **Conclusion:** Arterial phase radiomic-based models predicts TTR and DFS after RFA in HCC patients. Deep learning combined with machine learning model can stratify patients to allow for precision treatment strategies.

3288 | DEVELOPMENT OF A NOVEL PROGNOSTIC SCORE FOR 1-YEAR SURVIVAL IN IMMUNOTHERAPY-TREATED PATIENTS WITH UNRESECTABLE HCC

Spyridon Pantzios[1] Iakovos Vlachos[2] Antonia Syriha[1] Orestis Sidiropoulos[1] Maria-Stella Malatesta[1] Despoina Gyriki[1] Vaios Mosialos[1] Dina Tiniakos[2] Ioannis Elefsiniotis[1], [1]School of Health Sciences, National and Kapodistrian University of Athens, Greece, [2]Medical School, National and Kapodistrian University of Athens, Greece

Background: There is a lack in reliable and widely used prognostic scores to predict survival in patients with hepatocellular carcinoma (HCC) receiving immunotherapy. Possible biomarkers include ALBI grade and intratumoral lymphocyte infiltration, while disease burden possibly correlates with overall survival (OS). The aim of our study was to develop a prognostic score that could predict 1-year OS in patients with HCC receiving immunotherapy. **Methods:** We studied 100 patients who received 1st line immunotherapy in our center. Intrahepatic disease burden was evaluated with up-to-7 criteria. We did a univariate cox regression analysis to

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

assess which of the parameters is associated with OS. Factors strongly associated with OS were used in the multivariate model. We used the B coefficients from the multivariate model to produce a normalized score (LA-7 score) that could predict 1-year OS. Internal validation was done using ROC analysis and 10-fold cross-validation. Then, we separated our patients in three risk groups (low, intermediate, high) based on the new score and studied them for their baseline characteristics, response to immunotherapy and OS. **Results:** In univariate analysis, significant correlation with OS was found for ALBI grade ($p < 0.001$, HR = 2.725), BCLC stage ($p = 0.031$, HR = 1.809), MVI ($p < 0.001$, HR = 2.587), up-to-7 criteria ($p < 0.001$, HR = 0.218) and lymphocyte infiltration ($p = 0.005$, HR = 0.485). In the multivariate analysis we found that three factors were significantly correlated with OS; ALBI grade (grade II vs. grade I, $p = 0.025$, HR = 1.946), up-to-7 criteria (beyond vs. within, $p = 0.001$, HR = 3.506) and lymphocyte infiltration (no vs. yes, $p = 0.016$, HR = 1.889). The LA-7 score was calculated with the contribution of 1 point for ALBI grade II, 2 points for exceeding up-to-7 criteria and 1 point for absence of lymphocyte infiltration. The score had an AUROC of 0.755 for 1-year OS, with 75% sensitivity and 65.4% specificity. We established three risk groups; low (LA-7: 1-2), intermediate (LA-7: 3-4) and high (LA-7: 5). Objective response was reported in 34.8% of patients in the low risk group, compared to 18.5% in intermediate risk patients and 4.3% in high risk patients ($p = 0.031$). The median OS of the three groups was 41, 12 and 3 months, respectively ($p < 0.001$). The 1-year OS was 80%, 41% and 16%, the 2-year OS was 80%, 14% and 6%, and the 3-year OS was 62%, 7% and 6%, respectively. **Conclusion:** The LA-7 score is a promising tool for predicting 1-year OS in HCC patients undergoing immunotherapy. Further research should focus on its integration with other biomarkers, particularly in immunotherapy settings, to optimize patient management.

3289 | HEPATOCELLULAR CARCINOMA (HCC) IS MORE FREQUENT IN PATIENTS WITH DECOMPENSATED CIRRHOSIS

Nicole Welch[1] Ana Ostojic[1] Annette Bellar[1] Amy Attaway[1] Lars Deutz[1] Ryan Musich[1] John McMichael[1] Lopa Mishra[2] Srinivasan Dasarathy[1], [1]Cleveland Clinic, [2]Feinstein Institutes for Medical Research & Cold Spring Harbor Laboratory

Background: HCC is a significant complication of cirrhosis with variable incidence across liver disease etiologies. Less is known about disease compensation status and the incidence of HCC. Identifying the clinical characteristics of patients with/without HCC and with/without decompensation can inform targeted surveillance and prognostication. We aimed to compare demographics, etiology distribution, clinical status, and outcomes in cirrhosis patients with and without HCC. **Methods:** Using an electronic database of patients evaluated in the hepatology department at a large tertiary care center between January 2000 and December 2024, we identified patients with cirrhosis using ICD9 and ICD10 codes. Patients were further stratified by those who ether had compensated disease or had decompensation without recompensation to reduce disease course variability and by presence or absence of HCC diagnosis. Decompensation was defined by gastrointestinal bleeding, encephalopathy, ascites event. HCC was defined by biopsy, imaging, or physician documentation. Disease etiologies included metabolic-associated (MASLD), alcohol-related (ALD), combined metabolic and alcohol-related (MetALD), viral hepatitis-related (VHLD) liver disese, and other causes. Demographic, clinical, and laboratory variables were compared between those with/without HCC and/or decompensation using chi-square tests for categorical and Student's t-test for continuous variables. **Results:** Of 29,999 patients with cirhosis, 2,276 (7.6%) had confirmed HCC. 16,368[54.6%] had compensated disease (n = 15,325[93.6%] without HCC/13,631 [6.37%] with HCC) and 13,631[45.4%] had decompensated disease (n = 12,174 without HCC/1457 [10.7%] with HCC). The majority of patients were male (n = 9335[56.9%] compensated/ n = 7873[57.8%] decompensated, $p < 0.001$). The percent of patients with HCC in the decompensated group was higher than that of the compensated group (n = 58.3% vs 41.7%, $p < 0.001$). Patients with HCC were older (mean 63.1 vs 58.0 years, $p < 0.001$), more frequently male (74.6% vs 57.4%, $p < 0.001$), and more likely to have underlying

viral hepatitis (25.2% vs 9.6%, $p < 0.001$). The most frequent cause of initial decompensation was ascites (n = 7966[58.4%]), followed by hepatic encephalopathy (n = 5646[41.4%]]. Among those patients with cirrhosis prescribed statins, there was a higher percentage of decompensated patients (Compensated n = 5255 [48.9%] vs Decompensated n = 5493[51.1%], $p < 0.001$). Of those patients on Medicaid, there was a higher percentage with cirrhosis that was decompensated (n = 335[61.5%] vs. 210[38.5%]), while those with private insurance had a higher ($p < 0.001$) percentage with compensated disease (5928[54.3%] vs 4988 [45.7%]). **Conclusion:** HCC is more frequent in patients with decompensated cirrhosis who are older, have diabetes, and MetALD while statin use despite decompensation was associated less with HCC.

3290 | "HOT" IMMUNE MICROENVIRONMENT OF AFP^{LOW} HEPATOCELLULAR CARCINOMA PATIENTS HARBOURS PROLIFERATIVE NATURAL KILLER CELLS

Pushpa Yadav[1] Viniyendra Pamecha[1] Sherin Thomas[1] Gayatri Ramakrishna[1] Shiv Kumar Sarin[1] Nirupma Trehanpati[1], [1]Institute of Liver and Biliary Sciences

Background: Hepatocellular carcinoma (HCC) exhibits a heterogeneous tumor microenvironment (TME) characterized by immunologically "hot" versus "cold" phenotypes, significantly impacting therapeutic outcomes. Alpha-fetoprotein (AFP), a traditional HCC diagnostic marker, correlates with immunosuppressive mechanisms that influence TME classification. Our aim was to identify immunometabolic differences in AFP^{low} and AFP^{high} HCC patients. **Methods:** Total of ninety-eight patients (median age = 50 (30-78), M/F = 11/98), including HCC (n = 38) with serum AFP ≤15ng/mL {AFP^{low} HCC (n = 21)} and >15ng/mL {AFP^{high} HCC (n = 17)} and AFP^{low} chronic liver disease (CLD, n = 60) were analysed for plasma metabolomics using liquid chromatographic-mass spectrometry (LC-MS), plasma CXCL-9 and CXCL-10 levels by ELISA and immune-metabolic phenotyping in both PBMCs and tumor-infiltrated lymphocytes (TILs) by flow metabolic panels. **Results:** AFP^{low} HCC patients' plasma metabolomics profile revealed enriched nicotinate and nicotinamide synthesis along with carbohydrate metabolism pathways such as glycolysis, pentose phosphate, gluconeogenesis and mitochondrial electron transport chain pathway compared to AFP^{high} HCC patients (Figure 1A-B).

In AFP^{low} HCC patients, CXCL-9 [p value = 0.0002] and CXCL-10 [p value = 0.0158] chemokine levels were increased compared to AFP^{low} CLD patients, (Figure 1C).

Further, AFP^{low} patients also had significantly increased mTOR expression in tumor-infiltrated CD56 bright (immature) NK cells [p value = 0.0063] (Figure 1D). No significant difference was observed in the mTOR expression of CD56 dim (mature) NK cells isolated from either peripheral blood or liver tumor. **Conclusion:** Upregulation of the energy metabolism pathways is suggestive of increased immune activation and proliferation in AFP^{low} HCC patients. Resultant elevated levels of CXCL-9 and CXCL-10 promoting immune infiltration and proliferation in AFP^{low} HCC patients. Increased expression of mTOR which is linked to cell growth and division observed in immature NK cells in the tumor-microenvironment of AFP^{low} HCC may also be linked to the significantly upregulated energy metabolism.

In conclusion, in AFP^{low} HCC patients, proliferating immune cells show upregulated energy metabolism pathways, with CXCL-9 and CXCL-10 facilitating immune cell trafficking.

3291 | ASSOCIATION BETWEEN AIR QUALITY INDEX AND RISK OF HEPATOCELLULAR CARCINOMA: A NATIONWIDE POPULATION-BASED STUDY

Chun-Ying Wu[1] Kuei-Mao Wang[1] Chia-Da Wu[2], [1]National Yang MIng Chiao Tung University, Taiwan, [2]National Cheng Kung University, Taiwan

Background: Epidemiological evidence indicates association between air pollution and an increased risk of hepatocellular carcinoma (HCC). However, the results are controversial. **Methods:** We conducted a nationwide cohort study to investigate the association between air pollution and HCC based on the Taiwan National Health Insurance Laboratory Database (NHILD) and the Air Quality Monitoring System Database (AQMSD) between 1 January 2009 and 31 December 2020. Ten-year cumulative incidences of HCC and the Fine-Gray competing risk model was used to determine the association between air pollution and the subsequent HCC risk. **Results:** Among the 18,998,172 participants with a mean age of 41.2 years and equally distributed sex, we found the 10-year cumulative incidence of HCC increased progressively across AQI quartiles. The highest AQI group (Q4) exhibited the greatest 10-year HCC incidence at 0.92%, followed by Q3 at 0.59%, Q2 at 0.38%, and the lowest AQI group (Q1) at 0.40%. In the multivariate analysis, participants in the highest AQI quartile (Q4) had a significantly higher risk of HCC compared to those in the lowest quartile (Q1), with a hazard ratio (HR) of 1.86 (95% CI: 1.54–2.25). Each unit increase in AQI was associated with a 2% increase in HCC risk (HR: 1.02; 95% CI: 1.02–1.02). In the stratified analysis, the positive associations between higher AQI levels and HCC risk were observed across most subgroups. **Conclusion:** Higher air pollution associated with higher subsequent HCC risk was found in our nationwide cohort study.

3292 | CANCER-RELATED DEATH IN INDIVIDUALS WITH ALCOHOL-ASSOCIATED LIVER DISEASE

Pojsakorn Danpanichkul[1] Thanathip Suenghataiphorn[2] Do Han Kim[3] Donghyun Ko[4] Karecia Byfield[5] Romelia Barba[6] Ahmed Shukri[6] Chawin Lopimpisuth[7] Ornpailin Wanichthanaolan[8], [1]Texas Tech University Health Sciences Center, [2]Griffin hospital, [3]Mount Sinai Hospital, [4]Bridgeport hospital, [5]Thomas Jefferson Hospital, [6]texas tech university, [7]University of Miami, [8]Chiang Mai University

Background: Alcohol-associated liver disease (ALD) is a leading cause of liver cancer. While mortality from liver cancer in ALD has improved, little is known about trends in extrahepatic cancer-related deaths in this population. This study aimed to characterize national trends in liver and extrahepatic cancer-related mortality among individuals with ALD in the U.S. **Methods:** We used the National Vital Statistics System Multiple Cause of Death database (2011–2020) to identify decedents with ALD (ICD-10: K70) listed as a contributing cause and cancer (C*) as the primary cause of death. Cancers were categorized as liver or extrahepatic. Age-adjusted mortality rates (AAMRs) per 100,000 population were calculated using 2000 U.S. standard population weights and stratified by sex, race/ethnicity, census region, and urbanization level. Trends were analyzed using Joinpoint regression to estimate annual percent change (APC) with 95% confidence intervals (CI). **Results:** From 2011 to 2020, 14,566 cancer-related deaths listed ALD as a contributing cause. AAMRs per 100,000 for liver and extrahepatic cancer among ALD patients were 0.25 and 0.17, respectively, in 2020. Over the decade, AAMRs increased significantly for liver cancer (APC: 4.66%; 95% CI: 2.95–6.39) and extrahepatic cancer (APC: 5.73%; 95% CI: 3.99–7.49). In contrast, extrahepatic cancer-related mortality declined in the general population. Increases were more pronounced among males, non-Hispanic Whites, and residents of non-metropolitan areas. **Conclusion:** Despite national declines in extrahepatic cancer mortality, individuals with ALD experienced a significant rise in both liver and extrahepatic cancer deaths. These findings highlight the growing extrahepatic cancer burden in ALD and the need for expanded surveillance strategies.

3293 | MECHANISTIC INSIGHTS INTO PROGLUMIDE&RSQUO;S ROLE IN IMMUNE CELL EFFICACY AND RESISTANCE TO IMMUNE CHECKPOINT INHIBITOR THERAPY FOR HEPATOCELLULAR CARCINOMA

Priyanka Doneparthi[1] Hong Cao[1] Wenqiang Chen[1] Wenyu Dou[1] Hong-Bin Fang[1], [1]Georgetown University

Background: Hepatocellular carcinoma (HCC) is the fastest growing cause of cancer-related deaths worldwide. Treatment with immune checkpoint inhibitors (ICIs) has shown promise in HCC, but the response is still low at about 15%-20%. One reason for the low efficacy is the fibrosis in most livers that harbor HCC that prevent penetration of anti-cancer agents and also the penetration of tumoral CD8+ T-cells. Our laboratory discovered that the cholecystokinin-B receptor (CCK-BR) is overexpressed in HCC tumors. A prior study showed that the survival of mice bearing HCC xenografts was significantly improved when mice were treated with a CCK-BR receptor antagonist, proglumide, and PD-1 ICI. This study's primary objective is to understand the mechanisms by which the CCK-BR antagonist, proglumide, enhances the efficacy of immune checkpoint PD-1Ab therapy. **Methods:** Three significant areas of investigation were explored: changes to the tumor microenvironment (TME), the activity of the host T-cells, and the gut microbiome. C57BL/6 mice were injected subcutaneously in each flank with RIL-175 HCC cells (100,000). Once the mice had palpable tumors, they were divided into four groups of equal tumor size ($N = 10$ per group). Treatment included: PBS-control, proglumide (0.1mg/ml) in drinking water, PD-1Ab (50μg, ip, days 0, 7, and 14), and combination therapy with the PD-1Ab and proglumide. After 4 weeks of treatment, the tumors were excised and TME examined histologically. T-cells were isolated from the spleens and analyzed, and the microbiome was analyzed by whole genome 16s sequencing and compared to baseline. **Results:** Histologic analysis of the TME showed a 4.5-fold influx of CD8 T-cells, decreased M2-polarized macrophages ($P < 0.0001$), and >5-fold less fibrosis with the tumors of mice treated with the combined therapy. Combination treatment decreased the host T-cell exhaustion markers (TIM3, LAG3, and CD-279-PD-1) and proglumide increased T-cell cytokine release (TNFα, INFγ). The microbiome showed increased diversity and beneficial bacteria in the combination-treated groups. *Prevotella* genus decreased, and *Lactobacillus* species, known to promote T cell and immune cell activation significantly increased. *Eubacterium,* a beneficial bacterium that improves response to ICI, increased with the combined therapy. **Conclusion:** Co-administration of proglumide with ICIs appears to enhance the efficacy of PD-1 antibody therapy by remodeling the TME, changing a relatively “cold” tumor to a “hot” immune-responsive tumor, activating T-cells, and rendering the host microbiome to a population of bacteria that are beneficial.

3294 | SINTILIMAB PLUS BEVACIZUMAB AS SYSTEMIC THERAPY IN PATIENTS WITH CHILD-PUGH A AND CHILD-PUGH B ADVANCED HEPATOCELLULAR CARCINOMA: A MULTI-INSTITUTIONAL COHORT STUDY

Yuanxu Zhang[1] Weifeng Zhao[1] Youhan Miao[2] Wei Sun[1] Yang Li[3] XiuCheng Pan[4], [1]The First Affiliated Hospital of Soochow University, [2]Nantong Third People's Hospital, [3]The Affiliated Taizhou people's Hospital of Nanjing Medical University, [4]The Affiliated Hospital of Xuzhou Medical University

Background: Sintilimab plus bevacizumab is an approved first-line regimen for unresectable hepatocellular carcinoma (uHCC) in China. However, data on its safety and efficacy in patients with impaired liver function remain limited. We assessed the clinical outcomes of this combination therapy in HCC patients with Child-Pugh class A (CP-A) and class B (CP-B) liver function. **Methods:** In this multicentre retrospective cohort study, 99 patients with advanced uHCC (73 CP-A; 26 CP-B) who received first-line sintilimab and bevacizumab were included. Tumor response was assessed using modified RECIST criteria, and adverse events (AEs) were graded per CTCAE v5.0. Survival outcomes, including overall survival (OS), progression-free survival (PFS), and time to hepatic decompensation (TTD), were analyzed via Kaplan-Meier estimates and Cox proportional hazards models. **Results:** The objective response rates (ORR) of patients with Child-Pugh A and Child-Pugh B treated with Sintilimab plus bevacizumab were 50.7% and 57.7%, respectively, and both could achieve good anti-tumor efficacy. CP-B had inferior survival: median OS (15 vs 22 months, $p = 0.044$), PFS (8 vs 14 months, $p = 0.014$), and TTD (7 vs 15 months, $p < 0.001$) shown in the Figure. The Child-Pugh B cohort demonstrated comparable incidence rates of grade 3-4 adverse events (AEs) to the CP-A group (34.6% vs 34.2%). Hemorrhagic events and thrombocytopenia emerged as predominant grade 3-4 AEs in CP-B patients (15.4% for both). In multivariate analysis for OS, CP-B status remained an independent predictor of reduced survival (HR 2.744, 95% CI 1.152-6.537; $p = 0.023$). Deterioration in ALBI grade after 6 months of treatment was also an independent predictor of worse OS (HR 3.661, 95% CI 1.331-10.064; $p = 0.012$). For PFS, ALBI grade deterioration after 6 months remained a significant negative prognostic factor (HR 3.353, 95% CI 1.083–10.384; $p = 0.036$). **Conclusion:** Sintilimab plus bevacizumab demonstrated encouraging short-term anti-tumor activity in unresectable hepatocellular carcinoma across CP-A and CP-B, while survival outcomes were affected by differences in hepatic function reserve. Although the regimen was generally well tolerated, patients with impaired liver reserve require vigilant monitoring and comprehensive supportive strategies to maximize therapeutic outcomes.

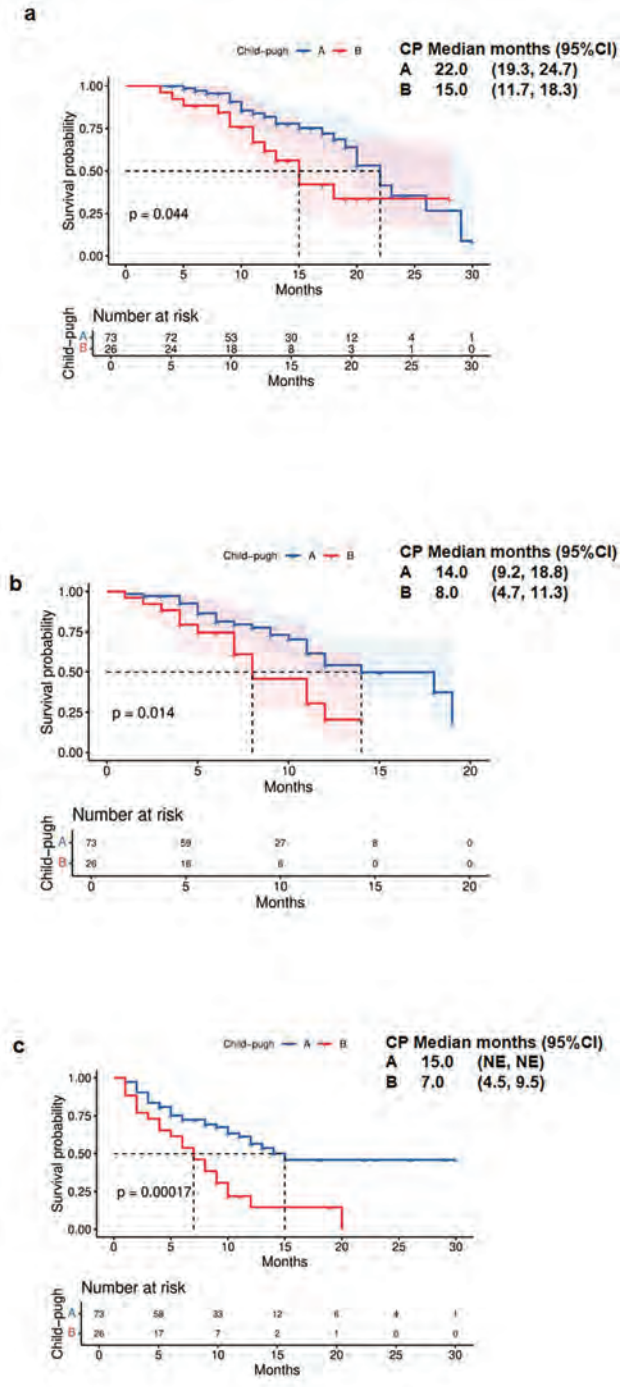

Figure. Overall survival (OS) by (a) Child-Pugh liver status (A vs B). Progression-free survival (PFS) by (b) Child-Pugh liver status (A vs B). Time to decompensation (TTD) by (c) Child-Pugh liver status (A vs B).

3295 | INTEGRATIVE SCRNA AND CLINICAL PROFILING UNCOVERS SDC2 AS A FUNCTIONAL BIOMARKER IN HEPATOCELLULAR CARCINOMA

yuhai hu

Background: Hepatocellular carcinoma (HCC) remains a leading cause of cancer-related mortality worldwide. Identifying tumor-specific surface receptors involved in intercellular communication is essential for understanding tumor progression and developing targeted therapies. **Methods:** We analyzed publicly available scRNA datasets of HCC and applied NicheNet to explore ligand-receptor interactions within the tumor microenvironment. Syndecan-2 (SDC2) was identified as a highly expressed receptor in malignant hepatocytes. To validate its clinical relevance, we analyzed transcriptomic data from The Cancer Genome Atlas (TCGA) and Gene Expression Omnibus (GEO) datasets to assess SDC2 expression. Additionally, we performed immunohistochemistry on liver tissue samples from 95 HCC patients and assessed the correlation between SDC2 expression and clinicopathological features. **Results:** scRNA analysis revealed that SDC2 was highly expressed in malignant hepatocytes and involved in multiple ligand-receptor interactions. SDC2 was involved in multiple ligand-receptor interactions, with its ligands originating from both malignant hepatocytes and hepatic stellate cells, including ANGPTL4, MDK, and PTN. To explore the role of SDC2 in HCC, we first analyzed its expression using data from the TCGA and GEO databases, We found that SDC2 expression was significantly upregulated in HCC tissues compared to adjacent non-tumorous liver tissues. At the protein level, we performed a tissue microarray (HLivH180Su31, Shanghai ChipScreen Biosciences Co., Ltd., Shanghai, China). A total of 95 HCC tissues and 81 adjacent non-tumorous tissues were successfully subjected to immunohistochemical staining and scoring. Similarly, compared with adjacent non-tumorous liver tissues, SDC2 expression was significantly upregulated in hepatocellular carcinoma. Higher SDC2 expression was associated with poor prognosis, advanced TNM stage, age, and survival status in HCC patients. **Conclusion:** SDC2 is a tumor-enriched receptor in HCC associated with disease progression and unfavorable prognosis. Both scRNA and clinical data suggest that SDC2 plays an important role in mediating intercellular communication within the tumor microenvironment and represents a promising biomarker and potential therapeutic target. Further studies are warranted to investigate its downstream signaling pathways and functional roles in HCC.

3296 | SIGNIFICANCE OF MEASURING INTERFERON-Γ-INDUCED PROTEIN-10 LEVELS IN PATIENTS RECEIVING SYSTEMIC THERAPIES FOR UNRESECTABLE HEPATOCELLULAR CARCINOMA

Hitomi Takada[1] Shinya Maekawa[1] Atsunori Tsuchiya[1] Nobuyuki Enomoto[2], [1]University of Yamanashi, [2]University of Yamanahsi

Background: Atezolizumab-bevacizumab (AB) and durvalumab-tremelimumab (DT) combination therapies are widely used for unresectable hepatocellular carcinoma (uHCC). However, the optimal predictors of therapeutic response remain unclear. Interferon-γ-induced protein-10 (IP-10) levels are considered potential biomarkers in immunotherapy for uHCC and other cancers. This study investigates the relationship between blood IP-10 levels and treatment response in patients with uHCC receiving AB or DT. **Methods:** This retrospective cohort included 106 patients who initiated immunotherapy for uHCC at our institution between November 2020 and September 2024. Inclusion criteria encompassed advanced-stage HCC (Barcelona Clinic Liver Cancer [BCLC] stage C) or intermediate-stage HCC (BCLC stage B), with an Eastern Cooperative Oncology Group (ECOG) performance status of 0-1, and Child-Pugh grade A or B. In these patients, IP-10 levels were measured at baseline and 1, 3, 6, and 12 weeks after induction in the AB group, and at baseline and 1, 2, 4, 8, and 12 weeks in the DT group. The association between IP-10 levels and treatment response was analyzed. IP-10 levels were measured via ELISA using stored plasma samples, and the ratio of post-induction to baseline IP-10 levels was calculated. **Results:** Of the 106 patients, 84 received AB and 22 received DT. The median age was 72 years (range 44–88), with 90 men (85%). Forty-four patients (42%) received as late-line therapy. The distribution of BCLC stages was 50 (47%) stage B and 56 (53%) stage C. The initial therapeutic responses were PR/SD/PD in 44/30/32 patients, corresponding to 42%, 28%, and 30%. The best responses were CR/PR/SD/PD in 3/45/28/30 patients, corresponding to 3%, 43%, 26%, and 28%, respectively.
Baseline IP-10 levels in the PR group as the initial therapeutic response were significantly higher than in the SD/PD group ($p = 0.0067$). Using ROC curve analysis, a baseline IP-10 level > 150 pg/mL predicted PR as the initial therapeutic response, and patients with high baseline IP-10 levels showed a higher response

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

rate compared to those with not-high levels (62 vs. 26%, $p < 0.001$).

Moreover, the non-PD group as the best response exhibited a lower IP-10 ratio (post-induction/baseline) before response evaluation compared to the PD group ($p = 0.015$). Progression-free survival (PFS) was longer in patients achieving an IP-10 ratio < 1—defined as a predictor of non-PD via ROC analysis—compared to those who did not ($p = 0.012$). Achieving an IP-10 ratio < 1 was the only factor independently associated with longer PFS (hazard ratio 2.0, $p = 0.006$). **Conclusion:** Patients with high baseline IP-10 levels are likely to have high therapeutic effects from the point of the initial assessment. Patients achieving IP-10 ratio < 1 are likely to show non-PD as best response. These findings suggest that IP-10 levels may be useful predictors of therapeutic response in patients receiving AB or DT for uHCC.

3297 | PERFORMANCE OF GALAD, GAAD, AND ASAP FOR EARLY HCC DETECTION IN CHRONIC LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Mohammad Jarrah[1] Ashwini Arvind[1] Purva Gopal[1] Sneha Deodhar[1] Ju Dong Yang[2] Neehar Parikh[3] Amit Singal[1], [1]UT Southwestern Medical Center, [2]Cedars-Sinai Medical Center, [3]University of Michigan Medical Center

Background: Hepatocellular carcinoma (HCC) is the third leading cause of cancer mortality worldwide, with a 5-year survival below 20%, primarily due to late-stage diagnoses. Blood-based multi-biomarker panels have shown promise to improve HCC surveillance in patients with cirrhosis, but we lack comparative data on their performance for early-stage HCC detection. **Methods:** We conducted a systematic review of PubMed, Ovid MEDLINE, and EMBASE databases from January 2010 to November 2024 to identify studies evaluating the performance of three commercially available biomarker panels (GALAD, GAAD, and ASAP) for HCC screening. Pooled estimates were calculated using the DerSimonian and Laird method for a random effects model. The study was conducted per Preferred Reporting Items for Systematic Review and Meta-analysis (PRISMA) guidelines. **Results:** We identified 44 studies ($n = 33{,}100$ patients), with 37 studies evaluating GALAD, 12 evaluating GAAD, and 11 evaluating ASAP for HCC screening. Nine studies were cohort studies, while the remainder were case-control studies. Pooled sensitivity and specificity estimates for early-stage HCC were: 70.2% (95%CI 66.5 – 73.7) and 87.2% (95%CI 84.4 – 89.6) for GALAD, 74.1% (95%CI 59.3 – 84.9) and 85.7% (95%CI 66.3 – 94.8) for GAAD, and 72.1% (95% CI 43.8 – 89.5) and 83.3% (95%CI 61.3 – 94.0) for ASAP. Among studies directly comparing biomarker panels in the same patients, there was no significant difference in sensitivity for early stage-HCC between GALAD and GAAD (RR 0.96, 95%CI 0.80 – 1.15) or between GALAD and ASAP (RR 1.12, 95%CI 0.79 – 1.60). The pooled sensitivity of GALAD for early-stage HCC was higher than that of ultrasound among studies directly comparing the two (79.0% (95%CI 62.2 – 89.6) versus 73.3% (95%CI 45.4 – 90.1), respectively); however, this difference was not statistically significant (RR 1.09, 95%CI 0.78 – 1.51). When combined with ultrasound, GALAD showed a pooled c-statistic of 0.89 (95%CI 0.73 – 1.00), compared to 0.84 (95%CI 0.80 – 0.88) for ultrasound alone. Studies were limited by inclusion of patients with non-cirrhotic liver disease, variability in biomarker panel cutoffs across studies, and substantial statistical heterogeneity ($I^2 > 50\%$). **Conclusion:** Multi-biomarker panels including GALAD, GAAD, and ASAP demonstrate promising performance for the early detection of HCC, supporting their further prospective validation as potential alternatives to ultrasound-based screening.

Yoshida[1] Teruki Miyake[1] Masashi Hirooka[1] Masanori Abe[1] Yoichi Hiasa[1] [1]Ehime University Graduate School of Medicine

Background: In metabolic dysfunction-associated steatohepatitis (MASH), palmitic acid (PA) absorbed from the intestine is increased. PA induces endoplasmic reticulum (ER) stress and interleukin-1 beta (IL-1β) production in hepatic stellate cells (HSCs). Protein kinase R-like endoplasmic reticulum kinase (PERK), an ER stress sensor, has been reported to regulate IL-1β. The aim of this study is to elucidate the mechanism of ER stress-induced IL-1β production in HSCs and to clarify the role of IL-1β in the progression of MASH-associated hepatocellular carcinoma (HCC). **Methods:** The human HSC cell line LX-2 cell was treated with PA. Reverse transcription polymerase chain reaction and western blotting were used to measure PERK and IL-1β expression. LX-2 cells were transfected with PERK siRNA or PERK plasmid, and IL-1β expression was measured. In addition, PERK knockdown cells were treated with PA, and the change in IL-1β was examined. The human HCC cell line HepG2 cell was treated with recombinant human IL-1β (rhIL-1β) or with an IL-1β neutralizing antibody (IL-1β NAb) in the conditioned medium (CM) from PA-treated LX-2 cells, and their proliferation was assessed by MTS (3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium) assay. Enzyme-linked immunosorbent assay was used to measure the IL-1β concentration in CM from LX-2 cells under different conditions. HepG2 cells were cultured in CM from LX-2 cells under different conditions, and their proliferation, migration, and invasion were assessed by MTS, scratch, and Transwell assays. RNA-sequencing (RNA-seq) analysis was performed on PA-treated LX-2 cells with or without PERK knockdown to identify the intermediate molecule in the PERK-mediated IL-1β production pathway. The change in IL-1β expression was examined following modulation of the identified molecule expression. **Results:** PA increased PERK and IL-1β expression in LX-2 cells. IL-1β was decreased by PERK siRNA transfection and increased by PERK plasmid transfection. The increase in IL-1β induced by PA treatment was suppressed in PERK knockdown cells. rhIL-1β promoted the proliferation of HepG2 cells, whereas IL-1β NAb suppressed the proliferation of HepG2 cells cultured in the CM from PA-treated LX-2 cells. The IL-1β concentration in the CM from PA-treated LX-2 cells was increased. The CM from PA-treated LX-2 cells enhanced the proliferation, migration, and invasion of HepG2 cells; however, these effects were suppressed by PERK knockdown. RNA-seq analysis identified p38δ mitogen-activated protein kinase (MAPK) as an intermediate molecule between PERK and IL-1β. The modulation of p38δ MAPK expression changed IL-1β expression. **Conclusion:** ER stress-induced IL-1β secretion via PERK/p38δ MAPK axis in HSCs facilitates MASH-HCC progression.

3299 | ASSESSING POST-TACE LIVER DECOMPENSATION RISK IN HCC: A COMPARATIVE ANALYSIS OF MELD 3.0, MELD-NA, CHILD-PUGH, AND ALBI SCORES"

Hasan Bualbanat[1] David Hudson[2], [1]Western University/ Transplant Hepatology Program, [2]Western University/ Department of Gastroenterology

Background: Background: & Aim: Patients with hepatocellular carcinoma (HCC) undergoing transarterial chemoembolization (TACE) are at risk of hepatic decompensation. Accurate pre-procedural prediction of such events is crucial for patient selection and optimization of outcomes. This study aims to evaluate and compare the predictive accuracy of MELD 3.0, MELD-Na, Child-Pugh, and Albumin-Bilirubin (ALBI) scoring systems in forecasting hepatic decompensation following TACE in patients with HCC. **Methods:** Methods:: This retrospective cohort study included 280 patients diagnosed with HCC who underwent TACE at our institution. We calculated MELD 3.0, MELD-Na, Child-Pugh, and ALBI scores for each patient immediately prior to TACE treatment. The primary endpoint was the occurrence of hepatic decompensation post-TACE, recorded as a binary outcome (yes/no). Receiver Operating Characteristic (ROC) curve analysis was performed to determine and compare the predictive accuracy of each scoring system, with the Area Under the Receiver Operating Characteristic Curve (AUROC) as the primary measure. Optimal cutoff values for MELD 3.0 and MELD-Na scores were identified using Youden's index. **Results:** Results:: Among the evaluated scoring systems, MELD 3.0 demonstrated the highest predictive accuracy with an AUROC of 0.81. MELD-Na showed slightly lower accuracy (AUROC 0.79), followed closely by Child-Pugh (AUROC 0.78), and ALBI scores (AUROC 0.75). The optimal cutoff scores identified for predicting hepatic decompensation were ≥ 16 for MELD 3.0 (sensitivity 69.0%, specificity 87.2%) and ≥ 14 for MELD-Na (sensitivity 66.7%, specificity 85.7%). **Conclusion:** Conclusion:: Our findings suggest that MELD 3.0 score provides superior predictive accuracy for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

hepatic decompensation in patients with HCC undergoing TACE, compared to MELD-Na, Child-Pugh, and ALBI scores. A MELD 3.0 score of 16 or higher effectively identifies patients at increased risk, aiding clinicians in decision-making and targeted patient management to minimize post-procedural complications.

3300 | TWO DECADES OF INTRAHEPATIC CHOLANGIOCARCINOMA: A MIXED-EFFECTS ANALYSIS OF AGE, SEX, TUMOR STAGE AND DEMOGRAPHICS

Ivan Mogollon[1] Aura Calderon[1] Julian Galindo-Ramirez[1] Juan Lopez-Alvarenga[1] Everardo Cobos[1], [1]The University of Texas Rio Grande Valley

Background: Intrahepatic cholangiocarcinoma (ICC), a subtype of cholangiocarcinoma arising from the bile ducts within the liver, is a rare but increasingly prevalent malignancy with poor prognosis. Due to vague clinical symptoms, ICC is often diagnosed at an advanced stage, limiting curative treatment options such as surgical resection. While systemic therapies are available, their efficacy remains modest, and survival outcomes vary widely. Understanding how survival has evolved over time and how demographic and clinical factors influence prognosis is essential to guide future interventions and improve patient care. This study aims to evaluate long-term survival trends in ICC and assess how factors such as age, sex, race, and tumor stage at diagnosis impact survival outcomes. **Methods:** We analyzed longitudinal survival data for intrahepatic cholangiocarcinoma patients diagnosed between 2000 and 2020 using relative survival statistics from the JPSurv program. Annual survival rates, tracked for up to 10 years post-diagnosis, were evaluated to assess trends over time and across patient subgroups. A mixed-effects panel regression model with a random intercept for year was applied to account for within-group correlations and the temporal dependency of survival. Fixed effects included sex, age group, and tumor stage, with interaction terms to test for differential trends. Joinpoint analysis identified time segments with changing survival trends, and the average absolute change in survival was used to quantify survival improvement between joinpoints. Post hoc comparisons were conducted using Fisher's notation to identify statistically homogeneous groups. **Results:** Survival rates demonstrated a consistent upward trend from 2000 to 2020. Females showed slightly higher survival than males, though this difference was not statistically significant. A significant survival advantage was observed among younger patients, with those aged $\geq$65 years showing the lowest survival and minimal improvement over time. Patients with localized tumors had the highest survival and greatest gains over time, while those with regional or unstaged lesions exhibited intermediate outcomes. Patients with distant metastases had persistently poor survival, underscoring the poor prognosis of late-stage disease. Survival improved across all racial groups, particularly in the early 2000s; however, disparities between racial groups remain evident. **Conclusion:** Despite incremental progress in ICC survival, substantial disparities remain by age and tumor stage. Early detection and timely, accessible treatment are critical to improving patient outcomes. Future strategies should prioritize the development of more effective therapies for advanced-stage disease and implement targeted interventions for older adults and underserved populations to reduce survival inequities.

3301 | SPP1 PROMOTES HEPATOCELLULAR CARCINOMA PROGRESSION THROUGH REGULATION OF M6A METHYLTRANSFERASES METTL3 AND METTL14

Yanqiu Li[1] Yao Liu[1] Xianbo Wang[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Hepatocellular carcinoma (HCC) is one of the most common malignant tumors in the world. Secretory phosphoprotein 1 (SPP1) plays an important role in a variety of tumors, and RNA N6-methyladenosine (m6A) modification is involved in the occurrence and development of tumors. However, the interaction mechanism between SPP1 and m6A methylation in HCC is still unclear. **Methods:** This study used a combination of in vitro and vivo experiments. SPP1 knockdown and overexpression cell lines were constructed in HuH7 cells, and the effect of SPP1 on the biological behavior of HuH7 cells was evaluated by cell viability detection and Transwell migration assay. The HCC subcutaneous tumor mouse model was established using Hepa 1-6 cells and treated with SPP1 and PD-L1 monoclonal antibody by intraperitoneal injection. Methylation sequencing technology was used to analyze the changes in the m6A modification spectrum of SPP1-knockdown HuH 7cells and control cells. qRT-PCR and Western blot were used to detect the expression levels of key genes and proteins. Immunofluorescence staining was used to observe the localization and distribution of proteins in cells. **Results:** SPP1 knockdown significantly inhibited HuH7 cell viability ($P < 0.001$) and reduced cell migration ability, while SPP1 overexpression promoted cell proliferation and migration. In the mouse HCC model, tumor growth was significantly inhibited in the SPP1 monoclonal antibody treatment group ($P < 0.01$), and combined PD-L1 treatment further enhanced the anti-tumor effect, and tumor weight was reduced. Methylation sequencing analysis found that SPP1 regulates the expression of multiple m6A methylases, especially METTL3 and METTL14. The gene and protein levels of METTL3 and METTL14 were significantly upregulated in the SPP1 overexpression group. Immunofluorescence staining showed that METTL3, METTL14 and SPP1 were expressed in HuHh7 and Hep3B cells, and there was a co-localization phenomenon. **Conclusion:** SPP1 participates in the proliferation and migration of HuH7 cells by regulating the expression of m6A methylases, especially METTL3 and METTL14. Inhibition of SPP1 can effectively inhibit the progression of HCC and has a synergistic anti-tumor effect when combined with PD-L1 therapy. The important role of the SPP1-m6A methylation axis in the development of HCC provides a new theoretical basis and potential therapeutic strategy for the targeted treatment of liver cancer.

3302 | LYMPHOCYTE-TO-MONOCYTE RATIO (LMR) AS A PROGNOSTIC INDICATOR IN PATIENTS WITH CHOLANGIOCARCINOMA

Chung-Hao Hsu[1] Chun-Ting Ho[2] Chien-Wei Su[2] Wei-Yu Kao[3] Yi-Hsiang Huang[2] Ming-Chih Hou[2] Jaw-Ching Wu[2], [1]School of Medicine, National Yang Ming Chiao Tung University, [2]Taipei Veterans General Hospital, [3]Taipei Medical University Hospital

Background: Cholangiocarcinoma (CCA) is a highly aggressive malignancy, often diagnosed at advanced stages, with a five-year survival rate below 25%. The lymphocyte-to-monocyte ratio (LMR), a marker reflecting systemic inflammatory response, has been associated with prognosis in several cancers. However, its role in CCA is not fully elucidated. This study aimed to evaluate the prognostic significance of LMR in patients with CCA. **Methods:** We retrospectively analyzed 912 patients diagnosed with CCA at Taipei Veterans General Hospital between 2014 and 2024. Baseline clinical characteristics, imaging data, and laboratory results were collected at diagnosis. The primary

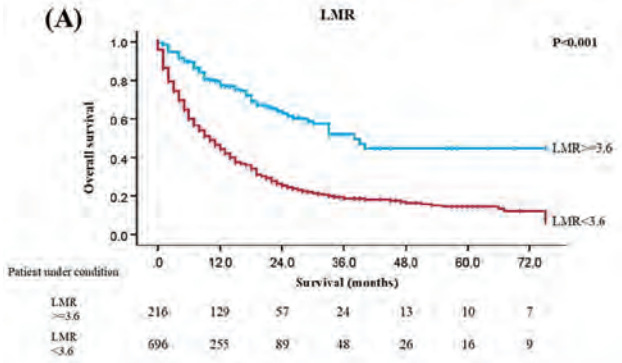
endpoint was overall survival (OS). Cox proportional hazards models were used for multivariate analysis to identify independent prognostic factors. Non-invasive serum markers including LMR, Prognostic Nutritional Index (PNI), AST-to-Platelet Ratio Index (APRI), Fibrosis-4 (FIB-4), Albumin-Bilirubin (ALBI) score, and Child-Pugh score—were evaluated for prognostic accuracy using the Akaike Information Criterion (AIC) and area under the ROC curve (AUROC). Cutoff values were defined by established clinical thresholds or the Youden index. Kaplan-Meier survival analyses were performed to compare OS across subgroups. **Results:** After a median follow-up of 9.0 months (IQR 4.0–18.0), 440 patients had died, with a 5-year OS rate of 20.2%. Multivariate analysis identified age, tumor stage and location, serum bilirubin, aspartate aminotransferase (AST), prothrombin time international normalized ratio (PT INR), carbohydrate antigen 19-9 (CA19-9) levels, treatment modality, surgery, LMR, and PNI as independent predictors of OS. Among all serum biomarker scores, LMR demonstrated the best prognostic performance (highest AUROC and lowest AIC). Patients with high LMR had significantly better OS (median 15.0 months, IQR 7.0–24.0) compared to those with low LMR (median 7.0 months, IQR 3.0–16.0; $p < 0.001$). High LMR was associated with favorable clinical features including earlier tumor stage, higher albumin, lower bilirubin and liver enzyme levels, greater likelihood of receiving treatment and surgery, and lower ALBI, APRI, PNI, FIB-4, the model for end-stage liver disease (MELD) scores, and Child-Pugh scores. **Conclusion:** LMR is an independent prognostic biomarker in CCA and may serve as a simple, non-invasive tool to stratify patients by survival risk.

Figure 1. Kaplan-Meier survival analysis and COX proportional hazardous models (COX PH) showed LMR can serve as an prognostic factor in CCA.
(A) Kaplan-Meier survival analysis in subgroup of LMR.
(B) COX proportional hazardous models (COX PH) of multiple serum index.



(B)

	AUROC	AIC	P value
PNI	0.645	6672.174	<0.001

3303 | INFLUENCE OF HISTOTRIPSY ON PATIENT-REPORTED QUALITY OF LIFE: A RETROSPECTIVE COHORT STUDY

Ahmed Sayed Ahmed[1] Chase Wehrle[1] Eren Berber[1] Federico Aucejo[1] Jaekeun Kim[1] David Kwon[1], [1]Cleveland Clinic, Section of Hepato-Pancreato-Biliary (HPB) Surgery, Cleveland, OH

Background: Histotripsy is a noninvasive, non-thermal focused ultrasound method used for the ablation of tumors, particularly in liver lesions. Although its effectiveness is under investigation, there is limited data on its effects on patient-reported quality of life (QoL). This study aimed to evaluate changes in QoL and functional health following histotripsy. **Methods:** This retrospective cohort study involved 14 patients who underwent histotripsy for liver tumors at a single center. Eligible patients had completed at least one patient-reported outcome measure (PROM) before and after treatment. PROMs were collected at a median of 27.5 days before treatment (range, 1–100) and 88.5 days after treatment (range, 5–264). Tools included the PROMIS-10 (used by 7 patients) and both PROMIS-10 and NCCN Distress Thermometer V2 (used by 7 patients). These instruments assessed general health, QoL, physical and mental health, social satisfaction, emotional well-being, fatigue, pain, and physical activity. PROMIS T-scores were analyzed. Descriptive statistics summarized changes between assessments. **Results:** Among the 14 patients included in the study, the primary cancer types were colorectal carcinoma (CRC) in 5 (36%), neuroendocrine tumors (NETs) in 3 (21%), breast cancer in 2 (14%), and other tumor types in 4 (29%). A total of 29 liver lesions were treated, with the highest concentration found in liver segment 3 (III). The treatment intent was palliative in 19 lesions (86%) and curative in 3 lesions (14%). The percentage of patients reporting “poor” general health dropped by 50% (from 14% to 7%), while those reporting “good” general health rose from 29% to 43%. The percentage of “poor” overall QoL ratings decreased from 14% to 0%, with increases in “fair” and “good” responses. Physical health saw a decline in “poor” ratings (14% to 7%) and an increase in “fair” responses (50% to 64%). Mental health remained mostly stable, with a slight rise in “good” ratings (7% to 14%). Social satisfaction improved, with “very good”

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

responses increasing from 7% to 21%, although "good" ratings decreased. Physical activity levels rose, with no patients reporting inactivity post-treatment, and more patients reporting being "a little" or "completely" active. Emotional distress showed mixed changes, with "sometimes" responses decreasing from 64% to 50%, but increases in both "rarely" and "often" categories. Fatigue severity shifted toward moderate levels (50% to 71%), and no patient reported severe fatigue post-treatment. The mean pain scores slightly decreased (3.21 to 3.00). The PROMIS physical health scores improved from 40.8 to 42.2, while the PROMIS mental health scores remained stable (44.4 to 44.2). Patients' perceived physical and mental changes also improved (from 2.07 to 2.36 and from 2.00 to 2.50, respectively). **Conclusion:** Histotripsy improved health, activity, and well-being in 14 patients; QoL benefits need further study.

3304 | ★ MACHINE LEARNING BASED OUTCOMES IN GALLBLADDER ADENOCARCINOMA (GBA) WITH LIVER METASTASIS

Sakhr Alshwayyat[1] Salsabeel Aljawabrah[2] Kholoud Alqasem[3] Yamen Alshwaiyat[1], [1]Jordan University of Science and Technology, [2]Sls0201969@ju.edu.jo, [3]King Hussein Cancer Center

Background: GBA with liver metastasis is a rare and aggressive malignancy with a poor prognosis and limited treatment guidance. Due to its late presentation and varied clinical behavior, its management remains challenging. This study is the first to apply machine learning (ML) to identify key prognostic factors and improve survival prediction, specifically in GBA patients with liver metastasis. **Methods:** Data were obtained from the SEER database (2004-2021). Patients who met any of the following criteria were excluded: diagnosis not confirmed by histology; previous history of cancer or other concurrent malignancies; or unknown data. To identify prognostic variables, we conducted Cox regression analysis and constructed prognostic models using ML algorithms to predict the 5-year survival. Patient records were randomly divided into training (70 %) and validation (30 %) sets. A validation method incorporating the area under the curve (AUC) of the receiver operating characteristic curve was used to validate the accuracy and reliability of the ML models. We also investigated the role of multiple therapeutic options using Kaplan-Meier survival analysis. **Results:** A total of 1,189 patients were included. Most patients (57.0%) were younger than 70 years, and the majority were female (72.6%). The racial distribution showed that 72.5% were white, followed by black (16.3%) and Asian or Pacific Islander (11.2%). T3 stage was the most common (60.1%), and nodal involvement was observed in 41.4% of the patients (N1,32.7%; N2,8.7%). Cancer-directed surgery was performed in 60.6% of patients, while 54.8% received chemotherapy. Additionally, 68.2% of the tumors measured ≥ 3 cm.

At 5 years, patients aged < 70 years had higher survival rates (OS: 5.5%, CSS: 5.9%) than those aged ≥ 70 years (OS: 2.7%, CSS: 3.1%). White patients had a 5-year CSS of 7.5%, followed by Asian or Pacific Islanders (6.0%), and Black patients (1.4%). Patients who underwent cancer-directed surgery had better outcomes (OS, 9.5%; CSS, 10.8%) than those who did not (OS, 0.3%; CSS, 0.3%). Chemotherapy was associated with improved survival (OS: 6.2%, CSS: 6.9%) compared to no chemotherapy (OS: 1.8%, CSS: 1.9%).

Multivariate Cox regression analysis identified older age and male sex as poor prognostic factors, while surgery and chemotherapy were good prognostic factors. Gradient boosting and Random Forest were the most accurate models. The ML models identified the T-category as the most significant prognostic factor, followed by age. **Conclusion:** ML enhances personalized medicine by identifying key prognostic factors in GBA with liver metastasis, which may guide treatment decisions for better patient management.

of Texas MD Anderson Cancer Center, Houston, TX, USA, [2]The University of Texas MD Anderson Cancer Center, Houston, TX, [3]The University of Texas MD Anderson Cancer Center

Background: Radiation therapy (RT) has emerged as an effective local therapy option for patients with unresectable HCC and is associated with improved OS. However, some patients still have poor outcomes after RT and biomarkers are needed to stratify prognostic groups. High circulating GH levels promote HCC proliferation and survival and associate with aggressive disease. In this study, we evaluated whether pre-treatment GH levels associate with overall survival (OS) and progression-free survival (PFS) in patients who underwent RT for unresectable HCC. **Methods:** Patients undergoing RT for HCC during 2017-2023 were identified from a prospectively maintained database. Pre-treatment blood samples were obtained, and patients without GH levels within 8 weeks of radiotherapy were excluded. A cutoff of 3.7 ng/mL for women and 0.9 ng/mL for men was used to categorize high vs low GH levels, as set by the Endocrine and Pituitary societies based on population studies and clinical trial data. The primary endpoint was OS and secondary endpoint was PFS, both measured from the time of RT. Kaplan-Meier method was used to estimate OS and PFS. Cox proportional hazards models were used to evaluate the association of OS or PFS with covariates. **Results:** Thirty-four patients were included. Median age was 67 years, 73.5% of patients were male, and 26.5% had high GH levels. Both groups were balanced regarding how many prior lines of therapy patients had received ($p = 0.999$). Median (IQR) follow-up time was 10 (4-25) months. The median PFS for the GH-low group was 7.9 months versus 3.9 months in the GH-high group ($p = 0.219$). The median OS was significantly higher for the GH-low group (15.2 months) compared with the GH-high group (10.6 months, $p = 0.025$). On multivariate analysis, high GH was significantly associated with an increased risk of death (HR: 2.66, 95% CI: 1.07-6.61; $p = 0.036$). **Conclusion:** High pre-treatment GH level associated with worse prognoses for patients with unresectable HCC undergoing RT. These results warrant further validation and potential integration of anti-GH therapy into personalized therapeutic management based on GH levels in HCC patients undergoing HCC.

3306 | PRESENTATION AND CLINICAL OUTCOMES OF PATIENTS WITH HEPATOCELLULAR CARCINOMA DIFFER BY TYPE OF STEATOTIC LIVER DISEASE

Ashwini Arvind[1] Megha Sheth[1] Mohammed Al-Hasan[2] Mohammad Jarrah[1] Dariel Solis[1] Celina Li[1] Pojsakorn Danpanichkul[3] Jordan Mayberry[2] Thomas Kerr[2] Thomas Cotter[1] Lisa Quirk[1] Sneha Deodhar[1] Nicole Rich[2] Amit Singal[1], [1]UT Southwestern Medical Center, [2]University of Texas Southwestern Medical Center, [3]Texas Tech University Health Sciences Center

Background: The updated AASLD nomenclature for steatotic liver disease (SLD) encompasses alcohol-related liver disease (ALD), metabolic dysfunction and alcohol-related liver disease (MetALD) and metabolic dysfunction-related steatotic liver disease (MASLD). We aimed to assess differences in hepatocellular carcinoma (HCC) presentation and outcomes between these groups. **Methods:** We studied a retrospective cohort of patients with cirrhosis and underlying SLD diagnosed with HCC between January 2010 and December 2024 at two US medical centers. We classified liver disease etiology according to alcohol use and cardiometabolic risk factors (CMRF) using the 2023 AASLD SLD criteria, independent of other chronic liver diseases. CMRF included BMI ≥ 25 (23 in Asians), type 2 diabetes, hypertension and dyslipidemia. We categorized patients with current or prior heavy alcohol use and no CMRF as ALD, current or prior heavy alcohol use and ≥ 1 CMRF as MetALD, and ≥ 1 CMRF without heavy alcohol use as MASLD. Surveillance receipt was defined as ultrasound, contrast-enhanced MRI or multiphase CT within 7 months before HCC diagnosis. We used multivariable logistic and Cox regression analyses to evaluate associations between SLD subtype and clinical outcomes. Multivariable models were adjusted for age, sex, race and Child-Pugh class. **Results:** Of 1124 eligible patients, 467 (41.5%) had MASLD, 583 (51.9%) had MetALD and 74 (6.6%) had ALD. Over 70% of patients across the three groups had concurrent viral liver disease. Compared to those with ALD and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

MetALD, patients with MASLD were older (median 55.7 and 57.6 vs. 61.7), a higher proportion were women (5.4% and 10.5% vs. 39.6%) and fewer were non-Hispanic White (48.6% and 36.5% vs. 26.8%) ($p < 0.001$ for all comparisons). Only 40.8% of patients had surveillance imaging. Patients with ALD were less likely to undergo surveillance than those with MetALD (aOR 0.41, 95%CI 0.23–0.70) or MASLD (aOR 0.46, 95%CI 0.25–0.81). A smaller proportion of ALD patients were diagnosed with early-stage HCC (BCLC 0/A) compared to MetALD and MASLD (29.8% vs. 38.6% and 44.4%, $p = 0.003$) but this was not significant in multivariable analysis (ALD vs. MetALD: aOR 0.70, 95%CI 0.42-1.17; ALD vs. MASLD: aOR 0.59, 95%CI 0.34–1.01). Only 30.8% underwent curative treatment, including 62.8% of those with early-stage HCC. Patients with ALD were less likely to receive curative treatment than those with MASLD (aOR 0.26, 95%CI 0.11–0.52) and MetALD (aOR 0.35, 95%CI 0.16–0.71) with similar differences in the subgroup with early-stage HCC (ALD vs. MASLD: aOR 0.33, 95%CI 0.11–0.94; ALD vs. MetALD aOR 0.54, 95%CI 0.20–1.43). Finally, ALD was associated with worse survival compared to MetALD (aHR 1.32, 95% CI 1.01–1.73) and MASLD (aHR 1.34, 95% CI 1.01–1.79). **Conclusion:** Patients with ALD-HCC have worse survival than those with MetALD-HCC and MASLD-HCC, partly related to differences in surveillance receipt, early-stage detection and curative treatment.

3307 | HCC IN THE RIO GRANDE VALLEY: UPDATED DATA ON LATINO POPULATION DISPARITIES AND TREATMENT

Rishika Trivedi[1] Sergio Hernandez-Llamas[1] Laura Reyes-Uribe[1] Yasitha Kakarlapudi[1] Andrea Morales-Acosta[1] Maria Pinzon-Torres[2] Edgar Lopez[1] Fernando Membreno[3] Jose Cruz[4], [1]DHR Health, Edinburg, Texas, [2]University of Monterrey, San Pedro Garza Garcia, Mexico, [3]DHR Health Liver Transplantation, Hepatobiliary Services, Mcallen, Texas, [4]DHR Health Hematology/Oncology, Edinburg, Texas

Background: Hepatocellular carcinoma (HCC) has steadily increased in the U.S. In recent years, with higher incidence among racial and ethnic minorities, particularly Latinos. This retrospective study examines the different etiologies, presentation of diagnosis, management, and outcomes in the Rio Grande Valley, home of 1.3 million Latinos. **Methods:** A retrospective chart review was conducted on patients with HCC diagnosis who were presented at the Liver Tumor Board of our institute between 2017 and 2023. This analysis includes updated data extracted from the electronic health records (EHR), such as medical history, laboratory results, and radiological studies required for each patient's staging and transplant eligibility assessment. Data on patients' clinical characteristics and treatment were also collected. **Results:** A total of 537 cases were reviewed, and 138 patients with complete clinical data were included in the analysis. 95% were identified as White/ Hispanic. The median age at diagnosis was 65.5 $\pm$ 9.6 years, with 69% male and 11.6% uninsured. The average BMI was 30.6, metabolic-associated steatotic liver disease (MASLD) was present in 48.5% of patients and 48.5% were alcohol-related.The longest average interval between initial imaging and diagnosis was seen in Viral Hepatitis (415.8 days). The highest rate of multifocal tumor involvement (54.5%) and the greatest proportion of patients who underwent liver transplant (18.2%) were observed in the MASLD and Alcohol-related group. The peak MELD-Na at diagnosis was found in Alcohol-related and Hemochromatosis (18.0). Vascular invasion was most frequent in the Viral Hepatitis and Alcohol-related group (35.0%). Complete survival (100%) was noted in the Autoimmune, Other, and Alcohol-related with Hemochromatosis cohorts (Table 1a). Ablative therapy was used in 93 (67.4%) of the patients. The number of patients sent for liver transplant evaluation was 59 (42.8%), and only 6

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(10.2%) patients received liver transplants. Of the total, 80 (58.0%) had disease progression, while the others faced challenges such as lack of transportation, inadequate family support, or insurance issues (Table 1b). **Conclusion:** In this predominantly Latino cohort with HCC, MASLD and alcohol were the most common underlying liver diseases. Social determinants of health, including access, support, and insurance, were key contributors to disease progression. Our data by staging is in concordance with the distribution of SEER incidence cases from 2012–2021. Despite multidisciplinary evaluation, the rate of transplantation at our institution is below the national average, highlighting the need to bridge this disparity in the Latino community.

3308 | KDM5A-DRIVEN REPROGRAMMING OF IL-1γ⁺ CD14+ MONOCYTES MEDIATES RESISTANCE TO ANTI-PD-1 THERAPY IN ADVANCED HEPATOCELLULAR CARCINOMA BY SUPPRESSING T CELL-MEDIATED ANTITUMOR IMMUNITY

Ronghua Jin[1] Wenying Qiao[1] Xuefeng Huang[1] Ziyi Li[1] Yang Wang[1] Xiaoxue Yuan[1] Xi Wang[1] Xiaoyan Ding[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality globally, with anti-PD-1 immunotherapy emerging as a promising therapeutic strategy. However, the clinical efficacy of immune checkpoint blockade remains limited, primarily due to complex and poorly understood immune evasion mechanisms. This study aims to characterize circulating immune signatures in HCC patients treated with anti-PD-1 immunotherapy, elucidate the role and mechanisms of IL-1β⁺ CD14⁺ monocytes in tumor immune evasion, and identify novel targets to improve HCC immunotherapy outcomes. **Methods:** Peripheral blood from 10 HCC patients undergoing anti-PD-1 treatment was analyzed via single-cell RNA sequencing (scRNA-seq). Paired tumor tissue samples from 4 patients receiving targeted immunotherapy were examined using multiplex immunofluorescence staining and spatial transcriptomics. To explore mechanisms, we integrated ATAC-seq analysis, in vitro monocyte-T cell co-culture experiments, and murine tumor models, combining single-cell and spatial omics with functional validation to comprehensively assess systemic immune responses to therapy. **Results:** Responders exhibited a higher abundance of CD8⁺ T cells and fewer CD14⁺ monocytes compared to non-responders. The accumulation of IL-1β⁺ CD14⁺ monocytes suppressed CD8⁺ T cell function and contributed to resistance. Spatial transcriptomics revealed increased infiltration of IL-1β⁺ CD14⁺ macrophages in non-responders, which interacted with T cells to inhibit antitumor activity—a pattern confirmed by multiplex immunofluorescence. Mechanistically, in non-responders, CD14⁺ monocytes showed synergistic upregulation of the immunosuppressive SOCS3 and pro-inflammatory IL-1β, leading to M1 macrophage reduction and CD8⁺ T cell dysfunction. These gene expression patterns were epigenetically regulated by KDM5A. In murine HCC models, combined IL-1β blockade and anti-PD-1 therapy decreased immunosuppressive factors, enhanced T cell infiltration, and significantly suppressed tumor progression and improved therapeutic efficacy. **Conclusion:** IL-1β⁺ monocytes play a key role in suppressing CD8⁺ T cell–mediated antitumor immunity. Targeting these monocytes enhances T cell responses and synergizes with anti-PD-1 therapy, offering a promising strategy to improve HCC immunotherapy outcomes.

3309 | LONG SHORT-TERM MEMORY–BASED PROJECTION OF HEPATOBILIARY CARCINOMA MORTALITY TRENDS USING CDC WONDER DATA.

Sri Harsha Boppana[1] Manaswitha Thota[2] Gautam Maddineni[3] Sachin Sravan Kumar Komati[4] Sai Lakshmi Prasanna Komati[5] C. David Mintz MD PhD[6], [1]Nassau University Medical Center / Johns Hopkins University, [2]Virginia Commonwealth University, [3]Creighton university school of medicine, [4]Florida International University, [5]Government Medical College, Ongole, [6]Johns Hopkins University

Background: Hepatobiliary malignancies persist among the top causes of cancer-related death worldwide, even as biomarker discovery and imaging techniques have advanced. Accurate projections of future mortality patterns are essential for public health planning and resource allocation. We therefore examined national mortality data and built a deep-learning model capable of forecasting upcoming trends in hepatobiliary cancer deaths based on demographic information. **Methods:** We retrieved annual death counts for hepatobiliary carcinoma from the CDC's WONDER database covering 1999 through 2020. After normalizing rates per 100 000 population, we converted age, sex, race and ethnicity classifications into numeric encodings. Trend analysis and visualization were performed in R. To predict future mortality, we designed a Long Short-Term Memory (LSTM) network with an input sequence window of 20 years and trained it to forecast the subsequent year's rate. The model underwent 80/10/10 split for training, validation and testing, respectively. We optimized parameters using the Adam algorithm (learning rate $3\times10_{50}$, batch size 32) and halted training when validation loss plateaued. Model performance was quantified by mean squared error (MSE) on both training and independent test sets. **Results:** Age-stratified analysis demonstrated steeply rising mortality among individuals over 65, with men and non-Hispanic populations exhibiting the highest rates. The LSTM network achieved a training MSE of 0.0061 and a validation MSE of 0.0020, indicating strong fidelity between predicted and observed values. Overlay plots of recorded versus projected mortality revealed tight alignment across the test interval, with residuals uniformly small and without systematic bias. **Conclusion:** Our findings confirm distinct demographic disparities in hepatobiliary cancer death rates and validate the LSTM approach for reliable near-term forecasting. Although the model leverages only publicly available demographic inputs—and thus omits clinical details such as tumor stage or comorbidity profiles—it provides a scalable tool for epidemiologic surveillance. Incorporating patient-level variables and extending the prediction horizon represent logical next steps toward personalized prognostic modeling and strategic health policy development.

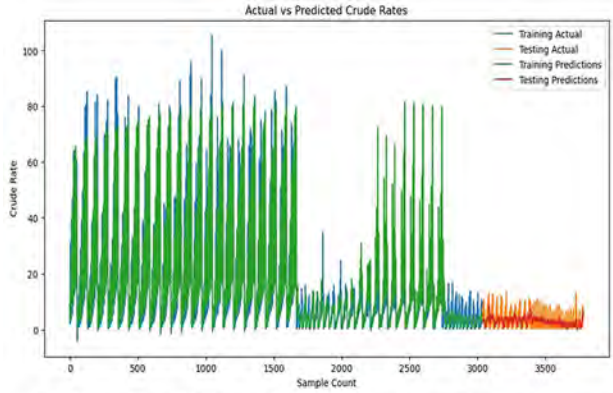

Figure 1. Actual versus LSTM-Predicted Hepatobiliary Cancer Mortality Rates: This plot compares observed crude death rates (per 100 000 population) from the CDC WONDER database (1999–2020) with values forecast by the LSTM network. Solid blue curves represent recorded rates, while the overlaid orange curves depict model predictions. Both training and test intervals are shown to emphasize the model's ability to replicate historical trends accurately.

3310 | ASSOCIATIONS BETWEEN DEPRIVATION INDEX AND POST-LOCOREGIONAL THERAPY MORTALITY AND ACUTE CARE UTILIZATION AMONG PATIENTS WITH HEPATOCELLULAR CARCINOMA

Merete Lund[1] Yue Jiang[2] Chidi Iloabachie[1] Arjun Juneja[1] Patrick Hazelrigg[1] Parsa Pazooki[1] Sydney Power[1] Gabe Lupu[1] Joyce Badal[1] David Seligson[1] Hanna Sanoff[1] David Mauro[1] David Gerber[3] Theodore Yanagihara[1] Sidney Barritt[1] Andrew Moon[4], [1]University of North Carolina - Chapel Hill, [2]Department of Statistical Science Duke University, Durham, NC, [3]University of North Carolina at Chapel Hill, [4]University of North Carolina

Background: Area Deprivation Index (ADI) scores are compiled block group percentiles based on the socioeconomic disadvantage in a region of interest and have been associated with health outcomes in many chronic diseases. The relationship between ADI and outcomes

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

among patients with hepatocellular carcinoma (HCC) receiving locoregional therapies (LRTs) is unclear. ADI may impact multiple steps in the pathway to diagnosis and treatment of HCC including disease etiology, initial diagnosis of HCC, access to care, treatment choices, and care utilization after treatment. This project sought to examine potential associations between ADI and outcomes in HCC patients receiving LRTs. **Methods:** We performed a retrospective analysis of patients with HCC who received LRTs within a single health system between 2014 and 2021. For patients with multiple treatments, we used only information from their initial treatment. We pulled ADI data from the Center for Health Disparities Research database for each patient based on their home address and categorized them into quartiles (e.g., 4th quartile, scores 76-100, greatest deprivation) and extracted other baseline sociodemographic and clinical characteristics. Outcomes of interest included post-treatment mortality and acute care utilization (ER visits or unplanned hospitalizations). A log-rank test was used to examine associations between ADI and outcomes, and a Cox proportional hazards model was used for the same analysis, adjusting for demographic and clinical characteristics. **Results:** There were 790 patients with HCC who received LRT in in our cohort. There were 146 procedures among 85 patients in quartile 1 (scores 1-25), 345 procedures among 190 patients in quartile 2 (scores 26 – 50), 432 procedures among 259 patients in quartile 3 (Scores 51-75), and 425 procedures among 256 patients in the top quartile (Scores 76-100). Median age for quartiles 2-4 was 64.4, 64.2, and 64.1 years, while median age for quartile 1 was statistically significantly higher at 68.3 years. Other demographic and clinical characteristics were similar across quartiles- 75% of patients were male, the most frequent treatment was TACE, and most patients were BCLC C. We did not identify a statistically significant association between ADI quartile and mortality in the unadjusted or multivariable models. 13% of procedures were associated with acute care utilization within 90 days for both the lowest and highest quartiles compared with 21% of procedures in both the 2nd and 3rd quartiles, a statistically significant difference. **Conclusion:** In this analysis, we did not identify statistically significant associations between ADI quartile and mortality, although there was sufficient evidence to suggest an association between ADI quartile and acute care utilization within 90 days. Procedures among patients in the lowest and highest ADI quartiles had lower unplanned ER visits or hospitalizations within 90 days of their procedures.

Patient-level characteristics (N = 790)

3311 | EXPRESSION AND FUNCTION OF MIR-1297 AND ITS TARGET THYMOSIN-Β10 IN HYPOXIA-INDUCED LENVATINIB RESISTANCE IN HEPATOCELLULAR CARCINOMA

Takayuki Kogure[1] *MARI SATOH*[1] *Kennichi Satoh*[1], [1]*Tohoku Medical and Pharmaceutical University*

Background: Lenvatinib has shown a superior response rate in hepatocellular carcinoma (HCC), although its overall survival remains comparable to sorafenib, suggesting potential drug resistance. Hypoxia in the tumor microenvironment is a pivotal factor in

resistance acquisition. Tyrosine kinase inhibitors that inhibit VGEF suppress angiogenesis, leading to significant hypoxia in the tumor microenvironment. This study investigates the mechanisms underlying lenvatinib resistance and the role of microRNAs (miRNAs) under hypoxic conditions in HCC. **Methods:** The human HCC cell lines PLC/PRF/5, HepG2, and Huh7 were cultured under normoxia (95% air and 5% CO_2) or hypoxia (94% N_2 with 1% O_2 and 5% CO_2). Anchorage-dependent proliferation was assessed using a metabolic assay, and induction of apoptosis was evaluated morphologically and activation of caspase-3/7. Genome-wide miRNA profiling was performed to identify resistance-related miRNA alterations. An argonaute2-based RIP assay followed by mRNA profiling was used to identify miRNA targets. **Results:** Lenvatinib inhibited cell proliferation in a concentration-dependent manner; however, its IC_{50} increased significantly under hypoxia, indicating the acquisition of resistance. Hypoxia reduced lenvatinib-induced apoptosis by 22.4% and 19.6% in PLC/PRF/5 and HepG2 cells, respectively, and also suppressed caspase-3/7 activation. Genome-wide profiling revealed 42 upregulated miRNAs in PLC/PRF/5 cells treated with lenvatinib under normoxia, and 28 of these downregulated under hypoxia. Further investigation was focused on miR-1297, which showed the most significant change. Forced expression of miR-1297 significantly reduced cell viability under hypoxia (PLC/PRF/5: 76.6%, HepG2: 67.1%) compared to negative controls (88.3%, 75.3%). RIP assays identified 88 significantly upregulated mRNAs under the miR-1297 overexpression, and TargetScan analysis identified TMSB10 mRNA as a direct target. Forced expression of miR-1297 reduced thymosin-β10 protein expression by 46.3% and 33.4% in PLC/PRF/5 and HepG2 cells, respectively. Silencing TMSB10 mRNA partially restored lenvatinib cytotoxicity, reducing viability by 14.7% and 13.5% under hypoxia. **Conclusion:** miR-1297 may play a role in hypoxia-induced lenvatinib resistance by targeting thymosin-β10, a protein associated with cell survival and proliferation. These observations suggest that miRNAs could be a potential target for overcoming lenvatinib resistance.

3312 | GERMLINE VARIANTS DO NOT INFLUENCE THE RATE OF SOMATIC MUTATIONS IN TERT IN HEPATOCELLULAR CARCINOMA

Chunmiao Cai[1] Salah Adlat[2] Dingzi Yin[1] Markcus Lee[1] Kirk Wangensteen[1], [1]Mayo Clinic, [2]Mayo Clinic, Rochester

Background: TERT promoter mutations and amplifications represent the most prevalent somatic genomic events in hepatocellular carcinoma (HCC). Also, germline Single Nucleotide Polymorphisms (SNPs) at the TERT locus have been found to be protective or risk factor for HCC. However, the relationship between the somatic events and inherited germline variants in TERT remains poorly understood. Here, we investigated the association between TERT somatic alterations and germline variations. **Methods:** Whole genome sequencing (WGS) data from The Cancer Genome Atlas Liver Hepatocellular Carcinoma (TCGA-LIHC) cohort were analyzed. TERT promoter mutations were detected using MuTect2, copy number variations were identified using ModelSegments, and germline variations were called using HaplotypeCaller. Four SNPs were selected for analysis, including rs2242652 and rs10069690, which are two protective loci in alcohol-related HCC, and rs2736098 and rs2736100, associated with increased risk. Somatic alterations, germline genotypes, and clinical metadata were integrated. Different genetic models were used to assess whether risk is driven by heterozygosity, homozygosity, or both. Stratified analyses were performed according to etiologic subgroups. Statistical significance was evaluated using chi-square or Fisher's exact tests with Benjamini-Hochberg correction. **Results:** Among 324 patients with available WGS data from TCGA-LIHC cohort, TERT promoter mutations were identified in 138 cases (42.6%), and TERT amplification was detected in 44 cases (13.6%), demonstrating high consistency with previously reported frequencies. Genotypes for the selected SNPs were successfully assigned to all patients. There was no statistically significant association between TERT promoter mutation status and any of the selected SNPs. For TERT amplification, a significantly lower frequency was observed in patients with the reference homozygous genotype (CC) at rs2736100 (4.7%) compared to those carrying CA or AA genotypes (15.8% for CA or AA; 17.8% for CA; 17.8% for AA; adjusted $P = 0.023$), when P-values were corrected within this single locus. However, these associations lost statistical significance after adjusting across all four tested loci (adjusted $P = 0.092$). Stratified analyses based on etiological subgroups did not show any differences, but the sample sizes might have limited analysis. The lack of significant associations between the two risk SNPs and TERT promoter mutations contrasts with findings from a previous study in a Chinese Han population, potentially due to differences in HCC etiology. **Conclusion:** Our findings suggest no clear association between four germline SNPs and either TERT promoter mutation or amplification, indicating that these germline variants are unlikely to serve as clinical predictors of TERT somatic alterations in HCC. Future research should examine the mechanism of the polymorphisms in altering HCC risk.

3313 | EXOSOMAL MIR-30A-5P DECISION TREE DISTINGUISHES RESPONDERS TO ATEZOLIZUMAB-BEVACIZUMAB THERAPY IN ADVANCED HEPATOCELLULAR CARCINOMA

Young-Sun Lee[1] Eunho Choi[1] Ha Seok Lee[1] Youngwoo Lee[1] Yang Jae Yoo[1] Taehyung Kim[1] Seong Hee Kang[1] Yim Sun Young[1] Young Kul Jung[1] Ji Hoon Kim[1] Yeon Seok Seo[1] Hyung Joon Yim[1] Jong eun Yeon[1] Kwan Soo Byun[1], [1]Korea University College of Medicine

Background: Atezolizumab in combination with bevacizumab is currently recognized as the standard initial treatment for patients with advanced hepatocellular carcinoma (HCC). Nevertheless, there is still no established biomarker that can reliably predict how patients will respond to this therapy. Previous research by our group suggested that miR-30a-5p could serve as a potential predictive biomarker. The objective of this study was to validate the clinical relevance of this exosomal microRNA in a larger group of patients. **Methods:** Blood samples were collected from patients with advanced HCC before they began treatment with atezolizumab and bevacizumab. After three cycles of therapy, patients were categorized as responders if they exhibited stable disease, partial response, or complete response, and as non-responders if their disease progressed. Extracellular vesicles were isolated from the serum, and exosomal RNA was analyzed using next-generation small RNA sequencing. The researchers used decision tree analysis to pinpoint microRNAs that could distinguish between responders and non-responders. **Results:** The study analyzed samples from 13 responders and 11 non-responders. Next-generation sequencing detected a total of 1,076 microRNAs, among which let-7c-5p, miR-30a-5p, and miR-192-5p were found at significantly higher levels in responders. In agreement with earlier studies, miR-30a-5p was notably elevated in responders, with a statistically significant difference ($p = 0.0039$). Decision tree analysis revealed that miR-30a-5p levels of 9.67 or higher could effectively separate responders from non-responders. Additionally, random forest modeling identified miR-30a-5p as the most important factor for classifying patients by treatment response. **Conclusion:** miR-30a-5p appears to be a promising exosomal biomarker for predicting which patients with advanced HCC are likely to benefit from atezolizumab and bevacizumab therapy.

Oncology, Department of Pathology, China Medical University Hospital, [4]Division of Hepato-Gastroenterology, China Medical University Hospital, Taichung, Taiwan

Background: Mucinous cystic neoplasm of the liver (MCN-L) is a rare, slow-growing cyst-forming epithelial tumor characterized by mucin-producing epithelium and ovarian-like stroma (OS). Due to its indolent nature and overlapping imaging features, it is frequently misdiagnosed as a simple hepatic cyst. This study aimed to describe the clinical, radiologic, and pathological characteristics of MCN-L and review outcomes following surgical resection. **Methods:** We retrospectively analyzed 17 patients diagnosed with MCN-L at a single tertiary referral center from 1994 to 2018. Demographics, imaging findings, serum and intracystic CA 19-9 levels, surgical outcomes, and pathological features were reviewed. **Results:** Among the 17 patients (15 females, 2 males; mean age: 57.5 years), all underwent complete surgical resection. Abdominal fullness was the most common presenting symptom. The mean tumor size was 10.4 cm, predominantly located in the left hepatic lobe. Preoperative sonography detected internal septation in 10 patients and mural nodules in a few. Serum CA 19-9 was elevated in 6 patients, and intracystic CA 19-9 levels were markedly elevated in all 4 aspirated cases (range: 1246.4–38705 U/mL). Only one patient had focal in situ adenocarcinoma. No recurrence was observed during a mean follow-up of 65.6 months. **Conclusion:** MCN-L is a rare hepatic cystic tumor with a strong female predominance and left lobe predilection. Internal septation and mural nodules on sonography should prompt suspicion. Despite its benign course, early surgical resection is critical to avoid malignant transformation and ensure excellent prognosis.

3315 | MEDICAL SPECIALTY TREATMENT PATTERNS IN THE MULTIDISCIPLINARY MANAGEMENT OF HEPATOCELLULAR CARCINOMA: THE MAYO CLINIC EXPERIENCE

Fatima Islam[1] Robert Lewandowski[2] Beau Toskich[1], [1]Mayo Clinic Florida, [2]Northwestern University Feinberg School of Medicine

Background: Hepatocellular carcinoma (HCC) is a heterogeneous disease process which requires the involvement of multiple medical specialties in its management. The patterns of medical specialty treatment utilization within a large health system are not well characterized. The aim of this study is to describe the frequency and sequence of medical specialty involvement in HCC management within a large, tertiary care health system. **Methods:** A retrospective review was conducted at the Mayo Clinic using the Mayo Data Explorer (MDE). HCC patients were identified by ICD code (C22.0) and comprehensive CPT codes for Interventional Radiology (IR), Surgery, Radiation Oncology, and Medical Oncology. Treatments were collected after May 2020, the FDA approval date of atezolizumab-bevacizumab, keeping in line with the current standard of therapy. Treatment sequence and specialty involvement were assessed descriptively. **Results:** A total of 2,965 HCC patients with 4,953 treatments across specialties were identified. For all treatments (N = 4,953), IR accounted for 39%, medical oncology 30%, surgery 23%, and radiation 8%. For procedural or infusion treatments (N = 2,643), 42% of patients saw IR as their first HCC provider, followed by surgery (29%), medical oncology (21%), and radiation oncology (8%). Among second treatments (N = 998), 48% were with IR, followed by surgery (25%), medical oncology (15%), and radiation oncology (12%). For third or further treatments (N = 633), most were with IR (57%), followed by surgery (19%), medical oncology (14%), and radiation oncology (10%). HCC patients averaged 13 sessions with medical oncology, 7.6 with radiation oncology, 1.6 with IR, and 1 with surgery. For patients with recorded BCLC stage, stage 0 (N = 43) had 51% treated by IR, stage A (N = 265) had 54% by IR, and stage B (N = 302) had 48% by medical oncology and 38% by IR. Stage C (N = 270) and D (N = 26) were mostly treated by medical oncology (73% and 77%, respectively). For patients having surgery first (N = 778), 6% had subsequent IR treatments, 4% second surgery,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

4% subsequent medical therapies, and 3% subsequent radiation. **Conclusion:** This data highlights the evolving landscape of HCC care, with IR providing the largest proportion of overall therapy while medical oncology serves a predominant role in both intermediate and advanced stage HCC. Understanding medical specialty involvement patterns for the treatment of HCC may better inform both programmatic and multidisciplinary care strategies.

3316 | CHARACTERISTICS AND TREATMENT OF PRIMARY HEPATIC PERIVASCULAR EPITHELIOID CELL TUMOR (PECOMA) IN ADULTS: A SYSTEMATIC REVIEW

Christos Triantos[1] Konstantinos Papantoniou[1] Ioanna Aggeletopoulou[1], [1]Division of Gastroenterology, Department of Internal Medicine, University of Patras, Patras, Greece

Background: Perivascular epithelioid cell tumors (PEComas) are a rare group of mesenchymal neoplasms with distinctive histological and immunohistochemical features. Due to their infrequent occurrence, primary hepatic PEComas present challenges in establishing evidence-based clinical guidelines and optimal management strategies. This systematic review aims to characterize the clinical presentation, diagnostic approach, treatment, and outcomes of adult patients with hepatic PEComa. **Methods:** We performed a systematic literature search in PubMed, Scopus and Cochrane libraries for English-language articles regarding hepatic PEComas using the terms: (perivascular epithelioid cell tumor) OR (PEComa) AND (liver) OR (hepatic), up to May 25, 2025. We included case series and case reports of adult patients diagnosed with primary hepatic PEComa after the age of 18. Included studies reported individual patient history, symptoms at presentation and a follow-up of at least two months. **Results:** A total of 145 studies encompassing 281 patients were included in the analysis. Most studies originated from Asia. The mean age at diagnosis was 46 years (IQR: 35,25–53,75) with a female predominance (74%). The underlying comorbidities were uncommon among the reported cases, and more than half were asymptomatic at presentation. Commonly reported symptoms were abdominal pain, abdominal discomfort, fever, weight loss, fatigue, vomiting, and nausea. During the diagnostic workup, 152 patients (54,1%) underwent ultrasound, 221 (78,6%) CT, 156 (55,5%) MRI, and 31 (11%) PET-CT. The tumor presented as a single liver lesion in almost 9 out of 10 patients. Tumors were most frequently positive for HMB-45, MELAN-A, smooth muscle actin (SMA) and vimentin, while they were commonly negative for S-100 and epithelial markers. Surgical excision was the primary treatment, and 74% of diagnoses were confirmed postoperatively. . A malignant phenotype was reported in 30 cases. The median follow-up duration was 24 months (IQR: 12–48); recurrence occurred in 17 patients (6%), and disease-related mortality in 8 patients 2.85%. **Conclusion:** Primary hepatic PEComa is a rare liver tumor with mostly benign clinical behavior and nonspecific presentation. Although surgical resection remains the cornerstone of management, prospective studies examining optimal patient treatment and surveillance strategies are currently lacking. Future studies are needed to support clinician decisions regarding this entity and improve patient care.

3317 | TREATMENT PATTERNS FOR PATIENTS WITH HEPATOCELLULAR CARCINOMA IN A NATIONAL MEDICAID COHORT

Ashwini Arvind[1] Gi Giamarqo[1] Dyanna Gregory[1] Karim Seif El Dahan[1] Lisa Quirk[1] Anna Tavakkoli[1] Amit Singal[1], [1]UT Southwestern Medical Center

Background: Treatment for hepatocellular carcinoma (HCC) remains underused in practice, particularly in patients of low socioeconomic status. We evaluated treatment patterns, correlates of treatment receipt, and risk of hepatic decompensation following treatment in a cohort of patients with Medicaid insurance coverage. **Methods:** We analyzed Medicaid registry data, including patients diagnosed with HCC between January 2016 and December 2019. We used multivariable logistic regression to assess associations between treatment receipt and patient characteristics, including age, sex, race/ethnicity, ascites and hepatic encephalopathy. Multivariable analyses adjusted for age, sex, race/ethnicity, liver disease etiology and underlying cirrhosis. Associations between treatment receipt and incident ascites and hepatic encephalopathy were also adjusted for baseline hepatic decompensation. **Results:** We identified 21339 eligible patients (66.1% male). Median age was 57 years, and 38.6% were White, 16.9% Black, 15.8% Hispanic, and 8.5% Asian/Pacific Islander (AAPI). HCC treatment was received by 43.5% of patients. Curative treatment, defined as liver transplantation, resection and local ablation, was received by 2.8%, 3.3% and 9.9% of patients, respectively. Locoregional treatment, including transarterial chemoembolization, transarterial radioembolization, and external beam radiation was received by 25.5%, 7.0% and 16.9%, respectively.

Receipt of any HCC treatment did not significantly differ by patient age, sex or race/ethnicity; however, those with ascites were less likely to undergo treatment (aOR 0.46, 95%CI 0.43-0.50). In univariable analyses, women (OR 0.75, 95%CI 0.69-0.81) and Black patients (vs. White: OR 0.89, 95%CI 0.79-0.99) were less likely to receive curative treatment; however, neither remained significant in adjusted analysis. In multivariable analysis, AAPI patients were more likely to receive curative treatment (vs White: aOR 1.22, 95%CI 1.10-1.37) and those with ascites were less likely to undergo curative treatment (aOR 0.67, 95%CI 0.60-0.74).

Receipt of treatment was associated with increased incident ascites (aOR 1.16, 95%CI 1.09-1.23) and HE (aOR 1.40, 95%CI 1.30-1.50). **Conclusion:** Demographic and clinical factors are associated with HCC

treatment receipt. HCC treatment is associated with increased risk of incident hepatic decompensation, highlighting the importance of careful patient selection. **Disclosures:** Ashwini Arvind: Nothing to Disclose, Gi Giamarqo: Nothing to Disclose, Dyanna Gregory: Nothing to Disclose, Karim Seif El Dahan: Nothing to Disclose, Lisa Quirk: Nothing to Disclose, Anna Tavakkoli: Nothing to Disclose, Amit Singal: Genentech: Consultant, AstraZeneca: Consultant, Bayer: Consultant, Eisai: Consultant, Exelixis: Consultant, Merck: Consultant, Elevar: Consultant, FujiFilm Medical Sciences: Consultant, Exact Sciences: Consultant, Glycotest: Consultant, Boston Scientific: Consultant, Sirtex: Consultant, HistoSonics: Consultant, HelioGenomics: Consultant, ImCare: Consultant, DELFI: Consultant, Curve Biosciences: Consultant, Catalym: Consultant, Verve: Consultant

3318 | ASSOCIATIONS BETWEEN LIVER DISEASE ETIOLOGY AND MORTALITY AFTER LIVER-DIRECTED THERAPY IN HCC

Chidi Iloabachie[1] Yue Jiang[2] Merete Lund[1] Arjun Juneja[1] Patrick Hazelrigg[1] Parsa Pazooki[1] Sydney Power[1] Gabe Lupu[1] Joyce Badal[1] David Seligson[1] Hanna Sanoff[1] David Mauro[1] David Gerber[1] Ted Yanaighara[1] A. Sidney Barritt IV[1] Andrew Moon[1], [1]UNC School of Medicine, [2]Duke University

Background: Hepatocellular carcinoma (HCC) is the most common cancer in patients with chronic liver disease and cirrhosis. Most patients with HCC receive one or more locoregional therapies (e.g., thermal ablation, transarterial chemo- or radioembolization, external beam radiation). The underlying liver diseases leading to HCC are changing rapidly. The degree to which liver disease etiology influences outcomes after locoregional therapies for HCC is uncertain. This study aimed to assess if the etiology of HCC is associated with mortality after liver-directed therapy. **Methods:** We performed a retrospective analysis of adults with non-metastatic HCC treated with liver-directed locoregional therapies from 4/4/2014 to 12/31/2021 at a large academic health system. Baseline sociodemographic and clinical characteristics were extracted. The primary outcome was time to death after initial treatment. Etiologies of HCC were categorized as alcohol-associated (ALD), metabolic dysfunction-associated (MASLD), HBV, HCV, and other (e.g., Wilson's disease, autoimmune hepatitis)/multiple. Mortality was determined via linkage to the state death database with confirmation by chart review. We performed unadjusted and multivariable proportional hazards regression to assess potential associations between etiology and mortality, adjusting for potential confounders. **Results:** This study included 808 patients with HCC with the following initial treatments: 207 laparoscopic thermal ablations, 130 percutaneous thermal ablations, 20 bland embolizations, 296 TACE, 91 TARE, and 64 SBRT. The most common etiologies among patients with only a single etiology were HCV (N = 288; 36%) and MASLD (N = 151; 19%). 259 patients had multiple etiologies (32%). In the multivariable model adjusting for age, year of therapy, sex, Charlson comorbidity index, Child-Pugh score, ECOG performance status, BCLC stage, and treatment type, patients with HCV-only etiology had a significantly lower hazard of death compared to those with MASLD-only (aHR 0.722; 95% CI 0.538–0.970). **Conclusion:** In this retrospective study, liver disease etiology was independently associated with mortality after liver-directed therapy for HCC. This suggests that liver disease etiology may have utility in risk stratification and prognostication for non-metastatic HCC.

3319 | HEALTHCARE COSTS OF STEATOTIC LIVER DISEASE-ASSOCIATED HEPATOCELLULAR CARCINOMA

Catherine Mezzacappa[1] Tamar Taddei[1] Pedro Ochoa-Allemant[2] David Kaplan[2] Amy Justice[1] Ronald Braithwaite[3], [1]Yale University, [2]University of Pennsylvania, [3]New York University

Background: The cost-effectiveness of screening for hepatocellular carcinoma (HCC) in steatotic liver disease (SLD) without cirrhosis is unknown. While the costs of HCC in cirrhosis have been measured, they are unknown in SLD without cirrhosis, a critical knowledge gap for evaluating the cost-effectiveness of HCC screening strategies in this population. **Methods:** Using Veterans Health Administration (VA) data between 2012-2024, we assessed outpatient, inpatient, pharmacy, and purchased care costs for adults with two elevated ALT levels $\geq$180 days apart and imaging-confirmed steatosis with no history of viral hepatitis or primary liver disease. We defined index date as date of first abnormal ALT in the SLD group and date of HCC diagnosis in the HCC group. Costs were measured for 3 years from index date and follow-up ended at death or 90 days after last VA contact. We adjusted for inflation and pro-rated costs to the proportion of each year that an individual remained in follow-up. We estimated the marginal costs of HCC using linear models with a gamma distribution adjusted for age, sex, and smoking. We stratified analyses by presence of known cirrhosis at index (diagnosis of cirrhosis or decompensation before or within 180 days after index) and, in HCC, receipt of an immune checkpoint inhibitor (ICI). **Results:** Of 336,657 Veterans with SLD (4,525 with cirrhosis) and 10,176 with HCC (6,243 with cirrhosis), over 99% accrued healthcare costs in all groups, suggesting high use of VA care. Median total cost per year differed by cirrhosis status. For example, those without cirrhosis had a median cost of $11,085 in year 1 compared to $43,514 in those with cirrhosis. Median costs were highest in year 1 for all stages of HCC across cirrhosis groups. The adjusted marginal cost of HCC was higher in Veterans with cirrhosis than those without cirrhosis each year. For example, in year 1, the marginal cost of BCLC 0/A HCC was $26,782 in Veterans without cirrhosis compared to $66,632 in those with cirrhosis. The largest contributors to HCC costs were outpatient care and ICI treatment. For example, median pharmacy costs in Veterans with BCLC C HCC without cirrhosis were $149,679 in recipients of ICIs compared to $49,049 in those not treated with ICIs. **Conclusion:** Receipt of ICIs and presence of cirrhosis dramatically alter the costs of HCC care. These differences should be considered when assessing the cost-effectiveness of potential HCC screening strategies in the population with SLD without cirrhosis. Observed cost differences may be attributable to treatment eligibility and synergistic effects of advanced liver disease with HCC.

3320 | THE RELATIONSHIP BETWEEN M6A MODIFICATION OF CHARACTERISTIC GENES OF DIFFERENT CELL SUBPOPULATIONS AND DISEASE PROGRESS IN THE WHOLE PROCESS OF HEPATITIS-CIRRHOSIS-LIVER CANCER: A COMBINED MULTI-OMICS STUDY BASED ON SINGLE-CELL RNA-SEQ DATA

Juanjuan Shi[1] Yikai Wang[1] Zihan Liu[1] Wenhao Wang[1] Ning Gao[1] Xin Zhang[1] Shuangsuo Dang[1], [1]The Second Affiliated Hospital of Xi'an Jiaotong University

Background: The m6A modification, as an important epigenetic mechanism, plays a pivotal role in chronic liver diseases and hepatocellular carcinoma (HCC). It is involved in processes such as hepatocyte injury, inflammatory cell recruitment, and activation of hepatic stellate cells (HSCs) during fibrogenesis. Therefore, this study aimed to investigate the effect of m6 A gene modification on the immune microenvironment during the progression of chronic liver disease. **Methods:** This study integrated multi-omics approaches to investigate the genetic and cellular mechanisms of m6A in liver diseases. First, we identified m6A-related single nucleotide polymorphisms (SNPs) associated with liver diseases using genome-wide association studies (GWAS) summary data. We performed functional annotation of these SNPs by integrating them with single-cell RNA sequencing (scRNA-seq) datasets. Macrophage/microglia cells were further clustered into distinct subpopulations based on transcriptomic profiles. We analyzed intercellular communication patterns among these cell subsets using ligand-receptor interaction mapping and identified key pathways involved in disease pathogenesis. **Results:** Based on the results of GWAS analysis, 100, 75, and 70 m6A-associated SNPs were screened from CHB, cirrhosis, and HCC samples. Single-cell transcriptomic profiling revealed distinct cellular compositions across different liver disease states: B-cells and T-cells were more prevalent in CHB patients; NKT cells increased in cirrhotic livers; while epithelial cells and fibroblasts were enriched in HCC samples. Analysis of cell-specific gene modules highlighted significant enrichment of macrophage/monocyte genes in pathways related to myeloid leukocyte activation and cytokine production regulation. Unsupervised clustering of macrophage/microglia cells identified eight distinct subpopulations, with Mac. Mono_SEPP1 shows unique communication patterns indicative of its role in disease pathogenesis. Finally, we identified a significant causal relationship between the m6A-related gene HLA-DPA1 and HCC development. **Conclusion:** Our results reveal that genes related to Mac.Mono_SEPP1 macrophage subpopulation plays a key role in liver disease progression through m6A modification. Among them, m6A modification of LA-DPA1 is a protective factor for HCC.

3321 | OBSERVATION ADMISSION FOLLOWING LOCOREGIONAL THERAPY FOR HEPATOCELLULAR CARCINOMA IS ASSOCIATED WITH SUBSEQUENT EMERGENCY ROOM VISITS AND HOSPITALIZATIONS

Gabriel Lupu[1] Yue Jiang[2] Chidi Iloabachie[1] Merete Lund[1] Arjun Juneja[1] Patrick Hazelrigg[1] Parsa Pazooki[1] Sydney Power[1] Joyce Badal[1] David Seligson[1] Hanna Sanoff[1] David Mauro[1] Nima Kokabi[1] Theodore Yanagihara[1] A. Sidney Barritt[1] Andrew Moon[3], [1]University of North Carolina at Chapel Hill, [2]Duke University, [3]University of North Carolina

Background: Hepatocellular carcinoma (HCC) has one of the lowest 5-year survival rates. Treatment varies by stage and includes locoregional therapy (LRT) such as thermal ablation, transarterial chemoembolization/radioembolization (TACE/TARE), or stereotactic body radiation therapy (SBRT). While post-LRT observation admissions are common, their association with subsequent emergency room (ER) visits and hospitalizations is unclear. This study examined the relationship between post-LRT observation admissions and later ER visits or hospitalizations. **Methods:** We performed a single-center retrospective analysis of adults with diagnosed HCC who underwent LRT from 4/4/2014 to 12/31/2021. The primary outcome was an ER visit or hospitalization within 90 days post-LRT. The main exposure was an observation admission immediately post-LRT. We collected data on demographics, liver disease etiology and severity, HCC stage, and LRT type. Unadjusted and adjusted multivariable logistic regression analyses were used to assess the association between observation admissions and subsequent ER visits or hospitalizations. **Results:** Among 763 patients, 1,266 LRT procedures were identified. Of these, 585 (46.2%) were TACE or bland embolization, 178 (14.1%) were TARE, and 503 (39.7%) were ablation therapies. An unplanned ER visit or inpatient admission occurred within 90 days in 234 (18.5%) procedures. Observation admission occurred in 328 procedures (25.9%). In unadjusted analysis, post-LRT observation admission was associated with higher odds of subsequent ER visit or hospitalization (OR 1.81; 95% CI: 1.33–2.44). After adjusting for potential confounders, observation admission remained associated with higher odds of subsequent ER visit or hospitalization (OR 1.73; 95% CI: 1.19–2.50). **Conclusion:** Our findings show a significant association between post-LRT observation admission and subsequent ER visits

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

or hospitalizations, even after adjustment for confounders such as severity of hepatic dysfunction, type of LRT, and year of procedure. Higher Charlson Comorbidity Index and Child-Pugh scores were also independently associated with 90-day ER visits and hospitalizations. Future work will investigate the relationship between these factors as potential predictors of decompensation. These findings may help guide risk stratification and post-LRT care planning.

3322 | TBX15 REGULATES SORAFENIB RESISTANCE IN HEPATOCELLULAR CARCINOMA THROUGH CGAS/STING PATHWAY

Hui Yuan[1] Mengfan Jiao[2] Chuanlong Zhu[3], [1]Jiangsu Province Hospital, The First Affiliated Hospital of, [2]nanjing medical university, [3]jiangsu province hospital

Background: In recent years, targeted therapy and immunotherapy have provided a new approach for the clinical treatment of patients with advanced hepatocellular carcinoma (HCC). However, as targeted therapies advance, drug resistance also increases. Therefore, in order to overcome drug resistance and develop effective targeted therapies, further exploration of HCC related molecular signaling pathways and corresponding targeted therapies is important. **Methods:** Differential genes were screened through TCGA and GEO databases. RNA sequencing was performed to uncover the downstream factor of TBX15 in HCC cells. The luciferase and co-ip assays were used to verify whether TBX15 acted as a transcription factor of HERC5 in HCC cells. **Results:** Compared with HCC patients' paracancer tissues, immunohistochemical and WB results indicated that TBX15 was lower in HCC tissues. IC50 results suggested that TBX15 could enhance the sensitivity of HCC cells to sorafenib. RNA-seq results showed that ferroptosis-related genes were significantly increased in TBX15-overexpressing HCC cells. We demonstrated that TBX15 increased ferroptosis in sorafenib resistant HCC cells (HCC-SR) in vitro. We further found that TBX15 could activate the cGAS/STING pathway in HCC-SR. Ferroptosis was inhibited after treatment of HCC-SR with cGAS inhibitors. We subsequently treated HCC-SR with cycloheximide and found that TBX15 enhanced the stability of cGAS in HCC-SR. Co-IP results indicated that TBX15 does not bind directly to cGAS. The above RNA-seq results suggested that HERC5, a key enzyme involved in ISG, was significantly increased in TBX15-overexpressing HCC cells. Then we found that the ISGylation level of cGAS increased significantly with the increase of TBX15 expression. We further constructed wild type and mutant HERC5 plasmids targeting the binding site between TBX15 and HERC5. The results showed that the co-mutations of 1452-1459 and 1623-1630 sites on HERC5 mRNA inhibited the transcriptional activity of TBX15. Finally, we found that compared with sorafenib alone, the tumor volume and weight of TBX15 combined with sorafenib group were reduced from 0.68 cm3 to 0.20 cm3 and 0.56 g to 0.14 g. **Conclusion:** TBX15 promotes ferroptosis by regulating

3323 | DISTINCT RECURRENCE PATTERNS AND INFERIOR POSTOPERATIVE OUTCOMES OF COMBINED HEPATOCELLULAR-CHOLANGIOCARCINOMA COMPARED WITH HEPATOCELLULAR CARCINOMA

Yeongseok Hwang[1] Subin Heo[2] In Hye Song[3] Young-In Yoon[4] SUNG WON CHUNG[5] Jonggi Choi[6] Danbi Lee[7] Ju Hyun Shim[7] Kang Mo Kim[7] YOUNG-SUK LIM[7] Lee Han-chu[7] Won-Mook Choi[7], [1]Asan medical center, [2]Department of Radiology and Research Institute of Radiology, University of Ulsan College of Medicin, [3]Department of Pathology, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, [4]Department of Surgery, Asan Medical Center, [5]Department of Gastroenterology, Asan Medical Center, [6]University of Ulsan, Asan Medical Center, [7]Department of Gastroenterology, Liver Center, Asan Medical Center

Background: Combined hepatocellular-cholangiocarcinoma (cHCC-CCA) is a rare liver malignancy that shares clinical and radiologic features with hepatocellular carcinoma (HCC), making preoperative diagnosis difficult. This study aimed to compare postoperative outcomes between cHCC-CCA and HCC in patients with very early or early-stage tumors. **Methods:** A retrospective cohort of 3,637 HCC and 148 cHCC-CCA patients, all pathologically diagnosed at BCLC stage 0 or A and treated with surgical resection between 2010 and 2018, was analyzed from a high-volume tertiary center in Korea. Overall survival (OS) and recurrence-free survival (RFS) were compared using multivariable Cox regression. Prognostic differences were further assessed via 1:4 propensity score (PS) matching and subgroup analyses. **Results:** Compared to HCC, cHCC-CCA patients were older (56.9 vs. 54.8 years; $p = 0.009$), had lower rates of diabetes (15.5% vs. 23.3%; $p = 0.04$) and hepatitis B infection (65.5% vs. 75.4%; $p = 0.004$), and showed higher rates of microvascular (35.1% vs. 26.2%; $p = 0.02$) and capsular invasion (18.2% vs. 8.2%; $p < 0.001$). The 5-year RFS and OS were significantly lower in cHCC-CCA (RFS: 47.9% vs. 58.5%; adjusted hazrd ratio [HR], 1.51; 95% confidence interval [CI], 1.22–1.88; $p < 0.001$; OS: 70.9% vs. 87.8%; adjusted HR, 2.48; 95% CI, 1.88–3.26; $p < 0.001$). These findings remained robust in the PS-matched cohort and across all clinical subgroups. Among patients with recurrence, those with cHCC-CCA had significantly worse OS (adjusted HR, 2.17; 95% CI, 1.56–3.03; $p < 0.001$)[WC1] and a higher rate of extrahepatic recurrence (23.0% vs. 7.7%; $p < 0.001$), particularly to the lungs and lymph nodes, whereas OS was comparable between groups in those without recurrence. **Conclusion:** cHCC-CCA is associated with significantly poorer postoperative outcomes than HCC, particularly in the setting of recurrence. Intensified surveillance for extrahepatic recurrence may be warranted in this population.

3324 | BREAKING RESISTANCE AND REWRITING THE SYSTEMIC PLAYBOOK: A SCOPING REVIEW OF COMBINATION TARGETED THERAPIES IN ADVANCED HEPATOCELLULAR CARCINOMA

Taseen Tanzil[1] Eric Welwin[1] Ibrahim Qadri[1] Samin Faiaz[1], [1]CUNY School of Medicine

Background: Hepatocellular carcinoma (HCC) is a highly aggressive liver cancer with limited options in advanced stages. In unresectable cases, targeted therapies have modestly improved outcomes but are limited in long-term effectiveness due to resistance, heterogeneity, and toxicity. Recent research has explored alternative modalities that overcome such barriers by combining tyrosine kinase inhibitors (TKIs) with immune checkpoint inhibitors (ICIs), or pairing targeted agents with cellular or anti-angiogenic therapies. This scoping review addresses the latest combination regimens with drugs such as sorafenib, lenvatinib, cabozantinib, regorafenib, and ramucirumab concerning their clinical impact and immunologic rationale. **Methods:** A review of preclinical and clinical studies on targeted combination therapies in HCC was conducted. Regimens combining TKIs with ICIs, VEGFR inhibitors, EGFR inhibitors, and immunomodulatory cell therapies were emphasized. Included studies were analyzed based on treatment setting (first-line vs. second-line), mechanism of synergy, objective response rate (ORR), progression-free survival (PFS),

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and safety. Selected trials were contrasted with each other to identify trends in efficacy, toxicity, and molecular targeting. **Results:** Several key findings emerged. Lenvatinib plus envafolimab and cabozantinib plus atezolizumab as front-line treatments demonstrated increased PFS and disease control, but with inconsistent OS benefit, compared to monotherapies. In resistant or second-line populations, regorafenib-based regimens enhanced immune activation, response durability, and early biomarker signals of T-cell and myeloid reprogramming. Additionally, preclinical pairing of sorafenib with NK cells or targeting VEGFR-2 (ramucirumab) blockade demonstrated synergy with angiogenesis, fibrosis, and apoptosis, providing opportunities to re-sensitize the tumor and reduce dose requirements. The limitations included small cohort sizes, incomplete OS data, and the need for validated predictive biomarkers, while toxicity was generally manageable across the board. **Conclusion:** This review illustrates an important shift in research towards combined immunotherapeutic HCC therapies that aim to avoid resistance and extend patient eligibility. The preliminary results from the observed clinical trials suggest moving towards these regimens, guided by known drivers and immune signatures. Future directions should focus on biomarker-based tumor selection, dose optimization, and combination with locoregional or cell-based modalities to offer a clear roadmap to enhance systemic impact.

Reference	Treatment Type	Clinical Scenario	Outcome	Year Published
Zhang et al.	Sorafenib + IL-12/IL-18-activated NK cells	Preclinical model of HCC	Increased tumor cell density, reduced angiogenesis and fibrosis, synergistic antitumor effect	2025
Zheng et al.	Camrelizumab (PD-1) + Apatinib (VEGFR2 inhibitor)	First-line for unresectable HCC	Better outcomes than sorafenib alone in CARES-310; approved in China	2025
Jiang et al.	Lenvatinib + Envafolimab (PD-L1 inhibitor)	Unresectable HCC, first-line	18.5 mo mOS, 9.4 mo mPFS, 40% ORR, 80% DCR, well tolerated	2024
Shi et al.	Lenvatinib + Gefitinib (EGFR inhibitor)	Lenvatinib-resistant HCC with EGFR↑	13.7 mo mOS, 4.4 mo mPFS, 30% ORR, 76.7% DCR; common toxicities (fatigue, rash, diarrhea)	2024
Kelley et al. / Yau et al.	Cabozantinib (VEGFR/MET/AXL) + Atezolizumab (PD-L1 inhibitor)	First-line for advanced HCC	6.9 mo mPFS vs. 4.3 (sorafenib); 16.5 mo mOS (not significant); higher grade 3/4 AEs	2022
Kim et al.	Regorafenib + Nivolumab	Front-line treatment of unresectable HCC	7.38 mo mPFS, 31% ORR, 80.5% 1-yr OS; favorable safety profile	2024
Galle et al.	Regorafenib + Pembrolizumab	Intermediate HCC (outside up-to-7)	Phase III trial ongoing (REPLACE); testing against TACE/TARE	2024
Taha et al.	Sorafenib + Ramucirumab (VEGFR-2 inhibitor)	Preclinical (HepG2 liver tumor cells)	Synergistic apoptosis, cell cycle arrest, ↓ VEGFR2/MMP-9/pSTAT 3, enhanced sorafenib cytotoxicity	2022

3325 | EVOLVING TRENDS IN THERAPY FOR HEPATOCELLULAR CARCINOMA AND THE IMPACT OF MULTIDISCIPLINARY MANAGEMENT – A REAL-WORLD STUDY OF 1,627 CASES OVER 5 DECADES

Chee-Kiat Tan[1] Kaina Chen[1] Boon Bee George Goh[1] Jason Chang[1] Wei-Lun Liou[1], [1]Singapore General Hospital

Background: There are many recent developments in locoregional and systemic therapies for hepatocellular carcinoma (HCC). There is also a growing advocate for multidisciplinary involvement in the management of HCC. Our weekly multidisciplinary HCC tumor board with the participation of hepatobiliary surgeons, hepatologists, medical and radiation oncologists, diagnostic and therapeutic radiologists and nuclear medicine physicians started in early 2021. The aim of our study is to examine the evolving trends of HCC therapy and the impact of multidisciplinary tumor board on HCC cases seen in our department over the past 5 decades. **Methods:** HCC patients seen in the Singapore General Hospital Department of Gastroenterology and Hepatology from 1980-2024 with documentation available were included in the study. The therapy received by the patient was categorised as curative (including local ablation), locoregional, systemic or best supportive care. This was analysed by successive decades starting from 1980, according to BCLC stage. **Results:** There were 1,627 patients with an overall median age of 64.3 years. 79% were males and the majority were hepatitis B related (63.4%). The median age in the 5 decades were 59.0, 61.4, 62.9, 65.6 and 69.4 years respectively. As seen in the table, there was a dearth of HCC therapy available in the early decade of 1980-1989. With the advancement of locoregional therapy (LRT), increasing more patients in BCLC B received LRT from 1990 with a significant increase in 2010-2019. Several systemic agents were available from the beginning of 2020, with a correspondingly significant increase in BCLC C patients receiving systemic therapy in 2020-2024. Curative therapy remained the main modality for BCLC 0 and BCLC A without any significant change over 5 decades. For BCLC D, although best supportive care (BSC) is prevalent, other active therapies such as LRT were also given in the earlier 4 decades. However, with the introduction of multidisciplinary tumor board in the current decade, no active therapies were given for BCLC D except for a small minority on systemic therapy. In this decade of

multidisciplinary tumor board, the most frequent therapies given were also appropriate to the BCLC stage. **Conclusion:** HCC therapy for our patients over the decades was in line with the advances globally. The multidisciplinary tumor board advocated for patients to receive appropriate therapy which included BSC for patients with advanced BCLC D disease unlike deviations in the previous decades.

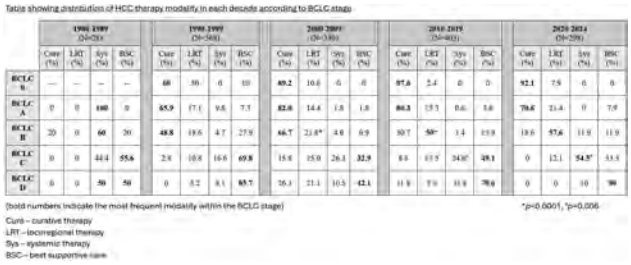

Table showing distribution of HCC therapy modality in each decade according to BCLC stage

	1980-1989 (N=20)				1990-1999 (N=308)				2000-2009* (N=530)				2010-2019 (N=402)				2020-2024 (N=299)

3326 | TRENDS AND FACTORS ASSOCIATED WITH HEPATOCELLULAR CARCINOMA DIAGNOSIS, STAGE, TREATMENT AND SURVIVAL

George Ioannou[1] vera yakovchenko[2] Tamar Taddei[3] Alexander Monto[4] Heather Patton[5] Monica Merante[2] Patrick Spoutz[6] Linda Chia[6] Jennifer Yudkevich[7] Ayse Aytaman[8] Atoosa Rabiee[9] Binu John[10] Boris Blechacz[11] Cincy Cai[12] HoChong Gilles[13] Anand Shah[14] Heather McCurdy[15] Puneet Puri[16] Janice Jou[17] Khurram Mazhar[18] Cesar Taborda-Vidarte[19] Sujan Ravi[20] Alpna Limaye[21] Amar Mandalia[22] Karlyn Rupert[23] Jason Dominitz[24] Jennifer Anwar[25] Timothy Morgan[26] Shari Rogal[27], [1]University of Washington Medical Center, [2]VA Pittsburgh Health Care System, [3]Yale University, [4]University of California, San Francisco, [5]VA San Diego Health Care System, [6]Pharmacy Benefits Management, Veterans Integrated Service Network 20, Vancouver, WA, [7]VA New York Harbor Healthcare System, Brooklyn, NY, [8]VA NY Harbor Healthcare System Brooklyn Campus, [9]Washington DC VA Medical Center, [10]University of Miami and Miami VA, [11]VA South Texas Health Care System, San Antonio, TX, [12]VA Loma Linda, [13]McGuire Veterans Affairs Medical Center, [14]VA Atlanta, [15]VA Ann Arbor, [16]VA Richmond, [17]OHSU, [18]VA North Texas Health Care System, Dallas, TX, [19]VA Tampa, [20]Birmingham VA Medical Center, Birmingham, AL, [21]Gainesville VA, [22]Orlando VA Medical Center, Orlando, FL, [23]VA Martinsburg Health Care System, [24]VA Puget Sound, [25]VA Long Beach, [26]VA Long Beach Healthcare System, [27]University of Pittsburgh

Background: The National Gastroenterology and Hepatology Program of the US Veterans Health Administration (VHA) established an ongoing program of biennial assessment of hepatocellular carcinoma (HCC) diagnosis, stage, HCC-directed treatment (type and timeliness), and survival. **Methods:** Out of >2000 patients with a new diagnosis of HCC in 2023 in VHA, a random sub-sample of 194 confirmed HCC cases were selected for a structured medical record review by expert hepatologists. Factors associated with stage at diagnosis, receipt of treatment and survival were assessed and compared to our prior extraction of HCC cases diagnosed in VHA in 2021. **Results:** Among 194 confirmed HCC cases in 2023 (42.8% cured HCV, 24.2% MASLD, 13.9% ALD, 5.2% active HCV, 4.1% MetALD), mean age was 73 years, 56.7% had cirrhosis diagnosed before HCC, 12.9% had cirrhosis diagnosed after HCC and 22.2% did not have cirrhosis. Stage at diagnosis was T1 in 17.5%, T2 in 42.3% and beyond T2 in 40.2%. Early-stage diagnosis (T1 or T2) was more common in the following groups: cirrhosis diagnosed before HCC (70.9%), HCC diagnosed by screening (86.3%), high performance status (73.0%), receipt of VA primary care (63.3%) or VA liver care (72.6%). Among 147 out of 194 patients (75.8%) who received HCC-directed treatments after a median of 68 days (IQR 39-107) from diagnosis, the most common, first-line treatment was Y-90 radioembolization (28.6%), followed by ablation (21.1%), transarterial chemoembolization (20.4%), systemic therapy (17.0%), surgical resection (7.5%) and external beam radiation (5.4%). Potentially curative treatments (overall 21.6%) were more common in the following groups: early-stage diagnosis (35.8%), diagnosed by screening (35.3%), pre-diagnosis liver care (28.2%). During a mean follow-up of 481 days, 84 (43.2%) died. Factors associated with lower all-cause mortality were: early-stage diagnosis, diagnosis via screening, CTP class A, MELD ≤10, absence of cirrhosis, cured HCV, receipt of curative treatments, VA primary or liver care and good performance status. Compared to the VHA HCC cases that were diagnosed in 2021, the cases in 2023 were more likely to have MASLD/MetALD (28.3% vs. 15.6%), to be diagnosed at stage T1/T2 (59.8% vs. 53.8%), and to receive Y90 (28.6% vs. 17.0%) and systemic therapy (17.0% vs. 10.9%) as first-line treatment and less likely to have active or cured HCV (48.0% vs. 62.8%). **Conclusion:** These results highlight the importance of HCC screening and engagement in care for HCC diagnosis, treatment, and survival while demonstrating the feasibility of developing a national quality improvement agenda for addressing persistent gaps in the HCC care continuum.

3327 | PROGNOSTIC IMPACT OF PROTEINURIA IN PATIENTS WITH ADVANCED HCC TREATED WITH ATEZOLIZUMAB PLUS BEVACIZUMAB

Young Mi Hong[1] Hyung Myung Cho[2], [1]Pusan National University School of Medicine, [2]Pusan National University Yangsan Hospital

Background: Proteinuria is a common adverse event associated with atezolizumab plus bevacizumab combination therapy. However, its prognostic implications in hepatocellular carcinoma (HCC) remain unclear. This study aimed to evaluate the clinical relevance of proteinuria and identify predictive factors for its development in HCC patients treated with atezolizumab plus bevacizumab. **Methods:** We conductive a retrospective observational study to investigate the development of proteinuria following atezolizumab plus bevacizumab treatment in patients with advanced HCC. Patients with low level of proteinuria (1+ or less on a dipstick test) at the initiation of therapy were included in the analysis. Overall survival (OS) was evaluated using Cox proportional hazards models and Kaplan–Meier analysis. Baseline clinical variables were analyzed to identify potential predictors of proteinuria development. **Results:** A total of fifty-five patients with advanced HCC treated with atezolizumab plus bevacizumab were enrolled. Grade 2 proteinuria developed during treatment in 19 patients (34.5%). Patients who developed grade 2 proteinuria had significantly longer OS compared to those who did not ($P = 0.022$). Additionally, OS differed significantly according to the severity of proteinuria developed during treatment ($P = 0.013$). In univariate analysis, a history of prior transarterial chemoembolization was the only predictive factor associated with the development of grade 2 proteinuria ($P = 0.044$). **Conclusion:** The development of proteinuria was associated with longer OS in patients with advanced HCC treated with atezolizumab plus bevacizumab. These findings suggest that proteinuria could serve as a potential predictive marker of treatment efficacy and should not be regarded solely as an adverse event.

3328 | ACCEPTABILITY OF BLOOD BIOMARKERS FOR LIVER CANCER SURVEILLANCE: CONSUMERS AND CLINICIANS' PERSPECTIVE

Lucinda Vaux[1] Angela Carberry[2] Rhian Jones[2] Brooke Gaggin[1] Mikaela Daniells[1] James O'Beirne[1], [1]Sunshine Coast University Hospital, [2]Sunshine Coast Health Institute

Background: Hepatocellular carcinoma (HCC) mortality is rising faster than any other cancer in Australia. Current HCC surveillance—ultrasound and alpha-fetoprotein—are suboptimal and challenged by poor sensitivity and limited access. Blood-based biomarkers represent a potential strategy to overcome these

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

barriers. There is limited data on clinician and patient perspectives in Australia.
Aim; To assess patient and clinician attitudes toward current HCC surveillance and the potential future role of blood-based biomarkers. **Methods:** Anonymous online surveys were distributed in December 2024 to patients undergoing HCC surveillance at a single health service in Queensland, Australia, and clinicians involved in HCC monitoring across Australia. The patient and clinician surveys contained 19 and 23 items, respectively. Descriptive analysis was performed to summarise responses. **Results:** A total of 105 patients (response rate: 32%) and 48 clinicians (response rate 55%) completed the survey. Summary of selected survey responses in Table 1.
Patient results: Most patients were male (52%) and 65 years or older (58%). Patients reported high levels of comfort with current surveillance methods – 92% *comfortable* with ultrasound and 93% with blood test. Most patients *agreed* or *strongly agreed* that blood tests (79%) and ultrasounds (80%) contribute to improved liver cancer surveillance. The effort required for attending appointments was perceived as low, with 89% of patients reporting *little* to *no effort* for blood tests, and 80% for ultrasounds. When given a choice, 70% preferred combined surveillance, 25% blood tests only, and 3% ultrasound only.
Clinician results: The majority of clinicians were hepatologists (83%), practising in metropolitan areas (83%). In evaluating current HCC surveillance practices, 88% of clinicians reported using both ultrasound and AFP. Regarding the effectiveness of ultrasound and AFP, 77% agreed that ultrasound contributes to effective surveillance, and 69% agreed for AFP. If accuracy were equal, 81% would prefer blood-based biomarkers over ultrasound and AFP. Overall, 92% *agreed* or *strongly agreed* that blood-based biomarkers could improve HCC surveillance, and 73% reported feeling *comfortable* using the test. However, clinicians remained cautious about eliminating ultrasound, only 29% *comfortable*, 48% *uncomfortable*, and 6% *very uncomfortable,* with this approach. Additionally, 27% believe there are moral or ethical consequences associated with only using blood-based biomarkers. **Conclusion:** Patients reported high levels of comfort and confidence with current HCC surveillance methods. Clinicians expressed comfort with the use of blood-based biomarkers and recognised their potential to enhance surveillance. Future research should focus on strategies for implementing blood-based biomarkers in clinical practice, with particular attention to patient acceptability and feasibility.

3329 | CLINICAL OUTCOMES OF IMMUNOTHERAPY FOR UNRESECTABLE HEPATOCELLULAR CARCINOMA IN PATIENTS WITH COEXISTING MALIGNANCIES

Haruhiko Takeda[1] Hiroki Morimura[1] Masayuki Ueno[1] Masako Mishima[1] Tadashi Inuzuka[1] Atsushi Takai[1] Ken

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Takahashi[2] Hiroshi Seno[1], [1]Department of Gastroenterology and Hepatology, Graduate School of Medicine, Kyoto University, [2]Center for Cancer Immunotherapy and Immunobiology, Graduate School of Medicine, Kyoto University

Background: The efficacy and safety of immunotherapy for hepatocellular carcinoma (HCC) in patients with coexisting malignancies remain unclear, as such cases are typically excluded from clinical trials. This study aimed to assess the clinical outcomes of immune checkpoint inhibitor (ICI) therapy in HCC patients with other cancer types. **Methods:** We retrospectively analyzed 126 unresectable HCC patients treated with atezolizumab plus bevacizumab (AB) or durvalumab plus tremelimumab (DT) at our institution between September 2020 and February 2025. We extracted the patients who contracted any cancers other than HCCs before and after the initiation of ICI treatment. We compared treatment efficacy and safety profiles between patients with and without coexisting cancers. All the statistical analyses were conducted with R. **Results:** The cohort included 74 patients with BCLC stage C, and 10 with Child-Pugh class B. Thirty five patients (28%) had a history of or concurrent other malignancies, and 28 (22%) had received anti-cancer treatment including surgery, chemotherapy or radiation therapy within 5 years before initiating ICIs. The most frequent coexisting cancer types were lung, genitourinary, gastric, esophageal and colorectal (n = 9, 9, 7, 4 and 3, respectively). Baseline HCC stage and liver function did not significantly differ between those with comorbid cancers and those without. The overall survival and progression-free survival were not significantly different between those with or without comorbid cancers. The objective response rate (evaluated with modified RECIST) was 36% with coexisting cancers vs. 34% without; disease control rate was 63% vs. 73%, respectively. Complex cases included patients with liver metastases from lung cancer under anti-PD-1 therapy and those whose general condition worsened due to oral cancer therapy despite initial remission with AB. Noteworthy cases included dual tumor regression after DT in patients with early-stage lung or gastric cancer and HCC, suggesting cross-cancer immunotherapy effects. In contrast, five patients developed new or progressive comorbid malignancies including lung, colon or gastric origin. One patient with early gastric cancer showed hyperprogressive disease resulting in mortal outcome, despite favorable HCC response. No increased incidence of immune-related adverse events was observed in patients with comorbid malignancies. **Conclusion:** While coexisting malignancies do not significantly affect the overall efficacy or safety of immunotherapy for HCC, individual cancer biology may influence outcomes. Cross-cancer predictive biomarkers are needed to optimize treatment in patients with multiple primary malignancies.

3330 | PERFORMANCE OF A MULTI-TARGET DNA-BASED BLOOD TEST FOR HEPATOCELLULAR CARCINOMA DETECTION IN A PREDOMINANTLY HISPANIC POPULATION IN SOUTH TEXAS

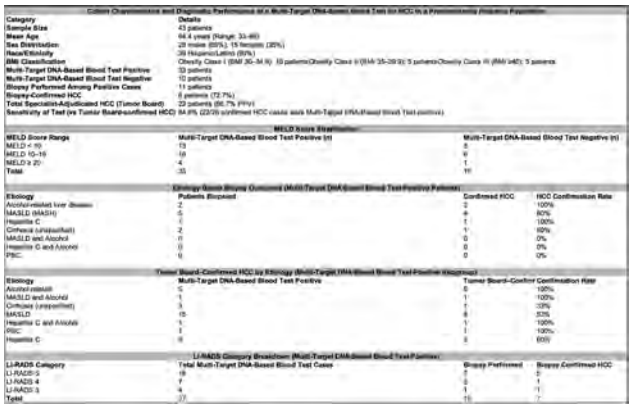
Rishika Trivedi[1] Prince Shah-Riar[2] Sergio Hernandez-Llamas[1] Laura Reyes-Uribe[1] Fernando Membreno[3] Jose Cruz[4], [1]DHR Health, Edinburg, Texas, [2]DHR Health, [3]DHR Health Liver Transplantation, Hepatobiliary Services, Mcallen, Texas, [4]DHR Health Hematology/Oncoloy, Edinburg, Texas

Background: Hepatocellular carcinoma (HCC) disproportionately affects Hispanic populations, particularly in South Texas, where MASH, obesity, and healthcare disparities are prevalent. A novel multi-target blood-based test, combining three methylated DNA markers (HOXA1, TSPYL5, B3GALT6), AFP, and sex in a logistic regression model, has shown promise for early HCC detection. However, prior validation studies lacked Hispanic representation. This study assessed its performance in a real-world, predominantly Hispanic cohort. **Methods:** A retrospective chart review was conducted at a tertiary care center in South Texas from January 2023 to May 2025. All patients who underwent the multi-target blood-based test as part of HCC evaluation were included. Clinical, laboratory, and imaging data, including LI-RADS classification, liver biopsy results, and tumor board adjudications, were extracted from the electronic health record. MELD scores and liver disease etiology were analyzed to assess test performance across clinical strata. **Results:** A total of 43 patients were included in the analysis (mean age 64.4 years; range 33–86), with 65% male and 90% identifying as Hispanic/Latino. Obesity was present in 46.5% of the cohort. Thirty-three patients tested positive using a multi-target DNA-based blood test. Among these, 11 underwent liver biopsy, with 8 cases confirmed as HCC (biopsy-confirmed PPV: 72.7%). An additional 14 were diagnosed by multidisciplinary tumor board review, yielding 22 total confirmed HCC cases (overall PPV: 66.7%; sensitivity: 84.6%). MASH was the most common etiology among test-positive patients. Biopsy-confirmed HCC was observed in 80% of MASH cases, and in 100% of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

those with alcohol-related or hepatitis C associated cirrhosis. Tumor board confirmed HCC was also seen in 100% of patients with alcohol-related, MASH, hepatitis C and alcohol overlap, and PBC-related cirrhosis. Most test-positive patients had MELD scores between 10–19, while those with MELD $\geq$20 were more likely to test negative. Among test-positive cases with available imaging, 16 had LI-RADS 5 lesions, 7 had LI-RADS 4, and 4 had LI-RADS 3. Of the LI-RADS 5 lesions that were biopsied, 5 of 7 were confirmed as HCC (71%). **Conclusion:** These findings demonstrate that the multi-target DNA-based blood test performs well in detecting HCC among a predominantly Hispanic cohort, including those with indeterminate LI-RADS lesions and lower MELD scores. With 84.6% sensitivity and 66.7% PPV by tumor board adjudication, the test shows promise as a noninvasive diagnostic adjunct in real-world settings. Despite the limited sample size, this study reinforces the test's potential role in expanding early HCC detection in underserved, high-risk populations, where traditional surveillance strategies often fall short.



Category	Details
Sample Size	43 patients
Mean Age	64.4 years (Range: 33–86)
Sex Distribution	28 males (65%), 15 females (35%)
Race/Ethnicity	39 Hispanic/Latino (91%)
BMI Classification	Obesity Class I (BMI 30–34.9): 10 patients/Obesity Class II (BMI 35–39.9): 5 patients/Obesity Class III (BMI ≥40): 3 patients
Multi-Target DNA-Based Blood Test Positive	33 patients
Multi-Target DNA-Based Blood Test Negative	10 patients
Biopsy Performed Among Positive Cases	11 patients
Biopsy-Confirmed HCC	8 patients (72.7%)
Total Specialist-Adjudicated HCC (Tumor Board)	22 patients (66.7% PPV)
Sensitivity of Test (vs Tumor Board–confirmed HCC)	84.6% (22/26 confirmed HCC cases were Multi-Target DNA-Based Blood Test positive)

3331 | TYROSINE KINASE INHIBITOR SEQUENCING IN UNRESECTABLE HEPATOCELLULAR CARCINOMA: A REAL-WORLD DUAL-CENTER RETROSPECTIVE ANALYSIS

Khalid Abumelha[1] Belinda Jiao[2] Jamil Asselah[3] Daphnee Lamoussenery[3] Jonathan Cools-Lartigue[4] Rhythm Sharma[5] Kim Ma[6], [1]Department of Medicine, McGill University, Montreal QC, [2]Department of Medical Oncology, McGill University, Montreal QC, [3]Cedars Cancer Center, McGill University Health Center, Montreal QC, [4]Department of Thoracic Surgery, McGill University Health Center, Montreal QC, [5]Lady Davis Institute, Jewish General Hospital, Montreal QC, [6]Segal Cancer Center, Jewish General Hospital, Montreal QC

Background: The treatment landscape of unresectable hepatocellular carcinoma (HCC) has evolved with first-line immunotherapy (IO) combinations, yet most patients progress within 12 months. Tyrosine kinase inhibitors (TKIs) remain foundational, particularly in second- and third-line therapy, though data beyond second line are limited, and access remains restricted in several Canadian provinces. **Methods:** We conducted a retrospective cohort study of 20 patients with unresectable HCC treated at two tertiary care centers (MUHC and JGH) between January 2021 and March 2025. Patients who received $\geq$1 TKI were included. Demographics, ECOG status, presence of cirrhosis, treatment duration per line, and overall survival (from first oncology visit to death or March 1, 2025) were collected. **Results:** The median age at oncology consultation was 66.9 years. Most patients (90%) had an ECOG of 0–1, and half had underlying cirrhosis. The overall median survival was 21.9 months. Survival varied significantly by clinical features: non-cirrhotic patients lived longer than cirrhotic ones (26.2 vs 13.0 months), and patients with ECOG 0–1 outlived those with ECOG 2 (28.9 vs 12.2 months). Access to treatment intensity was a strong prognostic factor—patients receiving three or more lines of therapy had markedly better survival than those receiving two or fewer lines (29.9 vs 4.8 months), highlighting the importance of longitudinal access to systemic therapy.
Median treatment durations were 4.3 months in the first-line setting, 6.1 months in second line, and 1.9 months in third line. The drop in third-line duration likely reflects worsening performance status, treatment-limiting toxicity, or resistant disease biology. Nonetheless, several patients maintained therapy beyond three months in later lines, suggesting continued benefit in selected cases.
Compared to benchmarks from pivotal trials such as IMbrave150 (OS 19.2 months), REFLECT (13.6 months), RESORCE (10.6 months), and CELESTIAL (10.2 months), real-world outcomes in our cohort —particularly among patients with preserved function and access to multiple therapies—were comparable or superior. **Conclusion:** This real-world study reinforces the value of TKIs across treatment lines in unresectable HCC. Outcomes were strongest in patients with ECOG 0–1, no cirrhosis, and access to multiple therapies. While third-line therapy was shorter in duration, it still offered benefit in selected cases. These findings support flexible sequencing strategies and underscore the need for broader TKI access and prospective validation in the IO era.

3332 | USE OF NON-STEROIDAL ANTI-INFLAMMATORY DRUGS, ASPIRIN, IBUPROFEN, AND ACETAMINOPHEN IN RELATION TO BILIARY TRACT CANCERS IN THE BILIARY TRACT CANCERS POOLING PROJECT (BITCAPP)

Ilona Argirion[1] Crystal Najib[2] Katherine McGlynn[3] Peter Campbell[4] Jill Koshiol[3], [1]Georgetown University, [2]University of Maryland, [3]National Cancer Institute, [4]Albert Einstein College of Medicine

Background: Non-steroidal anti-inflammatory drugs (NSAIDs) have been reported to reduce the risk of several cancers, leading to their proposed use as chemopreventive agents; nevertheless, their relationship with biliary tract cancers (BTCs) remains to be fully elucidated. **Methods:** Data from thirteen prospective studies in the Biliary Tract Cancers Pooling Project (BiTCaPP) were harmonized to investigate the association between NSAIDs, aspirin, ibuprofen, acetaminophen and BTCs. Hazard ratios (HR) and 95% confidence intervals (CI) were estimated using Cox proportional hazards regression after adjustment for sex, race, education, smoking, alcohol use, body mass index, and cardiovascular disease. Sensitivity analyses were conducted to assess the role of duration and intensity of use, presence of gallstones, and cholecystectomy on the observed associations. **Results:** During 19,036,644 person-years of follow up, 494 gallbladder cancer (GBC), 339 intrahepatic bile duct cancer (IHBDC), 499 extrahepatic bile duct cancer (EHBDC), and 291 ampulla of Vater cancer (AVC) cases occurred. NSAIDs were inversely associated with IHBDC (HR = 0.57 [95%CI: 0.44-0.73]) and EHBDC (HR = 0.76 [95% CI: 0.62-0.94]); similar results were found for aspirin ($HR_{IHBDC} = 0.58$ [95%CI: 0.45-0.75]; $HR_{EHBDC} = 0.80$ [95%CI: 0.64-0.98]). Ibuprofen use was inversely associated with IHBDC (HR = 0.71 [95%CI: 0.52-0.97]) and AVC (HR = 0.61 [95%CI: 0.43-0.86]). Increasing intensity of NSAID use was associated with decreased EHBDC risk ($p_{trend} = 0.04$), and increased intensity of aspirin use was associated with decreased IHBDC risk ($p_{trend} = 0.02$), while increasing intensity of acetaminophen use was associated with increased IHBDC and EHBDC risk ($p_{trend} = 0.003$ and 0.02, respectively). Results did not vary by cholecystectomy or gallstone status. **Conclusion:** NSAIDs mitigate chronic inflammation and could protect against IHBDC and EHBDC. Conversely, acetaminophen use may increase the risk of IHBDC and EHBDC.

3333 | INFLUENCE OF METABOLIC SYNDROME ON POST-ABLATION OUTCOMES IN EARLY-STAGE HEPATOCELLULAR CARCINOMA

Zahra Mohammadigoldar[1] Pedram Keshavarz[1] David Lu[1] Steven Raman[1] Jihane Benhammou[1] Rajat Singh[1] Vatche Agopian[2] Jason Chiang[1], [1]UCLA, [2]David Geffen School of Medicine at UCLA

Background: Hepatocellular carcinoma (HCC) is the most common cause of primary liver cancer, with increasing incidence noted in Western countries due to concomittent rise in metabolic dysfunction-associated steatohepatitis (MASH) cirrhosis. Thermal ablation has evolved to become standard of care in non-surgical candidates in early-stage HCC. There has been increased interest in characterizing the pro-tumorigenic pathways in HCC with relation to metabolic syndrome (MetS), a cluster of metabolic disorders that includes high BMI, diabetes, dyslipidemia, and elevated blood pressure. These factors have been linked to the development of HCC and potentially contributes to poor outcomes after locoregional therapy. The goal of this study was to evaluate the association between metabolic syndrome and clinical outcomes after thermal ablation - specifically local tumor progression, intrahepatic distant tumor progression, progression free survival, and overall survival. **Methods:** A total of 126 patients with early-stage HCC who were treated with thermal ablation between 2005 and 2022 in this IRB-approved single-institution retrospective cohort study. Patients were divided into two groups based on presence or absence of MetS (n = 65 versus n = 61, respectively). MetS was defined by the presence of at least three of the following criteria adapted from the NCEP ATP III guidelines: BMI >30 kg/m² (used as a surrogate for central obesity), elevated triglycerides (≥ 150 mg/dL or on lipid-lowering therapy), reduced HDL cholesterol (<40 mg/dL in men, <50 mg/dL in women or on therapy), hypertension ($\geq 130/85$ mmHg or on antihypertensives), and fasting glucose ≥ 100 mg/dL or diabetes diagnosis. Progression-free survival (PFS) were compared between the two groups, including local, distant intrahepatic, and overall PFS, as well as overall survival using using Kaplan-Meier curves with log-rank test. **Results:** Local PFS after thermal ablation was decreased in the MetS group compared to the non-MetS group (98 vs 184 months;

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

p = 0.10), although the difference was not found to be significant (Figure 1A). Intrahepatic distant PFS after thermal ablation was significantly reduced in the MetS group compared to non-MetS group (median time: 54 months versus 184 months; p = 0.009) (Figure 1B). Overall PFS rate was significantly reduced in MetS patients (26 versus 68 months; p = 0.01) (Figure 1C). Median overall survival showed a downward trend in the MetS group, (median time 126 vs 184 p = 0.14), although the difference was not significant (Figure 1D). **Conclusion:** Metabolic syndrome significantly correlates with increased recurrence risk, both local and intrahepatic distant among early-stage HCC patients after going standard of care thermal ablation. Interventions that target metabolic syndrome may potentially reduce the risk of progression after thermal ablation and or used as a strategy to keep early-stage HCC patients on the transplant list.

3334 | HYPOXIA-INDUCIBLE FACTOR 1A KNOCKOUT ENHANCES THE ANTITUMOR EFFICACY OF TYROSINE KINASE INHIBITORS IN AN ORTHOTOPIC HEPATOCELLULAR CARCINOMA MOUSE MODEL

Tania Payo-Serafín[1] Jennifer Martínez-Geijo[1] Carolina Méndez Blanco[1] Inés Martínez-Herráez[1] Daira Valencia-Sánchez[1] Beatriz San-Miguel[1] Andrés García-Palomo[2] Juan José Ortiz-de-Urbina[2] Francisco Jorquera[3] José Mauriz[1], [1]1. IBIOMED ULE, [2]1. IBIOMED ULE, 2. CAULE, [3]1. IBIOMED ULE, 2. CAULE, 3. CIBERehd ISCIII

Background: Hepatocellular carcinoma (HCC) is one of the deadliest cancers worldwide, largely due to late-stage diagnosis and limited therapeutic options. A hallmark of HCC is the hypoxic tumor microenvironment, which contributes to resistance to systemic therapies. Hypoxia-inducible factor 1α (HIF-1α) plays a pivotal role in the cellular adaptation to hypoxia, promoting survival and treatment resistance. For this, we investigated the effect of HIF1A knockout (KO) on the efficacy of the tyrosine kinase inhibitors (TKIs) sorafenib and regorafenib in an orthotopic mouse model of HCC. **Methods:** Huh-7 wild-type (WT) and HIF1A KO cells stably expressing luciferase activity were orthotopically injected into the liver of immunodeficient nude mice via ventral mid-laparotomy. Mice were randomized into six groups: WT control, KO control, WT + sorafenib, KO + sorafenib, WT + regorafenib, and KO + regorafenib. After five weeks of tumor development (confirmed via *in vivo* bioluminescence imaging using IVIS SpectrumCT Imaging System), mice received daily oral administration of the corresponding TKI or vehicle for three weeks and were sacrificed at the endpoint for tissue collection and analysis. Tumor progression was assessed by bioluminescence signal (total flux; photons/s), and pathophysiological parameters such as liver tumor burden index (LTBI; tumor-to-liver weight ratio), tumor burden index (TBI; tumor-to-body weight ratio) and hepatosomatic index (HSI; liver-to-body weight ratio) were assessed. **Results:** KO control mice showed a significant reduction in bioluminescence signal compared to WT control, indicating impaired tumor growth in the absence of HIF-1α. In both TKI treatment groups, HIF1A KO further enhanced the antitumor response: KO-treated groups exhibited markedly lower bioluminescence signal, LBTI, TBI and HSI compared to their respective WT-treated groups. **Conclusion:** Overall, our data suggest that HIF-1α plays a crucial role in tumor cell survival under hypoxic conditions in HCC. Its inhibition substantially improved the therapeutic efficacy of sorafenib and regorafenib in an orthotopic mouse model. Targeting hypoxia-driven mechanisms, such as HIF-1α activity, may represent a promising strategy to overcome resistance to TKIs in HCC.

◆ 3335 | ABSENCE OF MIR-122 IN MICE TRIGGERS PATHOLOGICAL REGENERATION AND LIVER FAILURE IN FIBROTIC CONDITIONS

Anna Cardona-Simó[1] Jordi Ribera[2] Irene Portolés[3] Aleix Fabregat Bolufer[4] Pedro Melgar-Lesmes[5] Gregori Casals[6] Wladimiro Jimenez[6] Manuel Morales-Ruiz[6], [1]Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain, [2]Centro de Investigación Biomédica en Red de Enfermedades Hepáticas y Digestivas (CIBERehd), Spain, [3]Centre de Recherche des Cordeliers, Sorbonne Université, INSERM, Université de Paris, France, [4]Biochemistry and Molecular Genetics Department, Hospital Clinic of Barcelona, Spain, [5]University of Barcelona, IDIBAPS, CIBERehd, Spain, [6]Hospital Clinic of Barcelona, IDIBAPS, University of Barcelona, CIBERehd, Spain

Background: miR-122 is the most abundant microRNA in the liver, playing a key role in hepatic physiology. While miR-122 has been extensively studied for its role as a tumor suppressor in hepatocellular carcinoma, its involvement in liver regeneration and in the hepatic fibrotic process remains unexplored. Our previous work showed that miR-122 expression is decreased in liver fibrosis in both patient samples and mouse models, and that its suppression in healthy livers leads to increased regeneration following partial hepatectomy. This study aims to determine whether miR-122 suppression can promote liver regeneration in fibrotic livers. **Methods:** We generated mice with miR-122 gene deficiency by CRISPR/Cas9. Fibrosis was induced by intraperitoneal injection of CCl_4 three times a week for four weeks. We performed partial hepatectomy (PHx) by resection of median and left lateral lobes (n = 20). A proteome analysis was carried out by mass spectrometry (LC-MS/MS). **Results:** At baseline, miR-122 knockout mice treated with CCl_4 (KO-CCl_4) exhibited a threefold increase in collagen fiber content compared to their wild-type CCl_4-treated counterparts. At day 2 post-PHx, KO-CCl_4 mice showed increased Ki67 expression and a trend toward elevated cyclin D1, suggesting increased proliferative activity. Nonetheless, this did not translate into functional regeneration and by day 7 post-PHx, 90% of the KO-CCl_4 mice had died. Proteomic analysis revealed that fibrotic KO livers had exaggerated metabolic activation, with increased protein synthesis and mitochondrial respiration, as a compensatory response to chronic injury. The absence of miR-122 also intensified a persistent inflammation and enhanced hepatic stellate cell activation, resulting in worsened fibrosis. The bioinformatic functional analysis of the proteomic results also showed that KO-CCl_4 mice post-PHx developed a severe inflammatory response marked by a cytokine storm, oxidative stress, extensive hepatocyte apoptosis, microcirculatory collapse, and features consistent with systemic inflammatory response syndrome, ultimately preventing effective regeneration. **Conclusion:** The absence of miR-122 disrupts the regenerative process by exacerbating inflammation, fibrosis and metabolic stress. Although miR-122 suppression transiently enhances hepatocyte proliferation, the resulting imbalance leads to hepatocellular damage and liver failure. These findings highlight the essential role of miR-122 in orchestrating effective regeneration under chronic injury.

◆ 3336 | INHIBITION OF NEUTROPHIL EXTRACELLULAR TRAP FORMATION BY ANTICOAGULATION ATTENUATES LIVER FIBROSIS AND IDENTIFIES CYSTATIN B AS A POTENTIAL TARGET FOR ANTIFIBROTIC THERAPIES

Yingjie Ai[1] Detlef Schuppan[1] Shiyao Chen[2], [1]Johannes Gutenberg University Mainz, [2]Zhongshan Hospital, Fudan University

Background: Neutrophil extracellular traps (NETs) play an important role in the progression of liver fibrosis by sustaining inflammation and activating hepatic stellate cells. Anticoagulants have shown antifibrotic potential in preclinical models, but the underlying mechanisms are incompletely understood. As coagulation factors are known to influence neutrophil activation and NETs release, it is hypothesized that anticoagulation may indirectly suppress NETs formation and thereby attenuate fibrosis. Cystatin B (CSTB) is a cysteine protease inhibitor involved in immune regulation and the control of proteolytic activity during inflammation, but its role in liver fibrosis and relation with NETs remains underexplored. This study aimed to investigate whether anticoagulant therapy mitigates liver fibrosis through modulation of NETs and CSTB to explore the feasibility

of combination therapy. **Methods:** Advanced liver fibrosis was induced in mice via intraperitoneal injection of thioacetamide (TAA, 150 mg/kg), three times per week for 12 weeks. Mice were then randomly divided into a treatment group (the factor X antagonist Edoxaban, Edo) and a control group (Ctr) (each n = 6). Edo was given as a suspension by gavage (30 mg/kg in 0.2 ml) daily for 3 weeks, while controls received the same volume of saline, from week 10-12 of TAA administration. Liver fibrosis was evaluated by collagen morphometry, RT-qPCR and WB. NETs formation and CSTB expression was assessed via RNA sequencing, WB and IHC. **Results:** Masson's trichrome and Sirius Red morphometry demonstrated significantly decreased hepatic collagen deposition in the Edo group. RT-qPCR and WB also showed significant downregulation of fibrosis-related transcripts and proteins including Col1a1, Fn and Acta2 in the Edo group. HE staining of the Edo group showed a significantly reduced neutrophil infiltration and IHC showed lower expression of NETs markers including Myeloperoxidase (MPO) and Neutrophil elastase (NE), and WB showed decreased levels of citrullinated histone H3 (CitH3), another marker of NETs formation, in the Edo vs the control group. Except for down-regulation of fibrogenesis and inflammation related genes, differential gene expression analysis revealed enrichment in the NETs formation pathway. Further correlation analysis of 68 NETs pathway genes identified CSTB to be positively correlated with 67 genes. CSTB was significantly downregulated in the Edo group (logFC = –2.89, p = 0.0016). WB and IHC validated a corresponding reduction at the protein level. **Conclusion:** CSTB is strongly associated with NETs-related gene expression and is significantly suppressed by anticoagulant therapy. Anticoagulation may prominently alleviate liver fibrosis through inhibition of NETs formation, suggesting a previously unrecognized regulatory role. Ongoing work will investigate CSTB's functional contribution to NETs formation and antifibrotic therapy.

◆ 3337 | MACHINE LEARNING IDENTIFIES PROTEO-TRANSCRIPTOMICS MODULES ASSOCIATED WITH FIBROGENESIS IN ADVANCE FIBROSIS IN A JAPANESE MASH COHORT

Ali Ebrahimi[1] Maria Paraskevopoulou[1] Banishree Saha[1] Ruixue Hou[1] Jen-Chieh Chuang[1] Saman Farahmand[1] Zoltan Derdak[1] Vandana Gupta[1] Hiroaki Yashiro[1] Paresh Thakker[1] Bernard Allan[1] Shinichi Aishima[2] Hideyuki Hyogo[3] Yuichiro Eguchi[3] Eisuke Murakami[4] Hirokazu Takahashi[3] Atsushi Nakajima[5] Masato Yoneda[6], [1]Takeda Development Center Americas, Inc., Cambridge, MA, United States, [2]Department of Scientific Pathology, Kyushu University, Japan, [3]Department of Hepatology, Division of Metabolism, Faculty of Medicine, Saga University, Saga, Japan, [4]Department of Gastroenterology and Metabolism, Hiroshima University, Hiroshima, Japan, [5]International University of Health and Welfare Department of Gastroenterology & Hepatology, Japan, [6]Department of Gastroenterology and Hepatology, Yokohama City University, Kanagawa, Japan

Background: Novel non-invasive biomarkers associated with active metabolic-associated steatohepatitis (MASH) and advanced fibrosis remain a huge unmet need. Machine learning (ML)-based multi-omics analysis provides a unique opportunity for biomarker discovery. The study conducts paired tissue/serum proteo-transcriptomic analysis from a Japanese MASH cohort to identify biomarker modules linked to active fibrogenesis in advanced fibrosis. **Methods:** 11K protein Somascan platform and bulk RNA-seq for a serum/tissue paired omics were performed across MAFLD to MASH (F0/F2: N = 78, F3/F4: N = 47) in a large Japanese cohort.

An ML model was applied to predict proteo-transcriptomic modules for advanced fibrosis. Modules were functionally characterized via pathway enrichment, assessed for their liver cellular origin in single-nuclei (Snuc) RNA-Seq, and associated with Nordic biomarkers of fibrogenesis and fibrolysis (Pro-C3/C4/C5/C6, CTX-III, C4M).

Proteomics signatures were cross-validated in a European cohort (LITMUS) to detect conserved and population-specific biomarkers. **Results:** Differential gene/protein analysis identified 338 serum proteins and tissue genes consistently upregulated in advanced fibrosis (F4-F3), including CHI3L1, CLSTN2, ADAMTSL2, MFAP4, ENPP2, and AKR1B10. Pathway analysis highlighted processes linked to extracellular matrix remodeling, immune responses, angiogenesis, glycosylation, and integrin activity.

The ML model identified 7 proteo-transcriptomic modules predicting advanced fibrosis with AUROC > 0.9 in this cohort.

A MASH liver Snuc-Seq dataset revealed hepatocytes and scar-associated non-parenchymal cells as the cellular sources of these biomarkers. Modules were found to be highly correlated with fibrogenesis biomarkers such as Pro-C3, Pro-C4, Pro-C5, and fibrolysis biomarkers (e.g., C4M).

Proteomics findings validated fibrosis-associated proteins from the LITMUS cohort with high correlation (~0.87), while identifying 550 new proteins for advanced

fibrosis. Over 50% of these proteins were regulated in tissue transcriptomics, with 36 being uniquely identified in our ML model. **Conclusion:** This is a first of a kind proteo-transcriptomics study of a Japanese MASH cohort powered by AI/ML that integrates histological features, tissue transcriptomics, and serum proteomics, identifying unique modules that are highly associated with advanced fibrosis and active fibrogenesis. The potential of these as non-invasive biomarkers and therapeutic targets is being actively evaluated.

◆ 3338 | NON-INVASIVE ESTIMATION OF PORTAL PRESSURE USING MACHINE LEARNING: DEVELOPMENT AND VALIDATION IN 670 CIRRHOTIC PATIENTS

Seul Ki Han[1] Moon Young Kim[1] Taesic Lee[1] Myung Jae Seo[1] Eui Young Oh[2], [1]Yonsei wonju severance christian hospital, [2]Yonsei University Wonju College of Medicine

Background: Clinically significant portal hypertension (CSPH), defined as hepatic venous pressure gradient (HVPG) $\geq$10 mmHg, is a key determinant of decompensation and mortality in cirrhosis. However, HVPG measurement remains invasive and is not widely applied in clinical practice. Although non-invasive fibrosis markers such as FIB-4 or transient elastography are widely used, they have limited correlation with portal pressure itself. This study aimed to develop and validate a non-invasive model to estimate portal pressure and predict CSPH using machine learning based on clinical parameters from a large real-world cirrhotic cohort. **Methods:** We retrospectively analyzed 670 patients with liver cirrhosis who underwent HVPG measurement. Clinical and laboratory variables were collected on the day of HVPG. After rigorous data cleaning and outlier exclusion using PCA and Mahalanobis distance, 618 patients were used for model construction. Feature selection was conducted via univariate linear regression and 250×4-fold cross-validation. Seven most predictive features (INR, albumin, platelets, ascites, hemoglobin, spleen size, and sodium) were used to develop HVPG estimation and CSPH prediction models using multivariate regression and logistic regression, respectively. Models were externally validated using independent datasets from another institution. **Results:** HVPG showed significant correlation with CTP and MELD scores. The final HVPG estimation model demonstrated acceptable performance (bias –0.011, RMSE 4.257, PCC 0.579). INR and albumin were the strongest predictors. The CSPH prediction model achieved an AUC of 0.82 in internal validation, with similar results in the external cohort. Model performance improved as more variables were added, and was comparable or superior to conventional prognostic indices. Blood pressure, sex, and alcohol intake also contributed to model performance. The model maintained predictive accuracy for CSPH without including imaging or endoscopic data. **Conclusion:** We present a machine learning–based model to estimate HVPG and predict CSPH using easily accessible clinical parameters. This model offers a non-invasive tool to stratify portal hypertension severity, potentially guiding endoscopic screening and risk-based medical therapy in cirrhosis. Further prospective validation in larger, diverse populations is warranted.

◆ 3339 | FIBROBLASTIC ACTIVITY IS PROGNOSTIC FOR FURTHER DECOMPENSATION AFTER TIPS IN PATIENTS WITH LIVER CIRRHOSIS

Alejandro Mayorca Guiliani[1] Simon Gairing[2] Eva Schleicher[2] Myriam Meineck[2] Michael Pitton[3] Julia Weinmann-Menke[2] Peter Galle[4] Diana Leeming[5] Morten Karsdal[5] Christian Labenz[2], [1]Nordic Bioscience, [2]Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg-University Ma, [3]Department of Radiology, University Medical Center of the Johannes Gutenberg-University Main. Mainz, [4]Department of Internal Medicine I, University Medical Center of the Johannes Gutenberg-University, [5]Nordic Bioscience A/S

Background: Background:: Severe liver disease engages mechanisms regulating immune function, ECM protein synthesis and degradation that result in

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

abnormal ECM formation. Circulating by-products of these mechanisms, or ECM biomarkers, provide information about disease activity and therapeutic efficacy. Here, we hypothesize that ECM biomarkers predict the risk of further decompensation in cirrhotic patients undergoing transjugular intrahepatic portosystemic shunt (TIPS) insertion. **Methods:** Methods:: 63 patients with cirrhosis and TIPS-insertion for refractory ascites or secondary prophylaxis after variceal bleeding were included and followed for 90 days. Serum samples from the right atrium and portal vein were taken during TIPS, then during outpatient visits. We measured white blood cell count, IL-6, IL-8, ammonia, C reactive protein, the propeptide of collagen type III (NordicPRO-C3 ™), the cleavage product of collagen type VI (NordicPRO-C6 ™), Calprotectin-Human Neutrophil Elastase (CPa9-HNE) a marker of neutrophil activation, Citrullinated Vimentin (VICM), a marker of macrophage activity and MMP-cleaved fragments of collagens type III (C3M) and IV (C4M). We clustered patients according to baseline values using silhouette and k-means clustering. Missing values were imputed using multivariate imputation by chained equations. **Results:** Results:: Ascites was the indication for TIPS insertion in 86% of patients. Median MELD was 12. 63% of patients had a further decompensation event within 90 days. Biomarkers in portal and central serum did not differ significantly. We identified 3 clusters (1 = 17 patients, 2 = 28 patients, 3 = 20 patients). 47% of patients in cluster 1 and 57% of patients in cluster 2 had a decompensation event within 90 days, while 90% of patients in cluster 3 did ($p = 0.013$). Cluster 1 was characterized by neutrophil (CPa9-HNE, $p < 0.001$), macrophage activation (VICM $p < 0.001$) and ECM degradation (C4M $p < 0.001$). Cluster 2 had lower ECM biomarkers, whilst cluster 3 had higher fibroblastic activity (PRO-C3 $p < 0.001$ and PRO-C6 $p < 0.001$). After 90 days, 53.8% of cluster 1 patients and 20% of cluster 2 patients transitioned to cluster 3. **Conclusion:** Conclusion:: ECM biomarkers identified inflammatory (cluster 1), quiescent (cluster 2) and pro-fibrotic (cluster 3) endotypes. Pro-fibrotic patients have significantly higher risk of further decompensation. ECM biomarkers show potential to dissect patient heterogeneity during severe liver disease and therapeutic effect, as well as prognosticate post-TIPS decompensation.

◆ 3340 | RAP1A MODULATES LSEC CAPILLARIZATION TO DRIVE HEPATIC FIBROSIS PROGRESSION

Guangwen Chen[1] Junjun Wang[1] Weiming Dai[2] Zhenyang Shen[1] Jianxiang Wang[1] Zhuqiong Lu[1] Hanjing Zhangdi[1] Yuecheng Guo[1] Qingqing Zhang[1] Qichao Ge[1] Yufei Yang[1] Lungen Lu[1] Hui Dong[1] Xiaobo Cai[1], [1]Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, [2]Peking University People's Hospital

Background: Liver sinusoidal endothelial cell (LSEC) capillarization has been demonstrated to exacerbate the progression of hepatic fibrosis. This study reveals the role of *Rap1a* in LSEC capillarization and hepatic fibrosis, uncovering mechanisms driving endothelial phenotypic switching. **Methods:** RAP1A expression was assessed in chronic liver samples from mice by immunofluorescence (IF). Single-cell RNA sequencing (scRNA-seq) data from GEO were analyzed via KEGG/GO enrichment. Scanning electron microscopy (SEM) was used to evaluate the fenestrae of LSEC in vitro and vivo. EC-specific *Rap1a* deficiency knockout mice ($Rap1a^{\Delta EC}$) was generated by breeding $Rap1a^{fl/fl}$ with the Cdh5-Cre mice. Histology, western blot (WB), immunohistochemistry (IHC), and RT-qPCR were used to assess the severity of capillarization and fibrosis in CCl4-induced hepatic fibrosis models. The RAP1A activity agonist 8-CPT-2ME-cAMP was administered at graded concentrations and evaluated its effects on LSEC capillarization and fibrosis progression in CCl_4-induced hepatic fibrosis models. **Results:** KEGG/GO analyses identified significant Rap1 signaling pathway enrichment in LSEC from metabolic dysfunction-associated steatohepatitis (MASH) mice compared to controls. RAP1A was primarily expressed in LSEC and its expression was downregulated during chronic liver injury. EC-specific *Rap1a* deficiency significantly decreased the fenestrae of LSEC in vitro and vivo and aggravated hepatic fibrosis. RNA-seq shows upregulation of Notch signaling in *Rap1a*-deficient LSEC. Mechanistically, RAF1 interacted with both RAP1A and Notch intracellular domain (NICD). The absence of RAP1A reduced RAF1 levels, impaired the formation of RAF1-NICD complex and enhanced NICD nuclear translocation to activate Notch signaling. Restoration of RAP1A activity attenuated capillarization and fibrosis in the CCl_4 model. **Conclusion:** *Rap1a* deficiency in LSECs promotes NICD nuclear translocation via the RAP1A -RAF1-NICD axis, activating the Notch signaling pathway and exacerbating capillarization with subsequent fibrosis. Restoration of RAP1A activity ameliorates both capillarization and hepatic fibrosis progression. These findings highlight *Rap1a* as a therapeutic target for attenuating LSEC-driven fibrosis.

◆ 3341 | SINGLE CELL FIXED RNA-SEQUENCING ANALYSIS REVEALED HSCS^{LMCD1+} IS A DRIVER OF LIVER FIBROSIS BY MODULATING AKT-PRAS40-4EBP1

Thi Thanh Thuy Le[1] Duc Pham[1] Hoang Hai[1] Tuan Anh Pham[1] Thi Ha Nguyen[1] Norifumi Kawada[1], [1]Osaka Metropolitan University

Background: Background and Aims: Single Cell Fixed RNA Profiling (FLEX) is a novel technology that captures RNA expression in single cells from frozen tissues. Herein, we applied FLEX in the murine model of cirrhosis progression and regression to discover novel targets for anti-fibrotic therapy. **Methods:** Methods: Thioacetamide (TAA) was administered intraperitoneally to mice at escalating doses ranging from 50 to 400 mg/kg over a 10-week period to induce liver fibrosis, while control mice received saline. Regression of liver fibrosis was assessed two weeks after TAA cessation. Frozen liver tissues from both mice and human samples were fixed, dissociated into single cells, and analyzed via single-cell RNA sequencing (scRNA-seq) following the 10X Genomics protocol. Multiplex flow cytometry, immunoblotting, immunohistochemistry, proteome cytokine array, and pharmacological inhibitors were used for molecular analysis. **Results:** Results:: Using FLEX technology, whole liver cells were preserved and analyzed at single cell resolution and classified into 10 major cell types under the transcriptome of 38,136 cells. Disease progression showed expansion of inflammatory and fibrogenic populations (macrophages, cholangiocytes, HSCs), while regression restored hepatocytes and LSECs. We identified 9 disctint HSCs subclusters with distinct signature genes and enrichment pathways in healthy control, fibrosis progression and regression. Notably, LIM-domain-related genes, including LIMA1, LIMK2, PDLIM2, PDLIM5, PDLIM7, FHL2, FHL3, and LMCD1, were significantly upregulated in cirrhotic HSCs from both mouse and human samples but were downregulated during fibrosis regression. Functional studies demonstrated that silencing LMCD1 attenuated HSC activation, whereas overexpression of LMCD1 strongly enhanced HSC activation via the AKT-PRAS40-4EBP1 pathway. Specific pathways inhibition using AZD8055 mitigated HSCs activation, both spontaneously and under TGF-β stimulation, and significantly reduced the phosphorylation of 16/39 proteins implicated in HSC activation, including CREB, c-JUN, TP53, WNK1, GSK3B, ERK1/2, P70S6K, and RSK1/2/3. Interestingly, treatment of AZD8055 attenuated TAA-induced liver fibrosis. LMCD1 highly expressed in fibrotic region and strongly correlated with fibrosis severity, with an area under the receiver operating characteristic (AUROC) curve of 0.92 (95% CI: 0.76–1; $p = 0.006$) for predicting MASLD-related fibrosis. **Conclusion:** Our single-cell transcriptomic atlas reveals the cellular and molecular reprogramming underpinning fibrosis progression and regression in the liver. HSC subclustering revealed novel activation marker LMCD1, upregulated during fibrosis and reduced in regression via LMCD1-AKT-PRAS40-4EBP1 axis. These findings provide a foundation for the development of targeted therapies aimed at mitigating liver fibrosis and its progression.

◆ 3342 | CONTINUOUS DIGITAL PATHOLOGY SCORING REVEALS FIBROSIS REVERSAL AND TREATMENT BENEFIT OF LANIFIBRANOR: INSIGHTS FROM A PRECLINICAL RODENT MODEL.

Guillaume Wettstein[1] reethika Chokkakula[2] Mathieu Petitjean[2] Arun Sanyal[3] Scott Friedman[4] Michael Cooreman[1] Pierre Broqua[1], [1]Inventiva, [2]PHARMANEST, [3]Virginia Commonwealth University, [4]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Lanifibranor is a pan-PPAR agonist targeting PPARα, PPARδ, and PPARγ—nuclear receptors that regulate metabolism, inflammation, and fibrosis. Its antifibrotic effects have been established in preclinical fibrosis models using conventional histological and biochemical assays and in the NATIVE Phase 2b trial (NCT03008070) using the NASH CRN histological grading and staging. Here, we apply FibroNest™, a high-resolution single-fiber digital pathology platform, to extract continuous phenotypic biomarkers and gain deeper insight into lanifibranor's treatment potential. **Methods:** The study used a therapeutic design in a CCl-induced mouse fibrosis model (N = 48) with escalating doses of lanifibranor (Table 1). Mouse liver were harvested and sections were stained with Picrosirius Red (PSR), scanned at 40X and assessed using three modalities: (1) hydroxyproline content (µg/mg wet liver), (2) conventional image analysis to determine PSR area %, and (3) the FibroNest™ platform, which provides high-resolution, continuous, phenotypic scores of fibrosis severity (Ph-FCS [1–10]) and ~100 quantitative histological features (qFT) as described in DOI: 10.1126/scitranslmed.add3949. **Results:** Ph-FCS tracked fibrosis progression and treatment response with greater sensitivity and precision than conventional assays, as evidenced by means, standard deviations, and with a high degree of statistical significance p-values (Tables 1–2) in the CCL4 study. Ph-FCS detected significant differences in fibrosis severity between weeks 3 and 6 of fibrosis induction, illustrating sensitivity to changes in fibrosis architecture beyond mere just collagen content. Ph-FCS showed significant fibrosis reduction at both 10 and 30 mg/kg lanifibranor doses. In contrast, hydroxyproline content and PSR area % detected significant effects only at 30 mg/kg, with 10 mg/kg showing a non-significant trend. qFT that most describe the progression and regression of fibrosis and individually assessed to provide insights to mechanism of action. **Conclusion:** Lanifibranor demonstrated antifibrotic activity in preclinical therapeutic models. High-resolution single-fiber digital pathology (Ph-FCS) offers a more sensitive and continuous assessment of fibrosis regression than traditional methods. These findings support Ph-FCS as a translational biomarker and further support lanifibranor's efficacy as an antifibrotic agent.

◆ 3343 | REGULATION OF COL1A1 BY BRD4 CONDENSATES IN HEPATIC STELLATE CELLS

Luke Doskey[1] Dawood Al Dawood[1] Maria Hernandez-Tejero[1] Sofia Jerez[2] Sheng Cao[3] Vijay Shah[3], [1]Mayo Clinic, [2]Mayol Clinic, [3]Mayo Clinic Rochester

Background: Liver fibrosis is progressive condition that may lead to cirrhosis, which presents excessive extracellular matrix and the dysregulation of collagen (COL) deposition and turnover. Hepatic stellate cells (HSCs) are the major depositors of COL in response to TGFβ, a key fibrosis regulator. Transcriptional condensates are phase separations of transcriptional machinery and nucleic acids, that create favorable biochemical environments to regulate gene transcription. The increased COL expression in fibrosis resembles the expression of genes regulated by transcriptional condensates. However, their role in liver disease is unknown. Thus, we aim to analyze the role of transcriptional condensates in pathological COL expression in liver fibrosis. **Methods:** Publicly available chromatin immunoprecipitation-sequencing data were mined to determine histone modifications and transcriptional regulator occupancy near the COL1A1 gene using Integrated Genomics Viewer and computeMatrix. Immortalized HSCSs (LX-2) were treated with I-BET151, a bromo and extra-terminal (BET) family of transcriptional regulators inhibitor before stimulation with TGFβ. COL1A1 expression was assessed using qPCR. BRD4 condensate dynamics were measured by fluorescence recovery after photobleaching (FRAP) in LX-2 cells expressing GFP-tagged BRD4. BRD4 condensate formation was analyzed by immunofluorescence imaging employing super-resolution microscopy. **Results:** Data mining showed that in response to TGFβ treatment, the COL1A1 locus is significantly modified by H3K27AC and occupied by the BET protein BRD4. This suggests the presence of super enhancers, which are clusters of positive gene regulatory elements that control the expression of multiple genes and recruit condensate-forming transcriptional regulators (e.g. BRD4). This observation implies condensate regulate *COL1A1* expression. TGFβ stimulation induced the formation of BRD4 condensates and concurrently increased the *COL1A1* expression 4.8-fold in LX-2 cells, which was decreased by 92% with BET inhibition. This demonstrates that COL1A1 expression is regulated by BRD4. FRAP further showed active diffusion of GFP-BRD4 into condensates in LX2 cells (79% recovery in 338 seconds). **Conclusion:** These findings propose a novel model of pathological COL expression, whereby BRD4 transcriptional condensates are formed in response to TGFβ stimulation to modulate the expression of pathological *COL1A1.* Thus, specific condensate targeting may be a therapeutic approach for treating liver fibrosis.

◆ 3344 | A NOVEL PROTEOMICS STRATEGY TO IDENTIFY NATURAL SUBSTRATES OF AMINOPEPTIDASES IN HUMAN CIRRHOSIS

Yiqun Qu[1] Mujia Li[2] Badwi Boumelhem[1] Miguel Cosenza-Contreras[2] Nelanka Halgamuge[3] Fiona Guan[4] Chuanmin Wang[4] Avik Majumdar[5] William Bachovchin[6] Jack Lai[6] Geoffrey McCaughan[4] Ken Liu[4] Oliver Schilling[2] Mark Gorrell[7], [1]Centenary Institute, [2]University of Freiburg, [3]University of Sydney, [4]Royal Prince Alfred Hospital, [5]Austin Health, [6]Tufts University, [7]The Centenary Institute, The University of Sydney, Sydney, Australia

Background: Fibroblast activation protein (FAP) and the similar aminopeptidase DPP4 are upregulated in cirrhosis, with myofibroblasts making FAP while DPP4 is ubiquitous. We report a novel approach to identify extracellular proteins that are digested by FAP/DPP4 in injured liver. **Methods:** Fibroblast activation protein (FAP) and the similar aminopeptidase DPP4 are upregulated in cirrhosis, with myofibroblasts making FAP while DPP4 is ubiquitous. We report a novel approach to identify extracellular proteins that are digested by FAP/DPP4 in injured liver.

Methods

Suspensions of fresh human liver cells from cirrhotic explants were incubated up to 72 h in supplemented William's E medium (Figure). Portions of each mixed liver cell culture were incubated with a selective inhibitor of either FAP or DPP4 for the final 24 hours before collecting cell culture supernatant (CCM). N-termini of peptides in CCM were labelled by Tandem Mass Tag (TMT) and then analyzed by high-resolution liquid chromatography–tandem mass spectrometry (LC-MS/MS; Q-Exactive Orbitrap) using data-dependent acquisition (DDA) and FragPipe, then statistically analyzed in RStudio to derive a proteome and DPP4- and FAP-degraded degradomes. **Results:** The cultivated liver cells were about 40-50% fibroblasts (FAP+SMA+), 40% hepatocytes (albumin+) and 10% macrophages (CD68+). The 23 CCM were subdivided into 4 groupings of etiologies (biliary, metabolic, viral and alcoholic). The CCM proteome contained 2,008-4,164 identifiable proteins of which 11-42 were differentially abundant after exposure to FAP inhibitor. In FAP degradomics,

3,231-7,256 TMT-labelled peptides were identified and 42 neo-N-termini derived from 18 human proteins were cleaved post-proline, which is the preferred site of hydrolysis by FAP. Proteins associated with matrix, TGF-beta, MMPs and innate immunity were prominent in both proteomics and degradomics datasets. Degradome analyses are ongoing. Novel N-termini, indicating potential aminopeptidase substrates, included known substrates and proteins associated with fibrosis, metabolism, inflammation, cell proliferation and matrix remodelling that were not previously known to be FAP substrates. **Conclusion:** This study aligns with our previous FAP degradomics[1] and is expanding the knowledge of the human liver proteome, and suggests roles of DPP4 and FAP in fibrosis and metabolism.

3345 | FIBROSIS MICROENVIRONMENT AFTER HBSAG CLEARANCE IS ASSOCIATED WITH HCC RECURRENCE IN HBV PATIENTS.

Michitaka Matsuda[1] Shinji Kondo[2] Tatsuya Kanto[1], [1]JIHS, National Institute for Global Health and Medicine, [2]JIHS, National Institute of Global Health and Medicine

Background: Hepatocellular carcinoma (HCC) pathogenesis is regulated by the microenvironment of the background fibrotic liver. We used spatial and single-cell transcriptome analysis for resolving the cellular microenvironment associated with HCC recurrence in patients with chronic HBV infection. **Methods:** We used surgically resected HCC specimens from the patients with chronic hepatitis B. For the GeoMx spatial transcriptome, liver tissue sections containing HCC and adjacent liver tissue were prepared. HBsAg and HBV-DNA were histologically detected by immunofluorescent staining and in situ hybridization. Under microscopy, ROIs were selectedfrom mild and advanced fibrosis areas based on the morphological information obtained by collagen staining. Each ROI was further divided into fibrosis and parenchymal areas by type1 collagen staining positivity, and area-specific transcriptomes were acquired using the masking method. Finally, HbsAg+/- early and advanced fibrosis transcriptomes were obtained and comparatively analyzed. Single-cell RNA sequencing (scRNA-seq) from the matched patients was used for spatial deconvolution analysis. HCC recurrence risk genes were defined from the liver transcriptome data of HBV patients. **Results:** Spatial deconvolution revealed that the fibrosis area consists of immune, vascular, and mesenchymal populations, while parenchyma dominantly consists of hepatocytes. Amongst early fibrosis, HBV-DNA was located in the cytosol at the HBsAg-positive area but not the HBsAg-negative area, indicating active viral replication at the HBsAg-positive area. Spatial deconvolution anlysis revealed that HBsAg-positive area has more macrophage and gdT than the HBsAg-negative area, suggesting an active innate response to the infected cells. Advanced fibrosis enriches more activated HSCs and lymphocytes, including immunosuppressive T cells, than early fibrosis. HBsAg was sparsely observed near the advanced fibrosis, suggesting fibrosis develops with HBsAg disappearance. Interestingly, HBV-DNA was located in hepatocyte nuclei at HBsAg-sparse area, suggesting cccDNA of HBV at the site. The recurrence risk gene signature was enriched at the HBsAg-sparse area surrounded by bridging firbosis, suggesting HBsAg clearance is associated with developing a precancerous microenvironment. **Conclusion:** Depending on the HBV infection status, the fibrosis microenvironment is heterogeneous across the tissue. Immunosuppressive microenvironment after HBsAg clearance was associated with early recurrence of HCC after surgical resection in chronic HBV patients.

Jiang[3], [1]Beth Israel Deaconess Medical Center/ Harvard Medical School, [2]Beth Israel Deaconess Medical Centra/Harvard Medical School, [3]Beth Israel Deaconess Medical Center/Harvard Medical School, [4]Beth Isreal Deaconess Medical Center/Harvard Medical School, [5]Beth Israel Deaconess Medical Center

Background: Precision Cut Liver Slice (PCLS) is a human tissue-derived 3D culture that preserves native liver microarchitecture and all resident cell types. As an ex vivo model, PCLS offers a promising alternative to animal studies, aligning with the recent NIH and FDA initiatives to reduce animal use. Through iterative refinement, we have extended PCLS viability in culture to 14 days. However, the cellular viability, function, and dynamic changes over time remain incompletely characterized. **Methods:** We procured liver tissue from healthy and diseased patients enrolled in the End-Stage Liver Disease Patient Registry and developed a protocol to generate PCLS capable of sustained culture for 14 days. We evaluated structural and functional changes through serial histology, gene expression profiling, whole-tissue viability assay, extracellular matrix (ECM) staining, and metabolic analysis using Seahorse assay. **Results:** PCLS from both normal and diseased liver maintained largely intact morphology throughout the 14-day culture period. Immunohistochemistry confirmed the preservation of all liver parenchymal and nonparenchymal liver cells. An innovative whole tissue imaging using live/dead differential staining showed $>85\%$ of viability at day 7 and $>65\%$ at day 14, with cell death initiating preferentially at the tissue periphery (Fig 1). Serial histological analysis revealed progressive portal fibrosis in normal liver derived PCLS, reaching bridging fibrosis by day 7, indicating active mesenchymal cell remodeling. Reticulin staining confirmed the integrity of lobular ECM throughout culture. Notably, focal hepatocellular regeneration is present, leading to the formation of nascent hepatocyte clusters, emerging after day 7. Finally, functional Seahorse assays corroborated the vitality of PCLS with robust oxygen consumption measured at days 3, 6 and 9 in both healthy and cirrhotic PCLS, supporting sustained metabolic activity. **Conclusion:** Using a refined protocol, we demonstrate that PCLS from both healthy and cirrhotic livers remain viable for up to 14 days, exhibiting dynamic, reproducible changes that reflect the inherent plasticity of liver tissue in an ex vivo environment. This platform offers a robust model for studying human liver biology and diseases outside the body.

3347 | COMBINING DIGITAL PATHOLOGY AND BIOMARKERS OFFER A TRANSLATIONAL FRAMEWORK TO QUANTIFY FIBROSIS AND LANIFIBRANOR TREATMENT RESPONSE IN A TAA-INDUCED CIRRHOSIS MODEL.

reethika Chokkakula[1] Guillaume Wettstein[2] Mathieu Petitjean[1] Arun Sanyal[3] Scott Friedman[4] Michael Cooreman[2] Pierre Broqua[2], [1]PHARMANEST, [2]Inventiva, [3]Virginia Commonwealth University, [4]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Lanifibranor is a pan-PPAR agonist regulating metabolism, inflammation, and fibrosis. Its antifibrotic activity has been demonstrated in patients with noncirrhotic MASH in the NATIVE Phase 2b trial (NCT03008070). While Biomarkers are increasingly favored over histology in clinical settings, they may not fully capture tissue-level responses. We explored the benefits of combining Biomarkers with digital histological biomarkers to construct a holistic metric of lanifibranor treatment response in a TAA-induced rodent cirrhosis model. **Methods:** Rats (N = 33) received TAA for 12 weeks to induce cirrhosis, followed by a 4-day washout and 2-week treatment with vehicle (n = 12) or lanifibranor 100 mg/kg (n = 13). Nineteen biomarkers (BM) were measured using immunohistochemistry (IHC), western blot, and qPCR to capture fibrosis biology, hepatic stellate cell activity, and liver tests (AST, ALT, albumin). Livers were stained with Picrosirius Red and H&E, scanned at 40X, and analyzed using the FibroNest platform to generate continuous phenotypic fibrosis scores (Ph-FCS, 1–10), fiber morphometry scores (fine, assembled, all fibers), collagen remodeling scores, and fibrosis architecture. Spearman correlation coefficients (ρ) were measured for these 25 continuous biomarkers. The FibroNest scores and BMs that exhibited most correlation (top 2) were normalized and assembled into an equi-weighed score (NEST(TAA)) whose performance is compared to the Ph-FCS alone. **Results:** Spearman correlations coefficient (r) ranged from -0.0266 to 0.788 (Panel A). Highest correlations were found for a-SMA % area (IHC), and col1a1 mRNA (qPCR). Each biomarker performance is compared by means, standard deviations, and p-values (Tables 1-2). BMs were more sensitive to spontaneous changes during the washout, which influenced the NEST score, integrating with tissue, protein, and gene expression data. Independently from these effects, the mean change from baseline (Lani100mpk vs Vehicle) of the Ph-FCS and the NEST(TAA) were the same (-1.98; -1.94, Panel B-C)) and superior to col1a1 and s-SMA% changes alone (-0.49; -2.22). **Conclusion:** Continuous quantitative digital pathology biomarkers can be integrated with complementary molecular or functional biomarkers to provide a multifaceted view of treatment response. While this study demonstrates feasibility, further validation is needed. Differences in response kinetics and biological variability may affect the sensitivity of each modality.

Table 1: Study Biomarkers Analytical performance

		Ph-FCS		col1a1 mRNA(qPCR)		a-SMA% Positive Area (IHC)		NEST(TAA)

3348 | HIGH-RESOLUTION DIGITAL PATHOLOGY DEMONSTRATES ANTIFIBROTIC AND ANTI-INFLAMMATORY EFFECTS OF LANIFIBRANOR IN THERAPEUTIC INTERVENTIONS USING TAA-INDUCED CIRRHOTIC RODENT MODELS.

Guillaume Wettstein[1] reethika Chokkakula[2] Louis Petitjean[2] Arun Sanyal[3] Scott Friedman[4] Michael Cooreman[1] Pierre Broqua[1], [1]Inventiva, [2]Pharmanest, [3]Virginia Commonwealth University, [4]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Histological staging in MASH is semi-quantitative categorical and limited by observer variability. To address this limitation continuous digital pathology biomarkers were applied to assess the antifibrotic and anti-inflammatory effects of lanifibranor, a pan-PPAR agonist (PPARα, δ, γ), in a therapeutic rat model of advanced liver cirrhosis due to thioacetamide (TAA). **Methods:** TAA-induced cirrhosis was established over 12 weeks in rats (N = 33), followed by a 4-day washout and 2-week treatment with either vehicle (n = 12) or lanifibranor 100 mg/kg (n = 13). Liver tissues were stained with Picrosirius Red (PSR) and H&E, scanned at 40X, and analyzed by: (1) conventional PSR % image quantification; (2) FibroNest™ platform for high-resolution phenotypic fibrosis scores (Ph-FCS, scale 1–10) and ~100 histological features (qFTs); and (3) quantitative tissue panels measuring healthy hepatocytes, immune and specialized cells via burden (count/mm²) and proportion (% of total cells), based on published methods (DOI: 10.1126/scitranslmed.add3949; 10.3390/ijms24108494). **Results:** Ph-FCS showed greater sensitivity than PSR% in tracking fibrosis severity and treatment response, with lower susceptibility to spontaneous regression during washout (Panels A,B). At 100 mg/kg, vehicle-corrected Ph-FCS showed significant fibrosis reduction (−41.8%, Panel D). The AI classifier used for feature extraction achieved 85–89% accuracy against > 15k annotated cells. Cell burden and percentage ratios are only marginally affected (panels C and E). Notably, the digital layering of fibrosis and inflammation (panels F–G) enabled the identification of faint, low-stoichiometry fibers associated with inflammatory foci, as well as distinct “hot” zones (areas of high immune- cells burden with partially established fibrosis) and “cold” zones (regions of low immune cells burden with established fibrosis). These spatial features add meaningful context to the interpretation of therapeutic effects. **Conclusion:** Lanifibranor showed strong antifibrotic and anti-inflammatory activity in a therapeutic cirrhosis model. Digital pathology biomarkers, including Ph-FCS and cellular panels, provided continuous, high-resolution metrics that outperform traditional readouts. These findings position digital pathology as a powerful translational tool to quantify therapeutic response and advance antifibrotic drug development.

3349 | LABORATORY AND ELASTOGRAPHY CHARACTERISTICS OF AT-RISK CLINICALLY SIGNIFICANT PORTAL HYPERTENSION (CSPH) IN THE UNITED STATES

Ritik Mahaveer Goyal[1] Apoorva Doshi[2] Sameer Rao[3] Komal Arora[4] Muhammed Maan[3] Paul Gaglio[3], [1]Rutgers New Jersey Medical School, [2]University of Alabama at Birmingham, [3]Rutgers NJMS, [4]NYMC/St Clare & St Mary's Hospital

Background: Clinically significant portal hypertension (CSPH) marks a critical transition in the course of chronic liver disease. Per Baveno VII criteria, CSPH can be reliably ruled out in individuals with liver stiffness measurement (LSM) <15 kPa and platelet count >150,000/μL. However, patients with compensated advanced chronic liver disease (cACLD) who fall outside these parameters are considered at increased risk and warrant further evaluation. This study aimed to describe the laboratory and elastographic profiles of individuals at risk for CSPH using a nationally representative U.S. sample. **Methods:** We utilized data from adults who underwent complete transient elastography (TE) as part of the National Health and Nutrition Examination Survey (NHANES) between 2017 and March 2020. Based on Baveno VII criteria, participants were categorized into two groups: "rule-out CSPH" (LSM <15 kPa and platelet count >150,000/μL) and "at-risk CSPH" (LSM ≥15 kPa or LSM <15 kPa with platelets <150,000/μL). Categorical and continuous variables were compared using chi-square and ANOVA tests, respectively. **Results:** Among 7,847 adults with complete TE data, 7,479 (95.3%) were classified as rule-out CSPH, while 368 (4.7%) were considered at-risk CSPH. Compared to the rule-out group, the at-risk CSPH group had significantly lower mean levels of total cholesterol (179.6 vs. 187.1 mg/dL, $p<0.05$), LDL (100.1 vs. 109.9 mg/dL, $p<0.05$), and HDL (50.7 vs. 53.7 mg/dL, $p<0.05$). No significant difference was noted in triglyceride levels ($p=0.83$). The at-risk group had significantly lower platelet counts (169.9 vs. 251.8 $\times10^3$/μL, $p<0.001$), higher ALT (29.97 vs. 22.38 IU/L, $p<0.001$), AST (30.02 vs. 21.39 IU/L, $p<0.001$), ALP (79.5 vs. 75.0 IU/L, $p<0.05$), and total bilirubin levels (0.56 vs. 0.47 mg/dL, $p<0.001$). Serum creatinine was higher (0.97 vs. 0.87 mg/dL, $p<0.05$), though serum sodium levels were not significantly different. CAP scores were elevated (294.6 vs. 261.7 dB/m, $p<0.001$), and mean LSM was significantly higher (15.98 vs. 5.26 kPa, $p<0.001$) in the at-risk group. **Conclusion:** Individuals at risk for CSPH demonstrated distinct biochemical and elastographic abnormalities, including elevated liver enzymes, higher CAP and LSM values, and significantly lower platelet counts. These findings support the need for closer monitoring and potential early intervention in this subgroup, many of whom may be undiagnosed or under-recognized in clinical practice.

Table: Laboratory and Elastography characteristics of patients with CSPH ruled out and at-risk CSPH

Laboratory Values	LSM<15kPa and Platelet count >150,000/uL (CSPH ruled out) (N=7,479)	LSM>15kPa and LSM < 15kPa + Platelet count ≤150,000/uL (at-risk CSPH) (N=368)	p-value
Total Cholesterol (±SE) (in mg/dL)	187.12(±1.13)	179.64 (±3.38)	<0.05
LDL (±SE) (in mg/dL)	109.85 (±1.03)	100.1 (±4.1)	<0.05
HDL (±SE) (in mg/dL)	53.75 (±0.43)	50.73 (±0.87)	<.05
TG (±SE) (in mg/dL)	109.86 (±2.64)	111.34 (±6.71)	0.83
Hemoglobin (±SE) (in g/dL)	14.22 (±0.05)	14.31 (±0.12)	0.45
Platelet Count (±SE) (x 1000/uL)	251.76 (±1.64)	169.92 (±3.91)	<.001
Serum ALT (±SE) (in IU/L)	22.38 (±0.3)	29.97 (±1.55)	<.001
Serum AST (±SE) (in IU/L)	21.39 (±0.2)	30.02 (±1.59)	<.001
Serum ALP (±SE) (in IU/L)	75.07 (±0.51)	79.51 (±1.22)	<.05
Serum Total Bilirubin(±SE) (in mg/dL)	0.47(±0.01)	0.56 (±0.02)	<.001
Serum Sodium(±SE) (in mmol/dL)	140.5(±0.3)	140.21 (±0.27)	0.13
Serum Creatinine (±SE) (in mg/dL)	0.87 (±0.01)	0.97 (±0.02)	<.05
CAP (±SE)	261.67 (± 1.4)	294.69 (±5.7)	<.001
LSM (±SE)	5.26 (± 0.05)	15.98 (±1.18)	<.001

Background: Fibroblast growth factor 21 (FGF-21) is a hepatokine with pleotropic biological effects and strong evidence for anti-fibrotic effects in clinical trials of subjects with MASH with F2-F3 and F4 fibrosis. FGF-21 agonism is likely having anti-fibrotic effects due to metabolic effects on hepatocytes, but direct anti-fibrotic effects of FGF-21 on primary human HSC in the context of MASH have not been established. Our goal was to test if FGF-21 agonism can directly block activation of primary human HSC in a MASH relevant model. **Methods:** We used a primary human hepatocyte and HSC sandwich culture in which the hepatocytes were plated on to collagen coated cover slips (20mm) in 12 well culture plates, treated with palmitate (200uM) for 16hrs to induce steatosis. Fresh primary HSC in collagen (0.01% in DMEM pH 7.4) suspension were layered on top and allowed to set for 2 hrs. The co-culture sandwich was treated with human FGF-21 (hFGF-21) at 400ng/ml. Post 24hrs, HSC activation in co-culture was examined by immuno-staining for a-SMA. To ascertain the specificity of the FGF-21 effect, the HSC were knocked down for the co-receptor β-klotho which is essential for FGF signaling (24 hrs). Knockdown was achieved by KLB silencer select siRNA for 24 hrs and confirmed by qPCR. The knocked down HSC in collagen suspension were then layered onto hepatocytes in collagen sandwich with prior palmitate (200uM) exposure. Following 24 hrs in co-culture the coverslips were immuno-stained for a-SMA. **Results:** Exposure of hepatocytes to palmitate resulted in activation of primary human HSC in co-culture, and this was significantly reduced by treatment with hFGF-21 (5 fold decrease; ****$P < 0.0001$) (Fig 1A). Knockdown on of β-klotho on HSC alone prior to co-culture resulted in a loss of the ability of FGF-21 to block HSC activation in co-culture with steatotic hepatocytes. **Conclusion:** hFGF-21 can block activation of primary human HSC stimulated by steatotic hepatocytes in a FGF – β-klotho receptor dependent manner. This provides experimental support for the premise that FGF-21 has a direct anti-fibrotic effect on human HSC, and supports the strong anti-fibrotic effects seen in MASH clinical trials.

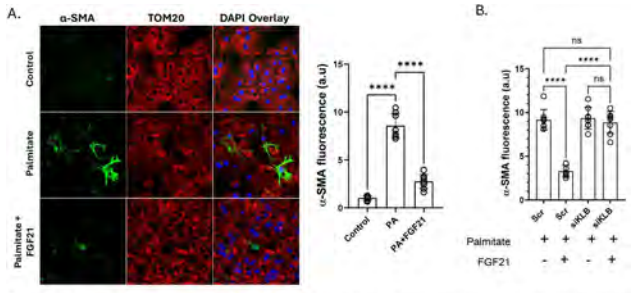

Figure 1. A. Primary human hepatocyte – HSC collagen sandwich culture, subjected to palmitate (200μM) with or without FGF21 (400ng/ml) for 24 hrs and immunostained for α-SMA and TOM20 (N=3) (****P<0.001) **B.** Quantification of α-SMA in the hepatocyte-HSC coculture in which the HSC are either siRNA knocked down for β-klotho (siKLB) or scramble (Scr) control and exposed to palmitate (200μM) with or without FGF21 (400ng/ml) for 24 hrs and immunostained for α-SMA and TOM20 (N=3) (****P<0.001).

3351 | THE DEUBIQUITINASE MYSM1 STABILIZES GSN TO EXACERBATE LIVER FIBROSIS BY INHIBITING HEPATOCYTE AUTOPHAGY

Han Ding[1] Le Wang[1] Songbo Zhao[1] Wanhua Ren[1] Qiang Zhu[1], [1]Shandong Provincial Hospital Affiliated to Shandong First Medical University

Background: Hepatocyte autophagy provides resistance to liver fibrosis. Deubiquitinases contribute to autophagy through modulation of the ubiquitination status of autophagy-related proteins. Myb-like SWIRM and MPN domains 1 (MYSM1), a histone H2A deubiquitinase, is upregulated in hepatocellular carcinoma (HCC); however, its impact on liver fibrosis remains unclear. Gelsolin (GSN) inhibits autophagosome formation by regulating actin depolymerization and has been demonstrated to interact with MYSM1 via CoIP mass spectrometry. This study investigates whether MYSM1 could promote the progression of liver fibrosis by regulating GSN to affect autophagy. **Methods:** Normal and fibrotic human liver samples were obtained. Mice primary hepatocytes were isolated. This study evaluated the relationship between MYSM1, GSN, hepatocyte autophagy, and liver fibrosis through immunohistochemistry, qRT-PCR, flow cytometry, immunofluorescence staining, Co-IP, transmission electron microscopy, and WB techniques. The study used MYSM1 hepatocyte knockout mice to investigate the function of MYSM1 in liver fibrosis. Additionally, mouse models with hepatocyte-specific MYSM1 overexpression and GSN knockdown were generated through the injection of AAV8-TBG-MYSM1 and AAV8-TBG-sh-GSN viruses, respectively. Liver fibrosis induced by carbon tetrachloride and nonalcoholic steatohepatitis induced by methionine-choline deficiency models were established. HEK293T cells underwent transfection with MYSM1 and ubiquitin mutant plasmids to examine the effect of MYSM1 on GSN deubiquitination. **Results:** Single-cell transcriptomic analysis revealed that MYSM1 is predominantly expressed in hepatocytes within the liver. During liver fibrosis, the expression of MYSM1 in hepatocytes significantly increased, correlating with both the severity of fibrosis and the degree of autophagy impairment. In vivo studies demonstrated that the deletion of MYSM1 reduced the accumulation of extracellular matrix and enhanced autophagy. Moreover, MYSM1 deletion resulted in decreased GSN expression. In contrast, overexpression of GSN ameliorated these effects. Co-IP mass spectrometry

confirmed an interaction between MYSM1 and GSN, indicating that MYSM1 stabilizes GSN by inhibiting its ubiquitination. Overexpression of MYSM1 notably decreased the levels of K29-linked ubiquitination on GSN. Additionally, GSN was found to hinder autophagy progression by blocking autophagosome formation and disrupting the autophagic flux in hepatocytes. **Conclusion:** MYSM1 promotes liver fibrosis by inhibiting the ubiquitination of GSN and the associated autophagy in hepatocytes. This study elucidates the mechanism and function of MYSM1 in the progression of liver fibrosis, providing a theoretical basis for the development of potential early interventions.

3352 | SELECTIVELY TARGETING HEPATIC STELLATE CELLS-DERIVED MICROFIBRIL-ASSOCIATED GLYCOPROTEIN 4 RETARDS LIVER FIBROSIS

Wenyue Wu[1] Wen Zhang[1] Hong Li[1] Haodong Ma[1] Ziyan Pan[1] Caihong Wang[1] Yameng Sun[1] Xuzhen Yan[1] Aiting Yang[1] Wei Chen[1] Hong You[2], [1]Beijing Friendship Hospital, Capital Medical University, [2]Capital Medical University

Background: Microfibril-associated glycoprotein 4 (MFAP-4) belongs to the fibrinogen-related protein superfamily and is a vital extracellular matrix (ECM) protein. However, the role of MFAP-4 in the pathogenesis of liver fibrosis has yet to be elucidated. **Methods:** Liver biopsies from cirrhotic patients with diverse etiologies and multiple murine models of liver fibrosis were used to investigate the expression pattern and cellular source of MFAP-4. The *in vivo* effects of silencing *Mfap4* in hepatic stellate cells (HSCs) were examined using adeno-associated virus vector (serotype 6) containing short-hairpin RNAs targeting *Mfap4*, under the regulatory control of either U6 ($U6^{siMfap4}$) or glial fibrillary acidic protein (GFAP; $GFAP^{siMfap4}$) promoter, in mouse models of carbon tetrachloride (CCl_4) or bile duct ligation (BDL)-induced liver fibrosis. The function of $MFAP4^+$ HSCs was assessed in Mfap4-Linker-tdTomato-P2A-DTR ($Mfap4^{DTR}$) mice by diphtheria toxin (DT)-mediated cell ablation, following CCl_4 or BDL. Histological staining, serum biochemistry, bulk RNA sequencing, and *in vitro* analyses were conducted to elucidate the roles of MFAP-4 in liver fibrogenesis. **Results:** MFAP-4 was predominantly enriched in activated HSCs and significantly upregulated in advanced liver fibrosis in both humans and mice. HSC-specific suppression of *Mfap4* in $U6^{siMfap4}$ and $GFAP^{siMfap4}$ mice markedly attenuated fibrosis and intrahepatic inflammation subjected to CCl_4 treatment or BDL operation, as indicated by downregulation of α-SMA, COL-1 and elastin, along with reduced serum ALT and AST levels. Mechanistically, transcriptomic profiling revealed that Mfap4 deficiency resulted in decreased expression of fibrosis-specific matrisome genes (LFMGs). Kyoto Encyclopedia of Genes and Genomes analysis identified notable downregulation of pathways related to ECM remodeling and focal adhesion in both $U6^{siMfap4}$ and $GFAP^{siMfap4}$ mice. Additionally, $Mfap4^{DTR}$ mice treated with low-dose DT exhibited marked ablation of $MFAP4^+$ HSCs, significant suppression of LFMGs, and attenuation of liver fibrosis. In vitro results demonstrated that *MFAP4* overexpression in human HSCs promoted the aggregation of elastin globules in two-dimensional culture conditions and significantly enhanced collagen gel contraction in three-dimensional environments. **Conclusion:** Selectively targeting HSC-derived MFAP4 significantly attenuates liver fibrosis, representing a promising therapeutic strategy for liver fibrosis.

3353 | THE ROLES OF THBS2-SPP1 AXIS IN HEPATIC STELLATE CELLS ACTIVATION AND LIVER FIBROGENESIS

Hong Li[1] Ning Zhang[1] Weng Zhang[1] Wenyue Wu[1] Ziyan Pan[1] Haodong Ma[1] Caihong Wang[1] Qi Han[1] Xuzhen Yan[1] Aiting Yang[1] Hong You[1] Wei Chen[1], [1]Beijing Friendship Hospital, Capital Medical University

Background: Thrombospondin-2 (THBS2) is markedly upregulated in fibrotic livers and correlates with fibrosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

stage, independent of etiology. This study aimed to elucidate the role and underlying mechanisms of hepatic stellate cell (HSC)-derived THBS2 in HSC activation and the progression of liver fibrosis. **Methods:** We generated HSC-specific *Thbs2* knockout mice (*Thbs2*$^{\Delta HSC}$) and HSC-specific human *THBS2* knock-in mice (h*THBS2*$^{KI\ HSC}$), subjecting them to intraperitoneal carbon tetrachloride (CCl_4) injection and bile duct ligation (BDL) to induce liver fibrosis. The involvement of the THBS2-SPP1 axis in fibrogenesis was interrogated using dual targeting strategies: extracellular SPP1 neutralization via intraperitoneal administration of inVivoMAb anti-mouse SPP1 antibody, and intracellular SPP1 suppression using AAV6-GFAP-sh*Spp1*, with parallel in vitro validation. **Results:** *Thbs2*$^{\Delta HSC}$ mice exhibited significantly reduced hepatic inflammation and fibrosis in both CCl_4- and BDL-induced models. Conversely, h*THBS2*$^{KI\ HSC}$ mice displayed markedly aggravated hepatic inflammation and fibrotic progression. Mechanistic studies revealed that *Thbs2* knockdown in HSCs substantially suppressed the expression of the pro-fibrotic effector Spp1, while *THBS2* overexpression robustly enhanced both SPP1 expression and its secretion—findings consistently validated in vitro. Notably, molecular interaction assays confirmed that THBS2 directly interacts with SPP1 in a dimeric configuration. Furthermore, we found intraperitoneal administration of inVivoMAb anti-mouse SPP1 neutralizing antibody and AAV6-GFAP-shSPP1-mediated *Spp1* silencing significantly attenuated fibrotic progression in CCl_4-treated h*THBS2*$^{KI\ HSC}$ mice, demonstrating distinct anti-fibrotic efficacy through coordinated blockade of extracellular SPP1 signaling and intracellular SPP1 biosynthesis. Additionally, we identified a novel THBS2 inhibitor through integrated virtual drug screening and surface plasmon resonance (SPR) validation. Pharmacodynamic evaluations confirmed the compound's potent anti-fibrotic effects in both CCl_4- and 3,5-diethoxycarbonyl-1,4-dihydrocollidine (DDC)-induced liver fibrosis mouse models, with significant improvements in histopathological features. **Conclusion:** HSC-derived THBS2 promotes liver fibrogenesis by regulating SPP1 expression and secretion. Targeting HSC-derived THBS2 can mitigate liver fibrosis. Further studies are warranted to investigate the specific mechanisms by which THBS2 regulates SPP1 in HSCs. **Disclosures:** Hong Li: Nothing to Disclose, Ning Zhang: Nothing to Disclose, Weng Zhang: Nothing to Disclose, Wenyue Wu: Nothing to Disclose, Ziyan Pan: Nothing to Disclose, Haodong Ma: Nothing to Disclose, Caihong Wang: Nothing to Disclose, Qi Han: Nothing to Disclose, Xuzhen Yan: Nothing to Disclose, Aiting Yang: Nothing to Disclose, Hong You: Nothing to Disclose, Wei Chen: Nothing to Disclose

3354 | HETEROZYGOUS G153D MUTATION OF LYSYL OXIDASE LIKE-1 GENE IS ASSOCIATED WITH LIVER FIBROSIS NON-REGRESSION

Wen Zhang[1] Wenyue Wu[2] Hong Li[2] Ning Zhang[2] Ziyan Pan[2] Haodong Ma[2] Caihong Wang[2] Xuzhen Yan[2] Aiting Yang[2] Wei Chen[2] Hong You[3], [1]Beijing Friendship Hospital, Capital Medical Univerity, [2]Beijing Friendship Hospital, Capital Medical University, [3]Capital Medical University

Background: Lysyl oxidase like-1 (LOXL1) is a copper-dependent enzyme crucial for extracellular matrix (ECM) cross-linking, thereby influencing tissue remodeling and fibrosis. While LOXL1 mutations are known to enhance ECM cross-linking in glaucoma, their role in liver fibrosis remains unclear. **Methods:** Genomic DNA from 168 patients with chronic hepatitis B virus (CHB)-related liver fibrosis was analyzed for LOXL1 single nucleotide polymorphisms (SNPs). Clinical characteristics and Ishak scores were compared between patients with and without LOXL1 mutations, both before and after antiviral treatment (AVT). In vivo, heterozygous Loxl1 G153D mutant mice were subjected to CCl_4-induced liver fibrosis. Transcriptome sequencing was performed during both the progression and regression phases to elucidate underlying mechanisms. In vitro experiments were conducted to investigate the biological effects of the LOXL1 G153D mutation. **Results:** Patients carrying the heterozygous LOXL1 G153D mutation exhibited significantly reduced fibrosis regression after 78 weeks of AVT (reversal rates: 26.3% in mutants ***vs***. 52.4% in non-mutants, $\boldsymbol{p} = 0.025$). Compared to non-mutant patients post-AVT, those with the mutation showed higher serum ALT and GGT levels, increased liver stiffness measurements (LSM), and elevated Ishak scores. In vivo, Loxl1 G153D mutant mice displayed more severe hepatic inflammatory infiltration, lipid accumulation, and pronounced perisinusoidal fibrosis during the spontaneous regression phase of CCl_4-induced liver fibrosis. Mechanistically, metabolism-related pathways were predominantly activated during fibrosis progression, while inflammation-related pathways were enriched during regression. In hepatic stellate cells (HSCs) harboring the LOXL1 G153D mutation, LOXL1 protein was significantly translocated to the cell membrane and extracellular space, markedly enhancing HSC migration and contractility. These findings suggest that the LOXL1 G153D mutation promotes extracellular secretion of LOXL1, facilitates intercellular communication, and increases ECM protein cross-linking and deposition, thereby impairing fibrosis regression. **Conclusion:** Our study demonstrates that the heterozygous LOXL1 G153D mutation is associated with impaired liver fibrosis regression following AVT in CHB patients. Furthermore,

3355 | A MASH PATIENT LIVER–DERIVED 3D FIBROSIS MODEL FOR THE DESIGN AND VALIDATION OF CANDIDATE THERAPEUTIC LIPID NANOPARTICLES

Tobias Raabe[1] Dylan Haseman[1] Andy Liu[1] Khushal Bantu[1] Vladimir Muzykantov[1] Drew Weissman[1] Jilian Melamed[1] Jia Nong[1], [1]University of Pennsylvania

Background: There is an urgent need for physiologically relevant human *in vitro* models of MASH (Metabolic Dysfunction-Associated Steatohepatitis) that capture the full complexity of liver fibrosis, especially as MASH is highly prevalent and deadly, yet without effective therapies. Key pathological features—such as hepatocyte senescence, hepatocyte ballooning, bridging fibrosis, and pro-fibrotic TREM2$^+$ scar-associated macrophages—are poorly recapitulated in current rodent models and even in some non-human primate systems. Moreover, the development of cell-type-specific therapeutic strategies is hindered by the lack of platforms suitable for efficient delivery and validation of targeted therapies within fibrotic tissue. **Methods:** We established a human 3D MASH fibrotic scar model by co-culturing hepatic organoids derived from explant MASH liver tissue of a 53-year-old male undergoing liver transplantation (McCarron et al., Hepatology, 2021) with primary human hepatic stellate cells/myofibroblasts and peripheral blood–derived macrophages. This triple co-culture system reconstructs key fibrotic components of human MASH. We then performed a targeted lipid nanoparticle (LNP) screen to identify formulations capable of selectively delivering mRNAs or siRNAs to hepatocytes, myofibroblasts, and macrophages within the organoid model. **Results:** In our 3D MASH fibrotic scar organoid model, hepatic organoids derived from MASH patient liver—but not from healthy donor liver—displayed epigenetically preserved hallmark features of human MASH: Immunofluorescence microscopy shows hepatocyte ballooning, >3-fold upregulation of nuclear p21 (a marker of senescence), strong myofibroblast proliferation, and extensive accumulation of scar-associated TREM2$^+$ macrophages localized to activated myofibroblasts. Further, single cell RNA sequencing confirms this and additionally reveals unprecedented transcriptome similarity to the fibrotic niche in human MASH livers. Our LNP screen identified cell-type-specific delivery vehicles for all three cell types. A lead formulation targeting myofibroblasts, when loaded with anti-YAP1 siRNA, achieved $>95\%$ knockdown of nuclear YAP1, suppressed myofibroblast proliferation, and induced senescence—without observable off-target effects on hepatocytes or macrophages. **Conclusion:** We present a robust human MASH liver derived 3D fibrotic scar organoid model that enables high-efficiency, cell-type-selective genome editing using LNPs. This system provides a powerful platform for screening and validating targeted therapeutics, supporting the development of precision interventions that modulate hepatocyte, myofibroblast, or macrophage function while minimizing off-target effects. This approach has broad potential to accelerate translational research in MASH and other fibrotic liver diseases.

3356 | MACHINE LEARNING-BASED FUSION OF CONTRAST-ENHANCED UPPER ABDOMINAL MRI SIGNATURES AND CLINICAL SCORES IMPROVES PREDICTION OF 1-YEAR MORTALITY IN ACUTELY DECOMPENSATED CIRRHOSIS

Qingren Cao[1] Lan Zhu[1] Chenxi Zhang[1] Juhua Li[2] Baoyan An[1] Dandan Weng[3] Minghao Cai[1] Zhuping Qian[1] Ziqiang Li[1] Ruokun Li[1] Haiguang Xin[1] Zhujun Cao[1] Qing Xie[1], [1]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [2]Wuwei People's Hospital, [3]Yuyao People's Hospital

Background: Patients with acutely decompensated cirrhosis (ADC) have poor outcome with 1-year mortality ranging from 20% to 63%. Traditional prognostic tools (CLIF-C AD, MELD-Na, MELD) demonstrate limited accuracy in predicting long-term mortality. Radiomics from contrast-enhanced upper abdominal MRI provides novel quantitative biomarkers. This study developed and validated a machine learning-based fusion model, combining liver and spleen radiomics with clinical prognostic scores, to enhance the predictive accuracy of 1-year mortality in patients with ADC. **Methods:** The current study was an imaging investigation of the RJH (Ruijin Hospital) cohort of adult patients with cirrhosis non-electively admitted for ADC between 2016 and 2023 (RJH-radiomics). Patients who were free of acute-on-chronic liver failure at the time of admission and underwent contrast-enhanced upper abdominal MRI (Philips) during the index admission were included for analysis. In addition to baseline clinical and lab data, sequences from T1, T2, diffusion weighted imaging, and portal phases were collected for features extraction. Patients were randomly divided in a ratio of 8:2 to train and test a machine-learning MRI radiomics model (termed RJH-ADC-MRI score) for predicting 1-year mortality. After training the radiomics model using KNN, the commonly used clinical models (MELD, MELD-Na, CLIF-C AD) were fused with the radiomics model using logistic regression (Figure 1). Furthermore, Kaplan-Meier survival analysis was performed for the fused model. An independent cohort was used for validating the performance of RJH-ADC-MRI score. **Results:** A total of 318 patients were included for this analysis (mean age 57 ± 10.3, 67% male, 45% HBV, median CLIF-C AD 45.77 [39.57, 51.32]). By 1-year follow-up, 75 patients died or received liver transplantation (LT), and the remaining 243 survived without LT. RJH-ADC-MRI score was developed based on four identified MRI features (three derived from the liver and one from the spleen) in the training set with 197 patients.

The Area Under the Curve (AUC) in predicting 1-year mortality of RJH-ADC-MRI score was 0.78, higher than that of CLIF-C AD (0.61), MELD (0.70) or MELD-Na (0.70) (P all < 0.05). Incorporating the RJH-ADC-MRI score into the commonly used models led to a further improvement in the model's predictive capabilities and reached a highest AUC of 0.85 (Figure 2). The RJH-ADC-MRI based MELD score could stratify patients into two risk groups with significantly different 1-year survival probability ($p < 0.001$) (Figure 3). These findings were successfully validated on both a test set and an independent external validation cohort ($n = 61$). **Conclusion:** Machine learning-based fusion of contrast-enhanced upper abdominal MRI signatures and clinical scores demonstrated higher accuracy in predicting 1-year mortality of patients with ADC compared to the traditional scores.

3357 | CLINICAL UTILITY OF A 50% RELATIVE DECLINE IN MRI-PDFF IN PREDICTING FIBROSIS IMPROVEMENT IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Daniel Huang[1] Rohit Loomba[2] Peter Daniel[3] Ricki Bettencourt[4] Egbert Madamba[5] Harris Siddiqi[5] Lisa Richards[2] Mildred Gottwald[6] Shibao Feng[6] Maya Margalit[6], [1]National University Hospital, Singapore, [2]University of California, San Diego, [3]National University Hospital, [4]University of California San Diego, [5]MASLD Research Center, University of California San Diego, [6]89Bio

Background: MRI-proton-density-fat fraction (MRI-PDFF) response (defined as $\geq$ 30% relative decline in liver fat content on MRI-PDFF) can help to detect resolution of metabolic dysfunction-associated steatohepatitis (MASH) resolution but there are limited data on whether it can reliably predict fibrosis improvement. The association of MRI-PDFF super-response (defined as $\geq$ 50% decline in liver fat content on MRI-PDFF) with the likelihood of fibrosis regression and MASH resolution has not been systematically assessed and quantified. We examined the association between MRI-PDFF super-response and fibrosis regression and MASH resolution in a multi-center randomized placebo-controlled trial. **Methods:** This is a secondary analysis of a large, multi-center, randomized, placebo-controlled trial study that included 163 participants (64% female) with biopsy-confirmed MASH with stage 2 or 3 fibrosis who were treated for 24 weeks with either pegozafermin or placebo and underwent

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

contemporaneous laboratory testing, MRI-PDFF, and liver biopsy at two time points (Loomba et al. NEJM 2024). The two *primary outcomes* were fibrosis improvement without worsening of MASH and MASH resolution with no worsening of fibrosis. We evaluated the outcomes among those with MRI-PDFF super-response and those with MRI-PDFF response. **Results:** The median (IQR) age and BMI of participants were 56.0 (48.0-62.0) years and 36.5 (32.2-40.2) kg/m^2. The proportion of patients who achieved super-response was significantly higher in participants treated with pegozafermin (pooled 15 mg, 30 mg, and 44 mg arms) versus placebo (57.8% versus 11.1%, $p < .0001$). After multivariable adjustment for age, sex, BMI, race/ethnicity, and type 2 diabetes, MRI-PDFF super response (adjusted OR 3.08, 95% CI 1.32-7.19, $p = 0.009$) remained an independent predictor of fibrosis regression without worsening MASH, but not MRI-PDFF response (adjusted OR 2.10, 95% CI 0.85-5.16, $p = 0.11$). Both MRI-PDFF response (adjusted OR 5.22, 95% CI 1.68-16.10, $p = 0.004$) and MRI-PDFF super-response (adjusted OR 7.29, 95% CI 2.68-19.78, $p < .001$) were statistically significant predictors of MASH resolution without worsening fibrosis. **Conclusion:** MRI-PDFF super-response predicts fibrosis regression without worsening MASH, and a greater likelihood of MASH resolution without worsening fibrosis than MRI-PDFF response. These data have important implications for clinical trial design in MASH and assessing dose response and dose selection for Phase 3.

3358 | SPATIAL TRANSCRIPTOMICS REVEALS GPNMB-POSITIVE MACROPHAGES AS DRIVERS OF FIBROTIC NICHES AND PROGNOSTIC INDICATORS IN CHRONIC LIVER DISEASE

Kenji Fukumoto[1] Kazumasa Soma[1] Seiya Kato[1] Yoichi Sasaki[1] Kazuhiro Murai[1] Yuki Makino[1] Yuki Tahata[1] Yoshinobu Saito[1] Takahiro Kodama[1] Hayato Hikita[1], [1]Osaka University Graduate School of Medicine

Background: Glycoprotein non-metastatic melanoma protein B (GPNMB) is upregulated in senescence-related conditions such as obesity and aging. This study explored its role in the hepatic microenvironment of chronic liver disease and its potential as a biomarker of disease progression. **Methods:** Single-cell RNA sequencing (scRNA-seq) was conducted in two chronic liver disease mouse models— hepatocyte-specific Mcl-1 knockout (hepatocyte apoptosis-driven) and Western diet–fed (MASH) mice—as well as in liver specimens from patients with MASH, chronic hepatitis B, alcoholic hepatitis, and Fontan-associated liver disease. In vitro studies used THP-1 and HepG2 cell lines. CosMx spatial transcriptomics was performed on MASH and HCV patient tissues. Serum GPNMB levels were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

measured in 936 patients with MASLD/MASH or HCV-related liver disease to assess cancer risk, and prognostic value was analyzed in an additional 290 HCV-cirrhosis patients. **Results:** scRNA-seq analysis of liver tissues from patients with chronic hepatitis revealed that CD68-positive hepatic macrophages showed high GPNMB expression across all chronic liver disease etiologies. Spatial transcriptomics in non-tumor regions from MASH and HCV patients revealed that GPNMB-positive macrophages highly expressed genes related to lipid metabolism, phagocytosis, and the senescence-associated secretory phenotype (SASP). Hepatic stellate cells within 20 μm of these macrophages showed elevated fibrosis-related gene expression, while nearby hepatocytes expressed apoptosis-related genes. In tumor areas, GPNMB-positive macrophages upregulated genes linked to tumor progression.

In mouse models of chronic liver disease, including apoptosis-driven chronic hepatitis and diet-induced MASH, hepatic macrophages showed increased GPNMB expression versus controls. Lysosomal stress from fatty acid loading or bafilomycin enhanced GPNMB and cytokine secretion (e.g., IL-6, TNF-α) in THP-1-derived macrophages. These findings were further supported by in vitro experiments, where phagocytosis of apoptotic bodies from HepG2 cells induced GPNMB expression in THP-1-derived macrophages.

Serum GPNMB levels were an independent risk factor for liver carcinogenesis in both MASLD and HCV cohorts, with 15.4 ng/mL as an effective cutoff for risk stratification. In a separate cohort of 290 HCV-related cirrhosis patients, GPNMB levels were significantly higher in those with decompensated cirrhosis than in those with compensated cirrhosis, and levels $\geq$ 18.8 ng/mL were associated with significantly shorter overall survival without liver transplantation. **Conclusion:** GPNMB is upregulated in hepatic macrophages under lysosomal stress induced by efferocytosis and lipid accumulation, contributing to hepatic fibrosis and hepatocyte death. Serum GPNMB may serve as a novel biomarker for assessing hepatocarcinogenesis risk and prognosis in patients with chronic liver disease. **Disclosures:** Kenji Fukumoto: Nothing to Disclose, Kazumasa Soma: Nothing to Disclose, Seiya Kato: Nothing to Disclose, Yoichi Sasaki: Nothing to Disclose, Kazuhiro Murai: Nothing to Disclose, Yuki Makino: Nothing to Disclose, Yuki Tahata: Nothing to Disclose, Yoshinobu Saito: Nothing to Disclose, Takahiro Kodama: Nothing to Disclose, Hayato Hikita: Nothing to Disclose

3359 | REGULATION OF DDX5 BY FL118 AND ITS ASSOCIATION WITH CELLULAR SENESCENCE DURING HEPATIC STELLATE CELL ACTIVATION

Thi Nga Ha[1] Hyon-Seung Yi[1], [1]Chungnam National University School of Medicine

Background: DDX5 (p68) is a DEAD-box RNA helicase that regulates transcription, RNA processing, and cell proliferation. Emerging evidence suggests that DDX5 plays a critical role in hepatic stellate cell (HSCs) activation, a key event in liver fibrosis progression. Our findings indicate that DDX5 contributes to HSCs activation via translational regulation and cellular senescence. **Methods:** We analyzed total and phosphorylated DDX5 (pDDX5) levels using antibody arrays in primary mouse HSCs (pHSCs) cultured for 1 and 4 days and in the human HSC line LX-2 following TGF-β treatment. To functionally assess DDX5, we used FL118, a small-molecule compound that binds to DDX5 and promotes its proteasome-mediated degradation. We evaluated its effects on α-SMA expression (a marker of HSCs activation) and global protein translation. **Results:** Antibody array analysis revealed an increase in total DDX5 and a reduction in pDDX5 during HSCs activation, observed both in day 4 pHSCs and TGF-β-treated LX-2 cells. TGF-β stimulation induced DDX5 expression in LX-2 cells, while in pHSCs, DDX5 expression increased initially but declined by day 7, suggesting stage-dependent regulation during activation. Public RNA-seq data confirmed DDX5 upregulation alongside ribosome biogenesis genes in LX-2 cells after TGF-β exposure, implicating DDX5 in translational enhancement during HSCs activation. Treatment with FL118 led to a marked reduction in total and phosphorylated DDX5, decreased α-SMA expression, and impaired global protein translation, supporting its antifibrotic potential via DDX5 degradation. In senescent HSCs, total DDX5 levels were reduced while pDDX5 remained unchanged, correlating with diminished protein synthesis and suggesting that DDX5 downregulation in senescence occurs independently of its phosphorylation status. **Conclusion:** DDX5 plays a pro-fibrotic role by promoting HSCs activation, likely through modulation of translation and cellular state. Its expression is dynamically regulated via post-translational mechanisms. Pharmacological targeting of DDX5 with FL118, which induces DDX5 degradation, may serve as a promising antifibrotic strategy by suppressing HSCs activation and global translation.

3360 | MULTIMODAL ASSESSMENT OF FONTAN-ASSOCIATED LIVER DISEASE IN A NOVEL OVINE MODEL USING ULTRASOUND AND HISTOLOGICAL QUANTIFICATION

Jennifer Kievert[1] Cameron DeShetler[1] Tatsuya Watanabe[1] Junya Matsuda[1] Fahd Taha[1] Joshua Spiess[1] Satoshi Yuhara[1] Joseph Leland[1] Syed Faizullah Hussaini[1] Jocelyhnn Zucco[1] Jingru Che[1] Rajesh Krishnamurthy[2] Aymen Naguib[3] Christopher McKee[3] Andrew Yates[3] David Brigstock[2] Sergio Carrillo[3] Christopher Breuer[1] John Kelly[1], [1]The Abigail Wexner Research Institute at Nationwide Children's Hospital, [2]Nationwide Children's Hospital, [3]Nationwide Children's Hospital

Background: Fontan Associated Liver Disease (FALD) is a universal and progressive disease in single ventricle heart patients that have undergone Fontan palliation; however, the natural history of the disease is poorly understood. This is primarily due to the inability of ultrasound elastography to distinguish between fibrosis and congestion, the infeasibility of performing longitudinal liver biopsy samples clinically, and the lack of relevant animal models. We developed a novel chronic ovine model of Fontan palliation and found significant liver fibrosis 1-year post-operation. Herein, we investigate FALD progression in the first 6 months following surgery using ultrasound elastography/doppler and liver biopsies. **Methods:** Six sheep were divided into 2 groups: complete Fontan (C-F) with both the inferior vena cava (IVC) and superior vena cava (SVC) connected to the main pulmonary artery (MPA) ($n = 3$) or incomplete Fontan (IC-F) with only the IVC to MPA connection ($n = 3$). Over 6 months, progression of liver disease was tracked through monthly ultrasound doppler/elastography, and bimonthly right liver biopsies. The biopsies were formalin fixed and histologically stained with picrosirius red for a blinded assessment of congestive hepatic fibrosis score (CHFS) and percent area of collagen. These results were compared to ultrasound elastography measurements to determine if increased stiffness accurately correlates with the degree of fibrosis. **Results:** The data reported spanned from pre-operation to 6 months post operation. There were significant increases in hepatic vein (HV) diameter (1.06 ± 0.15 cm to 1.78 ± 0.21 cm, $p < 0.001$) and IVC area (0.77 ± 0.38 cm^2 to 1.84 ± 0.65 cm^2, $p < 0.001$) for both cohorts. There was no statistical difference between cohorts for HV diameter ($p = 0.458$), however the C-F animals' IVC area increased significantly slower than the IC-F animals (0.24 cm^2/month vs 0.07 cm^2/month, $p = 0.003$). Ultrasound elastography around the central parenchymal area showed a non-significant ($p = 0.172$) increased tissue stiffness for both surgical groups (C-F:1.52 ± 0.25 m/s to 1.82 ± 0.43 m/s, IC-F: 1.3 ± 0.11 m/s to 1.68 ± 0.79 m/s). There was a nonsignificant increase in collagen quantification (3.689% to 8.89%, $p = 0.15$) and a significant increase in CHFS (0 to 1, $p = 0.018$) for both cohorts. Increases in central parenchymal stiffness had a significant positive correlation with the biopsy CHFS score (slope = 0.22, $R^2 = 0.51$, $p = 0.001$). There was a significant weakly positive trend between collagen quantification compared to central elastography (slope = 0.03, $R^2 = 0.25$, $p = 0.04$). **Conclusion:** An increase in liver stiffness was observed in both surgical cohorts; however, liver histology confirms only a mild degree of liver fibrosis. Liver elastography accurately follows FALD development in the sheep model when compared to CHFS and % area. Ongoing follow-up of these animals will lead to insights into the later period of FALD progression.

3361 | ALKBH5 AMELIORATES HEPATIC FIBROSIS BY REGULATING THE PI3K-AKT-FOXO3A SIGNALING AXIS

lingyu kong[1] Hongxin Piao[2], [1]Yanbian University, [2]Yanbian University Hospital

Background: Liver fibrosis is characterized by disruption of the liver's self-repair process, leading to excessive deposition of extracellular matrix (ECM). Abnormal activation of hepatic stellate cells (HSC) is a key factor in liver fibrosis.ALKBH5, a key protein for m6A demethylation modification, has been found to play an important regulatory role in the fibrotic process of various tissues, including pulmonary fibrosis, myocardial fibrosis, and renal fibrosis. However, its role in liver fibrosis is unclear.PI3K/AKT/FOXO3A is an important signaling axis involved in multiple biological processes, including cell growth, proliferation, differentiation, and apoptosis, and is closely related to liver fibrosis.The complex relationship between ALKBH5 and PI3K/AKT/FOXO3A and liver fibrosis needs further research. **Methods:** 1. Silencing of ALKBH5 gene in HSC cells by recombinant lentiviral transfection and determination of the transfection effect by protein imprinting assay. 2. Silencing of ALKBH5 gene in HSC cell lines, dividing the cells into HSC-T0 and HSC-T6 groups, and detection of cell proliferation by CCK8 assay, comparison of the migration ability of the cells by scratch assay, and detection of cell cycle by attrition cytometry. 3. 3. Use transcriptome sequencing to explore the differential gene expression before and after ALKBH5 gene silencing and Gene Ontology (GO) enrichment analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) enrichment analysis to investigate the gene changes in the downstream signaling pathway after knocking down ALKBH5 gene, so as to reveal the mechanism of action.4. Apply WB to explore the differences in the expression of key proteins in the PI3K/AKT/FOXO3A signaling axis between HSC-T0 and HSC-T6 cells. **Results:** The success of ALKBH5 knockdown in HSC-T6 group was verified by WB assay. The results of CCK8 and scratch assay showed that the cells in HSC-T6 group had accelerated cell proliferation and migration compared with the cells in HSC-T0 group; the results of attrition cytometry showed that the cells in HSC-T6 group were in G0/G1 phase. The results of high-throughput sequencing of the transcriptome showed that the differential gene was significantly enriched in the PI3K/AKT/FOXO3A signaling axis after silencing ALKBH5; after silencing ALKBH5, the results of the WB assay showed that in the HSC cells, the expression of PI3K, AKT, and FOXO3A proteins was down-regulated in the HSC-T6 group, and the expression of Collagen I and α-SMA proteins were up-regulated in the HSC-T6 group. **Conclusion:** ALKBH5 inhibits the proliferation and migration ability of HSC cells.
ALKBH5 affects HSC cells by regulating the PI3K/AKT/FOXO3A signaling axis.

3362 | BAICALEIN INDUCES HEPATIC STELLATE CELL SENESCENCE VIA INHIBITING GLYCOLYSIS BY CEBPZ/P53/HK2 SIGNALING PATHWAY TO INHIBIT LIVER FIBROSIS

Shuling Chen[1] Ruiqi Li[2] Dawei Yong[3] Jun Guo[1] Anyin Yang[4] Hongli Liu[2] Hao Ren[1] Jing Fan[5] Qingfang Xiong[1] Caiyun Zhang[5] Dandan Yin[1] Xixuan Wang[2] YongFeng Yang[1], [1]The Second Hospital of Nanjing, Affiliated to Nanjing University of Chinese Medicine, [2]The Second Hospital of Nanjing, Southeast University, [3]David_young1994@outlook.com, [4]Gaochun Hospital Affiliated to Jiangsu University, [5]Nanjing University of Chinese Medicine

Background: Liver fibrosis is a condition in which abnormal proliferation of connective tissue occurs in the liver. Baicalein (BA) is a flavonoid compound extracted from the dried root of *Scutellaria baicalensis*, which can inhibit the mechanisms of cancer development such as metastasis, angiogenesis, and inflammation without harming healthy cells. However, there has been little research on its effects in liver fibrosis. This study aimed to investigate the protective effect of BA on liver fibrosis and elucidate its potential mechanisms. **Methods:** Serum markers for liver injury, liver tissue histochemical staining, tissue immunofluorescence tissue immunohistochemistry, Western blotting analysis, real-time quantitative polymerase chain reaction(qRT-PCR), β-galactosidase staining, cell cycle detection, enzyme-linked immunosorbent assay (ELISA), Cellular Thermal Shift Assay (CETSA), Cleavage Under Targets and Tagmentation (CUT&Tag), Small Molecule pull-down

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(SM pull-down) and Surface Plasmon Resonance (SPR) were utilized to identify the targets of BA, as well as to detect the expression of proteins associated with cellular senescence, fibrosis markers, and signaling pathways. **Results:** Serum liver injury indicators, fibrosis markers, and histochemical staining results indicated that BA treatment significantly ameliorated liver injury, inflammation, and fibrosis in vivo. Concurrently, BA markedly inhibited the activation of human hepatic stellate cell (HSC) line (LX2 cell line). The results further suggested that BA significantly promoted the senescence of activated HSCs, with cell cycle arresting at the G1 phase. BA could promote cellular senescence by inhibiting glycolysis in activated HSCs. Mechanistic studies demonstrated that BA could directly bind to CEBPZ, and regulate p53/HK2 signaling pathway at the transcriptional level. The pharmacological inhibitor of p53, pifithrin-a hydrobromide, significantly suppressed the anti-fibrotic effects of BA. **Conclusion:** Our findings suggested that BA had a protective effect on liver fibrosis, and the underlying mechanism might be related to the CEBPZ/p53/HK2 signaling pathway.

3363 | SINGLE-CELL ANALYSIS OF HETEROGENEITY IN REVERTED HUMAN HEPATIC STELLATE CELLS

Xinjia Wang[1], [1]THE CLEVELAND CLINIC FOUNDATION

Background: Hepatic stellate cells (HSCs) are central mediators of liver fibrosis. While activated HSCs are known to drive fibrogenesis, their fate following removal of the causative insult remains unclear. We aimed to investigate whether human activated HSCs can revert to a less activated state, and to characterize the cellular and molecular features of such reversion using a human induced pluripotent stem cell (hiPSC)-derived multicellular liver model. **Methods:** We employed a hiPSC-derived liver culture system containing hepatocytes, HSCs, and macrophages. HSCs were activated by hepatitis C virus (HCV) infection and then subjected to antiviral treatment to induce HCV clearance. Reverted HSCs (rHSCs) were characterized via gene expression profiling, vitamin A quantification, functional assays, and single-cell RNA sequencing (scRNA-seq). The role of macrophage- derived IL-10 in HSC reversion was investigated through receptor knockdown and cytokine treatment experiments. **Results:** When HSCs are activated by a hepatitis C virus (HCV) infection and subsequently cured, they transition to a less active state. These are termed reverted HSCs (rHSCs). Comprehensive characterization revealed that rHSCs re-express some markers typical of naïve quiescent HSCs that had never been activated, including regaining lipid droplets and vitamin A storage; additionally, they display functions similar to quiescent HSCs. Notably, single-cell RNA sequencing of rHSCs uncovered considerable heterogeneity amongst the population; it identified subpopulations that express markers indicative of apoptotic and senescent pathways, as well as HSCs in a less activated state. Further analysis of the less activated cells revealed a subpopulation of rHSCs closely resembling quiescent HSCs. Functional characterization demonstrated that these cells maintained features similar to naïve quiescent HSCs. Subsequent comparative analyses revealed that rHSCs exhibit heightened sensitivity to re-stimulation, whether exposed to the same stimulus or new stimuli. To further elucidate the mechanisms driving HSC reversion, we investigated the roles of macrophages within the liver culture. **Conclusion:** Activated HSCs demonstrate plasticity, with the capacity to revert to a quiescent-like

state following removal of activating stimuli, though they retain increased sensitivity to re-stimulation. Macrophage-derived IL-10 plays a critical role in driving this reversion by regulating vitamin A metabolism. These findings provide insights into HSC dynamics and suggest potential therapeutic avenues for liver fibrosis by targeting HSC reversion.

3364 | FUNCTIONAL ROLE OF NICOTINAMIDE N-METHYLTRANSFERASE IN HEPATIC STELLATE CELL ACTIVATION AND LIVER FIBROSIS

Ji Hyun LEE[1] Jae Min KIM[2] Ji Hye YANG[2] Sung Hwan KI[1], [1]College of Pharmacy, Chosun University, [2]College of Korean Medicine, Dongshin University

Background: Hepatic stellate cells (HSCs) activation is important in the progression of liver fibrosis. Nicotinamide *N*-methyltransferase (NNMT), a nicotinamide metabolizing enzyme, regulates both NAD^+ and methionine metabolism. Recently, the expression of nicotinamide methyl metabolites has increased in patients with cirrhosis and the role of NNMT in various liver diseases has been investigated, but there is no study on the expression and its regulatory mechanism of NNMT on liver fibrosis. **Methods:** In this study, we explored the molecular mechanisms regulating NNMT expression and its functional role in hepatic stellate cell activation *in vitro* and *in vivo*. **Results:** We compared NNMT expression with that of glycine N-methyltransferase (GNMT), another hepatic methyltransferase, during HSC activation. Using GEO transcriptional data, we confirmed that NNMT expression specifically increases during HSC activation. Moreover, treatment of LX-2 cells (a human HSC line) with TGF-β resulted in transcription-dependent upregulation of NNMT. We further demonstrated that modulation of NNMT, through either inhibition or overexpression, affected TGF-β-induced HSC activation. Moreover, liver fibrosis induced by chemical was significantly improved in NNMT KO mice. **Conclusion:** NNMT plays a significant role in hepatic stellate cell activation and may serve as a novel therapeutic target for the prevention and treatment of liver fibrosis.

3365 | MACROPHAGE NRF1-FOXO1-KLF6 AXIS DRIVES MITOCHONDRIAL DYSFUNCTION AND INFLAMMATORY PROGRESSION IN LIVER FIBROSIS

Qiong Wu[1] Mingwei Sheng[2] Fengmei Wang[2], [1]Nankai University, [2]Tianjin First Central Hospital

Background: Liver fibrosis is a progressive condition driven by chronic injury, ultimately leading to cirrhosis. Immune dysregulation, particularly macrophage polarization, plays a crucial role in fibrosis progression. Pro-inflammatory M1 macrophages worsen inflammation and fibrosis, with their polarization influenced by metabolic shifts between glycolysis and oxidative phosphorylation. Nuclear factor erythroid 2- related factor 1 (Nrf1), a key redox-sensitive factor essential for mitochondrial homeostasis, has been extensively studied in hepatocytes but remains largely unexplored in macrophages in the context of liver fibrosis. This study aims to elucidate the immunoregulatory role of macrophage Nrf1 in liver fibrosis, potentially identifying novel therapeutic targets to mitigate or reverse fibrosis progression. **Methods:** Myeloid-specific Nrf1-knockout ($Nrf1^{M\text{-}KO}$) mice and Foxo1 knockout ($Foxo1^{M\text{-}KO}$) mice were developed to investigate the role and underlying mechanisms of macrophage Nrf1-Foxo1 axis across three murine models of liver fibrosis induced by a high-fat diet, carbon tetrachloride injection or bile duct ligation. Bone marrow-derived macrophages (BMDMs) were isolated from conditional mice, then stimulated with lipopolysaccharide (LPS, 100 ng/mL, 6 hours). CRISPR/Cas9 and siRNA approaches were used to assess downstream targets. **Results:** Nrf1 expression was significantly reduced in macrophages from fibrotic liver tissues, as confirmed by qRT-PCR and immunofluorescence staining in both human and murine models. $Nrf1^{M\text{-}KO}$ mice exhibited exacerbated liver fibrosis, characterized by elevated serum ALT/AST levels, increased collagen deposition, and upregulated fibrotic markers (TGF-β, Col1a1, TIMP1). Loss of Nrf1 promoted M1 macrophage polarization, enhanced inflammatory responses (elevated TNF-α, IL-1β, iNOS), and impaired mitochondrial function (reduced ATP production and increased mitochondrial ROS). In contrast, $Foxo1^{M\text{-}KO}$ mice exhibited attenuated fibrosis, reduced inflammation, and improved mitochondrial integrity. Mechanistically, Nrf1 directly interacted with Foxo1 to regulate the transcription of KLF6, a key mediator of mitochondrial function and macrophage polarization. These findings underscore the pivotal role of the Nrf1-Foxo1-KLF6 axis in macrophage-driven

inflammation and fibrosis, highlighting potential therapeutic targets for liver fibrosis. **Conclusion:** Our study highlights the functional properties of macrophage Nrf1-Foxo1 axis in controlling mitocondrial reprogramming and liver fibrosis progression.

3366 | TGF-β PROMOTES SCD146-MEDIATED HSC ACTIVATION BY UPREGULATING CD146 EXPRESSION IN HEPATOCYTES

Bingqing Yang[1] Chenxue Hou[1] Qi Wang[1] Yue Li[1], [1]Beijing Ditan Hospital, Capital Medical University, Beijing, China.

Background: Hepatic fibrosis represents a critical intermediate stage in the progression to cirrhosis. A cellular network composed of hepatocytes, macrophages, and hepatic stellate cells (HSCs) plays a central role in its pathogenesis. However, the interactions between HSCs and other hepatic cell types remain incompletely understood. This study aims to elucidate the mechanisms by which hepatocyte-derived CD146 regulates intercellular interactions and promotes hepatic fibrosis. **Methods:** Hepa1-6 cells were stimulated with TGF-β, and CD146 expression was assessed via Western blotting. CD146-overexpressing Huh7 cells were constructed and compared with control cells. Conditioned media (CM) from these cells were collected for proteomic analysis and used to treat the HSC cell line LX2 to assess the expression of fibrosis-related proteins. Additionally, recombinant CD146 protein(rhsCD146) was applied to LX2 cells to evaluate its direct effect on HSC activation. **Results:** TGF-β significantly upregulated CD146 expression in the Hepa1-6 cell in a time- and dose-dependent manner, suggesting a potential role in shaping the early fibrotic microenvironment via hepatocyte-derived CD146. To further investigate the mechanism of hepatocyte-mediated HSC activation, CD146-overexpressing Huh7 cells were generated, and their CM were used to treat LX2. Proteomic analysis of the CM identified the top 50 significantly differentially expressed proteins (fold change >1.5, $p < 0.05$), with soluble CD146 (sCD146) emerging as one of the most markedly upregulated factors.

Treatment of LX2 cells with either CM from CD146-overexpressing hepatocytes or rhsCD146 robustly activated the p38-MAPK pathway and induced collagen I (COL1A1) expression. In contrast, direct overexpression of CD146 in LX2 cells did not significantly alter fibrosis-associated gene or protein levels, indicating that sCD146—rather than intracellular CD146—plays a critical role in HSC activation. **Conclusion:** This study reveals that TGF-β induces CD146 expression in hepatocytes, promoting the shedding and secretion of sCD146, which in turn activates the p38-MAPK signaling pathway in hepatic stellate cells and enhances COL1A1 expression. These findings highlight a novel mechanism by which hepatocyte-derived sCD146 facilitates HSC activation and drives the progression of hepatic fibrosis.

3367 | FUT8-MEDIATED CORE FUCOSYLATION OF SPARC DRIVES HEPATIC FIBROSIS VIA COLLAGEN CROSSLINKING AND TGF-B SIGNALING

Hanjie Yu[1] Junhong Wang[2] Han Lin[3] Mengmeng Liu[4] Xue Li[4] Zhenghaoyu Huang[3] Xijuan Wei[4] Zheng Li[5] YONGHONG GUO[4], [1]The Third Hospital of Xi'an, [2]Department of Endocrine, Shanghai Pudong New Area Gongli Hospital, [3]School of Gongli hospital Medical Technology,University of Shanghai for Science and Techonology, [4]Department of Infectious Disease, Shanghai Pudong New Area Gongli Hospital, [5]Laboratory for Functional Glycomics, College of Life Sciences, Northwest University

Background: Hepatic fibrosis is characterized by a self-perpetuating cycle involving the activation of hepatic stellate cells (HSCs) and the pathological stiffening of the extracellular matrix (ECM). The specific role of glycosylation in this process remains to be elucidated. **Methods:** Bioinformatic analysis of enzyme fucosyltransferase 8(Fut8)expression patterns was conducted utilizing data from the TCGA and GEO databases. Fut8 knockdown was achieved via siRNA transfection in LX-2 cells. Lectin affinity glycoproteomics, principal component analysis, and hierarchical clustering were employed to identify core fucosylation-modified proteins. The expression of SPARC was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

validated by Western blotting, and the core fucosylation levels of SPARC were quantified through LCA immunoprecipitation. Fut8 overexpression was induced through adenoviral infection, while competitive inhibition of Fut8 was performed using 2-deoxy-2-fluoro-L-fucose (2FF) at a concentration of 100 μM, with a 48-hour pretreatment period. Control groups included normal HSCs and a group treated with TGF-β at 10 ng/mL as a positive control. Phenotypic and pathway analyses were conducted by assessing fibrotic markers collagens and α-Smooth Muscle Actin(α-SMA) via quantitative PCR and Western blotting.The interaction between SPARC and COL I was analyzed using AutoDock software to examine the impact of glycosylation on their binding interaction. Statistical analysis was conducted on data from three biological replicates using ANOVA followed by Tukey's test (GraphPad Prism 9.0; $p < 0.05$). **Results:** The results demonstrated a significant upregulation of Fut8 expression in fibrotic liver tissues, which was correlated with HSCs activation. Knockdown of Fut8 resulted in the downregulation of TGF-β/Smad2/3, Wnt/β-catenin, and integrin signaling pathways. Lectin affinity glycoproteomics identified 92 upregulated and 118 downregulated proteins following Fut8 inhibition, including SPARC-interacting type I collagen(COL I)and fibronectin (FN). Additionally, Fut8 knockdown led to reduced core fucosylation of SPARC and mitigated the pathological accumulation of COL I and FN. Overexpression of Fut8 led to increased levels of COL I, FN, and α-SMA ($p < 0.05$ compared to control). Molecular docking analysis reveals that core fucosylation of SPARC enhances its binding affinity to type I collagen via hydrogen bonding, with a binding energy of -5.53 kcal/mol, whereas non-core fucosylated SPARC does not bind. This interaction facilitates pathological crosslinking and stiffening of the ECM. **Conclusion:** These findings underscore that Fut8-mediated core fucosylation of SPARC augments its binding to COL I through conformational remodeling, thereby promoting ECM crosslinking and stiffness. Inhibition of core fucosylation by targeting Fut8 mitigates these fibrogenic pathways and alleviates hepatic fibrosis.

3368 | LIVER STIFFNESS RESPONSE AND HETEROGENEITY ASSESSED VIA MAGNETIC RESONANCE ELASTOGRAPHY IN ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED LIVER DISEASE: RESULTS: FROM PHASE 2 STUDIES OF FAZIRSIRAN

Chien-Lin Yeh[1] Talakad Lohith[1] Ozlem Yardibi[1] Jen-Chieh Chuang[1] Vandana Gupta[1] Chantal Beauchemin[1] Abeer Zeitone[1] Susana Gonzalez[1] Nirav Desai[1] Thomas Schluep[2] James Hamilton[2] Virginia Clark[3] Pavel Strnad[4] Rohit Loomba[5], [1]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [2]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, USA, [3]University of Florida, Gainesville, FL, USA, [4]University Hospital RWTH Aachen, Aachen, Germany, [5]University of California San Diego, San Diego, CA, USA

Background: Liver stiffness measurement (LSM) via magnetic resonance elastography (MRE) offers an alternative to liver biopsy for the detection and monitoring of fibrosis in patients (pts) with alpha-1 antitrypsin deficiency-associated liver disease (AATD-LD). Spatial heterogeneity of LSM via MRE has been characterized in pts with MASLD, viral hepatitis and PSC, but not AATD-LD. We evaluated spatial heterogeneity of LSM via MRE in pts with AATD-LD after fazirsiran treatment (an investigational siRNA therapy) and concordance between MRE- and biopsy-based liver fibrosis assessments. **Methods:** Baseline (BL) and post-treatment MRE and histology data from pts with AATD-LD who received fazirsiran or placebo in AROAAT-2001/-2002 (NCT03945292/NCT03946449) were included. LSM via MRE was an exploratory endpoint in both studies. MRE data were collected at BL and at one of the Week (Wk) 24/48/72/96 visits. Histograms were used to map LSM distribution within the tissue region of interest from BL to end of study and Kullback-Leibler divergence (K-L distance) was used to calculate the magnitude of shift. MRE heterogeneity metrics (entropy, variability, coefficient of variation [CoV]) were calculated, with significance of change determined by repeated measures ANOVA. **Results:** Overall, 20 pts enrolled in AROAAT-2001/-2002 treated with fazirsiran (n = 17) or placebo (n = 3) had BL and ≥ 1 follow-up MRE assessment. Both MRE imaging (Figure) and histograms showed a change in LSM after

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

fazirsiran treatment. Mean peak LSM across imaging slices was 7.8 kPa at BL and 4.6 kPa at Wk 48 after fazirsiran treatment (not significant); values remained similar in pts treated with placebo from BL to Wk 48 (5.8 vs 5.6 kPa). Based on MRE histograms, mean K-L distance from BL to Wk 48 after fazirsiran treatment was 3,000 across BL fibrosis stages defined by MRE (F1–3; n = 11) and 1,776 across BL fibrosis stages defined by biopsy-based METAVIR (F1–4; n = 11; differences not significant); no shift was observed for placebo or in pts with a BL F0 fibrosis stage. A larger shift was observed at higher BL MRE fibrosis stages, while treatment response was similar regardless of BL METAVIR stage. From BL to Wk 48 after fazirsiran treatment, heterogeneity assessed by mean entropy significantly decreased (5.2 vs 4.7 nats; $p < 0.05$); mean variability (81.7% vs 76.7%) and CoV (27.4% vs 25.3%) declined after treatment, although changes were not statistically significant. **Conclusion:** MRE imaging in AATD-LD using histogram-based spatial LSM distribution and heterogeneity metrics offer additional granularity relative to biopsy. After fazirsiran treatment, heterogeneity metrics indicated a trend towards improved liver stiffness uniformity across fibrotic regions. Further MRE image analyses using radiomics from larger cohorts of pts with AATD-LD may yield robust features for monitoring and predicting treatment response.

3369 | DEVELOPMENT OF A FIBROSIS INDEX USING MACHINE LEARNING TO PREDICT LIVER FIBROSIS PROGRESSION IN CHRONIC LIVER DISEASE

David Zhang[1] Alexandra Greb[1], [1]David Geffen School of Medicine at UCLA

Background: Timely identification of liver fibrosis progression is critical in chronic liver disease management. While several noninvasive modalities assess fibrosis stage, tools that predict fibrosis progression over time remain limited. We aimed to develop a predictive model using routinely available laboratory data and validate a fibrosis index for progression risk stratification. **Methods:** We conducted a retrospective chart review of adult patients ($\geq$ 18 years) at UCLA from January 2015 to December 2024 with chronic liver disease who underwent two or more liver fibrosis assessments (via Fibroscan, ultrasound elastography, MR elastography, or liver biopsy) at least one year apart. The primary outcome was fibrosis progression, defined as an increase of $\geq$1 fibrosis stage from baseline. Demographics, liver disease etiology, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

laboratory values were extracted. Generalized linear models (GLM) identified univariate and multivariate predictors. A random forest classifier was trained using the most significant variables to generate a probability score ("Fibrosis Index"). Model performance was evaluated using accuracy, positive predictive value (PPV), and negative predictive value (NPV). A web-based calculator was developed for clinical use. **Results:** A total of 230 patients were included. The cohort had a mean age of 58.6 years, with 59% female and diverse etiologies including MASLD/MetALD (52%), HBV (11%), and autoimmune liver disease (9%). On univariate and multivariate GLM, lower CO2 and higher AST and INR were independently associated with fibrosis progression ($p < 0.05$). These variables were used to train a random forest model, which achieved an accuracy of 0.84. The model's PPV was 85.7%, and NPV was 89.7%. The Fibrosis Index score, derived from model probabilities, was significantly associated with fibrosis progression ($p = 0.009$). A 40% threshold of the Fibrosis Index score demonstrated a PPV of 96% and an NPV of 97.6%. An online tool was developed to support clinical use (https://fibrosis-index.shinyapps.io/fibrosis_index/). **Conclusion:** We developed and validated a machine learning–based Fibrosis Index using routine labs to predict fibrosis progression in chronic liver disease. The index demonstrates strong predictive accuracy and may assist clinicians in identifying patients at higher risk for disease advancement.

3370 | EARLY TISSUE DAMAGE–DERIVED CELLS ORCHESTRATE THE FORMATION OF AGE-RELATED SENESCENT MICROENVIRONMENTS

Kwon Yong Tak[1] Seoyeong Lee[2] Juyeon Kim[3] Chuna Kim[3] Jong-Eun Park[2] Yongjun Koh[2], [1]Seoul St. Mary's Hospital, [2]KAIST, [3]KRIBB

Background: Recent findings suggest that senescent cells organize into spatially restricted niches, evolving from localized early aging environments into widespread aged regions. Using the Fibrotic Niche (FiNi)-seq technique, we previously enriched and profiled age-associated niches within fibrotic liver microenvironments. In this study, we extend FiNi-seq to early liver injury models to uncover the origin and trajectory of senescent niches and to track their maturation into aged microenvironments via transcriptional profiling of senescent cell populations. **Methods:** We collected liver cells from young (3 months) and old (22 months) mice using both control and FiNi-seq approaches and were evaluated using in-vitro culture and single-cell RNA sequencing (scRNA-seq) to elucidate the age driver populations. Their spatial context were validated using Visium spatial transcriptomics (GSE192742), in-house Stereo-seq, RNA-scope, and immunohistochemistry. To examine whether early liver injury initiates senescent microenvironments, we applied FiNi-seq and snFiNi-ATAC-seq to early damage models of DDC-diet and CCl4. **Results:** FiNi-seq identified specific cell types driving the formation of age-associated fibrotic niches within defined spatial regions (Figure 1).

When applied to early liver injury models, FiNi-seq revealed an increase in mesenchymal cell populations and a shift in myeloid cells marking the onset of fibrosis. We also observed expansion of Fibrotic EC as early as 7 days after DDC exposure (Figure 2).

FiNi-seq and FiNi-ATAC-seq of livers at 1 week, 3 weeks, and post-recovery stages showed progressive expansion of Fibrotic_ECs, even persisting post-recovery. Profiling chromatin accessibility revealed differential activity in acute damage versus aging and post-recovery (Figure 3).

Fibrotic_ECs in DDC injury exhibited transcriptional signatures of early inflammation, while aged counterparts displayed DNA damage–associated patterns. Although both promoted angiogenic transcription factor (TF) activity, the specific TF usage varied with the degree of inflammation and tissue context (Figure 3). **Conclusion:** This study reveals that early, mild tissue injury can initiate the formation of senescent microenvironments, using FiNi-seq and chromatin accessibility profiling. Fibrotic_ECs emerge early in liver damage and persist even after apparent tissue recovery, suggesting a durable reprogramming event. These cells display distinct transcriptional and epigenetic traits shaped by inflammation, hypoxia, and angiogenic cues, differing by context of age versus injury. This framework provides a new perspective on how cellular responses to damage can act as a central driver of aging phenotypes and opens the door for targeting early microenvironmental changes to delay or modulate age-related tissue decline.

3371 | POTENT ANTIFIBROTIC EFFECTS OF ONCOLYTIC REOVIRUS ON LIVER FIBROSIS VIA RESTORATION OF ACTIVATED HEPATIC STELLATE CELLS TO QUIESCENT STATUS FOLLOWING INTRAVENOUS ADMINISTRATION

Ikuho Ishigami[1] Kanako Nakagawa[1] Yuki Kibe[1] Shunsuke Inoue[1] Takuya Yamashita[2] Kazuya Nagano[2] Kazuo Ohashi[3] Hiroyuki Mizuguchi[1] Fuminori Sakurai[4], [1]Osaka University, [2]Wakayama Medical University, [3]Ohashi General Internal Medicine and Surgery Clinic, [4]Kindai University

Background: Liver fibrosis is often caused by chronic inflammation which is induced by various factors, including hepatitis virus infection and excessive alcohol consumption. Although many patients suffer from liver fibrosis, there are few curative medicines. A curative agent that not only suppresses the progression of fibrosis but also reverses fibrotic tissue to a healthy one is urgently needed. We previously revealed that mammalian orthoreovirus type 3 Dearing (reovirus), which has been actively studied as an oncolytic virus in clinical trials, significantly reduced the extracellular matrices (ECMs) in the tumors of subcutaneous tumor-bearing mice. These findings let us hypothesize that reovirus could show efficient anti-fibrotic effects on liver fibrosis. **Methods:** Liver fibrosis levels were evaluated by measuring fibrosis marker gene expression and ECM disposition 1 week after intravenous administration of reovirus in CCl4-induced liver fibrosis mice. Next, we examined which type of cells in the liver took up reovirus following intravenous administration. Furthermore, fibrosis marker gene expression in LX-2 cells (a human hepatic stellate cell line) was evaluated after reovirus treatment. Furthermore, we investigated the lipid storage and migration activity in LX-2 cells following reovirus treatment. **Results:** After intravenous administration, reovirus efficiently reduced the fibrosis marker gene expressions, including ACTA2 and COL1A, and the ECMs deposition in the liver to 1/10-1/3 without apparent hepatotoxicity or virus replication. Reovirus was mainly taken up by activated hepatic stellate cells. Fibrosis marker gene expressions were also apparently reduced in LX-2 cells by reovirus without apparent cell death or virus replication. Furthermore, PCA analysis of LX-2 cells indicated that reovirus treatment led to a transcriptome shift of activated status to quiescent one. Lipid storage and migration activity of LX-2 cells was significantly restored by reovirus treatment. **Conclusion:** Viruses have been generally considered to cause tissue fibrosis by chronic inflammation. Here, we demonstrated that reovirus showed significant anti-fibrotic effects on liver fibrosis mice and activated HSCs. Furthermore, reovirus not only suppressed fibrotic marker gene expressions, but also restored the properties of myofibroblast-like activated HSCs to quiescent HSCs. Together, this study showed

the potential of oncolytic reovirus of drug repurposing for the treatment of tissue fibrosis.

3372 | THE MECHANISM OF HYDROXYNIDONE IN THE TREATMENT OF LIVER FIBROSIS BY TARGETING CTSL-SIRT1 TO REGULATE LIPID METABOLISM REPROGRAMMING OF HEPATIC STELLATE CELLS.

hanjing zhangdi[1] Qichao Ge[2] Hui Huang[3] Yuecheng Guo[2] Yufei Yang[2] Qingqing Zhang[2] Junjun Wang[4] Zhenyang Shen[2] Yanping Ye[5] Ling Zhang[5] Ying Luo[5] Xiaobo Cai[2] Hui Dong[2] Hu Zhou[3] Lungen Lu[2], [1]Department of Gastroenterology, Shanghai General Hospital, S, [2]Department of Gastroenterology, Shanghai General Hospital, [3]Department of Analytical Chemistry, State Key Laboratory of Drug Research, [4]Department of Gastroenterology, Shanghai General Hospital., [5]Continent Pharmaceuticals Co.,Ltd., Beijing, China

Background: The imbalance of lipid metabolism homeostasis in hepatic stellate cells (HSC) can trigger its activation and lead to liver fibrosis. Our team confirmed that hydronidone(HDD) can reverse liver fibrosis in clinical patients through clinical phase II (54.8% improvement) and phase III trials (52.85% improvement). Accordingly, we will further explore the mechanism and therapeutic targets of HDD in reversing liver fibrosis. **Methods:** We constructed a mouse liver fibrosis model by intraperitoneal injection of CCL4 and DDC diet, and established a mouse liver fibrosis treatment model by oral administration of hydronidone. The activated and quiescent HSCs of mice before and after hydronidone treatment were screened by single cell sequencing. The therapeutic target of hydronidone was screened as CTSL protein by DARTS-MS analysis in mouse HSC. SPR, CETSA, fluorescence co-localization experiments, molecular docking and other experiments confirmed that CTSL was the target of hydronidone in HSC. The changes of RNA level, protein level and enzyme activity of CTSL before and after hydronidone treatment were detected by PCR, WB and specific fluorescence substrate consumption experiment. The changes of lipid metabolism in HSC before and after hydronidone treatment were detected by immunofluorescence, lipid fluorescence probe staining, mitochondrial fluorescence probe staining and lysosomal fluorescence probe staining. Through in-depth analysis of lipid metabolomics technology and IP-MS, the downstream protein of CTSL enzyme was screened as SirT1. The changes of lipid metabolism in HSC before and after treatment were detected by Seahorse test. To regulate the expression of CTSL and SirT1 in mouse hepatic stellate cells by constructing lentivirus. **Results:** Hydronidone was found to partially reverse liver fibrosis in both CCL4 and DDC treatment models. DARTS-MS screening showed that CTSL protein was the target protein of hydronidone in HSC, and hydronidone in HSC was detected to bind to CTSL protein stably. In addition, we found that hydronidone treatment did not change the RNA and protein levels of CTSL in HSC, but changed the enzyme activity of CTSL. CO-IP experiments confirmed the interaction between CTSL and SirT1, and overexpression of CTSL reduced the degradation expression of SirT1. When hydronidone treats TGF-β1-induced activated HSC, the endogenous lipid droplets of HSC will be partially restored, reducing the occurrence of β-oxidation in HSC and inhibiting HSC activation. Knockdown of SirT1 inhibited the therapeutic effect of hydronidone on activated HSC, increased lipid metabolism in HSC and reversed the therapeutic effect of hydronidone on activated HSC. **Conclusion:** By targeting the CTSL enzyme active site in HSC, hydronidone inhibits the degradation of SirT1 by CTSL, thereby protecting the intrinsic endogenous lipid droplets of HSC and inhibiting HSC activation, thereby reversing liver fibrosis.

3373 | DIAGNOSTIC VALUE OF SERUM SOLUBLE CD146 IN THE PROGRESSION OF CHRONIC LIVER DISEASE

Bingqing Yang[1] Yue Li[1] Xinhua Ren[1] Jingya Yin[1] Chenxue Hou[1] Qi Wang[1], [1]Beijing Ditan Hospital, Capital Medical University, Beijing, China.

Background: Chronic liver disease (CLD) has a high global prevalence and often progresses to hepatic fibrosis and cirrhosis, which, in severe cases, may lead to liver failure or hepatocellular carcinoma. Thus, there is an urgent need for more sensitive, specific, and cost-effective non-invasive biomarkers. This study aimed to investigate the expression pattern of serum soluble CD146 (sCD146) in chronic liver disease and evaluate its potential as a diagnostic marker. **Methods:** Serum samples were collected from 300 individuals at Beijing Ditan Hospital, Capital Medical University, including healthy controls undergoing routine physical examinations (n = 54) and patients at various stages of chronic liver disease (n = 246). Serum sCD146 levels were measured using enzyme-linked immunosorbent assay (ELISA). Differences in sCD146 expression across disease stages were analyzed, and correlations with FIB-4 scores were assessed. Receiver operating characteristic (ROC) curve analysis was conducted to evaluate the diagnostic performance of sCD146, including calculation of area under the curve (AUC), sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and optimal cutoff values. **Results:** Serum sCD146 levels were significantly higher in CLD patients than in healthy controls (466.28 ng/mL vs. 370.07 ng/mL, $P < 0.01$). sCD146 levels increased progressively with disease severity: chronic hepatitis (405.88 ng/mL), liver fibrosis (428.43 ng/mL), compensated cirrhosis (549.14 ng/mL), and decompensated cirrhosis (776.93 ng/mL), with statistically significant differences among groups ($P < 0.05$). A strong positive correlation was observed between sCD146 levels and FIB-4 scores ($\rho = 0.670$, $P < 0.01$). In cirrhotic patients, sCD146 levels rose with advancing Child-Pugh classification, with significantly higher levels in class C than class B (999.74 ng/mL vs. 623.08 ng/mL, $P < 0.05$).

ROC analysis showed increasing diagnostic performance of sCD146 across disease stages, with AUCs of 0.574 for chronic hepatitis, 0.689 for hepatic fibrosis, 0.794 for compensated cirrhosis, and 0.842 for decompensated cirrhosis. Notably, sCD146 showed the highest diagnostic efficacy in decompensated cirrhosis, with a Youden index of 0.6151, sensitivity of 75.00%, and specificity of 86.51%. These findings suggest that sCD146 may serve as a non-invasive serum biomarker for assessing CLD progression, particularly for identifying decompensated cirrhosis. **Conclusion:** This study demonstrates that serum sCD146 is significantly associated with the progression of chronic liver disease. sCD146 exhibits diagnostic value across various stages of CLD, with particularly high sensitivity and specificity in detecting decompensated cirrhosis, underscoring its potential as a non-invasive biomarker for disease monitoring and risk stratification.

	AUC(95%CI)	Cutoff value	Sensitivity(%)	Specificity(%)	PPV(%)	NPV(%)	Youden Index
Chronic Hepatitis	0.574(0.479,0.669)	396.0	56.18	61.11	71.43	44.19	0.1729
Liver Fibrosis	0.689(0.600,0.777)	389.2	69.95	52.45	33.33	90.37	0.3340
Compensated Cirrhosis	0.794(0.723,0.866)	451.1	74.63	77.64	58.15	87.92	0.5247
Decompensated Cirrhosis	0.842(0.775,0.910)	573.6	75.00	86.51	48.28	95.12	0.6151

3374 | A GENE EXPRESSION SIGNATURE CORRELATES WITH FIBROSIS SEVERITY IN PATIENTS WITH MASH, ALCOHOL-ASSOCIATED LIVER DISEASE, AND VIRAL HEPATITIS

Jennifer Chen[1] Srilaxmi Nerella[1] Carson Cable[1] Vijaya Prathigudupu[1] Mandana Khalili[1] Stephanie Christenson[1], [1]University of California, San Francisco

Background: Liver fibrosis is characterized by an accumulation of extracellular matrix proteins and leads to progressive organ dysfunction. While there have been advances in noninvasive diagnostic tests that detect advanced fibrosis, there is a paucity of tools that capture the heterogenous pathways that drive fibrogenesis. To develop a precision approach towards hepatic fibrogenesis, clinical biomarkers that measure dysregulated pathways among patients are needed, which will facilitate development of targeted therapies. We previously developed a gene signature score, the ceramide-YAP score, based on our preclinical studies in human hepatic stellate cells. Here, we aimed to elucidate the association between the ceramide-YAP score, fibrosis severity, and disease progression among patients with different etiologies of chronic liver disease. **Methods:** To explore the correlation between the

ceramide-YAP score and fibrosis severity among patients with different etiologies of chronic liver disease, we reviewed datasets in Gene Expression Omnibus of liver tissue samples that included fibrosis stage by histologic scoring from 2000-2023. This identified a total of 6 datasets. Raw genome profiling data were downloaded from GEO and normalized using previously validated methods. The ceramide-YAP score was generated on a per-subject basis by combining the log2 gene expression of the genes in the ceramide-YAP using the GSVA algorithm as previously performed. We utilized Mann-Whitney U tests to measure the association between the signature and histologic staging. **Results:** The Ceramide-YAP signature score significantly increased with fibrosis severity among patients with chronic hepatitis B, chronic hepatitis C, alcohol-associated liver disease, and MASH. Among patients with HCV cirrhosis, we did not observe an association between the ceramide-YAP score and progression to Child-Pugh B or C, death, or HCC. **Conclusion:** Our studies demonstrate that the ceramide-YAP score correlates with fibrosis severity among patients with alcohol-associated liver disease, MASH, HBV, and HCV infection. This work suggests that the ceramide and YAP pathways are dysregulated with fibrogenesis and may serve as biomarkers to identify patients whom may benefit from targeted therapies.

3375 | RESOLVING FIBROSIS BY STIMULATING HSC-DEPENDENT EXTRACELLULAR MATRIX REMODELING

Sachin Sharma[1] Vijaya Prathigudupu[1] Carson Cable[1] Alina Chen[1] Srilaxmi Nerella[1] Carlos Lizama Valenzuela[1] Tatsuya Tsukui[1] Jaejun Kim[1] Holger Willenbring[1] Aras Mattis[1] Balyn Zaro[1] Lia Serrano[2] Josh Coon[2] Richard Beresis[1] William DeGrado[1] Hyunil Jo[1] Stephanie Christenson[1] Jennifer Chen[1], [1]University of California, San Francisco, [2]University of Wisconsin-Madison

Background: Tissue fibrosis arises from a critical imbalance between the production and breakdown of extracellular matrix (ECM) components. While current strategies predominantly focus on curbing ECM production, the possibility of promoting ECM degradation to resolve fibrosis remains largely untapped. The role of hepatic stellate cells (HSCs) in ECM degradation is an intriguing area for investigation. We previously identified that inhibiting acid ceramidase (aCDase) increases ceramide to ameliorate liver fibrosis. Here, we describe mechanistic studies aimed at clarifying how targeting aCDase reduces tissue collagen, focusing on the role of HSC-mediated matrix degradation. **Methods:** Ceramide-treated HSCs were profiled by RNA sequencing, proteomics, and phosphoproteomics. Liver fibrosis induced by carbon tetrachloride (CCl_4) and fructose, palmitate, cholesterol, and *trans* fat (FPC) models was inhibited using a newly developed aCDase inhibitor compound 5A, and results were compared to those observed using an inducible HSC-specific deletion of aCDase. Mouse HSCs were isolated using flow cytometry and cell sorting. ECM remodeling was analyzed by immunostaining with an antibody that recognizes degraded type 1 collagen; collagen hybridizing peptide; Sirius red staining; and second harmonic generation microscopy following liver decellularization. We conducted gene set enrichment analysis on liver tissue samples from individuals with metabolic dysfunction-associated steatotic liver disease (MASLD) and stratified by fibrosis severity. **Results:** RNA sequencing and proteomics demonstrated that ceramide increased levels of matrix metalloproteinases (MMPs), including MMP1, to promote pericellular collagen degradation. Through phosphoproteomic analysis, we identified that the effects of ceramide on MMP1-mediated collagen degradation were dependent on PRKCα, ERK1/2, and AP-1 signaling since pharmacologic inhibition or siRNA depletion of each mitigated the effect of ceramide. Inducible deletion of aCDase in CCl_4-treated mice increased *Mmp1a* and *Mmp1b* expression in HSCs, increased collagen degradation, and promoted fibrosis regression. Inhibition of aCDase with compound 5A recapitulated these findings in the FPC model of fibrosis. Among MASLD patients, pathway analysis revealed that ceramide signaling is highly associated with ECM remodeling. **Conclusion:** These findings underscore the critical role of HSCs in ECM degradation. We identified a novel signaling axis in HSCs whereby ceramide promotes PRKCα-ERK1/2-AP1-MMP1 to increase collagen degradation. This work reveals potential targets to promote regression in patients with tissue fibrosis.

3376 | MEDICATION ADHERENCE IN WILSON DISEASE PATIENTS TREATED WITH TRIENTINE TETRAHYDROCHLORIDE SUPPLIED BY A SINGLE SOURCE SPECIALTY PHARMACY

jamie Heise[1] Veronica Tomor[1] Christina Dockery[1] Nick Manamley[2] Michael Heifets[1] Maria DiVito[3] Frances Youschak[3] Joshua Sherback[3] Frederick Askari[4], [1]Orphalan Inc, [2]Orphalan UK Ltd, [3]PANTHERx Rare Pharmacy, [4]University of Michigan Medical Center

Background: Wilson disease (WD) is a rare inherited disorder characterized by copper accumulation, which can be fatal if untreated. Prognosis improves significantly with early diagnosis, effective copper control, and sustained lifelong therapy. Adherence to treatment is essential for achieving optimal clinical outcomes; however, it remains a significant challenge for patients, and poor adherence is associated with disease progression. Trientine tetrahydrochloride (TETA-4HCl, Cuvrior®) received FDA approval in 2022 and became commercially available in April 2023. In the USA, TETA-4HCl tablets are dispensed to patients through a single-source rare disease specialty pharmacy.
Aim/Objective: Retrospective analysis to characterize the patient population and evaluate treatment adherence of TETA-4HCl. **Methods:** A pharmacy database of patients prescribed and having received at least one shipment of TETA-4HCl between May 2023 and December 2024 was evaluated. The following variables were collected and defined: Proportion of Days Covered (PDC): the proportion of days where patients actively have medication on hand over a given time (minimum time for calculation is 180 days); Gap days: defined as the number of days a patient does not have medication on hand based on shipment history (patients included if therapy > 4 months); treatment discontinuation with reasons, demographics and prescriber data. Gap days and PDC were calculated on eligible patients to assess adherence through April 30, 2025. **Results:** During the study period 142 patients were identified and included in the demographics: 78 (55%) males and 64 (45%) females with an overall mean (SD) age of 39 (15.7) years were prescribed TETA-4HCl. Forty-five patients (32%) traveled out of state to consult with their prescriber. Patient payer segmentation was 72% commercial, 15% Medicare, 10% Medicaid, and 3% uninsured. Prescribers were predominantly hepatologists and gastroenterologists at 64% and 23% respectively. Forty-six percent of patients indicated a history of treatment with more than one therapy. Most frequently reported were trientine hydrochloride capsules, zinc salts and penicillamine in that order. Twenty-four patients discontinued therapy; four of those were due to an adverse event. Ninety-three patients met the 180-day threshold for PDC calculation, and 126 were included in the gap day calculation. The mean (SD) PDC was 84 (24) %, with an average gap of 2.7 days per shipment. **Conclusion:** In this real-world analysis of patients with WD receiving TETA-4HCl through a single-source specialty pharmacy, adherence was consistently high with minimal interruption in therapy as described with a gap of 2.7 days per shipment and a low overall discontinuation rate of 17%. The extent to

which single-source pharmacy distribution mitigates barriers to access, reduces treatment burden, and facilitates adherence warrants further investigation.

3377 | ADOPTIVE TRANSFER OF MARCO⁺ MACROPHAGES ATTENUATE LIVER FIBROSIS AND SUPPRESS ECM GENE EXPRESSION IN HEPATIC STELLATE CELLS

Sofia Jerez[1] Shawna Cooper[1] Usman Yaqoob[1] Maria Hernandez-Tejero[1] Luke Doskey[1] Nidhi Jalan-Sakrikar[2] Sheng Cao[2] Vijay Shah[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Macrophages (Macs) play a dual role in liver injury, acting as promoters or suppressors of fibrosis depending on their phenotype and the environment. Macs expressing the scavenger receptor MARCO (Macrophage Receptor with Collagenous Structure) increase during fibrosis and have been associated with tissue repair, but their role in the liver remains unclear. Previous findings from our group, using scRNA-seq of fibrotic livers and bone marrow-derived macs (BMDMs), suggest that MARCO⁺ macs exhibit a pro-restorative phenotype. These results prompted us to investigate whether the adoptive transfer of MARCO⁺ BMDMs could attenuate fibrosis and modulate hepatic stellate cells (HSCs), which are the main secretors of extracellular matrix (ECM), in a carbon-tetrachloride (CCl_4)-induced mouse model of liver injury. **Methods:** MARCO expression was induced in BMDMs by LPS stimulus. Next, these cells were FACS-sorted into MARCO⁺ and MARCO- populations and were transferred via the tail vein into recipient mice undergoing CCl_4-induced liver fibrosis. Homing of BMDMs to the liver was confirmed via immunofluorescence, immunoblotting, and flow cytometry. Fibrosis was assessed by Picrosirius red staining. GeoMx DSP was utilized to spatially analyze the transcription profile of HSCs within regions enriched in MARCO⁺ versus MARCO- macrophages, in response to cell transfer. **Results:** Marco⁺ BMDMs successfully homed to the liver and reached injured areas as assessed by immunostaining. Adoptive transfer of MARCO⁺ BMDMs significantly reduced collagen deposition and bridging fibrosis (FC = 0.5, P < 0.05) compared to MARCO⁻ or no cell transfer. Spatial transcriptomic analysis revealed that HSCs from mice that received MARCO⁺ BMDMs (17 Regions of Interest [ROIs] analyzed) presented downregulation of ECM genes, including collagens *Col1a1* and *Col3a1* (FC = 0.3, P < 0.01) and modulatory components such as *Dcn* and *Ecm1* (FC = 0.4, P < 0.01). These transcriptional changes were not observed in fibrotic livers without cell transplantation (16 ROIs analyzed), indicating that the observed gene modulation was specific to the transferred MARCO⁺ BMDMs. Pathway analysis confirmed suppression of key fibrotic pathways, including collagen biosynthesis, collagen trimerization, and fibril assembly. **Conclusion:** Adoptive transfer of MARCO⁺ macs reduces liver fibrosis in vivo and exerts anti-fibrotic effects by downregulating the expression of ECM-related genes in HSCs. These findings highlight the therapeutic potential of MARCO⁺ macs as a cell-based strategy for treating liver fibrosis.

Background: Nucleic acid-induced activation of the anti-viral transcription factor interferon regulatory factor 3 (IRF3) mediates hepatic fibrogenesis in multiple experimental murine models. IRF3 promotes transforming growth factor-beta (TGFβ)-induced fibrotic responses of cultured hepatic stellate cells (HSCs). **Methods:** Short interfering RNA (siRNA)-mediated gene silencing was performed in human LX2 HSCs, and primary HSCs were isolated from wild-type (WT) and Toll-like receptor 3 knock-out (*Tlr3*$^{-/-}$) mice. Fibrogenic gene expression and accumulation of extracellular matrix proteins were determined by quantitative real-time polymerase chain reaction and Western blot analysis of conditioned media, respectively. The presence of cytoplasmic double-stranded RNA (dsRNA) was assessed by immunofluorescence. HSC-specific *Tlr3* knock-out (*Lrat-Cre;Tlr3*$^{fl/fl}$) and control *Tlr3*$^{fl/fl}$ mice were subjected to the chronic carbon tetrachloride (CCl_4) hepatic fibrosis model. **Results:** *IRF3* gene-silencing decreased TGFβ-induced collagen 1A1 (*COL1A1*) mRNA expression and extracellular accumulation in LX2 cells. In order to identify proximal recognition molecules critical to IRF3 activation in TGFβ-induced fibrotic responses, we utilized siRNA technology to assess the contributions of upstream receptors and convergent common adaptors. In addition to stimulator of interferon genes (*STING*), gene-silencing of *TLR3* decreased TGFβ-stimulated *COL1A1* mRNA expression and extracellular accumulation. *Tlr3*$^{-/-}$ primary murine HSCs exhibited decreased *Col1a1* mRNA expression as compared to HSCs isolated from WT mice. Cytoplasmic accumulation of dsRNA was observed both during differentiation of WT primary murine HSCs and upon TGFβ stimulation in LX2 cells. Finally, *Lrat-Cre;Tlr3*$^{fl/fl}$ mice exhibited decreased CCl_4-induced hepatic *Col1a1* mRNA expression as compared to control *Tlr3*$^{fl/fl}$ mice. **Conclusion:** Collectively, these findings identify a cell-intrinsic contribution for TLR3-dependent activation of IRF3 in fibrotic responses of HSCs, which is likely mediated by sensing of accumulated endogenous dsRNA by TLR3. **Disclosures:** Jared Travers: Nothing to Disclose, Yingting Zhang: Nothing to Disclose, Megan McMullen: Nothing to Disclose, Christina Cajigas-Du Ross: Nothing to Disclose, Emily Huang: Nothing to Disclose, Jianguo Wu: Nothing to Disclose, Laura Nagy: Nothing to Disclose

3379 | IDENTIFICATION OF TBX20 AS A MEDIATOR OF HEPATIC STELLATE CELL MEMORY AND PLASTICITY

Alvaro Gonzalez Dominguez[1] *Twinkle Bapuji Vhatkar*[1] *Maylene Yu*[1] *Xuedi Wang*[1] *Deniz Demircioglu*[1] *Saul Carcamo*[1] *Dan Hasson*[1] *Scott Friedman*[2] *Shuang Wang*[1], [1]*Icahn School of Medicine,* [2]*Icahn School of Medicine at Mount Sinai (ISMMS)*

Background: Following acute liver injury hepatic stellate cells (HSCs) are activated to repair the liver but without scarring; however, recurrent liver injury disrupts this balance generating a fibrotic organ. Thus, following repeated injury, HSCs can undergo cycles of activation/deactivation, with deactivated HSCs showing a sensitized response characterized by an intensified expression of fibrogenic genes (Kisseleva 2012, Troeger 2012). Our goal is to understand this maladaptive response of HSCs to repeated injury. **Methods:** In our murine model of fibrogenic memory, animals with or without previous fibrosis regression were exposed to acute carbon tetrachloride-induced liver injury. Single nucleus RNA and ATAC sequencing (snRNAsesq/ATACseq) were carried out at critical timepoints to characterize the transcriptomic and epigenomic changes in HSCs using R/Python packages. HSCs-specific *Tbx20* knockout mice were generated by crossing *Tg(Lrat:Cre)* mice with *Tbx20* floxed mice. **Results:** Following fibrosis regression, the transcriptome of HSCs returned to baseline but epigenomic changes remained as depicted by a drastically altered chromatin accessibility landscape. This "epigenetic memory" in HSCs from regressed mice leads to an increase in HSC plasticity following repeated injury, with novel subsets of HSCs taking up alternative cell identities, such as epithelial, endothelial, or immune. Computational pipelines to predict gene regulatory networks (GRNs) enriched in HSCs across different conditions identified dynamic changes in the TBX20 GRN with repeated injuries, pointing to Tbx20 as a mediator of cell memory and plasticity in HSCs. In line with this finding, knocking out *Tbx20* in HSCs did not affect HSC's response to initial injury but only affected their response to repeated injury. **Conclusion:** We describe for the first time how HSCs retain an epigenetic memory of previous insults, and how this memory leads to increased cell plasticity following repeated injuries to the liver. Furthermore we identify the *Tbx20* GRN as a key mediator of HSC's memory and plasticity.

3380 | ACTIVATION OF THE INTEGRIN αV-YAP-CTGF AXIS IN LSECS PROMOTES LIVER FIBROGENESIS IN CONGESTIVE HEPATOPATHY

Seiya Kato[1] Yoichi Sasaki[1] Kenji Fukumoto[1] Yuta Myojin[1] Kazuhiro Murai[1] Yuki Tahata[2] Yuki Makino[1] Yoshinobu Saito[1] Takahiro Kodama[2] Hayato Hikita[1], [1]Osaka University Graduate School of Medicine, [2]Osaka University

Background: Congestive hepatopathy (CH), such as right-sided heart failure, post-Fontan surgery and Budd-Chiari syndrome, progresses to liver fibrosis, eventually leading to cirrhosis and cancer despite an absence of significant inflammation. Liver sinusoidal endothelial cells (LSECs) play a key role in liver diseases through angiocrine signaling, which contribute to liver pathogenesis. This study aimed to elucidate the mechanism of CH, focusing on LSECs. **Methods:** Partial IVC ligation (pIVCL) was performed to induce hepatic congestion in mice. Single-cell RNA sequencing (scRNA-seq) was performed using murine livers after pIVCL. As in vitro experiments, primary murine LSECs or TMNK-1 cells, human liver endothelial cell line, were subjected to hydrostatic pressure stimulation (HPS). scRNA-seq and spatial transcriptomics were performed using human livers from patients with Fontan-associated liver disease (FALD). **Results:** The scRNA-seq analysis showed that the integrin signaling pathway and YAP were activated in pericentral LSECs after pIVCL. The most upregulated gene in pericentral LSECs was connective tissue growth factor (CTGF). HPS activated YAP through integrin αV, leading to the upregulation of CTGF and type IV collagen (COL4) expression in LSECs. HPS-induced CTGF upregulation in TMNK-1 cells was suppressed by siRNA-induced YAP silencing, a YAP inhibitor, or an integrin αV inhibitor. LSEC-derived CTGF upregulated the type I collagen (COL1) and COL4 expression in hepatic stellate cells (HSCs). We generated tamoxifen-inducible endothelial cell-specific CTGF knockout mice (Cdh5-CreERT2; $CTGF^{fl/fl}$), followed by pIVCL. CTGF knockout in LSECs suppressed pIVCL-induced liver fibrosis and portal hypertension, and even liver tumorigenesis. Treatment with an integrin αV inhibitor also improved pIVCL-induced liver fibrosis and portal hypertension with the decreased expression of CTGF, COL4 and COL1. The scRNA-seq analysis of clinical FALD samples showed YAP activation and CTGF upregulation in LSECs. Spatial transcriptomics revealed CTGF upregulation in pericentral LSECs from the perisinusoidal fibrosis, and increased COL4 expression in LSECs and increased COL1 expression in HSCs as fibrosis progressed to bridging fibrosis. **Conclusion:** The activation of the integrin αV–YAP–CTGF axis in LSECs plays a crucial role in CH pathology, and therefore, this axis could be a potential therapeutic target for CH.

3381 | THERAPEUTIC POTENTIAL OF EXERCISED EXTRACELLULAR VESICLES IN IMPROVING SARCOPENIA IN CHRONIC LIVER DISEASE

Sukriti Baweja[1] Preeti Negi[2] Anupama Parasar[2] Chhagan Bihari[2] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences, New Delhi, [2]Institute of Liver and Biliary Sciences

Background: Sarcopenia worsens outcomes in chronic liver disease patients, increasing morbidity and mortality. Exercise presents a promising intervention for sarcopenia. Recently, exercised extracellular vesicles (ExEVs), gained attention in muscle-liver crosstalk. This study aims to evaluate the therapeutic effects of ExEVs in sarcopenia-CLD model. **Methods:** ExEVs were isolated at baseline and immediately after 60 mins of hamster wheel running of C57/BL6J mice plasma, characterized using nanoparticle tracking assay and transmission electron microscopy. The ExEVs proteomic cargoes were assessed by mass spectrometry. Sarcopenia was developed in carbon tetrachloride (CCl_4)-CLD mice. After sarcopenia was developed, alongwith CCL4, the 1×10^8 ExEVs or resting EVs were administered intramuscularly on every alternate day and compared with CCl_4 alone (disease control) and vehicle control. Frailty, Grip strength, muscle size, Liver functions test (LFTs) and histology was measured. The gene expression for muscle atrophy (MYOD, Myogenin, MRF4) and myogenesis, myokines, hepatokines, and senescence associated genes were assessed in liver and muscle tissue using qRT-PCR. All parameters were evaluated at 8, 12 and 14 weeks of CCL_4 administration. **Results:** A significant >10-fold increase in total ExEV count post exercise ($p=0.02$) was found than the resting EVs. The ExEV size ranged between 80nm-280nm, with concentration of, $2.65\text{x}10^8 \pm 0.65$particles/ml with zeta potential -17.7 ± 2.4mV. ExEVs cargo proteins were enriched with >7 fold high levels of follistatin, FGF 21, fetuin-B, IGF-1, ApoE, retinol-binding protein-4 than resting EVs. The gait speed, liver frailty index were significantly low by week 8 ($p<0.001$) in CCl_4 mice along with significant increase in liver and muscle fibrosis ($p<0.0003$). By 12 and 14 week of

treatment with ExEVs+CCL4, a significant increase in body weight, muscle mass, muscle strength was found ($p < 0.0001$), while muscle fibrosis ($p = 0.05$), AST ($p = 0.03$), and ALT ($p = 0.05$) levels significantly declined compared to resting EVs+CCL4 and disease controls. The expression of muscle atrophy markers (MuRF1 and Atrogin-1) decreased ($p < 0.0001$), while markers of muscle myogenesis (MYOD, Myogenin, MRF4) increased ($p < 0.0001$) significantly in animals receiving ExEVs than resting EVs. Myostatin levels decreased ($p = 0.004$), while Myonectin ($p = 0.05$), IGF ($p = 0.002$), and IL-6 ($p = 0.01$) increased in muscle tissue while Hepatokines including Follistatin ($p < 0.0001$) and Lect2 ($p < 0.0001$) increased significantly in the liver. **Conclusion:** ExEVs are enriched with myokines and hepatokines. Treatment with ExEVs significantly improved muscle mass, strength, and liver function and modulated muscle regeneration and reduced atrophy. Thus, ExEVs possess potent therapeutic effects in mitigating sarcopenia in a CLD model and can serve as promising living drugs mediating beneficial muscle-liver crosstalk.

3382 | IDENTIFICATION OF NOVEL DRIVERS OF HSC ACTIVATION AND FIBROGENESIS THROUGH LEVERAGING COMPLEMENTARY PROTEOMIC ANALYSIS

Ian Green[1] James Rooney[2] Chunna Guo[2] Reese Baxter[2] Emely Bibian[1] Whitney Smith-Kinnaman[2] Samer Gawrieh[2] Amber Mosley[2] Jessica Maiers[3], [1]Indiana University Indianapolis, [2]Indiana University School of Medicine, [3]Indianapolis School of Medicine

Background: Liver fibrosis is driven by persistent liver injury, characterized by deposition of scar tissue. The major fibrogenic liver cells are Hepatic Stellate Cells (HSCs), which transdifferentiate into myofibroblasts, proliferate, migrate, and secrete matrix proteins. Targeting HSCs is an ideal therapeutic strategy to limit or reverse fibrosis, but has not been successfully achieved in the clinic. While numerous studies have utilized transcriptomics to gain insight into HSC pathophysiology, recent advancements in proteomic analyses have increased the depth of data obtained from approaches such as Mass Spectrometry (MS) and Olink; assessing both global abundance and protein thermal stability. We sought to leverage recently established proteomic techniques and analyses to identify novel drivers of HSC activation and fibrogenesis. **Methods:** Primary hHSCs (ScienCell) were treated with 2ng/mL TGFβ or vehicle for 8 or 24h. Cell lysates were processed directly for proteomic analysis, or incubated along a temperature gradient prior to removal of insoluble proteins to identify changes in protein stability. Soluble proteins were analyzed by TMT-Mass Spectrometry or the Olink Explore 3084 panel (cut off p-value < 0.05). Top targets were validated in patient samples and immortalized HSCs (LX-2 cells), and deleted from LX-2 cells using shRNA to determine their impact on HSC activation. **Results:** MS analysis identified 19 and 131 differently abundant proteins at 8 and 24h TGFβ treatment, while stability of 49 and 140 proteins were changed at 8 and 24h. Olink identified 66 and 150 differentially abundant proteins, and 73 and 196 differentially stabilized proteins at 8 and 24h respectively. Pathway analysis revealed enrichment of proteins involved in matrix organization and fibrogenesis, while changes in protein stability associated with translation initiation and elongation, and protein sorting and trafficking. We validated 5 proteins for investigation: TGFBI, PALLD, SERPINA1, STT3B, and DNAJB11. TGFBI, PALLD, SERPINA1, and DNAJB11 increased in response to TGFβ in LX-2 cells, and TGFBI increased in MASLD patients with F3/F4 fibrosis compared to F0/1. Knockdown of TGFBI, SERPINA1, or STT3B significantly blocked TGFβ-induction of HSC activation markers, highlighting potential fibrogenic roles for these proteins in fibrogenesis. **Conclusion:** Leveraging advanced proteomic techniques and analyses, we identified several novel drivers of HSC activation which could provide essential insight into therapeutic targeting of liver fibrosis.

3383 | ATP-CITRATE LYASE IN HEPATIC STELLATE CELLS PROMOTES LIVER FIBROSIS IN RESPONSE TO CHEMICAL INJURY

Shi Su[1] Lei Zhao[2] Ray Mastriani[3] Stephen Pinkosky[3] David Cohen[1], [1]Brigham and Women's Hospital/ Harvard Medical School, [2]Brigham and Women's Hospital, [3]Esperion Therapeutics, Inc.

Background: Activated hepatic stellate cells (HSCs) are a main driver of liver fibrosis. ATP-citrate lyase (ACLY) converts citrate to acetyl-CoA, which is a substrate for both lipogenesis and lysine acetylation reactions. Using the LX-2 human HSC line, we previously demonstrated that TGFβ-mediated activation increases ACLY expression. Knock down of ACLY reduced mitochondrial respiration and glycolytic activity of LX-2 cells at baseline and in response to activation. The aim of this study was to evaluate whether ACLY expression in HSCs promotes liver fibrosis in response to chemical injury. **Methods:** HSC-specific ACLY knockout (*HSC-Acly*$^{-/-}$) mice were generated by crossing *Acly*$^{f/f}$ with *Lrat*^{cre} mice. Mouse primary HSCs were isolated and cultured from both control (*Acly*$^{f/f}$) and *HSC-Acly*$^{-/-}$ mice for baseline characterization. Immunoblotting was used to assess the expression of key glycolytic enzymes associated with HSC activation and acetylation of lysine residues as an indicator of transcriptional activation. Age-matched chow fed *HSC-Acly*$^{-/-}$ and control mice were subjected to 4 weeks of carbon tetrachloride (CCl_4)-induced liver injury. ACLY expression in the liver post injury was measured using immunoblotting. Plasma hydroxyproline concentrations were measured using enzymatic assays. Liver sections were stained with Hematoxylin and Eosin for hepatocyte necrosis assessment and with trichrome for fibrosis. **Results:** Primary HSCs from *HSC-Acly*$^{-/-}$ mice exhibited lower glycolytic enzyme expression (20% reduction for Hexokinase 2, 62% reduction for Pyruvate kinase), in addition to distinct protein acetylation, versus controls. After CCl_4 treatment, ACLY expression was increased 2.3-fold in control livers, an effect that was markedly attenuated in *HSC-Acly*$^{-/-}$ mice (60% reduction compared to CCl_4 treated controls). In both *HSC-Acly*$^{-/-}$ and control livers, CCl_4 treatment induced substantial hepatocyte necrosis. However, plasma hydroxyproline concentrations in *HSC-Acly*$^{-/-}$ mice were 43% lower than control mice, in keeping with reduced fibrosis observed in livers of *HSC-Acly*$^{-/-}$ mice. **Conclusion:** Upregulation of ACLY in HSCs promotes liver fibrosis in response to chemical injury. We speculate that increased acetyl-CoA levels due to ACLY upregulation promotes histone acetylation, which in turn upregulates expression of glycolytic enzymes required for HSC activation. These findings suggest that ACLY inhibition may be of therapeutic value in the management of fibrotic liver diseases.

3384 | EFFECT OF MESENCHYMAL STROMAL CELL-DERIVED EXTRACELLULAR VESICLES PURIFIED BY PHOSPHATIDYLSERINE AFFINITY METHOD ON A MURINE MODEL OF LIVER FIBROSIS

Ryo Jimbo[1] Hiroyuki Abe[1] Masayuki Yamane[2] Tomoaki Yoshida[1] Naruhiro Kimura[1] Reina Sasaki-Tanaka[1] Takeshi Yokoo[1] Akira Sakamaki[1] Hiroteru Kamimura[1] Tatsuo Kanda[3] Atsunori Tsuchiya[4] Shuji Terai[1], [1]Graduate School of Medical and Dental Sciences, Niigata University, [2]Bio Science & Engineering Laboratory, FUJIFILM Corporation, [3]Uonuma Institute of Community Medicine, Niigata University Medical and Dental Hospital, [4]Faculty of Medicine, University of Yamanashi

Background: Mesenchymal stromal cells (MSCs) and extracellular vesicles (EVs) derived from MSCs have been shown to suppress liver fibrosis and chronic inflammation in cirrhosis, raising expectations for their clinical application. Although there are various extraction methods for EVs, the phosphatidylserine (PS) affinity method, an affinity purification technique targeting PS on the surface of EVs, is expected to extract EVs with higher purity by targeting PS. In this study, we aimed to evaluate the therapeutic efficacy of EVs purified by the PS affinity method against liver cirrhosis. **Methods:** 7- to 10-week-old female mice ($n = 10$) were treated with intraperitoneal injection of carbon tetrachloride twice weekly for 12 weeks to create a liver fibrosis model, and administered MSC-derived EVs purified by PS affinity (PS group), tangential flow filtration (TFF group), and size-exclusion chromatography (SEC group) at 8th weeks. Samples were collected 4 weeks after EVs administration and analyzed by serum biochemistry and liver tissue. **Results:** In serum biochemistry, AST was significantly decreased to

148.0 ± 181.3 IU/L in PS group compared to 454.1 ± 325.6 IU/L in the control group ($p < 0.05$), while it was 251.4 ± 178.7 IU/L in TFF group, and 252.2 ± 162.0 IU/L in SEC group, which were not significantly different from the control group. Changes in ALT were similar to those in AST. Sirius-Red staining of liver tissue showed a significant decrease in the positive area ratio of 3.4 ± 2.2% in PS group, 3.2 ± 2.1% in TFF group, and 3.3 ± 2.0% in SEC group, compared to 5.1 ± 2.9% in the control group ($p < 0.001$). Real-time PCR assay in liver tissue showed a significant decrease in mRNA expression of Timp1 in PS group compared to the control group ($p = 0.0397$), while no significant difference was observed in TFF and SEC groups ($p = 0.74$, $p = 0.42$). Similarly, the mRNA expression of Col1a1 was significantly decreased in PS group ($p = 0.018$) and not significantly different in TFF and SEC groups ($p = 0.71$, $p = 0.19$). **Conclusion:** The PS affinity-purified MSC-derived EVs showed comparable or better efficacy in improving fibrosis and liver injury compared with EVs purified by other methods, suggesting their usefulness for clinical application in the treatment of liver cirrhosis in the future.

3385 | CT-BASED LIVER MORPHOLOGY SCORING AS A TOOL FOR STRATIFYING AGE-RELATED LIVER DISEASE RISK

Nobuyuki Matsumoto[1] Hideaki Takahashi[1] Takuya Ehira[1] Hironori Aoki[1] Yoshihide Morikawa[1] Jun Ishida[1] Minoru Kanazawa[1] Yuki Mihara[1] Kazuma Terashi[1] Keisuke Tateishi[2], [1]St. Marianna University Yokohama City Seibu Hospital, [2]St. Marianna University School of Medicine

Background: Aging leads to both morphological and functional changes in various organs. While the relationship between age, organ morphology, and organ function has been suggested, research on liver morphology using imaging modalities remains limited. Although recent studies have focused on age-related decline in liver function and fibrosis, quantitative evaluation of morphological changes using CT imaging is scarce. This study aimed to evaluate age-related morphological changes of the liver in a population of generally healthy adults using non-contrast-enhanced CT, and to investigate the potential of such changes as non-invasive markers of aging and liver disease risk. **Methods:** We retrospectively analyzed adult cases who underwent non-contrast-enhanced abdominal CT at our institution between September 1, 2022, and March 31, 2024. Cases were included if they met the following criteria:

1) No abnormal findings requiring treatment or further evaluation, as determined by board-certified radiologists.

2) Results of routine blood tests (hematology and biochemistry) performed within 3 months before or after the CT scan were within 0.5 to 2.0 times the normal reference range.

Thirteen CT-based morphological parameters of the liver (e.g., left lobe hypertrophy, right lobe atrophy, surface irregularity) were each scored on a 0–4 scale. The sum of these scores was defined as the Liver Morphology Score (LMS). **Results:** Among 444 cases meeting the first criterion, 301 also satisfied the second and were included in the final analysis (145 males, 156 females; age range: 16–96 years; mean: 64.5, median: 68). The LMS ranged from 1 to 30 and tended to increase with age. Fatty liver was observed in 127 cases (42.2%). Adjusting the score by subtracting points for fatty liver improved its correlation with age. Although LMS showed a positive correlation with age, the values varied widely among elderly individuals (≥ 80 years), ranging from 3 to 30. LMS was also significantly correlated with the Fib-4 index, which itself had a stronger correlation with age than LMS. **Conclusion:** The Liver Morphology Score (LMS) showed a significant correlation with the Fib-4 index, suggesting its potential as an indicator of age-related hepatic fibrosis progression. Notably, considerable variation in morphology scores was observed even among individuals with similar Fib-4 indices, indicating that structural evaluation may contribute to risk stratification of liver disease in older adults and serve as a useful non-invasive screening tool. In the future, integration with AI-based imaging analysis may further enhance the objectivity and reproducibility of this modality. However, even at present, the liver morphology score holds promise as a cost-effective method for identifying high-risk individuals in clinical practice.

3386 | PKHD1 MUTATION PROMOTE HEPATIC STELLATE CELL ACTIVATE VIA SPP1 IN BILE DUCT CELL

Mengfan Jiao[1] *Chuanlong Zhu*[1], [1]*Nanjing medical university*

Background: Autosomal recessive polycystic kidney and hepatic disease (ARPKD) is a rare hereditary liver disorder, with polycystic kidney and hepatic disease 1 gene (PKHD1) being the most frequently mutated gene. The hallmark features of ARPKD encompass abnormal dilation of cholangiocytes, progressive hepatic fibrosis, and polycystic liver and kidneys as commonly observed clinical manifestations. **Methods:** Whole-exome sequencing revealed the presence of PKHD1 mutations in patients with congenital hepatic fibrosis (CHF). To explore the underlying mechanisms, single-cell RNA sequencing was performed on liver tissue samples. A *PKHD1*-deficient mouse model was established by deleting exons 3–4 of the *PKHD1* gene using CRISPR-Cas9 technology. DNA pull-down assays combined with mass spectrometry (MS) were employed to identify transcription factors upstream of differentially expressed genes. Dual-luciferase reporter assays were conducted to confirm the regulatory interactions between candidate transcription factors and their target genes. **Results:** Whole-exome sequencing identified a compound heterozygous mutation in PKHD1 in a patient with liver histology consistent with CHF (Figure1A, B). A *PKHD1*-deficient mouse model ($Pkhd1^{del3-4/del3-4}$) was generated and showed marked peribiliary fibrosis (Figure1C, D).

Single-cell RNA sequencing of liver tissues from CHF patients and controls revealed enhanced interaction between cholangiocytes and hepatic stellate cells, primarily driven by the secreted protein SPP1 from cholangiocytes and the integrin $\alpha 8\beta 1$ on hepatic stellate cells(Figure1E, F). SPP1 expression was significantly upregulated in mutant cholangiocytes and increased with age in $Pkhd1^{del3-4/del3-4}$ mouse livers (Figure1G, H). To explore the mechanism of SPP1 upregulation, DNA pull-down and MS identified candidate SPP1-binding proteins (Figure1I). Seven potential transcription factors were found, with p-STAT3 notably elevated in $Pkhd1^{del3-4/del3-4}$(Figure1J, K). Luciferase assays confirmed that p-STAT3 binds to and activates the SPP1 promoter, and mutation of the STAT3-binding site abolished this effect (Figure1L, M). AAV8-sh-SPP1 delivered via tail vein effectively reduced SPP1 expression in the liver and attenuated fibrosis in CHF mice (Figure1N, O). These findings suggest that targeting SPP1 may help limit fibrosis progression in CHF.

Conclusion: STAT3-mediated upregulation of SPP1 in PKHD1-deficient cholangiocytes contributes to fibrosis progression, and its inhibition alleviates liver fibrosis. This mechanism reveals a novel, disease-specific antifibrotic target for the treatment of CHF.

3387 | DIAGNOSTIC AND PROGNOSTIC PERFORMANCE OF MAGNETIC RESONANCE ELASTOGRAPHY AND MAGNETIC RESONANCE IMAGING-PROTON DENSITY FAT FRACTION IN PATIENTS UNDERGOING LIVER TRANSPLANTATION

Eun-Ki Min[1] *Seung Up Kim*[2] *Jae Geun Lee*[3], [1]*Departement of Surgery, Yonsei University College of Medicine, Seoul, Korea,* [2]*Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea.,* [3]*Department of Surgery, Yonsei University College of Medicine, Seoul, Korea*

Background: Accurate assessment of advanced fibrosis and steatosis is essential for prognostication in chronic liver disease. This study aimed to evaluate the diagnostic performance of magnetic resonance imaging (MRI) in assessing liver fibrosis and steatosis in patients undergoing liver transplantation (LT). **Methods:** Patients who underwent LT between January 2019 and December 2023 with pretransplant magnetic resonance elastography (MRE) and MRI-based proton density fat fraction (MRI-PDFF) examinations were included. Explanted livers were assessed for fibrosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

and steatosis, with cirrhosis subclassified using the Laennec system. Diagnostic performance was evaluated using area under the receiver operating characteristic curve (AUC) analysis. **Results:** Among 187 patients (median age, 57 years), 72.2% were male. Hepatitis B virus (55%) and alcoholic liver disease (21.4%) were the most common aetiologies. The median Model for End-Stage Liver Disease (MELD) score was 11. MRE detected cirrhosis (F4) with an AUC of 0.92 (95% confidence interval [CI], 0.87–0.97) and severe cirrhosis (F4c) with an AUC of 0.85 (95% CI, 0.79–0.91), at threshold values of 4.76 and 6.43 kPa, respectively. MRI-PDFF identified steatosis with an AUC of 0.83 (95% CI, 0.76–0.89) at a threshold of 2.80%. Comparisons of patients stratified by the threshold values for cirrhosis and severe cirrhosis revealed significant differences in MELD scores, history of portal hypertension-related complications, liver function parameters, and intraoperative transfusion requirements (all $p < 0.05$). **Conclusion:** MRI demonstrated high diagnostic accuracy for cirrhosis and steatosis in patients undergoing LT. MRE further stratified cirrhosis severity, correlating with liver function, prior decompensation, and transfusion requirements.

3388 | LIVER MESENCHYMAL STROMAL CELLS (LMSCS) REDUCE HEPATIC STELLATE CELL (HSC) MIGRATION AND EX VIVO HUMAN LIVER FIBROSIS

Alexander Washington[1] Esma Kesik[1] Patrick Starlinger[1] Timucin Taner[2] Enis Kostallari[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Platelet-derived growth factor (PDGF)-mediated activation of hepatic stellate cells (HSCs) is a key driver of liver fibrosis. Liver mesenchymal stromal cells (LMSCs) regulate liver homeostasis through a paracrine mechanism. Nevertheless, the effect of LMSCs signaling on HSC activation and liver fibrosis is unknown and is the aim of this study. **Methods:** In vitro, primary human HSC migration was studied using a transwell assay. In vivo liver fibrosis was induced in C57Bl/6J mice by carbon tetrachloride (CCl_4). Livers were analyzed by spatial transcriptomics (GSE259363) to plot co-expression of HSC markers (Acta2, Des, Pdgfrb) to LMSC markers (Cd44, Thy1, Vim, Nes). Ex vivo, human precision cut liver slices (hPCLS) were obtained using a Precisionary vibratome and analyzed by Western blot. PDGF treatment was used to activate HSCs in vitro and induce collagen deposition ex vivo. **Results:** To understand how spatial proximity between HSCs and LMSCs evolves during liver fibrosis, we analyzed our deposited spatial transcriptomics dataset. CCl_4-mediated liver fibrosis presented a reduced co-expression of HSC and LMSC markers compared to olive oil control (adj.$p < 0.05$), suggesting a role for HSC and LMSC crosstalk during liver homeostasis. To determine whether LMSCs affect HSC migration, a hallmark of HSC activation, we utilized a transwell assay, where HSCs were seeded in the upper chamber and no cells, HSCs as controls or LMSCs were seeded in the lower chamber in the presence of vehicle or PDGF. PDGF only or HSCs+PDGF increased HSC migration by 3-fold compared to vehicle or HSCs+vehicle ($n = 3$, $p < 0.05$). However, the presence of LMSCs (LMSCs+vehicle or LMSCs+PDGF) significantly abrogated HSC migration by 4.96-fold and 4-fold, respectively (transwell, $n = 3$, $p < 0.05$), suggesting that LMSCs reduce HSC activation. Finally, our findings prompted us to assess the role of LMSCs during ex vivo human liver fibrosis utilizing hPCLS from patient liver resections. PDGF treatment increased COL1 protein expression compared to vehicle by 2-fold, which was abrogated 2.4-fold by the presence of LMSCs ($n = 5$, $p < 0.05$), suggesting that LMSC are beneficial to human *ex vivo* liver fibrosis. **Conclusion:** Our results suggest that LMSCs inhibit HSC migration and reduce human ex vivo liver fibrosis.

Background: Activated hepatic stellate cells (HSCs), key drivers of liver fibrosis, utilize glycolysis, a metabolic process that generates acetyl groups for protein acetylation. Histone acetylation is an epigenetic process that promotes gene transcription. Nevertheless, how glycolysis directly affects the epigenetic regulation of HSC activation and subsequent liver fibrosis remains unknown and is the focus of this study. **Methods:** In vitro, cells were analyzed by western blot (WB), transwell, 5-ethynyl-2′-deoxyuridine (EdU) uptake, and liquid chromatography mass spectroscopy. In vivo, C57Bl/6J mice were fed choline-deficient high-fat diet (CDHFD) and treated with lysine acetyltransferase (KAT) inhibitor CPTH6. Livers were analyzed by immunofluorescence (IF) and Sirius red. Ex vivo, human precision cut liver slices (PCLS) from liver resections were analyzed by WB. PDGF was used to activate HSCs in vitro and fibrosis in PCLS. **Results:** To understand how histone acetylation is directly dependent on glycolysis, glucose carbons were ^{13}C-traced. PDGF-activated LX2 cells presented an increased percentage of glucose-derived carbons on the acetyl group of H3K9ac, gene promoter acetylation mark, compared to vehicle (incorporation of 1 or 2 heavier isotopes: 5.5-fold for M+1, 7.7-fold for M+2, $n = 5$, $p < 0.05$). However, acetate, another source of acetyl groups, did not participate in H3K9ac ($n = 3$), suggesting that activated HSCs utilize glycolysis for histone acetylation. To understand the importance of H3K9ac in HSC activation, we performed a pharmacological screen of epigenetic marks on primary human HSCs. CPTH6, a selective H3K9ac inhibitor, was the top molecule to reduce PDGF-mediated HSC proliferation by 1.8-fold (EdU, $n = 6$, $p < 0.05$) and migration by 1.6-fold compared to vehicle (transwell, $n = 6$, $p < 0.05$). Knocking down KAT2B, the enzyme leading to H3K9ac, confirmed these effects on proliferation (EdU, 1.9-fold decrease, $n = 6$, $p < 0.05$) and migration (transwell, 1.7-fold decrease, $n = 6$, $p < 0.05$), suggesting that H3K9ac promotes HSC activation. In vivo, in a MASH model of liver fibrosis, CDHFD-induced collagen deposition (19.1-fold by Sirius Red, 20.1-fold by IF, $p < 0.05$) was reduced by CPTH6 treatment (2.1-fold by Sirius Red, 3.2-fold by IF, $p < 0.05$, 10 mice/group). Finally, ex vivo human PCLS model demonstrated that CPTH6 abrogated PDGF-mediated collagen expression (4.5-fold, WB, $n = 5$, $p < 0.05$). **Conclusion:** Our results suggest that H3K9ac in HSCs is directly dependent on glycolysis and promotes HSC activation to amplify liver fibrosis.

3390 | POLYSTYRENE NANOPLASTICS PROMOTE HEPATIC STELLATE CELL ACTIVATION BY INDUCING STRETCH-INDUCED MECHANICAL STRESS

Jin-Kyu Park[1] Jae-Hyuk Yim[1] Su-Min Baek[1] Tae-Un Kim[1] Woo Jun Kim[1], [1]Kyungpook National University

Background: Global plastic pollution has led to increased risks of nanoplastics (NPs) ingestion and subsequent accumulation in the liver. However, there is a significant lack of toxicological studies evaluating the long-term effects of NPs on liver physiology, particularly regarding their impact on specific liver cell types. In our previous study, we demonstrated that polystyrene nanoparticles (PS-NPs) exacerbate liver fibrosis. In the present study, we aimed to investigate the direct effects of PS-NPs on hepatic stellate cells (HSCs), which play a central role in liver fibrogenesis. **Methods:** HSC activation was assessed by treating LX-2 cells, a human HSC line, with fluorescently labeled PS-NPs (200μg/mL, 200nm in diameter). Primary HSCs were isolated using an Optiprep density gradient, and after

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

PS-NP treatment, the protein expression levels of α-SMA, phosphorylated Smad2/3 (pSmad2/3), and pTGF-β receptor1(pTGFBR1) were compared through immunofluorescence(IF) and western blot(WB). Time-dependent cytoplasmic changes in HSCs were also examined. Furthermore, confocal microscopy was employed to assess the spatial relationship between PS-NPs and pTGFBR1. **Results:** After 6 hours of PS-NPs exposure, PS-NPs were engulfed by LX-2 cells, resulting in elevated expression of α-SMA and pSmad2/3. In primary HSCs, 24-hour PS-NP treatment induced nuclear translocation of Smad2/3 and significantly elevated pSmad2/3 levels, indicating direct activation of HSCs. PS-NPs also increased pTGFBR1 expression, but confocal analysis revealed no co-localization between PS-NPs and pTGFBR1. Notably, as the treatment time progressed, the pericellular PS-NPs were removed, revealing an empty space between the PS-NPs and the HSCs. During this process, HSCs extended cytoplasmic protrusions toward the PS-NPs, generating mechanical tension which enhanced α-SMA expression. **Conclusion:** This study provides the first evidence of direct HSC activation by PS-NPs via a mechanical stress-mediated mechanism. HSCs actively attempted to remove pericellular PS-NPs, recognized as xenobiotic materials, by stretching their cytoplasm. This mechanical stress contributed to HSC activation, suggesting that PS-NP accumulation in the liver may increase the risk of fibrosis by directly stimulating HSCs.

3391 | ASSESSMENT OF REGENERATIVE MACROPHAGE THERAPY PHARMACOLOGY SUPPORTS ANTI-INFLAMMATORY AND ANTI-FIBROTIC EFFECTS IN PRECLINICAL MODELS OF LIVER FIBROSIS

Joanna Sweetman[1] Jessica Llewellyn[1] Kayleigh Thirlwell[1] Anna Hoy[1] Olivia Matthews[1] Philip Starkey Lewis[1] Cecilia Rocchi[1] Keith Sutton[1] Lara Campana[1], [1]Resolution Therapeutics Ltd

Background: Resolution Therapeutics is developing a regenerative macrophage cell therapy (RMT), for end stage liver disease. Our lead asset, RTX001, was engineered to possess anti-inflammatory and anti-fibrotic properties. Safety, biodistribution and proof of concept of RTX001 were assessed in uninjured and CCl_4-treated NSG mice to support a successful Clinical Trial Application (CTA) filing. However, due to its immunodeficiency, the NSG strain has limited use in assessing the full pharmacology of RMT. In preparedness for the pivotal clinical trial we have:

1. Assessed the utility of liver fibrosis models (CCl_4, TAA, & CDAA HFD) to determine the pharmacology of RMT
2. Determined the mode of action (MoA) of the murine surrogate (mRTX001) of our product
3. Built a preclinical pharmacodynamic (PD) biomarker program to support and inform our clinical development programme (PD biomarker & potency strategies).

Methods: Liver fibrosis was induced in C57BL/6J WT mice by either CCl_4 IP dosing (4-12 weeks), TAA dosing in drinking water (6-12 weeks), or feeding with CDAA HFD (8-12 weeks). In intervention groups, mRTX001 (murine surrogate) was administered after establishment of disease. Injury, inflammation and fibrosis were assessed by measurement of liver function, collagen deposition, cytokine profile (MSD), proteomics (O-link) and transcriptomics (nCounter®). **Results:** Each model showed distinct inflammatory and fibrotic signatures. Importantly, CDAA HFD and TAA models were found to have an appropriate therapeutic window, with stable fibrosis after removal of insult. Here, we use the CDAA HFD to illustrate our findings. Efficacy of mRTX001 was confirmed by a reduction in collagen deposition (-30% picrosirius red staining) and improvement in liver function (-26% AST & -33% ALT). mRTX001 treatment led to an increase in liver macrophage numbers (F4/80 staining) at 24hrs, followed by a reduction at 72hrs, and a shift towards an anti-inflammatory, pro-regenerative chemokine and cytokine profile, affecting both the innate and

adaptive immunity responses. **Conclusion:** We assessed the pharmacology of a mRTX001 using a combination of models to reflect the broad spectrum of intended patient population. Our data shows that recruitment of macrophages, modulation of inflammation and collagen breakdown form the basis of the MoA of our product. The preclinical datasets provided direction for the development of our clinical biomarker and potency strategy. RTX001 has progressed to clinical testing in UK and Spain (EMERALD Phase 1/2 study).

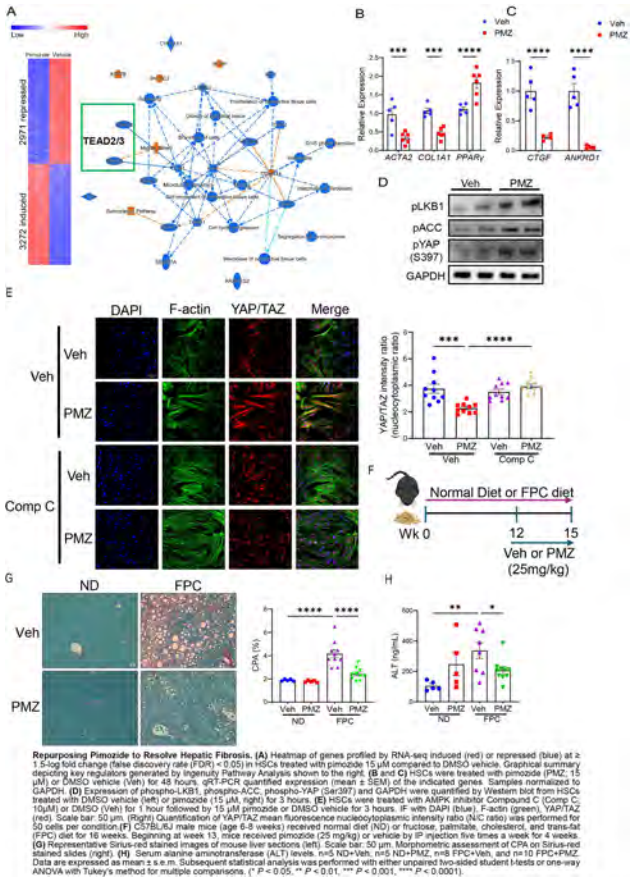
3392 | REPURPOSING PIMOZIDE TO REVERSE HEPATIC FIBROSIS VIA AMPK-YAP/TAZ SIGNALING IN HEPATIC STELLATE CELLS

Vijaya Prathigudupu[1] Nidhi Nautiyal[1] Amy Yu[1] Sachin Sharma[1] Aras Mattis[1] Jennifer Chen[1], [1]University of California, San Francisco

Background: Activation of hepatic stellate cells (HSCs) plays a pivotal role in hepatic fibrosis. Targeting their activation offers a promising approach for antifibrotic therapy, which currently lacks FDA-approved drugs. We previously performed a high-throughput small molecule screen, which identified pimozide, an antipsychotic drug in clinical use, as a potential inducer of HSC inactivation. Here, we aimed to validate this finding and discover the molecular mechanisms by which pimozide promotes HSC inactivation. **Methods:** RNA sequencing and Ingenuity Pathway Analysis (IPA) were performed on pimozide- or vehicle-treated primary human HSCs. We modeled HSC activation in vitro by culture on plastic. Hepatic fibrosis was induced in vivo using CCl_4 treatment for 6 weeks or the FPC (fructose, palmitate, cholesterol, trans fats) diet for 16 weeks. Pimozide was administered by intraperitoneal injection for 6 weeks in the CCl_4 model and 4 weeks in the FPC model. Fibrosis was assessed by hydroxyproline and Sirius red staining, and a blinded pathologist performed histological analysis. We performed qPCR, western blotting, and immunofluorescence on mouse liver tissues. **Results:** IPA analysis identified the YAP/TAZ pathway as a downstream pathway of pimozide. We observed that pimozide promotes YAP phosphorylation, inhibits YAP/TAZ nuclear localization, and decreases expression of their transcriptional targets. Furthermore, pimozide activated LKB1-AMPK signaling to inhibit YAP/TAZ. Notably, the inhibition of AMPK rescued YAP/TAZ activation, suggesting that pimozide is mediating YAP/TAZ signaling via AMPK. In the CCl_4 and FPC models of fibrosis, treatment with pimozide ameliorated fibrosis. In the FPC model, pimozide did not alter parameters of MASH such as steatosis, lobular inflammation, or ballooning, but was associated with decreased food intake and improved insulin sensitivity. **Conclusion:** Through a small molecule screen, we discovered that pimozide promotes HSC inactivation and ameliorates hepatic fibrosis. Mechanistically, our findings identify a novel cascade by which pimozide activates LKB1-AMPK to inhibit YAP/TAZ signaling in HSCs. These findings suggest that pimozide may be repurposed for the treatment of hepatic fibrosis.



Repurposing Pimozide to Resolve Hepatic Fibrosis. (A) Heatmap of genes profiled by RNA-seq induced (red) or repressed (blue) at ≥ 1.5-log fold change (false discovery rate (FDR) < 0.05) in HSCs treated with pimozide 15 μM compared to DMSO vehicle. Graphical summary depicting key regulators generated by Ingenuity Pathway Analysis shown to the right. **(B** and **C)** HSCs were treated with pimozide (PMZ; 15 μM) or DMSO vehicle (Veh) for 48 hours. qRT-PCR quantified expression (mean ± SEM) of the indicated genes. Samples normalized to GAPDH. **(D)** Expression of phospho-LKB1, phospho-ACC, phospho-YAP (Ser397) and GAPDH were quantified by Western blot from HSCs treated with DMSO vehicle (left) or pimozide (15 μM, right) for 3 hours. **(E)** HSCs were treated with AMPK inhibitor Compound C (Comp C; 10μM) or DMSO (Veh) for 1 hour followed by 15 μM pimozide or DMSO vehicle for 3 hours. IF with DAPI (blue), F-actin (green), YAP/TAZ (red). Scale bar: 50 μm. (Right) Quantification of YAP/TAZ mean fluorescence nucleocytoplasmic intensity ratio (N/C ratio) was performed for 50 cells per condition.**(F)** C57BL/6J male mice (age 6-8 weeks) received normal diet (ND) or fructose, palmitate, cholesterol, and trans-fat (FPC) diet for 16 weeks. Beginning at week 13, mice received pimozide (25 mg/kg) or vehicle by IP injection five times a week for 4 weeks. **(G)** Representative Sirius-red stained images of mouse liver sections (left). Scale bar: 50 μm. Morphometric assessment of CPA on Sirius-red stained slides (right). **(H)** Serum alanine aminotransferase (ALT) levels. n=5 ND+Veh, n=5 ND+PMZ, n=8 FPC+Veh, and n=10 FPC+PMZ. Data are expressed as mean ± s.e.m. Subsequent statistical analysis was performed with either unpaired two-sided student t-tests or one-way ANOVA with Tukey's method for multiple comparisons. 3393 | DIGITAL PATHOLOGY QUANTIFICATION REVEALS FIBROTIC SIGNATURES LINKED TO EARLY RECURRENCE IN PATIENTS WITH HEPATITIS B VIRUS-ASSOCIATED HEPATOCELLULAR CARCINOMA

Li Chen Michitaka Matsuda[1] Tatsuya Kanto[1], [1]Japan Institute for Health Security

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer mortality, with early and late recurrence posing significant challenges. Chronic hepatitis B virus (HBV) infection, a dominant HCC etiology, drives fibrogenesis that may influence tumor recurrence by altering the extracellular matrix and immune microenvironment. This study used high-resolution FibroNest™ digital pathology to identify phenotypic fibrosis features linked to recurrence timing and examine the role of HBsAg localization in modulating fibrosis. **Methods:** Liver tissues stained with PSR from HBV-infected HCC patients with early (N = 5) and late (N = 5) recurrence were analyzed using the AI-powered FibroNest™ platform. Fibrosis was quantified across four tissue regions—tumor border, intratumoral area, peritumoral area, and entire tissue—using composite scores for collagen deposition, morphometric traits (fine and assembled fibers), architectural features, and an integrated phenotypic fibrosis composite score (Ph-FCS), a continuous measure of fibrosis severity. Fibrosis scores were also compared between dense and sparse HBsAg+ localized regions within the early and late recurrence samples. **Results:** In analysis for entire tissue, the morphometric score for assembled fibers (early: 5.15 vs. late: 3.86, $p = 0.044$) and the Ph-FCS (early: 5.10 vs. late: 3.90, $p = 0.049$) were significantly elevated in patients with early recurrence. The Ph-FCS demonstrated strong discriminatory power between early and late recurrence, with an AUROC of 0.88, underscoring its potential as a reliable biomarker. No significant differences were observed within specific regional compartments. In the HBsAg+ localized analysis, Ph-FCS was significantly higher in antigen-dense regions (3.98 vs. 2.82, $p = 0.012$). Other fibrosis metrics exhibited non-significant trends toward higher values in dense areas. **Conclusion:** Full-tissue fibrotic burden and structural complexity are more strongly associated with early HCC recurrence than regional fibrotic patterns. Dense HBsAg+ microenvironments may drive localized fibrosis, linking antigen distribution to fibrotic remodeling. These findings highlight spatially resolved digital pathology's potential for recurrence risk stratification and suggest antifibrotic strategies targeting the tissue microenvironment in HBV-related HCC.

3394 | CONSTITUTIVE MAS1 G PROTEIN-COUPLED RECEPTOR PARTICIPATES IN THE PATHOGENESIS OF LIVER FIBROSIS

Sabine Klein[1] Fernando Magdaleno Verduzco[2] Robert Schierwagen[3] Frank Erhard Uschner[3] Maximilian Joseph Brol[4] Thomas Walther[5] Jonel Trebicka[3], [1]University Hospital Muenster, [2]Epistem Limited, 48 Grafton Street, Manchester, M1, [3]Department of Internal Medicine B, University Clinic Münster, 48149 Münster, Germany, [4]Department of Internal Medicine B, University Clinic Münster, 48149 Münster, [5]Department of Pharmacology and Therapeutics, University College Cork, Cork, Ireland

Background: The activation of the renin-angiotensin system (RAS) in experimental and human liver cirrhosis, leads to increased levels of angiotensin-II (Ang-II) and angiotensin type 1 receptor (AT1R) stimulation, thus contributing to liver fibrosis and portal hypertension (PTH). Mas-related G protein-coupled receptor (MAS1) is increased in the cirrhotic liver, representing an alternate mechanism that opposes the effects of the Ang-II/AT1R axis. Thus, we investigated the protective role of MAS1 as a potential antifibrotic receptor constitutively activated in liver fibrosis. **Methods:** Human blood samples were measured for Angiotensin levels. Gene and protein expressions were investigated in human donors and recipients. Wildtype (wt) and Mas-receptor knock out mice ($Mas1^{-/-}$) received CCl_4, MCD, WD or a bile-duct ligation (BDL) to induce liver fibrosis. BDL mice were treated with Ang(1-7) or AVE0991. To assess PHT, the portal pressure (PP) was measured. Murine livers were histologically analyzed and gene and protein expressions were measured. Hepatic stellate cells (HSC) were isolated from mice and cell lines were transfected with Mas1 plasmid. **Results:** MAS1 deficiency stimulates Ang-II/AT1R signaling and thereby aggravates fibrosis and PTH in BDL and CCl_4-mice. *In vivo* studies showed that Ang-(1-7) and AVE0991 lowered portal pressure (PP) in MAS1 deficient mice after BDL, suggesting another receptor different than MAS1 involved in vasoconstriction. *In vitro*, Ang-(1-7) did not attenuate expression of fibrotic markers and

contraction in MAS1 transfected HSC cells, suggesting that constitute activation of MAS1 is sufficient to relax HSC. **Conclusion:** Constitutive activation of MAS1 in HSC reduces liver fibrosis and PTH.

3395 | DOES IQR/MEDIAN OF LIVER STIFFNESS MEASUREMENT IMPACT THE ACCURACY OF PREDICTING OF ADVANCED FIBROSIS IN MASLD?

Michael Eiswerth[1] Laura Wilson[2] Samer Gawrieh[3] Raj Vuppalanchi[3] Bryce Hatfield[1] Arun Sanyal[1] Richard Sterling[1], [1]Virginia Commonwealth University, [2]Johns Hopkins University, [3]Indiana University

Background: Liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) is used to estimate fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD). A reliable LSM requires at least 10 valid measurements with the ratio of interquartile range to the median (IQR/M) $\leq$30%. However, for those with a reliable LSM, the impact of IQR/M across the range (1-30%) on the accuracy of LSM is not well defined. We hypothesized that a lower IQR/M within that range would improve the diagnostic performance of LSM by VCTE in predicting biopsy-proven advanced fibrosis (AF), F3-4. **Methods:** This was a prospective analysis of adult participants (pts) with MASLD in the NASH CRN who underwent liver biopsy within 6 months of LSM by VCTE evaluation. Pts were excluded if they had an IQR/M > 30% or less than 10 valid measurements. The degree of fibrosis was determined by central pathology review. Our objective was to evaluate the performance of LSM (analyzed as a continuous variable) across the IQR/M by tertile (1-10, 11-20, 21-30%) to identify AF by histology. Performance characteristics were calculated across tertiles at maximum Youden Index adjusted for age, race, sex, BMI, and type 2 diabetes (T2DM). **Results:** The cohort consisted of 1406 pts: mean (SD) age 52 (12), 39% male, 78% White/9% Asian/3% Black, 13% Hispanic, BMI 34.6 (6.6), 53% with T2DM, and 36% with AF by biopsy. The mean LSM was 12 (10.5) kPa and CAP 323 (51.5) dB/m. The mean days between biopsy and LSM was 52 (35). The mean IQR/M was 15.7 (6.9)%. The performance characteristics of LSM for predicting advanced fibrosis are shown in Table 1 for the entire cohort and each IQR/M tertile (1-10%, 11-20%, 21-30%). The sensitivity (Sn) was highest 1-10% IQR/M group while the specificity (Sp) and PPV was highest in the 21-30% IQR/M group with similar NPV across the groups. The AUROC was 0.88 for the entire cohort and comparable across the IQR/M groups (P = 0.09). **Conclusion:** In patients with IQR/M $\leq$30%, the IQR/M reliability metric did not significantly affect the accuracy of LSM in the diagnosis of AF among MASLD pts. LSM had high diagnostic accuracy for AF. Our results confirm that in patients with IQR/M $\leq$30%, LSM by VCTE demonstrate very good diagnostic accuracy. While LSM by VCTE performed well across all measured tertiles and was not better in the low (<10%) compared to high (21-30%) IQR/M, the performance by IQR/M varied when prioritizing Sn, Sp, or overall performance.

Table 1. Performance characteristics of LSM* to predict advanced fibrosis (F3-4) on biopsy by IQR/med%

			Model fixed at maximum Youden Index†				
IQR/M %¶	N (%)	Prevalence of advanced fibrosis	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	AUROC (95% CI)
Overall	1406 (100%)	36%	0.83	0.73	0.63	0.88	0.85 (0.83-0.87)
1-10%	360 (26%)	32%	0.68	0.84	0.67	0.85	0.84 (0.80-0.89)
11-20%	683 (49%)	36%	0.85	0.69	0.61	0.89	0.84 (0.81-0.87)
21-30%	363 (26%)	39%	0.75	0.86	0.77	0.85	0.87 (0.83-0.91)

3396 | GENE EXPRESSION PROFILING REVEALS THBS2 AS A CANDIDATE MEDIATOR OF PERIDUCTAL FIBROSIS IN PRIMARY SCLEROSING CHOLANGITIS

Tomohiro Katsumi[1] Keita Maki[1] Fumi Uchiyama[1] Fumiya Suzuki[1] Kyoko Hoshikawa[1] Hiroaki Haga[1] Yoshiyuki Ueno[1], [1]Yamagata University Faculty of Medicine

Background: Primary sclerosing cholangitis (PSC) is pathologically characterized by periductal concentric ("onion-skin") fibrosis. Previous studies have investigated the relationship between injured bile ducts and surrounding inflammatory and fibrotic responses. Spatial transcriptomics has recently enabled gene expression profiling based on morphological context, revealing distinct gene expression patterns in regions of bile duct injury and fibrosis. This study aimed to evaluate the involvement of highly expressed genes identified in specific spatial clusters in the pathogenesis of PSC. **Methods:** We analyzed gene groups that were highly expressed in clusters corresponding to bile duct injury and fibrotic regions in previous spatial transcriptomic analyses. Among these, we focused on genes related to inflammation and fibrosis. Protein levels of candidate genes were measured in serum samples by ELISA and compared between PSC patients and healthy controls. In addition, protein expression in liver tissues was evaluated by immunohistochemistry. **Results:** A total of 556 Visium spots were analyzed from PSC liver tissues, with an average of 3,336 genes detected per spot. In the cluster corresponding to bile duct injury with inflammatory cell infiltration, genes encoding chemokines such as CCL19, CXCL1, and CXCL6, as well as immune modulators such as SPP1, were highly expressed in addition to extracellular matrix markers such as COL and ACTA family members. Among these, Thrombospondin 2 (THBS2) exhibited particularly high expression. Serum THBS2 protein levels were significantly elevated in PSC patients (mean: 58.3 ng/mL) compared to healthy controls (mean: 31.0 ng/mL). Furthermore, THBS2 expression in liver tissue correlated with the degree of fibrosis severity. **Conclusion:** THBS2 was highly expressed in bile duct injury regions of PSC liver tissues. THBS2 is known to promote liver fibrosis via TLR4-FAK/TGF-β signaling pathways. The elevated serum levels of THBS2 in PSC patients further support its involvement in periductal fibrogenesis. Our findings suggest that THBS2 may serve as a potential marker and therapeutic target in PSC-related liver fibrosis.

3397 | PLATELET INDICES ARE ASSOCIATED WITH CHANGES IN LIVER STIFFNESS MEASUREMENT IN CHRONIC LIVER DISEASE

Robert Pecha[1] James Vu[1] Jordan Hollliday[1] Vikrant Rachakonda[2], [1]University of California Davis Medical Center, [2]Northern California VA Healthcare System

Background: Platelets are key drivers of fibrosis and inflammation in chronic liver diseases. The aim of the current study was to assess predictive relationships between platelet indices, non-invasive fibrosis markers, and fibrosis progression in chronic liver diseases. **Methods:** This retrospective study included 234 patients seen at the Northern California Veterans Affairs Hepatology Clinic (Sacramento, CA) between January 2018-March 2024. Inclusion criteria included chronic liver disease assessment with two vibration controlled transient elastography (VCTE) examinations; each examination was accompanied by laboratory testing. **Results:** Median age was 65 (IQR 53 – 73) years; 160 (68.4%) patients were male, and 150 (64.1%) were Caucasian. Fifty-four patients (23.1%) had chronic HCV, 6 (2.6%) had chronic HBV, and 202 (86.3%) had steatotic liver disease, defined as controlled attenuation parameter > 238 dB/m. Median interval between examinations was 24.1 (14.9 – 39.5) months. Ninety-three (40.1%) patients had compensated advanced liver disease (cALD) defined as liver stiffness measurement (LSM) > 10 kPA on index VCTE, and 71 patients (31.0%) had cALD on follow-up examination. Median platelet count (PC) was lower [201 (156 – 241) $x10^9/mm^3$ vs. 222 (177 – 270)$10^9/mm^3$, $p < 0.001$ by rank sum test], while mean platelet volume-to-platelet ratio (MPVR) was higher [0.052 (0.042 – 0.066) a.u. vs.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

0.047 (0.037 – 0.060) a.u., $p = 0.033$] in cALD patients. MPVR exhibited significant correlation with LSM (spearman rho = 0.0451, $p = 0.001$]. Overall, 106 (45.3%) patients experienced 20% or greater decline in LSM on second VCTE (LSM improvement). On multivariate logistic regression, only change in MPVR (Δ-MPVR) [OR 2.200 (95% CI 1.243 – 3.896. $p = 0.004$], change in AST (Δ-AST) [OR 0.996 (95% CI 0.992 – 0.999), $p = 0.032$], and change in CAP (Δ-CAP) [OR 0.994 (95% CI 0.990 – 0.997), $p = 0.001$] were associated with LSM improvement. Among patients with cALD, 43 experienced reductions in LSM to < 10 kPA (cALD regression), and these subjects exhibited greater decline in MPVR compared to cALD non-regressors [0.052 (0.043 – 0.067) vs. 0.434 (0.037 – 0.058), $p = 0.025$]. **Conclusion:** Platelet indices including PC and MPVR are correlated with LSM in ambulatory patients with chronic liver disease. Δ-MPVR, Δ-AST, and Δ-CAP are independently associated with 20% or greater improvement in LSM. Future studies are planned to prospectively validate platelet indices for outcome prediction in chronic liver disease.

3398 | COMPARING NON-INVASIVE FIBROSIS ASSESSMENT TO BIOPSY: EVALUATING A CONTEMPORARY COHORT

Muhammad Saad Faisal[1] Ammad Chaudhary[1] Mustafa Saadi[1] Kevin Harris[1] Yara Dababneh[1] Abdulmalik Saleem[1] Muhammad Qureshi[1] Reena Salgia[1] Andrew Watson[1], [1]Henry Ford Hospital, Detroit

Background: Accurate staging of liver fibrosis is essential for clinical decision-making in patients with chronic liver disease. While established non-invasive tests (NIT) such as Fibrosis-4 (FIB-4) score and Transient Elastography (TE) are widely used, recent advances introduce a need to evaluate diagnostic precision. Among these, Endoscopic Ultrasound-guided Shear Wave Elastography (EUS-SWE) and Endoscopic Ultrasound-guided Liver Biopsy (EUS-LB) represent promising advancements, offering both real-time imaging and histologic assessment in a single session. However, data on the comparative performance of EUS-SWE remains limited. We aim to evaluate the diagnostic accuracy of specific NITs using EUS-LB as the reference standard. **Methods:** This is a retrospective study conducted after IRB approval, reviewing all patients at a quaternary health care system who underwent EUS-LB from 2022–2024. Histological fibrosis staging from EUS-LB, based on the METAVIR score, served as the reference standard. Performance of TE, EUS-SWE, and FIB-4 was evaluated by comparative fibrosis staging across F0–F4 stages. TE and EUS-SWE were also assessed by sensitivity, specificity, accuracy and comparing mean values for F4 versus F0–F3. Secondary endpoints included procedural safety and biopsy adequacy. **Results:** 75 patients met our inclusion criteria. Mean age was 60.75 ± 10.57, predominantly male(66.7%). EUS-LB yielded a mean biopsy length of 23.61 ± 14.76 mm with 26.05 ± 14.87 complete portal tracts (CPT). 72 (96%) of the biopsy specimens were adequate with > 11 CPT. EUS-SWE was performed in 51(68%) patients, TE was performed in 32(42.7%) patients, and FIB- 4 score was calculated for all patients. EUS-SWE had a sensitivity of 75%, specificity of 57.1%, and accuracy of 62.7%. TE had a sensitivity of 55.6%, specificity of 69.6%, and accuracy of 65.6%. Among 23 patients who underwent both EUS-SWE and TE, Cohen's kappa coefficient for agreement on cirrhosis diagnosis was 0.34 (95% CI: –0.06 to 0.74), indicating fair but statistically uncertain agreement. Mean EUS-SWE and TE values progressively increased from F0–F4, however the difference of means between F4 versus F0-F3 was not significant (p = 0.072 for SWE and p = 0.065 for TE). Adverse events were noted in 1 patient (1.3%) with minor self-resolving bleeding from the biopsy site one day after EUS-LB. **Conclusion:** FIB-4, EUS-SWE and TE, while widely used, demonstrate moderate diagnostic accuracy in staging liver fibrosis, with increased precision in identifying advanced fibrosis/cirrhosis; F4. EUS-LB has emerged as an accurate and safe method for staging hepatic fibrosis while concomitantly assessing for portal hypertension. Importantly, this data challenges the accuracy of NITs which can have an important role in clinical decision making at the patient level including surgical risk stratification, indication for MASH therapies, cancer surveillance, and monitoring protocols.

Biopsy Score	N (%)	EUS- SWE (kPa) Mean ± SD	TE (kPa) Mean ± SD	Fib-4 score (n, %)
F0-F1	16 (21.33)	12.7 ± 4.22	12.3 ± 7.6	>2.67= 6 (37.5), 1.3-2.67= 1 (6) <1.3= 4 (25)
F2	12 (16)	11.8 ± 6.58	12.1 ± 6.36	>2.67= 2 (16.7), 1.3-2.67= 5 (41.7), <1.3= 5 (41.7)
F3	20 (26.67)	16.6 ± 7.75	11.8 ± 8.4	>2.67= 8 (40), 1.3-2.67= 9 (45) <1.3= 1 (5)
F4	27 (36)	18.2 ± 8.31	27 ± 26	>2.67= 13 (48.1), 1.3-2.67= 10 (37) <1.3= 4 (14.8)
Diagnostic Analysis*		**EUS-SWE**	**TE**	**P- Value**
Sensitivity (%)		75	55.6	0.5
Specificity (%)		57.1	69.6	0.69
Accuracy (%)		62.7	65.6	1.0
Statistical Significance of Mean Difference, F4 versus F0-F3 (p-value)		0.072	0.065	

Table 1. Comparison of mean values of EUS-SWE, TE and FIB-4 scores across different fibrosis stages along with data for diagnostic precision *Since diagnostic cut offs are not standardized for EUS-SWE, diagnostic evaluation was based on standardized cutoff values for TE.

3399 | THE ROLE OF IRON IN HEPATIC FIBROSIS SEVERITY IN BLACK AND WHITE PATIENTS

Michael Attanasi[1] Mathew Gregoski[2] Don Rockey[2], [1]Northwell Health, [2]Medical University of South Carolina

Background: The epidemiology of iron deposition in the liver and its impact on the development of fibrosis is understudied. The purpose of our study was to evaluate the epidemiology and association of iron with cirrhosis. We hypothesized that Black patients would have more iron deposition, but iron deposition would not be associated with cirrhosis. **Methods:** All adults who had a liver biopsy at our institution from January 1, 2013 through July 1, 2021 were identified. Histologic and complete clinical data were abstracted via the medical record. Iron grading was based on the presence of iron granules in hepatocytes, with grade 0 being absent granules at 400x field, grade 1 as granules seen at 250x field (trace), grade 2 with granules seen at 100x field (mild), grade 3 with granules seen at 25x field (moderate, present), and grade 4 with granules seen at 10x field (severe) as per standard histological assessment. Patients with liver lesions, hemochromatosis (determined through genetic testing), or who had undergone liver transplantation were excluded. Chi squared and Pearson correlation analysis were used to determine statistical significance using XLSTAT. **Results:** Of 3,572 patients having a liver biopsy, 839 met inclusion criteria; 189 patients were Black and 650 were White. Etiologies of the liver disease were significantly different between races, where Black patients were more likely to have viral and autoimmune hepatitis (based on serology/histology) and White patients were more likely to have ALD (based on history) and MASLD (based on history and clinical features). Black patients were more likely to have iron on biopsy than White patients (68/189 (36%) vs 179/839 (28%), $p < 0.01$) (Table 1). Pearson correlation demonstrated that the presence of iron was significantly correlated with cirrhosis ($r = 0.156$, $p < 0.0001$); this trend persisted for both Black and White races. Iron was not significantly associated with inflammation, but inflammation was associated with cirrhosis ($r = 0.207$, $p < 0.0001$) and race ($r = 0.077$, $p < 0.05$). The prevalence of cirrhosis was more prevalent in White patients than in Black patients (284 (44%) vs 65 (34%), $p < 0.05$). **Conclusion:** Although Black patients had a greater degree and prevalence of intrahepatic iron than white patients and iron was significantly associated with fibrosis, Black patients had a lower prevalence of cirrhosis than White patients.

Table 1. Population Description

Demographics	White	Black	Total	p
Total	650	189	839	-
Male	314 (48%)	92 (49%)	406	NS

3400 | STUDY ON THE DEGREE OF LIVER FIBROSIS BY FIB-4 INDEX AND ARFI TECHNIQUE IN PATIENTS WITH NON-ALCOHOLIC FATTY LIVER DISEASE AND NON-DIABETES

Trung Huynh[1], [1]Tam Anh Hospital

Background: Non-alcoholic fatty liver disease (NAFLD) is rising at an alarming rate and has become the most common cause of chronic liver disease worldwide.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

While the interplay between NAFLD and type 2 diabetes mellitus in terms of prevalence and disease progression risks has been extensively studied, the relationship between NAFLD and patients without diabetes has been less investigated. The FIB-4 index and ARFI (Acoustic Radiation Force Impulse) are two non-invasive, accurate, and cost-effective methods for diagnosing liver fibrosis, providing quick results suitable for Vietnam's healthcare context. However, studies on NAFLD in patients without diabetes in Vietnam remain limited. *Objective:* To evaluate the FIB-4 index and shear wave velocity (SWV) measured by the ARFI technique in non-diabetic patients with NAFLD. Additionally, to investigate factors related to liver fibrosis severity in these patients. **Methods:** A cross-sectional descriptive study was conducted on 107 patients diagnosed with NAFLD and without diabetes. **Results:** The mean age of study participants was 50.9 ± 15.2 years, with the youngest being 20 years old and the oldest 78 years old. Females accounted for a higher proportion than males (67.3% vs. 32.7%). All participants (100%) had dyslipidemia; 71% had insulin resistance; 67.3% had metabolic syndrome; 53.3% were obese; 47.7% had prediabetes; 30.8% had hypertension; and 3.7% had other comorbidities. Moderate fatty liver was the most common form, accounting for 63.5%, followed by severe fatty liver (20.6%), while mild fatty liver was the least common (15.9%).The mean FIB-4 value was 1.45 ± 1.83, ranging from 0.1 to a maximum of 13. The mean shear wave velocity (SWV) was 1.29 ± 0.44 m/s, with values ranging from 0.82 m/s to 3.43 m/s. There was a moderate positive correlation between FIB-4 and liver fibrosis stage (Spearman's $r = 0.438$; $p < 0.001$). A statistically significant correlation was found between age, platelet count, AST, GGT, and the degree of liver fibrosis ($p < 0.05$). Additionally, age, AST, and total cholesterol were significantly associated with advanced liver fibrosis ($p < 0.05$). **Conclusion:** There is a moderate positive correlation between the FIB-4 index and liver fibrosis stages assessed by ARFI. In non-diabetic patients with NAFLD, factors associated with significant liver fibrosis ($F \geq 2$) include age, platelet count, AST, and GGT levels. Factors associated with advanced liver fibrosis ($F \geq 3$) in this population are age, AST, and total cholesterol

Factor		OR	95% CI	p
Age		1,19	1,01-1,42	**0,047**

3401 | HIV COINFECTION EXACERBATES HBV-INDUCED LIVER FIBROGENESIS VIA AN EXOSOMAL MIR-103A-3P DEPENDENT PATHWAY

Min Xu[1] Olivia Mezzetti[1] Thien Nguyen[1] Sreya Biswas[2] Cecilie S. Bach-Nielsen[1] Charlotte Warner[1] Xiaoqiong Duan[3] Shasha Li[4] Yongtao Wang[1] Volney Spalding[1] Zeinab Heidariyan[1] Shadi Salloum[1] Xu Yu[5] Benjamin Burwitz[2] Raymond Chung[1] Wenyu Lin[1], [1]Liver Center and GI Division, Massachusetts General Hospital and Harvard Medical School, [2]Oregon National Primate Research Center, Oregon Health and Science University, [3]Institute of Blood Transfusion, Chinese Academy of Medical Sciences and Peking Union Medical College, [4]The Second People's Hospital of Fuyang City, [5]The Ragon Institute of Massachusetts General Hospital, MIT, and Harvard University

Background: HIV coinfection accelerates chronic hepatitis B virus (CHB)-induced cirrhosis compared to monoinfection. Exosomes in cell culture supernatants and patient serum can facilitate intercellular communication by transferring functional molecules such as miRNAs and proteins. Notably, HIV infection has been shown to upregulate miR-103a-3p expression. We sought to investigate the mechanisms by which HIV-induced miR-103a-3p in macrophages contribute to HBV-induced liver fibrogenesis. **Methods:** Exosomes were isolated from the supernatants of HIV-infected (HIVexo), uninfected (U937exo) U937 macrophages and patient plasma. HepG2-NTCP cells, human hepatic stellate (HSC) LX2 cells, primary human hepatocytes (PHHs), and primary HSCs (PHSCs), as well as 3D co-culture models and precision-cut liver slice (PCLS) models, were directly exposed to HIVexo or U937exo in both mono- and coculture with or without treatment with synthetic miR-103a-3p mimics, inhibitors, or siRNA-mediated knockdown of inhibitor of DNA-binding protein 2 (ID2) (target of miR-103a-3p). Rhesus macaque (RM) models of HBV mono- and SHIV/HBV coinfection were employed to confirm the *in vivo* effects of miR-103a-3p on liver fibrogenesis. **Results:** We found that miR-103a-3p is significantly upregulated in exosomes from HIV-infected U937 supernatants and plasma of HIV-positive patients. miR-103a-3p mimics promote HBV-induced liver fibrogenesis in NTCP-HepG2 and LX2 cell lines, a finding validated in PHHs and PHSCs. Furthermore, we found that SHIV/HBV co-infection led to a more pronounced upregulation of miR-103a-3p and profibrogenic gene expression in RM liver tissue compared to baseline levels. These effects were reversed following treatment with combination antiretroviral therapy (cART). We found that miR-103a-3p mimics exacerbate HBV-induced fibrogenesis, while miR-103a-3p inhibitors attenuate this effect. miR-103a-3p's effects are

mediated by downregulation of ID2 expression, which in turn is associated with increased expression of HIF1A, TGF-b1, and liver fibrosis related gene expression in HBV monoinfected and HIV/HBV coinfected single-cell culture and 3D triple-cell coculture models. **Conclusion:** HIV coinfection exacerbates HBV-induced liver fibrogenesis through upregulation of miR-103a-3p, which suppresses ID2 and consequently leads to overactivation of the HIF-1α and TGF-β1 signaling pathways. miR-103a-3p is a potential biomarker and therapeutic target for liver fibrosis in individuals coinfected with HIV and HBV.

3402 | TETRACHLOROETHYLENE IS ASSOCIATED WITH SIGNIFICANT LIVER FIBROSIS: A NATIONAL CROSS-SECTIONAL STUDY

Yinan Su[1] Jennifer Dodge[2] Brian Lee[2], [1]Keck School of Medicine of USC, [2]University of Southern California

Background: Tetrachloroethylene (PCE) is a volatile organic compound (VOC) used in dry-cleaning and the textile industry. Pre-clinical studies have linked PCE to hepatotoxicity via oxidative stress and activation of PPAR-α, a regulator of fatty acid metabolism in the liver, but clinical data represent a critical knowledge gap. In this national study, we studied association between PCE levels and liver fibrosis among US adults. **Methods:** We performed a cross-sectional study using the National Health and Nutrition Examination Survey between 2017-2020. Adults aged ≥20 were included and those with hepatitis B or C, current or former smoking, or missing data on PCE levels, alcohol intake, metabolic syndrome, or transient elastography (TE) were excluded. Significant liver fibrosis was defined as TE liver stiffness measurement > 8.2kPA. Detectability of blood PCE levels (ng/mL) was based on lower limits of detection. Associations between liver fibrosis and PCE were analyzed via multivariate logistic regression, adjusted for age, sex, race/ethnicity, poverty, education level, and metabolic syndrome. To strengthen causality of our findings, we performed a negative control analysis using VOC N-Acetyl-S-(2-hydroxyethyl)-l-cysteine (HEMA) as the exposure variable, given co-exposure between precursor substrates to HEMA and PCE. **Results:** Among 1,614 adults, 116 (7.4%) had detectable PCE. Individuals with detectable (vs. undetectable) PCE had higher prevalence of significant liver fibrosis: 12.6% (95%CI 5.9-24.8%) vs. 7.1% (4.8-10.3%). Participants with detectable (vs. undetectable) PCE were similar in age, sex, race/ethnicity, education status, but were less likely to have public health insurance and metabolic syndrome (Table). Detectable (vs. undetectable) PCE (aOR 3.17 [1.23-8.20]) and PCE concentration (aOR per 1 ng/mL increase 5.13 [1.09-24.26]) were associated with higher odds of significant liver fibrosis. In our negative control analysis, 35% of participants with detectable PCE had detectable HEMA. HEMA concentration (aOR per 1 ng/mL increase 0.86 [0.47-1.58]) was not associated with significant liver fibrosis. **Conclusion:** In this national study, PCE was associated with significant liver fibrosis, with a negative control analysis suggesting that this association is distinct to PCE. Our results should encourage prospective studies to confirm PCE as a contributor in liver disease progression to inform screening strategies and environmental policies.

Table. Demographics, socioeconomic and clinical characteristics of group with detectable vs undetectable PCE and HEMA

	PCE		HEMA	
	Detectable (n= 116)	Undetectable (n=1498)	Detectable (n=380)	Undetectable (n=707)
Characteristic	Weighted %, (95% CI)	Weighted %, (95% CI)	Weighted %, (95% CI)	Weighted %, (95% CI)

3403 | FROM TRIALS TO TARGETS: HYDRONIDONE'S MECHANISTIC ROLE IN REVERSING HEPATIC FIBROSIS

Qichao Ge[1] Zhangdi Hanjing[1] Hui Huang[2] Yuecheng Guo[1] Yufei Yang[1] Xin Luo[1] Qingqing Zhang[1] Junjun Wang[1] Zhenyang Shen[1] Mingwang Wang[1] Guangwen Chen[1] Yanping Ye[3] Ling Zhang[3] Ying Luo[3] Xiaobo Cai[1] Hui Dong[1] Hu Zhou[2] Lungen Lu[1], [1]Department of Gastroenterology, Shanghai General Hospital, [2]State Key Laboratory of Drug Research, Shanghai Institute of Materia Medica, [3]Continent Pharmaceuticals Co., Ltd., Beijing, China

Background: Hydronidone (HDD) has been demonstrated to have beneficial effects on alleviating liver fibrosis in phase II and phase III clinical trials conducted by our group. However, the direct targets of HDD remain unclear. **Methods:** Proteomics, 20K Human Proteome Microarray (20K HuProt), Pull Down/LC-MS/MS, Surface Plasmon Resonance (SPR) and Cellular Thermal Shift Assay (CETSA) were used to detect and validate target proteins of HDD in HSCs. Molecular docking technology was used to explore the HDD binding domain in the target protein. Histology, western blot (WB), immunofluorescence (IF) staining, and RT-qPCR were used to detect the antifibrotic effect of HDD on 3, 5-diethoxycarbonyl-1, 4-dihydropyridine (DDC) and carbon tetrachloride (CCl_4) mouse hepatic fibrosis models. The CCK8, WB, IF staining, cell-contraction assay and transwell assay were used to examine the activation of HSC. Seahorse assay was used to detect the metabolic changes of HSC. CHIP assay was used to investigate the transcriptional regulation. HSC-specific *Hif1a* knockout (*Hif1a*-KO^{HSC}) mice were generated by injecting LRAT-Cre-AAV9 into the *Hif1a*$^{flox/flox}$ mice. **Results:** In DDC and CCl_4-induced hepatic fibrosis mouse models, HDD alleviated liver damage and collagen accumulation(Figure 1A-C). Besides, HDD significantly inhibited the proliferation, migration and contraction in immortalized mouse-HSC(Figure 1D-G). Among all the proteins reversed by HDD, LOXL2 was one of the top-ranked proteins(Figure 2A-B). Furthermore, HDD significantly reversed the glycolytic reprogramming during HSC activation(Figure 2C-G). HDD also inhibited glycolytic metabolism in primary HSCs of mice and reduced liver lactate content(Figure 2H-K). Subsequently, our findings revealed that LOXL2 mediated glycolysis by deacetylating YBX1(K81) which could stabilize the *Hif1a* mRNA and promote its translation(Figure 3A-L). In *Hif1a*-KO^{HSC} mice, DDC and CCl_4-induced liver fibrosis were significantly reduced compared with *Hif1a*$^{flox/flox}$ mice(Figure 3M). As detected by 20K HuProt Microarray, Pull-down/LC-MS/MS and SPR, HDD targeted STAT3 in HSC (Figure 4A-C, 4F). CETSA and WB were used to validate that HDD could influence the thermal stability of STAT3(Figure 4D-E). Further molecular docking revealed that HDD directly bound to the conservative SH2 domain of STAT3, inhibiting the interaction of JAK1 and STAT3 and preventing subsequent dimerization and phosphorylation of STAT3(Figure 4G-L). Furthermore, we also validated that STAT3 directly regulated the transcription of *Loxl2* by the CHIP assay(Figure 4M-N). **Conclusion:** HDD reversed the glycolytic reprogramming mediated by LOXL2/YBX1/HIF1a axis during HSC activation. HDD alleviated liver fibrosis by directly targeting STAT3 which regulated *Loxl2* at transcriptional level in HSCs.

3404 | FIVE ANTI-FIBROTIC MICRORNAS ENRICHED IN EXTRACELLULAR VESICLES DERIVED FROM MESENCHYMAL STEM CELLS SUPPRESS HEPATIC STELLATE CELL FIBROGENESIS VIA DOWNREGULATION OF RHOA SIGNALING

Daiki Kawamoto[1] Toshihiko Matsumoto[2] Tsuyoshi Fujioka[1] Naoki Yamamoto[1] Taro Takami[1], [1]Yamaguchi University Graduate School of Medicine, [2]Yamaguchi University Graduate School of Medicine

Background: We have developed a liver regeneration therapy for decompensated liver cirrhosis (DLC) using cultured autologous bone marrow-derived mesenchymal stem cells (BMSCs). A clinical trial (jRCT2063200014) is currently underway, in which hepatic arterial infusion of these cells has improved liver function and fibrosis in patients with DLC. However, the precise anti-fibrotic mechanisms of BMSCs remain unclear. Therefore, we identified anti-fibrotic microRNAs (miRNAs) enriched in MSC-derived extracellular vesicles (MSC-EVs) and investigated the mechanisms by which they suppress fibrogenesis of hepatic stellate cells (HSCs). **Methods:** We compared the miRNA expression profiles in MSC-EVs from DLC patients with those in HSCs using microarray analysis. To identify anti-fibrotic miRNAs enriched in MSC-EVs, we transfected HSCs with miRNA mimics that were highly expressed in MSC-EVs but lowly expressed in HSCs and assessed the expression of fibrosis-related genes. We performed pathway analysis using RNA sequencing data from HSCs transfected with a cocktail of anti-fibrotic miRNAs. RhoA activity and cell motility of HSCs were evaluated using G-LISA assay and time-lapse cell migration assay, respectively. Furthermore, the anti-fibrotic miRNA cocktail was administered to CCl4-induced LC model mice and the resulting histological changes were evaluated. **Results:** We identified 11 miRNAs with normalized intensities $>1{,}000$ in MSC-EVs from DLC patients, with expression levels 100-fold higher than in HSCs. Transfection of these miRNA mimics into HSCs revealed five miRNAs that suppressed the expression of fibrosis-related genes (*ACTA2, COL1A1, COL1A2, COL3A1, and ELN*). Notably, transfection of a cocktail of these five miRNAs led to downregulation of all fibrosis-related genes. KEGG pathway analysis revealed downregulation of RhoA signaling pathway in the HSCs transfected with the miRNA cocktail, which was confirmed by G-LISA as reduced RhoA activity. Time-lapse cell migration assays showed that the miRNA cocktail treatment inhibited HSC migration. Moreover, administering the miRNA cocktail significantly reduced fibrotic areas in the livers of LC model mice. **Conclusion:** This study identified five anti-fibrotic miRNAs in MSC-EVs and elucidated a mechanism of action in suppressing fibrosis via downregulation of RhoA signaling in HSCs. These findings could lead to the development of novel therapeutic strategies for liver fibrosis.

3405 | WITH NO LYSINE KINASE 1 (WNK1) SIGNALING IN HEPATIC STELLATE CELLS PROMOTES GLUCOSE TRANSPORTER 1 (GLUT1) TRANSLOCATION TO THE PLASMA MEMBRANE AND EX VIVO HUMAN LIVER FIBROSIS.

Zeba Firdaus[1] Shalil Khanal[1] Alexander Washington[1] Jasmin Farmakes[1] Vijay Shah[2] Patrick Starlinger[1] Gina Razidlo[1] Matthew Schellenberg[1] Enis Kostallari[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Hepatic stellate cell (HSC) activation in response to platelet-derived growth factor B (PDGF) and transforming growth factor beta 1 (TGF) is a hallmark of liver fibrosis. HSC activation is characterized by increased glucose uptake and glycolysis to meet high energy demands. However, the signaling leading to this metabolic shift, subsequent HSC activation, and liver fibrosis remain unknown and are the aim of this study. **Methods:** In vitro, primary human HSCs or LX2 cells (HSC line) were analyzed by Western blot (WB) and immunofluorescence (IF). Chemical genetics consisted in generating a $WNK1^{T301G}$ mutant that utilizes bulky N6-substituted ATP-γ-S analog. Thiophosphorylated proteins were immunoprecipitated and analyzed by WB. Ex vivo, human precision cut liver slices (PCLS) were obtained utilizing a vibratome and analyzed by WB. **Results:** Our lab has previously identified WNK1 as a novel kinase in HSC activation that promotes glucose uptake (TLM 2024). Public RNA sequencing (GSE119606) demonstrated that HSCs expressed higher levels of WNK1 compared to WNK2, WNK3 and WNK4 (23971-fold, 104-fold, 25-fold, respectively, $n=3$, $p<0.05$). In addition, PDGF, but not TGF, increased WNK1 expression in HSCs (1.4-fold, $n=3$, $FDR<0.05$). More strikingly, PDGF, but not TGF, increased WNK1 phosphorylation, and thus activation by 3-fold (WB, $n=4$, $p<0.05$). Next, we assessed the effect of WNK1 on glucose transporter 1 (GLUT1) translocation to the

plasma membrane, a crucial step for glucose uptake. PDGF increased GLUT1 translocation to the plasma membrane by 1.5-fold compared to vehicle, which was abrogated by WNK1 selective inhibitor WNK-IN-11 (IF, $n = 3$, $p < 0.05$). To explore the widely unknown WNK1 downstream signaling, we employed chemical genetics. PDGF treatment of mutant WNK1^{T301G}-transfected LX2 cells increased thio-phosphorylation of several proteins compared to controls. PDGF stimulation led to increased AKT phosphorylation in HSCs by 8.5-fold, which was significantly reduced 3-fold by WNK-IN-11 ($n = 3$, $p < 0.05$), indicating that WNK1 activates downstream AKT. Functionally, we utilized our ex vivo 3D culture of human liver sections from consented patients to assess the effect of WNK1 on human liver fibrosis. We found that PDGF-mediated collagen 1 deposition in hPCLS was 2-fold abrogated by WNK-IN-11 ($n = 5$, $p < 0.05$). **Conclusion:** Together, these results identify WNK1 as a PDGF-activated kinase that promotes GLUT1 translocation to the plasma membrane and ex vivo human liver fibrosis.

3406 | MECHANISTIC AND CLINICAL APPLICATION STUDY ON GSTM3 KNOCKOUT PROMOTING REVERSAL OF LIVER FIBROSIS VIA INHIBITION OF HEPATIC STELLATE CELL ACTIVATION

Chenxue Hou[1] Yuanying Zhao[1] Lei Sun[1] Qi Wang[1] Yue Li[1], [1]Beijing Ditan Hospital, Capital Medical University, Beijing, China.

Background: Liver fibrosis, a key pathological step in chronic liver disease progression to cirrhosis, features dynamic reversibility that offers a critical therapeutic window. However, unclear reversal mechanisms and lacking precise diagnostic markers hinder effective efficacy assessment. Glutathione S-transferase Mu3 (GSTM3), a GST superfamily member involved in detoxification, metabolism, oxidative stress, and carcinogen handling, is upregulated in murine fibrosis models. Yet its role in fibrosis reversal and underlying mechanisms—given distinct progression/regression pathways—remain undefined. This study explores GSTM3's regulatory function in hepatic stellate cell (HSC) activation during fibrosis reversal and its molecular basis, aiming to establish GSTM3 as a novel therapeutic target and noninvasive biomarker. **Methods:** CCL4-induced fibrotic mice were allowed 4- or 12-week withdrawal to model spontaneous regression. Western blot and immunohistochemistry analyzed hepatic GSTM3 protein expression. LX-2 cells with GSTM3 overexpression/silencing were stimulated with TGF-β to assess fibrosis markers (elastin, COL1A1, fibronectin). RNA-seq identified differential pathways in GSTM3-silenced, TGF-β-activated LX-2 cells. Plasma GSTM3 levels in patients were measured via ELISA and correlated with severity. **Results:** ELISA showed higher plasma GSTM3 in fibrosis patients vs. controls, correlating with severity. Hepatic GSTM3 increased in CCL4 mice but decreased in regression models, correlating with resolution degree. TGF-β upregulated GSTM3 in LX-2 cells. GSTM3 silencing reduced elastin, COL1A1, and fibronectin; overexpression increased α-SMA, TIMP-1, and COL1A1. Transcriptomics revealed GSTM3 knockdown inhibited PI3K-Akt and PPAR pathways, blocking HSC activation. **Conclusion:** GSTM3 knockdown promotes fibrosis reversal by inhibiting HSC activation and collagen deposition. With dual tissue/serum expression, GSTM3 offers translational potential as both therapeutic target and noninvasive biomarker, providing a molecular strategy for precision management of liver fibrosis.

3407 | CAN YOU REASON YOUR WAY OUT OF CIRRHOSIS? EVALUATING THE IMPACT OF REASONING ON LARGE TRANSFORMER-BASED PRETRAINED MODELS FOR LIVER CIRRHOSIS MANAGEMENT

Ernest Saenz[1] Jose A. Benitez, M.D.[1] Manuel Linares[1] Andres Gomez Aldana[1], [1]Texas Liver Institute, University of Texas Health Science Center, San Antonio, United States

Background: Liver cirrhosis remains a major global health challenge, accounting for approximately 1.47 million deaths in 2021 (95% UI 1.37–1.58 million), equivalent to 2.4% of all global deaths that year. Rising prevalence of non-alcoholic fatty liver disease further amplifies this burden, driving both morbidity and healthcare costs worldwide. Large language models (LLMs) have emerged as promising aids, capable of extracting key clinical data and automating score calculations, but their effectiveness in hepatology may depend on explicit reasoning capabilities from the latest reasoning architectures implemented on their training. **Methods:** We conducted a three-phase evaluation of twelve state-of-the-art LLMs, six engineered for explicit chain-of-thought reasoning and six using standard next-token prediction, First, two hepatologist selected 58 MedQA multiple-choice items (A–D) and 41 PubMedQA yes/no/maybe questions, and we measured each model's accuracy. Next, one board-certified hepatologist crafted five clinical vignettes containing all required lab values to compute FIB-4 and MELD-Na scores, prompted each model to calculate directly from free text, and analyzed absolute error, signed error, and MAPE. **Results:** Across tasks, reasoning-enabled LLMs consistently outperformed non-reasoning models, while open-source status had no significant effect. In the MedQA benchmark, reasoning conferred a significant accuracy advantage ($F = 11.86$, $p = 0.0006$), with no main effect of open-source status ($p = 0.171$) or interaction ($p = 0.149$). In the PubMedQA task, all model categories achieved similar accuracy ($F = 0.435$, $p = 0.734$). For FIB-4 calculation, reasoning models reduced median MAE by 54.7% compared to non-reasoning counterparts (5.10 vs. 11.27; Mann–Whitney $U = 118$, $p \approx 7 \times 10^{-5}$), despite a mean bias of –7.66 and overall MAPE of 37.3%. MELD-Na predictions proved most challenging: only 12% of outputs fell within ± 5 points of the reference score, and 12% deviated by > 10 points, with no significant influence of reasoning ($p = 0.42$) or open-source status ($p = 0.38$). **Conclusion:** Reasoning-enabled LLMs significantly outperform their non-reasoning counterparts in numeric score calculation (FIB-4: 5.10 vs. 11.27 MAE, $p < 0.0001$) and contribute a robust main effect in multiple-choice hepatology Q&A (MedQA: $F = 11.86$, $p = 0.0006$). Open-source status does not substantially affect performance across tasks. Despite persistent challenges in MELD-Na accuracy and prediction outliers, our findings demonstrate that integrating explicit reasoning chains into LLM architectures yields a marked improvement over "original" non-reasoning models for liver cirrhosis management. We recommend prioritizing reasoning-capable LLMs when developing AI-driven clinical decision support tools in hepatology.

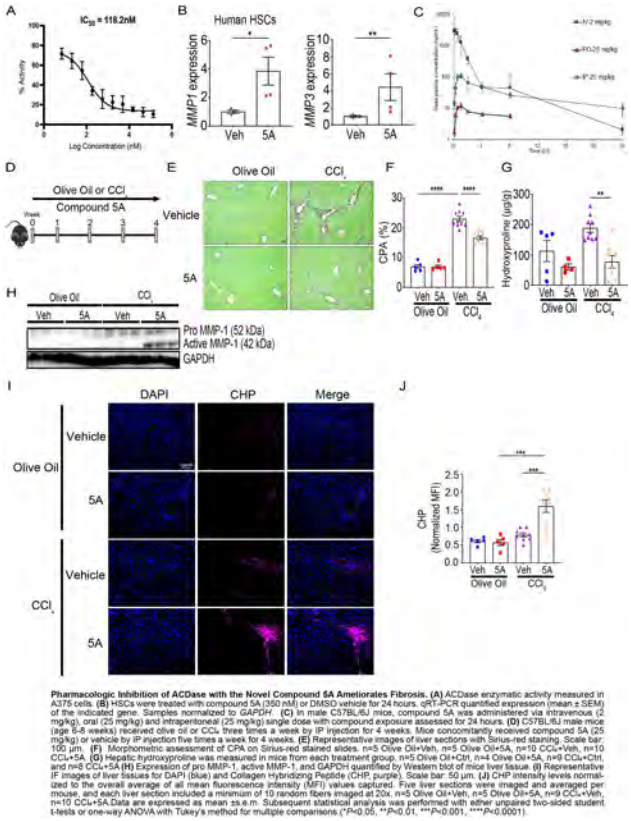
Background: Acid ceramidase (aCDase) is a key enzyme in sphingolipid metabolism and is upregulated in several diseases including cancer and fibrosis. Our previous studies demonstrated that aCDase inhibition or deletion in hepatic stellate cells (HSCs) ameliorated hepatic fibrosis in mouse models and *ex vivo* human precision cut liver slices. There are no FDA-approved therapies to inhibit aCDase, and current tool compounds often lack potency and metabolic stability. Thus, we aimed to develop novel aCDase inhibitors for the treatment of fibrotic diseases. **Methods:** Using structure-based drug design and systematic SAR cataloging, we identified covalent inhibitors of acid ceramidase (aCDase) through enzymatic assays on purified protein and primary hepatic stellate cell (HSC) lysates. HSC activation and collagen degradation were evaluated by qPCR, Western blotting, and immunofluorescence staining with a collagen hybridizing peptide. Cell viability was assessed in primary HSCs and HepG2 cells. Pharmacokinetic profiling of compound 5A was conducted following intravenous (IV), oral (PO), and intraperitoneal (IP) administration to determine its plasma concentration. Hepatic fibrosis was induced using the carbon tetrachloride (CCl_4) model, and compound 5A was delivered via IP injection. Fibrosis and collagen remodeling were assessed by hydroxyproline quantification, Sirius Red staining, collagen hybridizing peptide staining, and second harmonic generation (SHG) microscopy. **Results:** We screened over 50 compounds with various warhead groups, and discovered aryl-substituted heterocyclic urea as a new scaffold. We enhanced potency and metabolic stability through targeted modifications, which led to the discovery of compound 5A. Compared to tool compounds, compound 5A exhibited higher potency and metabolic stability. Furthermore, compound 5A promoted HSC inactivation and induced the production of collagenases to degrade collagen. Among CCl_4-treated mice, compound 5A significantly increased collagen degradation and ameliorated fibrosis. **Conclusion:** Through structure-based drug design, we discovered a novel aCDase inhibitor, compound 5A. Our findings identify compound 5A as a potent and metabolically stable aCDase inhibitor that effectively promotes hepatic stellate cell inactivation, enhances collagen degradation, and reduces liver fibrosis in vivo. These results support further development of compound 5A as a promising therapeutic candidate for the treatment of fibrotic liver disease.



Pharmacologic Inhibition of ACDase with the Novel Compound 5A Ameliorates Fibrosis. (A) ACDase enzymatic activity measured in A375 cells. **(B)** HSCs were treated with compound 5A (350 nM) or DMSO vehicle for 24 hours. qRT-PCR quantified expression (mean ± SEM) of the indicated gene. Samples normalized to *GAPDH*. **(C)** In male C57BL/6J mice, compound 5A was administered via intravenous (2 mg/kg), oral (25 mg/kg) and intraperitoneal (25 mg/kg) single dose with compound exposure assessed for 24 hours. **(D)** C57BL/6J male mice (age 6-8 weeks) received olive oil or CCl_4 three times a week by IP injection for 4 weeks. Mice concomitantly received compound 5A (25 mg/kg) or vehicle by IP injection five times a week for 4 weeks. **(E)** Representative images of liver sections with Sirius-red staining. Scale bar: 100 μm. **(F)** Morphometric assessment of CPA on Sirius-red stained slides. n=5 Olive Oil+Veh, n=5 Olive Oil+5A, n=10 CCl_4+Veh, n=10 CCl_4+5A. **(G)** Hepatic hydroxyproline was measured in mice from each treatment group. n=5 Olive Oil+Ctrl, n=4 Olive Oil+5A, n=9 CCl_4+Ctrl, and n=8 CCl_4+5A **(H)** Expression of pro MMP-1, active MMP-1, and GAPDH quantified by Western blot of mice liver tissue. **(I)** Representative IF images of liver tissues for DAPI (blue) and Collagen Hybridizing Peptide (CHP, purple). Scale bar: 50 μm. **(J)** CHP intensity levels normalized to the overall average of all mean fluorescence intensity (MFI) values captured. Five liver sections were imaged and averaged per mouse, and each liver section included a minimum of 10 random fibers imaged at 20x. n=5 Olive Oil+Veh, n=5 Olive Oil+5A, n=9 CCl_4+Veh, n=10 CCl_4+5A.Data are expressed as mean ±s.e.m. Subsequent statistical analysis was performed with either unpaired two-sided student t-tests or one-way ANOVA with Tukey's method for multiple comparisons.(*P<0.05, **P<0.01, ***P<0.001, ****P<0.0001).

Background: Activation of hepatic stellate cells (HSCs) is the main cause of liver fibrosis, which leads to cirrhosis, liver failure, and hepatocellular carcinoma. Understanding the mechanisms underlying HSC activation is essential, as there is currently no effective treatment for liver fibrosis. However, a major challenge in studying HSCs is that they spontaneously activate and transdifferentiate into myofibroblasts over time when cultured on plastic plates. Although recent studies have reported that the stiffness of the extracellular matrix (ECM) contributes to HSC activation, the details of the mechanism remain unclear. The aim of this study is to clarify the dynamics of HSC activation influenced by ECM stiffness with temporal progression. **Methods:** After perfusion of livers of BALB/c mice with pronase and collagenase, HSCs were isolated by density gradient centrifugation and seeded onto soft polydimethylsiloxane (PDMS) plates (0.2 kPa) as well as standard polystyrene plastic plates ($>$ 1 GPa). Single cell RNA-sequencing (scRNA-seq) was performed on six HSC samples: day 0 (immediately after isolation), days 1 and 3 for PDMS plates, and days 1, 3, and 8 for plastic plates. **Results:** Morphologically, day 1 HSCs on PDMS plates were rounded, while those on plastic plates exhibited characteristic protrusions. Integrated scRNA-seq data from six samples were clustered and annotated, identifying thirteen distinct HSC clusters. Gene set enrichment analysis demonstrated that the cluster which was predominantly composed of day 1 HSCs on PDMS plates highly expressed hallmark genes of unfolded protein response. Moreover, violin plots revealed that quiescent markers such as *Reln* and *Rgs5* were significantly higher in day 0 HSCs and remained elevated in HSCs of days 1 and 3 on PDMS plates compared to the plastic conditions on the same day. Myofibroblastic markers such as *Acta2* and *Col1a1* were most highly expressed in day 8 HSCs on plastic plates. Notably, inflammatory markers such as *Ccl2* and *Ccl7*, which are suggested to be expressed in the early period of HSC activation, were high and increased with ECM stiffness on day 1 and persisted at high level in day 3 HSCs on PDMS plates, whereas their expression declined in day 3 HSCs on plastic plates. **Conclusion:** ECM stiffness is one plausible factor contributing HSC activation. Since the initiatory phase of HSCs rapidly diminishes, culturing on softer matrices is more suitable for research in initiation of HSC activation.

3410 | PET-BASED MOLECULAR IMAGING OF INTEGRIN αVβ6 ENABLES NONINVASIVE ASSESSMENT OF LIVER FIBROSIS

TUO SHAO Yanzhang Tian[1] Xiaoyi Wang[2] Xin Gao[1] Huanhuan Song[2] Mengqi Wang[2] Xunchen Zhao[1] Congzhong Hu[1] Raymond Chung[3] Zhifang Wu[4], [1]Shanxi Bethune Hospital, [2]Soochow University, [3]Massachusetts General Hospital, [4]Shanxi Medical University

Background: The activation of latent transforming growth factor beta 1 (TGFβ1) on epithelial surfaces, accompanied by the upregulation of integrin αvβ6, plays a critical role in liver fibrogenesis. Molecular imaging targeting the integrin αvβ6 offers a potential noninvasive approach to assess its expression and function in the activation of TGFβ1 in the injured liver. This could provide valuable prognostic insights into chronic liver disease. The radiotracer ^{68}Ga-DOTA-R01-MG, a cystine knot peptide specifically targeting integrin αvβ6, has shown promise as a PET tracer. In this study, we aimed to compare the uptake of ^{68}Ga-DOTA-R01-MG between normal and fibrotic livers to evaluate its utility in assessing liver fibrogenesis. **Methods:** We utilized PET/CT to assess changes in integrin αvβ6 binding of ^{68}Ga- DOTA-R01-MG in the livers of mice with bile duct ligation (BDL)- and carbon-tetrachloride (CCl_4)-induced liver fibrosis compared with controls. We performed Sirius red staining to assess liver fibrosis, immunofluorescence to identify the location of integrin αvβ6 expressed in fibrotic liver. Additionally, we measured the expression levels of integrin αvβ6, CK19, F4/80 and alpha smooth muscle actin (α-SMA) at both the protein and mRNA levels in control and fibrotic livers. Autoradiography was also conducted to assess tracer uptake in liver sections from both animal models. *Ex vivo* analysis of frozen liver tissue from patients with fibrosis and cirrhosis verified the animal findings. **Results:** Fibrotic mouse livers exhibited significantly increased uptake and retention of ^{68}Ga- DOTA-R01-MG. The radiotracer demonstrated specific binding to integrin αvβ6, primarily expressed on activated bile duct epithelial cells. Hepatic tracer uptake at 30 minutes post-injection was notably higher in fibrotic livers compared to controls. Autoradiography and histopathological analysis corroborated the PET imaging findings, further supporting the specificity of the tracer. Additionally, mRNA and protein levels of integrin αvβ6 and its signaling complex were elevated in both fibrosis models compared to controls. Autoradiography further confirmed the PET imaging finding of high radioactivity

binding in fibrotic liver. The results obtained from analyses on human fibrotic liver sections supported the animal findings. **Conclusion:** Imaging hepatic integrin αvβ6 with PET and ^{68}Ga-DOTA-R01-MG offers a potential noninvasive method for monitoring the progression of liver fibrosis.

3411 | VERIFICATION OF THE EFFICACY AND SAFETY OF KEHUANG CAPSULE IN TREATING THE HEPATIC FIBROSIS INDUCED BY CHRONIC HEPATITIS B, A MULTICENTRIC, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED STUDY

Yifan Han[1] Jinghang Xu[1] yanyan yu[1] Yu Chen[2] Sikui Wang[3] Yong Pan[4] Mingqin Lu[5] Shuangsuo Dang[6] Jingbao Hu[7] Wei Li[8] Qingxian Cai[9] Qinshou Chen[10] Xiong Li[10] Guangming Li[11] Ming He[12] Zhan Zeng[13] Ning Lin[13] Xiaoyuan Xu[13], [1]Peking University Fisrt Hospital, [2]BEIJING YOUAN HOSPITAL,CAPITAL MEDICAL UNIVERSITY, [3]Liaocheng People's Hospital, [4]Xuzhou Infectious Disease Hospital, [5]The First Affiliated Hospital of Wenzhou Medical University, [6]The Second Affiliated Hospital of Xi'an Jiaotong University(Xibei Hospital), [7]Shenzhen Bao'an Traditional Chinese Medicine Hospital Group, [8]Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, [9]Shenzhen Third People's Hospital, [10]GaoZhou people's hospital, [11]The Sixth People's Hospital of Zhengzhou, [12]The First Affiliated Hospital of Nanyang Medical college, [13]Peking University First Hospital

Background: Infection with hepatitis B virus can cause chronic hepatitis B (CHB) with sustained inflammation of liver, which may cause hepatic fibrosis. Kehuang capsule (KHC) is an herbal medicine traditionally used to treat hepatic diseases and many components of KHC were reported to have anti-inflammatory effects. In this study, we evaluated the efficacy and safety of KHC treating CHB-induced hepatic fibrosis. **Methods:** This multicentric, randomized (1:1), double-blind, placebo-controlled study was conducted in 12 centers and enrolled adult Chinese patients with hepatic fibrosis induced by CHB. This study adopted the protocol of "C + T vs C + P" (C = conventional treatment = antiviral treatment, T = treatment = KHC 4# tid for 48 weeks Z P = placebo, Figure 1). The primary outcome measure was set as the percentage of cases whose liver stiffness measurement (LSM) value reduced ≥ 30%. The second outcome measures were set as fibrosis (FIB)-4 index, AST-to-platelet ratio index (APRI) scores, indices of hepatic function, indices of hepatic fibrosis, and hepatic fibrosis-related symptoms. **Results:** A total of 56 subjects finished the follow-up and were analyzed. Figure 2 shows the primary outcome measure, percentage of the patients whose LSM declined > 30% in treatment group was significantly higher than that of placebo group after treatment for 48 weeks (42.31% vs 9.09, P = 0.0099). In terms of the secondary outcome measures, the indices of hepatic functions (aspartate aminotransferase, alanine aminotransferase, total bilirubin, and β-glutamyltranspeptidase) and aspartate aminotransferase-to-platelet ratio index significantly ameliorated in treatment group after 12 weeks (Figure 3). The indices of fibrosis-4 ameliorate after 24 weeks, and pain in the right upper abdomen significantly ameliorated in treatment group after 48 weeks (Figure 4). In terms of safety, KHC did not add the incidence of adverse events. No drug-related ADE, ADE inducing drug withdrawal, ADE inducing reduction of dose, and ADE causing death were reported. **Conclusion:** KHC is a useful adjuvant with satisfactory efficacy and safety for the mainstream antiviral therapy in treating CHB-induced hepatic fibrosis.

3412 | HYDRONIDONE ACTIVATES THE PTEN–ATG7 AXIS TO RESTORE MITOPHAGY AND CURB OXIDATIVE STRESS IN HEPATOCYTES DURING EXPERIMENTAL LIVER FIBROSIS

Yuecheng Guo[1] Qichao Ge[1] Hanjing Zhangdi[1] Yufei Yang[1] Junjun Wang[1] Qingqing Zhang[1] Yanping Ye[2] Ling Zhang[2] Ying Luo[2] Xiaobo Cai[1] Hui Dong[1] Lungen Lu[1], [1]Shanghai general hospital, [2]Continent Pharmaceuticals Co.

Background: Chronic liver injury drives extracellular-matrix accumulation and hepatocyte damage, culminating in fibrosis. Hydronidone (HDD) is a newly identified anti-fibrotic compound. We aimed to investigate whether HDD protects hepatocytes during fibrogenesis and delineate the underlying mechanism. **Methods:** C57BL/6 mice received carbon tetrachloride (CCl_4, 6 weeks) to induce fibrosis; HDD (100 mg kg^{-1} day^{-1}, oral) was administered throughout. Hepatocyte apoptosis and oxidative stress were assessed by TUNEL staining and antioxidant-enzyme assays. Mitophagy and mitochondrial damage were monitored under a transmission electron microscope. Bulk RNA-seq, single-nucleus RNA-seq and protein microarrays, combined with drug-affinity-responsive-target-stability (DARTS) assays, were used to identify HDD targets. Hepatocyte-specific ATG7 knock-down was achieved with AAV8-TBG-shAtg7. **Results:** HDD down-regulated inflammatory and fibrogenic gene sets. ATG7 may be the core gene regulating mitophagy, oxidative stress and cell death in injured livers. HDD significantly up-regulated ATG7, accelerated mitophagic flux, reduced reactive-oxygen-species levels and decreased TUNEL-positive hepatocytes during liver fibrogenesis. Silencing ATG7 abolished HDD-mediated anti-fibrotic effects. Single-nucleus RNA-seq revealed an HDD-responsive hepatocyte cluster with high ATG7 expression. Proteomic screening and DARTS identified phosphatase-and-tensin homologue (PTEN) as a direct HDD target. HDD increased total PTEN and decreased its inhibitory phosphorylation. **Conclusion:** HDD mitigates hepatocyte injury in fibrotic liver by binding to PTEN and activating the PTEN–ATG7 pathway, which restores mitophagy and limits oxidative stress. These findings position HDD as a promising therapeutic candidate for liver fibrosis.

3413 | MITOCHONDRIAL UNCOUPLER PROMOTES HEPATIC STELLATE CELL ACTIVATION AND LIVER FIBROSIS BY IMPAIRING MITOCHONDRIA AND LYSOSOME FUNCTION

Ji Hyun LEE[1] Jae Min KIM[2] Ji Hye YANG[2] Sung Hwan KI[1], [1]College of Pharmacy, Chosun University, [2]College of Korean Medicine, Dongshin University

Background: Hepatic stellate cells (HSCs) play a central role in liver fibrosis. Mitophagy, the lysosome-dependent degradation of mitochondria, can be induced by carbonyl cyanide m-chlorophenyl hydrazone (CCCP). However, the role of CCCP-mediated mitophagy in HSC activation and liver fibrogenesis remains poorly understood. **Methods:** The effects of CCCP on mitochondrial function, mitophagy, and liver fibrogenesis in relation to lysosomal dysfunction were evaluated both *in vitro* and *in vivo*. Moreover, the antifibrotic effect of 5-aminoimidazole-4-carboxamide ribonucleoside (AICAR), which is representative AMPK activator, was also investigated. **Results:** CCCP treatment in HSCs led to mitochondrial dysfunction, evidenced by reduced mitochondrial membrane potential, mitochondrial DNA content, and ATP production, along with increased mitochondrial reactive oxygen species (mROS). CCCP also induced mitophagy but impaired mitophagic flux due to lysosomal dysfunction. Furthermore, CCCP upregulated plasminogen activator inhibitor-1 (PAI-1), an effect that was mitigated by mitochondrial division inhibitor 1 (Mdivi-1). This CCCP-induced increase in PAI-1 was attributed to lysosomal impairment. *In vivo*, CCCP administration in mice induced both mitophagy and liver fibrogenesis. Liver tissues from CCCP-injected mice showed elevated markers of hepatic fibrosis and mitophagy. Importantly, AICAR treatment reversed CCCP-induced mitophagy and the subsequent activation of HSCs, which is not dependent on AMPK activation. **Conclusion:** CCCP promotes hepatic fibrogenesis through mitochondrial dysfunction and lysosomal impairment, suggesting that CCCP-associated pathways may serve as potential therapeutic targets for liver fibrosis.

3414 | FUNCTIONAL EVALUATION OF BM-MSC–EVS ON LSEC NORMALIZATION AND HEPATIC PROGENITOR CELL INDUCTION

Seul Ki Han[1] Mi Ra Lee[2] Jin Suk Lee[2] Moon Young Kim[2] Soon Koo Baik[2], [1]Yonsei wonju severance christian hospital, [2]Yonsei University Wonju College of Medicine

Background: Liver sinusoidal endothelial cell (LSEC) normalization (deactivation) is important for suppressing the progression of liver fibrosis and cirrhosis by improving the liver's microenvironment and stabilizing various cells involved in liver fibrosis through cross-talk. Recent studies have revealed that the normalization (deactivation) of damaged (activated) LSECs enhances Wnt-β-catenin signaling in LSECs, which, in turn, promotes the activation of hepatic progenitor cells (HPCs) and strengthens regeneration. Therefore, LSEC normalization can serve as a critical and useful target for the treatment of liver fibrosis and liver regeneration. In this context, we aim to confirm LSEC normalization using LSEC-targeting extracellular vesicle (EVs). **Methods:** The cytotoxicity of exosomes at different concentrations was assessed using the CCK-8 assay in mouse primary LSECs. The non-cytotoxic concentration of exosomes (50 μg/ml) was then treated on LSECs, and changes in the expression of factors involved in the Wnt-β-catenin signaling pathway were analyzed using qPCR and Western blot. Additionally, the expression changes of markers related to proliferation and activation in HPCs induced by exosomes were examined using molecular biological techniques. **Results:** After treating LSECs with exosomes, the expression of relevant factors was analyzed 24 hours later. Gene expression of markers associated with the Wnt-β-catenin signaling pathway (eNOS, Wnt2, Wnt9b, β-catenin, caveolin1) was found to increase. Additionally, the expression of HGF and VEGF also showed an increase. Regarding protein expression changes, levels of eNOS, Wnt2, Wnt9b, and β-catenin were elevated. When HPCs were treated with exosomes, an increase in cell number was observed. Furthermore, in markers related to differentiation, the expression of Krt19, Sox9, and Epcam decreased, while the expression of CD133 and Alb increased. **Conclusion:** Using BM-MSC-derived EVs, we observed an increase in factors related to normalization in LSECs. Additionally, it appears that EVs can promote both proliferation and differentiation in HPCs.

3415 | LY6C^{LOW} MACROPHAGES MITIGATE LIVER FIBROSIS VIA GALECTIN-9-MEDIATED TIM-3 ACTIVATION

Eunmi Lee[1] Kyurae KIM[1] Sung Eun Choi[2] Min Jeong Kim[1] Katherine Po Sin Chung[2] Kwang Woo LEE[1] Jihyo Byun[1] Jaewoo Oh[1] Seungryong Choo[1] WON-IL JEONG[1], [1]KAIST, [2]Korea Advanced Institute of Science and Technology

Background: Despite the global prevalence of liver fibrosis, effective treatments remain unavailable to date. As an immune checkpoint molecule, T-cell immunoglobulin and mucin-domain containing-3 (TIM-3) plays a role in regulating both adaptive and innate immune cells, including macrophages, and is deeply involved in chronic liver disease. Here, we investigate how TIM-3 expression changes in macrophages in a spatio-temporal manner during liver fibrosis. **Methods:** Liver fibrosis was induced in wild-type (WT) and TIM-3 whole knockout (KO) mice using carbon tetrachloride (CCl_4). Single-cell RNA sequencing (scRNA-seq) analysis was performed in CCl_4-treated mouse livers. To explore the expression changes of TIM-3, macrophages of bone marrow, blood and liver were subjected to flow cytometry analysis. Other biochemistry, qRT-PCR, and immunostaining were performed. For *in vitro* mechanistic studies, bone marrow-derived macrophages (BMDMs) were stimulated with a specific recombinant galectin-9 (Gal-9) to evaluate its role. **Results:** In scRNA-seq analysis, Gal-9 was expressed in multiple cell types but TIM-3 expression was mainly observed in Ly6C^{low} macrophages. In normal mice, flow cytometry analysis revealed that TIM-3 expression was detected in most macrophages of blood and bone marrow, whereas its expression significantly increased in Ly6C^{low} macrophages but decreased in Ly6C^{high} macrophages of liver. Similarly, in liver fibrosis, TIM-3 expression was predominantly expressed in Ly6C^{low} macrophages, and these cells were observed near activated hepatic stellate cells. Interestingly, liver fibrosis was more aggravated in TIM-3 KO mice than WT mice although CCl_4-mediated liver injury was similar in both mice. Moreover, the expression of fibrosis-related genes such as *Col1a1* and *Tnf* was significantly elevated in TIM-3 KO mice. *In vitro*, Gal-9 treatment suppressed LPS-induced activation of WT BMDM but not in TIM-3 KO BMDM. **Conclusion:** Ly6C^{low} macrophages specifically express TIM-3, and its activation inhibits liver fibrosis. Therefore, our

findings may provide novel insights into therapeutic strategy for liver fibrosis through the Gal-9/TIM-3 axis in Ly6C^{low} macrophages.

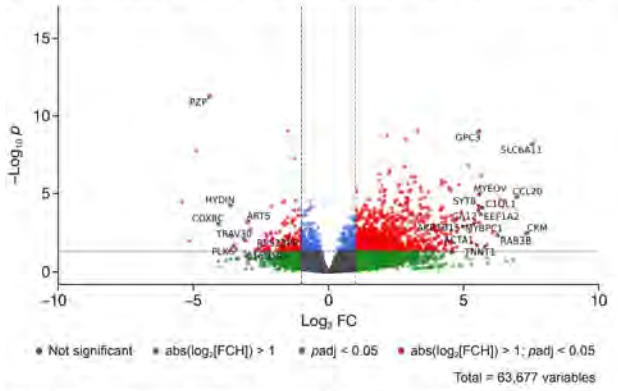
3416 | LIVER TRANSCRIPTOMIC SIGNATURES IN PATIENTS WITH ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED LIVER DISEASE WITH A PI*ZZ GENOTYPE ARE SIMILAR TO THOSE IN OTHER FIBROTIC LIVER DISEASES

Malin Fromme[1] Maria Paraskevopoulou[2] Ruixue Hou[2] Jen-Chieh Chuang[2] Nirav Desai[2] Susana Gonzalez[2] Tami Nussbaum[2] Abeer Zeitone[2] Pavel Strnad[1], [1]University Hospital RWTH Aachen, Aachen, Germany, [2]Takeda Development Center Americas, Inc., Cambridge, MA, USA

Background: Alpha-1 antitrypsin deficiency-associated liver disease (AATD-LD), caused by the protease inhibitor (Pi)*ZZ genotype, arises owing to accumulation of hepatic misfolded alpha-1 antitrypsin leading to cell stress, inflammation and cell damage, and subsequent liver fibrosis/cirrhosis. The underlying molecular mechanisms associated with fibrosis in patients (pts) with AATD-LD and a Pi*ZZ genotype are not fully understood. We aimed to identify and map differentially expressed genes (DEGs) associated with liver fibrosis in pts with AATD-LD with fibrosis and a Pi*ZZ genotype versus a healthy reference (Pi*MM) and compare Pi*ZZ transcriptomic signatures with those of other fibrotic liver diseases. **Methods:** Samples from pts with AATD-LD with fibrosis and a Pi*ZZ genotype were analyzed versus the Pi*MM reference. Bulk RNA sequencing and logistic regression were used to identify DEGs. DEGs were integrated with single nucleus RNA-sequencing (sNuc-seq) data consisting of pts with metabolic dysfunction-associated steatohepatitis (MASH) to map potential source cells in the liver. Functional characterization of DEGs was performed to link changes in gene expression to pathways using over-representation analysis (ORA) and ingenuity pathway analysis (IPA). Pathway analyses were extended to MASH and primary sclerosing cholangitis (PSC) data to enable cross-disease comparisons. **Results:** Bulk RNA sequencing data from 13 pts with AATD-LD and fibrosis with a Pi*ZZ genotype and 6 healthy individuals with a Pi*MM genotype were analyzed. Comparison of the Pi*ZZ and Pi*MM genotypes identified 1645 DEGs ($p < 0.05$), including 1277 upregulated and 368 downregulated DEGs (Figure). Of the upregulated DEGs in Pi*ZZ, 69% mapped to non-parenchymal cells (mesenchymal, immunocytes, cholangiocytes and endothelial) while 63% of downregulated DEGs were enriched in hepatocytes. ORA and IPA linked DEGs to pathways involved in cell stress, inflammation and extracellular matrix and collagen production; upstream regulators (e.g., *IL-1B, TNF* and *TGFB1*) of these pathways were enriched in the Pi*ZZ genotype. Canonical pathways associated with hepatic stellate cell activation and liver fibrosis were activated in the Pi*ZZ versus Pi*MM genotype and overlapped with pathways associated with fibrosis in MASH and PSC. **Conclusion:** This is the first known liver transcriptomics study including the Pi*ZZ genotype. In pts with AATD-LD and fibrosis with a Pi*ZZ genotype, transcriptomic profiles were similar to those identified in MASH and PSC. Findings from this study advance the understanding of AATD-LD pathophysiology and highlight potential non-invasive biomarkers with utility in the diagnosis and management of AATD-LD. Future research to further evaluate the importance of these biomarkers in AATD-LD pathophysiology and response to emerging therapy is currently under investigation.

Writing support provided by R Tooze, Oxford PharmaGenesis.

Figure. Volcano plot of DEGs in patients with AATD-LD and fibrosis with a Pi*ZZ genotype versus healthy individuals with a Pi*MM genotype.



DEGs with a significant change in expression were defined as abs(log$_2$[FCH]) > 1 and *p*adj < 0.05. The top 1% of upregulated and downregulated genes that adhered to the FCH and *p*adj criteria are annotated.
AATD-LD, alpha-1 antitrypsin deficiency-associated liver disease; abs, absolute; DEG, differentially expressed gene; FCH, fold change; NS, not significant; *p*adj, adjusted *p* value; Pi, protease inhibitor.

3417 | EPIDERMAL GROWTH FACTOR RECEPTOR MEDIATES HIV-RELATED LIVER INFLAMMATION AND FIBROSIS

Yongtao Wang[1] Shadi Salloum[1] Wenyu Lin[1] Min Xu[1] Ben Leaker[1] Eliana Epstein[1] Ava Brookshier[1] Zeinab Heidariyan[1] Tanvi Patel[1] Nadia Alatrakchi[1] Kenneth Tanabe[1] Georg Lauer[1] Raymond Chung[1],
[1]Massachusetts General Hospital and Harvard Medical School

Background: Although HIV is not directly hepatotropic, chronic liver disease has become a major cause of mortality in individuals infected with HIV, even under conditions of effective antiretroviral therapy (ART) suppression. Therefore, new strategies to slow HIV-induced liver fibrosis and the development of suitable are urgently needed. Our previous study supports the notion that epidermal growth factor receptor (EGFR) plays a significant role in liver disease, particularly in liver regeneration, fibrosis, and hepatocellular carcinoma (HCC). **Methods:** Bioinformatics analysis of single-cell RNA sequencing (scRNA-seq) data from peripheral blood mononuclear cells (PBMCs) and microarray data from primary Kupffer cells (pKCs, liver-resident macrophages) infected with HIV, were conducted. Livers from HIV gp120 protein-exposed mice were also investigated. Precision-cut liver slices (PCLS) were prepared from human livers and subsequently infected with HIV virus, along with supplementary treatment. Molecular assessments were further performed. **Results:** scRNA-seq data revealed that, compared with healthy donor, HIV infection was associated with upregulation of EGFR and its downstream genes in PBMCs, along with increased inflammation. Similarly, microarray data from pKCs showed that HIV infection resulted in the upregulation of EGFR and its downstream genes, while liver function signatures decreased and inflammatory and profibrogenic markers were induced. A prognostic liver signature (PLS) panel analysis also indicated that signatures predicting good prognosis or lower risk of progressive liver disease were significantly inhibited, whereas signatures (including EGF, a ligand that binds to EGFR) associated with poor prognosis or higher risk of liver disease progression were increased. More importantly, increased phosphorylation of EGFR was observed in the livers from HIV gp120 protein-exposed mice, accompanied by heightened inflammatory and fibrogenic gene expression. Using the *ex vivo* precision-cut liver slices (PCLS) model, HIV infection induced upregulation of EGFR expression, HIV gag mRNA, and inflammatory and profibrogenic gene expression. Additionally, treatment with erlotinib, an EGFR inhibitor, effectively mitigated HIV-induced EGFR expression and the associated inflammatory and profibrogenic responses in PCLS. **Conclusion:** HIV infection enhances hepatic EGFR signaling, leading to increased inflammation and profibrogenic activity in the liver. The findings suggest that targeting EGFR with inhibitors such as erlotinib may offer a potential therapeutic strategy to mitigate HIV-associated liver inflammation and fibrosis.

3418 | ANALYSIS OF CLINICAL CHARACTERISTICS AND LONG-TERM PROGNOSIS IN YOUNG HEPATITIS B CIRRHOSIS: A PROPENSITY SCORE MATCHING STUDY

Zhenhua Zhang[1] Pengyue Zhang[1] Xiaodan Hong[1],
[1]Second Affiliated Hospital of Anhui Medical University

Background: Cirrhosis is rare in young individuals, and clinical differences between young and elderly patients remain unclear. This study aimed to evaluate the clinical characteristics and prognosis of HBV-related cirrhosis in young patients. **Methods:** A hospital-based retrospective cohort of young cirrhosis patients was analyzed. Multivariable analysis identified risk factors for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

severe complications during follow-up, while the Cox proportional-hazards model assessed the prognosis of young and adult patients with HBV-related cirrhosis. Prognostic analysis was conducted using propensity score matching (PSM) to adjust for baseline differences between the groups. **Results:** The study included 545 patients with cirrhosis, including 119 in the younger group. Young patients with HBV-related cirrhosis exhibited significant differences from adult patients in gender, Alb, ALT, AST, and HBV titer. Kaplan-Meier analysis indicated a higher survival rate in the young group (log-rank test, $P = 0.04$); however, no significant difference remained after PSM. Youth was identified as an independent risk factor for gastrointestinal bleeding during follow-up (OR = 3.61, 95% CI: 1.62–8.00, $P = 0.002$). Additionally, age and elevated ALP levels were independent risk factors for survival. A Cox-based prediction model demonstrated good prognostic performance (C-index = 0.69). **Conclusion:** The prognosis of young patients with HBV-related cirrhosis was not superior to that of elderly after PSM. Special attention should be given to severe complications, particularly gastrointestinal bleeding, during follow-up. These findings may inform targeted interventions to reduce the burden of early-onset cirrhosis.

3419 | THYROID DYSFUNCTION REFLECTS DISEASE SEVERITY AND IS ASSOCIATED WITH SHORT-TERM MORTALITY IN HOSPITALIZED CIRRHOTIC PATIENTS

Christos Triantos[1] Konstantinos Papantoniou[1] Efthymios Tsounis[1] Evdoxia Avramopoulou[1] Pinelopi Filippopoulou[2] Ioanna Aggeletopoulou[1] Georgios Geramoutsos[1] Odyssefs Ampazis[1] Markos Marangos[2] Spilios Manolakopoulos[3] Konstantinos Thomopoulos[1] Marina Michalaki[4], [1]Division of Gastroenterology, Department of Internal Medicine, University of Patras, Patras, Greece, [2]Department of Internal Medicine, University of Patras, Patras, Greece, [3]Hippocrates General Hospital of Athens, [4]Division of Endocrinology, Department of Internal Medicine, University of Patras, Patras, Greece

Background: Non-Tyroidal Illness Syndrome (NTIS) refers to thyroid hormone abnormalities in critically ill patients despite an intact hypothalamic-pituitary-thyroid axis. This study investigates thyroid hormone alterations in hospitalized cirrhotic patients and their potential prognostic significance. **Methods:** We prospectively enrolled patients with cirrhosis of any etiology who were hospitalized at our center. Blood samples were collected upon admission and at discharge for survivors. Thyroid function tests—including T3, free T3 (fT3), T4, free T4 (fT4), and TSH—were measured alongside routine laboratory parameters. **Results:** A total of 72 patients were included (M/F: 56/16; median age: 63 years) Cirrhosis etiologies included ALD (n = 44), viral hepatitis (n = 10), ALD + viral (n = 6), MASH (n = 2), PBC (n = 3), and unknown (n = 7). Significant negative correlations were found between T3 and MELD (r = -0.266, $p = 0.026$), and CLIF-C/ACLF (r = -0.409, $p < 0.001$). fT3 was also negatively associated with MELD (r = -0.245, $p = 0.041$) and CLIF-C/ACLF (r = -0.334, $p = 0.005$). T4 inversely correlated with MELD (r = -0.406, $p < 0.001$) and Child-Pugh (r = -0.268, $p = 0.025$). TSH positively correlated with MELD (r = 0.364, $p = 0.002$) and Child-Pugh (r = 0.398, $p = 0.001$).

Patients with decompensated cirrhosis had significantly lower T3 (median 0.75 vs. 0.90 ng/mL, p = 0.039), lower fT3 (3.29 vs. 3.72 pmol/L, p = 0.014), and higher TSH (1.82 vs. 1.11 mIU/L, p = 0.038) compared to those with compensated disease. Among patients with paired samples at discharge, further thyroid dysfunction was noted, with a median decline in fT3 of 0.62 pmol/L (IQR: 0.05–1.13, p = 0.001) and T4 of 0.78 µg/dL (IQR: 0.16–1.75, p = 0.002). Eight patients died during hospitalization, and twelve more died within two months post-discharge due to liver-related complications. Those who died had significantly higher baseline TSH [median 2.36 mIU/L (IQR: 1.35–3.66) vs. 1.20 (0.83–2.78); p = 0.048] and lower fT3 [3.19 pmol/L (2.35–3.51) vs. 3.42 (3.10–4.12); p = 0.048] compared to longer-term survivors. **Conclusion:** Hospitalized patients with cirrhosis exhibit abnormal thyroid hormone profiles suggestive of NTIS, which correlate with liver disease severity and are associated with short-term mortality. Thyroid function testing at admission may provide valuable prognostic information in this vulnerable patient population.

3420 | CD146 PROMOTES THE PROGRESSION OF HEPATIC FIBROSIS VIA ACTIVATION OF THE P38-MAPK SIGNALING PATHWAY

Bingqing Yang[1] Chenxue Hou[1] Yixue Shu[2] Quan Sun[2] Qi Wang[1], [1]Beijing Ditan Hospital, Capital Medical University, Beijing, China., [2]Capital Medical University, Beijing, China.

Background: Hepatic fibrosis represents a common terminal pathway of various chronic liver diseases and may progress to cirrhosis or hepatocellular carcinoma. It is characterized by excessive deposition and insufficient degradation of the extracellular matrix (ECM). Currently, our understanding of the regulatory mechanisms underlying hepatic fibrosis remains limited, and effective therapeutic strategies are lacking. This study aims to investigate the role of CD146 in hepatic fibrosis and elucidate its potential molecular mechanisms. **Methods:** Mouse models of hepatic fibrosis were established using carbon tetrachloride (CCl_4) administration and a methionine-choline-deficient (MCD) diet. CD146 expression in hepatic tissues was assessed. To examine the role of CD146 in hepatocytes, mice overexpressing CD146 specifically in the liver (AAV8-CD146) and control mice (AAV8-GFP) were generated and subjected to a high-fat diet (HFD). Hepatic inflammation and fibrosis were evaluated, and transcriptomic analysis of liver tissues was performed. Additionally, hepatocyte-specific CD146 knockout mice ($CD146^{Alb\text{-}Cre}$) and their littermate controls ($CD146^{flox/flox}$) were constructed under CCl_4-induced fibrotic conditions to further validate the function of CD146. **Results:** Western blot and RT-qPCR analyses demonstrated that both CCl_4- and MCD-induced hepatic fibrosis significantly upregulated CD146 mRNA and protein levels in liver tissues. Under HFD conditions, AAV8-CD146 mice exhibited more pronounced hepatic inflammation and fibrosis compared to control mice, as evidenced by increased macrophage infiltration (F4/80 immunohistochemistry) and enhanced collagen deposition (Masson's trichrome staining). These findings suggest that CD146 overexpression exacerbates hepatic inflammatory responses and fibrotic progression. Conversely, in CCl_4-$CD146^{Alb\text{-}Cre}$ mice, macrophage infiltration and collagen deposition were markedly reduced, indicating that CD146 deficiency mitigates hepatic inflammation and fibrosis.

Mechanistic studies further revealed that CD146 overexpression significantly upregulated various pro-inflammatory genes (Il6, Il1β, Tnfα, Mcp1) and pro-fibrotic genes (Tgfβ, Col1a1, Col3a1), accompanied by activation of the p38-MAPK signaling pathway. In contrast, CD146 deletion suppressed the expression of these genes and their corresponding proteins. Taken together, these findings suggest that CD146 may promote hepatic inflammation and fibrosis by activating the p38-MAPK signaling pathway, thereby enhancing the expression of inflammatory and fibrogenic mediators. **Conclusion:** This study demonstrates that CD146 expression is upregulated during hepatic fibrosis. Its overexpression aggravates liver inflammation and fibrosis, whereas CD146 deletion exerts a protective effect. Mechanistically, CD146 may promote disease progression by activating the p38-MAPK signaling pathway.

◆ 3421 | INTERLEUKIN-22 PROMOTES LIVER REGENERATION BY REPROGRAMMING GLYCOLYTIC METABOLISM IN A MOUSE ALPPS MODEL

sheng wang[1] Jiale Lu[1] Fengsheng Dai[1] Cheng Zhang[1] MaoYun Liu[1] Yi Wang[1] YuQin Xie[1] Genshu Wang[2] DeWei Li[1] Hui Li[1], [1]Chongqing University Cancer Hospital, [2]The Second Affiliated Hospital of Guangzhou University of Chinese Medicine

Background: Associating Liver Partition and Portal vein ligation for Staged hepatectomy (ALPPS) enables curative resection in patients with previously unresectable liver cancer by rapidly inducing liver regeneration. However, the underlying molecular mechanisms remain unclear. Interleukin-22 (IL-22), a cytokine involved in tissue repair, may promote hepatocyte proliferation, but its role in ALPPS-induced regeneration and metabolic regulation is unknown. This study explores the contribution of IL-22 to liver regeneration in a mouse ALPPS model, with a focus on glycolytic metabolic reprogramming. **Methods:** Liver regeneration was induced using the ALPPS procedure in 8-week-old C57BL/6J mice. Global *Il22* knockout ($Il22^{-/-}$) mice were generated in-house using CRISPR/Cas9 gene editing technology. IL-22 signaling was inhibited in vivo via hydrodynamic injection of IL-22 binding protein (IL-22BP). Cytokine arrays were used to screen for differentially expressed cytokines in liver tissues. Single-cell RNA sequencing was performed to identify distinct cell clusters and analyze cell–cell interactions. AML12 cells were treated with recombinant IL-22 (rmIL-22) in vitro, and cell proliferation was assessed using EdU, CCK-8 and cell cycle analysis. RNA-seq was performed to identify differentially expressed genes following IL-22 stimulation, followed by enrichment analysis. Metabolic assays, including ^{13}C-glucose tracing, glucose uptake, lactate production assays, and Seahorse extracellular flux analysis, were performed to assess glycolytic flux. **Results:** Cytokine array profiling revealed IL-22 as the most significantly upregulated cytokine in liver tissues after ALPPS. IL-22 knockout or inhibition with IL-22BP significantly suppressed liver regeneration. RNA-seq and enrichment analyses revealed that ALPPS significantly promoted cell cycle progression and cytokine-receptor interactions. Single-cell RNA sequencing analysis showed a pronounced post-ALPPS accumulation of monocytes and natural killer T (NKT) cells in the regenerating liver. In vitro, rmIL-22 stimulation markedly enhanced the proliferative capacity of AML12 cells. Integrated transcriptomic and metabolic flux analyses further demonstrated that IL-22 regulates glycolytic metabolism during liver regeneration. **Conclusion:** This study identifies IL-22 as a key cytokine upregulated during ALPPS-induced liver regeneration, with NKT cells as a potential primary source. These findings support a model in which NKT cell–derived IL-22 promotes liver regeneration by driving glycolytic metabolic reprogramming.

◆ 3422 | HCV NAT+ CONSENT IS ASSOCIATED WITH INCREASED LIVER TRANSPLANTATION AND REDUCED WAITLIST MORTALITY IN PATIENTS LISTED WITH A MELD EXCEPTION FOR HCC

Puru Rattan[1] Farinaz Ghodrati[1] Nadim Mahmud[2], [1]University of Pennsylvania Perelman School of Medicine, [2]Hospital of the University of Pennsylvania

Background: The supply-demand mismatch in liver transplantation remains significant. In the last decade, direct-acting antiviral agents for the Hepatitis C virus (HCV) have expanded the donor pool by allowing HCV nucleic acid testing-positive (NAT+) organs to be safely transplanted. However, to receive HCV NAT+ organs, waitlist registrants must provide specific consent. We have shown that this HCV NAT+ consent reduces time to transplantation and waitlist mortality in the overall waitlisted population. It is unclear if this benefit extends to the unique population of registrants with hepatocellular carcinoma (HCC) who are listed with low Model for End-stage Liver Disease (MELD) scores and a

MELD exception. **Methods:** A retrospective cohort study using United Network for Organ Sharing (UNOS) data was conducted. All adult patients listed between 1/2016 and 10/2023 with an application for MELD exception for HCC were included. The primary exposure was the HCV NAT+ consent status at the time of registration. Two primary outcomes were considered: (1) time to transplantation and (2) time to waitlist mortality. All covariates were collected at time of registration. A time-dependent covariate to indicate active exception status was also created to occur 6 months after the first accepted MELD exception application. Time-to-event analyses were performed to evaluate the association between HCV NAT+ consent and the two outcomes accounting for competing risks. Both Fine-Gray subdistribution hazard ratios (sHR) and cause-specific hazard ratio (csHR) with 95% confidence intervals were calculated. **Results:** There were 15,852 patients in the analytical cohort with 4,954 (31.3%) having consented to receive HCV NAT+ organs. Those consenting were over-represented by registrants with HCV-related CLD and a higher MELD. The proportion of registrants consenting increased from 21% to 56% over the study length with an average increase of 6% per year. Overall, HCV NAT+ consent was associated with a significantly higher rate of transplantation (sHR 1.46, 95% CI: 1.33-1.61) and a marginally lower rate of waitlist mortality (sHR 0.82, 95% CI: 0.68-0.99). **Conclusion:** The proportion of liver transplant waitlist registrants, specifically those listed with a MELD exception for HCC, consenting for HCV NAT+ organs is increasing over time. This pattern is similar to the overall waitlist population but substantial center-level variation is more apparent. The benefit of HCV NAT+ consent in the form of increased likelihood of receiving a transplant and decrease waitlist mortality is clearly shown here. These findings provide evidence to support broadening the donor pool to HCV NAT+ organs to improve transplant access and reduce waitlist mortality even among the patients listed with a MELD exception for HCC. Furthermore, efforts to improve HCV NAT+ consent across all centers is needed.

◆ 3423 | IS MACHINE PERFUSION REPLACING LIVING DONATION FOR LIVER TRANSPLANTATION?

Vladislav Fomin Russell Rosenblatt[1] Robert Brown[1],
[1]Weill Cornell Medicine

Background: In order to increase the supply of organs in the face of ever-increasing demand, liver transplant (LT) centers have been utilizing living donation (LD) and, more recently, machine perfusion (MP). MP is a technique of preserving organs with circulating perfusate during the organ procurement process to increase access to previously marginal organs. LD provides increased access and superior outcomes, but does require a healthy donor to have surgery. Therefore, we aimed to study whether the increased use and comfort with MP is associated with a decrease in LD utilization. **Methods:** We analyzed 70,450 adult LTs from UNOS STAR file from 2016-2024. We focused on 27,685 low-MELD (<20) recipients, who typically have poor access to high-quality deceased donor organs but would be most likely benefit from MP or LD. Centers were categorized by annual LT volume (<25, 25-50, 51-100, >100 /year) and MP adoption patterns. We calculated pre- and post-adoption rates for both MP and LD programs, examined temporal trends, and assessed correlations between MP and LD program changes using chi-square tests, t-tests, and Pearson correlation coefficients. Centers were stratified by MP adoption intensity into terciles (low: $<6\%$, moderate: 6-28%, high: $>28\%$ increase) to examine differential LD response patterns through ANOVA. **Results:** During this period, there were 5,240 MP and 3,688 LD transplants. There was widespread adaptation of MP starting in 2022, accounting for 30% (2,875/9,498) of transplants by 2024 by 86 centers. LD experienced steady growth from 4.4% (283) to 6.5% (516) of transplants until 2022, after which there was a decline to 4.9% (493) of transplants. The mean MELD at transplant for MP patients was 21.2 and 16 for LD patients. Living donor rates increased significantly with center volume (3.0% vs 12.9%, $p<0.001$), while machine perfusion adoption peaked with medium-volume centers (12.0% vs 9.9% high-volume, $p<0.05$), surpassing the early advantage of high-volume centers. Use of LD predicted use of MP (+9.3%/year, $p < 0.001$) while MP did not predict LD (0.3%/year, $p = 0.58$). There was a non-statistically significant negative correlation (-0.42, $P = 0.082$) between an increase in MP and LD use. The 23 centers that had the largest year-to-year adaptation rate of MP

(42%) had a decrease in LD use -1.6%, the following year, suggesting substitution. While low (2.5%) and moderate (15.3%) rate of MP adaptation had a gradual increase in LD use 1.2% and 0.8%, respectively. **Conclusion:** As MP use increased over time, LD has had a decrease peaking in 2022 and declining every year since. This possible substitution was most prominent only among centers with aggressive MP adoption (>28% increase). While conservative and moderate MP adopters (86% of centers) maintained or increased their LD programs, demonstrating a complementary strategy. Ultimately, both strategies are needed to meet the increasing demand.

◆ 3424 | THE IMPACT OF COMBINED HEART-LIVER ALLOCATION ON HIGH-ACUITY LIVER TRANSPLANT CANDIDATES IN THE UNITED STATES: INTENTION-TO-TREAT ANALYSIS

Toshihiro Nakayama[1] Antony Attia[1] Marc Melcher[1] Tami Daugherty[2] Kazunari Sasaki[1], [1]Stanford University, [2]Stanford University Medical Center

Background: In the United States, high-acuity adult liver transplant candidates are bypassed by candidates for combined heart-liver transplant (CHLT) who accepted the heart. After the heart allocation policy change in 2018, access to CHLT has increased, raising concerns that a growing CHLT volume may disadvantage high-acuity liver candidates. The OPTN Ad Hoc Multi-Organ Transplantation Committee is currently debating standardized multi-organ allocation to ensure equitable access, making it essential to assess whether bypassed liver candidates are disadvantaged today. **Methods:** We analyzed OPTN match run data from January 2010 to September 2024, identifying 568 adult CHLT and 2,014 high acuity (MELD ≥ 35) adult candidates bypassed on the match run by CHLT candidates. The bypass cohort included only high-acuity candidates, as these patients are at increased risk for waitlist dropout and are more likely than lower MELD candidates to receive livers allocated to CHLT candidates. One-year graft survival of CHLT was compared between before (Era 1) and after the heart policy change on October 18, 2018 (Era 2). One-year intention-to-treat (ITT) survival of bypassed candidates —from the time of bypass until any death (waitlist dropout or post-transplant death)— were compared to a control cohort (three matched listings per bypassed candidate) matched by age at offer, gender, laboratory MELD score, blood type, and UNOS region. In Era 2 only, we conducted subgroup analyses of one-year ITT survival within UNOS regions stratified by CHLT volume, defining high-volume regions (UNOS 4, 5, 7, 9, 11; ≥ 30 CHLT cases in Era 2) and low-volume regions (all others; < 30 cases). **Results:** The number of CHLT has gradually increased, with 73 cases conducted in 2023. One-year graft survival worsened from 88.9% in Era 1 to 79.8% in Era 2 ($p < 0.01$), driven by early graft loss. In Era 1, one-year ITT survival was similar between bypassed candidates and matched controls (62.3% vs. 63.5%, $p = 0.91$). In Era 2, bypassed candidates exhibited inferior one-year ITT survival (72.8% vs. 77.3%, $p < 0.01$). This impact was particularly observed in high-volume regions (71.9% vs. 77.6%, $p < 0.01$), while no significant difference was observed in low-volume regions (74.2% vs. 76.9%, $p = 0.25$). **Conclusion:** CHLT volume has increased after the heart policy change, and the short-term outcomes are worsening. In the current era, adult candidates bypassed by CHLT candidates exhibited inferior ITT survival, especially in UNOS regions with high CHLT volume. Future simulation analyses are warranted to establish evidence-based allocation strategies that do not disadvantage either heart-liver or high-acuity liver candidates.

◆ 3425 | CLEVER-LG: A MULTIMODAL MACHINE LEARNING BIOMARKER FOR NON-INVASIVE DIAGNOSIS OF LIVER GRAFT INJURY

Soumita Ghosh[1] Cristina Baciu[1] Maryam Naghibzadeh[1] Amirhossein Azhie[1] Muhammad Enrizky Brilian[1] Sara Naimimohasses[1] Sandra Fischer[2] Sandra Holdsworth[1] Arya Rahmani[1] Elisa Pasini[1] Bima Hasjim[3] Michael Brudno[2] Daniel Decarvalho[1] Bastian Engel[4] Elmar Jaeckel[1] Richard Taubert[5] Mamatha Bhat[6], [1]University Health Network, [2]University of Toronto, [3]University of California, Irvine, [4]Medizinische Hochschule Hannover/ Hannover Medical School, Hannover, Germany, [5]Medizinische Hochschule Hannover/Hannover Medical School, Hannover, [6]Toronto General Hospital

Background: Graft injury affects over 30% of liver transplant recipients (LTRs), and its etiology—such as T cell–mediated rejection (TCMR) and metabolic dysfunction–associated steatohepatitis post-transplant (MASH-LT)—can currently only be confirmed through invasive liver biopsy. A non-invasive diagnostic tool is urgently needed to guide treatment and improve patient outcomes. This study aimed to develop CleVER-LG (Cell-free DNA Methylation with Clinical Variables for Early Recognition of Liver Graft Injury), a multimodal machine learning (MML) model that integrates clinical variables with circulating cell-free DNA methylation signatures to classify graft pathology. **Methods:** We analyzed plasma-derived methylation profiles from 135 LTRs (40 MASH-LT, 50 TCMR, and 45 Control-LT) and integrated these with clinical variables to develop CleVER-LG. Differential methylation analysis and pathway enrichment were performed to identify subtype-specific signatures. Feature selection was conducted using the Boruta algorithm, and multiple MMLs—including random forest (RF) and support vector classifier (SVC)—were evaluated using 5-fold cross-validation. **Results:** Distinct methylation signatures associated with graft injury subtypes were identified, revealing enrichment of lipid metabolism and mTORC1 signaling in MASH-LT, and immune response and platelet activation in TCMR. The RF-based CleVER-LG model achieved the highest performance, with a mean weighted AUROC of 0.8005 ± 0.0603. In comparison, unimodal models using only clinical variables or only methylation data showed relatively lower performance (AUROC 0.6016 ± 0.0497 and 0.7987 ± 0.0586, respectively). SHAP analysis of the combined model identified key genes—GPR35, SH3PXD2A, and LDLRAD4—as major contributors to model predictions, consistent with their known roles in hepatic inflammation, extracellular matrix remodeling, and fibrogenic signaling. **Conclusion:** CleVER-LG is a promising non-invasive diagnostic tool for liver graft pathology. By combining clinical and methylation data, it improves the classification of graft injury subtypes, potentially reducing reliance on biopsy and enabling more precise post-transplant monitoring.

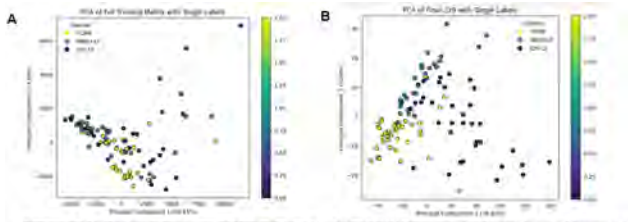

Figure 1 (A) Principal Component Analysis (PCA) of the FPKM (Fragments Per Kilobase of transcript per Million mapped reads)-normalized methylation data for > 5 million sites (full matrix after low reads removal but before feature selection). Each point represents a sample, and the first two principal components show distinct clustering. All the sites together show limited separation among the three graft pathology classes (indicated by color)—TCMR, MASH-LT, and Control-LT (Ctrl-LT)—indicating noise and redundancy in the high-dimensional data. **(B)** PCA of the FPKM - normalized methylation data for the 239 sites after feature selection. Here also, each point represents a sample, and the first two principal components are shown. The selected features reveal improved class separation, with clearer clustering of TCMR and MASH-LT groups. This highlights the effectiveness of Boruta-based feature selection in capturing biologically relevant variance in methylation signatures.

◆ 3427 | OLDER RECIPIENTS TRANSPLANTED WITH HEPATOCELLULAR CARCINOMA HAVE WORSE SURVIVAL DESPITE LOWER SEVERITY OF ILLNESS AND FEWER POST-TRANSPLANT COMPLICATIONS

Therese Bittermann[1] David Goldberg[2] David Kaplan[3] Douglas Schaubel[4], [1]Perelman School of Medicine, [2]University of Miami Miller School of Medicine, [3]University of Pennsylvania, [4]University of Pennsylvania Perelman School of Medicine

Background: Over the past two decades, the proportion of liver transplants (LTs) performed among patients aged ≥65 years has nearly doubled, with this group now representing one-fifth of the national volume. Hepatocellular carcinoma (HCC) is known to account for a substantial proportion of LTs in older individuals. The impact of HCC status and older age on post-transplant outcomes beyond mortality are poorly understood. **Methods:** This was a retrospective cohort study using a data linkage between inpatient and outpatient Medicare claims and the Organ Procurement and Transplantation Network and. All patients aged ≥65 years undergoing first LT alone between 1/1/2007-12/31/2019 with active Medicare coverage at LT were included. Patients were stratified by HCC status and age group (65-69, 70-72 and ≥73 years). Non-liver chronic conditions and rehospitalizations were captured using Medicare claims. Factors associated with post-transplant mortality were evaluated using Cox regression among patients alive with their native allograft at 1-year. **Results:** The cohort included 11,046 Medicare LT recipients with median follow-up time 4.6 years (IQR: 2.6-7.5). This Medicare cohort accounted for 76.8% of all LT recipients ≥65 years nationally during the study period. HCC prior to LT increased from 44.0% in patients 65-69 years to 51.4% in those ≥73 years ($p < 0.001$). Relative to non-HCC recipients, HCC recipients had less advanced liver disease at LT: median Model for End-stage Liver Disease 11 vs 22 ($p < 0.001$) and 20.0% vs 62.1% Child-Pugh class C ($p < 0.001$). Overall non-liver chronic condition burden post-LT was high, with differences being more apparent by HCC status than by age (Table). While most post-LT chronic conditions were more prevalent among non-HCC recipients, non-liver cancers were more common in HCC recipients (14.3% vs 10.4%; $p < 0.001$). Rehospitalizations at 30-, 90- and 365-days were also lower in the HCC group: 17.4% vs 19.1% non-HCC ($p = 0.025$), 33.8% vs 40.2% ($p < 0.001$), 51.9% vs 61.1% ($p < 0.001$), respectively. Yet, unadjusted long-term survival was not different by HCC status ($p = 0.259$). Adjusting for pre-transplant severity of illness, early non-liver chronic conditions and readmissions during the first post-LT year, the HCC group had greater all-cause mortality aHR 1.26 vs non-HCC ($p < 0.001$). **Conclusion:** In this highly representative cohort, older HCC recipients had less advanced liver disease at LT, fewer non-liver chronic conditions and fewer rehospitalizations after LT. The higher prevalence of non-liver cancers, known risk of HCC recurrence, and possibly other unmeasured markers of transplant fitness, may explain the worse post-transplant survival seen in older HCC recipients. Whether older HCC recipients derive survival benefit from LT requires further study, particularly in an era of expanding treatment alternatives.

Table – Prevalence of non-liver chronic conditions post-LT identified during follow-up by HCC status and age at LT (N=11,046)

	HCC at LT (N=4,966)	Non-HCC LT (N=6,080)	p-value
Diabetes	58.4%	61.4%	0.002

◆ 3428 | SURVIVAL OUTCOMES IN DCD AND DBD LIVER TRANSPLANTATION ARE EQUIVALENT IN THE ERA OF NORMOTHERMIC MACHINE PERFUSION

Michelle Nguyen[1] Michele Barnhill[1] Stephanie Ohara[1] Bashar Aqel[1] Blanca Lizaola-Mayo[1] Caroline Jadlowiec[1] Adyr Moss[1] Kunam Reddy[1] Amit Mathur[1], [1]Mayo Clinic Arizona

Background: Liver transplantation using donation after circulatory death (DCD) grafts has historically been associated with worse outcomes than donation after brain death (DBD), primarily due to ischemic complications from static cold storage (SCS). Normothermic machine perfusion (NMP) is now widely used to mitigate ischemia-reperfusion injury and improve graft viability, particularly in DCD transplantation. Its impact relative to contemporary DBD outcomes remains under investigation. **Methods:** We conducted a retrospective, single-center cohort study of adult liver transplants from the post-NMP era between 2022–2024, comparing DCD livers preserved with NMP (DCD-NMP) to all DBD livers including DBD-NMP and DBD-SCS. Primary outcomes were 1-year graft and patient survival. Secondary outcomes included early allograft dysfunction (EAD), ischemic cholangiopathy (IC), primary nonfunction (PNF), and hepatic artery thrombosis (HAT). Associations between donor type and outcomes were assessed using univariate and multivariable Cox models. **Results:** Among 780 liver transplant recipients, 458 received DCD-NMP grafts and 322 received DBD grafts (DBD-NMP n = 127, 39.4%; DBD-SCS n = 195, 60.6%). Donor age was higher in the DCD-NMP group (median 54.0 vs. 47.5 years; $p = 0.012$), and DRI scores were significantly higher (median 2.6 vs. 1.6; $p < 0.001$). DCD-NMP recipients were slightly older (median 62.0 vs. 59.0 years; $p = 0.022$) and had lower MELD scores at transplant (median 17.0 vs. 21.0; $p < 0.001$). Re-transplantation was less frequent in the DCD-NMP group (3.7% vs. 11.2%; $p < 0.001$) (Table 1). EAD occurred in 22.1% of DCD-NMP and 18.9% of DBD recipients ($p = 0.29$); adjusted odds showed no significant difference (aOR 0.77; 95% CI, 0.47–1.27; $p = 0.305$). Biliary anastomotic stricture was more common in DCD-NMP (17.7% vs. 2.8%; $p < 0.001$). Ischemic cholangiopathy was more frequent in DCD-NMP (6.1% vs. 1.2%; $p < 0.001$), with DBD recipients having lower odds (aOR 0.25; 95% CI, 0.08–0.79; $p = 0.018$). Rates of hepatic artery thrombosis (early 0.7% vs. 1.2%, $p = 0.39$; late 2.2% vs. 1.2%, $p = 0.33$) and primary nonfunction (0.9% vs. 0.6%, $p = 1.00$) were low and similar. One-year graft survival was 94.3% for DCD-NMP and 93.7% for DBD ($p = 0.77$); patient survival was 95.5% and 95.6%, respectively ($p = 0.99$). In multivariable analysis, overall (aHR 2.04; 95% CI, 0.65–6.44; $p = 0.223$) and graft survival (aHR 1.47; 95% CI, 0.61–3.54; $p = 0.394$) were comparable between groups. **Conclusion:** In the NMP era, LT using DCD grafts achieves graft and patient survival equivalent to that of DBD transplants, despite higher-risk donor profiles. These findings challenge longstanding biases against DCD use and support the broader adoption of DCD-NMP to safely expand the donor pool and reduce transplant waitlist mortality.

Table 1. Donor and recipient characteristics in DCD-NMP, and DBD (DBD-SCS and DBD-NMP) cases

Jaeckel[2] Michael Brudno[8] Gideon Hirschfield[2] Rahul Krishnan[9] Mamatha Bhat[2], [1]University of Toronto; University Health Network; Vector Institute, [2]University Health Network, [3]Center for Data Science, New York University, [4]Department of Gastroenterology and Hepatology, McGill University, [5]Department of Computer Science, University of Waterloo, [6]Faculty of Medicine, University of Toronto, [7]Canadian Donation and Transplantation Research Program, [8]University of Toronto; University Health Network, [9]University of Toronto

Background: Liver transplantation (LT) is a life-saving intervention for patients with end-stage liver disease (ESLD). However, between 12% and 20% of patients on the LT waitlist die before receiving an LT in the United States, and patient subgroups such as women and those with primary biliary cholangitis (PBC) remain disadvantaged in allocation. Our study objective was to enable more equitable prioritization by individualizing risk prediction with a more expressive class of statistical models. **Methods:** We created DynaMELD, a deep learning-based model of dynamic waitlist prioritization. DynaMELD uses a neural network to model complex interactions between covariates and leverages the rate-of-change (velocity) of time-varying biomarkers to predict risk of mortality or dropout. Our primary cohort comprised 53,046 patients with ESLD listed for LT from 2016 to 2023 from the U.S. Scientific Registry of Transplant Recipients (SRTR), and our external validation cohort comprised 466 patients waitlisted for LT at University Health Network (UHN) in Canada.

DynaMELD was integrated into the electronic health record system at UHN via a dashboard. We then conducted a silent trial of 380 patients waitlisted for LT at UHN, simulating real-time usage without influencing clinical decisions. The dashboard provides patient risk estimates and uses SHapley Additive exPlanations to visualize and interpret the individualized model predictions. **Results:** DynaMELD achieved a 90-day concordance that was 0.5% higher than MELD 3.0 ($p < 0.001$) on the SRTR cohort. Using pooled group concordance (PGCI) as a measure of fairness, DynaMELD achieves a PGCI 1.2% higher for women ($p < 0.001$), 8.3% higher for patients with PBC ($p < 0.001$), 7.2% higher for patients with primary sclerosing cholangitis (PSC; $p < 0.001$), and 1.5% higher for patients with acute-on-chronic liver failure Grade 1 ($p < 0.001$) compared to MELD 3.0. On the UHN cohort, DynaMELD achieves comparable 90-day concordance to MELD 3.0 while improving PGCI in the aforementioned subpopulations. In the silent trial, patients allocated under DynaMELD have a higher probability of receiving a transplant in the following 29 days than under MELD 3.0 ($p < 0.001$). DynaMELD effectively identified higher-risk patients, assigning increased priority to 6.7% more patients who subsequently died on the waitlist, with notable improvements for disadvantaged groups: 2.7% more women, 25.0% more PSC patients, and 56.3% more PBC patients were assigned increased priority, suggesting it would improve these patients' access to organ offers. **Conclusion:** DynaMELD provides more accurate, individualized predictions of waitlist mortality, potentially enabling more fair LT waitlist prioritization. Our study demonstrates the feasibility of deploying a deep learning-based risk scoring tool in the clinic to provide real-time, individualized risk prediction for patients on the LT waitlist.

◆ 3430 | FINITE HUMAN HEPATOCYTE EXPANSION IN CHIMERIC MOUSE LIVERS IS NOT OVERCOME BY TERT OVEREXPRESSION

Viktoriia Iakovleva[1] Eleftherios Michailidis[2] William Schneider[3] Catherine Freije[3] Alireza Ramandi[4] Chenhui Zou[4] Yingpu Yu[3] Corrine Quirk[3] Yichen Zhou[4] Briana Zeck[5] Alison Ashbrook[3] Tomoe Shiomi[5] Markus Grompe[6] John Poirier[7] Luis Chiriboga[5] Charles Rice[3] Ype De Jong[4], [1]Weill Cornell Medicine, [2]Department of Pediatrics, School of Medicine, Emory University, Atlanta, Georgia, [3]Laboratory of Virology and Infectious Disease, The Rockefeller University, New York, NY, [4]Division of Gastroenterology and Hepatology, Weill Cornell Medicine, New York, NY, [5]Department of Pathology, New York University Langone Health, New York, NY, [6]Papé Family Pediatric Research Institute, Oregon Health & Science University, Portland, OR, [7]Laura and Isaac Perlmutter Cancer Center, New York University Langone Health, New York, NY

Background: Human hepatocyte transplantation remains under investigation as a therapeutic modality for liver disease. However, the capacity of transplanted primary human hepatocytes (PHH) to divide and the cellular factors that affect engraftment remains undefined. While murine hepatocytes can divide extensively, the cell division limit for PHH may be governed by replicative aging. Here, we aimed to quantify PHH proliferative constraints and assess strategies to alleviate these constraints. **Methods:** PHH were serially transplanted into immunodeficient liver injury (FNRG) mice and serum human albumin (hAlb) was used to monitor humanization. To quantify productive seeding and expansion, PHH were transduced with lentiviruses encoding multiple fluorophores (Confetti) or encoding unique sequence barcodes. Confetti-labeled liver sections were imaged and barcodes were sequenced to quantify PHH engraftment and expansion. To assess whether telomere attrition limits expansion, PHH at various stages of serial passage were transduced with human telomerase reverse transcriptase (hTERT) before re-transplantation. **Results:** PHH effectively humanized FNRG livers through three rounds of serial transplantation, after which humanization sharply decreased with subsequent passages (Figure 1). Confetti labeling revealed that individual PHH gave rise to spatially distinct, monochromatic islands, supporting their clonal origin. Using image segmentation and a mathematical model, we estimated that islands had a

median diameter of 510.2 μm, corresponding to 16,423 hepatocytes per island, or ~14 cell divisions from a single founder cell. In parallel, high-complexity barcoding provided quantitative clonal resolution at scale. Barcode sequencing showed approximately ~10^4 unique PHH clones engrafted per liver and expanded to ~10^8 cells during each transplantation cycle. This ~10^4-fold increase equates to ~13.3 cell divisions, in close agreement with Confetti-based estimates. To assess whether replicative exhaustion limited expansion, we overexpressed wild-type hTERT in PHH prior to retransplantation. While hTERT did not significantly enhance engraftment or expansion as measured by hAlb levels in third or fourth transplant rounds, it did improve survival in fourth-round-transplanted mice compared to LVAA (catalytically dead) hTERT controls. **Conclusion:** In total, PHHs can expand efficiently for approximately 40 cell divisions during serial passaging, after which their ability to humanize chimeric livers diminishes. hTERT overexpression had no major impact on PHH humanization kinetics, as measured by hAlb levels, during the first four rounds of expansion. This suggests that alternative strategies are needed to extend their proliferative lifespan. These findings highlight the clonal limitations of human hepatocyte therapy and emphasize the need to overcome replicative barriers for sustained liver repopulation.

◆ 3431 | PREOPERATIVE EXERCISE THERAPY ALLEVIATES SURGICAL STRESS-PROMOTED COLORECTAL CANCER LIVER METASTASES BY SHIFTING KUPFFER CELLS TO AN ANTI-TUMOR PHENOTYPE

Janice Oh[1] Carolyn Tsung[1] Arad Jain[1] Yiyu Zhang[1] Hongji Zhang[1], [1]University of Virginia

Background: Colorectal cancer (CRC) is the second leading cause of cancer death in the US, with the majority of patients dying of hepatic metastasis. Surgical resection is the standard of care for hepatic metastasis of colorectal cancer. However, surgery-induced immunologic disturbances can evoke alterations in the host tumor environment to promote disease recurrence. Indeed, systemic and local inflammation and their sustained responses after surgery directly correlate with cancer outcomes for colorectal cancer. To date, strategies to mitigate the negative outcomes of surgical stress have only been shown to be minimally effective. However, preoperative exercise therapy (PEx) has emerged as a promising protective strategy against post-surgical inflammation and recurrence. Our recent findings demonstrate that PEx significantly attenuates liver surgery-induced hepatic inflammatory response. Based on novel data, we hypothesize that PEx ameliorates surgical stress-induced protumorigenic inflammatory responses and sustains an anti-tumor immune microenvironment in the liver. **Methods:** 8-week-old male wild-type mice were randomly divided into PEx and sedentary (Sed) groups, in which the PEx mice ran on a motorized treadmill one hour per day for four weeks. MC38 CRC cells were injected into the mice through the portal vein and surgical stress was induced using a partial hepatic ischemia and reperfusion model. Tumor growth was determined weekly by bioluminescence imaging. The CD45+ immune cells in the liver from Sed and PEx mice 3 weeks after tumor injection were submitted for single-cell RNA sequencing (scRNA-seq). Immune cell populations, Kupffer cells (KCs) and CD8 T cells function were quantified by flow cytometry. KCs from both Sed and PEx mice were isolated for metabolomics. **Results:** We found that 4 weeks of PEx significantly reduces hepatic metastatic tumor growth compared to the sedentary controls. Transcriptomic

analysis using scRNA-seq demonstrated substantial changes in the immune profiles, particularly that PEx shifts pro-tumor Kupffer cells (KC) towards an anti-tumor immunity phenotype. PEx KCs also promote recruitment of CD8+ T cells through the CXCL9-CXCR3+ axis. Furthermore, CXCL9 enhances the anti-tumor activity of CXCR3+ CD8+ T cells. Mechanistically, PEx-induced butyrate accumulation in KCs inhibits histone deacetylase 3, thereby promoting the transcription of CXCL9. **Conclusion:** These results demonstrate PEx remodels the liver microenvironment and enhances anti-tumor immune responses, primarily through CXCL9-CXCR3 axis-mediated interactions between Kupffer cells and CD8+ T cells. These findings provide a strong rationale for incorporating PEx into the treatment strategy for colorectal liver metastasis patients undergoing hepatic surgery, with the potential to reduce post-operative recurrence.

◆ 3432 | PREDICTING RECOMPENSATION AMONG LIVER TRANSPLANT CANDIDATES USING MACHINE LEARNING: INSIGHTS FROM THE UNOS REGISTRY

Damien Chua[1] Yang Hee Seung[2] Ming-Yao Pierre Lim[3] Nicole Shu Ying Tang[4] Donghyun Ko[5] Eunice Xiang-Xuan Tan[2] Mohammad Shadab Siddiqui[6] Margaret Teng[2] Mark Muthiah[2], [1]Lee Kong Chian School of Medicine, Nanyang Technological University Singapore, [2]Division of Gastroenterology and Hepatology, National University Hospital Singapore, [3]Chemical Technology, Ngee Ann Polytechnic, [4]Yong Loo Lin School of Medicine, National University of Singapore, [5]Mount Sinai Morningside and West, Icahn School of Medicine at Mount Sinai, [6]Division of Gastroenterology & Hepatology, Virginia Commonwealth University

Background: Recompensation, or the clinical recovery of liver function in patients initially deemed transplant candidates, remains poorly characterized in large populations. We aimed to identify predictors and develop a predictive model of recompensation among individuals listed for liver transplantation using data from the United Network for Organ Sharing (UNOS). **Methods:** We conducted a retrospective cohort study including adults listed for liver transplantation in the UNOS database between January 1, 2000, and December 31, 2024. Recompensation was defined as delisting due to clinical improvement. Extreme Gradient Boosting (XGBoost) was employed to develop a predictive model, using an 80:20 train-test split. Model performance was assessed via the area under the precision-recall curve (AUC-PR). Univariable logistic regression was performed to quantify the association between clinical features and recompensation. **Results:** Among 178,620 listed individuals, 11,753 (6.6%) were delisted due to improvement. Recompensated individuals had lower MELD scores (median 13 vs. 18), higher albumin levels (3.3 vs. 3.0 g/dL), and lower prevalence of diabetes, ascites, and hepatic encephalopathy (all $p < 0.001$). The XGBoost model achieved an AUC-PR of 0.950, accuracy of 89.8%, and specificity of 95.0%. Key predictors included MELD score, bilirubin, albumin, creatinine, and INR. Alcohol-associated liver disease and HCV were positively associated with recompensation, whereas MASLD and diabetes were negatively associated ($p < 0.001$). **Conclusion:** Recompensation occurs in a clinically distinct subset of liver transplant candidates and can be accurately predicted using machine learning. These findings have implications for refining transplant candidacy assessment and optimizing organ allocation policies.

◆ 3433 | DIGITAL TWIN TRAJECTORY MATCHING REVEALS EQUIPOISE BETWEEN SIMULTANEOUS LIVER-KIDNEY TRANSPLANTATION AND LIVER TRANSPLANT ALONE: A DEEP LEARNING ANALYSIS OF 11,152 UNOS REGISTRY PATIENTS

Eytan Palte[1] Elizabeth Verna[2] Giuseppe Cullaro[1], [1]Columbia University Irving Medical Center, [2]Columbia University Medical Center

Background: Simultaneous liver-kidney transplantation (SLKT) has become standard for patients with combined organ failure. Comparative effectiveness studies have been limited by methodologies that inadequately match by the dynamic decline in pre-transplant kidney function. We employed a novel digital twin approach using deep learning trajectory matching to compare 3-year event-free survival between SLKT and liver transplant alone (LTA). **Methods:** We identified 11,152 liver transplant recipients (UNOS, 2017-2025) with pre-transplant kidney function trajectories. We calculated longitudinal eGFR (2021 CKD-EPI) and extracted eGFR data including final eGFR, rate of late

decline, percentage of time below thresholds, and time to reach critical values. Deep learning autoencoders with 32-dimensional embeddings processed these patterns in 256-patient batches to create high-dimensional representations. Digital twins were generated by matching each SLKT patient to the most similar LTA patient using cosine similarity distance. Primary outcome was 3-year event-free survival (composite of death, liver graft failure). Cox proportional hazards models adjusted for Liver Donor Risk Index (LDRI), MELD at transplant, and Karnofsky Performance Scale (KPS). **Results:** After digital twin matching, 10,840 patients were analyzed (5,446 SLKT, 5,394 LTA) with median follow-up of 2.6 years. The deep learning matching achieved excellent balance with median cosine similarity distance of 0.3 between matched pairs. Trajectory analysis revealed successfully balanced pre-transplant eGFR decline patterns, with mean final eGFR of 7.9 ± 14.0 vs 8.5 ± 14.7 mL/min/1.73m² ($p = 0.04$) for SLKT vs LTA, respectively. SLKT patients had significantly lower LDRI (1.5 ± 0.3 vs 1.6 ± 0.4, $p < 0.001$) and better KPS (51.7% vs 73.5% with grade $< 50\%$, $p < 0.001$). The primary endpoint occurred in 2,067 patients(19.1% event rate). Three-year unadjusted event-free survival was 81.7% vs 80.1% (log-rank $p = 0.04$). After adjusting for LDRI, MELD at transplant, and KPS, this survival advantage was not statistically significant (adjusted HR 0.9, 95% CI 0.9-1.0, $p = 0.3$). **Conclusion:** Using innovative digital twin methodology with trajectory-based matching, we found no significant difference in 3-year event-free survival between SLKT and LTA after adjustment for donor quality and recipient factors. These findings demonstrate equipoise between treatment strategies and support decisions based on individual factors rather than presumed survival benefit. **Disclosures:** Eytan Palte: Nothing to Disclose, Elizabeth Verna: Nothing to Disclose, Giuseppe Cullaro: Ocelot Bio: Consultant, Retro Sciences: Consultant, Ipsen: Consultant

◆ 3434 | RISK STRATIFICATION FOR WAITLIST DROPOUT IN HCC PATIENTS BEYOND UCSF CRITERIA: A COMPETING-RISKS ANALYSIS

Butros Fakhoury[1] Ximena Parraga[2] Eyad Abdulrazzak[2] Behnam Saberi[2], [1]Virginia Commonwealth University, [2]Beth Israel Deaconess Medical Center

Background: Patients with hepatocellular carcinoma (HCC) listed for liver transplantation (LT) beyond the University of California, San Francisco (UCSF) criteria face a high risk of waitlist dropout due to tumor progression or death. Identifying predictors of dropout in this population is essential for optimizing candidate selection and management. We aimed to evaluate predictors of waitlist dropout using a competing-risks framework, accounting for liver transplantation as a competing event. **Methods:** This retrospective cohort study included HCC patients listed beyond UCSF criteria who received bridging locoregional therapy (LRT) between 2003 and 2023, using data from the OPTN/UNOS database Dropout was defined as waitlist removal due to death or clinical deterioration. Liver transplantation was treated as a competing event, while other reasons for removal were censored. Fine-Gray competing-risks regression was used to evaluate predictors of dropout, including interaction terms for Child-Pugh (CP) class and LRT modality (TACE, TARE, ablation, or combination therapy), age, Eastern Cooperative Oncology Group (ECOG) performance status, alpha-fetoprotein, tumor diameter, and tumor multinodularity. Subhazard ratios (sHR) with 95% confidence intervals (CIs) were reported. **Results:** A total of 1,347 patients were included: CP class A ($n = 538$), B ($n = 471$), and C ($n = 338$). TACE was the most common LRT ($n = 613$), followed by combination therapy ($n = 467$), TARE ($n = 147$), and ablation therapies ($n = 120$). The median follow up time was 7 months. Patients with CP class C receiving either TACE or combination LRT had significantly higher dropout risk (sHR 2.8, 95% CI 1.9–4.1; $p < 0.001$ and sHR 2.4, 95% CI 1.6–3.7; $p < 0.001$, respectively). Neither TARE nor ablation was associated with increased dropout risk across CP classes. No significant differences in dropout were observed between LRT modalities among CP class A or B patients. Elevated AFP (≥ 20 ng/mL) independently predicted higher dropout risk, regardless of tumor size or multinodularity. **Conclusion:** Among HCC patients listed beyond UCSF criteria, advanced liver dysfunction (CP class C) and recepients of TACE or combination LRT were associated with a two- to threefold increased risk of waitlist dropout. AFP ≥ 20 ng/mL was a strong, independent predictor of dropout irrespective of tumor burden. These findings highlight the need for individualized risk stratification and tailored

◆ 3435 | PLATELET-RICH PLASMA PERFUSION DURING STATIC COLD STORAGE REDUCES ISCHEMIA-REPERFUSION INJURY IN LIVER TRANSPLANTATION

Boris Yaremin[1] Catherine Anosova[1] Bakhtiyar Kazymov[1] Kamran Alekperov[1] Murad Novruzbekov[1], [1]Sklifosovsky Emergency Medicine Institute

Background: Ischemia-reperfusion injury contributes to primary graft dysfunction in 5-25% of liver transplants, limiting transplant success. Platelet-rich plasma contains concentrated growth factors (PDGF, TGF-β, VEGF) and anti-inflammatory mediators that promote tissue repair. We hypothesized that PRP perfusion during cold storage could protect against IRI without increasing thrombotic complications. **Methods:** Ten liver grafts received PRP perfusion between January-October 2024 with IRB approval. Autologous PRP was prepared by double-centrifugation, achieving 4.2 × 10^5 platelets/μL (3.1-fold increase over baseline). Following procurement, grafts were perfused via portal vein with 500 mL PRP diluted 1:4 in UW solution at 4°C, then stored in standard UW solution for 8.4 ± 2.1 hours. Thrombotic risk was assessed by thromboelastography, D-dimer, fibrinogen levels, and histological examination for microthrombi. IRI evaluation included serum transaminases, bilirubin, INR, histological Suzuki scoring, TUNEL staining for apoptosis, and oxidative stress markers (malondialdehyde, glutathione). **Results:** Recipients averaged 54.2 ± 11.8 years (60% male) with hepatitis C cirrhosis (40%), alcoholic liver disease (30%), PSC (20%), and HCC (10%). No thrombotic risk increase was observed: TEG parameters, D-dimer (245 vs 251 ng/mL, $p = 0.85$), and fibrinogen (312 vs 318 mg/dL, $p = 0.71$) remained unchanged post-perfusion. Histological examination revealed no microthrombi. Significant IRI protection was demonstrated at 24 hours post-reperfusion compared to historical controls: peak AST 1,248 ± 342 vs 2,156 ± 678 U/L ($p < 0.001$), peak ALT 986 ± 298 vs 1,742 ± 521 U/L ($p < 0.001$), total bilirubin 3.2 ± 1.1 vs 5.8 ± 2.3 mg/dL ($p = 0.003$), and INR 1.8 ± 0.3 vs 2.4 ± 0.6 ($p = 0.012$). Histological assessment showed improved Suzuki IRI scores (4.1 ± 1.2 vs 6.8 ± 1.8, $p < 0.001$), reduced TUNEL-positive hepatocytes (12.3 ± 3.8% vs 28.7 ± 7.2%, $p < 0.001$), and decreased oxidative stress markers. Clinical outcomes included 100% primary graft function vs 82% historical rate, reduced hospital stay (12.4 vs 16.2 days, $p = 0.04$), and no thrombotic complications. This pilot study demonstrates that PRP perfusion during static cold storage provides significant hepatoprotection without increasing thrombotic risk. The 42% reduction in peak transaminases and 60% decrease in hepatocyte apoptosis suggest substantial cytoprotective effects, likely mediated by growth factor release, anti-inflammatory mechanisms, and antioxidant properties of PRP components. **Conclusion:** PRP perfusion during static cold storage appears safe and effective in reducing ischemia-reperfusion injury in liver transplantation. This novel preservation enhancement technique warrants further investigation through randomized controlled trials to potentially establish its role in standard organ preservation protocols.

◆ 3436 | LOW BILE OUTPUT DURING NORMOTHERMIC MACHINE PERFUSION IS NOT PREDICTIVE OF POOR GRAFT OUTCOMES

Stephanie Ohara[1] Victoria Stevens[1] Kunam Reddy[1] Amit Mathur[1] Michelle Nguyen[1], [1]Mayo Clinic Arizona

Background: Bile production during normothermic machine perfusion (NMP) is often used as a surrogate for hepatobiliary function and liver graft viability, with thresholds such as ≥4 cc/hr proposed to guide acceptance. However, the predictive value of bile volume remains uncertain, particularly when other perfusion parameters are reassuring. This study evaluates whether low bile output during NMP is associated with adverse graft outcomes. **Methods:** We performed a single-center retrospective cohort study of adult liver transplants preserved using the TransMedics Organ Care System (OCS) between 2022 and 2024. Grafts were categorized by bile production rate during perfusion: low bile output (<4 cc/hr) and high bile output (≥4 cc/hr). The primary outcomes were early allograft dysfunction (EAD), primary nonfunction (PNF), ischemic cholangiopathy, and 1-year graft survival. **Results:** Of 579 NMP-preserved liver transplants, 347 had high bile output (≥4 cc/hr) and 232 had low bile output (<4 cc/hr). Donor and recipient characteristics are summarized in Table 1. Donor age was similar between groups (median 53.0 vs. 53.5 years; p = 0.79), as was the proportion of DCD donors (77.2% vs. 76.3%; p = 0.79). Pump time was longer in the low bile output group (median 14.1 vs. 12.2 hours; p < 0.001). Recipient age (median 62.0 vs. 61.0 years; p = 0.32) and MELD score (median 17.5 vs. 18.0; p = 0.17) were comparable. Perfusion characteristics are summarized in Table 2. End-perfusion lactate was slightly higher in the low bile group (median 0.690[IQR 0.37–1.16] vs. 0.54 [IQR 0.30–0.98] mmol/L; p = 0.005), though both groups demonstrated adequate lactate clearance. Rates of EAD (25.4% vs. 18.7%; p = 0.06), IC (6.9% vs. 3.5%; p = 0.07), and PNF (1.3% vs. 0.6%; p = 0.39) were comparable. One-year graft survival was equivalent between groups, both exceeding 95% (p = 0.8). **Conclusion:** Low bile output during NMP is not associated with inferior post-transplant outcomes and should not be used as a sole criterion for graft discard. These findings support a more nuanced, multiparametric approach to viability assessment, potentially expanding the use of NMP, particularly in marginal grafts.

Table 1: Donor and Recipient Characteristics Between ≥4 cc/hour vs < 4 cc/hour Groups

Variable	≥4 cc/hr	<4 cc/hr	Total (N=579)	p-value
Donor Age, median [IQR], years	53.0 [38.5, 61.0]	53.5 [40.0, 61.0]	53.0 [39.0, 61.0]	0.75
Donor BMI, median [IQR], kg/m²	28.6 [23.7, 33.2]	30.2 [26.1, 36.2]	29.0 [24.6, 34.8]	<0.001
Distance to Recipient Hospital, median [IQR], miles	274.0 [22.0, 593.0]	420.0 [102.8, 783.2]	278.0 [76.5, 765.0]	<0.001
Preservation Time, median [IQR], hours	16.1 [12.4, 20.2]	17.9 [14.3, 22.2]	16.7 [13.4, 20.8]	<0.001

Disease, Columbia University Irving Medical Center, New York, NY, [2]Division of Gastroenterology and Hepatology, University of California, San Francisco, CA, [3]Division of Gastroenterology and Hepatology, Duke University Hospital, Durham, NC, [4]Annette C. and Harold C. Simmons Transplant Institute, Baylor University Medical Center, Dallas, TX, [5]Division of Gastroenterology & Hepatology, Northwestern University FSOM, Chicago, IL, [6]Mailman School of Public Health, Columbia University, New York, NY, [7]Division of Gastroenterology and Hepatology, Northwestern University FSOM, Chicago, IL

Background: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality after liver transplantation (LT). Frailty independently predicts post-LT mortality but it's specific impact on CVD after LT has not been well-described. The purpose of this study was to investigate the association between frailty and the risk of post-LT cardiovascular events. **Methods:** We performed a retrospective chart review of adult patients who were enrolled in the prospective FrAILT cohort study and underwent LT between 1/1/2019-12/31/2022 at five LT centers. Pre-transplant frailty was assessed with the most recent Liver Frailty Index (LFI: grip, chair stands, balance testing) measured in an ambulatory setting prior to LT. The primary outcomes were major adverse cardiovascular events (MACE: acute coronary syndrome, coronary revascularization, congestive heart failure and cerebrovascular events) and composite cardiac events (CCE: MACE, atrial fibrillation and cardiac arrest). A time-to-event analysis was performed, with death as a competing risk. **Results:** 771 patients were included in the study (Table); 64% were male, the mean age was 57.3 ($\pm$10.9) years and mean MELD 3.0 score of 21.6 ($\pm$10.1). The mean ambulatory LFI was 3.86 ($\pm$0.73), with 21% classified as frail, 61% as pre-frail and 18% as robust using previously established LFI cut-offs. Twenty-two (3%) patients experienced a MACE, 57 (7%) experienced a CCE and 32 (4%) died within 1 year of LT. Pre-LT LFI was not associated with MACE on univariable (HR 1.71, 95% CI 0.84-3.49, $p = 0.14$, per 1.0 LFI) or multivariable analysis (HR 1.38, 95% CI 0.74-2.58, $p = 0.32$) adjusted for age, history of type II diabetes mellitus (DMII), coronary artery disease (CAD) and congestive heart failure (CHF). A history of CHF was significantly associated with MACE (HR 9.76, HR 3.53-27.01, $p < 0.01$); 27 (4%) patients had CHF, 25 of whom had CHF due to diastolic dysfunction. Pre-LT LFI was associated with CCE on univariable (HR 1.56, 95% CI 1.03-2.37, $p = 0.04$), but not multivariable (HR 1.25, 95% CI 0.82-1.91, $p = 0.30$) analysis adjusted for age, history of DMII, CAD, CHF or atrial fibrillation/flutter. A history of atrial fibrillation/flutter (HR 4.80, HR 2.36-9.78, $p < 0.01$) was associated with CCE. **Conclusion:** In this retrospective multi-center study, only 3% of LT recipients experienced a MACE and 7% a CCE within 1 year of LT. Pre-transplant frailty was not associated with MACE or CCE. Though CVD contributes to substantial morbidity and mortality in LT recipients, our findings suggest that pre-LT frailty does not significantly impact the overall cardiovascular risk profile of LT recipients.

Table: Baseline Clinical Characteristics

	Total	With MACE	Without MACE	P-value
N	771	22	748	
Sex, male (%)	490 (64%)	13 (59%)	477 (62%)	p=0.48

◆ 3438 | THE ROLE OF IGF-1 AND GDF-8 IN RESTORATION OF MUSCLE HEALTH ASSESSED BY ^{31}P MR SPECTROSCOPY AFTER LIVER TRANSPLANTATION.

Pavel Trunecka[1] Denisa Kyselova[1] Irena Mikova[2] Petr Sedivy[1] Monika Dezortova[1] Mariia Lunova[1] Dana Kautznerova[1] Milan Hajek[1], [1]Institute for Clinical and

Experimental Medicine, [2]Institute for Clilnical and Experimental Medicine

Background: Skeletal muscle is subject of deterioration during chronic liver disease contributing to frailty and impaired patient survival on transplant waiting list or after liver transplantation (LT). Besides assessment of sarcopenia and myosteatosis by pretransplant abdominal CT scan, there is possibility to assess a quality skeletal muscle using ^{31}P MR spectroscopy (MRS) by measuring concentration of macroergic phosphates. In contrast to CT, MRS can be performed repeatedly after liver transplantation and is more predictive of outcome than sarcopenia or myosteatosis [1)]. Insulin-like growth factor-1 (IGF-1) and myostatin (GDF-8) are well known moderators of skeletal muscle growth. Goals of our study was to determine relationship between pre-LT skeletal muscle characteristics and course of its metabolic state up to 12 months after LT. **Methods:** Presence of sarcopenia was assessed using skeletal muscle index and myosteatosis by measuring radiation attenuation of psoas muscle on pretransplant CT scan. Additionally, patients underwent resting ^{31}P MRS of the calf muscle before LT, and 6 and 12 months after. Area of M. gastrocnemius were calculated, and strength of plantar flexes were measured during each MRS session by dedicated ergometr. Plasma concentration of IGF-1 and GDF-8 were measured using commercially available Quantikine ELISA kits (R&D Systems) according to manufacturer's protocols. GDF-8 samples underwent an activation step to convert GDF-8 into its immunoreactive form. **Results:** 83 liver transplant recipients surviving at least 2 years from Tx (33 F, 50M) median age 59 (range 34 - 71) years were evaluated. We have found highly significant differences in concentration of GDF-8 and IGF-1 during the study period corresponding with significant increase in concentration of ATP in skeletal muscle despite very small changes in muscle volume and strength. We have found highly significant differences in concentrations of GDF-8 and IGF-1 measured during pre- and post-LT visits from patients, who presented with ATP muscle concentration bellow 50th percentile in comparison to recipients with "healthy" muscles ($p < 0.001$). **Conclusion:** We have found strong association between the content of ATP measured by ^{31}P MRS in skeletal muscle and concentrations of cytokines involved in skeletal muscle regulation during the first year after LT. Only very weak correlations between pre-LT presence of sarcopenia and myosteatosis and these cytokines concentrations after LT was found supporting our notion of superiority of ^{31}P MRS as a tool for precise skeletal muscle evaluation.

◆ 3439 | IMPACT OF ACUITY CIRCLES POLICY ON MULTIPLE LISTING IN LIVER TRANSPLANTATION

Vladislav Fomin[1] Russell Rosenblatt[2] Robert Brown[2], [1]Weill Cornell, [2]Weill Cornell Medicine

Background: Multiple listing (ML) is a practice that allows liver transplant candidates to register at multiple centers, historically providing advantages to patients with higher socioeconomic status. The 2020 Acuity Circles (AC) policy aimed to improve geographic equity in liver allocation by replacing donation service areas with broader distribution zones; however, the unintended consequences of this policy remain underexplored. We examined how this policy change affected ML patterns and waiting times across MELD scores. **Methods:** We analyzed UNOS liver transplant data (2016-2023) for adult candidates, comparing pre-AC (2016-2019) and post-AC (2020-2023) eras. ML was defined as a single patient registered at multiple centers on different dates. Our primary outcome was the change in ML rates between AC eras. For our secondary outcome, we analyzed changes in ML by

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

patient demographics and UNOS region, waitlist dynamics, and using difference-in-differences analysis and chi-square tests with Bonferroni correction for multiple comparisons. **Results:** Among 94,940 adult liver transplant candidates, ML rates declined significantly from 5.1% pre-AC to 3.1% post-AC (39% relative reduction, $p < 0.001$). White males remained overrepresented among ML patients and ML patients increased in age 53.9 to 54.8 years ($p = 0.017$). 5 of 11 UNOS regions (4, 5, 9, 10, 11) demonstrated significant decreases in ML after Bonferroni correction ($p < 0.0045$), with reductions ranging from 16% to 45% (mean 29%). The proportion of all transplanted patients who were ML declined from 1.6% (443 of 28,378) to 1.1% (346 of 32,884) ($p < 0.001$). ML patients had consistently lower MELD scores compared to single-listed (-2.9 points, $p < 0.001$). Multiple-listed patients had their MELD score increase from 17.2 to 17.8 ($p < 0.05$), and wait times decreased from 170 to 100 days ($p < 0.01$). For ML patients, the transplant rate increased significantly from 18.8% (443 of 2,361) in the pre-AC era to 22.5% (346 of 1,536) in the post-AC era ($p < 0.01$). Among ML patients, private insurance remained stable (66%), while the number of patients with college degrees increased (33.7% to 41.5% $p < 0.001$), suggesting increased concentration among higher socioeconomic status (SES) patients. **Conclusion:** The AC policy achieved substantial reductions in ML overall and across 6 UNOS regions. However, ML continues to be utilized by lower MELD patients to secure shorter wait times and higher transplant rates. While geographic disparities have improved, SES inequities in ML persist.

◆ 3440 | IMPACT OF COVID-19 VACCINATION ON THROMBOSIS RISK IN LIVER TRANSPLANT RECIPIENTS- A MULTICENTER PROPENSITY-MATCHED STUDY

Islam Mohamed[1] Basil Jalamneh[2] Hazem Nasser[3] Jonathan Ghobrial[4] Mirella Youssef[5] Archana Kharel[6] Ahmed Abdelwahab[7], [1]The Cleveland Clinic Foundation-Fairview hospital, [2]Cleveland Clinic Foundation-Internal Medicine, [3]Internal Medicine, University of Wisconsin-Madison, Madison, WI, United States, [4]Alleghany Health Network, [5]The Ohio State University, Columbus, OH, United States., [6]Cleveland Clinic Foundation, [7]The University of Toledo College of Medicine and Life Sciences, Toledo, OH, United States

Background: Covid-19 has significant impact on liver transplant recipients (LTR) including higher rates of hospitalization, ICU admission and mortality. Reports of increased thrombosis attributed to covid vaccine increased uncertainty about the vaccine in solid organ transplant recipients. Despite the plethora of data on positive covid vaccine outcomes on LTR, multiple case records reported increased Portal vein thrombosis (PVT) in vaccinated LTR. This study evaluates the effect of COVID-19 vaccination on thrombosis risk in LTR. **Methods:** Using data from the TriNetX US Collaborative Network, a propensity-matched cohort analysis was conducted. Cohort 1 (vaccinated) included 6,741 patients with liver transplant status who received at least one COVID-19 vaccine dose. Cohort 2 (unvaccinated) comprised 6,741 matched patients who did not receive vaccination. Hazard ratios (HR) and 95% confidence intervals (CI) were calculated for mortality, transplant-specific outcomes, mechanical ventilation, and thrombosis, using Kaplan-Meier survival analysis. **Results:** Of 919 vaccinated LTR; the mean age was 54.0 years ($\pm$14.6), predominantly male, with 62.8% (577/919) identifying as male and 37.2% (342/919) as female, and White individuals represented the majority: 70.4% (647/919). The median follow-up duration in the 1,245 days (IQR: 718 days). COVID-19 vaccination significantly reduced the risk of all measured outcomes. Vaccinated patients demonstrated a 16% reduction in liver transplant complications (HR: 0.84, 95% CI: 0.69–1.0, p0.004), a 23% reduction in post-transplant hospitalizations (HR: 0.77,95% CI: 0.52;1.15, p 0.35), a 36% reduction in ICU admission (HR: 0.64, 95% CI: 0.48–0.85, p 0.05), and a 29 % reduction in thrombosis risk (HR: 0.71, 95% CI: 0.48;1.047, p.2). However, there was increased risk of portal vein thrombosis (HR: 1.22, 95% CI: 0.70;2.13, p.05). **Conclusion:** COVID-19 vaccination was associated with a significant reduction in overall liver transplant complications, ICU admissions, and thrombotic events in liver transplant

recipients. While the vaccine demonstrated a favorable safety profile and protective benefit across most outcomes, a non-significant trend toward increased risk of portal vein thrombosis was observed. These findings support the overall benefit of COVID-19 vaccination in the liver transplant population, while highlighting the need for further investigation into post-vaccination portal vein thrombosis.

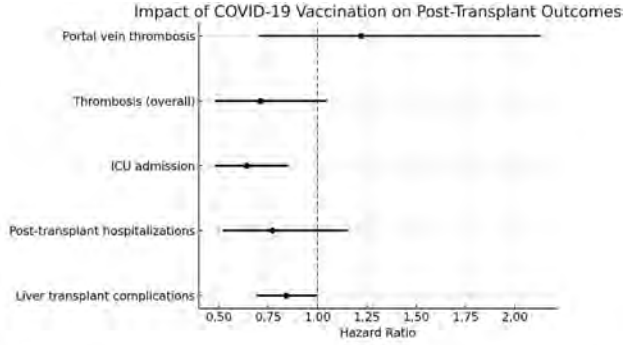

Figure.

Forest plot showing the impact of COVID-19 vaccination on clinical outcomes in liver transplant recipients. Vaccinated patients had a reduced risk of liver transplant complications, ICU admissions, and overall thrombosis compared to unvaccinated counterparts. Hazard ratios (HR) and 95% confidence intervals (CI) are displayed for each outcome. A non-significant increase in portal vein thrombosis was noted. The dashed vertical line indicates the reference value (HR = 1.0).

◆ 3441 | LOSS OF LIVER SYMPATHETIC INNERVATION EXACERBATES HEPATIC INJURY AND METABOLIC DYSREGULATION

Sadam Bhat[1] NUPUR SHARMA[1] Csaba Adori[2] Anupama Parasar[1] Ravinder Singh[1] Babu Mathew[1] Tore Bengtsson[3] Roshan Koul[1] Savneet Kaur[4] Manoj Sharma[1] Jaswinder Singh[5] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences, [2]Karolinsika Institute, Sweden, [3]Department of Molecular Biosciences, The Wenner-Gren Institute (MBW), Stockholm University, Stockh, [4]Institute of Live rand Biliary Sciences, [5]jassi2param@gmail.com

Background: Hepatic innervation has had little attention in hepatology research so far, largely because liver functions do not seem to be significantly affected after orthotopic liver transplantation (OLT). Nevertheless, long-term studies have shown the development of dyslipidemia, postprandial hyperglycemia, insulin resistance, and changes in intrahepatic blood flow after OLT. Whether the denervated and newly implanted liver can perform functions akin to those of a normally innervated liver remains an area worth investigating. However, the pattern of hepatic innervations and their functional role in the liver has not been well studied. Moreover, the effect of injury to these neuronal innervations in healthy and diseased states has remained obscure. We undertook to study the neuroanatomical pattern of innervations in an animal model of sympathectomy (SYMPy). **Methods:** Animals were categorized into four groups: control rats with intact hepatic sympathetic innervation (HSI), sympathectomized rats (SYMPy), rats subjected to bile duct ligation (BDL) with intact HSI, and SYMPy rats with BDL (BDL+ SYMPy). The anatomical distribution and characteristics of neuronal innervations were performed by using Immunolabeling-Enabled 3D Imaging of Solvent-Cleared Organs (iDISCO) methodology. The functional aspects were performed by the LC-MS-based proteomics of hepatic tissue under physiological and pathophysiological conditions. **Results:** We identified that the neural connections within the liver are predominantly sympathetic. After selective hepatic disruption of these sympathetic nerves (Sx) in healthy rats, this led to mild fat accumulation and inflammation in the liver. When Sx was combined with a liver disease model (SxBDL), an expedited onset of liver damage with metabolic dysfunction and increased fibrosis was observed in comparison to the control. The hepatic proteome of SxBDL showed increased inflammatory (NLRP3, MAPK, and PDGF), fibrogenic (TNFR2, Wnt, and FGF) pathways ($p < 0.05$, $FC > 1.5$) and metabolic dysregulation [increase in the tricarboxylic acid cycle and a decrease in the urea cycle ($p < 0.05$, $FC > 1.5$) and C3 ($FC > 2$, $FDR < 0.01$, $p < 0.05$, $R^2 > 0.95$) as a key driver of accelerated injury in SxBDL. **Conclusion:** We demonstrated the development of a neuropathic phenomenon following reduction in the sympathetic drive in the liver, with implications for both pathological and metabolic aspects of liver health, with an increased level of C3.

◆ 3442 | THE IMPACT OF GLP-1 AGONIST UTILIZATION ON POST LIVER TRANSPLANT OUTCOMES: A RETROSPECTIVE REVIEW

Taylor Seacor[1] *Garrick Gu*[1] *Anita Krishnarao*[2], [1]*University of Massachusetts Chan Medical School,* [2]*UMass Memorial Medical Center*

Background: Patients with metabolic dysfunction-associated steatohepatitis (MASH) have underlying cardiometabolic risk factors which persist following liver transplantation (LT) and can lead to recurrent MASH and cardiometabolic events. The rate of recurrent MASH after LT has been reported in up to 25% of patients with up to 20% of patients developing recurrent fibrosis within 2 years of LT. Given the emergence and demonstrated efficacy of GLP-1 agonists for type 2 diabetes (T2DM) and obesity, these therapies likely have benefit in the post-LT setting. This study was designed to analyze the potential clinical benefit associated with GLP-1 agonist use in patients with high risk cardiometabolic profiles after LT. **Methods:** We collected data from a global de-identified database (TriNetX) over a 5-year period and identified patients with an ICD label of T2DM and obesity as defined by a BMI $\geq$ 30 prior to LT. We then compared a cohort with GLP-1 agonist exposure (semaglutide, tirzepatide, liraglutide, dulaglutide) post-LT to a cohort without GLP-1 agonist exposure post-LT. GLP-1 agonist exposure was defined as at least one occurrence within 90 days post-LT. We then used propensity score matching to control for age, sex, INR, total bilirubin, creatine and albumin prior to LT in an attempt to match severity of liver disease prior to LT. Cohorts consisted of 2244 patients following matching. We assessed the primary outcome of mortality and secondary outcomes of graft rejection, hospital readmission, and myocardial infarction at 90-day and 1-year intervals post-LT. **Results:** GLP-1 agonist use was associated with decreased mortality at both 90-day (odds ratio [OR]: 0.28, P = 0.001) and 1-year ([OR]: 0.39, P = 0.0001) intervals post-LT. Rates of graft rejection in the GLP-1 agonist cohort were reduced at both 90-day ([OR]: 0.44, P = 0.001) and 1-year ([OR]: 0.69, P = 0.03) intervals post-LT. Rates of hospital readmission were significantly reduced at both 90-day ([OR]: 0.44, P = 0.0001) and 1-year ([OR]: 0.57, P = 0.0001) intervals post-LT. The rate of acute MI was not significantly different between cohorts at both 90-day ([OR]: 0.75, P = 0.25) and 1 year ([OR]: 0.86, P = 0.39) intervals post-LT. **Conclusion:** Our study showed that GLP-1 agonist use in the post-LT setting is associated with an increased survival benefit at both the 90-day and 1-year intervals. Additionally, there were significantly reduced rates of graft rejection and hospital readmission in the GLP-1 agonist cohort. This study highlights the potential need for earlier and increased utilization of cardiometabolic medications, particularly GLP-1 agonists after LT in a population at high risk for recurrent MASH and cardiometabolic events that could potentially impact outcomes beyond cardiometabolic events.

◆ 3443 | DIFFERENTIAL MACHINE PERFUSION ADOPTION RESHAPES ORGAN UTILIZATION PATTERNS IN LIVER TRANSPLANTATION

Vladislav Fomin Robert Brown[1] *Russell Rosenblatt*[1], [1]*Weill Cornell Medicine*

Background: Machine perfusion (MP) is a technique of preserving organs with circulating perfusate during the organ procurement process in liver transplantation (LT). Although there has been an increase in the utilization of MP, it has not been equally distributed among different-sized transplant centers. We hypothesized that MP changed the transplant landscape, and unequal adoption fundamentally alters organ utilization patterns. **Methods:** We analyzed 71,600 adult liver transplants (2010-2024) from UNOS data across 150 centers with MP data. We evaluated adult (age $\geq$18, single-organ, deceased donor transplantation. Centers were stratified by annual transplant volume into very low ($<$25), low (25-50), medium (51-100), and high ($>$100 LT/year) categories. We employed structural break analysis to identify technology tipping points, cross-correlation analysis with temporal lags to establish causal sequences, and examined donor quality sorting patterns. The primary outcomes were differences in MP adoption by center type. Secondary outcomes were transplant donor type utilization patterns with regard to MP utilization and center type. **Results:** MP was used in 5,240 transplantations with volume-dependent adoption: 95% of high-volume vs 17.6% of very low-volume centers utilized MP ($p<0.001$). Among 93 MP-adopting centers, 30 (32%) were early adopters (2016-2019), dominated by high (16) and medium (13) volume centers. 2022 was identified as the year in which there was a critical transplant volume inflection point for low, medium, and high-volume centers ($p<0.001$). 2022 was identified as the tipping point for MP use, growing

by 250%. Post-2022 total annual transplants increased by 28% (7,399 to 9,498), however, standard DBD declined from 65% to 47%, while DCD increased from 11% to 19% and ECD DCD increased from 1.4% to 10.6% (all $p < 0.001$). Center donor portfolio transformation patterns were volume-dependent: high-volume centers showed the largest standard DBD decline (-13%) and greatest DCD adoption (14%), while very low-volume centers increased their standard DBD usage (0.7%) and increased DCD usage (3.4%). **Conclusion:** MP adoption creates systematic differences in organ utilization patterns based on center volume. High-volume centers were the first to utilize MP, resulting in an early increase in their transplant volumes. This early adoption has culminated in increased utilization of ECD and DCD donors by high-volume centers at the expense of DBD organs, compared to low-volume centers. Overall, DBD volume has declined with a greater proportion of transplants now involving DCD and ECD donors.

◆ 3444 | QUANTITATIVE MRCP ACCURATELY DETECTS THE PRESENCE OF NON-ANASTOMOTIC STRICTURES IN PATIENTS AFTER LIVER TRANSPLANTATION

Andrea Dennis[1] Emmanuel Selvaraj[2] David Nasralla[3] Carlos Ferreira[1] John Karani[4] Arvind Pallan[5] Rutger Ploeg[6] Sara Upponi[7] Peter Friend[6], [1]Perspectum, Oxford, UK, [2]South Warwickshire University NHS Foundation Trust, Warwick, UK, [3]Royal Free Hospital, London, UK, [4]Department of Radiology, King's College Hospital, London, UK, [5]Department of Radiology, Queen Elizabeth Hospital Birmingham, Birmingham, UK;, [6]Nuffield Department of Surgical Sciences, University of Oxford, Oxford, UK, [7]Department of Radiology, Addenbrooke's Hospital, Cambridge, UK

Background: Advances in normothermic machine perfusion (NMP) have improved post-transplant liver function, but biliary complications, such as anastomotic (AS) and non-anastomotic (NAS) strictures, remain a common cause of morbidity and mortality after liver transplantation (LT). Quantitative magnetic resonance cholangiopancreatography (MRCP+) has shown utility in monitoring patients with biliary diseases, and here we assess MRCP+ metrics for identification of NAS after liver transplantation. **Methods:** Participants in the normothermic liver preservation trial by the Consortium for Organ Preservation in Europe (COPE) that underwent an MRCP within 6 months of LT were included in this study. The MRCPs were read by three radiologists (consensus) for AS and NAS, and analysed with MRCP + (Perspectum Ltd, Oxford) for quantitative assessment of biliary metrics. Principal component analysis (PCA) was performed, the levels of the key MRCP+ metric from the PCA was compared in LT recipients with or without NAS (Wilcoxon tests) and diagnostic accuracy assessed with area under the receiver operator curve (AUC). **Results:** In the total N = 83 LT recipients with MRCP (male sex = 71%, donation after circulatory death = 33%, NMP = 54%), 7 cases of NAS, 42 cases of AS and 3 with both were determined. PCA demonstrated two main components: one quantifying localised strictures and dilatations and a second quantifying the biliary tree's dimensions. The total length of strictures and dilatations was the single metric most representative of both components and was higher in patients with NAS compared to those without (150 mm [110-246] vs 42 mm [19-99], $p = 0.03$). When assessing the length of strictures and dilatations separately, only the latter was higher in patients with NAS compared to those without (95 mm [81-168] vs 28 mm [8-58], $p = 0.02$). Additionally, the number of dilatations was higher in those with NAS (16 [13-23] vs 2 [1-5]). The total length of strictures and dilatations identified LT recipients with NAS with a diagnostic accuracy of AUC = 0.75 (0.50-0.92), while number of dilatations had an AUC of 0.76 (0.51-0.94) for NAS. **Conclusion:** This study shows that the total length of strictures and dilatations, as well as number of dilatations, could identify LT recipients with NAS. This suggests that MRCP+ may have utility in effectively monitoring biliary complications after LT and further research should assess the ability to predict clinical outcomes and resulting patient management improvements.

◆ 3445 | LIVER FRAILTY INDEX PREDICTS POOR PHYSICAL ACTIVITY VOLUME AND INTENSITY (GENEACTIV® ACCELEROMETER) IN ADVANCED CHRONIC LIVER DISEASE: UK PROSPECTIVE CASE-CONTROL STUDY

Felicity Williams[1] Jonathan Quinlan[1] Amritpal Dhaliwal[2] Leigh Breen[1] Carolyn Greig[1] Ahmed Elsharkawy[2] Thomas Marjot[3] Janet Lord[1] Alex Rowlands[4] Matthew Armstrong[2], [1]University of Birmingham, [2]University Hospitals Birmingham, [3]University of Oxford, [4]University of Leicester

Background: Physical frailty leads to poor clinical outcomes in advanced chronic liver disease (AdvCLD). However, the volume and intensity of physical activity in AdvCLD remains unknown limiting the ability to tailor interventions for frailty. This study investigated (a) physical activity profiles in AdvCLD vs healthy controls (HC), (b) predictors of physical activity volume/intensity and their association with frailty, and (c) the physical activity volume and intensity achievable in AdvCLD. **Methods:** Outpatients with AdvCLD awaiting liver transplant were recruited, alongside age/sex matched controls (Birmingham, UK). Participants wore a GENEActivâ wrist-accelerometer for 14-days to measure physical activity volume and intensity, including most active continuous periods of the day. Measures of physical frailty included liver frailty index (LFI), gait speed, quadriceps strength, and thigh muscle ultrasound measures. **Results:** 42 AdvCLD (65% male, mean age 56, UKELD 52, 53% ArLD, 12% MASLD, 31% Autoimmune) and 17 HC (59% male, age 47) were recruited. Participants with ArLD had significantly lower volume of physical activity (mean[SD] acceleration 13.4 [4.6] vs 29.2[8.9]m*g*, $p < 0.01$) and spent proportionately more time at low physical activity intensities than HC (Intensity gradient -2.9 vs -2.4, $p < 0.01$). Older age and refractory ascites independently predicted both lower volume ($B = -0.24$, $p = 0.02$; $B = -7.6$, $p < 0.01$, respectively) and intensity ($B = -0.001$, $p = 0.02$; $B = -0.15$, $p = 0.04$, respectively). Lower LFI (less frail) and higher quadriceps strength were associated with higher physical activity volume ($B = -4.68$, $p = 0.03$; $B = 0.11$, $p < 0.01$, respectively) and intensity ($B = -0.21$, $p < 0.01$; $B = 0.004$, $p < 001$, respectively); but not chair stands. Physical activity volume and intensity across quartiles of LFI revealed a non-significant downward trend in volume as frailty worsened (Fig. 1A). Physical activity intensity differed significantly by LFI quartile ($p = 0.002$, Fig. 1B), with higher intensity in the 1st (most robust) and 2nd quartile than the 4th quartile (most frail) (-2.7 [0.2] vs 3.1[0.1], $p = 0.004$; -2.8[0.2] vs -3.1[0.1], $p = 0.02$, respectively). The most active continuous one-minute of the day was at a vigorous intensity in the most robust LFI quartile (red line, Fig. 1C), but only a slow walk for the most frail LFI quartile (purple line, Fig. 1C). **Conclusion:** Physical activity (especially intensity) is significantly reduced in patients with AdvCLD, being more pronounced in the most frail. Older age, refractory ascites and ArLD are associated with lower physical activity. The LFI is a valuable predictor of physical activity and could be used to prioritise and tailor exercise interventions. This study highlights realistic exercise targets in patients with AdvCLD (i.e. short bursts (i.e. < 5mins) of brisk walking) rather than those for the general population.

◆ 3446 | LONG-TERM LINEAR GROWTH OUTCOMES FOR PEDIATRIC LIVER TRANSPLANT RECIPIENTS WITH INBORN ERRORS OF METABOLISM

Srinidhi Mereddy[1] Leila Mahdavi[1] Nada Yazigi[2] Gabriel Gondolesi[2] Kimberly Chapman[3] Udeme Ekong[2] Khalid Khan[2], [1]Georgetown University School of Medicine, [2]Georgetown University Hospital, [3]Children's Hospital Los Angeles

Background: The second-leading indication of liver transplantation (LT) in pediatric patients has recently evolved to be treatment of inborn errors of metabolism, such as urea cycle disorders, MSUD, organic acidemias, etc.[1] While liver transplantation is often able to stabilize the primary metabolic disorder in children, the long-term implications of improved growth are not well characterized. This study investigates the linear growth in pediatric LT recipients over a 10-year period at MedStar Georgetown University Hospital. **Methods:** A retrospective chart review was conducted of pediatric patients who underwent LT as treatment for their metabolic disease at The Transplant Center for Children at MedStar Georgetown University Hospital between 2005 and 2020. Data extraction at key clinical time-points post-transplant (1 year, 5 years, 10 years) included the following parameters: body mass index (BMI) Z-score, weight Z-score, and height Z-score, diagnosis, and steroid use. Inclusion criteria required: 1) a diagnosis of inborn error of metabolism including Intoxication diseases such as Urea Cycle Disorder, Maple Syrup Urine Disease, Organic Acidemia, or Non-Intoxication diseases and 2) patients that only underwent one LT. **Results:** An unpaired sample t-test was performed in Microsoft Excel to compare BMI Z-score, Height Z-score, and Weight Z-score in patients with Intoxication diseases and Non-Intoxication diseases. Significantly abnormal BMIs, Weights, and Heights compared to age were noted at the time of transplant ($p = 0.0181$, $p = 0.0001$, $p = 0.0021$) and at 1 year post-transplant for only Weight and Height ($p = 0.0427$, $p = 0.01$), but not at 5 years and 10 years. None of the patients were found to be taking steroid immunosuppression past 6 months post-transplant, thus the relationship between steroid use and linear growth impact could not be assessed. **Conclusion:** Patients with both Intoxication and Non-intoxication diseases had abnormal Weight and Height up to 1 year post-transplant and abnormal BMI at the time of transplant, but after these time points these metrics were normalized. These findings indicate that liver transplant improved growth for patients and normalized linear growth long-term compared to solely medication management of metabolic disorders.[2,3]

◆ 3447 | LONGER DRIVING DISTANCE AND TIME TO TRANSPLANT CENTER ARE ASSOCIATED WITH INCREASED WAITLIST REMOVAL AND LOWER TRANSPLANT PROBABILITY IN PATIENTS WITH LOW MELD AT LISTING

John Esli Medina Morales[1] Mahinaz Mohsen[2] Vraj Shah[2] Margaret Carrel[3] Qianyi Shi[3] Tomohiro Tanaka[3], [1]Rutgers New Jersey Medical School; Washington University in St Louis, [2]Rutgers New Jersey Medical School, [3]University of Iowa School of Medicine

Background: Although longer travel time and traffic congestion have been associated with higher waitlist mortality among adult liver transplant (LT) candidates, their impact on patients listed with low initial MELD scores remains poorly understood. Rural disparities are also understudied in this population. Using travel distance to the listing transplant center (LTC) and time as proxies for access to high-volume centers, we evaluated their association with waitlist outcomes among LT candidates with low MELD at listing. **Methods:** We identified adult LT candidates in the United States listed between 2013 and 2023 with an initial MELD score ≤ 18 using data from nationwide transplant registry. Candidates with MELD exception points and listed with Status 1 were excluded. Travel distance and driving time from the patient's residence to the LTC were calculated and stratified into tertiles. Rurality was categorized as urban or rural using Rural-Urban Commuting Area (RUCA) codes. The primary outcome was waitlist removal due to death or clinical deterioration; the secondary outcome was receipt of LT. Competing risk regression was used to assess the association of travel burden and rurality with waitlist outcomes. **Results:** A total of 34,541 LT candidates with initial MELD ≤ 18 were included. The median age was 58 years (IQR 51–64), and the median MELD at listing was 14 (IQR 10–16). The most common etiologies were alcohol-associated liver disease (27%), metabolic dysfunction-associated steatohepatitis (26%), and hepatitis C (20%). Compared to those in the shortest travel group, candidates in the longest tertile of travel distance and driving time had a higher rate of waitlist removal due to death or clinical deterioration (travel distance: 21.5% vs. 24.3%; travel time: 30.3% vs. 35.5%; both $p = < 0.001$). On multivariable competing risk analysis, both longer driving distance and longer driving time were independently associated with increased risk of waitlist removal (adjusted subdistribution hazard ratio [aSHR] 1.20, 95% CI 1.05–1.18; and aSHR 1.20, 95% CI 1.14–1.28, respectively) and decreased probability of transplantation (aSHR 1.15, 95% CI 1.08–1.21; and aSHR 1.23, 95% CI 1.16–1.30, respectively). No differences were found on RUCA classification (Table 1). **Conclusion:** Among LT candidates with low MELD scores at listing, greater driving distance and travel time to the LT center, used as proxies for access to a higher level of care, were independently associated with a higher risk of waitlist removal and decreased probability of LT.

Table 1. Competing risk regression analysis for waitlist removal due to death or clinical deterioration or incidence of transplantation

	Waitlist removal		Transplantation	
	aSHR (95% CI)	p-value	aSHR (95% CI)	p-value

◆ 3448 | CREATINE METABOLISM DURING LIVER REGENERATION

Thi Linh Nguyen[1] Thi Nga Ha[1] Hyon-Seung Yi[1], [1]Department of Medical Science, Chungnam National University School of Medicine

Background: The liver has a remarkable regenerative capacity following to injury, a process that is critical for recovery in patients with liver disease. While various metabolic pathways have been implicated in liver regeneration, the role of creatine metabolism remains poorly understood. This study aimed to elucidate the impact of creatine deficiency on liver regeneration. **Methods:** A two-thirds partial hepatectomy (PH) model in mice was used to evaluate the role of creatine in hepatic regeneration. Creatine deficiency was induced by administering beta-guanidinopropionic acid (ß-GPA), a creatine analogue, while controls received standard drinking water. Liver regeneration was assessed by measuring the expression of proliferation markers and metabolic genes. Additionally, single-cell RNA sequencing was performed to identify key cells types involve in creatine transport. A reduced-size liver transplantation model in Sprague-Dawley rats was also employed to evaluate the effect of ß-GPA on liver regeneration in a clinically relevant context. **Results:** Expression of the creatine transporter gene *Slc6a8* increased during the

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

early phase of liver regeneration, paralleling the induction of proliferative markers such as PCNA and Ki67. ßGPA treatment significantly reduced hepatocyte proliferation, as evidenced by decreased PCNA and Ki67 expression. Single cell RNA sequencing revealed that Slc6a8 is predominantly expressed in hepatic stellate cells (HSCs) and upregulated upon activation. Furthermore, ß-GPA administration led to the upregulation of oxidative phosphorylation genes, indicating a shift in energy metabolism under creatine-deficient conditions. Moreover, ß-GPA treatment markedly delayed liver regeneration in reduced-size rat liver transplantation model, supporting its inhibitory effect in a clinically relevant setting. **Conclusion:** Creatine deficiency impairs liver regeneration and alters hepatic energy metabolism. These findings highlight creatine metabolism as a previously underappreciated contributor to liver regenerative capacity and a potential therapeutic target for improving recovery following liver injury.

◆ 3449 | EVALUATING THE ROLE OF FRAILTY IN EXTUBATION TIMING AND RECOVERY FOLLOWING LIVER TRANSPLANTATION

Ishan Antony[1] Noor Albusta[1] Ryan Nazemian[2] Bartholomew Kane[1] Ming Lin[1], [1]Lahey Hospital and Medical Center, [2]Lahey Clinic Medical Center

Background: Frailty is a clinical state of decreased physiologic reserve and increased vulnerability to health stressors. Frailty in cirrhotic patients is measured by the Liver Frailty Index (LFI) which is a simple, reliable, low-cost method that encompasses grip strength, chair stands, and balance. Early extubation (EE) has been associated with improved short-term outcomes in post-liver transplant (LT) patients. Little is known about the association between frailty, EE, and hospital outcomes. **Methods:** We conducted a multidisciplinary, retrospective, single-center cohort study to assess the effect of frailty on the rate of early extubation (EE, defined as the removal of the endotracheal tube post-LT surgery in the operating room) and the associations with the hospital and ICU length of stay (LOS) in cirrhotic patients undergoing LT. Statistical analysis included Chi-square tests to compare rates between groups, independent t-tests for mean comparisons, and linear regression analysis to evaluate the relationship between LFI scores and LOS. **Results:** A total of 360 cirrhotic LT patients between 01/2019 and 07/2023 were assessed, and 158 patients (44%) had LFI scores. Of the 158 patients, 111 patients were male (70%), 142 patients were white (90%), the mean age was 57 years (range 20–74 years), the mean BMI was 29.2 (range 17.7-43.7) and median MELD score was 21 at the time of LT (range 6 to 41). Alcohol (46%) was the most common cause of liver disease. Out of 158 patients, 38 patients (24.1%) were frail (LFI ≥ 4.5), and 120 patients (75.9%) were non-frail (LFI < 4.5). There were no statistical differences in the EE rates between frail and non-frail patients (76.32% vs. 79.17%, $P = 0.709$). Hospital and ICU LOS were significantly longer in frail patients compared to non-frail patients (33.18 vs. 4.23 days for ICU stay, $P < 0.001$; and 59.53 vs. 10.08 days for hospital stay, $P < 0.001$). However, amongst the frail patients with EE, hospital and ICU LOS were shorter compared to those with delayed extubation (26.79 vs. 53.78 days for ICU stay, $P = 0.012$; and 52.00 vs. 83.78 days for hospital stay, $P = 0.003$). Similarly, in the non-frail patients with EE, LOS was shorter compared to those with delayed extubation (2.93 vs. 9.16 days for ICU stay, $P < 0.001$; and 8.88 vs.14.60 days for hospital stay, $P < 0.001$). **Conclusion:** Frailty is associated with worse post-transplant outcomes. Frail patients had significantly prolonged ICU and hospital stays. Our study demonstrated that frailty does not affect the rate of EE in cirrhotic patients undergoing LT. However, in those patients who are frail, EE was associated with a significant reduction in the hospital and ICU LOS post-liver transplant. Based on our findings, we encourage EE in frail cirrhotic patients undergoing LT whenever possible. Our findings show the importance of factoring frailty into perioperative and post-LT care.

◆ 3450 | IMPACT OF CHANGING LIVER TRANSPLANT EXCEPTION POLICIES TO ADDRESS BLOOD TYPE DISPARITIES IN ACCESS TO TRANSPLANTATION

David Goldberg[1] Catherine Blandon[2] David Kaplan[3], [1]University of Miami, [2]University of Miami Miller School of Medicine, [3]University of Pennsylvania

Background: When the Acuity Circles (AC) liver allocation policy was implemented in the US in 2/2020, MELD exception policy changed to award MELD exceptions to patients based on the median MELD score at transplant -3 points (MMAT-3) for transplant recipients within 250 nautical miles (NM) of the transplant centers. In 6/2022, the policy was updated to award exceptions based on MMAT-3 for recipients within 150NM of donor hospital, thereby changing based on the location of the deceased donor. Concerns have been raised because patients receive the same MELD exception, regardless of blood type, despite vast differences in the MMAT based on blood type. We sought to simulate the impact of changing liver allocation to award MELD exceptions based on a blood-type specific MMAT. **Methods:** We conducted a simulation study using the Liver Simulated Allocation Model (LSAM) from the Scientific Registry of Transplant Recipients (SRTR). We simulated two scenarios: 1) current allocation using the MELD 3.0 score; and 2) MELD exception scores based on a blood type-specific MMAT. Because the current system awards MELD exceptions based on transplants within 150NM of the donor hospital, which varies for every donor, we instead used the blood type-specific MMAT for all transplants within each DSA from 1/1/2024-6/30/2024 using OPTN data. All simulations were iterated 10 times (standard LSAM procedure). **Results:** Awarding MELD exceptions using a blood-type specific MMAT was not simulated to change the overall number of liver transplants, with only small differences by blood type (Figure). However, the median number of transplants for patients with MELD exceptions was simulated to increase by 73 transplants overall, with increases of 108 and 18 for patients with blood type O and A, respectively, with a decrease in 56 transplants for exception patients with blood type B (Figure). Despite these changes, the overall and blood type-specific number of waitlist deaths did not change for the waitlist population, or the subset with MELD exceptions (Figure). **Conclusion:** Despite well-established differences in the median MELD score at transplant by blood type, current allocation policy awards the same MELD exceptions to all patients, thereby disadvantaging MELD exception patients with blood type A or O who should have equal access to transplant for those with blood type B or AB. Our simulations demonstrate that changing the allocation policy to a blood type-specific MMAT could mitigate this disparity, without impacting waitlist mortality. While these data are based on LSAM simulations, this remains the gold standard in the US for assessing the impact of policy changes. These data underscore the need to update MELD exception policies to account for the differences in MMAT based on blood type.

◆ 3451 | LONG-TERM OUTCOMES OF LIVER TRANSPLANTATION FOR ALCOHOL-ASSOCIATED HEPATITIS

Gene Im[1] Thomas Schiano[2] Sander Florman[2] Ashish Bibireddy[2] Giuseppe Cullaro[1] Smruti Rath[2], [1]Center for Liver Disease and Transplantation, Columbia University, [2]Icahn School of Medicine at Mount Sinai

Background: While studies of liver transplantation (LT) for alcohol-associated hepatitis (AH) have demonstrated excellent short-term survival and acceptable alcohol relapse rates, long-term outcomes are unknown. The aim of this study is to examine the long-term patient survival, allograft and alcohol outcomes after LT for AH as compared with other steatotic

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

liver disease (SLD) subtypes. **Methods:** We performed a retrospective study of patients who underwent LT for AH (and SLD), at Mount Sinai Hospital from 2012-2025 with a minimum of 5-year follow-up after LT, representing long-term outcomes of the first published experience of LT for AH in North America. Clinicodemographic, pathology and laboratory data were collected and analyzed. A LT cohort comparison analysis was performed for different SLD subtypes: AH, alcohol-associated cirrhosis (AC), MetALD and MASLD. Patients with co-occurring viral hepatitis, HIV, and HCC were excluded. The primary endpoint was overall survival and secondary endpoints were biomarker-confirmed alcohol relapse as per NIAAA definitions, reabstinence, and biopsy-proven allograft rejection (BPAR). Analysis of the primary endpoint was based on Kaplan-Meier and Cox regression analysis using R version 4.5.0. **Results:** Over the 13-year study period, 268 LT for SLD with long-term follow-up were analyzed: 93 (35%) MASLD, 18 (7%) MetALD, 90 (34%) AC, and 67 (25%) AH with median 7.3 years [5.4-9.3], including 11 (16%) AH patients >10 years. For the AH subgroup, median age was 43 years [37-51], mostly male (64%) and White (72%). Lab medians at LT for AH were bilirubin 32 mg/dL, INR 2.5, creatinine 3.1 mg/dL, mDF 107, MELD 40, and ACLF grade 3, consistent with grim prognosis. Psychosocial summary variables include median last drink 25 days [12-55] prior to presentation, 10 [5.5-12] drinks/day around presentation, 81% with severe AH as their first decompensation, and 19% prior failed alcohol rehabilitation. Alcohol biomarker monitoring rates after LT were 100% AH, 70% AC, 64% MetALD, and 17% MASLD. Alcohol relapse post-LT was higher for AH (30%, initial event median 261 days [131-516]; PEth 58 ng/mL [36-155]) and MetALD (41%, median 281 days [127-558]; PEth 76 [n/a]) compared to AC (15.5%, 830 days [430-1308]; PEth 90 [63-223]), $p=0.03$. Reabstinence rates were similar: 37% AH, 54% AC, and 71% MetALD, $p=0.27$. BPAR rates were similar: 16% AH, 21% AC, 28% MetALD, 20% MASLD, $p=0.67$. Overall and 5-year survival after LT for AH were both 92.5%, similar to AC (81%, 85%), MetALD (78%, 83%), and MASLD (81%, 85%), respectively; $p=0.21$ overall, $p=0.43$ at 5-years. Cox regression adjusted for age and sex demonstrated similar survival between SLD subgroups, $p=0.3$. **Conclusion:** Long-term patient survival, allograft and alcohol outcomes after LT for AH remain excellent, and similar to other steatotic liver disease subtypes. While relapse rates were higher in LT for AH and MetALD compared to AC, reabstinence was similar.

Hashimoto[10] Antonio Pinna[8] Masato Fujiki[10],
[1]Department of General Surgery, Digestive Diseases and Surgery Institute, Cleveland Clinic, Cleveland, [2]Department of Surgery, Columbia University Irving Medical Center, New York, NY, United States, [3]Department of Surgery, Kyoto University Graduate School of Medicine, Kyoto, Japan, [4]Department of Surgery, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan., [5]Department of Surgery, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan, [6]University of Rochester Medical Center, Rochester, [7]University of Rochester Medical Center, Rochester, NY, United States, [8]Transplant Center, Cleveland Clinic Florida, Weston, FL, United States, [9]Department of Surgery, Weill Cornell Medicine, New York, NY, United States, [10]Cleveland Clinic

Background: Early Allograft Dysfunction (EAD) and Small-For-Size Syndrome (SFSS) are commonly used to predict the outcomes of living donor liver transplantation (LDLT). However, they were not derived from large-scale LDLT databases and their binary definitions limit predictive accuracy compared to continuous scoring methods. The aim of this study was to devise and validate the novel Living-donor Allograft Dysfunction (LAD) score using early post-operative factors to predict early graft loss after LDLT. **Methods:** This study included primary adult LDLT-recipients from six centers in the US and Japan, divided into the derivation (n = 645) and validation cohorts (n = 389). The primary outcome was 90-day graft loss. Post-operative bilirubin, INR, and PLT were selected to create LAD scorebased on clinical relevance and a comprehensive literature review. The model was developed using logistic regression and evaluated with receiver operating characteristic (ROC) curves and Kaplan-Meier analyses. The optimal cut-off values for the LAD scores were calculated using the Youden index obtained from the ROC analysis. **Results:** Significant differences were observed between the derivation and validation cohorts in several factors, including graft type (right lobe: 61.3% vs. 53.6%; $P = 0.030$) and GRWR (0.91% vs. 0.84%; $P < 0.001$), highlighting the relevance of this validation study. Bilirubin, INR, and PLT on POD7 and 10 were associated with 90-day graft loss ($P < 0.001$). Higher LAD score was associated with increased risk of 90-day graft loss in both cohorts (Figure A and B). In the derivation cohort, LAD score-POD7 and -POD10 showed superior predictive accuracy versus EAD (AUROC 0.82 and 0.88 vs 0.73; $P < 0.001$, respectively) and SFSS-POD7 (vs 0.77; $P = 0.041$ and $P < 0.001$) (Fig. C). The validation cohort confirmed robust performance (AUROC 0.89 on POD7 and 0.91 on POD10), outperforming EAD (vs 0.80, $P < 0.001$ and $P = 0.004$) and SFSS-POD7 (vs 0.84, $P = 0.055$ and $P = 0.094$) (Fig. D). LAD score cutoffs of -3.00 (POD7) and -2.39 (POD10) effectively and similarly stratified graft survival between the US and Japan, indicating the generalizability of the score application despite population differences (Fig. E and F). **Conclusion:** The novel LAD score was developed and validated as a generalizable tool to provide accurate estimation of 90-day graft loss following LDLT compared to existing criteria. This can facilitate early treatment of graft dysfunction within 10 days during a potential window of opportunity. With its global applicability, the LAD score may also serve as a surrogate endpoint for LDLT research worldwide, as traditional metrics like graft loss become increasingly rare in certain areas.

◆ 3453 | TEMPORAL CHANGES IN RACIAL DISPARITIES IN LIVER TRANSPLANT OUTCOMES

ATSUSHI NISHIMAGI[1] Rikako Oki[1] Luckshi Rajendran[1] Emily Kerby[1] Adhnan Mohamed[1] Ahmed Nassar[1] Abbas Al-Kurd[1] Atsushi Yoshida[1] Marwan Abouljoud[1] Shunji Nagai[1], [1]Division of Transplant and Hepatobiliary Surgery, Henry Ford Hospital

Background: It has been reported that Black experience inferior graft survival (GS) following liver transplantation (LT), compared to White. However, it remains unclear about the impact of race on very long-term post-transplant outcomes. We evaluated and compared the racial influence on very long-term GS in LT. **Methods:** Adult LT alone performed from 2003-2013 were evaluated, using the United Network for Organ Sharing database. To mitigate the prognostic effects of early to mid-term post-transplant complications, we assessed conditional 10-year GS in 5-year graft survivors post-transplant, which was defined as the probability of GS after 5 years in those who survived for the first 5 years. The impact of race on GS was evaluated by Cox proportional hazard model. In Model 1, the risks were adjusted for HLA mismatch, recipients' age, gender, BMI, diabetes, MELD score at transplant, as well as donor age, gender, race, BMI, and donor types. In Model 2, in addition to the variables included in Model 1, socioeconomic factors including employment status, educational level, and insurance type were additionally adjusted for. **Results:** In total, 71,679 adult LT were performed from 2003-2013, of which 46,659 recipients survived at 5 years post-transplantation. Multivariable Cox regression analysis showed that Black had significantly poorer 5-year GS compared to White in both Model 1 and Model 2 ($p < 0.001$ for both, Fig.1). In contrast, when evaluating conditional 10-year GS among 5-year graft survivors, there was no significant difference in outcomes between Black and White in either Model 1($p = 0.097$) or Model 2 ($p = 0.928$). (Fig.2) The rate of cardiovascular disease and malignancy as a cause of death was higher in White compared to Black. (28.5% vs 24.8%, 34.4% vs 23.8%, $p < 0.001$) **Conclusion:** Black was associated with lower 5-year GS, whereas 10-year conditional GS between Black and White was comparable. Higher incidence of deaths due to CVD or malignancy in White might contribute to this finding. Further evaluations of factors contributing to disparities, including comorbid conditions and access to follow-up care, are necessary to address racial inequities in long-term post-transplant outcomes.

Background: There is no neoadjuvant therapy recommended by the primary hepatocellular carcinoma (HCC) guidelines. We conducted the Notable-HCC phase 1b trial to evaluate the safety, tolerability and preliminary effectiveness of neoadjuvant tislelizumab (TIS, a PD-1 inhibitor) plus stereotactic body radiotherapy (SBRT) followed by resection and adjuvant TIS in early stage resectable HCC. **Methods:** Patients received 3×8 Gy SBRT and two cycles of TIS as adjuvant therapy, then underwent the curative HCC resection scheduled 4 weeks later, followed by 16 cycles adjuvant PD-1 for up to 1 year. Primary endpoints were the surgery delay, radiographic and pathological tumor response, and safety. Secondary endpoint was survival. **Results:** A total of 20 patients were enrolled and 19 (95%) underwent surgical resection (one [5%] undergoing radiofrequency ablation). Curative R0 resection was achieved in all patients, and none postponed surgery for more than 6 weeks following neoadjuvant therap. The neoadjuvant therapy did not increase the difficulty of surgical resection, nor did it increase the incidence of post-operative complications. Per RECIST v1.1, ORR was 42.1% (8/19) and DCR was 100%. 2 patients achieved complete pathological response (pCR), and 6 reached major pathological response (MPR). In the adjuvant phase, 14 (73.7%) patients received regular adjuvant TIS, with a median cycle of 15 (range, 6-16). TRAEs of any grade during the adjuvant phase were reported in all these patients, with the majority being grade 1 to 2. Grade 3 TRAEs occurred in 4 patients, including decrease lymphocyte count, immune pneumonia and decreased platelet count. None of patients experienced grade 4 or 5 TRAEs. As of data cutoff (Jan 31, 2025). median follow-up duration was 18.23 months (range, 16.47-33.03) since the resection. Disease recurrence developed in 4 out of 19 patients, with DFS of 14.8, 11.0, 3.0 and 8.6 months, respectively. Median DFS and OS were not reached, with DFS and OS rates at 1 year of 86.4% and 100%, respectively. **Conclusion:** In patients with early-stage resectable HCC, neoadjuvant TIS combined with SBRT followed by adjuvant TIS yields clinical promising treatment response without delaying surgical resection, and achieved satisfactory survival benefits with preliminary follow-up data. Continued follow-up is being conducted to assess long-term efficacy and safety.

3455 | SIMULTANEOUS LIVER-KIDNEY AND KIDNEY-AFTER-LIVER TRANSPLANTATION BEFORE AND AFTER THE 2017 ORGAN PROCUREMENT AND TRANSPLANTATION NETWORK POLICY: A SINGLE-CENTER EXPERIENCE

Carolina Lopez-Silva[1] Malak Elsawy[1] Manuj Shah[1] Fizza Naqvi[1] Benjamin Philosophe[1] Ahmet Gurakar[1], [1]Johns Hopkins University

Background: Simultaneous liver-kidney (SLK) and kidney-after-liver (KAL) transplantation are two modalities for managing patients with end-stage liver disease and renal dysfunction. Simultaneous liver-kidney (SLK) transplantation involves performing both transplants during the same surgery, while kidney-after-liver (KAL) refers to delayed kidney transplantation following liver transplant alone. In 2017, the Organ Procurement and Transplantation Network (OPTN) established stricter eligibility criteria for SLK transplantation. The impact of this policy on SLK and KAL utilization remains under investigation. **Methods:** We conducted a retrospective cohort study of patients undergoing SLK or KAL transplantation at Johns Hopkins Hospital from January 1st, 2009, to June 1st, 2024. Baseline demographic and clinical characteristics were compared between groups. Logistic regression was used to estimate the odds of receiving SLK versus KAL before and after the 2017 OPTN policy change. Post-transplant mortality was assessed using Cox proportional hazards models, with survival time defined from transplant date to death or end of follow-up. **Results:** A total of 152 patients were included (118 SLK, 34 KAL). KAL recipients were older (60.4 vs. 55.9 years, $p = 0.038$) and had higher mean BMI (30.7 vs. 27.7, $p = 0.028$). Sex, race, and MELD scores did not significantly differ between groups. Liver disease etiology differed significantly ($p = 0.025$), with hepatocellular carcinoma more common among KAL recipients (29.4% vs. 6.8%). The odds of receiving SLK were significantly higher during the pre-policy period (OR 4.91, 95% CI: 2.13–12.5, $p < 0.001$). In Cox models, transplant type and policy era were not associated with mortality. However, older age was associated with higher post-transplant mortality (HR 1.06 per year, 95% CI: 1.00–1.13, $p = 0.047$), and patients > 65 years old had a significant higher risk of post-transplant mortality (HR 4.02, 95% CI: 1.60-10.1, $p = 0.003$), compared to younger patients, after adjusting for sex, BMI and MELD score. **Conclusion:** SLK and KAL recipients differed by BMI and liver disease etiology. The 2017 OPTN policy was associated with reduced SLK use but not with changes in mortality. Older age, and specifically age > 65, was independently associated with higher risk post-transplant

3456 | THE IMPACT OF SYSTEMIC CHEMOIMMUNOTHERAPY IN COMBINATION WITH LOCOREGIONAL THERAPIES ON REJECTION IN LIVER TRANSPLANT SECONDARY TO HEPATOCELLULAR CARCINOMA (HCC).

Khadyoth Nanneboyina[1] Ali Khurram[1] Judith Pozzerle[2] Ashwini Mehta[2] Parvez Mantry[2], [1]Methodist Dallas Medical Center, [2]The Liver Institute at Methodist Dallas Medical Center

Background: Liver transplantation (LT) is the gold standard treatment for unresectable HCC. However, many patients with HCC are outside of the Milan criteria for LT eligibility. In such cases, downstaging therapies decrease tumor burden and increase transplant eligibility. Traditional downstaging methods include locoregional therapy (LRT) but recently, systemic therapy, particularly immune checkpoint inhibitors (ICIs), have shown promise. The use of ICIs in the treatment of HCC raises the concern for increased possibility of rejection following LT. **Methods:** This study was a single-center retrospective outcome analysis of all patients diagnosed with HCC who underwent LT between June 2018 and March 2024 (n = 93) with primary endpoints being a) post-LT transplant rejection and b) Rejection Activity Index (RAI) grade. Explant pathology was examined to assess tumor viability, grade, and lymphovascular invasion. Patients were categorized into 2 groups: 1) LRT alone and 2) combination of LRT and systemic therapy. LRT included Transarterial chemoembolization, Radioembolization, Microwave Ablation, and Stereotactic Beam Radiation Therapy. Systemic therapies included Nivolumab + Ipilimumab, Atezolizumab + Bevacizumab, Sorafenib, Lenvatinib, Ramuricumab, and Cabozantinib. Data analysis was performed with T-test. **Results:** 78 patients received LRT alone and 15 patients received combination therapy. Median total tumor diameter on MRI prior to treatment initiation of the LRT group was 3 cm vs. 4.6 cm in the combination group ($p = 0.02$). Median alpha-fetoprotein (AFP) prior to treatment initiation of the LRT group was 5.4 ng/mL vs. 12.3 ng/mL in the combination group ($p = 0.004$). Within the combination group, 2 patients received Nivolumab + Ipilimumab, 7 received Atezolizumab + Bevacizumab, 6 received Sorafenib, 3 received Lenvatinib, 1 received Ramucirumab, and 2 received Cabozantinib. The incidence of transplant rejection in the LRT group was 22.6% vs. 20% in combination group ($p = 0.43$). The median RAI grade of rejection (in patients who had evidence of rejection) in the LRT group was 5 vs. 6 in the combination group ($p = 0.44$). The incidence of serious infections requiring hospitalization in the LRT group was 15.4% vs. 6.7% in the combination group ($p = 0.11$). **Conclusion:** Our results show that combination therapy for the treatment of HCC was associated with similar rates of transplant rejection, RAI grade of rejection, and serious infections requiring hospitalization compared to patients who received LRT only. This preliminary data suggests that systemic therapies, such as ICIs, are safe to use for downstaging of HCC to potentially improve outcomes and increase transplant eligibility.

	LRT Only	Combination Therapy	P-Value
Sample Size	78	15	
Median Total Tumor Diameter on MRI prior to Initiation of Therapy (cm)	3	4.6	0.018
Median AFP prior of Initiation of Therapy (ng/mL)	5.4	12.3	0.004
Median # of Viable Tumors at Explant	1	2	0.004
Incidence of Lymphovascular/Perivascular Invasion	14.1%	26.7%	0.100
Incidence of Transplant Rejection	22.6%	20%	0.43
Median RAI Grade of Rejection (in Patients w/ Rejection)	5	6	0.436
Incidence of Serious Infections Requiring Hospitalization	15.4%	6.7%	0.11

3457 | LONG-TERM FOLLOW-UP IN LIVER TRANSPLANTATION AND COMBINED CARDIAC SURGERY: VALIDATION AND REFINEMENT OF THE LT+CS RISK SCORE USING ADVANCED MACHINE LEARNING

Laura Batista de Oliveira[1] Chase Wehrle[2] Sarah Wehbe[2] Jason Singer[2] Mazhar Khalil[2] Masato Fujiki[1] Michael Tong[3] Charles Miller[2] Sobia Laique[1] Alejandro Pita[2] Koji Hashimoto[2] Cristiano Quintini[2] Teresa Diago-Uso[2] Maan Fares[4] Andrea Schlegel[2] Nicholas Ruthmann[4] Jamak Modaresi Esfeh[5], [1]Cleveland Clinic, [2]Digestive Disease Institute, Cleveland Clinic, Cleveland, OH, [3]Heart, Vascular and Thoracic Institute, Cleveland, [4]Heart, Vascular and Thoracic Institute, Cleveland Clinic, Cleveland OH, [5]Cleveland Clinic Foundation

Background: Combined liver transplantation (LT) and cardiac surgery (CS) is a therapeutic option for patients with end-stage liver disease (ESLD) and severe cardiac dysfunction. Despite its potential, evidence on long-term outcomes and prognostic factors remains limited. In 2023, our center published the LT-CS-1.0 risk score. Of note, the previously defined LT+CS risk score has not yet been prospectively validated. **Methods:** Forty-six patients underwent single-staged LT+CS (2005-2023) and had a minimum 1-year follow-up. Univariate and multivariate analyses Cox proportional hazards models assessed independent predictors of long-term survival (1 and 5 years) and a machine learning based Leave One Out Cross Validation (LOOCV) technique was used to validate and refine the LT-CS-2.0 risk score. Patients aged <18 years, those without combined intervention, and those lacking ≥ 1-year active follow-up were excluded. **Results:** One- and five-year survival rates were 74.2% and 50%, respectively. Negative predictors of 5-year survival included GFR (OR = 1.02, p = 0.031), CKD (OR = 0.13, p = 0.026), and valve surgery (OR = 6.67, p = 0.045). CKD had the strongest multivariate impact (HR = 12.28, 95%CI = 1.01–152.43). After implementing LT-CS-1.0 in 2022, survival improved (log-rank $p<0.001$). LOOCV highlighted MASH (2.66), renal dysfunction (2.63), and aortic stenosis (2.20) as key contributors. The LT-CS-2.0 score predicted 5-year OS with an AUC of 0.683 (p = 0.03), and 0.863 ($p<0.0001$) in valve surgery patients. Kaplan-Meier analysis showed significantly higher survival in low-risk vs. high-risk groups (log-rank p = 0.001).

Post-operative morbidity was also compared between high and low-risk groups. High-risk patients according to the LT+CS-2.0 score experienced more complications (OR = 3.12, p = 0.0781) inpatient, at 3 months (OR = 9.71, p = 0.00152), 6-months (OR = 7.97, p = 0.00335) and 12-months (OR = 6.61, p = 0.00705). During the in-hospital period, high-risk patients showed a non-significant increase in the odds of complications (OR: 3.12; p = 0.0781). CCI (Comprehensive Complication Index) was higher at 3-months (OR: 9.71; p = 0.00152), 6 months (OR: 7.97; p = 0.00335), and 12-months (OR: 6.61; p = 0.00705) in the LT+CS-2.0 High-risk cohort. **Conclusion:** This study provides the largest analysis to date of long-term outcomes following combined liver transplantation and cardiac surgery. This study provides prospective validation of the LT+CS-1.0 risk score, confirms key predictors of survival and refines risk stratification with the LT+CS-2.0 score.

3458 | PRE-TRANSPLANT PROTON PUMP INHIBITOR USE IS ASSOCIATED WITH INCREASED RISK OF LIVER ALLOGRAFT REJECTION, FAILURE, AND MORTALITY: A PROPENSITY-MATCHED MULTI-CENTER COHORT STUDY

ali osman[1] Mohammad Adam[2] Abdelaziz Mohamed[3] Jeffrey Crippin[1], [1]Washington University St. Louis, [2]University of Missouri-Kansas City, [3]One brooklyn health/interfaith medical center

Background: Proton pump inhibitors (PPIs) are commonly prescribed to patients with liver cirrhosis awaiting liver transplantation. However, their impact on post-transplant outcomes—including graft rejection, failure, and mortality—remains unclear. This study evaluates the association between pre-transplant PPI use and liver transplant outcomes. **Methods:** We conducted a retrospective cohort study using data from 146 healthcare organizations in the TriNetX Global Collaborative Network. Adult liver transplant recipients were categorized based on PPI exposure within one month (n = 9,516) and within six months (n = 13,095) prior to transplant. Three comparisons were analyzed: (1) PPI use within one month vs. no PPI use (n = 24,078); (2) PPI use within six months vs. no PPI use; and (3) PPI use vs. H2 blocker use (n = 1,578) within six months. Propensity score matching was applied to adjust for demographics, clinical comorbidities (e.g., cirrhosis, portal hypertension, hepatic encephalopathy, CKD, diabetes, and primary liver cancer), and baseline laboratory values (e.g., total bilirubin, sodium, albumin, INR, prothrombin time, BMI). To confirm continuity of PPI therapy post-transplant, we conducted a separate analysis using PPI use as an outcome. Among 6,771 patients in the PPI group, 5,247 had documented PPI prescriptions after transplant, whereas the control group had 0% documented PPI use. Additionally, a Kaplan-Meier curve was generated to assess PPI continuation over time, demonstrating sustained PPI use in the PPI group post-transplant. **Results:** Pre-transplant PPI use was significantly associated with increased risk of liver allograft rejection or failure across all comparisons. In the 1-month comparison, the rate of rejection/failure was 13.4% in PPI users vs. 7.1% in non-users (RR = 1.87; $p < 0.0001$). Five-year survival probability was lower among PPI users (63.0%) compared to non-users (68.2%) (HR = 1.40; $p < 0.0001$). Compared to H2 blocker users, PPI users also demonstrated a significantly higher incidence of rejection or graft failure. **Conclusion:** Pre-transplant PPI use is associated with increased risk of liver transplant rejection, graft failure, and reduced survival. These findings warrant further investigation to confirm causality and guide peri-transplant acid suppression strategies.

Demographics After Matching

Cohort Comparison: Values for 'PPI within 1 month prior to transplant, no H2 blockers' are shown in purple, and values for 'No PPI, No H2 blockers' are shown in green.

Characteristic	Cohort Comparison	P-Value	Std diff.
Age at Index	54.2 ± 14.9 / 54.9 ± 15.6	0.005	0.049
White	61.8% / 63.5%	0.041	0.036
Unknown Race	19.6% / 17.9%	0.013	0.043
Female	37.7% / 38.0%	0.694	0.007

3459 | PSYCHOLOGICAL SYMPTOM BURDEN BEFORE AND AFTER LIVER TRANSPLANTATION: PATTERNS AND PREDICTORS IN A SINGLE-CENTER COHORT

Kishore Botla[1] Hannah Klatzkow[1] Alvaro Noriega Ramirez[1] Dyanna Gregory[1] Arjmand Mufti[1] Thomas Kerr[1] Lisa VanWagner[1] Amit Singal[1] Sarah Lieber[1], [1]University of Texas Southwestern Medical Center

Background: Liver transplantation (LT) significantly impacts physical and psychological wellbeing. Beyond anxiety and depression, patients frequently experience social isolation and stress; however, how these symptoms evolve from pre- to post-LT remains unclear. Aging is also increasingly recognized as a key factor influencing psychological health in transplant recipients, yet its role in shaping recovery trajectories is understudied. We aimed to characterize psychological symptoms pre- vs. post-LT and identify factors associated with greater psychological burden. **Methods:** Adult LT recipients (LTRs) prospectively enrolled at a large academic center completed baseline (waitlist) and either 6- or 12-month post-LT surveys, including: 1) PROMIS (Patient-Reported Outcomes Measurement Information System) anxiety, depression, and social isolation; 2) NIH Perceived Stress Scale; and 3) Brief-COPE (survey that assesses reliance on certain coping strategies). Primary analyses assessed differences between pre- vs. post-transplant scores using t-tests or ANOVA. Change scores were calculated as both absolute and percent differences between pre- and post-LT values to characterize the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

magnitude and direction of psychological symptom evolution. Multivariable analyses were used to evaluate factors associated with increased psychological symptoms post-LT. **Results:** 68 LTRs completed pre- and post-LT assessments (mean age 50.1 ± 14.1 years; 38.2% female; 83.8% white; 23.5% Hispanic). Psychological symptoms did not vary by sex, race/ethnicity, income, employment, psychiatric history, or hospitalization duration at pre- or post-LT timepoints. Compared to recipients aged 65 or younger, older recipients had lower reliance on acceptance coping strategies pre- (5.3 ± 1.6, p = 0.02) and post-LT (3.0 ± 1.7, p = 0.002), with a greater decline over time. More early post-LT hospitalizations were also linked to reduced acceptance coping (5.0 ± 4.2, p = 0.03). A history of substance use was associated with elevated anxiety (54.6 ± 10.4, p = 0.008), depression (52.1 ± 9.2, p = 0.01), and stress (15.1 ± 6.6, p = 0.03) pre-LT, but also with significant reductions in depression (45.5 ± 8.8, p = 0.01) and stress (11.1 ± 6.1, p = 0.03) post-LT. **Conclusion:** Older LTRs and those with frequent early hospitalizations demonstrated lower usage of adaptive coping strategies post-LT. While recipients with a history of substance use demonstrated higher psychological burden pre-LT, they showed notable improvements post-transplant —highlighting an opportunity for resilience-focused interventions spanning both the pre- and post-transplant periods. These findings underscore the psychological heterogeneity of LTRs and support the need for tailored psychosocial support, particularly for aging recipients and those with early post-LT complications.

Figure 1. Psychological Symptom Mean Survey Scores and Change Scores Pre- vs. Post-LT, Stratified by Subgroup

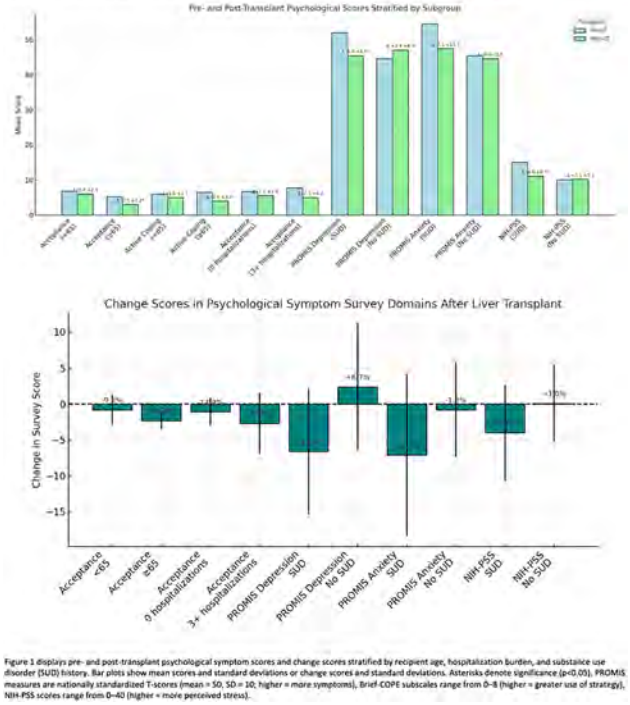

Figure 1 displays pre- and post-transplant psychological symptom scores and change scores stratified by recipient age, hospitalization burden, and substance use disorder (SUD) history. Bar plots show mean scores and standard deviations or change scores and standard deviations. Asterisks denote significance (p<0.05). PROMIS measures are nationally standardized T-scores (mean = 50, SD = 10; higher = more symptoms), Brief-COPE subscales range from 0–8 (higher = greater use of strategy), NIH-PSS scores range from 0–40 (higher = more perceived stress).

3460 | MOLECULAR PATTERNS ASSOCIATED WITH RECURRENCE AND SURVIVAL IN INTRAHEPATIC CHOLANGIOCARCINOMA (ICCA) / HEPATOCHOLANGIOCARCINOMA (HCC-CCA) AFTER LIVER TRANSPLANTATION

Maarouf Hoteit[1] Peter Abt[1] Salvatore Priore[1] Rashmi Tondon[1] Samir Abu-Gazala[1] Parul Agarwal[1] Kelley Weinfurtner[1] Moira Hilscher[2] Kirk Wangensteen[2], [1]University of Pennsylvania, [2]Mayo Clinic Rochester

Background: The Organ Procurement and Transplant Network (OPTN) recently approved a pathway for exception points in patients with unresectable intrahepatic cholangiocarcinoma (iCCA) with single tumors 3 cm or less in size. Various oncogene mutations have been described that may modulate tumor behavior and clinical outcomes in intrahepatic choangiocarcinoma. This cohort study aims to explore oncogene mutations in iCCA found in explanted livers, and whether the genetic changes are associated with post transplant recurrence and survival. **Methods:** We reviewed the liver transplant registry at the University of Pennsylvania (1997-2022) to identify subjects with iCCA or hepatocholangiocarcinoma (HCC-CCA) found on explant. Tumor nodules with histologically confirmed iCCA or HCC-CCA were identified and sampled for molecular testing. Tumor tissue DNA was sequenced and analyzed for mutations in 247 genes commonly mutated in cancers (PennSeq Comprehensive Tumor Panel). We correlated the molecular patterns with post liver transplant outcomes. **Results:** Over a 25-year period, a total of 947 liver transplants were performed with either a preoperative or postoperative diagnosis of primary

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

liver cancer. A total of 44 (4.6%) had evidence of iCCA or HCC-CCA on explant pathology. Of the 44 patients, 23 had tumor tissue samples were amenable to molecular testing and were included in the analysis. Patients were 96% Male, 74% White, and 48% had hepatitis C. The histology was consistent with HCC-CCA in 14/23 (61%) and iCCA in 9/23 (39%). The median size of the largest tumor was 2.3 cm, the median tumor nodule number was 3. 21/23 (91%) had either a nodule $>$ 3cm (6/23, 26%) or more than one tumor nodule (20/23, 87%). Most tumors analyzed had no necrosis (15/23, 65%). The median 3-year overall survival of the cohort was 56%, and 3-year recurrence-free survival was 43%. The overall recurrence rate was 48% (11/23). Mutations that previously have been associated with aggressive tumor behavior were found in 48% (11/23) of patients (9 *TP53*, 1 *KRAS*, 1 *CDKN2A*). In patients with any high-risk mutations detected compared to those without any mutation in these genes, there was a trend of a higher 3-year cumulative recurrence risk (58% vs 33%, $p = 0.13$), and of worse recurrence-free survival (36% vs 50%, $p = 0.22$), and worse overall survival (45% vs 67%, $p = 0.29$) at 3 years. **Conclusion:** In this single center study, we noted a trend for worse post transplant outcome in patients with iCCA and HCC-CCA and somatic mutations in *TP53*, *KRAS*, or *CDKN2A*. Multicenter studies are needed to confirm the findings, which may allow for improved ability to risk-stratify patients with iCCA undergoing evalaution for liver transplantation.

3461 | MULTIMODAL MULTIPHASIC IMAGE-BASED DEEP TRANSFER LEARNING FOR PREDICTION OF HEPATOCELLULAR CARCINOMA RECURRENCE AFTER LIVER TRANSPLANT

Rex Wan-Hin Hui[1] Keith Chiu[2] Chenlu Wang[3] Ho-Ming Cheng[1] Trevor Wu[1] Sarah Choy Sin Yu[1] Tiffany Cho-Lam Wong[4] Lung-Yi Mak[1] James Fung[1] Man-Fung Yuen[1] Philip Leung-Ho Yu[3] Albert Chi-Yan Chan[4] Wai-Kay Seto[1], [1]Department of Medicine, The University of Hong Kong, [2]Department of Radiology and Imaging, Queen Elizabeth Hospital, Hong Kong, [3]Department of Mathematics and Information Technology, The Education University of Hong Kong, [4]Department of Surgery, The University of Hong Kong

Background: Liver transplant (LT) is the best curative treatment option for early stage hepatocellular carcinoma (HCC). Despite stringent patient selection, HCC recurrence can still occur after LT. We studied the use of deep transfer learning for predicting post-LT HCC recurrence. **Methods:** Recurr-NET LT, a multimodal multiphasic residual-network random survival forest model, was developed for predicting post-LT recurrence. Recurr-NET LT was trained based on transfer learning from the original Recurr-NET model (a deep learning model trained, tested and externally validated on 1231 patients receiving curative resection for HCC), and further incorporated pre-LT computed tomography scans and clinical parameters from LT patients. All patients receiving LT for HCC between 2009 and 2020 in Queen Mary Hospital, Hong Kong were included in this study, and were divided in a 6:4 ratio into training and validation cohorts. The diagnostic performance of Recurr-NET LT was compared against other clinical prediction scores (RETREAT score and MORAL score) for post-LT recurrence. **Results:** This analysis included 163 patients (Age 58.3 +/- 7.2 years at LT, 75.5% male, 91.4% with viral hepatitis, 65.6% deceased donor LT (DDLT) and 34.4% living donor LT (LDLT), 82.8% within UCSF criteria, 56.4% received pre-LT bridging therapy). The cumulative 2-year and 5-year recurrence risks were 8.6% and 16.6% respectively. The Recurr-NET LT model predicted recurrence within 2 years and 5 years with area under curve (AUC) of 0.871 (specificity 0.823, sensitivity 0.333) and 0.805 (specificity 0.811, sensitivity 0.667) respectively. The Recurr-NET LT model significantly outperformed the original Recurr-NET (2-year AUC 0.519, 5-year 0.646) in predicting post-LT recurrence (both $p < 0.001$). The Recurr-NET LT model also outperformed the RETREAT and MORAL scores respectively (2-year AUC ranging from 0.546-0.769, 5-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

year AUC ranging from 0.544-0.684) (all $p < 0.05$). The diagnostic performance of Recurr-NET LT remained robust in various subgroup analysis (stratified by DDLT/LDLT, in/ out of UCSF criteria, use of bridging therapy respectively), with AUC remaining > 0.7 at all time-points. **Conclusion:** Recurr-NET LT had superior diagnostic performance over conventional clinical prediction scores, highlighting its potential as a prognostication model in LT for HCC.

3462 | CYTOMEGALOVIRUS-RNA ACCURATELY IDENTIFIES CLINICALLY SIGNIFICANT INFECTION NEEDING PREEMPTIVE THERAPY IN LIVER TRANSPLANTED CHILDREN: A PROOF-OF-CONCEPT STUDY

Emanuele Nicastro[1] Eleonora Severi[1] Ilaria Passera[1] Michele Totaro[1] Lorenza Matarazzo[1] Laura Fornataro[1] Francesco Morotti[1] Alessandra Tebaldi[1] Ezio Bonanomi[1] Michela Bravi[1] Angelo Di Giorgio[1] Samuele Covini[1] Marta Dolci[1] Domenico Pinelli[1] Marco Enrico Giovanni Arosio[1] Lorenzo D'Antiga[1], [1]ASST Papa Giovanni XXIII, Bergamo, Italy

Background: Preemptive therapy (PET) is safe and effective in controlling Cytomegalovirus (CMV) infection after pediatric liver transplantation (LT) and allows to observe the kinetics of quantitative CMV-DNA viral load till it reaches the treatment thresholds. While an early detection of low-to-moderate CMV-DNA levels may not indicate active viral replication, awaiting the viral load to exceed the treatment threshold may lead to viremic breakthroughs and CMV disease. We assessed the capacity of quantitative CMV-RNA (UL21.5 mRNA) to identify active viral replication, and its accuracy in predicting clinically significant CMV infection (csCMVi) in LT children. **Methods:** This is a prospective observational proof-of-concept study. Children were followed for 6 months after LT, and both CMV-DNA and CMV-RNA were determined once a week in the first 12 weeks and at +4, +5, +6 months. Children were treated with iv ganciclovir for PET and in case of CMV disease. Cut-off for PET was CMV-DNA ≥ 100,000 IU/mL (142,800 cp/mL) in low-intermediate risk, and ≥ 50,000 IU/mL CMV-DNA (71,400 cp/mL) in high-risk children. csCMVi was defined in presence of CMV disease or the need for PET. **Results:** One-hundred and forty-four comparative quantitative CMV-RNA and CMV-DNA determinations were obtained from 12 children. Of 52 CMV-DNA-positive specimens, 17 (32%) were also CMV-RNA-positive, while CMV-RNA was undetectable in CMV-DNA-negative specimens. CMV-DNA was significantly higher in CMV-RNA-positive (56,499 ± 102,577 copies/mL) than in CMV-RNA-negative specimens (1,189 ± 1,382; $P < 0.0001$) (Figure). All children with csCMVi had early detectable CMV-RNA, peaking simultaneously to CMV-DNA (median CMV-DNA: 65,906 cp/mL; median CMV-RNA: 767 cp/mL); conversely, none of those with persistently low DNAemia proved CMV-RNA-positive. **Conclusion:** In this first pilot study, CMV-RNA had 100% sensitivity and specificity in predicting csCMVi after pediatric LT. The early detection of CMV-RNA marks virion assembly and a substantial risk of organ damage, and could guide the initiation of antivirals without risk of overtreatment.

3463 | POST-TRANSPLANT OUTCOMES IN DIRECTED VERSUS NON-DIRECTED LIVING DONOR LIVER TRANSPLANTATION

Avesh Thuluvath[1] Talan Zhang[2] Russell Rosenblatt[3] Alyson Fox[1] Jason Hawksworth[4] Benjamin Samstein[5] Jean Emond[4] Elizabeth Verna[1], [1]Division of Digestive and Liver Diseases, Columbia University Irving Medical Center, New York, NY, [2]Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, [3]Division of Gastroenterology and Hepatology, Weill Cornell Medicine, New York, NY, [4]Center for Liver Disease & Transplantation, Columbia University Irving Medical Center, New York, NY, [5]Center for Liver Disease & Transplantation, Weill Cornell Medicine, New York, NY

Background: Living donor liver transplantation (LDLT), including non-directed living donation, offers a critical opportunity to overcome the current organ shortage and decrease waitlist mortality. The impact of non-directed living donation on post-liver transplant (LT) outcomes is unclear. In this retrospective United Network for Organ Sharing (UNOS) study, we compared post-LT patient and graft survival in directed versus non-directed LDLT. **Methods:** We analyzed the UNOS database to identify adult patients who underwent LDLT from 1/1/2002-12/31/2022. Patients who underwent multi-organ transplantation or were waitlisted with status 1 designation were excluded. The effects of directed versus non-directed grafts on post-LT patient and graft survival were estimated using a weighted Cox proportional hazards model after applying inverse probability of treatment weighting (IPTW) based on a propensity score model including recipient age, sex, MELD score, blood type, and graft type. **Results:** A total of 5158 directed and 212 non-directed LT recipients were identified. Non-directed LT recipients were more likely to be female (58% vs. 45%, $p < 0.01$), blood type A (50% vs 42% $p < 0.01$), have metabolic dysfunction-associated steatotic liver disease (21% vs 14%, $p < 0.01$) and receive a left lobe graft (17% vs 10% $p < 0.01$) compared to directed LT recipients. Non-directed LT recipients were less likely to have blood type O (34% vs 47%, $p < 0.01$) and have HCV (8% vs 22%, $p < 0.01$). Non-directed LT recipients had similar MELD scores at LT compared to directed LT recipients (15.7 vs 15.4, $p = 1.0$). Non-directed donors were older than directed donors (39.7 vs 36.9 years, $p < 0.01$). After IPTW, 1-year patient and graft survival were significantly higher in non-directed LT recipients compared to directed LT recipients ($p = 0.03$ for patient and graft survival). However, at 2- and 3-years post-transplant, patient and graft survival were similar between both groups (Figure). **Conclusion:** Long term outcomes after directed and non-directed LDLT are similar after accounting for critical factors such as recipient age, sex, MELD, blood type and graft type. While 1-year patient and graft survival are higher in non-directed LT recipients, longer term outcomes are comparable. This early difference could reflect differences in surgical techniques and immediate post-LT care at LT centers that perform more non-directed LDLT. Overall, our findings demonstrate that non-directed LDLT results in excellent outcomes and presents an important opportunity to increase the potential donor pool.

3464 | FROM BURDEN TO RECOVERY: PREDICTING POST-TRANSPLANT WELLBEING FROM BASELINE FINANCIAL TOXICITY

Hannah Klatzkow[1] Kishore Botla[1] Alvaro Noriega Ramirez[1] Dyanna Gregory[1] Arjmand Mufti[2] Thomas Kerr[2] Lisa VanWagner[2] Amit Singal[1] Sarah Lieber[1], [1]University of Texas-Southwestern, [2]University of Texas Southwestern Medical Center

Background: Liver transplant recipients (LTRs) face significant financial challenges before and after surgery; it remains unclear how this burden evolves post-transplant, or how it impacts psychological wellbeing. We aimed to evaluate associations between pre- vs. post-LT financial toxicity and associated psychological distress. **Methods:** Adult LTRs were prospectively followed at a large academic transplant center from baseline (waitlist) to post-LT (12 months) and completed the following surveys: 1) Comprehensive Score for Financial Toxicity - Functional Assessment of Chronic Illness Therapy (COST-FACIT), 2) Patient-Reported Outcomes Measurement Information System (PROMIS)-Anxiety/Depression, 3) Decision Regret Scale. COST-FACIT, scored from 0-44 with lower scores indicating greater financial toxicity, was collected at baseline and 12 months; psychological measures were assessed at 6-12 months post-LT. Clinical variables were manually extracted from the electronic health record. General linear models were used to assess the association between waitlist financial toxicity

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and post-LT outcomes, adjusting for age, sex, race/ethnicity, education, transportation access, and if transplant was performed for an alcohol-related indication. COST-FACIT was modeled as a continuous predictor and change in score was also assessed as a continuous outcome. **Results:** Among 64 adult LTRs (mean age 49.8 ±14.3 years; 39.1% female; 85.9% White, 21.9% Hispanic), those with higher pre-LT financial toxicity had significantly greater improvement in COST-FACIT scores post-transplant ($p < 0.001$); however, higher pre-LT financial toxicity was associated with higher post-LT anxiety ($p = 0.003$) and depression scores ($p = 0.002$). Having access to transportation was associated with worse financial toxicity at 1 year ($p = 0.017$) and higher anxiety scores ($p = 0.045$), potentially reflecting unmeasured social or structural vulnerabilities. Other covariates, including age, sex, race/ethnicity, education, and alcohol-related transplant indication were not significantly associated with post-LT financial or psychological outcomes. Models adjusted for demographic covariates but did not assess for effect modification. **Conclusion:** Greater baseline financial toxicity was associated with higher post-transplant psychological distress, including anxiety and depression scores. However, these patients experienced greater improvement in financial toxicity post-LT. These findings highlight the importance of early risk identification and support for LTRs who may be experiencing financial toxicity.

Table 1: Multivariable Linear Regression Models Evaluating the Association Between Baseline Financial Toxicity, Sociodemographic Factors, and Post-Transplant Financial and Psychological Outcomes

	Effect of Baseline COST-FACIT		Effect of Transportation Availability		Effect of Age		Effect of Alcohol-Related Transplant	
Parameter	Estimate (Standard Error)	P-Value	Estimate (Standard Error)	P-Value	Estimate (Standard Error)	P-Value	Estimate (Standard Error)	P-Value

3465 | COVID-19 AND POST-TRANSPLANT AND BILIARY OUTCOMES AMONG LIVER-TRANSPLANT RECIPIENTS: A PROPENSITY SCORE MATCHED ANALYSIS

Iqra Arshad[1] Ahmed Basil Nasir[2] Kamran Qureshi[3], [1]SAINT LOUIS UNIVERSITY HOSPITAL, [2]Saint louis Univeristy Hospital, [3]SSM Saint louis University Hospital

Background: The impact of the COVID-19 Pandemic on higher morbidity and mortality among solid organ transplant (SOT) recipients has already been well described [1,2]; however, its association with increased mortality and post-transplant and biliary complications among liver-transplant (LT) recipients remains unclear and is not well explored. This study aims to assess the impact of COVID-19 infection on mortality and post-transplant and biliary outcomes among LT patients from a nationwide perspective. **Methods:** A retrospective cohort study was conducted using data from the TriNetX research network. Patients aged ≥18 years having a liver transplant recipient status secondary to any etiology of liver cirrhosis and before the index diagnosis of COVID-19 infection were identified using ICD-10-CM codes. Data on demographics and clinical outcomes were extracted. Cohorts were stratified based on their COVID-19 status and matched on characteristics, including demographics (age, gender, race), comorbidities (Charlson Comorbidity Index), and immunosuppressive therapies, using propensity score. Univariate regression analysis was used to assess the primary outcome, i.e., all-cause mortality. Secondary outcomes included liver transplant complications, biliary complications, ERCP interventions, thrombotic complications, sepsis, acute kidney injury (AKI), and need for ventilatory support. Odds ratios (ORs) and 95%

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

confidence intervals (CIs) were calculated. **Results:** After propensity score matching, 7,437 patients in each cohort were analyzed for primary and secondary outcomes. All-cause mortality was found to be significantly higher among the COVID-19 LT group (OR (95% CI):1.13[1.024, 1.244]) compared to the control group. Among secondary outcomes, transplant-related complications, i.e., failure, rejection, and infections (OR (95% CI): 1.48 [1.37,1.61]), biliary complications including cholangitis (OR (95% CI): 1.80 [1.54,2.11]), and biliary obstruction (OR (95% CI): 1.31 [1.18,1.45]), sepsis (OR (95% CI): 1.52[1.4,1.65]), and AKI (OR (95% CI): 1.23 [1.15,1.31]) were significantly higher among the COVID-19 LT group compared to the control group. Other outcomes i.e., thrombotic complications, bile duct leak/perforation, and ERCP with interventions i.e., dilatation of ampulla/CBD and endoscopic stone removal, were higher among the COVID-19 LT cohort compared to control, but did not yield statistical significance. **Conclusion:** Study suggests that COVID-19 increases the risk of all-cause mortality and post-transplant and biliary complications among LT patients. A plausible explanation for this could be the complex interplay between proinflammatory state induced by coronavirus and the immunocpmromised status of LT patients, but the exact causal mechanism is unknown to date. Large prospective longitudinal studies are warranted to ascertain the causal relationship.

Clinical Outcomes	Incidence % (N)		Propensity matching analysis
	LT recipients With COVID-19 N=7,437	LT recipients w/o COVID-19 N= 7,437	aOR [95%CI]
All-Cause Mortality	13.1% (977)	11.8% (879)	1.13[1.024, 1.244]
Liver-Transplant related Complications (Failure, Rejection, infection and other complications)	24% (1,785)	17.4 (1,305)	1.48 [1.37,1.61]
Biliary Complications			
Cholangitis	5.8%(435)	3.33% (248)	1.80 [1.54,2.11]
Bile Duct Obstruction CBD stones with/without cholangitis	12.8% (957)	10%(754)	1.31 [1.18,1.45]
Bile Duct Leak/perforation	0.4% (31)	0.35% (26)	1.19 [0.71,2.01]
ERCP	0.57%(43)	0.62% (46)	0.93[0.62,1.42]
ERCP with Intervention			
Endoscopic Dilatation of ampulla and bile duct	1.05%(78)	0.98% (73)	1.07[0.778,1.47]

3466 | EXAMINING THE IMPACT OF INFLAMMATORY BOWEL DISEASE REGARDING POST-TRANSPLANT OUTCOMES IN PRIMARY SCLEROSING CHOLANGITIS

Yashasavi Sachar[1] Gurpreet Malhi[1] Luis Antonio Diaz[2] Gopika Punchhi[1] Rokhsana Mortuza[1] Mayur Brahmania[3] Vipul Jairath[1] Juan Pablo Arab[4] Mohammad Qasim Khan[1], [1]Division Of Gastroenterology, Department Of Medicine, Western University, [2]Pontificia Universidad Católica de Chile, [3]O'Brien Institute of Public Health, Cumming School of Medicine, University of Calgary, [4]Virginia Commonwealth University

Background: Primary sclerosing cholangitis (PSC) is an immune-mediated disease characterized by biliary inflammation and fibrosis. PSC has a high comorbidity rate with Inflammatory Bowel Disease (IBD). Approximately 40% of patients with PSC progress to Liver Transplantation (LT). This study assesses the impact of IBD in individuals with PSC undergoing liver transplantation (LT), in terms of overall survival and post-transplant complications. **Methods:** This retrospective cohort study included individuals with PSC identified and underwent LT between Jan 1, 2000, to December 31, 2021, with follow-up up till December 31, 2023. Statistical analysis included a Kaplan-Meier survival curve, descriptive statistics regarding post-transplant characteristics and logistic regression analysis of binary primary and secondary outcones. Primary outcomes included 1 and 5-year mortality, with secondary outcomes including post-transplant malignancy and all-cause infection. **Results:** A total of 251 patients with PSC were identified. Of those, 114 LT recipients were included, with 92 (80%) diagnosed with PSC & IBD, and 22 (20%) diagnosed with PSC only. Baseline characteristics were similar for PSC and PSC-IBD groups in terms of age, sex, MELDNa, and immunosuppression used. The PSC-IBD population largely had Ulcerative Colitis (N = 72, 78%), with diagnosis being made before PSC (N = 54, 59%). Regarding transplant, significantly more DCD patients were identified in PSC cohort, with N = 10, 43%, vs N = 12, 13% in PSC-IBD, p = 0.02. The most common PSC phenotype was classic (N = 93, 71%). No differences in immunosuppression choice were noted between PSC and PSC-IBD groups. Overall survival post-LT was 77%, with no significant difference in 1-year (91% vs 85%, p = 0.537), or 5-year mortality (84% vs 82%, p = 0.861) between PSC and PSC-IBD groups, respectively. Overall, the most common cause of death was sepsis

(43%), followed by malignancy (30%) and graft dysfunction (30%). No differences in the cause of survival were identified between PSC and PSC-IBD groups. Multivariate analysis did not demonstrate concurrent IBD diagnosis with PSC as a significant determinant affecting 1-year, 5-year survival, post-op infection, or post-op malignancy. However, increasing MELD-Na (OR 1.11 CI 1.03-1.20, $p < 0.05$), and need for pre-LT ERCP (OR 9.27, CI 1.52-56.5, $p < 0.05$) were both associated with increased risk of post-LT 5-year mortality. **Conclusion:** Over a 22-year evaluation period, concurrent IBD did not appear to confer increased risk of mortality, infection- or malignancy-related complications in PSC patients undergoing LT. This is likely reflective of the availability of more robust therapies to manage IBD during this period, and ongoing close follow-up by specialists in an IBD center of excellence.

3467 | STEATOTIC LIVER DISEASE PHENOTYPES AND RISK OF SIMULTANEOUS LIVER-KIDNEY TRANSPLANTATION ELIGIBILITY: A COMPETING RISK ANALYSIS OF NATIONAL REGISTRY DATA

Roy Wang[1] Nadim Mahmud[1], [1]Hospital of the University of Pennsylvania

Background: Steatotic liver disease (SLD) can precipitate renal dysfunction through chronic kidney disease and acute kidney injury. However, among patients initially listed for liver transplant alone (LTA), little is known about progression of renal disease and ultimate need for simultaneous liver-kidney transplantation (SLKT) among different SLD phenotypes. We aimed to evaluate the association between SLD phenotype and rates of SLKT listing using national registry data. **Methods:** This was a retrospective cohort study using United Network for Organ Sharing data from 2002 to 2023. Adult patients initially listed for LTA were included. SLD was categorized into metabolic dysfunction-associated steatotic liver disease (MASLD), alcohol-associated liver disease (ALD), and metabolic and alcohol-associated liver disease (MetALD) using a validated algorithm. Time-updated glomerular filtration rate (GFR) was computed per the 2021 CKD-EPI formula using waitlist follow-up data. The primary outcome was waitlist development of SLKT criteria, defined as either (1) GFR ≤ 60 for 90 days with dialysis initiation or GFR ≤ 30, or (2) 6 consecutive weeks of GFR ≤ 25 or dialysis. We used both cause-specific hazard models and Fine and Gray competing risk regression, adjusted for *a priori* selected variables and with 5-year maximum follow-up, to evaluate the association between SLD phenotype and development of SLKT criteria. Competing events included death and liver transplantation. **Results:** A total of 69,627 patients were listed for LTA, of which 26,729 had MASLD, 15,554 had MetALD, and 27,344 had ALD. MASLD patients tended to be older (median age 61 vs 54 [MetALD] vs 53 [ALD]; $p < 0.001$) and more often female (47.9% vs 20.7% vs 31.9%; $p < 0.001$). Patients with ALD had lower median BMI ($p < 0.001$), but higher rates of ascites ($p < 0.001$) and higher median MELD score at listing ($p < 0.001$). MASLD patients had the lowest GFR at listing (75.0 vs 80.0 [MetALD] vs 83.3 [ALD]; $p < 0.001$) and the largest portion of patients meeting SLKT criteria (6.4% vs 3.0% vs 1.9%; $p < 0.001$) during follow-up. In cause-specific hazards regression, SLD phenotype was significantly associated with waitlist development of SLKT criteria ($p = 0.01$), with MASLD (hazard ratio [HR]: 1.30, 95% CI: 1.08-1.56) and MetALD (HR: 1.31, 95% CI: 1.06-1.61) demonstrating higher risk relative to ALD (Figure A/B). Cumulative incidence function curves, as estimated from Fine and Gray models, demonstrated numeric differences among SLD phenotypes in probability of meeting SLKT criteria, however these differences were not statistically significant ($p = 0.10$; Figure C). **Conclusion:** Patients with MASLD and MetALD had higher biological hazard of meeting SLKT criteria while listed for LTA, potentially from higher rates of competing events in ALD patients. Future investigation is needed to evaluate real-world differences in SLKT eligibility between SLD phenotypes.

3468 | PERIOPERATIVE OUTCOMES WITH THE ADDITION OF NORMOTHERMIC REGIONAL PERFUSION TO NORMOTHERMIC MACHINE PERFUSION IN DCD LIVER TRANSPLANTATION

ATSUSHI NISHIMAGI[1] Rikako Oki[1] Saleh Al-Juburi[1] Luckshi Rajendran[1] Emily Kerby[1] Adhnan Mohamed[1] Ahmed Nassar[1] Abbas Al-Kurd[1] Atsushi Yoshida[1] Marwan Abouljoud[1] Shunji Nagai[1], [1]Division of Transplant and Hepatobiliary Surgery, Henry Ford Hospital

Background: The use of normothermic machine perfusion (NMP) and normothermic regional perfusion (NRP) in liver transplantation (LT) has increased in recent years, due to the expansion of the utilization of donation after circulatory death (DCD) donors. However, the clinical benefit of adding NRP to NMP remains unclear. The aim of this study was to investigate the potential clinical advantage of adding NRP to NMP in LT from DCD donors. **Methods:** We evaluated adult LT cases from DCD donors using NMP with or without NRP, performed between January 2024 and May 2025. Patients were divided into two groups based on the use of NRP. All NMPs were initiated at donor hospitals (on-site NMP). Post-operative liver function tests, lactate values, and short-term outcomes were compared between the two groups. **Results:** This study included 82 adult LT patients. Among them, 24 patients underwent LT using NMP combined with NRP, whereas 58 patients underwent LT using NMP alone. Donor age was significantly higher in the NMP+NRP group than in the NMP group (61 vs 52 years; $p = 0.001$). The incidence of early allograft dysfunction (EAD) was similar between the NMP+NRP and NMP groups (16.7%, [$n = 4$] vs 13.8%, [$n = 8$]; $p = 0.74$). There were no significant differences in peak of AST (840 vs 775 IU/L; $p = 0.53$), ALT (220 vs 218 IU/L; $p = 0.37$), INR (2.05 vs 2.06; $p = 0.68$), and total bilirubin (5.0 vs 3.6 mg/dL; $p = 0.33$) (NRP with NMP vs NMP alone). The median lactate level at 1.5 days postoperatively was significantly higher in the NMP+NRP group (1.7 vs 1.4 mmol/L; $p = 0.02$); however, both values remained within the normal reference range. Furthermore, the proportion of patients with lactate levels above the normal range (>2.1 mmol/L) at 1.5 days post-operatively was significantly higher in the NMP+NRP group compared to the NMP group (25.0%, [$n = 6$] vs 5.9%, [$n = 4$]; $p = 0.02$). There were no significant differences in postoperative ICU stay (3 vs 3 days; $p = 0.54$) or hospital stay (8 vs 10 days; $p = 0.33$) between the groups. In the NMP+NRP group, there was one case of graft loss due to postoperative hepatic ischemia which occurred immediately after transplant that required re-transplantation. There were no cases of perioperative mortality in either group. Patients who received LT from donors aged 60 years or older were divided into two groups based on use of NRP. There were 13 cases of NMP+NRP and 8 cases of NMP alone. We also compared perioperative outcomes, but no differences were found between the two groups. **Conclusion:** The results of this study showed that adding NRP to NMP did not provide significant benefits in perioperative outcomes.This study compares short-term outcomes. Comparisons of mid- to long-term outcomes remains necessary.

3469 | THE ROLE OF LDLR+ MYELOID-DERIVED SUPPRESSOR CELLS (MDSCS) IN LIVER TRANSPLANTATION

Jinzhen Cai[1] Xin Zhou[1] Xinqiang Li[1], [1]the Affiliated Hospital of Qingdao University

Background: Liver transplantation (LT) epitomizes a convergence of medical innovation and complex surgical prowess, providing a lifeline for patients grappling with end-stage liver diseases. However, immune rejection profoundly impacts patient prognosis. Investigating the underlying mechanisms of immune rejection is crucial for enhancing clinical outcomes and advancing scientific knowledge. Understanding these processes provides vital insights that can lead to improved therapies, better patient prognoses, and a deeper comprehension of immunological responses in the context of transplantation. **Methods:** We employed multi-omics approaches to analyze liver transplant samples from clinical patients and mice, utilizing single-cell RNA sequencing (scRNA-seq) and bulk RNA sequencing (bulk RNA-seq). Phenotypic and functional validation of MDSCs and their subtypes was conducted using flow cytometry, multiplex immunohistochemistry (mIHC) and co-culture experiments. **Results:** Analysis of scRNA-seq in human and murine revealed an association between MDSCs and liver transplant rejection. In mice, MDSC scores at various time points within the first week post-liver transplantation (LT) displayed a normal distribution trend, mirroring the flow cytometry results from peripheral blood of clinical patients one-month post-LT. Furthermore, the analysis identified a unique subset of LDLR+ M-MDSCs, with mIHC confirming the spatial expression of relevant proteins. Flow cytometry demonstrated the dynamic changes of LDLR+ M-MDSCs within multiple tissues (liver, spleen, blood, bone marrow and lymph nodes) in the mouse orthotopic liver transplantation (OLT) models, highlighting their elevated levels during the acute postoperative phase. Co-culture experiments demonstrated that LDLR-/- M-MDSCs exhibited reduced expression levels of functional molecules (Arg-1 and iNOS) and a significantly diminished capacity to induce the expression of inhibitory receptors (TIGIT, PD1 and CTLA-4) and functional molecules (GZMB, IFN-β and IL-2) in CD8+ T cells. **Conclusion:** LDLR+ M-MDSCs demonstrated superior immunosuppressive properties, indicating their potential clinical value in mitigating rejection and inducing immune tolerance.

3470 | EFFECTIVENESS OF HCC DOWNSTAGING STRATEGIES FOR PATIENTS WITHIN AND BEYOND UNOS DS CRITERIA

Nishtha Singh Erin Duggan[1] Ian Dinmore[2] Sarah Stucky[2] Tea Binder[2] Dustin Carpenter[2] Benjamin Samstein[2] Juan Rocca[2] Alexander Berman[2], [1]Weill Cornell Medicine, NYP, [2]Weill Cornell Medicine

Background: Hepatocellular carcinoma (HCC) beyond Milan criteria for liver transplant is typically managed with downstaging strategies including locoregional therapies and/or systemic therapies. While the United Network for Organ Sharing has a defined criteria for downstaging towards transplant eligibility (UNOS-DS criteria), many patients initially staged beyond the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

UNOS-DS criteria can also respond to treatment and eventually become eligible to transplant listing. This study aims to compare the effectiveness in downstaging strategies for patients with HCC within versus beyond UNOS DS criteria. **Methods:** We retrospectively reviewed our institutional database of HCC patients locoregional therapies (LRT) and/or systemic therapies with the goal of downstaging toward transplant listing eligibility. Patients were stratified into two cohorts based on initial tumor burden: within UNOS DS criteria versus beyond UNOS DS criteria. Clinical, radiological, and biochemical data were collected, including demographic details, tumor characteristics, treatment modalities, alpha-fetoprotein (AFP) dynamics, and survival outcomes. Primary endpoints were effective downstaging to Milan criteria. **Results:** A total of 91 patients were included in the analysis: 70 (77.7%) met UNOS downstaging (DS) criteria, while 21 (23%) were categorized as beyond UNOS DS. Baseline characteristics—including age, gender distribution, etiology of cirrhosis, ECOG status, and comorbidities—were largely comparable between groups, except for a significantly larger tumor size and a higher number of lesions in the beyond UNOS group ($p < 0.05$). The downstaging success rate was 34.3% (n = 24) in the UNOS DS group and 57.1% (n = 12) in the beyond UNOS group. Locoregional therapy (LRT) was utilized as the primary downstaging approach in 76% (n = 16) of beyond UNOS patients and 60% (n = 42) of UNOS DS patients ($p < 0.05$). The most common LRT modalities employed were Y90 radioembolization (16 in UNOS DS vs. 12 in beyond UNOS, $p < 0.05$), followed by TACE, SBRT, and MWA. Of the 91 patients, 33 underwent surgical resection and were excluded from the focused transplant analysis. The proportion of downstaged patients subsequently listed for transplants was similar between both the groups, UNOS DS group (24/42, 57.1%) and the beyond UNOS group (10/16, 62.5%). Actual transplant rates were more frequent 66.7% (n = 16/24) in the UNOS DS group and 50% (n = 5/10) in the Beyond UNOS group. **Conclusion:** Effective downstaging with locoregional therapies allows many HCC patients beyond UNOS criteria to achieve transplant eligibility. While both groups show similar listing rates after downstaging, actual transplant rates remain higher for those within UNOS criteria, highlighting the importance of patient selection and tailored management.

3471 | PLATELET RECOVERY AFTER LIVER TRANSPLANTATION: A NEW LOOK AT TIMING AND RISK FACTORS

Jamie Yang[1] Phillip Chen[1] Daniela Markovic[2] Nilofar Najafian[3] Yetunde Adebambo[2] Steven-Huy Han[4], [1]UCLA Department of Internal Medicine, Los Angeles, CA, USA, [2]UCLA Department of Medicine, Division of General Internal Medicine and Health Sciences Research, [3]Creighton University School of Medicine, Phoenix, AZ, USA, [4]Vatche and Tamar Manoukian Division of Digestive Diseases; David Geffen School of Medicine at UCLA

Background: Thrombocytopenia, a marker of clinically significant portal hypertension, occurs in up to 90% of patients following liver transplantation (LT). While prior studies suggest platelet counts typically recover within 2 to 4 weeks, some patients experience delayed or persistent thrombocytopenia, which has been linked to poorer graft function and reduced survival. However, the precise timeline and contributing factors remain

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

poorly defined. We aimed to quantify the duration of platelet recovery after LT and assess whether socio-demographic factors influence this process. **Methods:** We conducted a retrospective study of 735 liver transplant recipients within a large health system. After excluding patients with normal pre-transplant platelet counts (n = 69), 666 patients with pre-transplant thrombocytopenia were included. Platelet resolution was defined as a count $> 150 \times 10^9$/L. Demographic data—including age, sex, race, and ethnicity—were collected. Platelet counts were tracked monthly for up to 5 years post-transplant, and at each time point, the proportion of patients with platelet resolution was calculated. Multivariate analysis was then used to evaluate associations between demographic factors and platelet recovery. **Results:** Our cohort consisted of 666 patients (60.0% male, 45.2% Hispanic, 45% non-white, mean age 57 years). Platelet resolution occurred in 50% of patients between 3 and 8 months post-transplant, and in 75% between 23 and 31 months (Figure 1). Multivariate analysis showed that female sex was significantly associated with faster platelet recovery (Recovery Ratio 1.59, 95% CI 1.32–1.92; $p < 0.0001$), as was younger age less than 45 (RR 1.39, 95% CI 1.07–1.80; $p < 0.05$). Hispanic patients tended to have slower recovery, while Black patients showed a trend toward faster recovery, though these differences were not statistically significant. **Conclusion:** In this large, diverse cohort of liver transplant recipients, platelet recovery occurred more gradually than previously reported, with most patients achieving resolution over several months to years. Female sex and younger age were independently associated with faster recovery. The longer recovery timeline may reflect our stricter definition of resolution, extended follow-up, and the real-world diversity of our population. Given the link between persistent thrombocytopenia and adverse outcomes, ongoing monitoring of platelet trends may help identify patients at risk for post-transplant complications.

3472 | SPATIAL MOLECULAR ANALYSIS REVEALS NOVEL MECHANISMS AND CELLULAR PARTICIPANTS IN THE PROGRESSION OF ANTIBODY-MEDIATED LIVER ALLOGRAFT INJURY.

Mylarappa Ningappa[1] Catherine Gestrich[2] Brandon Higgs[1] Lori Schmitt[2] Kyle Soltys[1] George Mazariegos,[1] Chethan Ashokkumar[1] Rakesh Sindhi[1], [1]Children's Hospital of Pittsburgh of UPMC, Hillman Center for Pediatric Transplantation, [2]Children's Hospital of Pittsburgh of UPMC, Department of Pathology

Background: To define spatial molecular and cellular landscape of antibody-mediated injury in liver transplant rejection. **Methods:** Residual formalin-fixed-paraffin embedded 'for cause' liver biopsy sections were obtained from recipients with no rejection, T-cell-mediated and antibody-mediated rejection (NR, TCMR, ABMR). We first compared the spatial whole transcriptome of TCMR biopsies with (n = 7) and without (n = 4) circulating donor-specific anti-HLA antibodies (DSA) with Visium, technology (10X Genomics) to identify DSA-related mechanisms. Next, spatial molecular imaging (SMI) with 6000 genes (CosMx, Nanostring) defined the cellular landscape of independent biopsies with ABMR (n = 2) compared with 4 TCMR and 3 NR biopsies. Cell-specific genes were used to enumerate liver parenchymal and immune cells. **Results:** Twenty subjects with median (range) age 3.1 years (0.97-26.3) included 11 males, 9 females, 17 white and 3 non-white recipients. While TCMR is associated with portal and pericentral proteasomal and immune synapse signaling, DSA during TCMR was associated with an intralobular germinal-center-like allograft response with upregulated (p-adj. < 0.01) CD40 (CD40, TRAF1, ICAM1), chemokine (CXCL10, CX3CL1), T-follicular (ICOS, IRF7, PDCD1) and complement (C1QC, CD55) signaling. For each signaling pathway, gene counts increased progressively along the direction of sinusoidal blood flow from portal to central regions. SMI of 398 fields of view (FOVs), 0.25mm by 0.25 mm each, across nine independent biopsies (mean 44 FOVs per biopsy) revealed progressive increases in cell proportions (Figure 1) from NR to TCMR and ABMR for B-cells (1% vs 2% vs 4%), T-helper/Tc-memory (1% vs 2% vs 4%), Th17 (1% vs 1% vs 2%), Tc (3% vs 6% vs 6%), erythroblastoid macrophages (3% vs 4% vs 8%), and fibroblasts (3% vs 5% vs 7%). Spatial localization of CD40, ICOS, C1QC, and antibody-secreting IGHG2+B-cells to the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

intralobular region was confirmed in a rejection biopsy with DSA. **Conclusion:** Antibody-mediated liver allograft injury likely begins with intralobular germinal-center-like reaction during T-cell-mediated rejection. Progression to frank antibody-mediated rejection is associated with increasing liver graft infiltration by B-cells, Th/TH17 cells, macrophages, and fibroblasts.

3473 | COMPARISON OF THE 6-MINUTE WALK TEST AND THE LIVER FRAILTY INDEX IN PREDICTING LIVER TRANSPLANT MORTALITY

Amani Elshaer[1] Bridgette McNally[1] Carolyn Mead-Harvey[1] Elizabeth Carey[1], [1]Mayo Clinic Arizona

Background: Recent years have emphasized the importance of assessing functional status in liver transplant candidates, given its prognostic value pre- and post-transplant. Although multiple assessment tools exist, comparative studies are lacking, leaving uncertainty about the optimal method to use in clinical practice. The AASLD guidance does not specify a preferred frailty tool, allowing centers to choose based on practice. At our institution, we use both the Six Minute Walk Distance (6MWD) and Liver Frailty Index (LFI) to evaluate candidates, enabling a comparison of their prognostic value. **Methods:** This retrospective study analyzed 298 patients evaluated for liver transplant; 213 had 6MWD and 82 had LFI assessments. We stratified 6MWD as frail (<250 m), prefrail (250–350 m), and robust (>350 m). LFI was categorized as frail (≥ 4.5), prefrail (3.2–4.4), and robust (<3.2). Multivariate analysis compared outcomes between the two tools. The primary endpoint explored pretransplant outcomes (waitlist/transplant or deceased/denied). Secondary endpoints were post-transplant ICU stay, hospital stay, readmission rate, graft loss, and mortality. **Results:** The patient's baseline characteristics were similar across both groups. Pre-transplant outcomes (waitlist/transplanted vs deceased/denied) showed no significant differences by frailty category for LFI ($p=0.252$) or 6MWD ($p=0.468$). Post-transplant outcomes were comparable between the 6MWD ($n=196$) and LFI ($n=59$) groups, with no significant differences in ICU days (2.0 vs. 2.6; $p=0.319$), total hospital stay (8.3 vs. 9.4 days; $p=0.890$), or 30-day readmissions (2.4 vs. 2.6 days; $p=0.379$). However, graft loss was higher in the LFI group (10.2% vs. 3.1%; $p=0.035$), while mortality rates were similar (8.7% vs. 10.2%; $p=0.796$). Within LFI strata, no outcome differed significantly by frailty, though frail patients trended toward increased graft loss (18.2%, $p=0.564$) and mortality (27.3%, $p=0.144$). Among 6MWD categories, only hospitalization duration varied significantly ($p<0.001$), with frail (11.7 ± 10.1 days) and prefrail (10.3 ± 12.0 days) patients having longer stays than robust patients (7.2 ± 5.7 days). **Conclusion:** Our research showed that 6MWD and LFI are similar, lacking significant differences in predicting outcomes before and after transplantation. Due to their similarities, 6MWD serves as a user-friendly assessment tool, requiring minimal personnel training per patient, making it practical for clinical settings. Ongoing research and data collection are essential for identifying the most reliable assessment tool for evaluating patients in transplantation.

3474 | TRENDS AND REGIONAL VARIATION IN UTILIZATION OF U.S. LIVING LIVER DONORS WITH CLASS II/III OBESITY AND ASSOCIATED RECIPIENT SURVIVAL, 2002-2023

Leandro Sierra[1] Chase Wehrle[1] Jamak Modaresi Esfeh[1] Alejandro Pita[1] Koji Hashimoto[1] Sobia Laique[1], [1]Cleveland Clinic Foundation

Background: Rising obesity in living liver donors (LLDs) raises safety and outcome concerns. Organ shortages, despite these risks, have prompted centers to include LLDs with Class II and III obesity. This study characterizes U.S. trends in utilizing these donors and associated recipient survival across U.S. regions. **Methods:** Using the UNOS database, we identified adult LLDs from 2002 to 2023. We excluded pediatric donors and recipients, multi-organ transplants, and retransplants to focus on first-time adult LDLT. Donor BMI was classified according to WHO criteria, focusing on Class II (BMI 35–39.9) and Class III (BMI $\geq$40). Class I obesity was excluded from this specific analysis as most centers will use donors with Class I obesity, and this study aimed to evaluate trends associated with higher classes of obesity. We assessed temporal trends in the number of donors with obesity overall and by UNOS region. Recipient survival was analyzed using Kaplan-Meier curves and log-rank tests, initially comparing broader Western (Regions 5 and 6) and Eastern (Regions 1, 2, 3, 9, 11) groupings, with further analysis exploring individual UNOS regions. **Results:** Among a total of 142 LLDs with Class II or III obesity identified from 2002 to 2023, the utilization of such donors increased over the study period, accounting for 9.2% of all LLDs by 2023. The highest proportion of these 142 donors with obesity were observed in Regions 2 (21.8% of the total cohort of donors with obesity), 4 (14.1%), and 9 (17.6%). Western regions utilized a similar absolute number of Class II and III donors with obesity compared to Eastern regions (69 vs. 73 total donors, respectively; $P > 0.05$). Donor mean age was 35.1 $\pm$ 9.2 years (West vs. East, $P > 0.05$), with 45% male donors overall (West 40% vs. East 50%, $P = 0.17$). While initial analysis showed higher recipient 1-, 5-, and 10-year survival rates in Western regions (95.6%, 85.4%, and 79.0%) versus Eastern regions (91.2%, 70.8%, and 57.1%; $p = 0.04$), subsequent region-specific analysis indicated this Western advantage was predominantly driven by markedly higher survival in Region 6. No significant differences in recipient MELD scores or comorbidities were observed between the broad Western and Eastern regions. **Conclusion:** Recipient survival with livers from donors with obesity was higher in Western versus Eastern UNOS regions, primarily driven by exceptionally high survival rates in UNOS Region 6. This suggests that specific center practices, regional expertise, or patient selection protocols in Region 6 may significantly influence LDLT outcomes when using donors with obesity. Disseminating best practices from such high-performing regions is crucial to improve national LDLT survival rates and address these disparities.

3475 | IMPACT OF DONOR-RECIPIENT RELATIONSHIP AND HLA MATCHING ON LONG-TERM GRAFT SURVIVAL IN LIVING DONOR LIVER TRANSPLANTATION

MUHAMMAD AHMAD NADEEM[1] Sapana Verma[1] Tetsuya Tajima[1] Chase Wehrle[1] Puneet Bansal[1] Antonio Giuseppucci[1] Koki Takase[1] Hiroshi Horie[1] Jaekeun Kim[1] David Kwon[1] Charles Miller[1] Jiro Kusakabe[1] Koji Hashimoto[1] Alejandro Pita[1] Masato Fujiki[1], [1]Cleveland Clinic

Background: The use of anonymous living donors has significantly increased, expanding unrelated living donor liver transplantation (LDLT) in the United States. This raises concerns regarding potential adverse outcomes associated with increased human leukocyte antigen (HLA) mismatches. We report our experience with anonymous donation, focusing on the impact of HLA matching on transplant outcomes. **Methods:** A retrospective cohort study was conducted, including adult and pediatric patients who underwent LDLT at a single academic center between 2012 and 2024. Recipients were categorized based on donor genetic relationship into related or unrelated donors (including emotionally related and anonymous donors). HLA mismatches at classical class I and II loci were classified into two groups: 0–3 and 4–6 mismatches. The primary outcome measured was graft survival, analyzed using Kaplan-Meier survival curves, with differences between groups assessed by the log-rank test. **Results:** A total of 234 primary LDLT recipients were included: 22 (9.6%) received left lateral segment grafts, 96 (41.0%) left lobe, 106 (45.3%) right lobe, and 10 (4.3%) other graft types. The proportion of anonymous donors increased substantially over the study period (Fig. 1), with 115 (49.1%) LDLTs involving unrelated donors. Of these, 10 were prior kidney donors.

Among related donor-recipient pairs, 100 (84.0%) had 0–3 HLA mismatches, which was similar to unrelated pairs, with 98 (85.2%) ($p = 0.85$) (Fig. 2). The incidence of rejection did not significantly differ between genetically related and unrelated donor-recipient pairs (27.0% vs. 25.2%, $p = 0.76$). Similarly, ten-year graft survival was comparable between the two groups ($p = 0.32$). However, recipients with 4–6 HLA mismatches had significantly lower ten-year graft survival compared to those with 0–3 mismatches ($p < 0.05$) (Fig. 3, 4). **Conclusion:** Anonymous and unrelated donors represent an increasingly important source of donors in LDLT. Our findings underscore the significance of optimal HLA matching. Strategies aimed at minimizing HLA mismatches are recommended to maximize the benefits of anonymous donations.

3476 | TRANSPLANTXAI: AN EXPLAINABLE AI/ML MODEL FOR PREDICTING PATIENT SURVIVAL FOLLOWING LIVER TRANSPLANTATION

Bhavik Tadigotla[1] Prasun Jalal[1] Abbas Rana[1], [1]Baylor College of Medicine

Background: Accurate post-transplant mortality prediction is critical for early intervention, patient counseling, and resource allocation. Yet risk scores often exclude sociodemographic factors and rely on static thresholds, limiting transparency and individualized risk interpretation. Our aim was to develop an explainable machine learning model (ML), trained on clinical and sociodemographic features, to predict recipient survival 90 days post-liver transplant. **Methods:** TransplantXAI is a supervised ML model built on a cohort of 42,384 recipients from the United Network for Organ Sharing (UNOS). It uses 13 recipient clinical features identified as significant predictors of survival in the Survival Outcomes Following Liver Transplant (SOFT) score, and 3 recipient sociodemographic features: sex, race/ethnicity, and region. The cohort was split 70/30 (training/testing), with 5-fold cross-validation in the training set to optimize model performance. For model explainability, we used SHapley Additive exPlanations (SHAP) to generate global and individual-level feature contributions, clarifying each variable's influence on survival. **Results:** With an AUC of 0.7045, TransplantXAI outperformed MELD and matched other ML models predicting 90 day survival post-liver transplant. SHAP analysis found functional status at transplant, prior malignancy, and MELD as the top 3 drivers influencing model predictions. TransplantXAI also revealed non-clinical disparities in survival within our cohort. Specifically, male sex correlated with positive SHAP values (indicating a contribution to improved survival), while female sex correlated with negative SHAP values (indicating a contribution to poorer outcomes). In race/ethnicity, White recipients had positive SHAP values, while all other groups (Black, Multiracial, Hispanic, Pacific Islander, Asian, and American Indian) had negative SHAP values. Geographic disparities were also evident: UNOS regions 2, 3, and 5 had positive SHAP values, while all others had negative values. **Conclusion:** Our explainable ML model enables actionable opportunities for intervention by identifying patient-specific risk drivers. In revealing non-clinical disparities, TransplantXAI enables clinicians to tailor care plans—such as prioritizing size-matched donor livers for female recipients, or addressing language and community health barriers. By merging clinical and sociodemographic insights, TransplantXAI sets a precedent for transparent and equity-aware tools in transplant hepatology.

3477 | ASSOCIATION BETWEEN GUT MICROBIOTA AND CARDIOVASCULAR RISK IN LIVER TRANSPLANT RECIPIENTS

Rehan Razzaq[1] Nicole Lulkin[2] Shilpa Jasti[3] Madison Nguyen[4] Alexis Kim[4] Vaishali Patel[4] Amon Asgharpour[3] Idris Yakubu[1] Anh Bui[1] Margery Connelly[5] Mohammad Siddiqui[1], [1]VCU Health System, [2]Virginia Commonwealth University School of Medicine, [3]Virginia Commonwealth University, [4]VCUHS, [5]Labcorp

Background: Liver transplant (LT) recipients are at a heightened risk for atherosclerotic cardiovascular disease (ASCVD); however, the underlying mechanisms responsible for this association remain poorly defined. In the general population, emerging research suggests that gut microbiota may function as mediators in the development of ASCVD by promoting plaque formation, instability, and endothelial dysfunction. Given the absence of corresponding data in LT recipients, we conducted the present study to examine the relationship between gut microbiota and the risk of ASCVD in LT recipients. **Methods:** The study prospectively enrolled 170 LT recipients into a natural history study evaluating cardiometabolic complications after LT surgery. All patients had blood work done after an overnight fast at time of enrollment and patients were followed every 3-6 months after enrollment. Trimethlyamine-N-oxide (TMAO) is a gut microbiota-dependent metabolite that has been associated with CVD risk and was used in the current study. All ASCVD events were adjudicated by

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

study investigators. Diagnostic performance and time to event analysis was performed. **Results:** The median TMAO value of the study cohort was 4.95 (1st, 3rd quartiles: 2.70, 10.18) and patients receiving a LT for HCV or MASH cirrhosis had higher values when compared to other etiologies. No significant differences in TMAO levels were noted in patients who developed post-LT metabolic dysfunction associated steatotic liver disease (MASLD) compared to those who did not (9.87 ± 14.0 vs. 9.42 ± 13.0, $p = 0.83$). A total of 32 ASCVD events occurred after a median follow up of 26 months after enrollment. After adjusting for age, gender, and ethnicity, TMAO was significantly associated with higher risk of ASCVD (HR 1.032, 95% CI 1.015, 1.049, $p < 0.001$) and a trend towards all-cause mortality was noted (HR 1.026, 95% CI 1.000, 1.054, $p = 0.052$). At the max Youden Index to predict 2-year future risk of ASCVD, the diagnostic performance are: AUROC 0.71 (95% CI: 0.59, 0.84), Sensitivity 0.67, Specificity 0.66, NPV 0.85, and PPV 0.41. **Conclusion:** The research highlights the potential role of gut microbiota in ASCVD development, particularly focusing on the metabolite trimethylamine-N-oxide (TMAO). Although a trend between all-cause mortality and TMAO levels was noted, it wasn't statistically significant, likely due to the small sample size. Larger studies are needed to determine how TMAO can improve risk stratification in LT recipients.

3478 | LIVER-SPECIFIC DELETION OF NAT10 IMPAIRS LIVER REGENERATION IN A MOUSE PARTIAL HEPATECTOMY MODEL

Jiale Lu[1] sheng wang[1] Fengsheng Dai[1] MaoYun Liu[1] Yuqin Xie[2] Yi Wang[1] Cheng Zhang[2] DeWei Li[1] Hui Li[1], [1]Chongqing University Cancer Hospital, [2]Chong Qing University Cancer Hospital

Background: Impaired liver regeneration after injury or surgery can lead to life-threatening complications such as liver failure and small-for-size syndrome, highlighting the need to identify key molecular regulators of this process. N-acetyltransferase 10 (NAT10), the only known enzyme that catalyzes N4-acetylcytidine (ac4C) modification on RNA, regulates mRNA stability and translation. While NAT10 is implicated in various cellular processes, its role in liver regeneration remains unknown. This study aims to investigate whether NAT10 promotes hepatocyte proliferation and liver regeneration and to elucidate the underlying mechanisms driving this process. **Methods:** Liver regeneration was induced by 70% partial hepatectomy (PHx) in 8-week-old C57BL/6J mice. RNA sequencing was performed to identify key regulators involved in liver regenerative by using liver tissue at 48 hours post-PHx. Liver-specific *Nat10* knockout mice ($Nat10^{LKO}$) were generated by crossbreeding $Nat10^{fl/fl}$ mice with Alb-Cre transgenic mice. Liver tissues and serum samples were collected at 0, 48, 72, and 120 hours post-PHx. The liver-to-body weight ratio was calculated to assess regenerative progression. Serum biochemical analyses were performed to evaluate liver function. Liver tissues were subjected to immunohistochemistry (IHC) and western blotting (WB). **Results:** RNA sequencing analysis showed that NAT10 expression was significantly upregulated in liver tissues following PHx compared to sham-operated controls. $Nat10^{LKO}$ mice exhibited a significantly lower liver-to-body weight ratio at both 48 and 120 hours post-PHx compared to $Nat10^{fl/fl}$ mice. Serum biochemical analysis indicated delayed liver function recovery in $Nat10^{LKO}$ mice, as evidenced by persistently elevated AST and ALT levels. IHC showed reduced Ki67 and PCNA expression, indicating impaired hepatocyte proliferation. WB analysis revealed decreased expression of cell cycle regulators, including Cyclin D1, Cyclin A2, Cyclin E1, CDK1, and CDK4. In addition, phosphorylated STAT3 levels were also reduced in $Nat10^{LKO}$ mice, suggesting impaired activation of regenerative signaling pathways. **Conclusion:** Liver-specific deletion of NAT10 impairs

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

liver mass restoration, delays liver function recovery, reduces proliferative activity, and suppresses key cell cycle and regenerative signaling pathways, including STAT3 phosphorylation. These results suggest that NAT10 may serve as a potential therapeutic target for improving liver regeneration in the context of liver injury or resection.

Disclosures: Jiale Lu: Nothing to Disclose, sheng wang: Nothing to Disclose, Fengsheng Dai: Nothing to Disclose, MaoYun Liu: Nothing to Disclose, Yuqin Xie: Nothing to Disclose, Yi Wang: Nothing to Disclose, Cheng Zhang: Nothing to Disclose, DeWei Li: Nothing to Disclose, Hui Li: Nothing to Disclose

3479 | EFFICACY AND SAFETY OF TENOFOVIR ALAFENAMIDE FOR HBV PROPHYLAXIS IN HBV-NEGATIVE LIVER TRANSPLANT RECIPIENTS WITH HBCAB-POSITIVE DONORS:UPDATED 24-WEEK INTERIM ANALYSIS

Aiwei Zhou[1] Zhifeng Xi[1] Kang He[1] Hanyong Sun[1] Yongbing Qian[1] Wei Geng[1] Jie Cao[1] Lei Xia[1] Jianjun Zhang[1] Qiang Xia[1], [1]Renji Hospital

Background: Liver transplantation (LT) remains the definitive treatment for end-stage liver disease, yet donor organ shortages persist. Strategic utilization of HBcAb-positive grafts may expand the donor pool, though this necessitates effective HBV prophylaxis given the risk of *de novo* infection. Tenofovir alafenamide (TAF) demonstrates comparable antiviral efficacy to tenofovir disoproxil fumarate (TDF) with superior renal and bone safety profiles. This interim analysis evaluates TAF's prophylactic efficacy and safety through 24-week follow-up in HBV-negative recipients with HBcAb-positive liver allografts within a Chinese transplant cohort. **Methods:** This prospective single-arm study enrolled HBsAg-negative and HBV-DNA-negative LT recipients (aged ≥ 12 years) receiving allografts from HBsAg-negative/HBcAb-positive deceased donors. TAF prophylaxis (25 mg/day) was initiated immediately after LT and continued until treatment-limiting adverse events (AEs) or consent withdrawal. Protocol-defined monitoring included weekly laboratory tests (week 1-4), transitioning to biweekly (week 5-12) and monthly (week 12-24), and transient elastography (FibroScan) at week 12 and 24. Key efficacy endpoint of this interim analysis was the positive rate of HBV-DNA or HBsAg at week 24. Safety endpoints included changes in hepatic and renal function, and incidence of treatment-emergent AEs. This trial is registered with ClinicalTrials.gov, number NCT04703465. **Results:** Between July 30, 2022 and May 25, 2025, 17 patients (mean age 50.7 years; 64.7% male) were enrolled, with 16 patients (94.1%) completing 24 weeks of TAF treatment and follow-up. During the study, no patient was detected HBV-DNA-positive or HBsAg-positive. Liver function remained stable at week 24: mean ALT 23.3 U/L (95% CI, 17.0 to 29.7), AST 25.2 U/L (95% CI, 20.9 to 29.3), and median TBIL 13.6 μmol/L (IQR, 9.6 to 18.7). Liver stiffness (mean LSM 7.0 kPa; 95% CI, 6.5 to 7.5) at week 24 showed minimal change from week 12 (Δ +0.1 kPa; IQR, -1.1 to +0.3). Renal function exhibited a median eGFR decline of -9.5 mL/min/1.73 m² (IQR, -18.3 to -3.3) between week 24 and week 0, with serum creatinine increasing by +6.8 μmol/L (95% CI, -8.3 to +21.9). Seven patients (41.2%) experienced serious AEs, none treatment-related, and no proteinuria or grade ≥ 3 hepatic abnormalities were observed. **Conclusion:** TAF provides effective HBV prophylaxis in HBV-negative LT recipients with HBcAb-positive allografts, with no virological breakthroughs observed. Hepatic parameters remained stable throughout follow-up. Despite a modest decline exhibited in renal function, no proteinuria occurred. These findings support the feasibility of utilizing HBcAb-positive donors under TAF prophylaxis to address organ shortages, with preserved graft and renal safety over 24-week follow-up. Future studies should prioritize randomized comparisons with TDF and extended monitoring of renal function.

3480 | MATERNAL AND FETAL OUTCOMES IN PATIENTS WITH AUTOIMMUNE HEPATITIS POST LIVER TRANSPLANTATION

Madeline Koehn[1] Caroline Conlon[1] Richard Hass[2] Sarah Boudova[1] Tammy Tran[1] Lisa Coscia[3] Michael Moritz[3] Serban Constantinescu[3] Tatyana Kushner[4] Danielle Tholey[1], [1]Thomas Jefferson University Hospital, [2]Jefferson College of Public Health, Thomas Jefferson University, [3]Transplant Pregnancy Registry International, [4]Weill Cornell Medicine

Background: Autoimmune hepatitis (AIH) is a chronic, immune-mediated liver disease with a higher prevalence in women. AIH is associated with an increased risk of rejection, recurrent AIH and graft loss post-LT compared to other etiologies. Pregnancy in LT patients can be associated with increased risk of maternal and fetal complications. Yet, data on pregnancy outcomes for AIH patients post-LT are scarce. This study analyzes

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

the impact of AIH-indicated LT on maternal and fetal outcomes. **Methods:** A retrospective analysis was done evaluating post-LT pregnancies in the Transplant Pregnancy Registry International (TPRI) between 1985-2024. Descriptive analyses were performed, including Chi-squared test for categorical variables and t-tests for continuous variables ($p < 0.05$ significant), to assess maternal and fetal outcomes for pregnancies in patients transplanted for AIH compared to a control group of all other indications. **Results:** In total, 429 women with 846 pregnancies were included (AIH cohort: 62 women, 125 pregnancies; control cohort: 367 women, 721 pregnancies). The majority of patients were white with similar age, BMI and rate of planned pregnancies. Transplant to conception interval <1-year post-LT was significantly shorter in the AIH group (11% vs 4%, $p = 0.002$). Pregnancy, maternal and neonatal outcomes were similar in each cohort (table 1). Incidence of gestational diabetes (8% vs 7%, $p = 0.89$), hypertensive related complications (pre-eclampsia 17% vs 15%, $p = 0.46$; HELLP 2% vs 1%) and infections during pregnancy (15% vs 17%, $p = 0.82$) were similar. The AIH group had more prednisone (62% vs 29%, $p < 0.001$) and mycophenolate exposure (11% vs 5%, $p = 0.03$) during pregnancy. Live birth rate (68% vs 74%, $p = 0.25$), miscarriage (27% vs 20%, $p = 0.11$), stillbirth (2% vs 1%, $p = 0.54$) and birth defects (8% vs 8%, $p = 0.34$) were not different between groups. AIH patients had a higher rate of graft loss at any time after pregnancy (24% vs 13%, $p = 0.002$). There was a nonsignificant trend to higher rates of rejection during (8% vs 4%, $p = 0.11$) and after (7% vs 5%, $p = 0.33$) pregnancy. Neonatal jaundice (13% vs 9%, $p < 0.001$) and NICU admission (20% vs 15%, $p < 0.001$) were increased in the AIH group. **Conclusion:** Pregnancy outcomes are overall similar in women post-LT for AIH vs allcomers. However, AIH patients displayed higher rates of graft loss, neonatal jaundice and NICU admission. Increased graft loss may be due to shorter LT to conception intervals in the AIH group and altered immune factors post-LT and post-partum. Despite higher mycophenolate exposure in the AIH group, there were no differences in birth defects, miscarriage, live birth or still birth rates. More data is needed to assess mycophenolate's impact on our other neonatal outcomes. Improved preconception counselling, closer monitoring of liver tests in the peri- and post- partum periods, and multidisciplinary management with maternal fetal medicine and neonatology may be beneficial in this cohort.

3481 | TEMPORAL TRENDS IN MEDIAN WAIT TIME FOR LIVER TRANSPLANTATION AND WAITLIST OUTCOMES IN THE U.S.

Ha Tran[1] Naim Alkhouri[2] Michael Rothberg[3] Dev Gupta[4] Olajide Adekunle[3] Phuc Le[3], [1]Cleveland Clinic, [2]Summit Clinical Research, [3]Cleveland Clinic, Center for Value-Based Care Research, [4]Case Western Reserve University

Background: Major policy changes have reshaped liver transplant allocation over the past two decades, including Share 35 and acuity circles. Evaluating trends in waitlist outcomes—transplantation, death, and dropout—can help assess the real-world impact of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

these policies. **Methods:** We conducted a retrospective cohort study using the United Network for Organ Sharing registry to examine temporal changes in waitlist outcomes. We included adult candidates waitlisted for liver transplantation between 1/1/2005 and 6/30/2024 and excluded those listed for multi-organ transplants or with missing data. Primary outcome was time from waitlist registration to one of three mutually exclusive events: transplant, death on the waitlist, or dropout (removal for reasons other than transplant or death). We estimated annual median times of each outcome overall and by MELD score, hepatocellular carcinoma (HCC) status, and liver etiology. Trends over time were assessed using Joinpoint software. **Results:** We included 205,437 patients. Overall, median wait time to transplant increased by 8 days/year from 2005–2013, plateaued between 2013–2017, and then declined by 22 days/year from 2017–2020 and 7 days/year from 2020–2024. In contrast, median time to death and dropout declined throughout the study period (p-values < 0.01). Lower MELD scores were associated with longer wait times. In patients with MELD ≤ 14, median time to transplant increased between 2005-2013, then decreased by 6 days/year from 2014–2022 and 58 days/year after 2022. Median time to death and dropout also decreased consistently in this group. Compared to those without HCC, patients with HCC experienced longer wait times. For this group, median time to transplant increased steadily, peaking at 250 days in 2016, then plateaued between 2016-2022 before declining to 128 days in 2024. Time to dropout peaked at 330 days in 2019 then falling to 163 days in 2024. By etiology, patients with alcohol-associated liver disease had the shortest wait time to transplant, followed by those with metabolic-dysfunction associated steatohepatitis and hepatitis C. Three groups had similar decreasing wait time to death and dropout. **Conclusion:** Waitlist outcomes for liver transplant candidates have improved over the past two decades, but disparities persist by MELD score, diagnosis of HCC, and etiology. Our study highlights the impact of evolving allocation policies, shifting clinical populations, and expanded eligibility on access. Continued monitoring is needed to ensure equitable and timely allocation.

3482 | PUMP-SOFT SCORE: MACHINE PERFUSION AS A PREDICTOR OF SHORT-TERM POSTOPERATIVE MORTALITY IN LIVER TRANSPLANTATION

Gwendolyn Henry[1] Carter Burns[1] George Cholankeril[1] Abbas Rana[1], [1]Baylor College of Medicine

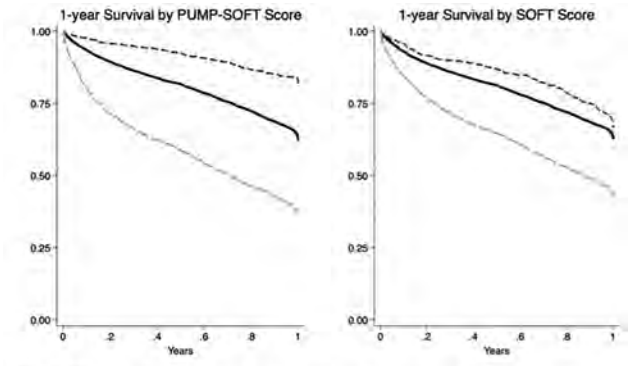
Background: Liver transplantation is the only curative procedure for patients with end-stage liver disease, and the growing disparity between donor organs and eligible recipients represents a considerable barrier to treatment. One avenue for addressing this discrepancy is through the use of machine perfusion to maximize graft preservation and increase the utility of marginal allografts. Early evidence suggests that machine perfusion could also have a positive impact on decreasing short-term postoperative mortality. Currently, there are no liver transplant risk scores that take into account whether machine perfusion was utilized for the donor organ when assessing a patient's post-transplant mortality risk. Our aim for this study was to create a novel risk index for assessing 90-day post-transplant mortality which incorporates machine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

perfusion as a predictive variable, the PUMP-SOFT score. **Methods:** Through univariable and multivariable regression of de-identified patient-level data collected by the Organ Transplant and Procurement Network, we identified significant risk and protective factors from a sample of 64,791 patients. Points were allocated according to odds ratios from 25 significant recipient factors and 2 significant donor factors to generate the PUMP-SOFT score. **Results:** Machine perfusion had a significantly protective effect on survival, reducing short-term postoperative mortality risk by 40% (OR 0.601, CI 0.47-0.77). The most significant risk factors identified through our analysis were two previous transplants (OR 4.2., CI 2.50-7.19), recipient serum sodium 155-160 mEq/L (OR 3.7, CI 1.90-7.27) and 150-155 mEq/L (OR 2.2, CI 1.53-3.22), and moribund pre-transplant clinical presentation based on Karnofsky scores (OR 1.7, CI 1.42-2.11).

The PUMP-SOFT score has a *C*-statistic of 0.68 (CI 0.666-0.689) for 90-day mortality, which is significantly higher than that of both the original SOFT score (0.65, CI 0.639-0.662) and the BAR score (0.61, 0.594-0.618) when applied to this modern cohort of patients. Figure 1 includes Kaplan-Meier curves showing the 1-year survival probability for both the PUMP-SOFT score and original SOFT score where patients are divided into the 10th, 50th, and 90th percentiles. **Conclusion:** The PUMP-SOFT score is an novel approach to characterization of postoperative mortality risk because it incorporates the effect of machine perfusion as a predictive variable. This novel scoring system represents an improvement upon established risk scores like the SOFT score and BAR score. Our results from this study also support the notion that machine perfusion could have a protective effect on short-term post-transplant mortality. Thus, perfusion should be incorporated as a predictive factor in future risk assessment indices, especially as utilization of machine perfusion systems continues to grow in order to ameliorate the current organ shortage associated with liver transplantation.



PUMP-SOFT Risk group	OR	p-value	CI
10th percentile (low)	0.302	0.000	0.247,0.371
50th percentile (moderate)	0.603	0.000	0.553,0.658
90th percentile (high)	3.376	0.000	3.08,3.70

3483 | A RANDOMIZED MULTI-CENTER TRIAL OF A TELEMETRIC INTERVENTION TO PREVENT REJECTION IN ADOLESCENTS AT RISK AFTER LIVER TRANSPLANTATION (IMALT)

Eyal Shemesh[1] Ravinder Anand[2] Rachel Annunziato[1] Emily Fredericks[3] Jennifer Garcia[4] Nitika Gupta[5] Alyssa Kriegermeier[6] Krupa Mysore[7] Vicky Ng[8] Steven Lobritto[9] Shreena Patel[10] Emily Perito[11] Elizabeth Rand[12] Rene Romero[5] Robert Venick[13] Sarah Duncan-Park[1] Jeffrey Mitchell[2] Sarah Anderson[2] Margaret Stuber[14] Miguel Reyes-Múgica[15] George Mazariegos[16] Benjamin Shneider[17], [1]Icahn School of Medicine at Mount Sinai, [2]The Emmes Company, LLC, [3]University of Michigan Medical Center, [4]Miami Transplant institute, University of Miami, [5]Emory University School of Medicine, [6]Ann and Robert H. Lurie Children's Hospital of Chicago, [7]Baylor College of Medicine, [8]Hospital for Sick Children, [9]Columbia University, [10]Children's Hospital Los Angeles | USC Keck School of Medicine, [11]Benioff Children's Hospital University of California, San Francisco, [12]Children's Hospital of Philadelphia / University of Pennsylvania, [13]David Geffen School of Medicine at UCLA, [14]UCLA David Geffen School of Medicine, [15]University of Miami, Miller School of Medicine, [16]Children's Hospital of Pittsburgh, [17]Texas Children's Hospital

Background: Nonadherence is a major cause of late acute cellular rejection (ACR) and a risk for graft loss in liver transplant recipients. Identifying and treating clinically significant nonadherence remains an unmet medical need in liver transplantation and throughout medicine. The Improving Medication Adherence in Adolescents who had a Liver Transplant (iMALT – NCT03691220) study sought to address this need. **Methods:** iMALT was a prospective, block-randomized, controlled multisite study in 13 pediatric transplant centers in the USA and Canada. A two-year manualized telemetric intervention (TI) was compared to standard of care (SOC). Eligible adolescents at risk for rejection were identified by a medication level variability index (MLVI) of $>$ 2.0. The primary outcome was a composite end-point of ACR centrally determined by 3 masked pathologists, death, re-transplantation, or consent withdrawal. iMALT was powered for a 50% reduction in rejection based upon the MALT cohort study (Am. J. Transpl. 17:2668-2678), in which 53% of adolescents with MLVI $>$ 2.0 had ACR. Safety analyses examined medication toxicity that may be related to enhanced

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

adherence. **Results:** Among 148 participants (TI n = 72, SOC n = 76), mean age was 15.5 years, averaging 10.0 years after liver transplant. There was no attrition in this complicated patient population and the study was uninterrupted by the COVID-19 pandemic. There were 6 primary events in the TI group (8.3%) and 12 in SOC (15.8%) (OR 0.50, 95% CI 0.17-1.45, p = 0.203). There were improvements in all secondary outcomes in the intervention relative to SOC, including significant changes in maximal ALT (Table). No adverse/safety events were observed. **Conclusion:** iMALT did not observe a statistically significant improvement in its primary end-point, however improvements were noted in all relevant outcomes in the intervention group compared to SOC. The study was unexpectedly underpowered, as rejection incidence was lower than observed in the precursor MALT study. In iMALT unlike in MALT, participating sites used MLVI to detect nonadherence and inform clinical care, which made standard of care more effective. This likely led to reduced incidence of rejection compared to the MALT study. We posit that objective and reliable identification of nonadherence using MLVI, coupled with telemetric intervention, is a powerful approach to addressing clinically significant nonadherence in adolescents after liver transplant.

Table (Other Endpoints)

Background: Coronary artery disease (CAD) assessment in liver transplantation (LT) candidates remains challenging. This study evaluates the clinical utility of a risk-adapted protocol for pre-LT CAD evaluation, integrating cardiac catheterization (Cath) and functional testing, and its impact on post-LT outcomes. **Methods:** A retrospective cohort analysis of 745 LT recipients (2020–2024) managed under a protocol stratifying candidates by cardiovascular risk. High-risk patients underwent pre-LT Cath, with CAD severity categorized as non-obstructive ($<75\%$ stenosis, $n=328$) or obstructive ($\geq 75\%$ stenosis, $n=36$). Outcomes included cardiac death, myocardial infarction (MI), graft survival, and mortality. Adjusted Cox regression and Kaplan-Meier survival analyses were performed. **Results:** Implementation of the protocol achieved high 3-year patient (82–85%) and graft survival (80–85%) across all groups (no cardiac Cath, non-obstructive, and obstructive CAD groups), despite prevalent comorbidities (diabetes: 46.9%, HTN (33.5%), obesity (33.5%), and dyslipidemia (19.9%). Post-LT MI occurred in 19 patients (2.6%), 12 patients underwent cardiac Cath and 7 patients managed conservatively. Adjusted Cox models showed no independent association between CAD severity and mortality (obstructive CAD HR 1.96, 95% CI 0.83–4.66, *p* = 0.12) or graft failure (HR 1.49, 95% CI 0.68–3.29, *p* = 0.31). 14 patients (3.8%) developed contrast induced nephropathy and only one patient required dialysis. **Conclusion:** A risk-adapted CAD assessment protocol demonstrated significant clinical utility, facilitating tailored management and yielding low post-LT cardiac complications and excellent survival rates despite high comorbidity burdens. These results advocate for protocol-driven, multidisciplinary risk stratification to optimize LT outcomes. Prospective validation is warranted to refine criteria and expand applicability.

3485 | THE PROFILE AND OUTCOMES OF LIVER TRANSPLANTATION IN THE UNITED STATES AND 30 EUROPEAN COUNTRIES

Zobair Younossi[1] Giacomo Germani[2] Robert Wong[3] Maria Stepanova[4] Fatema Nader[5] Vincent Karam[6] René Adam[7] Saleh Alqahtani[8] Linda Henry[1] Patricia Burra[9], [1]The Global NASH Council, [2]3. Department of Surgery, Oncology and Gastroenterology, University of Padova, Italy, [3]VA Palo Alto Healthcare System, [4]The Center for Outcomes Research in Liver Diseases, [5]Center for Outcomes Research in Liver Diseases, CORLD, [6]The European Society for Organ Transplantation, Amsterdam, the Netherlands, [7]Hopital Paul Brousse, Division of Transplant Surgery, Villejuif, France, [8]Liver, Digestive, and Lifestyle Research Section, and Organ Transplant Center of Excellence, King, [9]Department of Surgery, Oncology and Gastroenterology, University of Padova, Italy

Background: Due to varying etiologies of chronic liver disease (CLD) and differences in clinical and demographic factors, regional differences in liver transplantation (LT) may exist. We aimed to describe LT recipients in the United States and 30 European countries over the past two decades. **Methods:** We combined data from two large transplant registries: the U. S. Scientific Registry of Transplant Recipients (SRTR) and the European Liver Transplant Registry (ELTR), years 2000-2022. Common clinical parameters and post-LT mortality were collected. **Results:** We included 237,813 LT recipients (109,048 LT from Europe [30 countries], 128,765 from the U.S.). Compared to SRTR, LT recipients from ELTR were younger, more often male, and had lower BMI, lower MELD scores, and few cirrhosis complications (all $p<0.0001$). Hepatocellular carcinoma (HCC) was more frequent in ELTR: 29% vs. 20%. ELTR also had more chronic hepatitis B (CHB) (9% vs. 3%) and alcohol related liver disease (ALD) (30% vs. 23%), and less chronic hepatitis C (CHC) (18% vs. 27%) and NASH/MASH (7% vs. 19%) (all $p<0.0001$). Over time, HCC rates initially increased (peak of 30% in 2015 for SRTR, 35% in 2016 for ELTR), then declined. Major trends included rising ALD (15% to 45% in SRTR, 25% to 41% in ELTR) and decreasing CHC (40% to 7%; 25% to 7%) (all trend $p<0.0001$) (Figure). NASH/MASH also increased: 9% to 28% in SRTR, 5% to 12% in ELTR, while CHB decreased: 6% to 2%; 11% to 6%. In patients without HCC, the three most common CLD etiologies were identical: ALD, NASH/MASH, and primary sclerosing cholangitis. In patients with HCC, NASH/MASH has become the most common etiology in the U.S. by 2022, while ALD was the most common and the fastest growing in ELTR. In proportional hazards models, a

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

more recent calendar year was independently associated with lower mortality in both registries: ELTR aHR = 0.983 (0.979 - 0.987), SRTR aHR = 0.955 (0.953 - 0.957) per year ($p < 0.0001$). Other predictors of higher post-LT mortality included older age, male sex, higher MELD score, grade III/IV hepatic encephalopathy, HCC, and CHC (all aHR > 1.0, $p < 0.01$), consistent across registries and HCC status. **Conclusion:** Data from two large regional transplant registries confirm that ALD and NASH/MASH are continuing to emerge as major etiologies for liver transplantation, emphasizing the importance of improving global awareness of both metabolic and alcohol-related comorbidities contributing to steatotic liver disease.

3486 | ANTI-THYMOCYTE GLOBULIN-BASED INDUCTION IMMUNOSUPPRESSION IN LIVER TRANSPLANT RECIPIENTS WITH NON-IMMUNE CHRONIC LIVER DISEASES

Alexander Scherer[1] Andrej Sikoski[1] Albert Zhang[1] Marco Lacerda[1] Marwan Ghabril[1] Naga Chalasani[1] Eric Orman[1] Chandrashekhar Kubal[1], [1]Indiana University School of Medicine

Background: Use of anti-thymocyte globulin (ATG) as induction immunosuppression (IS) is not common practice in liver transplantation (LT). There is lack of studies describing the use of ATG in this population, particularly so in disease-specific patient populations. Our study reports on impact of IS in patients with non-immune primary diagnoses such as alcohol-associated liver disease, MASH, viral hepatitis, and other diagnoses. **Methods:** In April 2020 a practice change was incorporated in our program in response to the COVID-19 pandemic; wherein patients with non-immune primary diseases no longer received ATG-based IS. Patients with immune diseases (autoimmune hepatitis (AIH), primary biliary cirrhosis (PBC), or primary sclerosing cholangitis (PSC)) continued to receive ATG, whereas patients with age > 65, extreme frailty, or recent infection did not receive ATG and both subsets were excluded from analysis. Pediatric recipients, simultaneous multiorgan transplants, and retransplants were also excluded. In this cohort study, our primary endpoint was acute rejection (AR), diagnosed based on clinical suspicion and histologic confirmation. Outcomes were compared across the two eras stratified by ATG-based IS (Era 1: 1/2016-3/2020, Era 2: 4/2020-12/2023). **Results:** Of a total of 867 patients with non-immune primary liver diseases, 447 were in Era 1 and 420 in Era 2. Baseline characteristics and differences between cohorts are reported in Figure 1. ATG was given to 87% of patients in Era 1 and 3% in Era 2 ($p < 0.001$). Overall, 124 patients (14.3%) experienced AR. AR was more common in Era 2 (19.1% vs. 9.8% in Era 1, $p < 0.001$). In multivariable Cox regression, the predictors of AR were MELD at transplant (HR 1.02, $p = 0.024$), non-ATG IS (HR 1.61, $p = 0.013$), male donor (HR 1.54, $p = 0.04$) and Black race (HR 2.90, $p < 0.001$). In subgroup analysis, Black race was only significantly associated with AR in patients who did not receive ATG ($p < 0.001$ vs. $p = 0.056$ in Black patients with ATG IIS). Death after transplant ($p = 0.30$) or graft loss ($p = 0.40$) were not statistically different between the two eras. **Conclusion:** A shift in IS strategy to omit ATG from induction in patients with non-immune etiologies was associated with increased AR, at-risk population being recipients with Black race or male donors. There may be a role for ATG-based IS in a select group of patients.

3487 | NON-ABO ANTIBODIES AND THEIR IMPACT ON LIVER TRANSPLANT REJECTION: A RETROSPECTIVE STUDY

Nino Gudushauri[1] Irakli Lemonjava[2] Irakli Tskhakaia[2] Richard Kalman[2] Victor Navarro[3] Salvatore Mignano[2] Manjula Balasubramanian[2], [1]Jefferson Einstein Philadelphoa Hospital, [2]Jefferson Einstein Philadelphia Hospital, [3]Jefferson Health System

Background: Non-ABO antibodies are immune proteins that target blood group antigens outside the ABO system. They are clinically significant in both transfusion medicine and transplantation. Key systems include Rh, Kell, Kidd, Duffy, MNS and Lewis. We decided to undertake a study to determine the correlation between non-ABO antibodies and its association with antibody-mediated rejection, and T cell-mediated rejection (ATCMR). **Methods:** The study evaluated 183 liver transplant recipients over five years, excluding 14 patients (13 due to post-transplant mortality, 1 lost to follow-up) from an initial cohort of 197. Participants were stratified based on non-ABO antibody status: 7 positive and 176 negative. Data on liver allograft rejection episodes were extracted from medical records and categorized as clinically suspected rejection, definite or indeterminate T-cell mediated rejection (TCMR), and definite, indeterminate, or probable antibody-mediated rejection (AMR).

Comparisons between groups utilized Chi-square or Fisher's Exact tests, depending on expected cell counts, with 2×2 contingency tables constructed for each rejection category.

The study protocol received approval from the Institutional Review Board, adhering to ethical standards for research involving human subjects. **Results:** The study aimed to investigate whether the presence of non-ABO antibodies is associated with an increased risk of rejection in transplant patients. While the non-ABO positive group exhibited higher rates of both clinically suspected and biopsy-proven T cell-mediated rejection compared to the non-ABO negative group, these differences did not reach statistical significance. This lack of significance may be attributed to the small sample size of the non-ABO positive group, limiting the study's power to detect meaningful differences.

Gender-based analysis revealed that non-ABO positive females had higher rates of both clinically suspected and biopsy-proven T cell-mediated rejection compared to their non-ABO negative counterparts. However, these differences were not statistically significant. In males, all non-ABO positive patients experienced clinically suspected rejection, with half having biopsy-proven T cell-mediated rejection. These rates were higher than those in non-ABO negative males but did not achieve statistical significance. **Conclusion:** These findings suggest a potential trend toward increased rejection rates in patients with non-ABO antibodies, particularly among females. However, due to the limited sample size, especially in the non-ABO positive group, definitive conclusions cannot be drawn. Further studies with larger cohorts are necessary to validate these observations and to explore the underlying mechanisms contributing to these potential differences.

3488 | CAD-LT SCORE PREDICTS CARDIAC MORTALITY AND GRAFT SURVIVAL IN LIVER TRANSPLANT RECIPIENTS: A RETROSPECTIVE COHORT ANALYSIS

Maryam Abdulla[1] Waleed Haj Ahmad[1] Syeda Shamsi[1] Ahmad Alissa[1] Dimitri Raptis[2] Dieter Broering[3] Manhal Izzy[4] Khalid Bzeizi[3] Saleh Alqahtani[5] Fuat Saner[6] Bandar Aljudaibi[3], [1]Alfaisal Univeristy, [2]King Faisal Specialists Hospital and Reseach Centre, [3]King Faisal Specialists Hospital and research Centre, [4]Department of Medicine, Vanderbilt University, [5]Johns Hopkins University, [6]King Faisal Specialists Hospitala and Research Centre

Background: Cardiovascular disease significantly impacts outcomes in liver transplantation (LT). The CAD-LT score, a risk-stratification tool, may enhance pre-transplant cardiac evaluation yet the score has not been validation in LT cohorts in Asia. This study assesses its predictive utility for post-LT cardiac events and survival in a cohort of middle eastern LT recipients. The aim of the study is to to evaluate the association of CAD-LT scores with cardiac complications, mortality, and graft survival in LT recipients. **Methods:** Retrospective analysis of 745 LT adult recipients (2020–2024). Data included demographics, comorbidities, pre/post-transplant cardiac assessments (echocardiography, nuclear stress tests, cardiac catheterization), and CAD-LT scores (stratified as high-, intermediate-, or low-risk). Outcomes included cardiac events (myocardial infarction [MI], arrhythmias, cardiac death), patient survival, and graft survival. Statistical analyses utilized chi-square tests and Kaplan-Meier survival curves. **Results:** The cohort had median age 56.9 years, 62.9% male, with prevalent comorbidities: diabetes (46.9%), hypertension (33.5%), and obesity (33.5%). CAD-LT scores categorized 41.1% as high-risk, 37.7% intermediate-risk, and 20.1% low-risk. High-risk patients exhibited higher cardiac mortality (12/97 deaths, 12.3%) and MI rates (19/97 events, 19.6%) versus low-risk (1.6% mortality, $p < 0.001$) post-LT. Survival analysis revealed high-risk CAD-LT patients had significantly lower 1-year survival (84.1% vs. 41.2% low-risk, $p < 0.001$) post-LT and graft survival (77.1% vs. 41.2%, $p = 0.003$). Non-obstructive cardiac cath findings correlated with better survival (alive: 289/327 vs. obstructive: 30/37, $p = 0.02$). **Conclusion:** This is the first study to validate CAD-LT in Middle Eastern LT recipients. The CAD-LT score effectively stratifies cardiac risk in LT candidates, with high-risk scores strongly associated with post-transplant mortality, graft failure, and cardiac events. Integration of this tool into pre-LT evaluation may guide tailored management, improving outcomes. Further prospective validation is warranted

3489 | AN INCREASE IN REGULATORY B CELLS AND A REDUCTION IN T HELPER 17 CELLS PLAY A CRUCIAL ROLE IN ACHIEVING TOLERANCE IN LIVER TRANSPLANTATION

Soon Kyu Lee[1] Seon-Yeong Lee[1] Ho Joong Choi[1] Young Kyoung You[1] Jeong Won Jang[1] Pil Soo Sung[1] Ji Won Han[1] Mi-La Cho[1] Jong Young Choi[1], [1]College of Medicine, The Catholic University of Korea

Background: This study investigates the dynamics of regulatory B cells (Bregs) during immunosuppression (IS) tapering and their contribution to tolerance in liver

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transplantation (LT) patients. **Methods:** We prospectively enrolled 15 LT patients who had normal liver function, no history of rejection, and had undergone LT more than five years ago. Patients were followed up every three months, and IS doses were tapered by 25% every 6–9 months. At each visit, blood samples were collected, and the proportions of T cells and B cells were analyzed by flow cytometry. Confocal microscopy and in vitro analysis were also performed to assess Breg function in LT patients. **Results:** Over a median follow-up of 42 months, eight patients successfully discontinued IS without rejection (tolerance group). One patient experienced rejection (rejection group), while the remaining six patients reduced their IS dose to 25% without rejection (minimization group). During IS tapering, Treg cells and the Treg/Th17 ratio increased in the tolerance group but decreased before rejection in the rejection group (Figure A). Similarly, the tolerance group exhibited an increase in Bregs and the Breg/Th17 ratio, whereas a decrease was observed in the rejection group (Figure A, B). Moreover, a negative correlation between Bregs and Th17 cells and a significant positive association between Bregs and plasmablast B cells were identified. In liver tissue, confocal analysis showed a significant increase in Tregs and Bregs in the tolerance group compared to the rejection group (Figure C). In vitro analysis demonstrated a reduction in Th17 cells following Breg treatment, and vice versa (Figure D). Furthermore, treatment with *Faecalibacterium*, enriched in the tolerance group, led to an increase in Bregs and IL-10 levels. **Conclusion:** During IS tapering, Bregs increase and contribute to the achievement of tolerance in LT patients. These findings suggest that Bregs may serve as potential biomarkers and therapeutic targets for promoting tolerance in LT.

3490 | CONSEQUENCES OF MELD CUTOFFS AND SCORE TRAJECTORIES IN LIVER TRANSPLANTATION

Tomohiro Tanaka[1] Michael Jones[2] George Wehby[2] David Axelrod[3], [1]University of Iowa School of Medicine, [2]University of Iowa, College of Public Health, [3]University Hospitals

Background: The effects of applying specific MELD score thresholds under the current Acuity Circle (AC) policy, compared to the prior Share-35 (S35) policy, and the consideration of MELD dynamics remain insufficiently examined. This study investigates how MELD-based cutoffs and intra-individual MELD changes and trajectories affect liver transplant (LT) outcomes under current allocation frameworks. **Methods:** We analyzed all adult LT candidates recorded in the OPTN waitlist dataset from January 2016 to Decemer 2023, reformatted into a person-day structure to enable daily event modeling. Candidates who were inactivated on the waitlist or listed as Status 1 were excluded. MELD reflected MELD-Na before July 2023 and MELD 3.0 thereafter, based on the date of the observation. Regression discontinuity was applied at MELD thresholds (35 for S35; 33 and 37 for AC) using pooled logistic regression (PLR) to estimate the causal effect of MELD on transplant offers and completions. Separately, using a 70:30 split into development and validation sets, we constructed PLR models to estimate next-day waitlist death / dropout, defined as death or removal the day after the respective MELD was recorded. Predictors of interest included current MELD, MELD change (absolute ΔMELD), rate of change (ΔMELD/day), and their interactions. Coefficient-based scores reflecting the dynamics of MELD (MELD-DY) were derived using MELD and absolute ΔMELD or ΔMELD/day, with interactions when applicable. **Results:** We evaluated 19,193,222 person-day observations across 63,028 unique patients. Regression discontinuity models revealed that, during the S35 era, the MELD threshold of 35 was associated with marked increases in both offer and transplant rates (RR 2.40; 95% CI: 2.25–2.56 and OR 2.15; 95% CI: 1.83–2.53). In contrast, the AC thresholds showed more modest effects at MELD 33 (RR 1.29; 1.21–1.38 and OR 1.15; 0.92–1.44) and MELD 37 (RR 1.25; 1.10–1.42 and OR 1.38; 1.14–1.67). Absolute ΔMELD was associated with reduced waitlist mortality among patients with lower MELD scores (<28), but with increased mortality in those with higher MELD scores. This crossover was driven by a significant interaction between MELD and ΔMELD ($p < 0.001$). ΔMELD/day was associated with higher waitlist mortality (OR 1.23; 1.21-1.27). In the validation cohort of 1,734 decedents, 211 (12.1%) were reclassified to higher priority with MELD-DY scores

derived from ΔMELD/day compared to the original MELD (Figure), although the concordance index did not differ significantly (0.784 vs. 0.781; p = 0.38). **Conclusion:** MELD thresholds continue to pose challenges to seamless score-based allocation under the Acuity Circle policy. MELD dynamics are significantly associated with waitlist mortality and may enhance future allocation models. Together, these findings highlight the need to move beyond fixed cutoffs toward more continuous, trajectory-informed approaches to MELD-based allocation.

$$MELD_DY = round\left(MELD + 1.20 * \frac{absolute\ \Delta MELD}{Days\ since\ last\ recorded\ MELD}\right)$$

3491 | ILEAL BILE ACID TRANSPORTER INHIBITORS FOR REFRACTORY PRURITUS IN LIVER TRANSPLANT RECIPIENTS: A CASE SERIES

Mary Chandran[1] Shaurya Prakash[2] Neil Shah[2],
[1]University of North Carolina Health, [2]University of North Carolina at Chapel Hill

Background: Persistent pruritus after liver transplantation (LT) can significantly impact quality of life and is often linked to biliary complications. Standard treatments may be ineffective. Ileal bile acid transporter (IBAT) inhibitors, such as odevixibat and maralixibat, have demonstrated efficacy in treating cholestatic pruritus in other contexts but remain underexplored in the post-LT setting. **Methods:** We present three liver transplant recipients with persistent, treatment-resistant pruritus who were treated with IBAT inhibitors. Clinical response, tolerability, and impact on immunosuppression levels were assessed. **Results:** Case 1: A 56-year-old male living donor LT recipient developed persistent pruritus six weeks post-transplant due to biliary strictures requiring repeated endoscopic retrograde cholangiopancreatographies (ERCPs) and stenting. Pruritus persisted despite standard treatments. Odevixibat 3600 mcg daily was initiated nine months post-LT, leading to significant symptom improvement. Early diarrhea resolved within days. Pruritus remained controlled until acute rejection and recurrent biliary complications caused transient recurrence. Symptoms remained manageable on odevixibat. Tacrolimus levels remained stable and in goal on IBAT therapy.
Case 2: A 49-year-old female living donor LT recipient developed pruritus three weeks post-LT, coinciding with a bile leak and biliary stricture requiring ERCP and stenting. Symptoms persisted despite standard treatments. Odevixibat 3600 mcg daily was initiated 10 months post-LT, resulting in near-complete pruritus resolution. Six weeks later, she was hospitalized for diarrhea of unclear etiology, but symptoms improved without stopping IBAT therapy. Immunosuppression levels remained stable, and pruritus control persisted.
Case 3: A 31-year-old female deceased donor LT recipient, transplanted at 22 months old, developed pruritus 27 years post-LT during pregnancy. Symptoms continued postpartum despite standard treatments. Maralixibat 28.5 mg daily was started 29 years post-LT, leading to significant improvement, with itching reduced to 1–2 days per week. She continued hydroxyzine and doxepin as needed but reports improved quality of life. Tacrolimus levels remained stable without dose adjustment. **Conclusion:** IBAT inhibitors may represent a safe and effective option for managing refractory pruritus in liver transplant recipients, with potential benefits extending beyond symptom control to meaningful improvements in quality of life. Importantly, these agents were well-tolerated and did not disrupt immunosuppressive regimens or graft function. Given the significant burden of post-LT pruritus and the limited efficacy of existing treatments, further prospective studies are warranted to evaluate long-term safety, efficacy, and optimal clinical use of IBAT inhibitors in this population.

3492 | SEX MISMATCH AND BODY SIZE MISMATCH IN DECEASED DONOR LIVER TRANSPLANTATION IN THE UNITED STATES: MISMATCHING IS ASSOCIATED WITH WORSE OUTCOMES

Nolberto Jaramillo[1] Bryan Cabrera Valdes[1] Maria Mosquera[1] Ryosuke Misawa[1] Seigo Nishida[1] Kenji Okumura[1], [1]Westchester Medical Center

Background: Sex-based differences exist not only in waitlist but also in post-transplant outcomes. Sex mismatch may be associated with increased mortality in heart transplantation, however, this remains unknown in liver transplantation (LT). The aim of this study is to assess sex mismatch in LT recipients in a nationwide cohort. **Methods:** Adult deceased donor LT recipients between January 2004 and December 2023 in the UNOS database were included in this study. Multi-organ transplant and re-transplant cases were excluded. Body surface area index (BSAi), defined as the ratio of donor BSA to recipient BSA, was used to categorize the size match (small-for-size: BSAi < 0.78; normal-for-size BSAi 0.78-1.24; large-for-size BSAi > 1.24). **Results:** A total of 124,192 recipients (sex match: female recipient F-F N = 20,155 and male recipient M-M N = 52,709; sex mismatch: female recipient F-M N = 21,472 and male recipient M-F N = 29,856) were identified during the study period. Small-for-size grafts were seen more in the female to male group (18%) and large-for-size grafts were seen more in the male to female group (15%) ($P < 0.001$).

Unadjusted analysis showed that male recipients of female grafts had an increased risk of 5-year graft failure (hazard ratio [HR]: 1.08; 95% confidence interval [CI]: 1.05, 1.12; $P < 0.001$) and 1-year graft failure (HR: 1.13; 95% CI: 1.08, 1.18; $P < 0.001$) compared to male recipients of male grafts. Multivariable Cox regression analysis showed that sex mismatch was associated with 5-year graft failure (HR: 1.04; 95% CI: 1.01-1.06; $P = 0.007$) and 1-year graft failure (HR: 1.05; 95% CI: 1.01-1.09; $P = 0.008$). In the F-F group, small-for-size and large-for-size were associated with graft failure and mortality. In M-M and M-F groups, small-for-size was associated with 1-year graft failure and mortality but not large-for-size. In F-M, large-for-size was associated with 1-year graft failure and mortality but not small-for-size.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Conclusion: Sex mismatching is associated with post-transplant mortality and graft failure. In addition to sex matching, body size mismatch was also associated with post-transplant mortality and graft failure.

3493 | SINGLE CELL RNA-SEQUENCING REVEALS IMMUNOMODULATORY ROLE OF HEPATIC CXCL12+ KUPFFER CELLS IN TREG-MEDIATED LIVER GRAFT TOLERANCE THROUGH CXCR4 AXIS

Yurong Luo[1] Jinzhen Cai[1], [1]The Affiliated Hospital of Qingdao University

Background: Acute rejection after liver transplantation involves the participation and interaction of various immune cells. Kupffer cells (KCs) regulate the inflammatory and immune environment in the graft region by secreting multiple chemokines and cytokines. CXCL12 (SDF-1) and its receptor CXCR4 play key roles in immune cell migration, activation, and regulation, with their significance in liver transplantation gaining increasing attention. **Methods:** Single-cell sequencing and mIHC were used to analyze clinical samples from patients with mild, severe and chronic rejection, as well as liver transplant model samples from mice at different stages of rejection. C57BL/6 to C3H acute rejection model was established. At 1, 2, 3, and 4 weeks post-transplant, FMC, H&E staining, and IHC were used to assess surface markers and functional changes in KC subsets. Macrophage and Treg subsets in the liver, spleen, lymph nodes, bone marrow, and peripheral blood were also monitored. In vitro, primary human and mouse KCs and $CD4^+$ T cells were isolated, and a co-culture system was established by KC transfection. Enrichment analysis and WB were performed to investigate underlying signaling pathways. **Results:** This study analyzed macrophage heterogeneity and gene expression, identifying five distinct KC subsets, with $CXCL12^+$ KCs gene expression, identifying five distinct KC subsets, with $CXCL12^+$ KCs primarily located in Cluster C1. We revealed interactions and functional differences between human and mouse KC subsets and Tregs during liver transplant rejection, with a notable activation of the NF-κB signaling pathway. Further analysis indicated that ligand-receptor signaling between $CXCL12^+$ KCs and Tregs significantly increased during rejection. $CXCL12^+$ KCs likely play a crucial role throughout the rejection process, especially during acute and chronic phases. In early acute rejection, $CXCL12^+$ KCs were highly adjacent to $CXCR4^+$ Tregs, suggesting potential immunoregulatory interactions. Experimental validation showed dynamic immune cell changes, with $CXCL12^+$ KCs and $CXCR4^+$ Tregs significantly colocalizing in early acute rejection. Additionally, we explored the role of immune cell dynamics in liver transplant tolerance. In vitro, CXCL12 enhanced KC regulation of Treg proliferation via NF-κB pathway activation, providing a novel therapeutic target for immune tolerance and regulation in liver transplant rejection. **Conclusion:** This study found that the expression specificity of CXCL12 was increased in KCs during acute liver rejection, and the ligand receptor signaling between CXCL12+Kupffer cells and CXCR4 +Treg was significantly enhanced. CXCL12 activated the NF-κB signaling pathway in KCs, thereby promoting Treg cell activation and enhancing immune tolerance, providing a possible new target for clinical treatment.

3494 | SEVERE ACTIGRAPHY-MEASURED SLEEP DYSFUNCTION IS ASSOCIATED WITH DISEASE SEVERITY AND POOR QUALITY OF LIFE IN ADVANCED CHRONIC LIVER DISEASE: UK PROSPECTIVE CASE-CONTROL STUDY

Felicity Williams[1] Jonathan Quinlan[2] Amritpal Dhaliwal[3] Leigh Breen[1] Carolyn Greig[1] Ahmed Elsharkawy[3] Thomas Marjot[4] Alex Rowlands[5] Janet Lord[1] Matthew Armstrong[3], [1]University of Birmingham, [2]University of Birmingham, UK, [3]University Hospitals Birmingham NHS Foundation Trust, [4]University of Oxford, [5]University of Leicester

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Prevalence of patient-reported sleep disturbance is high in advanced chronic liver disease (AdvCLD), but objective, home-based evidence is lacking. To effectively treat sleep disturbance in AdvCLD, a thorough understanding of variability (vs other disease populations), predictors and impact of sleep disturbance is needed. Using wrist-worn actigraphy, we aimed to investigate (a) sleep indices in AdvCLD compared to healthy controls (HC) and chronic inflammatory disease (CID; inflammatory bowel or arthritis), (b) predictors of poor sleep and (c) the impact on quality of life (QoL). **Methods:** Outpatients with AdvCLD awaiting liver transplant, in parallel to age/sex matched CID and HC were recruited from Birmingham, UK. All wore a GENEActivâ wrist accelerometer for 14-days at home. Clinical characteristics, disease severity (UKELD), and quality of life (QoL) (Chronic liver disease questionnaire [CLDQ]) were recorded. Sleep window, sleep onset, the midpoint of sleep, sleep duration (excluding any waking periods during the sleep window) and sleep efficiency were calculated for each valid day and averaged across all valid days. **Results:** 44 AdvCLD (63% male, mean age 54, UKELD 52, 50% ArLD), 13 CID (46% male, age 45) and 17 HC (59% male, age 47) participants were recruited. The AdvCLD group had a later sleep onset (mean[standard deviation (SD)] 00:01[1.76] vs 22:56[0.84hrs], $p = 0.02$, 95% CI -2.01 to -0.17hrs) and midpoint (03:55[1.73] vs 03:01 [0.81], $p = 0.02$), shorter sleep duration (5.99hrs[1.34] vs 6.95hrs[0.88], $p = 0.01$, 95% CI 0.23 to 1.68hrs) and lower sleep efficiency (77.8%[7.35] vs 85.4%[9.06], $p = < 0.001$) compared to HC (Fig. 1A&C). Additionally, sleep duration (5.99hrs[1.34] vs 6.95hrs[0.92], $p = < 0.001$ 95% CI 2.81 to 11.9hrs) and efficiency (77.8%[7.35] vs 84.8%[6.5], $p = 0.02$ 95% CI 0.17 to 1.76%) were significantly less compared to those with CID (Fig. 1B&D). Worse sleep efficiency was associated with increased fatigue and reduced emotional function ($r = 0.37$ $p = 0.02$; $r = 0.37$, $p = 0.03$, respectively). UKELD independently predicted sleep duration ($B = -1.58$, $p = 0.02$). Longitudinal assessment ($n = 13$) showed liver transplant for AdvCLD improved sleep window and sleep duration (7.2hrs[1.4] vs 8.8hrs[1.9], $p = 0.003$, 95% CI 0.66-2.53hrs; 5.5hrs[0.9] vs 6.9hrs [1.5], $p = 0.003$ 95% CI 0.58-2.17hrs, respectively). **Conclusion:** Patients with AdvCLD have significantly worse actigraphy-measured sleep disturbances (onset, duration, efficiency) compared to healthy individuals and patients with other chronic inflammatory conditions. Sleep disturbance was independently predicted by disease severity, and negatively associated with QoL measures, but improved with liver transplant. Tailored sleep interventions in AdvCLD are required to enhance patient QoL, with particular focus on those patients with severe disease.

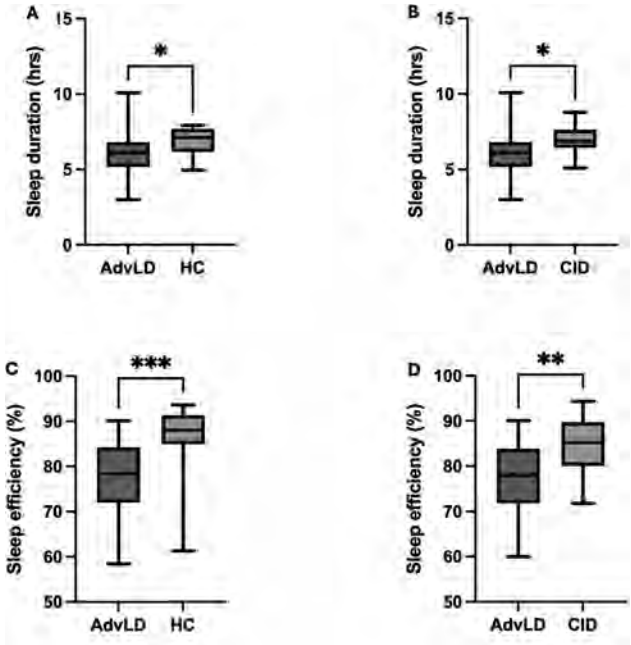

Figure 1. Comparison of sleep duration and efficiency between patients with advanced chronic liver disease (AdvLD), healthy controls (HC), and chronic inflammatory disease (CID)

A: Comparison of sleep duration between AdvLD and HC

B: Comparison of sleep duration between AdvLD and CID

C: Comparison of sleep efficiency between AdvLD and HC

D: Comparison of sleep efficiency between AdvLD and CID

3495 | SUPERIOR BIOAVAILABILITY OF TACROLIMUS IN LIVER TRANSPLANT RECIPIENTS TREATED WITH EXTENDED-RELEASE LCP-TACROLIMUS (ENVARSUS) COMPARED TO PROLONGED-RELEASE TACROLIMUS (ADVAGRAF) AFTER 12 WEEKS OF CONTROLLED THERAPY WITHIN A MULTICENTRE, RANDOMISED, CONTROLLED CLINICAL TRIAL ("ENGRAFT")

Hans Schlitt[1] Ben James[2] Ines Holub-Hayles[2] Edward Geissler[2] The Germany EnGraft Study Group[3], [1]Surgery, Univ. Hosp. Regensburg, [2]Univ. Hosp. Regensburg, Germany, [3]Germany

Background: Oral tacrolimus formulations exhibit low and variable bioavailability, leading to high dose requirements and dose-dependent toxicities. Our clinical trial in liver transplant recipients tests if extended-release LCP tacrolimus (LCPT, administered as Envarsus®) improves systemic tacrolimus exposure per milligram of drug versus prolonged-release tacrolimus (PR-Tac, administered as Advagraf™); potential pharmacokinetic and clinical outcome advantages are also explored. **Methods:** Between December 2020 and October 2023, the planned 268 liver transplant recipients were enrolled at 15 German sites in a phase IV, investigator-initiated trial sponsored by the University Hospital Regensburg ("EnGraft"; EUCT: 2024-518033-28-00) and funded in part by Chiesi GmbH. Participants were randomised 1:1 within 14 days post-transplant to a standard immunosuppressive regimen containing either once-daily LCPT (test) or once-daily PR-Tac (comparator). After a 12-week *Controlled Treatment Phase*, blood tacrolimus trough levels were centrally measured to mitigate bias and the dose-normalised trough concentration (C/D ratio) was calculated as an estimate of drug bioavailability (primary endpoint; two-sided $\alpha = 0.05$; 90% power to show a difference of 0.4 ng/ml mg^{-1} in C/D ratio). Clinical parameters are being collected during a 3-year *Follow-up Phase* to explore whether a superior C/D ratio confers longer-term benefits. **Results:** The *Controlled Treatment Phase* was completed in 2024 and analysed in 2025. In 243 (90.7%) patients producing primary endpoint data, a highly statistically significant difference between the mean C/D ratio measured in the LCPT arm (1.80 ng/ml mg^{-1}) and the PR-Tac arm (1.13 ng/ml mg^{-1}; $p < 0.0001$, ANCOVA) was characterised by similar mean blood trough levels across both groups (7.6 mg/ml LCPT; 7.3 mg/ml PR-Tac), but an appreciably lower mean daily dose in the LCPT arm (5.7 mg/day LCPT; 8.1 mg/day PR-Tac). Rates of biopsy-proven rejection (2.3% LCPT; 4.5% PR-Tac) and *de novo* tremor (18.2% LCPT; 21.8% PR-Tac) were not substantially different. Kidney function at 12 weeks shows a similar decreasing trend. The 3-year *Follow-up Phase* is currently ongoing. **Conclusion:** For the first time in liver transplantation, superior bioavailability of LCPT has been unequivocally demonstrated in a large, multicentre, prospective study statistically powered to test the C/D ratio as a primary endpoint. After the last study visit in October 2026, the final analysis will reconcile drug pharmacokinetics with long-term efficacy and safety data.

3496 | CLOSING THE GAP: THE IMPACT OF A CULTURALLY AND LINGUISTICALLY TAILORED LIVER TRANSPLANT PROGRAM

Luis Lopez[1] Gonzalo Hagerman-Sucar[2] Juan Caicedo-Ramirez[3], [1]Northwestern Univeristy Feinberg School of Medicine, [2]Universidad Panamericana School of Medicine, Mexico City, Mexico, [3]Lurie Children's Hospital

Background: Hispanic patients represent the largest minority group on the liver transplantation (LT) waiting list. The Hispanic Transplant Program (HTP) at Northwestern Memorial Hospital (NMH) was created in 2006 to provide culturally and linguistically competent and congruent care to remove barriers to kidney transplantation. This program led to a 91% increase in waiting list additions and a 74% and 62% increase in living donor kidney transplants (LDKT) and deceased donor kidney transplants (DDKT), respectively. The mean annual ratio of Hispanics to Non-Hispanic Whites (NHW) increased by 70% in LDKT and 43.8% in DDKT, suggesting a significant reduction in disparities between Hispanics and NHW. In 2010, the program expanded to include liver transplantation services, forming the Hispanic Liver Transplant Program (HLTP). The HTP was adapted from an English-only program that incorporates Spanish in all patient-facing materials, employs a bilingual and bicultural staff, and addresses deep seated cultural values for Hispanic transplant candidates. No resources were diverted from the English-speaking program towards the HTP. **Methods:** Program-specific data from the OPTN center data for NMH as of 11/30/2024, were used to assess changes in transplant program characteristics before (1999-2009) and after (2011-2021) HLTP implementation. Data collection included the number of waiting list additions, living donor liver transplants (LDLTs), and deceased donor liver transplants (DDLTs) for both Hispanics and NHWs. The percent change of LDLTs and DDLTs between the pre-HLTP period and post-HLTP period was calculated. The mean annual ratio of Hispanic to NHW patients was calculated for LDLTs and DDLTs using the formula ([Hispanic LDLT / All LDLT] / [NHW LDLT / All LDLT]) to evaluate disparities in transplant access. Unpaired t-tests were performed to compare differences in the mean annual ratios between the two time periods. **Results:** During the post-HLTP period, Hispanic waiting list additions rose by

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

69%, LDLTs by 89%, and DDLTs by 99%. The mean annual ratio for Hispanic to NHWs increased by 13% (pre-HLTP: 0.15; post-HLTP: 0.16; $p = 0.85$). The DDLT ratio rose significantly by 85% (pre-HLTP: 0.11; post-HLTP: 0.21; $p < 0.001$). Among NHWs, waiting list additions decreased by 24%, LDLTs by 12%, while DDLTs increased by 14%. **Conclusion:** Culturally competent programs can offer a scalable strategy to increase access to LT among Hispanic patients. The number of Hispanic patients added to the waiting list, LDLTs, and DDLTs increased in the post-transplant period, suggesting that the HTP potentially contributed to increased awareness, subsequent access, and acceptance of LT services. Since the establishment of the HTP, new centers have taken the initiative to implement this model of transplant care into their own programs. The center-level and national-level impact of these programs should be assessed in future studies.

	NHW			Hispanic			Mean Ratio (SD)			
	Pre HLTP (1999-2009)	Post HLTP (2011-2021)	% Change	Pre-HLTP (1999-2009)	Post-HLTP (2011-2021)	% Change	Pre HLTP (1999-2009)	Post HLTP (2011-2021)	% Change	p-value
Waiting List Additions	1495	1129	-24	145	248	69	-	-	-	-
LDLT	114	100	-12	9	17	89	0.15 (.28)	0.16 (.16)	13	0.85

3497 | A STEPWISE INSTITUTIONAL PROGRESSION TO TOTAL ROBOTIC LIVER TRANSPLANTATION: FIRST U.S. EXPERIENCE USING BOTH DECEASED AND LIVING DONOR GRAFTS

Nishtha Singh[1] Juan Rocca[1] Erin Duggan[1] Carolyn Waite[1] Peter Liou[2] Dustin Carpenter[1] Rebecca Craig-Schapiro[1] Benjamin Samstein[1], [1]Weill Cornell Medicine, [2]Columbia University Irving Medical Center

Background: Robotic liver transplantation (RLT) remains a technical frontier in minimally invasive liver surgery, with only a handful of programs worldwide having completed total robotic liver transplantation (TRLT). We report the stepwise progression of our New York-based program culminating in three consecutive TRLTs in April–May 2025, becoming the first U.S. center to perform TRLT using both deceased and living donor grafts. **Methods:** We retrospectively reviewed nine RLT cases performed between 2023 and 2025, evaluating recipient and donor selection, graft type, surgical technique for hepatectomy and implantation, incision approach, intraoperative conversions, anastomotic times, blood loss, reoperations, and transplant outcomes. **Results:** The first three cases employed a hybrid approach: robotic native hepatectomy with open implantation of partial grafts from laparoscopic living donor hepatectomy. During our transition to robotic donor hepatectomy (RDH), logistical limitations in robotic team availability redirected our TRLT efforts toward whole grafts from deceased donors. Of five such cases, three required conversion, while the last two were completed entirely robotically. After this experience, and once we were able to run two simultaneous robotic teams, we successfully performed a TRLT using a right lobe graft fully recovered robotically from a living donor. Indications and outcomes were consistent with accepted transplant standards (Table 1). Technical refinements included a left-to-right piggyback hepatectomy, partial caval clamping for side-to-side cavocavostomy, omission of venovenous bypass, and Pfannenstiel incision with hand assistance. Prior U.S. reports described TRLT using only deceased donors (Washington University) or only living donors (Virginia Commonwealth University), but not both. **Conclusion:** To our knowledge, we are the first program in the United States to complete TRLT using both deceased-donor and living-donor grafts. Our stepwise progression and cumulative experience confirm the feasibility and reproducibility of a technically simplified approach adapted from prior reports and our own institutional refinement. This evolution underscores the importance of strategic program development, dual-robotic team capability, and progressive case complexity—laying the foundation for broader, safe adoption of TRLT in centers with advanced minimally invasive liver surgery expertise.

3498 | SUBJECTIVE SLEEP DISTURBANCE, OBJECTIVE SLEEP QUALITY, AND PATIENT REPORTED QUALITY OF LIFE: INTERIM RESULTS: FROM THE MULTI-CENTER LIVCOG COHORT STUDY

Anna Gurian[1] Oluomachukwu Anaenugwu[1] Jacqueline Theroux[1] Minjee Kim[2] Lauren Cogar[2] Nianfu Song[1] Julia Yoshino Benavente[2] Sumeet Asrani[3] Michael Wolf[2] Douglas Schaubel[1] Marina Serper[4], [1]Perelman School of Medicine, University of Pennsylvania, [2]Feinberg School of Medicine, Northwestern University, [3]Baylor University Medical Center, [4]University of Pennsylvania Health System

Background: Subjective poor sleep is common among liver transplant recipients (LTRs). Further study of relationships between objective sleep measures, reported sleep-quality, and quality of life (QoL) measures is needed. **Methods:** This is an interim analysis of the prospective NIDDK-funded LivCog cohort study, which investigates LTR cognition, QoL,

health behaviors, and outcomes. At 3-, 12- and 24-months post-LT participants wore a wrist Actigraph (ActiGraph GT3X-BT) for 8 consecutive days to measure time in bed, sleep duration, and sleep efficiency (percent time spent sleeping while in bed). Indicator variables for sleep quality were created for short sleep duration (<6h), poor sleep efficiency (<80%), and late sleep timing (sleep midpoint after 4:00am). Patient reported QoL measures include PROMIS Depression, Anxiety, Pain, Fatigue, Social Isolation, and Sleep Disturbance (T-Score >55). We modeled each QoL measure using the generalized estimating equations (GEE) version of logistic regression, adjusted for age, sex, liver disease diagnosis, pre-transplant hepatic encephalopathy (HE), and month of follow-up. **Results:** Among n = 174 LTRs, median age is 55 (IQR 50-63); 84.3% are white; 63.95% are male; 25.6% had alcohol associated liver disease (ALD); 20.1% had MASLD/MASH;16.3% had hepatocellular carcinoma (HCC); and 50.58% had pre-LT HE. At 3 months post-LT, 32.6% reported subjective sleep disturbance, and Actigraphy data showed that 39.5% had short sleep duration; 21.5% had poor sleep efficiency; and 26.7% had late sleep timing. Pre-transplant HE (OR = 3.30 95%CI: 1.45, 7.71) and short sleep duration were significantly associated with subjective sleep disturbance (OR = 2.74; 95%CI: 1.18, 6.40). Poor sleep efficiency was significantly associated with anxiety (OR = 3.10; 95%CI: 1.18, 8.84); late sleep timing was significantly associated with fatigue (OR = 2.29; 95%CI: 1.04, 5.08), social isolation (OR = 2.99; 95%CI: 1.20, 7.47), and subjective sleep disturbance (OR = 2.89; 95%CI: 1.31, 6.35). Additionally, subjective sleep disturbance was predictive of anxiety (OR = 3.81; 95%CI: 1.73, 8.39), pain (OR = 2.50; 95%cI: 1.16, 5.39), and fatigue (OR = 3.07; 95%CI: 1.39, 6.80). **Conclusion:** Both actigraphy collected sleep data and patient reported sleep disturbance are associated with poorer patient reported QoL measures. Pre-transplant HE is associated with subjective sleep disturbance.

Table 1. Covariate-adjusted odd ratios (OR). PROMIS score indicator is the outcome (separate models) and sleep quality indicator is the exposure of primary interest.

	PROMIS Score (>55) Domain					
Impaired sleep Quality Indicator	Depression	Anxiety	Pain	Fatigue	Social Isolation	Sleep Disturbance
Total sleep <6 hours	0.64	1.38	1.08	0.77	0.94	2.74*
Sleep efficiency <80%	2.07	3.10*	0.81	1.27	1.22	0.85
Sleep mid-point after 4:00 a.m.	1.00	1.36	1.32	2.29*	2.99*	2.89*
PROMIS T-score >55 Sleep disturbance	2.06	3.81*	2.50*	3.07*	2.14	n/a

*Statistically significant (p<0.05); higher PROMIS scores=worse symptoms

3499 | GEOGRAPHIC DISTANCE AND IMMUNOSUPPRESSIVE ADHERENCE IN LIVER TRANSPLANT PATIENTS

Daniel Gryzlo[1] Irene Helenowski[2] Jonah Rubin[1],
[1]Loyola University Medical Center, [2]Stritch School of Medicine, Loyola University Chicago

Background: Geographic and rural-urban disparities are known to impact health outcomes, but remain understudied in adult liver transplant populations. Our transplant center has outreach clinics extending up to 160 miles from the main hospital. We aim to evaluate the impact of distance from our transplant center on medication adherence and clinical outcomes. **Methods:** We conducted a single-center, retrospective cohort study of adult liver transplant recipients (greater than 18 years) who underwent transplant at Loyola University Medical Center from 09/2012-05/2023. Inclusion required ≥ 3 tacrolimus trough levels between 1–6 years post-transplant with exclusion of levels drawn after biopsy-confirmed rejection. We measured the Medication Level Variability Index (MLVI) which is the standard deviation of Tacrolimus troughs to determine adherence. Demographics, SIPAT, and Charlson and Elixhauser comorbidity indexes were collected. Distance and drive time were calculated via Google Maps from home Zip Code to transplant center. The primary outcome was non-adherence as defined by an MLVI >2.0. Secondary outcomes included death and re-transplantation. Multivariable logistic regression was used to assess associations between distance from transplant center and outcomes. **Results:** Of the 365 patients included, 246 (67.4%) were male. The mean age at transplant was 58.16 years with a mean MELD of 25.44 at transplant. The range of distances was from 1.4 miles up to 366 miles. Of the patients, 176 lived less than 25 miles, 88 lived 25 to 50 miles, 57 lived 50 to 100 miles, and 44 lived greater than 100 miles from the center. Patients living <25 miles from the center were older and with higher Charlson (p = 0.024) and Elixhauser (p = 0.002) comorbidity indices. Multivariable logistic regression showed those living 25-50 miles away had significantly lower odds of non-adherence (OR 0.44, 95% CI 0.20-0.94, p = 0.038) compared to those within 25 miles. Otherwise there was no significant differences in adherence at other distances. There was no difference in mortality based on distance. **Conclusion:** In this cohort of liver transplant recipients, geographic distance from the transplant center was not associated with worse immunosuppressive adherence. Although comorbidities differed

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

significantly, they did not affect outcomes with our analyses. Interestingly, patients living 25 to 50 miles away had significantly better adherence, but the significance is unclear. These findings suggest that factors beyond proximity influence adherence and mortality.

3500 | TEMPORAL TRENDS IN LIVER TRANSPLANTATION IN THE UNITED STATES (2016-2022) : A NATIONWIDE ANALYSIS OF PROCEDURAL VOLUME, MORTALITY, AND HEALTHCARE COSTS

Yordanos Tafesse[1] Bekure Siraw[2] Parth Patel[2] Ashok Kumar[2] Ebram Said[2], [1]Ascension Saint Joseph Hospital - Chicago, [2]Ascension Saint Joseph Hospital

Background: Liver transplantation remains a definitive treatment for end-stage liver disease and select hepatic malignancies. Understanding national trends in liver transplant volumes, outcomes, and healthcare utilization is essential for optimizing resource allocation and guiding future health policy. We aimed to evaluate recent trends in liver transplantation in the United States, focusing on transplant volume, in-hospital mortality, and inflation-adjusted hospitalization costs. **Methods:** In this descriptive study, we analyzed data from the National Inpatient Sample (NIS) from 2016 to 2022. We included adult patients who underwent liver transplantation, identified using ICD-10 Procedure Coding System (PCS) codes. We assessed quarterly trends in three key outcomes: number of liver transplants performed, in-hospital mortality rates, and the median cost of hospitalization (adjusted to 2022 USD using the average quarterly Consumer Price Index data from the U.S. Bureau of Labor Statistics). **Results:** A total of 49,223 liver transplant-related hospitalizations were identified between 2016 and 2022. The mean age of the cohort was 52.3 years (standard deviation [SD]: 16.2), with a predominance of male patients (62.6%). The racial and ethnic distribution comprised 66.7% White, 8.1% Black, and 16.4% Hispanic individuals. The vast majority of procedures (95.4%) were performed at urban teaching hospitals. The annual volume of liver transplants demonstrated an overall upward trajectory, increasing from 5,879 in 2016 to 7,987 in 2022. A transient decline was noted in 2020, likely attributable to the disruptions associated with the COVID-19 pandemic. Despite the rising procedural volume, the overall in-hospital mortality rate remained stable throughout the study period, with a mean mortality rate of 2.9%. The median hospitalization cost, adjusted for inflation, showed a gradual increase over time. Specifically, the median annual cost rose from $136,761 in 2016 to $145,261 in 2022, reflecting a modest upward trend in resource utilization. **Conclusion:** From 2016 to 2022, the volume of liver transplants in the United States increased substantially, while in-hospital mortality rates remained stable. The consistent mortality rate despite increased transplant volume may reflect improvements in perioperative care and patient selection. However, rising hospitalization costs highlight the need for continued evaluation of cost-efficiency in liver transplant care.

3501 | METTL3-MEDIATED M6A MODIFICATION PROMOTES ACTIVATION OF CD8+T CELLS THROUGH UP-REGULATING AUTOPHAGY IN ACUTE REJECTION AFTER LIVER TRANSPLANTATION

Xiaolong Chen[1] Wenfeng Zhu[2] Xuejiao Li[3], [1]The First Affiliated Hospital of Jinan Universirty, [2]The Second Affiliated Hospital of Guangzhou Medical University, [3]The Third Affiliated Hospital of Sun Yat-sen University

Background: Previous studies and ours have demonstrated the critical role of CD8+T cells in acute rejection (AR) after liver transplantation (LT). m6A RNA modification has been reported to be involved in the regulation of immune cell function and survival recently. However, its role in AR remains to be elucidated. **Methods:** m6A RNA modification levels in activated T cells were assessed in liver grafts from AR patients after LT. Rat acute hepatic rejection model and one-way mixed lymphocyte reaction model were then established to confirm the methylation levels of CD8+T cells. Moreover, changes of RNA in activated CD8+T cells were examined and MeRIP-seq was conducted to identify the specific targets of methyltransferases. Furthermore, underlying mechanisms of methylation in the regulation of function and survival CD8+T cells were explored. **Results:** m^6A RNA levels in CD8+T cells were elevated in both AR patients and rats after liver transplantation. METTL3 was confirmed to mediate m^6A RNA modification of activated CD8+T cells in vitro, which promoted their activation. RNA sequencing results indicated that the autophagy related signaling plays an important role in allo-antigen triggered activation of CD8+T cells. ATG12 was determined as the direct target of METTL3 through MeRIP-qPCR. Mechanistically, METTL3 enhances autophagy of T cells by up-regulating Atg12 expression through IGF2BP2 recognized stabilizing of Atg12 mRNA, resulting in promotion of T cell survival, proliferation and function. **Conclusion:** METTL3-mediated m^6A modification promotes activation of CD8+T cells through up-regulating autophagy in acute rejection after liver transplantation, thereby offering a theoretical foundation for identifying novel therapeutic targets for the prevention and treatment of AR following liver transplantation.

3503 | LIVER TRANSPLANTATION IN THE SETTING OF PRE-OPERATIVE ACUTE PANCREATITIS: IS DELAY JUSTIFIED?

Niwen Kong[1] Nikki Duong[1] Amir Hossein Gougol[1], [1]Stanford University

Background: Acute pancreatitis (AP) triggers both local and systemic inflammatory responses, increasing the risk of surgical interventions due to potential complications such as bleeding, infection, and abdominal compartment syndrome. Consequently, there is a general consensus to postpone surgical procedures—including liver transplantation (LT)—during necrotizing AP. However, the safety of early surgical intervention in patients with mild AP remains unclear. Furthermore, in liver transplant candidates presenting with acute liver failure or acute-on-chronic liver failure, delaying in LT is associated with a higher risk of mortality. We aim to assess the safety of LT in patients identified with mild AP in peri-operative period. **Methods:** We conducted a retrospective study in patients who underwent LT between 1/2015 and 4/2024 at Stanford University Hospital. Peri-transplant pancreatitis was defined as acute pancreatitis, identified via ICD-10 code, occurring within 30 days before or 7 days after transplantation. The primary outcome was the need for re-transplantation between 30 days and 1 year from index liver transplantation. Secondary outcomes included hospital and intensive care unit (ICU) length of stay, dialysis requirement within 30 days, readmission within 30 days and 6 months. Propensity score matching was employed to minimize the impact of confounding variables. **Results:** A total of 738 patients underwent LT during the study period. Among them, 29 patients (3.9%) had peri-transplant AP. Patients with AP were younger (mean age 50.1 vs. 55.6 years), higher proportion of males (82.8% vs. 64.6%), and had higher rates of pre-transplant renal dysfunction (62.1% vs. 48.1%). They also had higher baseline bilirubin levels (8.6 ± 8.5 vs. 5.5 ± 7.0 mg/dL), MELD scores (27.4 ± 12 vs. 18.7 ± 11.5), and MELD-Na scores (28.8 ± 12.4 vs. 19.3 ± 12.8).

Overall, the rate of organ failure requiring re-transplantation was low with no significant difference between the two groups; one patient in the AP group and three patients in the non-AP group ($p = 0.148$). After propensity score matching, no statistically significant differences were found between the groups for ICU length of stay, hospital length of stay, dialysis requirement, or 30-day and 6-month readmissions. **Conclusion:** Peri-transplant AP did not deteriorate post-operative outcomes in patients undergoing LT. Randomized clinical trials are warranted to determine safety of liver transplant in patients with peri-

3504 | ARRB2 IN HEPATOCYTES PROMOTE M2 MACROPHAGE POLARIZATION AMELIORATES HEPATIC ISCHEMIA-REPERFUSION INJURY THROUGH UPREGULATING METABOLITE 6-KETOLCA

genshu wang[1] qiwei yang[1] Tao Huang[1] Xiaowen Wang[2], [1]Guangdong Provincial Hospital of Chinese Medicine, [2]The Third Affiliated Hospital of Sun Yat-sen University

Background: Hepatic ischemia-reperfusion injury (IRI) is an important factor affecting the prognosis of liver transplantation patients. The role of Arrb2 in liver injury is unclear. Our study aimed to determine the role of Arrb2 in hepatic IRI and to identify its underlying mechanisms. **Methods:** An analysis of clinical samples was conducted to assess the association between Arrb2 expression and prognosis of liver transplantation; A 70% hepatic ischemia/reperfusion model in mice was established to verify the mechanism of Arrb2 in hepatocytes promoting M2 macrophage polarization in attenuating hepatic IRI by regulating 6-ketoLCA; A model of hypoxia/reoxygenation in vitro was established to investigate the molecular mechanism of 6-ketoLCA in promoting M2 macrophage polarization and pharmacological screening. **Results:** Arrb2 in hepatocytes has been shown to provide significant liver protection against hepatic IRI, primarily through promoting the polarization of liver macrophages to M2; Arrb2 remodels bile acids and the up-regulates 6-ketoLCA through Cyp7a1 in hepatocytes, promoting M2 polarization of macrophages, thereby alleviating hepatic IRI; Mechanistically, TGR5 plays a crucial role in promoting the induction of M2 polarization in macrophages by 6-ketoLCA; Pharmacological screening indicates that dutasteride enhances the activity of the Arrb2 promoter and upregulates Arrb2 expression in hepatocytes, thereby mitigating hepatic IRI. **Conclusion:** Arrb2 in hepatocytes attenuates hepatic IRI by promoting macrophages towards the M2 phenotype through bile acid. Moreover, dutasteride, a selective agonist of Arrb2, emerges as a promising targeted therapeutic agent for the clinical management of liver injury.

3505 | IMPACT OF OBESITY ON PRE- AND POST-LIVER TRANSPLANTATION OUTCOMES: A COMPARATIVE ANALYSIS ACROSS BMI CLASSES

Nazli Begum Ozturk[1] Ahmed Aref[1] Usman Bin Hameed[1] Tatjana Blazin[1] Ewelina Niedzialkowska[1] Laith Jamil[1], [1]Beaumont Hospital, Royal Oak

Background: The number of overweight and obese patients undergoing liver transplantation (LT) in the United States is rising. Obesity is a known risk factor for perioperative complications in abdominal surgery in general, but its specific impact on LT remains debated. Previous research has suggested increased length of stay and morbidity, including vascular and biliary complications in obese patients. We aimed to investigate our tertiary center's experience in overweight and obese patients undergoing LT. **Methods:** A single-center analysis of all adult patients who underwent LT at our transplant center between 2013-2023 was conducted. Clinical, laboratory, histological, and follow-up data were retrieved from electronic medical records. Patients were stratified into six BMI classes:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

underweight (BMI < 18.5), normal weight (BMI 18.5–24.9), overweight (BMI 25.0–29.9), class I obesity (BMI 30.0–34.9), class II obesity (BMI 35.0–39.9), and class III obesity (BMI ≥ 40.0). Primary outcomes were intensive care unit (ICU) and hospital length of stay. The categorical variables are reported as numbers and percentages, and the continuous variables are reported as means and standard deviation or median with interquartile range. Kaplan-Meier curves with Log-rank test were applied to compare survival outcomes. Statistical significance was defined as $p \leq 0.05$ for all the parameters. **Results:** A total of 239 LT recipients were identified, with 15% of the patient with normal weight, 30% with overweight, 26% with class I obesity, 9% with class II obesity, and 5% with class III obesity and 0.01% underweight. Pre-LT total bilirubin levels were markedly elevated in class III obesity (24 mg/dL) compared to both class I obesity (6.2 mg/dL, $p = 0.01$) and normal weight (4.8 mg/dL, $p = 0.02$). Class III obesity patients had significantly lower hemoglobin (8.4 g/dL) than normal weight (10 g/dL), $p = 0.01$, and lower platelet counts (52 x 10^3/mm^3) compared to normal weight (84 x 10^3/mm^3), $p = 0.03$. Class III obesity patients required longer ICU length of stay (LOS) (median = 12 days) compared to normal weight (median = 5 days), $p = 0.001$, and longer hospital LOS (25 days) compared to normal weight (11 days), $p = 0.01$. Moreover, post-LT infections were more frequent in class III obesity patients (50%) compared to normal weight patients (13.9%), $p = 0.05$. **Conclusion:** Patients with class III obesity exhibited significantly inferior pre- and post-LT outcomes compared to normal weight. Elevated bilirubin, lower hemoglobin, and lower platelet counts in patients with class III obesity suggest greater pre-LT frailty. Postoperatively, patients with class III obesity required prolonged hospital, and ICU stays and experienced higher infection rates. However, survival outcomes were not significantly different across BMI groups.

3506 | PRE-TRANSPLANT LIPASE ELEVATION AND ITS PROGNOSTIC IMPLICATIONS: DIFFERENTIATING BIOCHEMICAL ABNORMALITIES FROM CLINICALLY SIGNIFICANT PANCREATITIS IN PATIENTS UNDERGOING LIVER TRANSPLANTATION

Peyton Crest[1] Francis Yao[1] Chris Freise[1] John Roberts[1] Nghiem Ha[1], [1]University of California, San Francisco

Background: Lipase elevation is common in critically ill patients, including those awaiting liver transplantation, but its clinical significance—whether indicative of pancreatitis or a transient biochemical abnormality—remains unclear. We aimed to assess the relationship between pre-transplant lipase elevation, radiographic (RP) or intraoperative pancreatitis (IOP), and post-transplant outcomes. **Methods:** Included were adults who underwent liver transplantation between 1/2020 and 3/2025 with elevated lipase (≥ 78 U/L) within 14 days pre-transplant. RP was defined by imaging evidence of peripancreatic inflammation, necrosis, or fluid collections. IOP was defined as gross evidence of inflammation, necrosis, firmness, and/or surrounding saponification. Kaplan-Meier and Cox regression were used to assess associations with post-transplant mortality (death or graft failure). **Results:** Among 90 patients, 60% were male with a median age of 57; transplant etiologies were alcohol-associated (39%) followed by MASLD (23%). Overall, 20 patients (22%) died or had graft failure within 36 months. RP or IOP was found in 10 patients (11%); all 5 patients with IOP died within 1 month while the majority (60%) with RP died by 13 months. Cumulative rates of post-transplant mortality at 12 months did not differ among patients with clinically significant elevated lipase

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

(≥3xULN) but differed in those with either RP or IOP (Figure). Clinically significant lipase elevation (≥3xULN) alone was not associated with mortality (HR 1.03, 95%CI 0.25-4.32). RP/IOP was associated with post-transplant mortality (HR 8.51, 95%CI 3.16-22.97), even after adjusting for age, alcohol-associated etiology, creatinine, MELD, and lipase (HR 17.32, 95%CI 4.42-67.80). RP/IOP was associated with postoperative complications including pancreatitis, biliary complications, or intraabdominal infection (HR 3.57, 95%CI 1.59-7.97). Lipase ≥5xULN predicted RP/IOP (OR 7.97, 95%CI 1.40-45.10), remaining significant after adjusting for age, alcohol-associated etiology, MELD, and renal dysfunction (OR 6.75, 95%CI 1.01-45.03). **Conclusion:** In patients undergoing liver transplant, radiographic or intraoperative evidence of pancreatitis—but not isolated biochemical lipase elevation ≥3xULN—is a significant predictor of post-transplant morbidity and mortality. Elevated lipase ≥5xULN warrants further evaluation with dedicated cross-sectional pancreatic imaging to identify clinically significant pancreatitis and guide perioperative management.

3507 | NORMOTHERMIC MACHINE PERFUSION REDUCES EARLY ALLOGRAFT DYSFUNCTION IN TECHNICALLY CHALLENGING DCD LIVER TRANSPLANTATION

ATSUSHI NISHIMAGI[1] Rikako Oki[1] Luckshi Rajendran[1] Emily Kerby[1] Adhnan Mohamed[1] Ahmed Nassar[1] Abbas Al-Kurd[1] Atsushi Yoshida[1] Marwan Abouljoud[1] Shunji Nagai[1], [1]Division of Transplant and Hepatobiliary Surgery, Henry Ford Hospital

Background: Normothermic machine perfusion (NMP) has been shown to reduce the incidence of early allograft dysfunction (EAD), minimize various postoperative complications, and improve overall survival in liver transplantation(LT). Intraoperative blood transfusion is known to be associated with the risk of EAD, it remains unclear how the advent of NMP may modify the impact of such intraoperative risk factors for EAD. The aim of this study is to evaluate the effects of NMP in technically challenging DCD LT requiring massive transfusion. **Methods:** Adult LT alone from DCD donor which were performed from 2015-2024 were evaluated. Patients were divided into two groups based on the amount of intraoperative blood transfusion. Logistic regression analysis was performed to identify risk factors associated with the development of EAD in each group. All NMPs were initiated at donor hospitals (on-site NMP). **Results:** This study included 201 adult DCD liver transplant patients, in which LT was performed using NMP in 100 patients and non-NMP- in 101 patients. The incidence of EAD was significantly lower in the NMP group compared to the non-NMP group (22.0% [n = 22] vs 57.4% [n = 58]; $p < 0.001$). We divided patients into two groups based on transfusion volume: the high blood transfusion group (RBC + Cell Saver ≥10 units, n = 78) and the low blood transfusion group (<10 units, n = 123). NMP significantly reduced the incidence of EAD compared to non-NMP in both the high transfusion group (26.2%, [11/42] vs 55.6%, [20/36]; $p = 0.008$) and the low transfusion group (19.0%, [11/58] vs 59.4%, [38/64]; $p < 0.001$). The risk of EAD was evaluated after adjustment for donor and recipient characteristics. In the high transfusion group, NMP was independently associated with a significantly lower risk of EAD (OR = 0.17, 95% CI: 0.05–0.53, p = 0.002). Donor age (OR = 1.06, 95% CI: 1.01–1.12, p = 0.02) and donor BMI (OR = 1.10, 95% CI: 1.02–1.18, p = 0.02) were also identified as independent risk factors. In the low transfusion group, NMP remained a protective factor against EAD (OR = 0.15, 95% CI: 0.06–0.37, $p < 0.001$). donor gender (male) (OR = 3.50, 95% CI: 1.29–9.50, p = 0.01), and donor BMI(OR = 1.08, 95% CI: 1.01–1.16, p = 0.023) were also identified as independent risk factors. **Conclusion:** NMP significantly reduced the risk of EAD. This benefit is also seen in challenging liver transplant cases that involve large amounts of blood transfusion.

3508 | A META-ANALYSIS OF THE EFFECT OF CIRRHOSIS ON MORTALITY AFTER HEART TRANSPLANT ALONE IN THOSE WITH A FONTAN

Christopher Danford[1] Sophie Hansen[2] James Trotter[1] Ian Lindsay[2] Ross Butschek[1], [1]Intermountain Medical Center, [2]University of Utah

Background: Hepatic complications are increasingly recognized after the Fontan operation. The majority of patients with a Fontan will ultimately developed advanced hepatic fibrosis and cirrhosis[1], but the effect of this on outcomes after heart transplant alone and who may benefit from combined heart-liver transplant is not well established. We conducted a systematic review and meta-analysis of the effect of cirrhosis and measures of liver function on mortality after heart transplant alone in those with a Fontan. **Methods:** We searched PubMed, CINAHL, and MEDLINE databases for articles reporting the effect of liver-related variables on mortality after heart transplant alone in the Fontan population on July 18, 2024. We excluded cross-sectional studies or review articles. Studies were required to be case reports, case series, retrospective or prospective cohort studies and report the effect of liver-related variables such as cirrhosis, MELD score (and components thereof) on mortality after heart transplant alone in those who had previously undergone the Fontan operation. Two reviewers independently reviewed studies for inclusion and extracted variables of interest. A single-arm random effects meta-analysis was conducted in RStudio (version 1.3.1093). **Results:** We identified three studies including a total of 598 patients that met criteria for inclusion. All three studies reported the effect of MELD-Xi on post-transplant mortality. MELD-Xi was not associated with increased risk of mortality after heart transplant alone (HR 1.06, 95% CI 0.93-1.20) (Figure 1). Heterogeneity was high (I^2 = 70%). The effect of cirrhosis on mortality after heart transplant alone was only reported in two studies, but was also not significant (HR 5.08, 95% CI 0.98-26.3). **Conclusion:** While neither cirrhosis nor MELD-Xi was statistically significantly associated with increased mortality after heart transplant alone in those with a Fontan, there was a trend towards increased risk of mortality in those with cirrhosis and higher MELD-Xi score. One limitation is the definition of cirrhosis used as imaging characteristics alone are not reliable in diagnosing cirrhosis in those with congestive hepatopathy. Berg et al. did not provide the definition used for cirrhosis while Sganga et al. allowed for both imaging or biopsy findings to diagnose cirrhosis. While there is likely a point where patients would benefit from combined heart-liver transplant as compared to heart transplant alone, further research is needed with precise definitions of cirrhosis and liver function to determine this.

3509 | A MULTI-STAGE-RESOLVED FLUX PLATFORM QUANTIFIES SUBSTRATE-SPECIFIC MODULATION OF HEPATIC METABOLISM DURING EX VIVO LIVER PERFUSION

Amin Amin[1] Shawn Burgess[2], [1]University of Texas Southwestern Medical Center, [2]University of Texas Southwestern

Background: Normothermic machine perfusion (NMP) has transformed liver preservation, yet the optimal metabolic conditions to sustain or rehabilitate marginal grafts remain undefined. Defining how specific substrates regulate hepatic metabolism ex-vivo is critical to designing targeted perfusates for organ maintenance or metabolic rescue. We developed a stage-resolved, isotopically traced ex-vivo liver perfusion platform capable of quantifying substrate-specific metabolic fluxes. Glucose and glycerol were chosen as physiologically relevant substrates that are routinely modulated in clinical NMP protocols and represent key metabolic nodes in gluconeogenesis, glycolysis, and mitochondrial oxidation. **Methods:** Livers from fed and fasted mice were perfused with a 3% BSA based perfusate in a non-recirculating oxygenated system (figure) and subjected to serial lobectomies at 30-minute intervals. Real-time oxygen consumption was monitored using inline sensors. Two independent multi-stage experiments were performed. In the glucose experiment, livers were perfused through three stages: Stage 1 with 0 mM glucose; Stage 2 with either 5 or 20 mM unlabeled glucose alongside [U-$^{13}C_3$]lactate and [U-$^{13}C_3$]pyruvate; and Stage 3 with the same glucose concentration but with tracer switched to [U-$^{13}C_6$]glucose, allowing resolution of specific and important fluxes. In the glycerol experiment, tracer composition remained constant ([3-^{13}C]lactate and [U-$^{13}C_3$]pyruvate), while glycerol was increased stepwise across stages (0, 0.3, 1.5 mM). Lobes were snap-frozen after each stage for GC-MS analysis. Fluxes were quantified using Isotopomer Network Compartmental Analysis (INCA). **Results:** Metabolic flux analysis revealed that glucose concentration was a major determinant of hepatic carbon routing. In fasted livers, 20 mM glucose suppressed gluconeogenic flux and enhanced PDH activity relative to 5 mM Glucose, reflecting greater glycolytic engagement. In contrast, fed livers exhibited stable fluxes across glucose stages, consistent with lower catabolic demand. Insulin did not significantly impact fluxes within either nutritional state. In the glycerol experiment, increasing glycerol concentrations led to dose-dependent suppression of lactate-derived gluconeogenesis and altered pyruvate cycling and TCA fluxes—despite minimal effects on oxygen consumption. These substrate-driven changes were resolved with high temporal precision using serial lobectomy, confirming both liver viability and methodological robustness. **Conclusion:** This platform enables high-resolution, quantitative mapping of hepatic metabolism during ex vivo perfusion. By revealing distinct, substrate-specific flux patterns with intra-organ resolution, it provides a mechanistic foundation for optimizing perfusate composition and developing targeted strategies to preserve or rehabilitate donor livers under NMP.

3510 | NON-TRADITIONAL INDICATIONS IN PEDIATRIC LIVER TRANSPLANTATION: A 20-YEAR SINGLE-CENTER RETROSPECTIVE STUDY OF LONG-TERM OUTCOMES

Stephanie Chau Nguyen[1] William Zhu[1] Kimberly Chapman[2] Udeme Ekong[3] Khalid Khan[3] Gabriel Gondolesi[3] Nada Yazigi[3], [1]Georgetown University School of Medicine, [2]Children's Hospital Los Angeles, [3]Georgetown University Hospital

Background: Liver transplantation has become a viable and safe option for pediatric patients with indications beyond traditional diagnoses often including biliary atresia, autoimmune hepatitis, and hepatoblastoma. Given the relative novelty of these expanded indications, this abstract aims to briefly summarize our single center experience performing liver transplantation for nontraditional indications. **Methods:** We conducted a single-center retrospective review of pediatric liver transplantation from 2003 to 2024. A comprehensive chart review was performed to identify transplant

indication, patient and graft survival, graft rejection, retransplantation rate, biliary complications, and vascular complications. Statistical analysis was performed using Pearson's Chi-squared test of independence. **Results:** Among the 315 pediatric liver transplant recipients in our cohort, 112 patients (35.6%) underwent transplantation for nontraditional indications. Patient survival at 1, 3, and 5 years post-transplant was 97.3%, 97.3%, and 96.4% in patients with nontraditional indications compared to 94.6%, 92.6%, and 91.6% in those with traditional indications. Similarly, graft survival at 1, 3, and 5 years post-transplant was 96.6%, 96.6%, and 94.8% in the nontraditional group and 93.7%, 91.8%, and 91.0% in the traditional group. In terms of retransplantation, 5.36% (n = 6) of nontraditional patients as compared to 8.87% (n = 18) of traditional patients were retransplanted. Rejection rates were 25.9% (n = 29) in the nontraditional group compared to 19.7% (40) in the traditional group. Biliary complications were documented in 18.8% (n = 21) of nontraditional recipients and 23.6% (n = 48) of traditional recipients. Vascular complications occurred in 19.2% (n = 39) of traditional patients and 4.47% (n = 5) of nontraditional patients. Of note, vascular complications occurred significantly more frequently in patients with traditional indications ($p < 0.001$). There were no other significant comparisons among the two groups. **Conclusion:** Our findings suggest that while patient and graft survival, rejection rate, and biliary complication rates were comparable between traditional and nontraditional transplant recipients, pediatric patients with nontraditional indications had significantly less vascular complications. These results highlight the need for a larger multicenter study to better define long-term outcomes for nontraditional pediatric liver transplantation.

3511 | LIVER TRANSPLANTATION IN INDIVIDUALS WITH HIV – CHANGES IN INDICATIONS AND OUTCOMES AFTER THE ADVENT OF DIRECT-ACTING ANTIVIRALS FOR HEPATITIS C VIRUS

Ewan Glassey[1] Abdul Rahman Hakeem[2] Bruno Sensi[1] Kaushik Agarwal[1] Varuna Aluvihare[3] Kate Childs[4], [1]King's College Hospital, London, [2]King's College Hospital NHS Trust, [3]King's College Hospital, [4]Kings College Hospital, London

Background: Liver transplantation (LT) in a person living with human immunodeficiency virus (PLWH) was first performed in 1995 and was seen as a challenging indication. Early case series into this population revealed hepatitis C virus (HCV) as the most common aetiology requiring transplant. The introduction of direct acting antivirals (DAAs) for HCV in 2015 significantly improved outcomes in all HCV patients. We aim to demonstrate the impact of curative HCV treatment on LT in PLWH in a single centre review. **Methods:** Cases were reviewed of all LT performed in PLWH at King's College Hospital, London since 2007. Data was extracted from NHS Blood and Transplant (NHSBT) as well as local medical records. Data on demographics, liver disease, HIV treatment and complications, post-LT complications and long-term outcomes were reviewed. Further analysis was made between pre and post 2015 - when DAAs for HCV were introduced. **Results:** 35 LTs were performed in PLWH since 2007. 5-year overall survival to date was 21/29 (72.4%) and 1-year overall survival 31/34 (91.2%). Common aetioloies for LT were HCV 8 (22.9%), non-cirrhotic portal hypertension 7 (20%) with MASLD 4 (11.4%), drug induced liver injury 3 (8.6%), hepatitis B virus 2 (5.7%), hepatitis B plus delta 2 (5.7%) less common.

In the 2007-2014 group (before DAAs) there were 18 LT compared with 17 in 2015-2024. All 8 of the HCV patients were in the pre-2015 group, accounting for 8/18 (44.4%) as a cause for liver disease requiring transplant. Only 1 of those had achieved cure with interferon/ribavirin prior to transplant. From 2015 onwards no LT were performed for HCV infection, with the most common cause leading to transplant being non-cirrhotic portal hypertension 5/16 (31.2%).

Survival between groups: 5-year overall survival pre-2015 was 61.1% vs 90.9% 2015 onwards ($p = 0.041$), 1-year overall survival pre-2015 83.3% vs 100% 2015 onwards ($p = 0.045$).

The overall rate of thrombotic complications in 90-days post-transplant was low: hepatic artery thrombosis 3 (8.5%), portal venous thrombosis 1 (2.9%), hepatic venous thrombosis 1 (2.9%). Incidence of sepsis 90 days post LT was not significant pre-2015 6/18 (33.3%) vs 3/17 (17.6%) in 2015 onwards ($p = 0.14$). **Conclusion:** This single centre review demonstrates a clear shift in most common cause for LT in PLWH. We also demonstrate that overall outcomes in this population in the post DAA era are much improved. Medical and surgical care advances have improved LT outcomes in this population.

3512 | ASSESSING KIDNEY DYSFUNCTION IN INPATIENTS WITH DECOMPENSATED CIRRHOSIS: A GLOBAL-AKI COHORT STUDY

Kavish Patidar[1] Giovanna Saracino[2] Ann Ma[3] Adrià Juanola[4] Elsa Solà[5] Simone Incicco[6] Salvatore Piano[6], [1]Houston Methodist Hospital, [2]Baylor University Medical Center, [3]Clichy France, [4]Hospital Clinic i Provincial de Barcelona, [5]Stanford, [6]University of Padova

Background: Accurate assessment of kidney function is important in patients with cirrhosis, though inadequately captured by current glomerular filtration rate (GFR) estimating equations that were developed for patients with chronic kidney disease (eg CKDI-EPI 2021). Recently, we updated a validated a novel race neutral equation to estimate GFR in patients with cirrhosis (GFR Assessment In Liver disease, GRAIL 2.0). We showed that it estimates GFR better than current estimating equation in stable outpatients with decompensated cirrhosis as compared to measured GFR. However, the use of eGFR in unselected hospitalized patients with dynamic kidney function (acute kidney injury) is not well characterized. **Methods:** In this prospective, multicenter, cohort study, we examined adults ($\geq$18 years) with decompensated cirrhosis who were hospitalized for AKI, at 65 centers across five continents. Inclusion criteria were adult patients with cirrhosis admitted to hospital for the treatment of a complication of liver disease and diagnosed with AKI. We compared GRAIL 2.0 (age,BUN,albumin,creatinine,sex, Asrani AASLD 2024) to the reference standard (CKD-EPI 2021, Inker NEJM 2021). The primary outcome of interest was need for renal replacement therapy or death. Cumulative incidence functions of mortality were developed through competing risks analysis and compared with Gray's test. Liver transplantation was considered a competing risk for mortality **Results:** Between July 1, 2022, and May 31, 2023, we enrolled 1210 patients who were hospitalized with AKI and had the variables needed to compute GRAIL 2.0. Overall 139 patients required RRT (11.5%), 55 received a LT (n = 4.5%) and 380 patients died (31.4%).

Overall, both GRAIL and CKD-EPI during index hospitalization were associated with RRT and mortality within 28-days. Patients with an estimated GFR < 30 ml/min had higher incidence of mortality. Discordance was noted where 309 patients (25.5%) were classified as having a GFR < 30 ml/min according to GRAIL 2.0 but not with CKD-EPI (overestimation). Those patients had a cumulative incidence of mortality similar to patients with both GRAIL 2.0 and CKD-EPI < 30 ml/min, and significantly higher than those with both $\geq$ 30 ml/min (Figure; $p < 0.001$). Results were consistent in male and female and in patients with MELD **Conclusion:** Use of eGFR for prognosis is acceptable in the inpatient setting with dynamic changes in kidney function. CKD-EPI may overestimate kidney function. In patients with decompensated cirrhosis, use of race neutral eGFR developed in patients with liver disease (GRAIL 2.0) may serve as a viable alternative for prediction of kidney related outcomes as well as transplantation decisions.

3513 | NEIGHBORHOOD SOCIOECONOMIC DEPRIVATION IS ASSOCIATED WITH DELAYS AND MORTALITY IN THE LIVER TRANSPLANT CARE CONTINUUM

Carolina Lopez-Silva Lynette Sequeira[1] Vedant Jain[2] Valerie Thompson[2] Juliette Dixon[2] Tyrus Vong[2] Alexandra Strauss[2], [1]Johns Hopkins Hospital, [2]Johns Hopkins University

Background: Social determinants of health significantly influence liver transplant (LT) access and outcomes. The area deprivation index (ADI), a composite measure of neighborhood-level socioeconomic status (nSES), has been used to evaluate the impact of nSES on health-related outcomes. We examined the association between nSES (as estimated by ADI) and timing of transplant care and outcomes. **Methods:** We conducted a retrospective cohort study of adults referred for LT evaluation at an urban transplant center between August 1, 2016, and December 31, 2019. ADI was dichotomized at the sample median. Demographic and clinical characteristics were compared by ADI group. Time from referral to evaluation, listing, and death were assessed using Kaplan-Meier curves with log-rank tests. Cox proportional hazards models adjusted for age and sex were used to evaluate associations between ADI and each outcome. **Results:** Among 1,377 referred patients, 712 lived in low nSES (high ADI) neighborhoods and 665 in high nSES (low ADI) areas. Patients from low nSES

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

neighborhoods were more likely to be Non-Hispanic Black (23.3% vs. 11.1%, $p < 0.001$), insured by Medicaid (25% vs. 13.5%, $p < 0.001$), and less likely to have alcohol-related liver disease (19.4% vs. 29.6%, $p < 0.001$). Age, sex, and median MELD scores did not significantly differ between groups. Kaplan-Meier analysis showed statistically significant delays for patients from low nSES neighborhoods in evaluation (median 26 vs. 25 days, $p = 0.031$) and listing (791 vs. 626 days, $p < 0.001$), and shorter survival after referral (774 vs. 822 days, $p < 0.001$). In adjusted Cox models, low nSES was independently associated with reduced likelihood of evaluation (HR 0.870, 95% CI 0.768–0.986, $p = 0.029$), listing (HR 0.703, 95% CI 0.581–0.851, $p < 0.001$), and increased risk of death (HR 1.407, 95% CI 1.148–1.726, $p = 0.001$). **Conclusion:** We found that neighborhood disadvantage leads to significant delays along the transplant care continuum and is associated with a higher risk of mortality. This highlights the role of neighborhood-level social determinants in influencing transplant access and outcomes and underscores the need for targeted interventions to address these inequities.

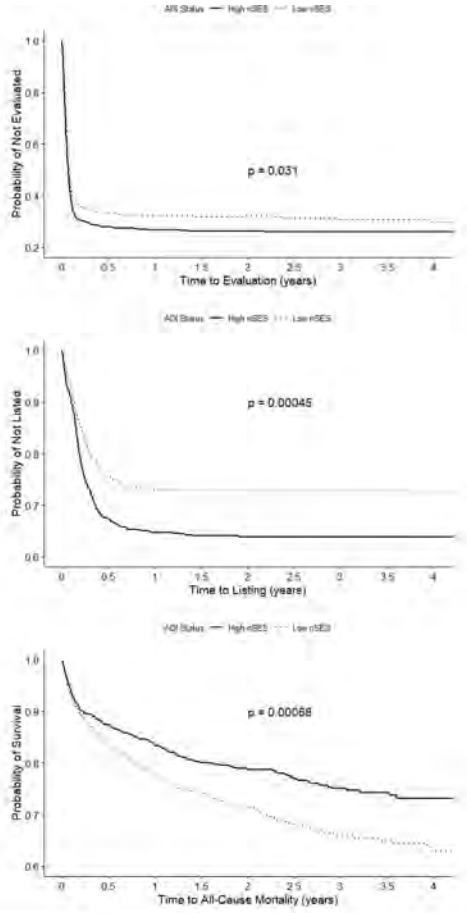

Figure 1. Kaplan-Meier curves comparing time to evaluation, time to transplant listing, and all-cause mortality following referral for liver transplant evaluation, stratified by neighborhood socioeconomic status (nSES). Time is shown in years from the date of referral. Log-rank tests were used to assess statistical differences between nSES groups.

3514 | COMPARISON OF MELD, MELD-NA, AND MELD 3.0 SCORING SYSTEMS IN TRANSPLANT PRIORITIZATION IN THE TURKISH POPULATION: A MULTICENTER STUDY

Kenan Moral[1] MUHSIN MURAT MUHIP HARPUTLUOGLU[2] Haydar Adanır[3] Nilay Danış[4] Murat Kıyıcı[5] Murat Dayangac[6] Sencan Acar[7] Derya Arı[8] Ramazan Idilman[9] Zeki Karasu[10] Sabahattin Kaymakoğlu[11] Nimet Yılmaz[12] Gupse Adali[13] Murat Akyıldız[14] Ahmet Uyanikoglu[15] Onur Keskin[16] Murat Kekilli[1] Sezai Yılmaz[2] Gülşah Fidan Özkumur[3] Doğancan Gavcar[17] Efe Erbay[17] Mesut Akarsu[4] Fatih Eren[5] Mehmet Refik Göktuğ[5] Amir Salar Nazari[18] Meral Akdoğan Kayhan[8] Dilara Turan Gökçe[8] Hale Gökcan[9] Zeynep Melekoğlu Ellik[9] Ilker Turan[10] Fulya Günşar[10] Elvan Işık[10] Mehmet Akif Yağlı[11] Alper Akın[11] Baver Ordu[13] Genco Gencdal[19] Osman Yüksekyayla[15] Burcu Gürbüz[16] Mehmet Cindoruk[1] Tarkan Karakan[1] Gökhan Kabacam[20], [1]Gazi University Department of Gastroenterology and Hepatology, [2]Inönü University Liver Transplantation Institute, [3]Akdeniz University Department of Gastroenterology and Hepatology, [4]Dokuz Eylül University Department of Gastroenterology and Hepatology, [5]Uludağ University Department of Gastroenterology and Hepatology, [6]Medipol University Mega Hospital Department of General Surgery, [7]Florence Nightingale Hospital Liver Transplant Unit, [8]Ankara Bilkent City Hospital Department of Gastroenterology and Hepatology, [9]Ankara University Department of Gastroenterology and Hepatology, [10]Ege University Department of Gastroenterology and Hepatology, [11]Istanbul University Istanbul Faculty of Medicine Department of Gastroenterology and Hepatology, [12]Sanko University Department of Gastroenterology and Hepatology, [13]University of Health Sciences Umraniye Research and Training Hospital, [14]Koç University Deparment of Gastroenterology and Hepatology, [15]Harran University Department of Gastroenterology and Hepatology, [16]Hacettepe University Department of Gastroenterology and Hepatology, [17]Dokuz Eylül University Department of Internal Medicine, [18]Medipol University Mega Hospital School of Medicine, [19]Koç University Department of Gastroenterology and Hepatology, [20]Guven Hospital Liver Transplantation Center

Background: The Model for End-stage Liver Disease Sodium (MELD-NA) score is widely used to predict mortality in patients awaiting liver transplantation. Recently, MELD-3.0 has been proposed as an alternative model for mortality prediction in patients with cirrhosis. This study aims to evaluate the effectiveness of the MELD-3.0 score in predicting mortality among patients listed for liver

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

transplantation, and to compare its performance with that of the MELD and MELD-NA scores. **Methods:** The area under the receiver operating characteristic curves (AUROC) were calculated to assess the discriminative power of MELD-3.0, MELD-Na, and MELD in predicting mortality at 3 months. DeLong's test was used to compare the AUROC values. The cutoff score for MELD3.0, indicating a high risk of 3 month mortality, was identified using Youden's Index. Kaplan–Meier method was employed to estimate transplant free survival (date of listing to date of transplantation or death) curves for patients with MELD3.0 scores above and below this cutoff, and these curves were compared using log-rank analysis. **Results:** The study included a total of 1689 patients. Hepatitis B was identified as the primary cause of cirrhosis, affecting 491 individuals (29%), while MASH was the second most common cause, with 335 cases (20%). In the context of three-month mortality, the MELD 3.0 score had the highest predictive score with an AUC of 0.753 ($p < 0.05$). In comparison, the MELD-Na score demonstrated an AUC of 0.747 ($p < 0.05$), while the MELD score had an AUC of 0.725 ($p < 0.05$). The optimal cutoff value for the MELD score was determined to be 18, yielding a sensitivity of 69% and a specificity of 65%. For the MELD-Na and MELD 3.0 scores, the ideal cutoff was 21, with the MELD-Na score exhibiting a sensitivity of 69% and a specificity of 68%, and the MELD 3.0 score showing a sensitivity of 72% and a specificity of 66%. A statistically significant difference was observed between the MELD score and MELD-Na/ MELD 3.0 scores ($p < 0.001$). However, no statistically significant difference was found between the MELD-Na and MELD 3.0 scores ($p = 0.170$). For individuals with MELD > 21, transplant free survival was 1.6 years, whereas for those with MELD ≤ 21, it was 3.3 years, with a statistically significant difference ($p < 0.05$). **Conclusion:** Although both MELD 3.0 and MELD-Na are superior to the MELD score in forecasting 3-month mortality, there is no statistically significant difference between MELD 3.0 and MELD-Na in terms of mortality prediction at 3 months. Larger studies from various countries are necessary to validate the MELD 3.0 score.

3515 | RISK FACTORS FOR SEVEN-DAY GRAFT LOSS IN PEDIATRIC LIVER TRANSPLANTATION: A RETROSPECTIVE ANALYSIS OF THE SRTR DATABASE

Louis Borsellino[1] Sohail Khan[1] Melanie Vugelman[1] Katherine Connors[1] Alexandra Zois[2] Olzhas Zhorayev[3] Jorge Ortiz[2], [1]Touro College of Osteopathic Medicine, [2]Garnet Health Medical Center, [3]George Mason University

Background: Early graft loss (EGL) in pediatric liver transplantation (pLT) is a rare but catastrophic complication, resulting in significant morbidity, mortality, and strain on the donor pool. This report aimed to identify clinical and perioperative risk factors associated with graft failure within the first seven days post-pLT (7-day GL). **Methods:** We conducted a retrospective analysis of the Scientific Registry of Transplant Recipients (SRTR) database between 2015 and 2024. Cases of 7-day GL were compared to a control cohort of patients with one-year graft survival. Donor, recipient, and operative variables were evaluated using multivariable

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

logistic regression. **Results:** Among 4,112 pLT procedures, 137 cases (3.3%) experienced 7-day GL, including 63 deaths within the first 7 days. Primary causes of graft failure included primary nonfunction (PNF), vascular thrombosis (arterial or venous), infection, rejection and recurrent disease. Key risk factors for 7-day GL were retransplantation (OR: 2.42, $p = 0.002$), donor-to-patient height ratio (OR: 1.73, $p < 0.001$) and prolonged cold ischemia time (OR: 1.08, $p = 0.019$). Male donor sex was associated with a lower risk of 7-day GL (OR: 0.67, $p = 0.033$). Partial liver grafts had significantly higher odds of PNF compared to whole liver grafts (OR: 6.03, $p = 0.008$), as well as cold ischemia time (OR: 1.22, $p = 0.001$). Predictors of patient mortality within seven days included PNF (OR: 129.18, $p < 0.001$), thrombosis (OR: 65.11, $p < 0.001$), higher PELD scores (OR: 1.04, $p = 0.003$) and increased donor-to-patient height ratio (1.66, $p = 0.043$). Living donor transplantation was not significantly associated with reduced 7-day GL ($p = 0.124$) or mortality within the first 7 days ($p = 0.056$) compared to deceased donor pLT, although it comprised only 14.8% of the cohort ($n = 609$). **Conclusion:** Although accounting for only 3% of pLT cases, 7-day EGL represents the most serious adverse clinical outcomes. Clinicians must remain vigilant in improving modifiable risk factors, particularly graft size matching and minimizing cold ischemia time, which may improve early outcomes in pLT.

3516 | CONFRONTING THE COMPLEXITY OF PML: DIFFICULT MANAGEMENT DECISIONS

Ahmer Khan[1] Kinga Grzybowski[1] Aheed Javaid[2] Richard Kalman[1] Maria Lagarde[1], [1]Jefferson Einstein Philadelphia hospital, [2]Jefferson Abington Hospital

Background: Progressive multifocal leukoencephalopathy (PML) is caused by reactivation of JC virus (JCV). Initial infection with JCV occurs in childhood and antibodies can be found in most adults. JCV remains latent in kidneys and lymphoid organs, but in the context of profound cellular immunosuppression, JCV can reactivate. We present a therapeutic dilemma in a patient post liver transplantation who presented with concerns for PML. **Methods:** 56-year-old male with a past medical history of HCV cirrhosis post liver transplantation in early 2024 and multiple episodes of biopsy proven T-cell mediated rejection presented with a chief complaint of bilateral vision loss and intermittent confusion that were progressive over three weeks. **Results:** Current medications included mycophenolate and prednisone. Previously on tacrolimus, this was held due to development of PRESS. Physical examination and laboratory studies including liver function testing were unremarkable. An MRI of the brain demonstrated an increased burden of white matter signal abnormalities in multiple regions of the brain that were suspicious for PML. Other leading differentials included CNS immune reconstitution syndrome, atypical PRESS or posttransplant lymphoproliferative disorder. He underwent a lumbar puncture with CSF analysis as well as a brain biopsy. Unfortunately, his CSF PCR demonstrated JC virus, and a brain biopsy was consistent with PML. When we attempted to minimize his immunosuppression, his aminotransferases rose significantly, reflecting acute rejection which was reflected on a subsequent liver biopsy. **Conclusion:** PCR is the preferred approach to the diagnosis of PML. Brain biopsy remains the gold standard in patients who are difficult to diagnose. In patients without evidence of HIV infection who develop PML, the mainstay of therapy is discontinuation or reduction of any immunosuppressants when feasible. Unfortunately, when we attempted to reduce the doses of his immunosuppressants, he developed severe acute rejection with his ALT and AST rising to 2550 IU/L and 1600 IU/L respectively.

We were unable to reduce his immunosuppressants to suitable levels to treat his biopsy proven acute rejection and concurrently prevent progression of PML. After conversations with the patient's family, the decision was made to send him home on hospice without any of his immunosuppressive medications. This case highlights the difficult and rare balancing act that we encounter with HIV negative patients on immunosuppression who develop PML.

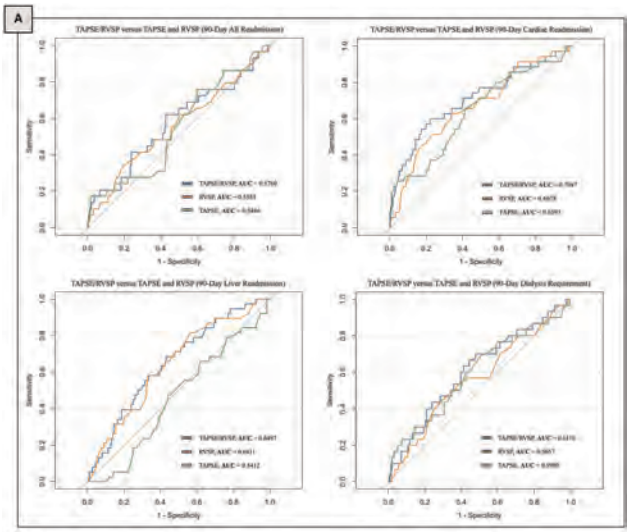
3517 | TRICUSPID ANNULAR PLANE SYSTOLIC EXCURSION (TAPSE) TO RIGHT VENTRICULAR SYSTOLIC PRESSURE (RVSP) RATIO: A NOVEL TOOL TO PREDICT CARDIAC OUTCOMES IN LIVER TRANSPLANT RECIPIENTS

Hong Lin[1] Melica Nikahd[2] Antonio Alvarez Castaneda[1] Khalid Mumtaz[1] Chathur Acharya[1], [1]The Ohio State University Wexner Medical Center, [2]The Ohio State University

Background: Patients with right ventricular (RV) dysfunction and portopulmonary hypertension (PoPH) face worse outcomes after liver transplantation (LT). Right ventricular systolic pressure (RVSP) is commonly used to assess RV hemodynamics prior to LT, but it only reflects afterload and does not account for RV adaptability, potentially overestimating risk in preserved RV function. Tricuspid annular plane systolic excursion (TAPSE) measures RV contractility and detects compensatory hypertrophy but ignores afterload. We hypothesize that the TAPSE/RVSP ratio may better assess RV-pulmonary coupling and predict post-LT cardiac outcomes. **Methods:** This retrospective study examined data from LT patients at The Ohio State University (2016-2020), analyzing pre-transplant transthoracic echocardiograms (TTE) within one year of LT. Receiver operating characteristic (ROC) curves assessed TAPSE/RVSP ratio, RVSP, and TAPSE in predicting 90-day all-cause and cause-specific (cardiac, hepatic, renal) readmissions as well as hemodialysis (HD) requirement. DeLong's test was used to compare areas under the curve (AUC); Wilcoxon rank-sum test and logistic regression were used to evaluate associations. **Results:** Out of 464 LT recipients, 226 had complete data. A majority were male (60.2%) and white (93.3%). Median values: RVSP 30.9 mmHg (12–61), TAPSE 2.60 cm (0.8–4.2), TAPSE/RVSP 0.092 cm/mmHg (0.014–0.217). ROC analysis of 90-day outcomes of all-cause, cardiac, and liver-related readmissions, as well as HD requirement (Figure 1A) revealed that TAPSE/RVSP outperformed RVSP alone ($p = 0.042$) and TAPSE alone ($p = 0.008$) in predicting cardiac readmission. Additionally, it was superior to RVSP ($p = 0.044$) for predicting HD requirement and to TAPSE ($p = 0.03$) for liver-related readmission, while performing similarly for 90-day all-cause readmissions. Wilcoxon/logistic regression supported these findings, though TAPSE/RVSP showed borderline significance for HD prediction (Figure 1B). On multivariate analysis (adjusted for age/sex/race/ESRD/PoPH), TAPSE/RVSP was associated with cardiac ($p = 0.0001$), liver ($p = 0.015$), and all-cause readmission ($p = 0.024$). **Conclusion:** The TAPSE/RVSP ratio, a novel, previously unreported metric in LT, predicts 90-day cardiac readmission better than RVSP or TAPSE alone while performing comparably for other outcomes. A lower ratio reflects impaired RV-pulmonary coupling, identifying maladaptive RV dysfunction and patients with high risk of cardiac morbidity post-LT.

A



B

Wilcoxon Rank Sum Test: TAPSE/RVSP Comparison Group	No Readmission	Readmission	P-value	Interpretation
90-day cardiac readmission	0.09 (0.07, 0.11)	0.07 (0.05, 0.09)	<0.001	**Significant**
90-day hepatic readmission	0.09 (0.07, 0.11)	0.07 (0.06, 0.09)	0.0036	**Significant**
90-day hemodialysis requirement	0.09 (0.07, 0.11)	0.08 (0.06, 0.1)	0.050	Borderline significance; needs more data

3518 | COMPARABLE LONG-TERM OUTCOMES FOLLOWING LIVER TRANSPLANTATION IN PSC AND PSC-AIH OVERLAP SYNDROME: AN INTERNATIONAL COHORT STUDY

Matthew Peverelle[1] Andrew Chen[1] Ryan Hirsch[2] Deepak Joshi[3] Remco van Dijk[4] Adam Testro[1] Jeremy Nayagam[3], [1]Austin Hospital, [2]Monash Health, [3]King's College Hospital, [4]Leiden University Medical Center

Background: Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease that often requires

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

liver transplantation (LT). It is complicated by PSC recurrence (rPSC) in up to 27% of cases which increases the risk of graft failure and need for re-transplantation. A subset of patients present with PSC-autoimmune hepatitis (AIH) overlap syndrome, characterized by features of both biliary stricturing and hepatocellular inflammation. Treatment for PSC-AIH typically involves immunosuppression directed at the AIH component; however, LT is often still required. Outcomes after LT for PSC-AIH remain poorly defined. The aim of this study was to compare long-term post-LT outcomes between patients with PSC and PSC-AIH overlap syndrome. **Methods:** This retrospective cohort study included adult patients who underwent their first LT for PSC or PSC-AIH between 2000–2018 at three transplant centers: Austin Hospital (Melbourne, Australia), King's College Hospital (London, United Kingdom) and Leiden University Medical Centre (LUMC)(Leiden, Netherlands). Patients with early post-LT mortality, early retransplantation (<3 months from LT) or cholangiocarcinoma on explant were excluded. Data collected included demographics, liver disease characteristics, transplant details, immunosuppression and post-LT outcomes including rPSC, graft rejection, retransplantation, and survival. **Results:** A total of 265 patients were included in the analysis (218 PSC; 47 PSC-AIH) (84 Austin Hospital; 138 King's College; 43 LUMC) with mean follow-up of 9.9 years (no difference between groups). PSC-AIH patients were significantly younger at diagnosis (mean 25.1 vs. 38.3 years) and more frequently female (49% vs. 33%). Donor graft features were comparable as were cold and warm ischaemia times. Hepaticojejunostomies were more common in PSC patients than PSC-AIH patients (66% vs. 40%; $P=0.001$). Post-LT immunosuppression were similar in each group.

There was no significant difference in rates of rPSC (34.8% PSC-AIH vs. 41.3% PSC), $P=0.46$), rejection after 12 months (26% vs. 17%, $P=0.15$) or retransplantation (10.6% vs.12%, $P=0.79$). However, PSC-AIH patients had lower overall mortality (26.2% vs. 10.6%, $P=0.023$). After multivariate adjustment for confounders, this trended towards but did not remain significant ($P=0.078$). Hepaticojejunostomy emerged as an independent risk factor for rPSC (HR: 2.08 (1.13-3.83),$P=0.018$) and retransplantation (HR: 10.58 (2.35-47.58), $P=0.002$) in the overall cohort. In PSC patients, higher ALP levels at year 1 predicted rPSC diagnosis in year 2 (2.20 ± 1.40 x ULN vs.1.05 ± 0.71, $P=0.04$). **Conclusion:** Patients with PSC-AIH overlap have comparable rates of rPSC, graft rejection, retransplantation tand survival to those with isolated PSC following LT. These findings suggest that LT outcomes in PSC-AIH are at least equivalent to PSC, supporting similar management and surveillance strategies post-transplant.

3519 | MYOCARDIAL PERFUSION IMAGING: LIMITED PREDICTIVE VALUE FOR OBSTRUCTIVE CAD AND POST-TRANSPLANT OUTCOMES IN LIVER TRANSPLANT CANDIDATES

Ibrahim Alrajhi[1] Maryam Maryam[2] Waleed Haj Ahmad[3] Syeda Shamsi[3] Ahmad Alissa[2] Dieter Broering[4] Manhal Izzy[5] Mohamed Tahir[1] Saleh Alqahtani[6] Saad Alghamdi[7] waleed Alhamoudi[1] Bandar Aljudaibi[1], [1]King Faisal Specialists Hospital and Research Centre, [2]Alfaisal Univeristy, [3]Alfailsal Univeristy, [4]King Faisal Specialisits Hospital and Research Centre, [5]Vanderbilt University Medical Center, [6]Johns Hopkins University, [7]Washington University in St. Louis

Background: Cardiovascular risk assessment, including myocardial perfusion imaging (MPI), is routinely done in liver transplant (LT) candidates due to the high prevalence of coronary artery disease (CAD). However, the predictive value of MPI for obstructive CAD and post-LT outcomes remains unclear. The aim of the study is to to evaluate whether pre-transplant MPI can predict obstructive CAD and post-LT mortality and cardiac events. **Methods:** Retrospective analysis of 745 LT recipients (2015–2022) with pre-transplant MPI

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

stress testing. Significant CAD was defined as ≥75% stenosis on cardiac catheterization. Outcomes included mortality, graft failure, and cardiac events (cardiac death, myocardial infarction [MI], arrhythmia, heart failure). Statistical analysis utilized chi-square tests, logistic regression, and Kaplan-Meier survival analysis. **Results:** Among 514 patients undergoing MPI, 91% (468/514) had normal results, while 8.5% (44/514) showed abnormalities. Only 34.6% (178/514) received β-blockers during testing. Abnormal MPI demonstrated poor sensitivity for obstructive CAD (4.3%). Post-LT, 13% (97/745) died, with 12.3% (12/97) attributed to cardiac causes. Cardiac catheterization revealed significant CAD in 4.8% (36/745). However, 93%% (29/31) of significant CAD patients had normal MPI results. MPI abnormalities did not independently predict mortality (OR 1.2, 95% CI 0.7–2.1) while the presence of significant of CAD on cardiac cath (OR 1.7, 95% CI 0.73-4.28) may indicate a clinically relative risk of mortality. The sensitivity and specificity of MPI for predicting significant CAD were 4.3% and 93.8%, respectively, with positive and negative predictive values of 6.5% and 90.9 %. **Conclusion:** MIBI has limited utility in predicting obstructive CAD or post-LT outcomes in LT candidates, as most obstructive CAD cases occurred in patients with normal MIBI. Over-reliance on MIBI may underdetect high-risk CAD, highlighting the need for integrated risk stratification, including invasive angiography in select patients. Further studies should optimize peri-transplant cardiac screening protocols.

	Significant CAD	Not Significant CAD	Total
MPI Abnormal	2	44	46
MPI Normal	29	439	468
Total	31	483	514

3520 | NEAR-INFRARED SPECTROSCOPY (NIRS) COULD PREDICT GRAFT QUALITY IN ADULT LIVER DONORS

Noelia De Armas[1] Julen Ramon[1] Diego López[1] Isabel Jaén[1] Adela Rojas[1] Gerardo Blanco-Fernández[1] Demetrio Pérez[1], [1]University Hospital Complex Badajoz

Background: In recent years, there has been an improvement in the outcomes of liver transplantation (LT), leading to an increase in its indications and demand for donor livers. To address this shortage, the use of livers from donors with expanded criteria has been introduced, where monitoring the degree of hepatic steatosis (HS) is crucial. The presence of HS >30% in donor livers has been associated with worse outcomes, with reduced survival of both the recipient and the graft and increased postoperative complications. In the process of the evaluation of the donor liver, significant discrepancies have been observed between the subjective opinion of the surgeon regarding the degree of HS and the results of the pathology study of the liver biopsy.

In recent years, the use of near-infrared spectroscopy (NIRS) systems, such as the INVOS device has become more widespread. This device measures the regional oxygen saturation (rSO2) of a tissue using infrared light.

The aim of the present study is to determine the usefulness of monitoring hepatic rSO2 using the INVOS system in the assessment of liver donors. **Methods:** An observational, longitudinal, and prospective study was conducted of adult patients undergoing liver transplantation at our center between 08/01/2020 and 06/01/2022.

We measured rSO2 by placing the sensor on the donor skin at the right hypochondrium and on the liver surface. At the end of the LT, a biopsy of the liver graft is taken, which is sent to the Pathology Service for analysis. **Results:** The rSO2 measurements on the donor skin were obtained in 27 patients (93.1%), while the measurements on the donor liver were taken in 18 patients (62.1%).

Donors with lower preoperative AST values had statistically significantly higher rSO2 values measured on the skin ($p = 0.046$). This same trend toward higher rSO2 values on donor skin in patients with lower transaminase values was also observed in the case of ALT, although the difference was not significant ($p = 0.110$). A trend was also observed toward higher rSO2 values on donor skin in patients with a lower Donor Risk Index (DRI), although the results did not reach statistical significance ($p = 0.07$)

We found a statistically significant relationship between the rSO2 values measured on the donor liver and the degree of steatosis ($p = 0.001$). Patients with lower rSO2 values had a higher degree of HE in the subsequent pathology study. rSO2 values >57% measured on the donor liver were associated with HS <30% (S:92%; E:75%). **Conclusion:** The measurement of hepatic rSO2, both through the skin and directly on the donor liver, is associated with key parameters of LT success, such as DRI, transaminases, and the degree of HS.

3521 | OUTCOMES OF LOW-DOSE VALGANCICLOVIR IN TREATMENT OF POST LIVER TRANSPLANT CYTOMEGALOVIRUS VIRAEMIA: A RETROSPECTIVE, SINGLE-CENTRE STUDY

Alison Rowley[1], [1]King's College Hospital

- **Background:** Cytomegalovirus (CMV) viraemia is associated with direct and indirect adverse effects in post-liver transplant patients [1].
- To date, valganciclovir (VGV) 900 mg BD is a standard dose for post-transplant CMV viraemia treatment [2]. However, haematological adverse reaction and renal function limit its use.
- In prophylaxis context, lower dose VGV has shown non-inferiority [3], but limited studies evaluating lower dose VGV in treatment context.

At King's College Hospital, VGV 900 mg OD has been prescribed in post-liver transplant CMV viraemia. Anecdotal experience has shown good outcomes and tolerability. **Methods:** A retrospective, descriptive service evaluation was conducted at a liver transplant centre at King's College Hospital NHS Foundation Trust. From January 2019 to January 2024, patients receiving valganciclovir for post-liver transplant CMV viraemia were identified and followed up for at least 3 months. Baseline characteristics and outcomes representing response to treatment (time to eradicate CMV, incidence of CMV infection, and treatment escalation), tolerability (haematological adverse reaction, renal function, and early discontinuation or dose reduction), and resistance were documented. **Results:** A total of 106 patients were included in the study. 98% of the population had asymptomatic viraemia. 72% of the population achieved viral eradication within 1 month, with only 2% had to undergo treatment escalation. Despite leukopenia (34%), neutropenia (33%), and thrombocytopenia (17%) occurred within 3-month course, only 10% of the patients need dose adjustment (7%) or early discontinuation (3%). Resistance was observed in 1 patient, leading to prolonged treatment course. **Conclusion:** In this hospital setting, most of the population receiving once-daily dosing of valganciclovir attain favourable outcomes with good tolerability. Resistance event was infrequent but should be carefully managed.

Gastroenterology, Hepatology, and Nutrition, Virginia Commonwealth University Health S, [4]Hume-Lee Transplant Center, Virginia Commonwealth University Health System; Richmond VA

Background: Spur cell anemia (SCA) is common in patients (pts) undergoing liver transplant (LT). The prevalence of SCA, its natural history and how it impacts survival in pts undergoing LT is poorly defined. To address this gap in knowledge, we examined the prevalence of SCA and its associations in those undergoing LT and its impact on 1 year survival. **Methods:** In this retrospective analysis, all pts receiving LT transplanted between 10/18-4/24 with 1 year of follow up data were included. All data were extracted from the electronic medical records from the time of listing until the time of most recent follow up post-LT under the approved Liver Transplant Registry. SCA was defined by the presence of spur cells on peripheral smear or by clinical record. Those with and without spur cell anemia were compared by univariate and multivariate analysis. The primary outcomes were prevalence and predictors of SCA and its impact on 1-year pt survival. **Results:** 451 pts met eligibility: mean (SD) age was 52 (13), 56% were male, 77% White/16% Black/3% Asian, and 95% non-Hispanic. The etiologies of liver disease were MASLD (25%), alcohol (49%), HCV (11%), autoimmune hepatitis (3%), PBC (2.5%), and PSC (6%) with MELD 23.3 (11.5). At LT, 55% had SCA. Pts with SCA were younger (49 vs 56), had higher total (13.7 vs 4.8 mg/dL) and direct (8.2 vs 3.1 mg/dL) bilirubin, INR (2.29 vs 1.56), MELD (28 vs 17), lower Hgb (9.1 vs 11.3 g/dL)(all $p < .0001$), were more likely to have ascites (61% vs 33%; $p < .001$), hepatic encephalopathy (HE) (63% vs 42%), acute kidney injury (AKI) (79% vs 38%) and more likely to have alcohol-related liver disease (71% vs 41%)(all $p < .0001$) and less likely to have diabetes (46% vs 58%; $p = .03$). Independent predictors of SCA at LT were age ($p = .0002$), HE ($p = .02$), AKI ($p < .0001$), and alcohol-related liver disease with < 6mo sobriety ($p = .01$). SCA resolved by 1-year after LT in 94% and developed in 4%. Those with SCA at the time of LT had slightly lower 1-year survival (96% vs 98%; $p = .01$). After adjusting for liver disease etiology and MELD, SCA remained associated with lower 1-year survival ($p = .04$). **Conclusion:** SCA is common in those undergoing LT and related to both demographic and clinical factors and more common in those with alcohol-related liver disease. While it resolves in the majority, it is associated with lower 1-year survival. Future studies to determine why those with SCA at time of LT have lower survival are needed. **Disclosures:** Hasan Alroobi: Nothing to Disclose, Kevin Houston: Nothing to Disclose, Richard Stravitz: Nothing to Disclose, Amon Asgharpour: Nothing to Disclose, Scott Matherly: Nothing to Disclose, Joel Wedd: Nothing to Disclose, Hannah Lee: Nothing to Disclose, Mohammad Siddiqui: Nothing to Disclose, Vaishali Patel: Nothing to Disclose, Sayed Aseem: Kezar: Consultant, David Bruno: Nothing to Disclose, Richard Sterling: ABIM: GI Specialty Board, Abott: Grant/Research Support, AbbVie: Grant/Research Support, Roche: Grant/Research Support, GSK: Grant/Research Support, HCV Vax: Grant/Research Support, Gilead: Grant/Research Support, Zydus: Grant/Research Support, Vertex: Consultant, Madrigal: Advisor, Gigagen: Grant/Research Support

3523 | DISPARITIES IN SCREENING FOR AND PREVALENCE OF LOW BONE MINERAL DENSITY FOLLOWING LIVER TRANSPLANT

Katherine Cooper Darya Herscovici[1] Jenna Patel[1] Deepika Devuni[1], [1]UMass Chan Medical School

Background: Liver transplant recipients (LTR) experience accelerated bone loss, especially in the first post-LT year, placing them at increased the risk of osteoporosis and its associated complications. There are limited recent data regarding screening for and the incidence of low bone mineral density (BMD) in LTR. In this study, we characterize BMD screening, treatment, and follow up in adult LTR. **Methods:** This is a retrospective analysis of LTRs at a safety net hospital and LT center between 2017-2022. We assessed the rate BMD screening, defined as receipt of a dual x-ray absorptiometry (DEXA) scan, following LT. Timing of screening was categorized as early ($\leq$ 6 months), standard (6-18 months), and delayed ($\geq$ 18 months). To identify factors associated with screening, we compared sociodemographic factors in those with and without a DEXA scan. Screening recipients were categorized as Low BMD or Normal BMD. Low BMD included those with either osteoporosis (OPo, T-score $\leq$ -2.5) or osteopenia (OPe, -2.4 $\geq$ T-scores $\leq$ -1.0) on initial DEXA scan. Treatment of Low BMD was categorized as None, Calcium/Vitamin D only, and BMD-specific treatment. Repeat DEXA scans were assessed for improvement as available. Factors associated with Low BMD, BMD Treatment and BMD improvement were explored. **Results:** Among 266 LTR, 44% ($n = 118$) underwent BMD screening (27 early, 33 standard, 58 delayed). The median time to DEXA was 512 days (IQR 201-1143). Receipt of post-LT DEXA did not differ by age ($p = 0.20$), sex ($p = 0.35$), race/ethnicity ($p = 0.34$), or liver disease etiology ($p = 0.36$). Low BMD was identified in 76.3% patients ($n = 90$) with OPe prevalence of 47.5%($n = 56$) and OPo prevalence of 28.8% ($n = 34$). The most common site of low BMD site was the femoral neck ($n = 82$) followed by lumbar spine ($n = 53$) and total hip ($n = 33$). Prevalent Low BMD decreased with increasing BMI: $<$ 22 -

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

88.9%, 22-24 - 85.7%, 25-29 - 77.5%, 30-34 - 67.9%, and ≥ 35 - 66.7%. Most Low BMD patients (n = 66) received treatment but only 25 received BMD-specific therapy with Alendronate (n = 8), Denosumab (n = 3), Zoledronic Acid (n = 11) or Biologics (n = 4). Patients who received BMD-specific therapy were more likely to have OPo (84.0% vs. 20.0%, p < 0.01) and MASLD (32.0% vs. 15.1%, p-0.05). BMD status varied by timing of DEXA scan, where early scans identified lower rates of Low BMD compared to standard/delayed DEXA (66.7% vs. 79.8%). Patients with normal DEXA (7.1%, n = 2) were less likely to have a repeat scan than patients with OPe (14.3%, n = 8) or OPo (26.5%,n = 9). Improvement in BMD was noted in 82% of those with initial Low BMD, and this was mostly observed in those who received BMD-specific treatment (90.9% vs. 44.4%, p = 0.02). **Conclusion:** Less than 50% of LTR in this cohort received screening for BMD, and among those screened the prevalence of Low BMD was exceedingly high. Early screening may miss cases low BMD, suggesting that repeat testing is needed after ≥ 6-18 months, even when initial scans are normal, to allow for adequate treatment.

3524 | PLASMA CELL-RICH REJECTION AFTER LIVER TRANSPLANTATION: NEW INSIGHTS INTO EVOLVING RISK FACTORS AND ETIOLOGIES

Thuy-Duyen Nguyen[1], [1]Mayo Clinic

Background: Plasma cell-rich rejection (PCRR) is an important and potentially severe cause of allograft dysfunction following liver transplantation (LT), with the potential to progress to graft failure and necessitate re-transplantation. PCRR is considered part of the spectrum of antibody-mediated rejection (AMR) and T-cell mediated rejection (TCMR). Despite its clinical significance, there is limited research on the risk factors that predispose liver transplant recipients to developing PCRR, highlighting a critical gap in the current understanding of its pathogenesis and prevention. **Methods:** Our study involved comprehensive data collection across 3 institutional sites of liver transplant recipients with liver biopsies demonstrating evidence of PCRR based on the 2016 update from the Banff Working Group on liver allograft pathology – plasma-cell rich infiltrate with etiology of liver disease other than autoimmune hepatitis (AIH). We compared this group to those who were transplanted for autoimmune hepatitis with liver biopsies demonstrating plasma cell hepatitis. **Results:** A total of 60 patients were identified in our patient cohort with 45 patients transplanted for an etiology excluding AIH and 15 patients transplanted for AIH. In the Non-AIH group, the most common etiology for liver transplant was primary sclerosing cholangitis (26.7%) and metabolic associated steatohepatitis (24.4%). The AIH group had more females (86.7% vs 49%, p = 0.03). Similar allografts were seen in both groups with no significant difference in average age of donor, donor:recipient gender mismatch and cold ischemic time. PCRR was more common within the first 2 years of transplant. The average rejection activity index score was 6.7 in the non-AIH group despite immunosuppression being therapeutic in 80% at time of PCRR. Sixteen percent of the PCRR cases had a prior infection with cytomegalovirus. **Conclusion:** This study represents the largest case series to our knowledge in evaluating PCRR. In the most recent series published in 2023, Ozturk et al. identified hepatitis C virus (HCV) as the most common underlying cause associated with

PCRR. However, with the advent of highly effective antiviral therapies, the incidence of HCV-related liver transplantation has significantly declined. In contrast, our findings suggest that patients undergoing transplantation for primary sclerosing cholangitis (PSC) and metabolic dysfunction-associated steatohepatitis (MASH) exhibit a higher incidence of PCRR, indicating a potential shift in the at-risk population. Further when compared to those transplanted for AIH, overall treatment and risk factors appeared similar between the two groups.

Ozturk et al. Histologic and clinical outcomes of patients developing post-liver transplant plasma cell-rich rejection. Am J Clin Pathol. 2023. 160(1): 49-57

3525 | PULMONARY FUNCTION TESTS AND FRAILTY ARE NOT ASSOCIATED WITH POST-LIVER TRANSPLANT VENTILATOR TIME, LENGTH OF INDEX HOSPITALIZATION OR RESPIRATORY COMPLICATIONS

Elina Stoffel[1] Avesh Thuluvath[2] Yuan Zhang[1] Elizabeth Verna[1], [1]Columbia University Medical Center, [2]Columbia University Irving Medical Center

Background: Pulmonary function tests (PFTs) are routinely performed during liver transplant (LT) evaluation, but their impact on post-LT outcomes is unclear. The interplay between pulmonary function and frailty is also unknown. We hypothesized that frailty could impair thoracic respiratory muscles, resulting in prolonged ventilator dependence and increased risk of respiratory complications after LT. In this retrospective study, we examined associations between pre-LT frailty, PFTs, and post-LT outcomes. **Methods:** We conducted a retrospective study of adults with cirrhosis who received LT at a large volume LT center from 2/2016-12/2024 and underwent pre-LT PFTs and frailty assessment using the Liver Frailty Index (LFI: grip strength, chair stands, balance). Patients with multi-organ or prior liver or lung transplants were excluded. Patients were classified as frail or not frail using established LFI cut-offs. Pulmonary function (FVC, FEV_1, FEV_1/FVC ratio, and DLCO) was assessed using spirometry $\pm$ body plethysmography and categorized as normal (FEV_1/FVC ratio $\geq 70\%$, FVC $\geq 80\%$, FEV_1 $\geq 80\%$), obstructive (FEV_1/FVC ratio $< 70\%$), or restrictive (FEV_1/FVC ratio $\geq 70\%$, FVC $< 80\%$) patterns. Primary outcomes were post-LT ventilator time, index ICU length of stay (LOS), and total index hospital LOS. The secondary outcome was post-transplant respiratory complications (a composite endpoint including pneumonia, pulmonary edema and pleural effusions) during the index admission. Multivariable linear and logistic regression were used to assess associations. **Results:** 175 patients were included (Table 1); 65% were male and the mean age was 60.7 years (SD $\pm$ 13.4). The most common etiologies included alcohol-associated liver disease (25%) metabolic-associated liver disease (17%) and autoimmune etiologies (AIH, PSC < PBC) (18%). Mean MELD score at LT was 15.3 $\pm$ 6.9. Mean LFI was 4.13 $\pm$ 0.79; 41 (23.4%) classified as frail. On univariable analysis, obstructive lung disease was associated with longer ventilator time ($p = 0.05$) but not index ICU LOS, hospital LOS, or respiratory complications. On multivariable analysis adjusting for age, BMI, MELD score, intra-op fluids, and history of COPD, asthma or CHF, obstructive lung disease was no longer associated with ventilator time or hospital LOS. Obstructive lung disease with frailty was associated with greater ventilator time ($p < 0.01$) and ICU LOS ($p = 0.04$) compared to obstructive lung disease without frailty. However, this association did not persist in adjusted models. **Conclusion:** Pre-LT PFT patterns were not associated with post-LT ventilator time, ICU LOS, or hospital LOS. These results differ from prior data suggesting that restrictive lung disease is associated with longer post-LT ventilator time, ICU LOS and hospital LOS. Additionally, our findings suggest that frailty is not associated with ventilator time or respiratory outcomes as hypothesized.

3526 | DELISTING DUE TO CLINICAL IMPROVEMENT (DCI) AS A SURROGATE FOR RECOMPENSATION IN THE ERA OF EFFECTIVE TREATMENTS FOR SEVERAL ETIOLOGIES OF DECOMPENSATED CIRRHOSIS: ANALYSIS OF UNOS DATA

Alexandra McCullough[1] Nadim Mahmud[1] K Rajender Reddy[2] Therese Bittermann[3], [1]Hospital of the University of Pennsylvania, [2]University of Pennsylvania, [3]Perelman School of Medicine

Background: Recompensation is increasingly being recognized as a tangible outcome for patients with decompensated cirrhosis for whom therapeutic strategies exist to interrupt and potentially reverse disease progression. Delisting from the liver transplant (LT) waitlist due to clinical improvement may be utilized as a surrogate for recompensation. Given that existing data in this context remain limited, we aimed to examine their rates and predictors. **Methods:** This retrospective cohort study using the Organ Procurement and Transplantation Network database identified ≥18-year-old patients listed for first LT alone between 01/01/2005 and 12/31/2024. Patients with acute liver failure or listed for primary liver malignancy were excluded. Characteristics of patients were obtained at waitlisting and waitlisting removal. Delisting due to clinical improvement (DCI) was identified using waitlist removal codes and was compared by disease etiology. A secondary outcome of relisting after prior DCI was also examined. We developed two recompensation criteria: (i) DCI plus MELD/MELD-Na by ≥3 points (DCI-MELD3) and (ii) DCI plus improvement in Child-Turcotte-Pugh (CTP) class (DCI-CTP). **Results:** Among 127,168 patients listed for LT, there were 8,747 that had DCI. Delisting rates were highest in hepatitis B (HBV) at 9.9%, alcohol-associated liver disease (ALD) at 8.3%, and autoimmune hepatitis (AIH) at 8.2%. Patients who were delisted within 3 years of initial listing had higher MELD, bilirubin, and INR and were more likely to have ascites at both initial listing and removal when compared to those delisted in ≥3 years (all $p < .001$). Among the patients with DCI, 49.1% achieved DCI-MELD3 and 48.6% DCI-CTP. Additionally, 9.6% were subsequently relisted after DCI, of which 33.0% were for hepatocellular carcinoma. On univariable analysis, meeting DCI-MELD3 or DCI-CTP were equivalent in their association with reduced relisting for LT: HR 0.77 and HR 0.79 versus meeting neither, respectively ($p = 0.005$ and $p = 0.03$; Table). In multivariable analyses, only patients who met both definitions had a significantly lower likelihood of relisting with an adjusted HR 0.52 ($p < 0.001$, Table). Other factors independently associated with increased relisting included: albumin <3.5 g/dL at initial DCI, male sex, and diagnosis of metabolic dysfunction-associated steatohepatitis, hepatitis C, primary biliary cholangitis, and primary sclerosing cholangitis (versus ALD as reference) (all $p < .001$). **Conclusion:** DCI occurred in a meaningful proportion of patients listed for LT, especially in HBV, ALD, and AIH. Nearly half of patients met criteria for improvement by MELD or CTP criteria alone at the time of delisting, with close to ten percent being subsequently relisted. Meeting both MELD and CTP-based definitions was linked to the lowest relisting risk, which may support their use in identifying true recompensation.

	HR (95% CI)	p-value
Unadjusted Recompensation criteria met at delisting		
Neither criteria	Reference	
MELD improvement ≥3 points only	0.769 (0.640-0.925)	0.005
Improvement in CTP class	0.792 (0.642-0.977)	0.03
Improvement MELD ≥3 points and CTP class	0.467 (0.383-0.569)	<.001
Adjusted* Recompensation criteria met at delisting		
Neither criteria	Reference	
MELD improvement ≥3 points only	0.865 (0.718-1.04)	0.13
Improvement in CTP class	0.861 (0.697-1.06)	0.164
Improvement MELD ≥3 points and CTP class	0.525 (0.429-0.643)	<.001

**Multivariable model adjusted for sex, age at delisting, and primary liver disease*

3527 | ASSOCIATION BETWEEN PRE-LIVER TRANSPLANT CORONARY ARTERY DISEASE RISK AND ALL-CAUSE MORTALITY AFTER LIVER TRANSPLANT: A SINGLE CENTER EXPERIENCE

Alexander Dile[1] Joshua Musalia[1] Tanner Thornsberry[1] Patricia Guzman Rojas[1] Askanda Osman[1] Matthew Still[1] April Gettelfinger[1] Victor Akinditan[1] Jordan Voss[1] Debra Yen[2] John Barnes[1] Jacob Ciricillo[1] Yeshika Sharma[3] Elizabeth Sprague[1] Nadia Alam[1] Clifford Ukarajit[1] Kyra Simmons[1] Edward Danso[4] Khurram Bari[1] Michael Schoech[1] Shimul Shah[5] Adam Myer[1] Kristina Lemon[1] Ralph Quillin[1] Alex Chang[1] Christine Haugen[1] Courtney Jones[1] Tiffany Kaiser[1] Luis Lara[1] Inuk Zandvakili[1] Bianca Wolmarans[1] Wei-Wen Hsu[1] Amoah Yeboah-Korang[1], [1]University of Cincinnati College of Medicine, [2]University of California San Francisco, [3]Baylor University Medical Center, [4]Greater Accra Regional Hospital, [5]Massachusetts General Hospital

Background: CVD is a leading cause of death after LT. Pre-LT CAD risk stratification guides pre-op optimization. Limited data exists on the relationship between pre-LT CAD risk stratification and all-cause mortality post-LT. The primary aim of this study was to examine the association between pre-LT CAD risk classification and all-cause mortality post-LT. **Methods:** Patients who had LT at a single center from 2012 to 2018 with follow-up through 2024 were reviewed. Pre-LT CAD risk groups were: low (no CAD risk factors, age < 40, and achieves ≥ 4 METs), intermediate (< 2 CAD risk factors, no diabetes, and no MASH), high (silent MI on ECG, new wall motion abnormality on ECHO, new EF $< 50\%$, diabetes, MASH, or ≥ 2 CAD risk factors), and very high (prior CAD, PCI, MI, CABG, or CVD). CVD included CAD, CVA, PAD, or aortic atherosclerosis. CAD risk factors included: hypertension, hyperlipidemia, CKD with eGFR < 40, left ventricular hypertrophy, tobacco use, family history of early CAD, and age > 60. Post-LT all-cause mortality for the other CAD risk groups were compared to low risk. **Results:** Among 576 LT recipients, 37.5% were female, mean age at LT 57 $\pm$ 10 years, 92.0% White. Primary indication for LT was MASH 29.9%, and alcohol 24.0%. Before LT, average BMI was 30 $\pm$ 6, tobacco use 51%, hypertension 46.5%, diabetes 36.5%, hyperlipidemia 22.1%, CAD 13.9%, CHF 7.1% and atrial fibrillation 5.0%. Pre-LT CAD risk groups included 7.3% low risk, 16.5% intermediate risk, 60.5% high risk, and 15.7% very high risk. By the end of 2024, 147 deaths (25.5%) had occurred. Infections accounted for 32% of deaths, cancer 16.3%, liver allograft failure 13.6%, CVD 11.6%, respiratory failure 3.4%, renal failure 2.7%, other 13.6%, and undetermined 6.8%. All-cause mortality in the CAD low risk group was 19.5%, intermediate risk 23.7%, high risk 25.4%, and very high risk 31.5%. Compared to low CAD risk, all-cause mortality OR in intermediate risk was 1.28 (95% CI 0.52, 3.17), high risk 1.41 (95% CI 0.63, 3.16), and very high risk 1.89 (95% CI 0.78, 4.6). **Conclusion:** Most LT recipients were considered to be high CAD risk based on the pre-LT CAD risk classification protocol at a single center. Increasing pre-LT CAD risk was associated with higher odds of all-cause mortality post-LT which were not statistically significant.

Andrea Gianatti[1] Sandro Sironi[4] Stefano Fagiuoli[4], [1]ASST Papa Giovanni XXIII, Bergamo, Italy, [2]ASST Bergamo Est, Seriate, Italy, [3]ASST Papa Giovanni XXIII, Bergamo, Italy., [4]ASST Papa Giovanni XXIII, Bergamo, Italy; University of Milano-Bicocca, Monza, Italy

Background: Veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS) after liver transplantation (LT) is a rare complication, and best treatment and long-term outcome are still undefined. Aim of this study is to evaluate the management and outcome of VOD/SOS after LT. **Methods:** All patients transplanted at Liver Transplant Center of the ASST Papa Giovanni XXIII Hospital in Bergamo who consecutively developed VOD/SOS were retrospectively evaluated. **Results:** Among the 1123 adult patients who underwent LT between 1997-2022, 37 (3%) patients [70% males, median age 51 years, 49% viral-etiology, 19 % Hepatocellular carcinoma (HCC), Model for End-Stage Liver Disease (MELD)-Na 14 (11-26)] had histologically proven VOD/SOS. All patients presented with ascites, associated with hydrothorax in 4 (11%) cases. Median time of VOD/SOS onset was 45 (10-432) days and median hepatic venous pressure gradient (HVPG) was 13.5 (8-22) mmHg. In 6 (16%) patients VOD/SOS developed 24 (13-201) days after acute cellular rejection (ACR), whereas 2 (5%) patients had concomitant ACR and VOD/SOS occurrence. After two months from VOD/SOS onset, 18 (49%) of patients solved ascites: 5 (28%) spontaneously, 2 (11%) with defibrotide and 11 (61%) after transjugular intrahepatic portosystemic shunt (TIPS) placement. TIPS placement was independently associated with ascites resolution at 2 months [HR 3.26 (1.25-8.46), $p = 0.015$]. Overall, during a median follow up of 62 months, 14 (38%) patients showed spontaneous clinical improvement after a median time of 41 days (17-259) and 23 (62%) underwent TIPS placement, The latter patients had HVPG reduced from 14 (3-40) to 8 mmHg (2-20), 3 (13%) developed porto-systemic encephalopathy, which resolved with medical therapy in 2 cases and with TIPS caliber reduction in the other one. Patients treated with TIPS had higher HVPG values and were younger compared those patients who experienced spontaneous clinical improvement [HR 4.4 (1.61-12.10), $p = 0.004$ and HR 0.96 (0.93-0.99), $p = 0.016$, respectively]. Overall, 4 (11%) patients needed re-OLT, 1 (3%) for tipsitis, 1 (3%) for hepatic arterial thrombosis and 2 (5%) for delayed dysfunction of graft whereas 15 patients died, 3 (8%) for HCV recurrence, 3 (8%) for hepatocellular carcinoma (HCC) recurrence, 4 (11%) for sepsis, 1 (3%) for lung cancer, 2 (5%) for myocardial infarction, 2 (5%) for ictus. The 1-, 3-, and 5-year survival rates did not differ significantly between patients who experienced spontaneous resolution of ascites and those who required TIPS placement [100%, 97% and 71% vs 95%, 73%, and 56%, respectively (HR = 4.75; 95% CI: 0.58–38.7)]. **Conclusion:** VOD/SOS is a rare post-LT complication associated with ACR in nearly a quarter of cases. HVPG $\geq$ 13.5 mmHg at VOD/SOS diagnosis identified patients without spontaneous clinical improvement that need TIPS placement. TIPS appears to be a safe and effective treatment for SOS/VOD, with no significant impact on long-term survival.

3529 | PRE-TRANSPLANT ECHOCARDIOGRAPHIC PREDICTORS OF POST-TRANSPLANT CARDIAC EVENTS

Ali Albenmousa[1] Saleh Alqahtani[2] Dieter Broering[3] Dimitrios Raptis[4] Mohamed Tahir[5] Maryam Abdulla[6] Waleed Haj Ahmad[6] Syeda Shamsi[6] Ahmad Alissa[6] Manhal Izzy[7] Bandar Aljudaibi[8], [1]Consultant transplant hepatologist, King Faisal Specialist Hospital and Research Center, [2]Consultant Gastroenterologist, King Faisal Specialist Hospital and Research Center, [3]Liver Transplant Surgeon, King Faisal Specialist Hospital and Research Center, [4]Consultant Hepatobiliary surgeon, King Faisal Specialist Hospital and Research Center, [5]Consultant Cardiologist, King Faisal Specialist Hospital and Research Center, [6]Medical student, Alfaisal University, [7]Vanderbilt University Medical Center, [8]Transplant Hepatologist, King Faisal Specialist Hospital and Research Center

Background: Echocardiography is integral to pre-LT cardiac risk assessment and Cardiac disease is a leading cause of morbidity and mortality post-LT. The pre-LT echocardiographic assessment has significantly evolved in the recent years. This study explores its predictive value for post-LT cardiac outcomes. The aim of the study is to determine the utility of contemporary echocardiographic markers in predicting post-LT cardiac events. **Methods:** Among 745 adult LT recipients, pre-transplant echocardiograms assessed left ventricular function (systolic and diastolic), and valvular disease. Outcomes included cardiac death, MI, and arrhythmias. **Results:** The mean age at LT was 56 years, with 267 female patients constituting 37.1%

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

of the cohort. Among the patients, 220 (29.7%) developed liver cirrhosis secondary to Metabolic Associated Fatty Liver Disease. The prevalence of systolic dysfunction, defined by an ejection fraction (EF) of $<45\%$, was low(0.4%). Diastolic dysfunction, characterized by abnormal left ventricular (LV) relaxation, filling, diastolic distensibility, or diastolic stiffness, was present in 12.3% of patients pre-LT and was associated with higher rates of cardiac death (3.2% vs. 1.1%, $*p^* = 0.04$) and heart failure (4.8% vs. 0.9%, $*p^* < 0.01$), after controlling for confounding factors such age, gender, diabetes, hypertension, obesity and, smoking history. An EF $<45\%$ (0.4%) correlated with 100% mortality ($n = 3$). Trace tricuspid regurgitation was observed in 78.1% of patients. Patients with abnormal right ventricular pressure (RVP) (2.6%) exhibited an increased risk of MI (HR = 2.4, $*p^* = 0.02$). Notably, 95.7% of patients with a normal EF ($>55\%$) still experienced cardiac events, with a 19.6% incidence of MI. **Conclusion:** Diastolic dysfunction, valvular abnormalities, and elevated RVP on pre-LT echocardiography predict post-transplant cardiac morbidity. Comprehensive cardiac evaluation beyond EF and right ventricular systolic pressure is essential for risk stratification.

3530 | FROM BENCH TO COMPUTATIONAL MODELING: INTEGRATING MITOCHONDRIAL STRESS DATA FROM A RAT HEPATIC ISCHEMIA-REPERFUSION INJURY MODEL INTO A PRECLINICAL AND HUMAN QUANTITATIVE SYSTEMS TOXICOLOGY PLATFORM

Joohyun Kim[1], [1]Yale University School of Medicine

Background: Hepatic ischemia-reperfusion injury (IRI) is a key driver of liver dysfunction after surgery and transplantation, involving intricate mitochondrial, oxidative, and inflammatory mechanisms. Quantitative systems toxicology (QST) modeling provides a powerful framework to integrate mechanistic experimental data, simulate injury dynamics, and evaluate biomarkers and therapeutic strategies in IRI. **Methods:** Hepatic mitochondria were isolated from sham- and IRI-treated rats ($n = 5$/group, 1 h ischemia + 1 h reperfusion), after which mitochondrial respiration was assessed via extracellular flux analysis. Sequential addition of substrates (pyruvate/malate, succinate/rotenone, or NADH) and modulators (oligomycin, FCCP, rotenone, antimycin A) allowed evaluation of electron transport chain (ETC) function. Cytochrome c addition assessed outer membrane integrity, while alamethicin was used to permeabilize the inner membrane for NADH delivery to mitochondrial complex I. DPI and azide were used to inhibit complexes I and IV, respectively. A QST model of preclinical and human liver biochemistry (DILIsym®) was used to explore mechanistic hypotheses in hepatic IRI based on the obtained experimental data. **Results:** In the IRI group, pyruvate/malate-induced oxygen consumption rate (OCR) was reduced to 40%, indicating impairment in the TCA cycle or complex I. Succinate/rotenone treatment yielded similar OCR between groups, suggesting intact complex II and downstream ETC function. NADH-driven respiration was preserved in IRI, indicating functional complex I and implicating TCA cycle dysfunction upon IRI. These and additional biomarker data were used to estimate a proof-of-concept parameterization of hepatic IRI in DILIsym®, which recapitulated maximum aminotransferase levels observed in IRI rats, and generated predicted aminotransferase profiles that aligned with historical human IRI data following 60 minutes of liver ischemia. **Conclusion:** Subcellular bioenergetic data from animal models of hepatic IRI offer mechanistic insights that can be leveraged in QST modeling to inform human translation. This integrative approach serves as a bridge between preclinical findings and clinical trial design, supporting hypothesis generation while helping to reduce reliance on further animal experimentation.

3531 | HEPATIC RESERVE AND REGENERATION IN LIVING DONORS AFTER RIGHT HEPATIC LOBECTOMY: A PILOT STUDY OF THE ORAL CHOLATE CHALLENGE TEST

Michael McRae[1] Joanne Imperial[2] touraj shokati[2] Gregory Everson[3], [1]Custom DX Solutions LLC, [2]HepQuant, LLC, [3]HepQuant

Background: Donor safety and outcomes are a primary concern for living donor programs. Although regeneration typically occurs rapidly after resection, short-term functional impairment is common. In this study, we used the oral cholate challenge test to measure the recovery of function over 6 months in living donors who underwent right lobectomy. **Methods:** 12 donors were recruited from the Adult-to-Adult Living Donor Liver Transplantation Cohort Study (A2ALL) (Everson et al., 2013) at two clinical centers. Donors were tested pre-donation and post-donation (7 days, 3 months, and 6 months). HepQuant DuO test parameters, including portal hepatic filtration rate (HFR) and hepatic reserve (HR%), were quantified from 20- and 60-min concentrations of orally administered d4-cholate (40 mg) (McRae et al., 2024). Hepatic volumes (mL/kg body weight) after right lobectomy were measured at the same intervals using CT. HR%, which is a score from 100% (full hepatic reserve) to 0% (no hepatic reserve) representing cholate clearance indexed to healthy controls with lean body mass, was compared to the percentage of pre-donation liver volume by CT. **Results:** The mean age of donors was 38 years (range 21–54), body mass index 25 ± 3, and M:F ratio of 4:8. The liver volume remaining immediately after right lobectomy was estimated at 32% ± 4% of pre-donation. Pre-donation laboratory values were normal; by day 7, bilirubin, INR, and ALT were higher and albumin was lower; by 3 months, values trended towards the pre-donation levels and by 6 months, all values returned to pre-donation levels. The mean portal HFR, 26 ± 9 mL/min/kg pre donation, was significantly lower post donation at day 7 (13 ± 6 mL/min/kg, $p = 0.003$). At 3 months, portal HFR recovered to 17 ± 6 mL/min/kg but was still significantly lower than pre donation ($p = 0.014$). At 6 months, portal HFR recovered to pre-donation levels, 24 ± 16 mL/min/kg ($p = 0.682$). The initial loss and recovery of hepatic function further quantified by HR% mirrored the regeneration of liver volume by CT (Pearson $r = 0.6$, $p < 0.001$) (Figure). **Conclusion:** The oral cholate challenge test measured alterations in the portal circulation and cholate uptake following right lobe donation and quantified the recovery of function associated with regeneration of liver volume. Although additional studies with longer term follow up are warranted, the oral cholate challenge test may be useful in the initial assessment and monitoring of liver function in living donors.

3532 | PREDICTORS AND RISK STRATIFICATION OF SIGNIFICANT CORONARY ARTERY CALCIFICATION IN LIVER TRANSPLANT CANDIDATES: A CROSS-SECTIONAL ANALYSIS

Sohil Khurana[1] Reanay Berezovskiy[1] Toby Bradford[1] Nabil Dagher[1] David Stern[1] Sanjaya Satapathy[1], [1]Northshore- LIJ Health System (Northwell Health)

Background: Coronary artery calcium (CAC) scoring by computed tomography is increasingly used for cardiovascular risk assessment in liver transplant candidates, but predictors of significant calcification remain poorly characterized. **Methods:** We conducted a cross-sectional study of 254 liver transplant candidates based on our institutional risk stratification protocol, 66 underwent CAC scoring. Significant coronary calcification was defined as CAC score ≥100. Clinical, demographic, and laboratory parameters were analyzed using univariate and multivariate logistic regression to identify predictors of significant calcification. A clinical risk score was developed and validated. **Results:** Of 66 patients who underwent CAC scoring out of 254 patients, 32 (48.5%) had significant coronary calcification. In multivariate analysis, male sex (OR 4.17, 95% CI 1.31-16.53, $p = 0.025$), metabolic dysfunction-associated steatohepatitis (MASH) (OR 4.44, 95% CI 1.47-13.62, $p = 0.008$), and Other/Multiracial ethnicity (OR 3.23, 95% CI 1.20-8.70, $p = 0.019$) were independently associated with increased odds of significant calcification. Conversely, higher MELD scores were protective (OR 0.94 per point, 95% CI 0.88-0.99, $p = 0.031$). A clinical risk score incorporating age, MELD score, race, MASH, sex, and cardiovascular

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

risk factors (hyperlipidemia, hypertension, diabetes) was developed. The score stratified patients into low (≤ 3 points), intermediate (4-6 points), and high risk (>6 points) categories, demonstrating good discrimination for identifying patients with significant coronary calcification. **Conclusion:** Male sex, MASH, and Other/Multiracial ethnicity are independent predictors of significant coronary calcification in liver transplant candidates, while higher MELD scores appear protective. The proposed clinical risk score may help identify patients who would benefit most from CAC screening before liver transplantation.

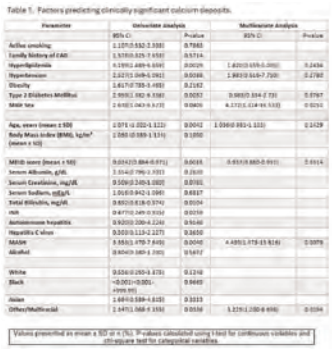

Figure 1. ROC curve for clinical risk model

3533 | SURVIVAL BENEFIT OF LIVER TRANSPLANTATION IN ALCOHOL-ASSOCIATED LIVER DISEASE: INSIGHTS FROM A NATIONAL CLAIMS DATABASE

Wanzhu Tu[1] Lauren Nephew[1] Yining Li[1] Shihui Jiang[1] Yang Li[1] Chi Nguyen[1] Jing Su[1] Naga Chalasani[2] Suthat Liangpunsakul[1] Samer Gawrieh[1], [1]Indiana University, [2]Indiana University Medical Center

Background: Alcohol-associated liver disease (ALD) is a leading indication for liver transplantation (LT), yet access remains limited and practice varies among transplant centers. Few studies have quantified the real-world survival benefit of LT in this population, which is critical to inform clinical and policy decisions. **Methods:** We conducted an observational study using the Optum claims database, which includes individuals covered by commercial insurance and Medicare Advantage plans. Using validated ICD codes, we identified 373,025 adults with incident ALD between January 1, 2017, and August 31, 2024, excluding those with prior LT. Among them, 3,453 received LT. Logistic regression was used to examine factors associated with receiving LT. Cox proportional hazards regression was applied to compare mortality between LT recipients and non-recipients, while controlling for patient demographics and comorbidities. **Results:** Female sex (OR = 0.78; 95% CI:0.73–0.84), older age (OR = 0.949; 95% CI:0.947—0.952), African American race (OR = 0.597; 95% CI:0.509–0.700), and the presence of non-liver-related chronic diseases were associated with a lower likelihood of receiving LT. In contrast, cirrhosis (alcoholic or unspecified), ascites, hepatic encephalopathy (HE), and gastrointestinal (GI) bleeding were associated with increased likelihood of LT. The median time from initial ALD diagnosis to LT was 330 days. Among the 369,572 patients who did not undergo LT, 38.2% died, compared to 13.2% of those who received LT. Among those who died, the median survival after the initial ALD diagnosis was approximately 1,000 days for LT recipients and 355 days for non-recipients. In adjusted analyses, LT was associated with a significantly lower risk of mortality (HR = 0.37; 95% CI: 0.34–0.40). Other factors associated with reduced mortality included female sex (HR = 0.88; 95% CI: 0.87–0.89), Asian race (HR = 0.71; 95% CI: 0.68–0.74), and Hispanic ethnicity (HR = 0.95; 95% CI: 0.93–0.97). Conversely, the presence of ascites (HR = 2.07; 95% CI: 2.04–2.09), HE (HR = 1.62; 95% CI: 1.59–1.66), hepatorenal syndrome (HR = 1.55; 95% CI: 1.53–1.58), and GI bleeding (HR = 1.08; 95% CI: 1.06–2.0) was associated with increased mortality. Chronic conditions such as diabetes, heart failure, cancer, and kidney disease also elevated mortality risk. **Conclusion:** LT is associated with substantially improved survival in patients with ALD but remains underutilized in certain subgroups, including women and African Americans. Fndings from the current study highlight the life-saving potential of LT and support the need for initiatives to promote more equitable access for all eligible ALD patients.

Figure (A) Kaplan-Meier survival curves comparing overall survival between patients who received liver transplantation (LT) and those who did not. **(B)** Distribution of survival times among deceased patients, stratified by LT status. Vertical dashed lines indicate the median survival time for deceased LT recipients and non-recipients.

3534 | MECHANISTIC TARGET OF RAPAMYCIN INHIBITORS (MTORI) UTILIZATION AMONG U.S. LIVER TRANSPLANT RECIPIENTS IS LARGELY DRIVEN BY CENTER PREFERENCE

Therese Bittermann[1] David Goldberg[2] David Kaplan[3] Douglas Schaubel[4], [1]Perelman School of Medicine, [2]University of Miami, [3]University of Pennsylvania, [4]University of Pennsylvania Perelman School of Medicine

Background: Clinical trials have suggested that mechanistic target of rapamycin inhibitors (mTORi) may offer benefits for liver transplant (LT) recipients with renal dysfunction or hepatocellular carcinoma (HCC). Real world data on the utilization of mTORi in LT on a broad scale are lacking. Yet, these data are vital to understand barriers to evidence-based prescribing, quantify missed opportunities or inappropriate medication use, and inform future practice guidelines and new drug development. **Methods:** This was a retrospective cohort study using a data linkage of Medicare inpatient, outpatient and prescription claims and the Organ Procurement and Transplantation Network database. Adult (age 18+) recipients of first LT between 1/1/2007-12/31/2019 were included. mTORi utilization was identified from claims data with follow-up starting at LT date for all patients. Using Cox regression, we modeled the time until mTORi initiation, stratified by center and adjusting for predictors observed at transplant and a set of 18 time-updating Medicare-derived comorbidity indicators. In addition, we modeled duration of mTORi use (which accounted for stoppages) using linear regression and adjusting for predictors observed at LT. **Results:** Of 17,239 patients with overall median follow-up time 3.8 years (IQR: 1.2-7.1), 20.5% were prescribed mTORi. Median time from LT to mTORi initiation was 5.0 months (IQR: 2.0-14.6). Considerable heterogeneity in mTORi utilization was observed across the 120 LT centers (Figure 1A). Over 50% of centers prescribed mTORi to 10-20% of patients. Patient factors independently associated with mTORi initiation are shown in Figure 1B. mTORi initiation decreased over time (adjusted HR = 0.98 per calendar year, $p < 0.001$). Prediction of mTORi initiation improved minimally with addition of time-updating post-LT comorbidity variables (c-index 0.63 from 0.60 with baseline variables at LT only), but a significant increase in predictive power was observed when center also included in the model (c-index 0.70). Among the 3,535 patients prescribed mTORi, median (total) duration of use was 12.9 months (IQR: 4.8-37.0 months). Patient factors independently associated with increased mTORi duration included increasing age at LT (1.3 months per 5 year increase; $p < 0.001$) and primary sclerosing cholangitis diagnosis (10.2 months; $p < 0.001$). mTORi duration was not associated with history of hepatocellular carcinoma or renal dysfunction at LT (all $p > 0.05$). **Conclusion:** Patients initiating mTORi appear to have a less favorable risk factor profile, with rates being significantly increased among patients who are older or incur comorbidities. mTORi use varies considerably across centers, independent of patient case-mix. Duration of therapy is overall short. These issues must be accounted for in future studies evaluating the relationship between mTORi utilization and outcomes such as survival.

Factors affecting mTORi utilization among U.S. liver transplant recipients (n=17,239)

3535 | USING THE ROCHESTER EXPERIENCE IN LIVING DONOR LIVER TRANSPLANTATION (LDLT) FOR UNRESECTABLE COLORECTAL LIVER METASTASIS (CRLM) TO EVALUATE THE UTILITY OF CIRCULATING TUMOR DNA (CTDNA) IN SURVEILLANCE FOR DISEASE RECURRENCE

Abigail Loszko[1] Matthew Byrne[1] Cristina Jimenez-Soto[2] Mariana Chávez-Villa[3] Jennifer Melaragno[4] Nicholas

Lim[2] Benyam Addissie[2] Yuki Bekki[2] Amit Nair[2] Koji Tomiyama[2] Roberto Hernandez-Alejandro[2],
[1]Department of Surgery, University of Rochester Medical Center, [2]Transplant Institute, University of Rochester Medical Center, [3]Division of Transplant Surgery, Mayo Clinic, [4]Department of Pharmacy, University of Rochester Medical Center

Background: CRLM is a growing indication for liver transplantation in the United States, with 153 cases performed across 33 centers as of March 2025. ctDNA is also emerging as a powerful biomarker in transplant oncology, offering improved surveillance and early recurrence detection. We report our institutional experience using ctDNA in LDLT for CRLM. **Methods:** Single-center, retrospective cohort analysis of adults who underwent LDLT for CRLM from 9/2019-10/2024. ctDNA results from Signatera molecular residual disease assays were assessed when available. Descriptive statistics and Kaplan-Meier analysis were performed using Stata MP 18. **Results:** 25 patients underwent LDLT for CRLM: 15 (60%) male; median age 44 years (IQR 40-53). 24 (96%) had synchronous liver metastases. Median time to LDLT was 18.9 months (IQR 14.3-22.5) from CRLM diagnosis and 9 months (IQR 6.6-15.1) from primary resection.

Postoperatively, 11 (44%) patients had biliary leaks. 7 (28%) returned to the operating room for bleeding or vascular complications. 1 patient underwent deceased donor retransplant for acute hepatic artery thrombosis. 3 (12%) were medically treated for biopsy-proven rejection. Overall survival (OS) at 1, 2, and 3 years was 100%, 90%, and 90%; recurrence-free survival (RFS) was 71%, 51%, and 38% (Figure). 13 patients (52%) developed post-transplant recurrence, most commonly in the lung (n = 9), followed by liver (2), peritoneum (2), colorectal resection site (1), and bone (1). 2 patients had multi-organ involvement at detection. All 5 deaths followed disease recurrence; both patients with liver recurrence died.

ctDNA results were available in 19 patients (76%). All 5 with pre-transplant testing had negative results, with median RFS of 12.2 months (IQR 11.7–26.9) after LDLT. Among 18 patients with post-transplant ctDNA results, 9 (50%) remained persistently negative (median RFS 26.9 months, IQR 12.6–36.2), and the other 9 (50%) had at least one positive result (median RFS 11.8 months, IQR 9.3–12.6). Of 9 patients with both imaging-confirmed recurrence and post-transplant ctDNA data, ctDNA was positive in 7 (sensitivity 78%), preceding imaging in 2 cases by 1 and 9 months. Among the 9 with persistently negative ctDNA, 7 remained recurrence-free (negative predictive value 78%). **Conclusion:** Our transplant oncology experience with LDLT for CRLM demonstrates acceptable outcomes, likely driven by careful selection and multidisciplinary management. ctDNA in post-LT surveillance shows promise in recurrence risk stratification.

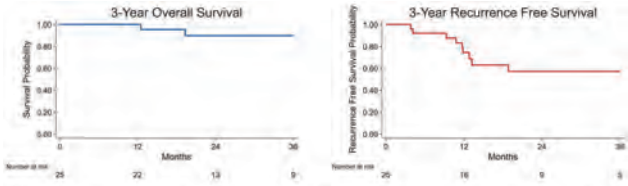

Figure. Overall and recurrence free survival proportions of living donor liver transplant recipients for colorectal liver metastases over a three-year period.

3536 | UTILIZATION AND OUTCOMES OF MARGINAL LIVER DONORS AT A HIGH-VOLUME TRANSPLANT CENTER

Yasmeen Saker[1], [1]University of Florida

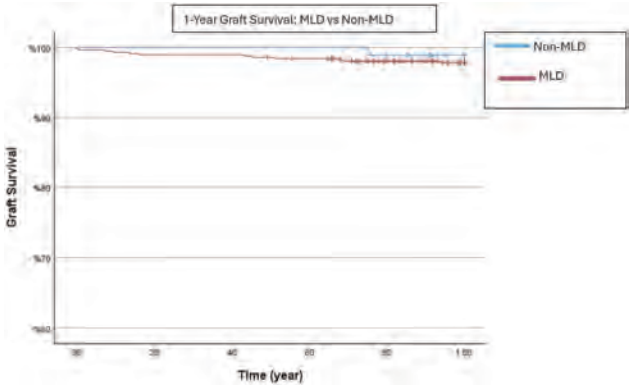
Background: The demand for liver transplantation continues to rise and outpaces donor availability. This has led to increased utilization of marginal liver donors (MLDs) across transplant centers. Most center outcomes compare single risk factor MLDs and do not encompass the multiple risk factors that define MLDs. This study aimed to describe utilization patterns of MLDs, and graft survival outcomes associated with the use of these MLDs at a high-volume center. **Methods:** We conducted a retrospective cohort study of adult liver transplant recipients at the University of Florida who received liver transplant between January 2019 and September 2024. Donors were classified as MLDs if they met at least one predefined high-risk criterion: age > 65 years, BMI > 30, ICU stay > 4 days, serum sodium > 160 mmol/L, abnormal liver function tests (ALT > 105 U/L, AST > 90 U/L, or bilirubin > 3 mg/dL), substance use history, extrahepatic malignancy, donation after circulatory death (DCD), cold ischemic time > 12 hours, and/or viral hepatitis (HBsAg, HBcAb, or HCV Ab positivity). Patients were followed until graft failure or their last clinic visit. Graft failure was defined as the need for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

retransplantation or death. Graft survival at 1 and 3 years was estimated using Kaplan-Meier analysis and compared to recipients of non-MLD grafts using log-rank testing ($p < 0.05$ considered significant). **Results:** During the study period, a total of 649 liver transplants were performed at our center, of which 559 (86.1%) were classified as MLDs. Among these, 58.7% had substance use history, 45.4% had demographic risk (age, BMI, or cancer), and 31.7% had abnormal labs. Viral hepatitis was present in 24.7%, DCD in 11.3%, and ICU stay >4 days in 4.1%. Over half (55.6%) had multiple marginality criteria. Donors had a median age of 42 years; recipients had a mean age of 53.5, mean MELD-Na of 26.5, and 60.8% were male.

One- and three-year graft failure rates were 5.6 vs 1.1% and 8.1% vs 2.3% in the MLD vs non MLD groups respectively ($P = 0.4$). One- and three-year graft survival for the MLD recipients was 97.8% and 88.3%, respectively, which was not significantly different from non-MLDs (98.9% and 91.2%, $p = 0.514$ and $p = 0.58$, respectively). **Conclusion:** At a high-volume center, MLDs comprised the majority of transplants and yielded excellent short- and long-term graft survival, comparable to non-MLDs. These findings support broader, data-driven use of marginal donors and challenge traditional risk assumptions in liver allocation.



Disclosures: Yasmeen Saker: Nothing to Disclose

3537 | NEW SUBMISSION: INSTITUTIONAL APPROACHES TO LIVER TRANSPLANT EVALUATION FOR ALCOHOL-ASSOCIATED LIVER DISEASE (ALD): A PROTOCOL-BASED COMPARISON

Esra Alagoz[1] Megan Saucke[1] Brian Fisher[1] Marina Serper[2] Sheila Eswaran[3] Keren Ladin[4] John Rice[5] Brian Lee[6] George Therapondos[7] Mohamed Shoreibah[8] Marc Ghobrial[9] Neha Jakhete[10] Christine Hsu[11] Michael Lucey[5], [1]University of Wisconsin School of Medicine and Public Health, [2]University of Pennsylvania Health System, [3]Rush University Medical Center, [4]Tufts University, [5]University of Wisconsin, [6]Keck School of Medicine, [7]Ochsner Medical Center, [8]University of Alabama at Birmingham, [9]Houston Methodist, [10]University of Maryland, [11]National Institute of Diabetes, Digestive

Background: Background:: Despite increasing acceptance of early liver transplantation (LT) for selected patients with alcohol-associated liver disease (ALD) (i.e. patients with <6 months abstinence), national guidelines leave room for center-level discretion, resulting in differing interpretations and applications of key criteria and the potential for institutional variation in evaluation and listing practices. **Methods:** Methods:: We conducted a comparative analysis of internal LT evaluation protocols dated from 2019 to 2025 from a purposive sample of seven sites in the geographically diverse ACCELERATE LT consortium. We reviewed all documents that included alcohol-specific criteria. Protocols were analyzed based on the principles of qualitative document analysis using inductive thematic analysis. **Results:** Results:: Across institutions, we found heterogeneity and ambiguity in how evaluation criteria for ALD were articulated. Only 4 centers had explicit criteria for early LT. Themes that emerged during analysis include approaches to evaluation, criteria for abstinence, psychiatric conditions, social support, and patient collaborativeness. All centers had flexible language in their policies, allowing for evaluation criteria to be applied on a case-by-case basis, subject to committee approval. The urgency of LT was addressed across all centers, with explicit benchmarks for MELD and/or MDF scores guiding prioritization decisions. The presence of unmanageable psychiatric conditions was an exclusion criterion at all centers. The most elaborate aspects of the protocols pertained to assessments of social support systems and patient collaborativeness, which referred to the patient's demonstrated prior engagement with care, including insight into their diagnosis of alcohol use disorder and a willingness to adhere to post-LT care plans. All centers evaluated social support systems that might mitigate the risk of post-LT return to drinking. Factors that were considered inconsistently across centers included patient finances, housing, history of incarceration, and negative legal consequences of alcohol use. **Conclusion:** Conclusion:: Our analysis demonstrated differences in how transplant centers define eligibility for ALD patients, challenging the consistency in access to LT and highlighting a need for greater transparency to promote fair and evidence-informed selection processes. A prospective study is needed to demonstrate whether center-specific policies align with clinical decision making and post-LT outcomes.

3538 | PSYCHOLOGICAL, SOCIODEMOGRAPHIC AND SEX-RELATED PREDICTORS FOR WAITLIST ENROLLMENT, LIVER TRANSPLANTATION AND SURVIVAL

Maria Rosina Troppmair[1] Johanna Lentsch[1] Claudia Kohl[2] Nadin Haslwanter-Egger[2] Messina Bath[1] Marlene Panzer[1] Lorenz Michael Pammer[1] Rupert Oberhuber[3] Katharina Huefner[2] Herbert Tilg[1] Heinz Zoller[1] Benedikt Schaefer[1], [1]Department of Medicine I, Medical University of Innsbruck, Innsbruck, Austria, [2]Department of Psychiatry, Medical University of Innsbruck, Innsbruck, Austria, [3]Department of Visceral, Transplant and Thoracic Surgery, Medical University of Innsbruck, Innsbruck

Background: End-stage liver disease and liver transplantation (LT) are strongly associated with psychological distress, depression and addiction. A comprehensive psychiatric evaluation is integrated in the pre-transplant assessment at our center. This study aims to evaluate the impact of psychiatric risk factors, social environment and sex on pre- and post-transplant outcomes. **Methods:** In this single-center retrospective study, candidates for LT that underwent standardized psychiatric evaluation at our center were included. We analyzed the impact of psychological and sociodemographic covariates on waitlist enrollment, LT and overall survival. **Results:** Between 2007 and 2021, 991 patients were evaluated (25.3% females), 695 (70.1%) of them were listed for transplantation (23.2% females) and 572 (82.3%) of the listed patients underwent LT (23.4% females). Transplanted patients showed a significantly longer median survival (12.9 years) than patients who did not undergo LT (2.2 years, $p < 0.001$). The majority of LT candidates had a history of harmful drinking (51% of females, 65.4% of males), which was associated with significantly worse survival in the overall cohort, but not in the subgroup of patients that underwent LT. Similarly, patients with high psychiatric risk estimate had significantly shorter survival in the overall cohort (Figure A), but not if they underwent LT (Figure B). Patients who were not listed or transplanted (n = 419) were more often living alone (26.3% vs. 17.9%, $p = 0.004$), had a weaker social network (86.7% vs. 95.1%, $p < 0.001$) and lower educational attainment (apprenticeship/blue collar: 63.5% vs. 53.5%, $p = 0.006$; higher education: 6.1% vs. 10.9%, $p = 0.017$), higher rates of addiction treatment (24.2% vs. 13.4%, $p < 0.001$), psychiatric disorders (41.4% versus 32%, $p = 0.004$), and an higher AUDIT risk score (> 15 points 34.8% vs. 19.4%, $p < 0.001$). Female sex was identified as a negative predictor for being listed for LT (*OR* 0.58, $p = 0.032$), whereas strong social support increased listing probability (*OR* 2.4, $p = 0.018$) in a multivariate regression analysis. **Conclusion:** Psychological disorders, limited social support and substance abuse were associated with a lower likelihood of being listed for liver transplantation and receiving a transplant. However, these factors did not affect post-transplant survival, highlighting the importance of an impartial approach when assessing transplant eligibility.

3539 | TRENDS AND DEMOGRAPHIC DIFFERENCES IN REASONS FOR REMOVAL FROM THE LIVER TRANSPLANT WAITLIST: A NATIONWIDE OPTN ANALYSIS FROM 1988 TO 2025

Razan Aburumman[1] Saqr Alsakarneh[2] Saif Aburumman[3] Saine Tahmazian[1] Mohammad Abuassi[4] Syed-Mohammed Jafri[5], [1]Henry Ford Hospital, [2]University of Missouri, [3]The University of Medicine, [4]UCF/HCA Florida North Florida Hospital, [5]Henry Ford Health System

Background: Equity in liver transplantation access and outcomes remains a national priority. This study examines patterns and disparities in removal from the liver transplant waitlist across gender, race, ethnicity, citizenship, and insurance type. **Methods:** We conducted a retrospective analysis of patients removed from the liver transplant waitlist using data from the Organ Procurement and Transplantation Network (OPTN) spanning January 1988 to April 2025. Removal reasons and demographic characteristics were analyzed. SPSS IBM version 26.0 was used for the analysis. Chi-square tests were used to compare the distribution of reasons for removal across groups. **Results:** A total of 345,472 individuals were removed from the liver transplant waitlist between January 1988 and April 2025. The top three reasons for removal were deceased donor transplant (196,201 patients; 56.8%), death while on the waitlist (44,332; 12.8%), and being deemed too sick to transplant (28,033; 8.1%). Males were more likely than females to be removed due to deceased donor transplant (58.5% vs. 54.0%, $p < 0.001$). In contrast, females were more likely to be removed for living donor transplant (3.6% vs. 2.5%, $p < 0.001$), death (13.9% vs. 12.2%, $p < 0.001$), and condition improvement (7.4% vs. 5.3%, $p < 0.001$). Non–U.S. citizens were more likely to be removed for being too sick (9.1% vs. 8.1%, $p < 0.001$) and for receiving a transplant in another country (0.2% vs. 0.0%, $p < 0.001$). Patients with public insurance were more likely to be removed for being too sick (9.7%) compared to those with private insurance (7.2%), self-pay (6.0%), or other insurance types (5.4%, $p < 0.001$). Black patients had the highest proportion of removal for deceased donor transplant (60.2% vs. 56.7% for White and 55.7% for other races, $p < 0.001$), while White patients had the highest rate of removal for living donor transplant (3.2% vs. 1.8% Black and 2.6% other races, $p < 0.001$). non-Hispanic patients were more likely to undergo deceased donor transplant (57.1% vs. 55.2% Hispanic, $p < 0.001$), while Hispanic individuals were more likely to be removed due to being too sick (9.5% vs. 7.9%, $p < 0.001$) or dying on the waitlist (13.9% vs. 12.6%, $p < 0.001$). **Conclusion:** Significant disparities exist in removal from the liver transplant waitlist by gender, race, ethnicity, citizenship, and insurance type. These findings highlight the need for targeted interventions to address structural inequities in transplant access and outcomes

3540 | REAL-WORLD CLINICAL OUTCOMES OF ADJUVANT RADIOTHERAPY AFTER CURATIVE LIVER RESECTION FOR STAGE IIIB INTRAHEPATIC CHOLANGIOCARCINOMA

Shilei Bai[1] Yizhe Dai[2] Kui Wang[1], [1]Eastern Hepatobiliary Surgery Hospital, [2]Department of Hepatic Surgery IV, the Eastern Hepatobiliary Surgery Hospital, Second Military Medica

Background: The benefit of adjuvant radiotherapy (ART) for intrahepatic cholangiocarcinoma (ICC) with lymph node metastasis after curative liver resection remains unclear, primarily due to a lack of clear comparisons between ART and non-ART groups in existing studies. **Methods:** Using a large single-center database and validating with the SEER database, we analyzed ICC patients who underwent liver resection with confirmed hilar lymph node metastasis. Inverse probability of treatment weighting (IPTW) and multivariate Cox regression analyses were employed to evaluate the effect of adjuvant radiotherapy on long-term overall survival (OS) and time to recurrence (TTR). **Results:** Among 366 ICC patients with pathologically confirmed hilar lymph node metastasis after surgery, 85 received adjuvant radiotherapy, while 279 did not. IPTW created weighted cohorts of 278.8 non-ART patients and 87.4 ART patients. After IPTW adjustment, ART was associated with significantly lower 1-, 3-, and 5-year recurrence rates and improved 1-, 3-, and 5-year OS (TTR: 40.80% vs. 55.90%, 62.41% vs. 80.49%, 70.87% vs. 83.49%, P = 0.011; OS: 74.11% vs. 54.51%, 39.46% vs. 25.13%, 33.51% vs. 17.12%, P = 0.005).In the subgroup of patients with fewer than 6 lymph nodes dissected, ART significantly reduced recurrence rates and prolonged survival at all timepoints (TTR: 52.2% vs. 70.03%, 68.40% vs. 86.61%, 78.06% vs. 91.37%, P = 0.014; OS: 72.01% vs. 36.70%, 30.37% vs. 15.23%, 26.34% vs. 10.64%, P = 0.006). However, in patients with >6 lymph nodes dissected, ART did not significantly affect recurrence or survival (TTR: 51.8% vs. 37.57%, 68.31% vs. 79.07%, 60.79% vs. 79.07%, P = 0.085; OS: 74.76% vs. 59.93%, 42.80% vs. 28.93%, 35.47% vs. 21.10%, P = 0.058).In the SEER validation cohort, among patients with <6 lymph nodes dissected (55 ART vs. 212 non-ART), 1-, 3-, and 5-year OS was significantly better in the ART group (90.27% vs. 67.72%, 36.68% vs. 24.63%, 18.06% vs. 13.05%, P = 0.043). In patients with >6 lymph nodes dissected (23 ART vs. 102 non-ART), there was no significant difference in OS (90.91% vs. 68.39%, 30.08% vs. 25.00%, 12.51% vs. 17.40%, P = 0.710). **Conclusion:** For ICC patients with hilar lymph node metastasis, adjuvant radiotherapy is recommended to improve long-term prognosis if fewer than 6 lymph nodes are dissected during surgery.

3541 | SEX-SPECIFIC PERFORMANCE OF NON-INVASIVE BIOMARKERS FOR PREDICTING GRAFT LOSS AND MORTALITY AMONG LIVER TRANSPLANT RECIPIENTS

AlShaima AlHinai[1] Thierry Fotsing Tadjo[1] Shuang Wang[2] Aridj Bouragbi[2] Marc Deschenes[1] Philip Wong[1] Tianyan Chen[1] Frédéric Lamonde[3] Agnihotram V. Ramanakumar[3] Nasim Saberi[4] Denis Charron[4] Jeffrey Barkun[4] Giada Sebastiani[5], [1]Division of Gastroenterology and Hepatology, McGill University Health Centre, Montreal, Canada, [2]School of Medicine and Health Sciences, McGill University, Montreal, Canada, [3]Research Institute, McGill University Health Centre, Montreal Canada, [4]Department of Surgery, McGill University Health Centre, Montreal, Canada, [5]Division of Gastroenterology and Hepatology, Research Institute, McGill University Health Centre

Background: Biological sex influences liver disease progression, yet its impact on post-transplant outcomes and the performance of non-invasive biomarkers remains underexplored. In liver transplant recipients, graft steatosis and fibrosis are common complications contributing to graft loss and mortality. Understanding whether biomarker performance differs by sex is critical for optimizing long-term care. We aimed to evaluate sex-specific differences in

post-transplant outcomes and in the prognostic performance of non-invasive fibrosis and steatosis biomarkers for predicting graft loss and mortality. **Methods:** This retrospective longitudinal study included all adult liver transplant recipients at a single center in Montreal, Canada, between 2000 and 2021. Primary outcomes were graft loss (defined as death or re-transplantation) and all-cause mortality. We assessed the performance of the biomarkers AST-to-Platelet Ratio Index (APRI), fibrosis-4 index (FIB-4), and hepatic steatosis index (HSI), using sex-stratified survival analyses. Fibrosis was defined as APRI >1 or FIB-4 >3.64, and hepatic steatosis was defined as HSI >36. **Results:** Among 608 liver transplant recipients included (30% women), incidence of graft loss was higher in men (20.6, 95% CI 16.5-25.9 per 100 person-years) than women (11.8, 95% CI 7.5-8.4). All-cause mortality rates were similar between men (40.7, 95% CI 34.7-47.6 per 100 person-years) and women (39.3, 95% CI 30.9-50.1). In men, high BMI was associated with graft loss ($p=0.028$) while high AST was associated with mortality ($p=0.034$). In women, donor age and high FIB-4 were associated with mortality ($p=0.054$ and $p=0.0202$, respectively). Kaplan-Meier analysis showed APRI >1 and FIB-4 >3.64 predicted graft loss in men ($p=0.006$ and $p=0.005$, respectively, see Figures). No biomarkers predicted mortality in men or any outcome in women. **Conclusion:** APRI and FIB-4 were predictive of graft loss in men but not in women, highlighting significant sex-based differences in biomarker performance and post-transplant risk factors. These findings underscore the need for sex-specific approaches in the prognostication and management of liver transplant recipients.

3542 | CYSTATIN C-TO-SERUM CREATININE RATIO IS INDEPENDENTLY ASSOCIATED WITH KEY CLINICAL OUTCOMES FOLLOWING LIVER TRANSPLANTATION

Alexander Prete[1] *Bernardo Valencia*[1] *Zachary Fricker*[1], [1]*Beth Israel Deaconess Medical Center*

Background: Sarcopenia, marked by the loss of skeletal muscle mass, strength, and function, portends worse outcomes following liver transplantation. Despite the high prevalence of sarcopenia in the advanced cirrhosis community, a readily accessible serum biomarker to characterize its presence remains elusive. The ratio of cystatin C-to-serum creatinine (cystatin C/sCr, or the "CC ratio") has been proposed in other disciplines as a potential marker of sarcopenia given the robust influence of muscle mass on creatinine (but not on cystatin C). We sought to investigate the association between the pre-transplant CC ratio and key clinical outcomes post-transplantation to elucidate the value of this metric. **Methods:** We conducted a single center, retrospective cohort study of patients who underwent liver transplantation at an urban academic medical center from 2019-2024 with a pre-operative CC ratio measured as part of standard medical care. Outcomes of interest included post-transplant hospital length of stay (LOS), ICU LOS, and 30-day and one-year hospital re-admission. We assessed for the association of the CC ratio with these outcomes using multivariable linear (for numerical outcomes) or logistic (for categorical outcomes) regression. Covariates included age, BMI, sex, Liver Frailty Index score, simultaneous liver-kidney transplantation, and MELD-Na score. **Results:** We identified 51 patients for inclusion (Table 1). Adjusting for our covariates, we found that the CC ratio was independently associated with post-transplant hospital LOS (OR 1.81, 95% CI 1.57-2.10, $p<0.01$), ICU LOS (OR 1.63, 95% CI 1.25-2.13, $p<0.01$), and one-year hospital re-admission (OR 1.54, 95% CI 1.08-2.21, $p=0.02$). Among all covariates assessed, the CC ratio had the greatest strength of association with post-transplant hospital LOS. Other than MELD-Na, the CC ratio was the only variable that independently associated with the outcomes of ICU LOS and one-year hospital re-admission. **Conclusion:** Our study demonstrates the potential for the CC ratio to serve as a tool for risk stratification among those with advanced cirrhosis being considered for liver transplantation. Our results also underscore the benefit of quantifying pre-transplant metabolic status by using an easily repeatable metric that could be monitored over time. Larger, prospective multi-center trials are needed to further assess the practical utility of this novel measurement.

3544 | HAPLOIDENTICAL LIVING DONOR LIVER TRANSPLANTATION FOR STEROID-REFRACTORY HEPATIC GVHD IN A PEDIATRIC PATIENT POST-HSCT

URVI KAPOOR[1];, STEVEN J. LOBRITTO[2], MONICA BHATIA&SUP1, [1]DIVISION OF PEDIATRIC HEMATOLOGY/ONCOLOGY/STEM CELL TRANSPLANTATION, COLUMBIA UNIVERSITY MEDICAL CENTER [2];DIVISION OF PEDIATRIC GASTROENTEROLOGY AND LIVER TRANSPLANTATION, COLUMBIA UNIVERSITY MEDICAL CENTER Urvi Kapoor Steven Lobritto[1] Monica Bhatia[2], [1]Columbia University Medical Center, [2]Columbia University

Background: Hepatic graft-versus-host disease (GVHD) is a rare but life-threatening complication following allogeneic hematopoietic stem cell transplantation (HSCT). Patients with steroid-refractory GVHD have high mortality, with limited salvage options. Liver transplantation post-HSCT poses unique challenges due to dual alloimmunity and is rarely pursued, particularly in pediatric patients. We report the first known case of a pediatric patient with steroid-refractory hepatic GVHD successfully treated with haploidentical living donor liver transplantation (LDLT). **Methods:** This is a single-patient case report conducted via retrospective chart review. Clinical, laboratory, and transplant data were collected and analyzed to evaluate disease course, treatment response, and post-transplant outcomes. **Results:** An 11-year-old male, who received a matched unrelated allogeneic HSCT for severe aplastic anemia, developed progressive hepatic GVHD characterized by profound ductopenia and severe cholestasis. His disease was refractory to corticosteroids and multiple additional lines of therapies, including ruxolitinib, mesenchymal stromal cells, infliximab, sirolimus, anti-thymocyte globulin, alpha-1 antitrypsin, cyclophosphamide, and emapalumab. His course was further complicated by Epstein-Barr virus (EBV)–associated post-transplant lymphoproliferative disorder (PTLD), which was successfully treated with rituximab. Fifteen months after HSCT, and seven months following resolution of EBV viremia, he underwent successful LDLT from a haploidentical parental donor. The haploidentical donor was selected to preserve the potential for future treatment with EBV-specific cytotoxic T lymphocytes (CTLs) in the event of EBV recurrence. Post-transplant immunosuppression included tacrolimus and mycophenolate mofetil (MMF). At six months following LDLT, the patient remains clinically well, with normal liver function, sustained full donor chimerism, and no evidence of GVHD or PTLD. **Conclusion:** This case demonstrates that haploidentical LDLT can be a viable and life-saving salvage therapy in select pediatric patients with progressive, treatment-refractory hepatic GVHD. Despite the risks of dual alloimmunity, a successful outcome was achieved through careful patient selection, timing, and multidisciplinary coordination. This approach may warrant consideration in cases of irreversible hepatic injury. Additionally, the case underscores the absence of liver-specific GVHD

3545 | EXPANDED UTILIZATION OF LIVER TRANSPLANTATION IN CRITICALLY ILL CANDIDATES WITH CHRONIC LIVER DISEASE DOES NOT THREATEN CENTER-BASED OUTCOME METRICS

Laura Barr[1] Therese Bittermann[2], [1]Perelman School of Medicine, University of Pennsylvania, [2]Perelman School of Medicine

Background: Liver transplantation (LT) in patients with chronic liver disease (CLD) may be high-risk when patients are critically ill in the intensive care unit (ICU). Recent studies show that outcomes in LTs from the ICU have improved significantly. The impact of center experience with ICU LTs on outcomes is unknown outside of acute liver failure (ALF). This study aimed to assess center heterogeneity in practices and the impact of center ICU LT experience on post-transplant outcomes. **Methods:** Using United Network for Organ Sharing data, we performed a retrospective analysis of all adult LTs performed between 1/1/2014-12/31/2023 in which patients were in an ICU prior to transplant (tx). The last follow-up date was 12/31/2024. We excluded re-tx, multi-organ tx (except liver-kidney), and ALF. Resource utilization, in-hospital mortality and 1- and 3-year mortality were compared by center ICU LT volume quartiles. The association between center ICU LT volume in the prior year and 1-year post-LT mortality was evaluated using multivariable logistic regression. **Results:** In total, 9,542 LTs were performed in ICU patients across 130 centers (12.8% of total LTs). By comparison, ICU LTs represented 8.8% of total LTs from 2004-2013 ($p = < 0.001$). There were no ICU LTs at 16/146 (11.0%) centers. ICU LT patients were 58% male, median age 54 (IQR 45, 62) and 52% with disease etiology of alcohol-associated liver disease. At LT, 61% were on dialysis, 21% on a ventilator and 47% on life support. Median center ICU LT volume from 2014-2023 was 48 (IQR 20,90). Proportion of overall LT volume in ICU recipients was nearly 4x greater at centers in the highest vs lowest quartile of ICU LT volume (19.4% vs 5.9%; $p < 0.001$). Utilization of dialysis, life support and of concurrent critical care therapies in ICU LT recipients was higher at high volume centers ($p < 0.001$ for all; Table). In-hospital, 1-year and 3-year mortality for ICU LTs overall were 6.2%, 10.4% and 23.1%, respectively, with no differences across center volume quartiles (all $p > 0.05$). Though statistically significant, minimal differences in overall 1-year and 3-year mortality were observed (Table). Adjusting for severity of illness, center volume of ICU LTs in the prior year was associated with a small but significant reduction in 1-year post-LT mortality: aOR 0.96 per 5 ICU LTs ($p < 0.001$). **Conclusion:** Experience with and selection of LT candidates with CLD patients in the ICU varies widely across centers. Expansion of LT for ICU candidates does not appear to threaten center-based metrics and may ultimately lead to a small, yet measurable improvement in short-term survival post-LT.

Resource Utilization and Outcome Metrics by Center Volume Quartile of ICU LT 2014-2023 (N=130 centers)

	Center ICU LT volume 1-20	Center ICU LT volume 20-50	Center ICU LT volume 51-89	Center ICU LT volume 90+	P-value

3546 | ONE YEAR POST TRANSPLANT OUTCOMES IN HCV POSITIVE DONOR TO HCV NEGATIVE RECIPIENT LIVER TRANSPLANTATION: A DESCRIPTIVE ANALYSIS OF AN ARIZONA TRANSPLANT CENTER'S EXPERIENCE

Raha Sadjadi[1] Vanessa Eller[2] Leith Ghani[2] Anandalakshmi Ponnaluri[3] Pooja Rangan[2] Giorgio Roccaro[4] Karn Wijarnpreecha[5], [1]University of Arizona, College of Medicine Phoenix, [2]University of Arizona College of Medicine Phoenix, Banner University Medical Center Phoenix, [3]Banner University Medical Center Phoenix, [4]Emory University School of Medicine, [5]University of Arizona College of Medicine-Phoenix

Background: The persistent gap between the demand for liver transplantation (LT) and the availability of suitable donor organs continues to drive morbidity and mortality among patients on the LT waiting list. The advent of direct-acting antiviral agents (DAAs) has transformed the management of hepatitis C virus (HCV), offering an opportunity to safely expand the donor pool using HCV positive (+) grafts. We present one year post transplant outcomes following the use of HCV+ grafts in HCV negative (-) LT recipients at Banner University Medical Center in Phoenix (BUMCP), Arizona. **Methods:** This is a retrospective cohort study of patients who underwent LT at BUMCP from 2015 - 2021. Data and outcomes were manually collected from 520 patient charts and compared between (1) LT recipients who received an HCV – graft (n = 478) and (2) HCV – LT recipients who received an HCV + graft (n = 42). Descriptive analyses were performed to compare hospital admissions, infections, acute kidney injury (AKI), biliary complications, hepatic artery stenosis/thrombus, graft failure (GF), acute cellular rejection (ACR), stage of chronic kidney disease (CKD), end stage renal disease (ESRD), post transplant diabetes, and hepatocellular carcinoma (HCC) recurrence in the one year following liver transplant. **Results:** There were no statistically significant differences between the two groups in rates of hospitalization, AKI, infection, GF, ACR, hepatic artery stenosis/thrombosis, CKD stage, ESRD, PTDM, or mortality within one year post-transplant. However, HCV – LT recipients had a higher percentage of biliary stricture (p = 0.01) in the first year post LT. HCV + LT recipients had a higher percentage of HCC recurrence within the first year following LT (p = 0.02). **Conclusion:** Our findings support the safety and efficacy of utilizing HCV+ donor livers without fibrosis in HCV– recipients. The observed increase in HCC recurrence in the HCV+ may be more reflective of an overall small sample size compared to the total number of HCV – patients in the study and not actually a biological difference in the incidence of recurrent HCC post transplantation. Therefore, HCV+ grafts should not be categorically excluded for recipients with prior HCC, though careful selection and surveillance remain warranted. This strategy offers a viable pathway to expand the donor pool without compromising short-term outcomes.

Table 1: Demographics and One Year Post Transplant Outcomes

	HCV – donor to recipient (n = 478)	HCV + donor to negative recipient (n = 42)	p value
Demographics			
MELD at transplant	23.90	23.26	
Age at transplant	54.73 years	57.2 years	
Percentage female	38.28%	30.95%	
1 year post transplant outcomes			
Mean admissions in year post transplant	2.21	2.25	
Days hospitalized	19.70	16.98	
Reasons for Admission			
Infection	52.7%	47.06%	0.59
ACR or liver chemistry abnormalities	32.15%	17.65%	0.12
AKI	14.56%	14.71%	1
Biliary obstruction	11.82%	5.88%	0.4
Complications			
GF	1.26%	0%	0.80
ACR	24.27%	19.05%	0.79
AKI	37.92%	38.46%	1
Infection	42.86%	42.50%	1
Biliary stricture	25.57%	7.89%	0.02
Hepatic artery stenosis/thrombosus	22.57%	15.38%	0.42
CKD - stage 3 - stage 4 - stage 5	 19.5% 2.1% 2.52%	 14.29% 2.38% 2.38%	0.29
Post transplant diabetes	8.76%	7.69%	0.74
ESRD	2.34%	2.63%	1
HCC recurrence	1.97%	13.64%	0.02
Death in 1 year	8.12%	6.52%	1

3547 | THE ASSOCIATION OF CHRONIC KIDNEY DISEASE WITH METABOLIC SYNDROME AND PERIRENAL ADIPOSE TISSUE IN LIVER TRANSPLANT RECIPIENTS

SEDA NUR BEYATLI[1] Hale Gökcan[2] Ayşegül Gürsoy Çoruh[3] Barış Kırkıcı[3] Zeynep Melekoglu Ellik[4] Volkan Yilmaz[4] Özge Koç[4] Muhammed Fatih Acehan[4] AMED TRAK[4] Ramazan Idilman[2], [1]Ankara University School of Medicine, Department of Internal Medicine, Ankara, Turkey, [2]Ankara University Institute of Hepatology, School of Medicine, Ankara, Türkiye, [3]Ankara University School of Medicine, Department of Radiology, Ankara, Türkiye, [4]Ankara University School of Medicine, Department of Gastroenterology, Ankara, Türkiye

Background: Chronic kidney disease (CKD) is a major complication affecting long-term survival after liver transplantation (LT). Its development is influenced by factors such as preoperative renal function, intraoperative hemodynamic changes, nephrotoxic drugs, metabolic syndrome (MS), and visceral adipose tissue (VAT). Perirenal fat tissue may contribute to the development of CKD through metabolic and mechanical effects. This study aims to assess the relationship between CKD, MS, andperirenal fat tissue in LT recipients. **Methods:** A total of 109 adult liver transplant recipients, with a minimum follow-up of 1 year at Ankara University Gastroenterology and Hepatology Polyclinics between 2005-2024 were enrolled in the analysis. Demographics, laboratory and radiological data were collected. Based on abdomen CT analysis, measurements of VAT, subcutaneous adipose tissue (SAT), total fat area (TFA), VAT/TFA ratio, VAT/SAT ratio, and right-left perirenal fat thickness (PFT) were performed, and their associations with MS and CKD development were analyzed. **Results:** Among 109 patients, 70 (64.2%) were male with a median age of 61 years (range 53.5–67 years). Median follow-up was 8 years (range 5.5–12.5 years). Living donor LT was performed in 87 (79.8%) of the patients. Hepatitis B virüs ($n = 39$, 35.8%).) was the main indication to LT. CKD developed in 35 (32.1%) patients, of whom 65.7% had MS. Also MS developed in 52 patients (47.7%) post-LT, 44.2% of them developed CKD.

Pre-transplant DM, anti-diabetic and antihypertensive medication use before and after, post-transplant hypertension, metabolic syndrome before and after LT, MASLD before LT, and increased post-transplant waist circumference were significantly more common in patients with CKD ($p < 0.05$). Additionally, pre-transplant fasting glucose, post-transplant triglycerides, postprandial glucose, HbA1c, and C-peptide levels were higher in these patients ($p < 0.05$).

Compared to those without MS, patients developed MS had significantly higher post-transplant VAT [165.1 (113.1-246.9) vs 116.8 (62.8-205.8) $p = 0.014$], TFA [393.2 ± 138.5 vs 319.5 ± 166.7,$p = 0.026$], right PFT [3.14 ± 1.06 vs 2.6 ± 1.07, $p = 0.010$] and mean PFT [3.62 ± 1.04 vs 3.12 ± 1.18, $p = 0.020$].VAT [161.1 (101.6-216.2) vs 146.1 (73.5-225.9)], SAT [188.8 (151.4-272.2) vs 166.3 (116.9-257.6), TFA [395.4 ± 158.4 vs 337.9 ± 154.3], and right PFT [3.13 ± 10.92 vs 2.74 ± 1.15], values were higher in the CKD group compared to the non-CKD group, however not statistically significant. **Conclusion:** The development of MS and CKD is common after LT. Visceral and perirenal fat tissue are important indicators in the diagnosis of MS. CKD is a multifactorial condition and the presence of MS increases the risk of developing CKD. The relationship between visceral and perirenal fat tissue and CKD requires large-scale studies.

3549 | BIOLOGIC USE AND RISK OF ACUTE CELLULAR AND ANTIBODY-MEDIATED REJECTION IN LIVER TRANSPLANT RECIPIENTS WITH INFLAMMATORY BOWEL DISEASE

Ishan Antony Noor Albusta[1] Ethan Chivi[2] Katelyn Wing[2] Sana Baban[2] Yixin Kong[1] Neev Mehta[1] Mohamed Akoad[1] Raza Malik[3] Amir Qamar[4], [1]Lahey Hospital and Medical Center, [2]UMASS Chan Medical School, [3]Lahey Hospital & Medical Center, [4]Lahey Clinic Medical Center

Background: Inflammatory bowel disease (IBD) is a common comorbidity in liver transplant (LT) recipients, particularly those with primary sclerosing cholangitis (PSC). The management of IBD in the post-LT setting is complex, with increasing use of biologic therapies such as anti-TNF agents, anti-integrins, and interleukin inhibitors. However, the safety of these agents following LT remains unclear, notably with regard to the risk of acute cellular rejection (ACR) and antibody-mediated rejection (AMR). **Methods:** We conducted a retrospective cohort study of 85 adult LT recipients with a diagnosis of IBD at Lahey Hospital from 2000-2024. The study was approved by the institutional review board. Demographics, immunosuppressive regimen, and post-LT biologic therapy were reviewed. Patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

were stratified by post-LT biologic use. Rejection events were identified from the electronic health record and defined based on clinician documentation and pathology reports. **Results:** Among 85 LT recipients with IBD, 68 (80%) were male and 77 (91%) were White. The predominant IBD subtype was ulcerative colitis (UC) (58%), followed by Crohn's disease (42%). PSC was the most common indication for LT, accounting for 78% of cases. The cohort was predominantly maintained on tacrolimus-based immunosuppression (87%), mycophenolate (64%), and corticosteroids (24%). Post-LT biologic therapy was used in 24 patients (28.2%), including anti-TNF agents (13/85, 15%), vedolizumab (10/85, 12%), ustekinumab or risankizumab (12/85, 14%), and upadacitinib (1/85, 1%). Rejection occurred in 4 patients overall (4.7%): 2 ACR and 2 AMR (2.35%). One episode of ACR occurred in each group (4.8% in biologic vs 1.6% in non-biologic), and both AMR episodes occurred in the non-biologic group. **Conclusion:** In this single-center cohort of LT recipients with IBD, biologic therapy was not associated with an increased risk of acute rejection. ACR occurred in only two patients, one in each treatment group, while AMR was observed exclusively in the non-biologic group. These findings suggest that the use of biologics post-LT does not confer additional risk of allograft rejection in this population. The absence of AMR among biologic users is noteworthy, given that biologics could theoretically modulate immune activation pathways involved in alloimmune response. Our cohort was largely composed of patients with PSC and UC, consistent with the established PSC-IBD overlap population. Prospective studies with larger sample sizes and longer follow-up are needed to confirm these findings and assess the long-term impact of biologic exposure on graft and patient outcomes.

3550 | IMPACT OF RECIPIENT MELD SCORE ON OUTCOMES FOLLOWING TRANSPLANTATION WITH MARGINAL LIVER DONOR GRAFTS

Yasmeen Saker[1], [1]*University of Florida*

Background: The optimal allocation of marginal liver donor (MLD) grafts remains a topic of debate, particularly regarding whether high MELD recipients derive comparable benefit despite increased baseline risk. This study aimed to assess whether recipient MELD score modifies the association between marginal graft use and graft survival. **Methods:** We conducted a retrospective cohort study of adult liver transplant recipients at the University of Florida who received transplants between January 2019 and September 2024. Donors were classified as MLDs if they met at least one predefined high-risk criterion: age >65 years, BMI >30, ICU stay >4 days, serum sodium >160 mmol/L, abnormal liver tests (ALT >105 U/L, AST >90 U/L, or bilirubin >3 mg/dL), substance use, extrahepatic malignancy, donation after circulatory death (DCD), cold ischemic time >12 hours, and/or viral hepatitis (HBsAg, HBcAb, or HCV Ab positivity). Donors not meeting any of these were considered non-MLDs. Characteristics like macrosteatosis $>30\%$, prolonged hypotension, and high-dose inotropes were excluded due to inconsistent availability.

To assess whether MELD score modified the association between MLD and graft survival, recipients were stratified by MELD-Na at transplant: <15, 15–28, 29–32, 33–36, and >37—aligned with acuity circle-based allocation thresholds. Graft survival at 1 and 3 years was estimated using Kaplan-Meier analysis; differences between MELD strata were compared using the log-rank test ($p<0.05$ significant). **Results:** Among 559 adult liver transplant recipients who received MLDs during the study period, the mean MELD-Na at transplant was 26.5 (range 6–53). One-year graft survival exceeded 97% across all MELD strata, ranging from 97.4% in MELD 15–28 to 98.4% in MELD 29–32, and 98.2% in recipients with MELD >37. Three-year survival ranged from 82.1% in MELD <15 to 93.2% in MELD 29–32, with survival in the MELD >37 group reaching 84.2%. No statistically significant differences were observed across MELD categories for either one-year ($p=1.0$) or three-year ($p=0.7$) survival.

In reviewing specific MLD criteria, no donors aged >65 and only one DCD donor were used in the MELD >37 group ($p<0.001$). Donors with prolonged ICU LOS were used across all MELD strata but were most frequently utilized in the MELD 29–32 and 33–36 groups ($p<0.001$). When stratified by acuity threshold, recipients with MELD >37 demonstrated comparable outcomes to those with MELD ≤ 37, with 1 year survival rates of 98.2% vs. 97.8% ($p=0.80$) and 3 year survival rates of 84.2% vs. 89.8% ($p=0.23$). **Conclusion:** In this institutional cohort, MLD graft survival at 1 and 3 years remained high across MELD strata, with no significant differences between high- and low-MELD recipients. These findings support individualized MLD allocation to high-acuity patients, as MELD score should guide and not restrict clinical decisions.

3551 | PROTON PUMP INHIBITOR USE IS ASSOCIATED WITH A TWO-FOLD INCREASED RISK OF LIVER TRANSPLANT COMPLICATIONS: A PROPENSITY-MATCHED ANALYSIS OF 48,192 RECIPIENTS

Kate Solpari Scarlet Yang[1] Jessica Siguencia[1] Tatyana Kushner[1], [1]Weill Cornell Medical College

Background: While prior studies have suggested PPI-related adverse events in cirrhotic patients, the impact of PPI use on post-transplant outcomes remains poorly characterized. We aimed to evaluate the association between PPI use and liver transplant (LT) complications using a large real-world database. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network, analyzing data from 104 healthcare organizations. LT recipients were identified and stratified into two cohorts: those receiving PPIs (omeprazole, pantoprazole, esomeprazole, rabeprazole, or lansoprazole) post-transplant and those without PPI exposure. Outcomes included any transplant complication (T86.4), rejection (T86.41), transplant failure (T86.42), transplant-related infection (T86.43), need for re-transplantation, and mortality, assessed from one day post-index event. Propensity score matching was performed for demographics, underlying liver disease etiology, and immunosuppressive medications. Risk ratios and Kaplan-Meier analysis were used to compare relative risk and complication free survival, respectively. **Results:** Among 86,505 patients undergoing LT (mean age 60 ± 18 years, 66.2% White, 59.7% male, mean follow up ~1450 days), 52,312 (60.5%) had evidence of PPI use. After propensity matching, 24,096 patients were included in each cohort. The PPI cohort demonstrated significantly higher rates of any transplant complication (31.1% vs 15.4%, Risk Ratio [RR] 2.03, 95% CI 1.96-2.10, $p < 0.001$). Specifically, PPI use was associated with increased risk of rejection (17.8% vs 9.2%, RR 1.93, 95% CI 1.84-2.03), liver transplant failure (11.9% vs 6.6%, RR 1.79, 95% CI 1.69-1.90), and liver transplant infection (3.3% vs 0.8%, RR 4.06, 95% CI 3.48-4.74), all $p < 0.001$. Moreover, the need for re-transplant was significantly increased in the PPI group (9.0% vs 1.4%, RR 6.29, 95% CI 5.62-7.03) along with all-cause mortality (22.9% vs 13.0%, RR 1.76, 95% CI 1.69-1.83), both $p < 0.001$. Kaplan-Meier analysis revealed reduced transplant complication-free survival in PPI users (48.3% vs 62.1% at end of follow-up, log-rank $p < 0.001$), with a hazard ratio of 2.12 (95% CI 2.04-2.21) (Figure 1). **Conclusion:** PPI use was common in the post-transplant setting and was associated with a two-fold increased risk of overall complications, a four-fold increased risk of transplant-related infections, and a six-fold risk of re-transplantation. Several mechanisms may explain these findings, including PPI-induced reduction in mycophenolate absorption leading to subtherapeutic immunosuppression, alterations in gut microbiota promoting bacterial translocation, impaired neutrophil function, and potential drug interactions with calcineurin inhibitors. These findings suggest the need for judicious PPI prescribing in LT recipients and warrant prospective studies to establish causality and optimal acid suppression strategies.

3552 | IMPACT OF EARLY-ONSET ARRHYTHMIAS ON OUTCOMES AFTER LIVER TRANSPLANTATION

umesh bhagat[1] ankit agrawal[1] akshat banga[2] mohamed abdelbaky[3] archana kharel[4] shalini tripathi[1] prabhat kumar[5] luisa recinos[6], [1]Cleveland clinic, [2]mount auburn hospital, [3]presbyterian hospital, [4]Clevelend clinic, [5]Virginia commonwealth univeristy, [6]saint peters university hospital

Background: Cardiac disease is a common cause of morbidity and mortality after liver transplantation (LT). However, data on the incidence and impact of new-onset arrhythmia in the postoperative period are sparse. We aim to assess the incidence and adverse events of arrhythmia in patients readmitted 30 days after LT. **Methods:** National Readmission Database (NRD) 2016-2021 was queried to identify patients with no pre-existing arrhythmia who underwent LT. Patients readmitted after 30 days were divided into two cohorts of with and without new onset arrhythmia. The primary outcome was all-cause mortality. Secondary outcomes included cardiac adverse events, ICU stay and respiratory failure. Statistical analysis was performed using StataCorp. 2021. **Results:** A total of 35,419 patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

were discharged post-LT LT of which 10,485 were readmitted after 30 days. Among these, 922 were diagnosed with new-onset arrhythmia (8.79%). The most common arrhythmia was atrial fibrillation (31.47%), followed by supraventricular (5.83%) and ventricular tachycardia (4.83%). Patients with arrhythmia had higher odds of mortality (aOR 1.84, 95% CI: 1.03–3.30, p = 0.03), cardiac arrest (aOR 1.47, 95% CI: 1.09–1.97, p < 0.001, cardiogenic shock (aOR 4.39, 95% CI: 1.66–11.61, p < 0.001), and ACS (aOR 3.95, 95% CI: 2.14–7.30, p < 0.001), ICU stay (aOR 1.87, 95% CI: 1.33–2.61, p < 0.001) and respiratory failure (aOR 1.95, 95% CI: 1.43–4.22, p < 0.001). **Conclusion:** New-onset arrhythmia 30-days after LT is significantly associated with poor prognosis. These findings underscore the need for comprehensive cardiac risk assessment and ongoing surveillance in this high-risk population.

	Odds ratio	95% conf.- interval	P
Mortality	1.84	1.03- 3.30	0.039

3553 | DIFFERENTIAL OVERALL MORTALITY AND HEALTHCARE UTILIZATION FOR LIVER TRANSPLANT RECIPIENTS BY REGIONAL, HOSPITAL AND INSURANCE CHARACTERISTICS

Monica Tincopa[1] Mohammed Abu-Rumaileh[2] Bisher Sawaf[3] Mhd kutaiba Albuni[4], [1]University of California, San Diego, [2]University of Toledo, [3]The University of Toledo, [4]TriHealth- Good Samaritan Hosptial

Background: Liver transplantation (LT) is a lifesaving procedure for patients with end-stage liver disease. However, disparities in LT outcomes persist, resulting in barriers to health equity. The aim of this study was to evaluate associations of demographic, socioeconomic and hospital characteristics on post-LT outcomes including overall mortality and measures of healthcare utilization. **Methods:** We conducted a retrospective analysis of the National Inpatient Sample (NIS) database to identify adult LT recipients using ICD-10 coding. Demographic data, medical comorbidities, hospital characteristics, and socioeconomic indicators were examined. Outcomes included overall mortality, length of hospital stay (LOS), and total hospital charges (TOTCHG). Univariate and multivariate linear and logistic regression with propensity score matching assessed associations of covariates with outcomes of interest. **Results:** A total of 47,175 LT recipients were identified. The mean age (±SE) was 59.1 (±0.48) years, with 63.1% male sex, 67.4% White and 15.9% Hispanic ethnicity. Multivariate analysis showed that overall mortality was significantly associated with age (OR 1.04, 95% CI 1.03-1.05), teaching hospitals (OR 0.68, 95% CI 0.51-0.91), comorbidity index (OR 1.39, 95% CI 1.33-1.45), insurance type (OR 0.77, 95% CI 0.66-0.90), and hospital location (OR 0.59, 95% CI 0.38-0.91) (Table). Both length of stay (LOS) and total hospital charges (TOTCHG) were significantly associated with comorbidity burden (LOS β = +0.75 days, TOTCHG β = +$9,784; both p < 0.001). Insurance status significantly influenced outcomes, with Medicaid patients showing a markedly higher risk of overall mortality (OR: 9.78, p = 0.003) and prolonged hospital stays. Regional variations in outcomes were also noted, with some regions demonstrating better survival rates and lower healthcare costs. **Conclusion:** Long term overall mortality and healthcare utilization post-LT are independently impacted by hospital characteristics, region and insurance type, posing potential barriers to health equity for this population. Characterizing underlying drivers of these disparate outcomes are urgently needed to ensure optimal healthcare outcomes and minimize healthcare costs.

Table: Multivariate analysis showing predictors of overall mortality for liver transplant recipients.

Predictor	Odds Ratio	95% CI	P-value
Race	0.99	0.90 – 1.09	0.82
Age	1.04	1.03 – 1.05	**<0.001**
Sex (Female vs. Male)	0.86	0.67 – 1.09	0.21
Teaching Hospital	0.68	0.51 – 0.91	**0.009**
Income Quartile by ZIP Code	0.96	0.86 – 1.07	0.42
Comorbidity Index	1.39	1.33 – 1.45	**<0.001**
Insurance Type	0.77	0.66 – 0.90	**0.001**
Hospital Location	0.59	0.38 – 0.91	**0.01**

3554 | EARLY EXTUBATION FOLLOWING LIVER TRANSPLANTATION: AN UPDATED ANALYSIS OF A PROSPECTIVE COHORT

Justin Lin[1] Jade Pace[1] Ahmed Aboseria[1] Michael Attanasi[1] Sanjaya Satapathy[1] Nabil Dagher[2], [1]Northwell Health, [2]Northshore- LIJ Health System

Background: Early extubation after orthotopic liver transplantation (OLT) may enhance recovery, though

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

optimal timing and associated risks and benefits remain under investigation. This prospective cohort study evaluates the impact of early extubation on post-operative recovery, complications, and healthcare resource utilization. **Methods:** Adult OLT recipients at a single center between December 2019 and November 2024 were prospectively enrolled. Patients were stratified into early extubation (within 12 hours, $n = 137$) and late extubation (after 12 hours, $n = 151$) cohorts. Baseline demographics and clinical data were collected from institutional databases and reported to UNOS/OPTN. The Liver Frailty Index (LFI) was used to assess preoperative frailty. Acute kidney injury (AKI) was defined per KDIGO criteria as an increase in serum creatinine > 0.3 mg/dL within 48 hours or $\geq 50\%$ within 7 days, or initiation of renal replacement therapy within 14 days post-OLT. Patients undergoing simultaneous kidney transplantation or on pre-OLT dialysis were excluded from AKI analysis. **Results:** Early extubation was associated with significantly better preoperative functional status (Karnofsky score: 78% vs. 75%, $p = 0.039$; LFI: 4.36 vs. 4.74, $p = 0.005$), shorter ICU stays (5.2 vs. 7.8 days, $p < 0.001$), and reduced hospital length of stay (13.5 vs. 17.6 days, $p < 0.001$). These associations remained significant after adjustment for age, sex, BMI, MELD 3.0, and diabetes. The incidence of AKI was lower in the early extubation group (41.4% vs. 58.6%, $p = 0.003$), with no difference in reintubation rates between groups. **Conclusion:** Early extubation following liver transplantation is associated with improved recovery metrics, including reduced ICU and hospital stays, and a lower incidence of AKI. These findings support early extubation as a safe and cost-effective strategy that may enhance post-transplant outcomes. Broader implementation of protocolized early extubation should be considered in the absence of contraindications. Further multicenter studies are warranted to develop standardized guidelines.

3555 | INCIDENCE AND PREDICTORS OF POST-TRANSPLANT MALIGNANCY IN LIVER TRANSPLANT RECIPIENTS: A SINGLE-CENTRE COHORT STUDY

Francisco Idalsoaga[1] Abed Saqah[2] Pedro Acuña[3] Hashaal Alkhurassi[2] Saad Moteb Aldosari[2] Abdelrahman Sallam[2] Reyad Elzaanoun[2] Siddhant Maini[2] Gopika Punchhi[2] Rokhsana Mortuza[2] Luis Antonio Diaz[4] Mohammed Qasim Khan[2] Juan Pablo Arab[5], [1]Pontificia Universidad Católica de Chile, Western University, [2]Western University & London Health Sciences Centre, London, Canada., [3]Escuela De Medicina, Pontificia Universidad Católica dDe Chile, Santiago, Chile., [4]Pontificia Universidad Católica de Chile. University of California San Diego, San Diego, California, [5]Virginia Commonwealth University School of Medicine, Richmond, VA, USA.

Background: Cancer is a significant long-term complication following liver transplantation (LT). We aimed to characterize the incidence and risk factors associated with post-transplant cancer in a cohort of LT recipients in a Canadian tertiary care center. **Methods:** Retrospective cohort study including patients who underwent LT between 2007–2018 (minimum follow-up 60 months after LT). Demographic data, immunosuppression regimens and cancer diagnoses were analyzed. The analyses included univariate and multivariate Cox regression models. **Results:** We included 575 LT recipients from a single center in Ontario, Canada. The median age was 53.6 years [IQR: 48–61], and 173 (30.0%) were women. The main causes of cirrhosis were alcohol-associated liver disease (ALD) in 22.9%, hepatitis C virus (HCV) infection in 20.8%, metabolic dysfunction-associated steatotic liver disease (MASLD) in 13.3%, and primary sclerosing cholangitis (PSC) in 11.1%. Additionally, 148 patients (25.7%) had hepatocellular carcinoma (HCC) at the time of LT. A total of 55 (9.7%) developed malignancies during follow-up; the most frequent were non-melanoma skin cancer (20 cases, 36.3% of all cancers, and 3.48% of all LT recipients), head and neck neoplasms (6 cases, 10.9% of all cancers and 1.04% of all LT recipients), post-transplant lymphoproliferative disorder (PTLD) (5 cases, 9.0% of all cancers and 0.87% of all LT recipients), gastrointestinal cancers (5 cases, 9.0% of all cancers and 0.87% of all LT recipients) and neuroendocrine

tumors (4 cases, 7.2% of all cancers and 0.70% of all LT recipients). The average time between transplant and cancer diagnosis was 27.3 ± 19.1 months. Additionally, 20 patients (3.4%) developed HCC post-transplant, of which 18 (90%) were recurrences. The types of cancer varied significantly by etiology ($p = 0.004$). Among patients with SLD and viral hepatitis, the most common cancer types were non-melanoma skin cancer (38.1% and 50%, respectively), while among those with autoimmune liver diseases, gastrointestinal cancers were the most frequent (27.2%). Among patients with a history of HCC prior to transplantation, 16.8% developed a non-HCC cancer, with non-melanoma skin cancer being the most frequent (40%). In multivariate Cox regression models, age at transplantation, gender, post-transplant alcohol use, tobacco use, and cirrhosis etiology were not associated with cancer development. However, a history of pre-transplant HCC was significantly associated with cancer risk (HR 2.66, 95% CI 1.39–5.07, $p = 0.003$). **Conclusion:** Cancer occurred in 9.7% of liver transplant recipients, typically within the first three years. Patients with a history of prior HCC at the time of transplantation were three times more likely to develop non-HCC cancer. These findings underscore the necessity of cancer surveillance in post-transplant recipients, particularly among those with a history of HCC.

3556 | FIBROSIS AND STEATOSIS PROGRESSION AFTER LIVER TRANSPLANTATION DIFFERS BASED ON THE PRETRANSPLANT ETIOLOGY OF LIVER DISEASE

Michael Attanasi[1] Mathew Gregoski[2] Don Rockey[2], [1]Northwell Health, [2]Medical University of South Carolina

Background: Although liver transplantation is performed for a variety of different diseases, the natural history of fibrosis progression after liver transplantation is largely unknown. Here, we hypothesized that different causes of liver disease may be associated different progression of fibrosis progression rates after transplantation, perhaps related to the etiology of initial liver disease. **Methods:** All adults who underwent liver transplantation and had a liver biopsy at our institution from 1/1/2013 through 7/1/2021 were examined. Histology, fibrosis stage (F0-F4), rejection activity index (RAI), and complete clinical data were abstracted via the medical record through 9/21/2021. Patients who did not have a fibrosis stage recorded or who had surgical complications of transplant were excluded. The etiology of liver disease was determined pre-transplant based on typical clinical criteria and confirmed histologically on explant histology. Patients were grouped based on the pre-transplant etiology of their liver disease, and time to progression of each stage of fibrosis and grade of steatosis was recorded. The median time to developing each fibrosis stage was calculated with trendlines plotted. **Results:** Of 515 transplant patients having a liver biopsy, we identified 347 patients who met inclusion criteria, representing 1,133 biopsies. Females had a higher prevalence of AIH and PBC (respectively: 29/145 (20%) vs 10/224 (4%); 18/145 (12%) vs 1/224 (1%); $p < 0.0001$), and males had a higher prevalence of ALD and HCV (respectively: 48/224 (21%) vs 14/145 (10%); 104/224 (46%) vs 33/145 (23%); $p < 0.01$ and 0.0001). AIH, PBC, and PSC was more prevalent in Black patients then White patients (respectively: 20/80 (25%) vs 19/276 (7%); 8/80 (10%) vs 11/276 (4%); 12/80 (15%) vs 9/276 (3%); $p < 0.0001$, $p < 0.05$, and $p < 0.05$), and ALD and MASLD was more prevalent in White patients (respectively: 58/276 (21%) vs 2/80 (3%); 54/276 (20%) vs 2/80 (3%); $p < 0.0001$). Viral liver diseases had the highest rate of fibrosis progression (Figure 1a). Rejection severity was not correlated with fibrosis for any etiology. Steatosis grade progressed most rapidly with MASLD and HCV (Figure 1b) and progressed slowest in ALD. **Conclusion:** In conclusion, viral liver diseases had the most rapid fibrosis progression. The majority of HCV patients

included in this analysis were transplanted prior to the introduction of direct acting antiviral medications, and as such serve as a baseline for expected rapid fibrosis progression. Steatosis progression is most rapid in MASLD and HCV and least rapid in patients ALD.

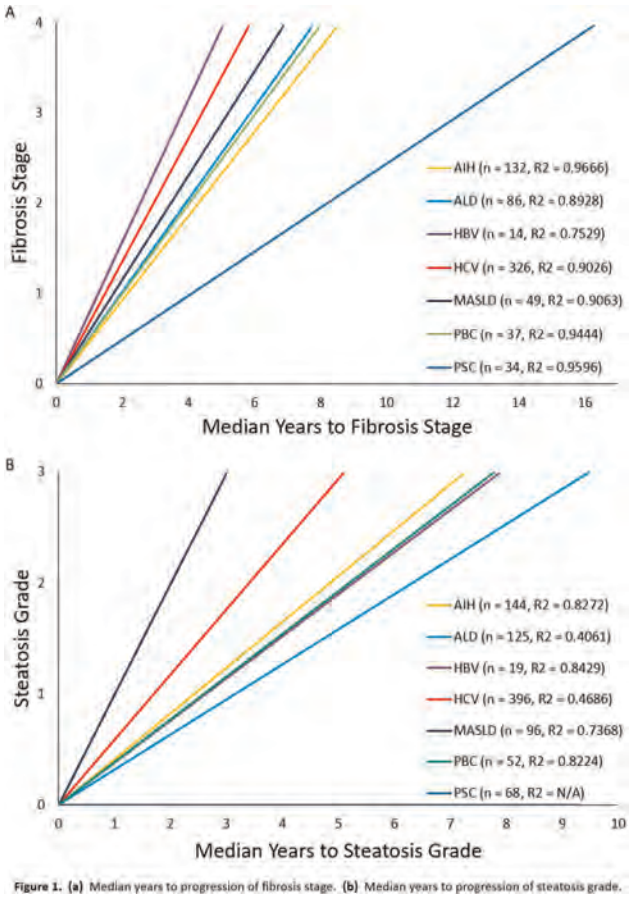

Figure 1. **(a)** Median years to progression of fibrosis stage. **(b)** Median years to progression of steatosis grade.

3557 | GRADING CHATGPT'S RESPONSES TO QUESTIONS ABOUT LIVING DONOR LIVER TRANSPLANT

Russell Rosenblatt[1] Pamela Cobbs[2] Brett Fortune[3] Kristina Chacko[3] Whitney Jackson[4] Hyosun Han[5]

Danielle Brandman[1], [1]Weill Cornell Medicine, [2]Columbia University Irving Medical Center, [3]Montefiore Medical Center, [4]University of Colorado Denver, [5]University of Southern California

Background: Living donor liver transplant (LDLT) provides better outcomes and improved access for patients with liver disease. However, both patients and non-transplant providers are poorly educated about LDLT. Increasingly, artificial intelligence (AI) is utilized by patients to learn about complex medical conditions and treatments. As our patients rely on this tool, physicians must evaluate their efficacy and accuracy to minimize misinformation. We assessed the performance of Chat Generative Pretrained Transformer (ChatGPT) in answering common questions about LDLT. **Methods:** Chat Generative Pretrained Transformer (ChatGPT) is a commonly used technology created by OpenAI Foundation. We asked 9 separate questions with the following themes: education (1-2), risks for donors (3-5, 7), outcomes for donors (5-7), and how to find a donor (8-9). We had 2 medical directors of LT and 4 LDLT programs grade each response based on a Likert scale – for accuracy (rated 1 to 6) and completeness (rated 1 to 3), with higher scores being better. Additionally, we had a donor champion coordinator evaluate the questions focused on how to find a donor (questions 8 and 9). Mean scores were calculated and ranges were reported. **Results:** The mean accuracy of responses was 5, with individual respondents ranging from 4.3-5.4 and individual questions from 4.3-5.3. For categories, the accuracy was highest (5.1) in the risks for donors and lowest for education (4.8). The highest mean score for a question was 5.3 for "Will I die at younger age if I donate my liver?" The lowest mean score for a question was 4.3 for both "What is a living donor liver transplant?" and "What is the risk of dying if I donate my liver?" No respondents graded any response lower than a 4/6.
Completeness of responess was graded at a mean 2.7, with individual respondents ranging from 2.5-3 and individual questions from 2.2-3. Question 5 and 6 – both discussing risk of future liver disease and mortality – were voted 3/3 by 5 of the 6 respondents. The lowest mean score was 2.3 for question 7 – "Can I drink alcohol after donating my liver?" No respondent graded any response lower than a 2/3. **Conclusion:** As AI becomes increasingly utilized to learn about medical issues and procedures, it is equally vital for providers to keep pace and remain aware of its strengths and pitfalls. The accuracy of ChatGPT was assessed quite positively by medical directors of LT programs and LDLT programs and most of the answers were graded as complete. While there were errors and omissions, ChatGPT represented LDLT as reasonably as can be expected. Further and recurrent analysis will be needed to keep up with new technologies and their changes over time.

3558 | SHOULD ACUTE PANCREATITIS DELAY LIVER TRANSPLANTATION? INSIGHTS FROM A PROPENSITY-MATCHED COHORT STUDY

Sameer Rao[1] *Niwen Kong*[2] *Ritik Mahaveer Goyal*[1] *Manas Gunani*[3] *Paul Gaglio*[1] *Amir Gougol*[2] *Nikki Duong*[2], [1]*Rutgers New Jersey Medical School,* [2]*Stanford University,* [3]*Allegheny General Hospital*

Background: Liver transplantation (LT) is the definitive treatment for end-stage liver disease (ESLD). While LT is typically delayed in cases of necrotizing pancreatitis due to higher post-operative risks, the impact of mild acute pancreatitis on transplant timing remains unclear. This study evaluates the effect of pre-operative acute pancreatitis on post-transplant outcomes. **Methods:** We conducted a retrospective cohort study using the TriNetX database and International Classification of Diseases-10 codes to compare one-year post-operative outcomes in LT recipients with vs. without acute pancreatitis within 30 days prior to transplant. Patients with pancreatic neoplasms, pseudocysts, abscesses, or multi-organ transplants were excluded from the study. The two groups were 1:1 propensity score matched based on demographics and clinical covariates. The primary outcome was graft failure. Secondary outcomes included infectious (sepsis, peritonitis, cytomegalovirus infection), graft-related (rejection, infection), surgical (hemorrhage, ileus, abscess), systemic (acute kidney injury, encephalopathy, cardiovascular/cerebrovascular events) complications, and all-cause mortality. Relative risks (RRs) with 95% confidence intervals (CIs) were calculated; $P < .05$ was considered significant. **Results:** Our study included 138 patients with acute pancreatitis ≤30 days before LT (mean age 48 ± 14.2 years; 67.4% male) and 10,611 patients without acute pancreatitis in the same period (mean age 54.5 ± 12.4 years; 76.1% male). After 1:1 propensity score matching, 136 patients per group were followed for one year. Patients with acute pancreatitis within 30 days prior to LT had similar risk of graft failure (RR 1.00; 95% CI 0.54–1.84; P = 1.00). The acute pancreatitis group also had similar risk for other clinical outcomes such as sepsis (RR 1.32; 95% CI 0.83–2.09; P = 0.24), peritoneal abscess (RR 1.10; 95% CI 0.48–2.50; P = 0.82), post-operative hemorrhage (RR 1.00; 95% CI 0.62–1.61; P = 1.00), ileus (RR 1.08; 95% CI 0.53–2.20; P = 0.84), transplant rejection (RR 0.78; 95% CI 0.50–1.20; P = 0.25), liver transplant infection (RR 1.30; 95% CI 0.59–2.86; P = 0.51), CMV infection (RR 1.25; 95% CI 0.77–2.02; P = 0.36), acute kidney injury (RR 0.99; 95% CI 0.84–1.61; P = 0.90), pneumonia (RR 1.21; 95% CI 0.62–2.36; P = 0.57), and mortality (RR 1.40; 95% CI 0.64–3.04; P = 0.39). There was a tendency towards higher risk of encephalopathy (RR 1.71; 95% CI 0.93–3.17; P = 0.08), but it did not reach statistical significance. **Conclusion:** This is the first national real-world data study to demonstrate that LT within 30 days of acute pancreatitis does not significantly increase post-transplant complications. While recent pancreatitis warrants careful evaluation, it should not be considered a strict contraindication. Further prospective studies are needed to validate these findings and guide transplant candidacy decisions in this complex patient population.

Table – Comparison of one-year post-transplant outcomes in patients with vs. without acute pancreatitis ≤30 days prior to liver transplant

Clinical outcomes after propensity matching	N (136)	%	*Relative Risk	Confidence interval	P-value
Sepsis	33	24.26	1.32	(0.83,2.09)	.24
	25	18.38			
Peritonitis	20	14.71	1.67	(0.85,3.27)	.13

3559 | PRE-TRANSPLANT GLP-1 RECEPTOR AGONIST USE AND POST-LIVER TRANSPLANTATION OUTCOMES: A RETROSPECTIVE COHORT STUDY

Joanna Jiang[1] Sandra Boutros[2] Stacey Culp[2] Chathur Acharya[2] Vivek Mendiratta[2] Melissa McGowan[2] Nicole Gray[3] Lindsay Sobotka[2], [1]The Ohio State Wexner Medical Center, [2]The Ohio State University Medical Center, [3]Ohio State University

Background: Glucagon-like peptide 1 (GLP-1) receptor agonists (RAs) are increasingly used in patients with metabolic dysfunction-associated fatty liver disease (MAFLD), one of the most common etiologies for end-stage liver disease requiring liver transplantation (LT). The use of GLP-1RAs has been associated with adverse outcomes in certain surgical settings. However, their impact on post-LT outcomes has yet to be studied. **Methods:** A retrospective cohort study was conducted of adult LT recipients who underwent LT between 7/20/2016 and 12/6/2024 at The Ohio State University Medical Center. Patients were stratified by documented duration of GLP-1 use, either within 12 months or more prior to LT. Primary outcomes included: reintubation, post-LT length of stay (LOS), post-LT infection, return to OR for bleeding, hepatic artery thrombosis, acute cellular rejection, renal dysfunction requiring dialysis, biliary strictures/ischemia, graft loss, and all-cause mortality. Chi-squared and Fisher's exact tests were used. Logistic regression controlled for pre-transplant BMI. **Results:** Thirty-eight LT recipients were using GLP-1 prior to LT and were compared to 120 LT recipients not utilizing GLP-1 RA. Twenty of the GLP-1 patients had taken it within two weeks of LT. Gender, race, and age at LT did not differ significantly between the groups. Pre-LT MELD at time of waitlist was lower in the GLP-1 group (17.6 vs 21.3; $p = 0.008$). Pre-LT BMI was significantly higher in the GLP-1 group compared to controls (32.8 vs 29.4; $p = 0.002$), as was pre-transplant diabetes (92.1% vs 27.5%; $p < 0.001$), hyperlipidemia (84.2% vs 30.8%; $p < 0.001$), and coronary artery disease (63.2% vs 32.5%; $p < 0.001$). Patients taking GLP-1 medications had higher rates of return to OR for bleeding, prolonged intubation, renal dysfunction, graft loss, and LOS (Table 1). One-year mortality did not differ significantly. A sensitivity analysis that included only those who had used GLP-1 medications within two weeks of their LT ($n = 20$) showed similar significant differences in outcomes when compared to the non-GLP-1 group. **Conclusion:** Patients on GLP-1 had increased complications in the immediate post-LT course; however, further research is needed to clarify the long term benefits of GLP-1 medications on improving control of metabolic conditions which typically worsen post-LT outcomes.

Table 1: Comparison of Outcomes Between Liver Transplant Recipients on GLP-1s and Controls

Variable	Control (N=120) N (%)	GLP-1s (N=38) N (%)	p-value
Infection post LT	36 (30.3)	16 (42.1)	0.261
Return to OR for bleeding	8 (6.7)	9 (23.7)	**0.009**
Reintubated	3 (2.5)	6 (15.8)	**0.013**
Hepatic artery thrombosis	2 (1.7)	1 (2.6)	0.811
Acute cellular rejection	24 (20.2)	3 (8.1)	0.085
Renal dysfunction requiring renal replacement	13 (10.9)	11 (28.9)	**0.030**
Biliary pathology	51 (42.9)	13 (34.2)	0.297
Graft loss in 1 year	7 (5.8)	7 (18.4)	**0.020**
Mortality within 1 year	6 (5.0)	5 (13.2)	0.064
LOT in ICU (time from admit to transfer order) – hours	40 (26 – 58)	73 (42.5 – 102.5)	**< 0.001**
LOT in the hospital after OLT – days	8.5 (7 – 12)	11 (8 – 15.5)	**0.017**

3560 | EARLY POST-TRANSPLANT ENTERAL NUTRITION SHORTENS HOSPITALIZATION AND PREVENTS ICU READMISSION AFTER LIVER TRANSPLANTATION

Ali Shaat[1] Muhammad Ali Butt[1] Catherine Briere[1] Audrey Paradis[1] Han LI[1] Ming Lin[1] James Hendele[1] Amir Qamar[1] Mohamed Akoad[1] Bartholomew Kane[1] Sarah Meade[1] Raza Malik[1], [1]Lahey Hospital & Medical Center

Background: Malnutrition is a modifiable risk factor that impairs recovery after liver transplantation (LT), yet the optimal timing of postoperative enteral tube feeding (TF) remains uncertain. We aimed to evaluate how TF timing affects 28-day postoperative outcomes in LT recipients with preoperative diagnoses of moderate-to-severe malnutrition. **Methods:** In this single-center, retrospective cohort study at Lahey Hospital & Medical Center (01/01/2024–12/31/2024), 32 adult LT recipients with moderate-to-severe malnutrition were stratified by TF

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

initiation: ≤48 hours (Early TF), 48 hours–7 days (Intermediate TF), and >7 days (Delayed TF). Over a 28-day period, we compared initial ICU and hospital length of stay (LOS), infection rates, readmission, ascites requiring paracentesis, graft rejection, discharge disposition, and all-cause mortality. Continuous variables were compared using Student's t-test or Mann-Whitney U test and categorical variables were assessed using Fisher's exact or Chi-square testing. **Results:** Among 32 liver transplant recipients, 20 received early TF, 6 received intermediate TF, and 6 received delayed TF. Baseline demographics are summarized in Figure 1. Hospital LOS increased progressively with delayed initiation of enteral nutrition. The early feeding group (Group 1) had a median stay of 11 days (IQR 8.8–23.5), compared to 22 days (IQR 17–27) in the intermediate group (Group 2; $p = 0.044$), and 38.5 days (IQR 25.8–54.3) in the delayed group (Group 3; $p = 0.006$ vs. Group 1).

Median initial ICU stay rose from 2 days (IQR 1–3.3) in Group 1 to 3.5 days (IQR 1.3–5.8) in Group 2 and 4 days (IQR 2.3–5.0) in Group 3, though these increases were not statistically significant ($p = 0.26$ and 0.15, respectively). ICU readmission within 28 days occurred in 0% of patients in Group 1, 33% in Group 2, and 83% in Group 3, with a statistically significant difference between Groups 1 and 3 ($p < 0.001$).

Rates of postoperative infection (55% vs. 33% vs. 67%), ascites requiring paracentesis (25% vs. 17% vs. 17%), acute rejection (0% vs. 17% vs. 0%), 30-day readmission (25% vs. 17% vs. 33%), and discharge disposition did not differ significantly across groups. There were no deaths in any cohort. **Conclusion:** In post-LT patients with moderate-to-severe malnutrition, early initiation of TF within 48 hours was associated with significantly shorter hospital LOS and markedly lower ICU readmission rates compared with delayed TF. Although trends toward shorter ICU LOS and lower complication rates were observed in the early cohort, these did not reach statistical significance. No differences were seen in infection, ascites, rejection, readmission, disposition, or mortality across groups. These findings support early TF initiation soon after transplant to enhance recovery and reduce resource utilization. Limitations of the study include the small cohort size; further prospective studies are warranted to confirm these results.

3561 | PRELIMINARY STUDY ON PREDICTING HEPATOCELLULAR CARCINOMA RECURRENCE POST-LIVER TRANSPLANT USING LI-RADS AND LESION VOLUME METRICS

Emma Stevenson[1] Stephanie Harmon[1] Ross Filice[2] Peter Choyke[1] Theo Heller[3] Ismail Turkbey[1] Christine Hsu[4], [1]National Cancer institute, [2]Georgetown University, [3]NIH/NIDDK, [4]National Institute of Diabetes, Digestive

Background: Liver transplantation (LT) is associated with lower hepatocellular carcinoma(HCC) recurrence rates than resection but despite this, post-LT HCC recurrence still occurs in 5-15% of cohorts. Most of recurrence prediction models utilize tumor characteristics discovered on liver explant tissue, but there can be approximately 22%-30% discordance between pathological and radiological tumor characteristics. Therefore, we explore radiomics in predicting HCC recurrence. **Methods:** This is retrospective study with patients who were liver transplanted for HCC at a tertiary center. Primary outcomes evaluated included HCC recurrence and mortality. Each patient had multiphasic contrast-enhanced T1 MRI scans pre-LT. Total tumor volume (TTV) was analyzed with three groups by summing volumes of 1) LIRADS-3 or higher lesions, 2) LIRADS-4 or higher lesions, 3) only LIRADS-5 lesions. Treated lesions were included in the TTV summation. All except 6 patients had untreated HCC on MRI images. Wilcoxon tests compared median TTV, age, and gender between recurrence and mortality groups at varying time points. The Cox proportional hazards model was used to evaluate the association between TTV, age, and gender with time to post-transplant recurrence and mortality to identify independent predictors of these outcomes. **Results:** Out of 168 patients, 21 had HCC recurrence, thus resulting in a cumulative incidence rate of 0.31% and median time to recurrence of about 34 months (IQR: 11.4, 65.5). Median age of age of cohort is 70 (IQR: 66,74) and majority is male (n = 130, 77%). 66 were Caucasian, 50 Black, 22 Asian, 11 Hispanic, and 25 were multi-racial/other/unknown. All HCC recurrence occurred within 2 years post-LT. Etiology of liver disease was predominantly Hepatitis C

(54%), followed by chronic hepatitis B (13%), steatotic liver disease (alcohol and non-alcohol) (20%), others (13%). LI-RADS 5+ TTV had a statistically significant association with overall recurrence (p = 0.02), and recurrence at 6- and 12-months post-LT (p = 0.04 and p = 0.002 respectively). The optimal TTV cutoff to differentiate overall recurrence from non-recurrence was 42.2 cm3 (p = 0.001) with any volumes greater being associated with recurrence. However, in an age and gender adjusted multi-variate analysis, TTV LIRADS-5+ group (HR = 1.2 [0.8-1.8], p = 0.5) did not independently predict recurrence. In the multivariate analysis, with TTV of LI-RADS 3 or greater group, increased age independently predicted 12-month morality (HR = 1.96 [1.06-3.62], p = 0.031). **Conclusion:** HCC recurrence occurred early in this cohort and TTV of LIRADS-4 or greater lesions is associated with HCC recurrence but did not independently predict in age and sex adjusted multivariate analysis. Age was the strongest predictor of post-LT mortality. This highlights that TTV alone is not able to predict mortality but when combined with patient factors, such as age, it can result in significant associations.

	LI-RADS 3+ Lesion Patients			LI-RADS 4+ Lesion Patients			LIRADS 5+ Lesion Patients		
	TTV p-value	Age p-value	Gender p-value	TTV p-value	Age p-value	Gender p-value	TTV p-value	Age p-value	Gender p-value

3562 | OUTCOMES OF RETRANSPLANTATION FOR AUTOIMMUNE LIVER DISEASES: A NATIONAL RETROSPECTIVE COHORT STUDY

Justin Ong[1] Brian Horwich[2] Jeffrey Kahn[2] Jennifer Dodge[3] Oluwakemi Ayeni[3] Susie Lee[4] Steve Kim[4], [1]Keck School of Medicine, University of Southern California, [2]Keck Hospital of USC, [3]Keck School of Medicine, USC, [4]Keck School of Medicine of USC

Background: Liver retransplantation (reLT) is indicated after primary allograft failure and accounts for up to 10% of liver transplants (LT) in the United States. Late graft loss (LGL), ≥ 1 year (y) from primary transplant, in autoimmune liver disease (AILD) is often due to rejection or recurrence of primary disease. Outcomes after reLT for LGL in AILD compared to other indications are not well understood. **Methods:** This retrospective cohort study included adult recipients with reLT between March 2002 and December 2021 in the United Network for Organ Sharing database. Those with < 1y between primary and reLT or diagnosis of hepatitis C virus were excluded. ReLT indication was classified as AILD (autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC)) or non-AILD. Outcomes included LGL (death with recurrent disease or 2nd reLT, censoring at death without recurrence, death or reLT within 1 y of LT, or at last follow-up and patient survival. Kaplan-Meier estimates of outcomes were compared via the log-rank test. Cox regression estimated hazard ratios (HR) for risk of LGL. **Results:** A total of 1,969 patients (38.4% AILD, 61.6% non-AILD; median age 45 and 47 y, 43.3% and 42.5% female, respectively) were included. Over a median follow-up time of 4.8 y (IQR 2.0-9.0), LGL was identified in N = 80 for AILD and N = 62 for non-AILD. Fifteen-year cumulative incidence of LGL was higher for AILD (0.22, 95% CI 0.18-0.28) vs. non-AILD (0.13, 0.09-0.18; p = 0.002) and for AIH (0.24, 0.15-0.36) and PSC (0.25, 0.19-0.33) vs. PBC (0.03, 0.008-0.12; p = 0.002 and 0.006, respectively). In univariable analysis among AILD, risk of LGL was higher for AIH (HR 7.54, 1.77-32.08, p = 0.006) and PSC (HR 5.64, 1.38-23.13, p = 0.02) vs. PBC, and MELD (HR 1.02 per unit increase, 1.00-1.05, p = 0.06), while age (HR 0.94 per y increase, 0.93-0.96, p < 0.001) was associated with decreased LGL. After adjusting for age and MELD, risk of LGL remained elevated for AIH (HR 3.23, 0.74-14.14, p = 0.12) and PSC (HR 3.93, 0.95-16.27, p = 0.06) though the associations were attenuated. Patient survival at 15 y was higher for AILD (0.48, 0.43-0.54) than non-AILD (0.45, 0.40-0.50, p = 0.01) and higher for PSC (0.54, 0.47-0.60) compared to AIH (0.39, 0.26-0.52, p = 0.04) and PBC (0.37, 0.24-0.50, p = 0.03). **Conclusion:** AILD was associated with a two-fold increase in LGL after reLT compared to other indications, but superior patient survival. Among AILD, LGL was more common in AIH and PSC compared to PBC. Though LGL is more common in AILD, excellent survival supports the continued practice of reLT in this group.

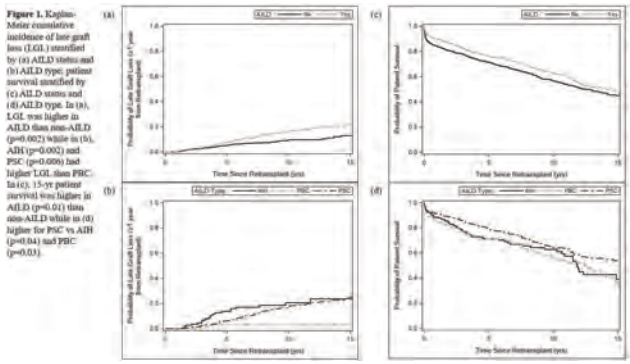

Figure 1. Kaplan-Meier cumulative incidence of late graft loss (LGL) stratified by (a) AILD status and (b) AILD type; patient survival stratified by (c) AILD status and (d) AILD type. In (a), LGL was higher in AILD than non-AILD (p=0.002) while in (b), AIH (p=0.002) and PSC (p=0.006) had higher LGL than PBC. In (c), 15-yr patient survival was higher in AILD (p=0.01) than non-AILD while in (d) higher for PSC vs AIH (p=0.04) and PBC (p=0.03).

3563 | IMPACT OF PRE-EXISTING DIABETES ON POST-TRANSPLANT INFECTIONS AND MORTALITY IN LIVER RECIPIENTS: A TIME-INTERVAL PROPENSITY-MATCHED ANALYSIS

Mohammad Abuassi[1] Mahmoud Y Madi[2] Hadi Abou Zeid[3] Badi Rawashdeh[4] Kia Saeian[4] K Raj Prasad[4], [1]University of Central Florida, [2]University of Texas Austin Dell Medical School, [3]Mayo Clinic, [4]Medical College of Wisconsin

Background: Diabetes mellitus (DM) is prevalent among liver transplant (LT) recipients, but its impact over distinct postoperative intervals remains insufficiently explored. We assessed the incidence of infections, including cholangitis, sepsis, and all-cause mortality over four distinct postoperative intervals. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network, a global federated health platform aggregating de-identified electronic health records from over 120 healthcare organizations. Adult LT recipients (2014–2024) were stratified by DM status and matched 1:1 (n = 17,065/group) using propensity scores for demographics and MELD-Na components. We evaluated infections (including cholangitis), sepsis, and all-cause mortality across four postoperative intervals: 0–30 days, 1–3 months, 3–6 months, and 6–12 months. Risk ratios (RR) with 95% confidence intervals (CI) were calculated. **Results:** DM was associated with persistently higher infection risks. In the early postoperative period (0–30 days), diabetic recipients had increased rates of surgical site infections (1.10% vs 0.65%, RR 1.68, 95% CI 1.32–2.14), candidiasis (1.00% vs 0.67%, RR 1.50, 95% CI 1.17–1.92), and Gram-negative sepsis (0.46% vs 0.30%, RR 1.51, 95% CI 1.05–2.16). The heightened risk of surgical site infections, candidiasis, and Gram-negative sepsis persisted into the 6–12 month postoperative period. Cholangitis incidence was higher in diabetic recipients across multiple intervals, including 1–3 months (0.9% vs 0.6%, RR 1.50, 95% CI 1.15–1.94) and 3–6 months (1.3% vs 0.8%, RR 1.61, 95% CI 1.23–2.12). Despite increased infection risks, 1-year survival remained slightly higher in diabetic recipients (92.53% vs 91.68%, HR 0.88, 95% CI 0.81–0.95, p = 0.0003). **Conclusion:** Pre-existing diabetes compounds infection risk conferred by immunosuppression in liver transplant recipients. This dual vulnerability is associated with significantly higher rates of infections and related complications but does not result in diminished 1-yr survival potentially reflecting improved perioperative management strategies. These findings highlights the need for individualized prophylactic protocols, enhanced microbiologic surveillance, and proactive management strategies to improve outcomes and resource utilisation in diabetic recipients. The impact of optimizing diabetes control pre and perioperatively on these complications is unknown and should be studied using more granular data.

3564 | GRAFT SURVIVAL FOLLOWING LIVER TRANSPLANTATION FROM MARGINAL DONORS: DO SPECIFIC RISK CRITERIA IMPACT OUTCOMES DIFFERENTLY?

Yasmeen Saker[1], [1]University of Florida

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: The 2023 OPTN/SRTR Annual Data Report highlights an 8.5% rise in liver transplant waitlist registrations, emphasizing the need to expand donor utilization, including marginal liver donors (MLDs). Although MLD features often inform clinical decisions, their specific impact on graft survival remains unclear. This study examined whether commonly used MLD criteria are associated with differences in 1- and 3-year graft survival. **Methods:** We retrospectively analyzed adult liver transplant recipients at the University of Florida between 01/2019 and 09/2024. Donors were classified as MLDs if they met at least 1 predefined high-risk criterion: age >65 years, BMI >30, ICU stay >4 days, serum sodium >160 mmol/L, abnormal LFTs (ALT >105 U/L, AST >90 U/L, or bilirubin >3 mg/dL), substance use, extrahepatic malignancy, donation after circulatory death (DCD), cold ischemic time >12 hours, and/or viral hepatitis (HBsAg, HBcAb, or HCV Ab positivity). Data on steatosis, hypotension, and inotropic support were unavailable and excluded. Donor risk factors were grouped into six clinically relevant categories to reflect common allocation considerations: demographic risk (age, BMI, and history of cancer), viral hepatitis, abnormal labs (liver tests and sodium), history of any substance use, DCD status, and ICU LOS. A seventh category captured donors with >1 risk factor. Graft survival at 1 and 3 years was estimated using Kaplan-Meier analysis and compared across groups via log-rank testing. Statistical significance was defined as a p-value <0.05. **Results:** We analyzed 559 liver transplant recipients of grafts from MLDs. Overall graft survival was 97.8% at 1 year and 88.3% at 3 years. Initial survival comparisons across the defined donor risk categories did not demonstrate significant differences in survival. Similarly, the presence of multiple marginal risk factors was not associated with worsened graft outcomes ($p=0.5$).

Subsequently, each donor risk category was independently compared against its respective control group—recipients whose donors did not meet that specific criterion. Across these pairwise analyses, most donor risk factors—including DCD status, viral hepatitis, substance use history, abnormal liver chemistries, and high-risk demographics—were not associated with statistically significant differences in graft survival. The presence of multiple marginal risk factors did not correlate with worsened survival ($p=0.5$). Only the criteria of donor ICU stay >4 days was significantly associated with reduced 1 and 3-year graft survival (91.3% vs 98.1%, $p=0.02$ and 56.2% vs. 89.0%, $p=0.009$ respectively). **Conclusion:** Most individual and combined MLD risk factors were not associated with inferior graft survival. However, prolonged donor ICU stay (>4 days) was linked to significantly worse outcomes and should be a key consideration in donor selection and allocation strategies.

Table: Graft Survival by Donor Marginal Risk Factor

Donor Risk Criteria	1-Year Survival (%)	P-value	3-Year Survival (%)	P-value
Substance Use	98.8	0.07	88.0	0.73
Viral Hepatitis	99.3	0.19	87.4	0.86
DCD	100	0.22	96.8	0.06
Abnormal Labs	98.3	0.19	89.0	0.79
ICU LOS	91.3	**0.02**	56.2	**0.009**
Demographic Risk	97.2	0.37	89.4	0.65

3565 | FEW PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE INITIALLY DECLINED FOR LIVER TRANSPLANTATION RECEIVE TRANSPLANT AND HAVE HIGH 3-YEAR MORTALITY

Jennifer Flemming[1] Nazia Selzner[2] Kyla Naylor[3] Graham Smith[3], [1]Queen's University Cancer Research Institute, [2]University of Toronto, [3]ICES-Western

Background: Outcomes are excellent for patients receiving liver transplant (LT) with <6 months of alcohol abstinence for alcohol-associated liver disease (ALD). However, limited data have described outcomes of those with <6 months of abstinence who were referred and ultimately declined for LT wait-listing. We describe the long-term outcomes of patients with <6 months of abstinence who were initially declined LT wait-listing for ALD. **Methods:** Individuals declined for LT waitlisting from the University of Toronto ALD pilot program from May 2018 – October 2020 were linked to administrative healthcare data and followed to October 2023. The primary objective was to describe 6-month, 1-year and 3-year overall survival which was calculated using the Kaplan-Meier method and factors associated with LT-free survival were evaluated with adjusted Cox regression. We also assessed healthcare utilization, medical alcohol use disorder (MAUD) treatment and LT re-referral. **Results:** We included 391 individuals declined for LT waitlisting for ALD (median age 54, 29% female, 59% co-morbid viral hepatitis, 11% hepatocellular carcinoma) with a median MELD-Na of 18 (IQR 14-24) and followed for a median of 20 months (IQR 3-43). Overall, 282 (72%) had further decompensation events and 205 (52%) received MAUD treatment. The median number of gastroenterology/hepatology outpatient visits was 9 (IQR 3-19), emergency room visits was 3 (IQR 1-6) and hospital admissions was 2 (IQR 0-3). In total, 40 (10%) were re-referred for LT and 17 (5%) ultimately received LT. Overall, 252 (64%) died with a median survival of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

22 months (IQR 3-55). 6-month, 1-year and 3-year survival was 68%, 59% and 38% respectively (Figure). After adjusted Cox regression, older age was the only factor associated with mortality (per 5-year increase HR 1.07, 95% CI 1.01-1.14). **Conclusion:** After being declined for LT for ALD, patients have high ongoing healthcare utilization and 3-year mortality. Few are re-referred for evaluation and only 5% receive LT. These results can be used in discussion with ALD patients declined LT for goals of care discussions.

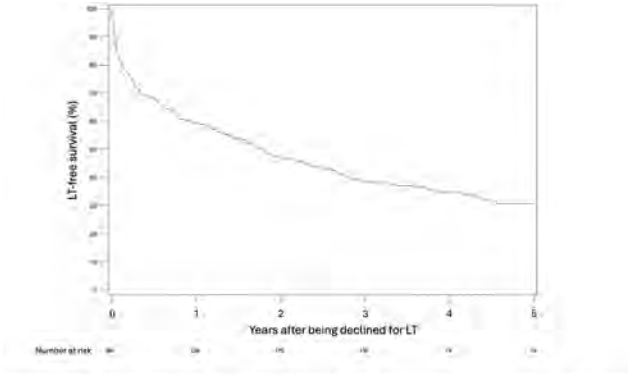

Figure: Liver transplant (LT) free survival for individuals declined for LT wait-listing for alcohol-associated liver disease.

3566 | IMPACT OF SWITCH FROM STANDARD-RELEASE TACROLIMUS (PROGRAF®, ADVAGRAF®) TO MELTDOSE® TACROLIMUS (LCPT) (ENVARSUS®) ON HEADACHES/ MIGRAINES: THE E-MIG STUDY

LUCY MEUNIER[1] Karim Gebara[1] José Ursic-Bedoya[1] Magdalena Meszaros[1] Stephanie Faure[1] Georges-Philippe Pageaux[1], [1]CHU Montpellier

Background: Tacrolimus (Tac) has long been the cornerstone of immunosuppressive therapy in liver transplantation (LT). However, its use is sometimes limited by toxicity, particularly neurotoxicity, which primarily manifests as tremors, headaches, and migraines. A prolonged-release formulation known as life cycle pharma (Tac-LCP) offers a more stable pharmacokinetic profile, potentially reducing neurological adverse effects such as tremors. Nonetheless, studies specifically evaluating the impact of this new formulation on headaches and migraines remain scarce. The aim of this study was to assess the evolution of neurological symptoms, particularly headaches and migraines, following therapeutic conversion to Tac-LCP. **Methods:** We conducted a retrospective, single-center study including adult patients who underwent conversion to Tac-LCP after LT, either due to toxicity associated with standard Tac formulations or for bioavailability-related reasons. The primary endpoint was the impact of Tac-LCP conversion on the improvement of headaches and migraines. Diagnosis and classification of headaches and migraines were based on the International Classification of Headache Disorders, 3rd edition (ICHD-3). Symptom severity and improvement were assessed using the Clinical Global Impression-Severity (CGI-S) and Clinical Global Impression-Improvement (CGI-I) scales, respectively. **Results:** A total of 82 patients were included, 59.8% of whom were male, with a mean age of 58 years. The primary indication for LT was alcohol-related liver disease (35.4%). Neurological toxicity accounted for 61% of conversions, with 30.5% (n = 25) directly related to headaches or migraines. Among patients suffering from headaches or migraines, 28% (n = 7) rated themselves as severely or extremely ill according to the CGI-S. The median time from LT to conversion to Tac-LCP was 369 days (range: 15–12,967 days). Compared with patients converted for other reasons, those with Tac-associated headaches or migraines were predominantly female (68% vs. 28.1%; p = 0.002) and had significantly more family history of headaches or migraines (40% vs. 8.9%; p = 0.005). Tacrolimus trough levels prior to conversion were higher in patients with headaches or migraines (6.9 vs. 5.5 ng/mL; p = 0.007), although no significant difference was observed in post-conversion levels between patients whose symptoms resolved and those who did not. Following conversion to Tac-LCP, 72% (n = 18) experienced clinical improvement in headache or migraine symptoms, with 48% (n = 12) achieving complete symptom resolution (Figure 1). **Conclusion:** Conversion to Tac-LCP appears to be effective in alleviating Tac-associated neurotoxicity, particularly in patients with headaches and migraines. These findings warrant confirmation in other centers, and a multicenter study is currently underway.

3567 | VALIDATION OF GEMA-NA AND GEMA-AI IN AN AMERICAN COHORT OF PATIENTS ON THE LIVER TRANSPLANT WAITING LIST

Austin Halupnik[1] Patrick Ten Eyck[2] MANUEL LUIS RODRIGUEZ PERALVAREZ[3] Antonio Sanchez[4] Marta Tejedor[4], [1]University of Iowa Carver College of Medicine, [2]University of Iowa, [3]Hospital Universitario Reina Sofía, IMIBIC, CIBERehd, Córdoba, Spain., [4]University of Iowa Healthcare

Background: The most used liver transplantation (LT) allocation system is the Model for End-Stage Liver Disease (MELD). Women are disadvantaged with higher dropout rates and lower transplant rates. The Gender-Equity Model for Liver Allocation (GEMA) model and its variant GEMA-Na improved 90-day mortality prediction in wait-listed patients, with a greater effect in women. A new artificial intelligence variant, GEMA-AI, showed an even better discrimination in predicting mortality or delisting. No head-to-head comparison of MELD-based and GEMA-based models has been performed in the United States. **Methods:** We retrospectively analyzed data from all adults listed for LT (2016-2023) at the University of Iowa. Severity of liver disease was assessed with both the MELD-based scores (MELD, MELD-Na, MELD 3.0) and GEMA-based scores (GEMA, GEMA-Na, GEMA-AI). Data was collected until the time of transplant, exclusion from the WL (due to worsening or death, or to improvement), or until February 28, 2025. The ROC curve (receiver operating characteristic curves; AUC) of the different allocation systems was compared at 90 and 180 days of listing. Reclassification of patients using MELD 3.0, GEMA-Na, and GEMA-AI against MELD-Na as the reference category was estimated. **Results:** The study included 297 patients, 69% male, mean age 56 ± 11.2 years. The most common etiology of cirrhosis was alcohol (41%), followed by metabolic associated steatotic liver disease (27%), viral (14%), and other (18%). 42% had refractory ascites. 77 (26%) received a transplant, 59 (20%) were excluded due to worsening or death and 108 (36%) were excluded due to improvement. Mean MELD, MELD-Na, MELD3.0, GEMA, GEMA-Na and GEMA-AI scores were 18 ± 9, 20 ± 9, 18 ± 12, 19 ± 10, 21 ± 10 and 22 ± 8, respectively. No significant differences were found in AUC using any measure (MELD-Na, MELD3.0, GEMA, GEMA-Na, GEMA-AI) when compared to MELD-Na, although GEMA-AI had the highest AUC for women numerically (Figure 1). This difference was not statistically significant, likely due to our limited sample size and limited number of events. When compared to MELD-Na, 36 (12%) patients reclassified with MELD 3.0. Of them, 8 (3%) gained points, of which 3 were women. When compared to MELD-Na, 54 (21%) patients reclassified with GEMA-Na. Of them, 26 (10%) gained points, of which 12 were women. When compared to MELD-Na, 61 (23%) patients reclassified with GEMA-AI. Of them, 46 (18%) gained points, of which 30 were women. **Conclusion:** In our study, neither MELD3.0 nor any of the GEMA derived systems were able to demonstrate a statistically significant improvement in prediction of mortality when compared to MELD-Na. The limited number of events and the small sample size are the most likely explanation. However, GEMA-AI showed the greatest numerical AUC for women. Larger multicenter studies with a more diverse patient population are needed to better understand potential differences between these allocation models.

Lucio Caccamo[1] Mirella Fraquelli[1] Maria Francesca Donato[1] Pietro Lampertico[1], [1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [2]University of Milan, Milan, Italy

Background: Vibration controlled transient elastography (VCTE; Fibroscan®) is a non-invasive method to assess liver stiffness measurement (LSM) and evaluate liver fibrosis. VCTE has also been widely used in post-liver transplantation (LT) setting to identify graft damage. Spleen stiffness measurement (SSM) is known to improve non-invasive diagnosis of clinically significant portal hypertension (CSPH) but data in the post-LT setting are limited. The aim of this study was to evaluate changes in SSM, spleen size and liver stiffness following LT. **Methods:** From January 2022 to July 2024, all consecutive LT recipients transplanted at our centre with available SSM pre-LT were enrolled. Patients with re-LT, splenectomy or without SSM pre-LT were excluded. SSM was measured by VCTE Fibroscan® (Echosens, Paris) before LT and at 3-6-12 months after surgery, while LSM was assessed only after LT at the same time points. Ultrasonographic and biochemical data were also collected. Single linear regression models were performed at different time points to evaluate the relationship between SSM, platelet count and spleen diameter. **Results:** Twenty-nine recipients (median age 63 years, 59% males, 38% viral-etiology, 28% with HCC; 7 DCD grafts; donor age 58 years, 100% on CNI-based immunosuppression) were studied. Median SSM significantly decreased from 60 kPa pre-LT to 27, 25.5, 27 kPa at 3, 6, 12 months post-LT, respectively ($p < 0.05$). Spleen diameter reduced from 15 cm pre-LT to 14, 12, 12.4 cm at 3, 6, 12 months post-LT ($p < 0.05$), whereas platelet count significantly improved over time (67,000, 155,000, 147,000, 145,000/mm^3, $p < 0.05$). A significantly negative relationship between platelet count and SSM was found at 12 months and persisted significant after accounting for potential confounders (recipient and donor age, gender). Notably 4 patients experienced an increase in SSM and a positive relationship between SSM and vascular complications was found. **Conclusion:** Our study showed that SSM significantly decrease early after LT and this reduction remains stable over time, reflecting the resolution of portal hypertension. This improvement was further supported by the concurrent increase in platelet count and decrease in spleen size. Our results indicate that platelet increase after LT and SSM reduction are both good non-invasive markers of portal hypertension improvement. Further studies are needed to explore the role of SSM after LT in predicting vascular complications.

3569 | LONG-TERM LIVER TRANSPLANT OUTCOMES IN AMERICAN INDIANS ARE COMPARABLE TO OTHER ETHNICITIES DESPITE UNIQUE CHALLENGES

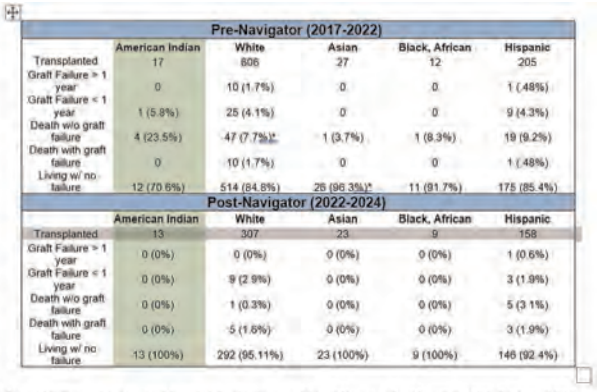
Alejandro Gonzalez[1] Sandra Elmasry[1] Blanca Lizaola-Mayo[1] Nathan Delafield[1] Adam Milam[1] Rolland Dickson[1] David Chascsa[1], [1]Mayo Clinic Arizona

Background: American Indian (AI) patients experience disproportionately lower access to liver transplantation (LT) compared to non-Hispanic White (NHW) patients. At Mayo Clinic Arizona (MCA), deferral and denial of AI patients have been attributed to psychosocial and multifactorial challenges. To reduce these disparities, a Navajo Patient Navigator program was implemented to provide longitudinal support and improve transplant candidacy. The aim of this study was to assess long-term post-transplant outcomes among AI patients pre- and post-navigator implementation, compared to other ethnicities, to determine whether healthcare disparities persist beyond access and into post-transplant outcomes. **Methods:** We performed a retrospective cohort

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

analysis of all transplanted patients at MCA with pre Navigator data from January 2017-April 2022 and post Navigator data from May 2022-October 2024. Pre-transplant data included demographics, transplant indication, and psychosocial parameters. Post-transplant data included graft failure and mortality from a liver or non-liver cause. The data was analyzed using Fisher's exact test for comparison of AI against other demographic groups and a p-value for significance was set at 0.05. **Results:** Pre-navigator data included 2405 LT referrals to MCA with 83 (3.5%) being AI. AI had a lower rate of evaluation, presenting and listing for transplant. The most common cause for deferral or denial of AI patients was either psychosocial alone or multifactorial parameters. Post transplant, four AI patients died and one patient had a graft failure while 47 NHW patients and 19 Hispanics died (Table 1).
Post-navigator data included 1649 LT referrals to MCA with 133 (8.1%) being AI. AI patients had a lower rate of evaluation, presentation, and listing. The most common cause for deferral or denial of AI patients was medical reasons with a significant decrease in denial due to psychosocial reasons. There have been no graft failures or mortality events in the transplanted AI population. **Conclusion:** AI populations face well-documented healthcare disparities throughout the LT process. Our results indicate that after hiring a Navigator there was an increase in referrals for LT and a decrease in deferral or denial due to psychosocial or multifactorial factors. Post transplant survival with a functioning graft increased in the AI and non AI patients in the post Navigator period, most pronounced in AI patients. These data suggest the Navigator has improved both pre- and post- transplant metrics. Post-transplant care such as follow up or medication adherence is likely improved; however, further studies would be required to characterize this more clearly. While our data are limited by the single-center design and follow up time as other studies show the full impact of navigators may take up to 566 days to emerge, our findings highlight the critical importance of early interventions in addressing LT disparities.



Pre-Navigator (2017-2022)					
	American Indian	White	Asian	Black, African	Hispanic
Transplanted	17	806	27	12	205
Graft Failure > 1 year	0	10 (1.7%)	0	0	1 (.48%)
Graft Failure < 1 year	1 (5.8%)	25 (4.1%)	0	0	9 (4.3%)
Death w/o graft failure	4 (23.5%)	47 (7.7%)*	1 (3.7%)	1 (8.3%)	19 (9.2%)
Death with graft failure	0	10 (1.7%)	0	0	1 (.48%)
Living w/ no failure	12 (70.6%)	514 (84.8%)	26 (96.3%)*	11 (91.7%)	175 (85.4%)
Post-Navigator (2022-2024)					
	American Indian	White	Asian	Black, African	Hispanic
Transplanted	13	307	23	9	158
Graft Failure > 1 year	0 (0%)	0 (0%)	0 (0%)	0 (0%)	1 (0.6%)
Graft Failure < 1 year	0 (0%)	9 (2.9%)	0 (0%)	0 (0%)	3 (1.9%)
Death w/o graft failure	0 (0%)	1 (0.3%)	0 (0%)	0 (0%)	5 (3.1%)
Death with graft failure	0 (0%)	5 (1.6%)	0 (0%)	0 (0%)	3 (1.9%)
Living w/ no failure	13 (100%)	292 (95.11%)	23 (100%)	9 (100%)	146 (92.4%)

3570 | ECHOING RISK: THE ROLE OF RIGHT VENTRICULAR SYSTOLIC PRESSURE (RVSP) IN LIVER TRANSPLANT OUTCOMES

Hong Lin[1] Antonio Alvarez Castaneda[1] Khalid Mumtaz[1] Chathur Acharya[1], [1]The Ohio State University Wexner Medical Center

Background: Right ventricular systolic pressure (RVSP), a key measure of right heart function on transthoracic echocardiogram (TTE), plays a critical role in assessing cardiopulmonary hemodynamics in liver transplantation (LT) candidates. Elevated RVSP is strongly associated with portopulmonary hypertension (PoPH) and right ventricular dysfunction, both of which increase post-LT morbidity and mortality. However, the predictive value of RVSP for short-term independent post-LT outcomes remains incompletely characterized. Our study investigates the relationship between pre-LT RVSP and post-LT morbidity, leveraging a large cohort to determine its utility as a prognostic marker. **Methods:** This single-center retrospective study analyzed LT recipients at The Ohio State University (2016–2020) who underwent TTE within one year prior to LT. Using the Youden J statistic, we derived optimal RVSP thresholds for predicting 90-day readmission (all-cause, cardiac, hepatic, and renal) and hemodialysis requirement. We then compared these data-driven cutoffs against conventional fixed thresholds (30, 35, 40, and 45 mmHg). **Results:** Of 243 patients, the mean age was 55.5 years (SD 10.1), with a majority being male (60%) and white (91.3%). The optimal RVSP thresholds for predicting 90-day hemodialysis need, cardiac readmission, and hepatic readmission were 32.8, 32.8, and 28 mmHg, respectively. For all-cause readmissions, the optimal thresholds were 36 mmHg (30-day) and 32.65 mmHg (90-day) (Figure 1A). ROC analysis (Figure 1B) revealed that RVSP best predicted cardiac readmission (AUC 0.673), followed by hepatic readmission (AUC 0.641), 90-day all-cause readmission (AUC 0.597), hemodialysis requirement (AUC 0.566), and 30-day all-cause readmission (AUC 0.557). All thresholds outperformed fixed cutoffs (30-45 mmHg; McNemar's test p-value < 0.05). On multivariate analysis (adjusted for age, sex, race, ESRD/PoPH), RVSP has a strong association with cardiac ($p = 0.002$), hepatic ($p = 0.033$), and all-cause readmission ($p = 0.029$). **Conclusion:** Our data reveal

RVSP as a valid predictive marker for post-LT readmissions, with optimized thresholds (28-36 mmHg) offering superior risk stratification. RVSP demonstrated the strongest association with cardiac and liver readmission, while maintaining modest predictive value for other outcomes. Optimal thresholds for cardiac mortality from larger cohorts are warranted.

A

Outcome Measure	Optimal RVSP threshold (mmHg)	Sensitivity	Specificity	AUC	Youden J
90-day cardiac readmission	32.8	0.629	0.665	0.673	0.293
90-day liver readmission	28	0.816	0.436	0.641	0.252
90-day all-cause readmission	32.65	0.486	0.703	0.597	0.189
90-day hemodialysis requirement	32.8	0.453	0.664	0.542	0.118
30-day all-cause readmission	36	0.400	0.750	0.566	0.150

3571 | IMPACT OF TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT ON WAITLIST AND POST-TRANSPLANT OUTCOMES IN LIVER TRANSPLANT CANDIDATES

Li Peng Margaret Teng[1] Shyna Gunalan[2] Ethan Tham[2] Ryan Lim[2] Do Han Kim[3] Daniel Huang[4] Mazen Noureddin[5] Mark Muthiah[6] Eunice Tan[7] Mohammad Siddiqui[8], [1]National University Health System, [2]Yong Loo Lin School of Medicine, National University of Singapore, [3]Department of Medicine, Mount Sinai Morningside and West, Icahn School of Medicine at Mount Sinai, [4]National University Hospital, Singapore, [5]Houston Methodist Hospital, [6]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [7]Division of Gastroenterology and Hepatology, National University Hospital, Singapore, [8]Division of Gastroenterology, VCU & Richmond VA Med Center, VA, USA

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is utilized to manage refractory ascites or variceal hemorrhage in patients with decompensated cirrhosis. However, its effects on transplant candidacy, perioperative outcomes, and long-term prognosis remain unclear. This study aims to evaluate the clinical indications, outcomes, and peri-transplant implications of TIPS in liver transplant candidates. **Methods:** We conducted a retrospective cohort study of adult liver transplant candidates listed in the United Network for Organ Sharing (UNOS) database from January 1, 2000, to January 3, 2025. Waitlist outcomes include the presence of portal hypertension-related complications, time-to-transplant and waitlist survival. Post-transplant outcomes include graft survival and overall post-transplant survival. These outcomes were compared between patients with and without TIPS, and across liver etiologies among TIPS recipients. **Results:** Among 169,681 waitlist registrants (19,940 with TIPS, 149,741 without TIPS), TIPS was associated with higher odds of portal vein thrombosis during waitlist (OR: 1.414, 95% CI: 1.317 to 1.518, $p < 0.001$) and lower odds of ascites during waitlist (OR: 0.924, 95% CI: 0.866 to 0.987, $p = 0.02$). TIPS recipients had significantly higher 90-day and 1-year time-to-transplant and waitlist survival. There were minimal differences in graft survival and overall post-transplant survival between patients with TIPS and without TIPS. Among TIPS recipients, patients with alcohol-associated liver disease and metabolic dysfunction-associated steatotic liver disease (MASLD) had significantly lower 90-day and 1-year time-to-transplant and higher 1-year waitlist survival compared to patients with hepatitis C (HCV). **Conclusion:** TIPS is associated with improved waitlist survival and timely transplantation without negatively impacting post-transplant outcomes. These findings support the use of TIPS as a bridging and management strategy in liver transplant candidates with portal hypertension.

3572 | RISK OF LIVER TRANSPLANT REJECTION AFTER COVID-19 VACCINATION

Jordan Voss[1] Mridula Bethi[1] Wei-Wen Hsu[1] Matthew Still[1] Ralph Quillin[1] Shimul Shah[2] Khurram Bari[3], [1]University of Cincinnati, [2]Massachusetts General Hospital, [3]University of Cincinnati, University Hospital Inc Program

Background: T cell-mediated rejection (TCMR), also known as acute cellular rejection, affects over 30 percent of liver transplant recipients resulting in increased morbidity and mortality. One hypothesized risk factor for TCMR is COVID-19 vaccination which may provide the inflammatory stimuli necessary for T cell activation and proliferation. In contrast to existing protein subunit and viral vector vaccines, two of the FDA-approved COVID-19 vaccines employ novel mRNA vaccine systems and thus may cause unique side effects. To date, 12 cases of TCMR following immunization for COIVD-19 have been reported. These are limited to case reports which are subject to reporting bias and do not establish causality. Here we present the first study to systematically evaluate the risk of TCMR following COVID-19 vaccination. **Methods:** We retrospectively identified all patients at our institution undergoing liver transplantation between 2014 and 2023 who also received one or more doses of any COVID-19 vaccine AND had a history of biopsy-proven TCMR occurring after 9/15/2020 (90-days prior to first vaccine availability in the United States). Using a self-controlled case series (case-crossover) study design and mixed-effects logistic regression models, we calculated the odds ratio of rejection in the 30 days following COVID-19 vaccination (case window) compared to the odds of rejection prior to or greater than 30 days after vaccine administration (control window). **Results:** In our cohort, 106 biopsy-proven rejection events occurred in 83 patients. Fifty-five percent were male, and 83% were Caucasian. The most common etiology of liver disease was alcohol (40%) followed by MASH (31%). Eleven cases of TCMR occurred within 30 days of administration of a COVID-19 vaccine. The odds ratio for rejection within 30 days of receiving a COVID-19 vaccination is 0.675 (95% CI 0.216 – 2.114, $P = 0.494$). Rates of immunosuppression non-adherence were similar in the case (12%) and control windows (11%). **Conclusion:** COVID-19 vaccination does not increase the risk of T cell-mediated rejection in liver transplant patients.

3573 | IS IT BETTER TO HAVE ONE COMMITTED DONOR OR MANY POTENTIAL LIVING LIVER DONORS?

Lauren Callans[1] Nicole Ng[2] Nathaly Llore[3] Alyson Fox[4] Juan Rocca[5] Jason Hawksworth[4] Benjamin Samstein[2] Danielle Brandman[6] Russell Rosenblatt[6], [1]New York Presbyterian - Weill Cornell, [2]NYP Weill Cornell, [3]NewYork- Presbyterian/Columbia University Medical Center, [4]Columbia University Medical Center, [5]NewYork-Presbyterian/Weill Cornell Medical Center, [6]Weill Cornell Medicine

Background: With persistent organ shortages, living donor liver transplant (LDLT) is an attractive alternative to deceased donor LT (DDLT), as it both mitigates the time on the waitlist and confers better outcomes. Identifying factors that lead to successful LDLT is critical to increasing LDLT. It remains unclear whether having one committed donor is better than many potential donors, due to concerns like the bystander effect. This study evaluated the differences in outcomes of high or low numbers of donor inquiries on LT-related outcomes. **Methods:** Adult patients undergoing LT evaluation at two large academic medical centers in New York City with transplant listing dates between 2023-2024 were retrospectively reviewed. Patients were stratified into either a high (more than 5 donor inquiries per patient) or a low inquiry group (1-2 donor inquiries). The primary outcome of this study was LDLT, with secondary outcomes including receiving any LT and waitlist time. Multivariate analysis was performed, controlling for age at listing, sex, and MELD at listing. This study was IRB approved. **Results:** 17 patients and 87 patients were included in the high and low inquiry groups, respectively. The high inquiry group had a higher prevalence of white race (94% vs 59%, $p = 0.006$), and both groups were mostly male. The mean MELD (13) and age at listing (41 vs. 55) were not significantly different. 53% of the high inquiry group received LDLT while 29% received DDLT (Figure). Among the low inquiry group, 51% received DDLT while 21% underwent LDLT. Although there was no significant difference in receiving any type of transplant (LD or DD) between the two groups (82% vs. 77%, $p = 0.48$), in multivariable analysis, patients in the high inquiry group were more than four times more likely to receive LDLT (OR 4.59, CI 1.35-15.6, $p = 0.02$). The high inquiry group had a shorter waitlist time on average (59 vs. 116 days), but this difference was not statistically significant ($p = 0.33$). In the high inquiry group, 82% of the prospective donors underwent further evaluation, and 59% were approved, as compared to the lower inquiry group with 56% inquiries evaluated and 28% approved ($p = 0.045$ and $p = 0.01$, respectively). **Conclusion:** Donor inquiry amount did not change the odds of receiving any transplant. However, patients with a higher number of inquiries were more than four times more likely to receive a LDLT than their lower inquiry counterparts. Those with a high number of inquiries tended to spend less time on the waitlist and had a higher proportion of donor evaluations and approvals, suggesting that more inquiries increases the probability of a possible donor match without an observed bystander effect. Future directions include evaluating the recipient and donor characteristics, including factors such as socioeconomic, psychological, and/or medical that may be related to higher approval rates, and strategies used by recipients to obtain increased donor inquiry frequency.

3574 | OUTCOMES OF LIVER TRANSPLANTATION FROM HCV-NAT-POSITIVE DONORS IN HCV-NAT-NEGATIVE RECIPIENTS: A SYSTEMATIC REVIEW AND SINGLE-ARM META-ANALYSIS

Mariana Del Col[1] Dante Souza[2] Maria Cirleide Farias[3] Maria Carolina Martins[4], [1]Universidad Nacional de Mar del Plata, [2]TriHealth Good Samaritan Hospital, [3]Faculdade de Ciências Médicas Afya - Itabuna, [4]Universidade Salvador

Background: With the advent of direct-acting antiviral agents (DAA), liver transplantation from Hepatitis C Virus (HCV) Nucleic Acid Test (NAT)-positive donors in HCV-negative recipients has been proposed to increase the organ pool. **Methods:** PubMed, Embase,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and Cochrane databases were searched for randomized controlled trials and observational studies evaluating outcomes from HCV-NAT-negative patients receiving grafts from HCV-NAT-positive donors. A single-arm meta-analysis of proportions estimated the graft loss, mortality, sustained virologic response (SVR) to DAA by 12 weeks after the end of therapy, acute cellular rejection (ACR), cytomegalovirus (CMV) infection, while a meta-analysis of means estimated time to start treatment and hospital stay. Quality assessment was performed per Cochrane recommendations. Heterogeneity was examined with I2 statistics, and a random-effects model was used. **Results:** A total of 11 observational studies met inclusion criteria, comprising 258 transplants, with 19 (7.4%) being simultaneous liver-kidney transplantations. The mean age of recipients and donors ranged from 56 to 60 and 32 to 42, respectively. Recipients had a mean Model for End-Stage Liver Disease (MELD) at transplantation ranging from 19 to 25.7, and 164 (63.6%) were male. The most common end-stage liver disease (ESLD) etiology was Nonalcoholic steatohepatitis (30.4%), followed by Alcohol-associated liver disease (27.6%) and HCV (10.8%). The median follow-up ranged from 6 to 16.4 months. Graft loss occurred in 4.02% (95% CI: 1.07% to 8.20%; fig. 1A), mortality was 4.05% (95% CI: 1.48% to 7.48%; fig. 1B), SVR by 12 weeks was achieved in 89.45% (95% CI: 75.98% to 98.39%; fig. 1C), ACR occured in 9.87% (95% CI: 5.63% to 14.92%; fig 1D), and CMV infection transpired in 13.43% (95% CI: 3.06% to 28.17%; fig. 1E). The pooled mean time from transplant to DAA initiation was 46.3 days (95% CI: 18.9 to 75.71; fig 1F) and hospital stay 19.9 days (95% CI: 9.79 to 29.14; fig 1G). **Conclusion:** These findings suggest that, in carefully selected patients, the use of HCV-NAT-positive grafts in HCV-NAT-negative patients in the DAA era appears to be efficacious and well tolerated. However, due to the limitations of observational studies and inherent heterogeneity, further comprehensive and controlled trials are needed to validate these findings and understand the long-term outcomes.

3575 | MORE THAN THE SUM? EVALUATING LIVER TRANSPLANT OUTCOMES IN METALD VERSUS SINGLE-ETIOLOGY DISEASE

Avi Toiv[1] Neal Doshi[1] Syed-Mohammed Jafri[2], [1]Henry Ford Hospital, [2]Henry Ford Health System

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) and alcohol-associated liver disease (ALD) are the leading indications for liver transplantation (LT) in the United States. Recently, we have recognized a growing subset of patients with metabolic dysfunction and alcohol-related liver disease (MetALD) attributed to a dual pathology, raising new questions about post-transplant risk profiles. While ALD and MASLD have been individually studied in relation to transplant outcomes, the postoperative course and complication burden in patients with combined disease remains poorly characterized. This study aimed to compare post-transplant survival and complications among patients with ALD, MASLD, and MetALD. **Methods:** A retrospective cohort study of all LT recipients who underwent LT for ALD, MASLD, or MetALD at a high-volume academic transplant center between January 2014 and September 2023. Kaplan-Meier analysis was used to evaluate survival. Descriptive statistics and regression analysis were used to assess complication rates. **Results:** 578 LT recipients were included: 40 (7%) with ALD, 199 (34%)with MASLD, and 339 (59%) with MetALD. Mean age at transplant ALD 50.4 ± 10.0 years; MASLD 60.7 ± 6.9; MetALD 54.1 ± 9.5; $p < 0.01$) and sex varied significantly across groups ($p = 0.003$), with a higher proportion of men in the MetALD group (69.5%) versus ALD (55%) and MASLD (55.8%). Mean hospital length of stay was similar across etiologies (composite mean 13.5 days, $p = 0.92$). Rate of biliary stricture in the MetALD group (30.3%) was significantly higher than in ALD (22.5%) and MASLD (19.1%) ($p = 0.015$). Post-transplant complications, including bile leak, early rejection, and graft loss, did not differ significantly between groups. No significant differences in survival were seen between groups (Figure). **Conclusion:** Post-transplant survival and overall complication burden were equivalent among patients with ALD, MASLD, and MetALD; however, biliary stricture occurred at a significantly higher rate in patients with MetALD. These findings suggest that although LT recipients may have similar risk profiles for survival and most post-transplant

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

3576 | ASSOCIATION OF PRE-TRANSPLANT CORONARY CT ANGIOGRAPHY VERSUS DOBUTAMINE STRESS ECHOCARDIOGRAM WITH MAJOR ADVERSE CARDIAC EVENTS WITHIN ONE YEAR OF LIVER TRANSPLANTATION

Hoang Anh Richardson[1] Ashley Spann[1] Samuel Nwosu[1] Donald Sengstack[1] Benjamin French[1] Jayant Bagai[1] Alexandra Shingina[2] Jeffrey Carr[1] Manhal Izzy[1], [1]Vanderbilt University Medical Center, [2]University of Michigan Health

Background: Cardiovascular complications are a major cause of non-graft related morbidity and mortality after liver transplantation (LT). Non-invasive cardiac testing is common in transplant evaluation, however, whether coronary computed tomography angiography (CCTA) or dobutamine stress echocardiogram (DSE) are predictive of major adverse cardiac events (MACE) after LT warrants investigation. **Methods:** This retrospective cohort study of adult patients with cirrhosis evaluated for LT between Janurary 2019 and December 2023 included all candidates with CCTA obtained during LT evaluation. The primary outcome was MACE [atrial/ventricular arrhythmia, acute coronary syndrome, revascularization, angina, heart failure, cardiac arrest, all-cause mortality] within one-year after LT. CCTA findings were categorized into none-to-mild coronary artery disease (CAD) as defined by CAD-RADS 0-1 and moderate-severe CAD by CAD-RADS 2-5. Successfully completed DSEs, defined as achieving target heart rate and satisfactory quality, were categorized as positive or negative for ischemia. Multivariable logistic regression models evaluated CCTA and DSE findings for associations with MACE, adjusting for age, sex, diabetes, and pre-event statin use. Predictive accuracy for each model was assessed using C-statistic. **Results:** Among 153 eligible patients, 108 underwent DSE. The incidence of MACE at one year was 32.0% (Table 1). The leading etiology of cirrhosis was metabolic dysfunction-associated steatohepatitis, followed by alcohol-associated liver disease. Moderate-severe CAD vs none-to-mild CAD by CCTA was not associated with an elevated risk of MACE after adjusting for covariates (OR 0.92, 95% CI [0.409, 2.073], p = 0.842); C-Stat for CAD-RADS was 0.62. Of the successfully completed DSEs (103/108), 6.8% were positive for ischemia. Positive DSE was not significantly associated with MACE (OR 2.78, 95% CI [0.66, 11.75], p = 0.163) after adjusting for covariates; C-Stat for DSE was 0.65. Pre-event statin use was associated with an approximately 2-fold increase in odds of a MACE event (OR = 2.10, p = 0.055) on multivariate analysis. **Conclusion:** CCTA and DSE results were not significantly associated with increased odds of MACE at one year post transplant, whereas pre-event statin use was associated with increased odds of MACE, reflecting the high-risk profile for this subgroup. The modest predictive performance of both modalities highlights the need for improved cardiac risk stratification tools in this high-risk population.

Table 1. Study group characteristics and outcomes

Variable	No MACE Event	MACE Event	Overall
Total	104	49	153
Sex			
Male	66 (63.5%)	29 (59.2%)	95 (62.1%)
Female	38 (36.5%)	20 (40.8%)	58 (37.9%)
Race			
White	99 (95.2%)	46 (93.9%)	145 (94.8%)
Non-White	5 (4.8%)	2 (4.1%)	7 (4.6%)
Unknown	0 (0%)	1 (2.0%)	1 (0.7%)
Diabetes Mellitus			
Diabetic	68 (65.4%)	32 (65.3%)	100 (65.4%)
Non-Diabetic	36 (34.6%)	17 (34.7%)	53 (34.6%)
Pre-Event Statin			
Statin use	42 (40.4%)	29 (59.2%)	71 (46.4%)
Non-Statin use	62 (59.6%)	20 (40.8%)	82 (53.6%)
CCTA Grade			
None-to-mild CAD	46 (44.2%)	21 (42.9%)	67 (43.8%)
Moderate-Severe CAD	46 (44.2%)	20 (40.8%)	66 (43.1%)
Inconclusive	12 (11.5%)	8 (16.3%)	20 (13.1%)
DSE			
Positive for Ischemia	3 (2.9%)	4 (8.2%)	7 (4.8%)
Negative for Ischemia	70 (67.3%)	26 (53.1%)	96 (62.7%)
Inadequate or Unavailable DSE Results	31 (29.8%)	19 (38.8%)	50 (32.7%)

3577 | CHARACTERIZING OUTCOMES AND DONOR CHARACTERISTICS OF LIVER TRANSPLANT RECIPIENTS WITH HIGH NUMBER OF DONOR INQUIRIES

Nicole Ng[1] Lauren Callans[1] Nathaly Llore[2] Alyson Fox[3] Juan Rocca[1] Jason Hawksworth[4] Benjamin Samstein[1] Danielle Brandman[5] Russell Rosenblatt[5], [1]NewYork-Presbyterian/Weill Cornell Medical Center, [2]NewYork-Presbyterian/Columbia University Medical Center, [3]Columbia University Medical Center, [4]NewYork-Presbyterian/Columbia University Medical Center, [5]Weill Cornell Medicine

Background: Living donor liver transplantation (LDLT) provides excellent outcomes and improves survival compared to deceased donation at all MELD scores. Nevertheless, LDLT is still underutilized, in part due to both medical and non-medical barriers affecting both recipients and donors. It is unclear whether a high number of donor inquiries translates to better outcomes, including shorter waitlist time and decreased mortality, or if there is a bystander effect. This study assessed the outcomes of LT recipients who generated high volumes of inquiries and their donor characteristics. **Methods:** Adult patients undergoing LT evaluation between 2018-2024 with over five donor inquiries at two large academic medical centers were retrospectively reviewed. The primary outcome of the study is whether patients received LDLT. The secondary outcomes are waitlist mortality, post-LT 1-year survival, number of donors evaluated and approved, and donor's relation to the patient. Descriptive statistics were performed. This study was IRB approved. **Results:** 55 patients who underwent LT evaluation had over five donor inquiries per recipient, with a mean of 21 inquiries per person. 53 patients were listed. The majority of recipients were White (91%) and male (62%). 47 patients (85%) underwent LT, with 24 (44%) LDLT and 23 (42%) DDLT. The mean age at listing and LT were 45 and 46 years, respectively, with low MELD scores at listing (14) and LT (16). The mean MELD score at LT for LDLT was 16 compared to 18 for DDLT. There were no significant differences in age, gender, or MELD for those receiving LDLT vs DDLT. The most common primary liver diagnoses were Metabolic Dysfunction-Associated Steatotic Liver Disease (22%), primary sclerosing cholangitis (18%), and hepatocellular carcinoma (11%). Only 5% of patients died while awaiting any LT. The mean time to transplant was 331 days, but 328 days for LDLT and 349 days for DDLT ($p > 0.05$). Of the 38 patients transplanted $>$ 1 year ago, there was 100% 1-year survival.

There were a total of 1076 donor inquires with 82% who underwent further evaluation and 59% approved. Most living donors were friends (46%) and family members, excluding parents and children (21%). The majority of donors were White (92%), and half were female. There was no correlation between the number of donor inquiries and time to transplant, age at listing, MELD at listing, or MELD at transplant. **Conclusion:** In this observational study, most individuals with over 5 donor inquiries underwent LT and half received LDLT. Those who received a LDLT spent less time on the waitlist and had lower MELD scores at time of transplant than that of DDLT. Further studies are needed to investigate whether the number of donor inquiries directly correlates to better outcomes.

3578 | THE EFFECT OF REDUCED DOSE RABBIT ANTI-THYMOCYTE GLOBULIN INDUCTION IN LIVER TRANSPLANTATION: A RETROSPECTIVE, SINGLE-CENTER COHORT STUDY

Jinzhen Cai[1], [1]The Affiliated Hospital of Qingdao University

Background: Liver transplantation (LT) is effective for end-stage liver disease. However, the induction dose of rabbit anti-thymocyte globulin (rATG) is still controversial. This study aimed to evaluate the effect of a novel reduced dose of rATG in Chinese LT patients. **Methods:** This retrospective study at Qingdao University Affiliated Hospital enrolled LT patients receiving intraoperative 50 mg rATG followed by 25 mg/d for 3 consecutive days post-LT. Baseline data, liver and renal function, blood routine, acute rejection and infections

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

within 30 days were analyzed. **Results:** A total of 29 LT patients were enrolled, with an average age of 51.7 years, including 18 liver cancer patients. For all patients, ALT and AST levels quickly returned to normal within one-month post-LT. Total bilirubin decreased to normal, and lymphocyte counts increased to normal within the same period. In the 18 liver cancer patients, there were no significant differences in liver function between those meeting Hangzhou criteria and those beyond, except for total bilirubin, during the one-month follow-up. Additionally, 8 of the 29 patients had viral infections (CMV and EBV), and only one patient showed signs of acute rejection. **Conclusion:** This study is the first to report reduced-dose rATG induction therapy for LT recipients in China. Liver cancer or cirrhosis patients who received this therapy during LT showed rapid recovery of liver function and lymphocyte levels to normal ranges without significant renal function impact, along with a low acute rejection rate and no increase in CMV infections. however, this promising strategy needs validation through multicenter studies with larger, more diverse cohorts to confirm its clinical applicability.

3579 | LIVER FRAILTY INDEX IS ASSOCIATED WITH INCREASED INTRA-OPERATIVE BLOOD PRODUCT REQUIREMENTS DURING LIVER TRANSPLANTATION

Jade Pace[1] Ahmed Aboseria[1] Justin Lin[2] Michael Attanasi[1] Anwesha Satapathy[2] William Han[2] Bheesham Dayal[2] Sanjaya Satapathy[1], [1]Zucker School of Medicine at Hofstra/Northwell, [2]Northwell Health

Background: Frailty is an emerging predictor for pre- and post-transplant adverse outcomes in liver transplant patients. However, research on its intra-operative impact is lacking. This study utilizes the Liver Frailty Index (LFI) to examine how pre-operative frailty translates into blood transfusion requirements at the time of transplantation. **Methods:** All patients from December 2019 to November 2024 from our institution who received liver transplants were collected. Blood products administered intra-operatively were recorded, including packed red blood cells (pRBCs), platelets, fresh frozen plasma (FFP), and cryoprecipitate. Physical function was evaluated using the LFI, which includes gender, dominant hand grip strength, time to do five chair stands, and balance testing in three different positions, with patients classified as non-frail (<4.5), or frail (≥ 4.5). All assessments were conducted by a licensed physical therapist using standardized protocols. Kruskal-Wallis analysis was used to determine the relationship between frailty categories of non-frail and frail with the amount of blood products used intra-operatively. Logistic regression comparing age, BMI, sex, race, MELD, and LFI to total blood products and with pRBCs was performed. Statistical significance was determined at $p<0.05$. **Results:** We identified 288 patients that met inclusion criteria. Of these, 227 patients had Liver Frailty Indices. The mean LFI was 4.5. The mean number of units of total blood products, pRBCs, platelets, FFP, and cryoprecipitate given intra-operatively was 26, 11, 3, 9, and 3 units, respectively. There were significant increases in median total blood product (24 ± 24 vs 18 ± 20, $p=0.005$), pRBC (10 ± 10 vs 8 ± 8, $p=0.004$), platelets (4 ± 3 vs 3 ± 2, $p=0.014$), FFP (10 ± 8 vs 6 ± 8, $p=0.013$), and cryoprecipitate (3 ± 3 vs 2 ± 2, $p=0.012$) requirements for frail patients compared to non-frail patients (Figure 1). Logistic regression adjusting for age, BMI, sex, race, and MELD demonstrated that $LFI>4.5$ was significantly associated with total blood products (Odds Ratio [OR] 1.018; 95% Confidence Interval [CI] 1.005-1.032; $p=0.009$) and with pRBCs (OR 1.047; CI 1.013-1.081; $p=0.006$). **Conclusion:** Frail patients required more units of blood products intra-operatively during liver transplant after adjusting for age, BMI, sex, race, and MELD score.

3580 | EXPEDITED LT EVALUATION IN THE AGE OF THE COVID-19 PANDEMIC AND BEYOND: A COMPARATIVE STUDY INVESTIGATING WAITLIST DECISIONS IN PATIENTS WITH AND WITHOUT ALCOHOLIC LIVER DISEASE

Claire Maher[1] *Kwang Il Seo*[2] *Brian Wentworth*[1], [1]*University of Virginia School of Medicine,* [2]*Kosin University College of Medicine*

Background: Alcoholic liver disease (ALD) is the leading indication for liver transplantation (LT) in the US. The social isolation of the COVID-19 pandemic further exacerbated this trend, resulting in an increase in ALD-related hospital admissions and LT during this period. Many of these patients undergo expedited LT evaluation, although listing practices compared to similar expedited LT evaluation in non-ALD patients are unknown. **Methods:** We conducted a retrospective cohort study of all adult patients who underwent expedited LT evaluation during an inpatient admission at a single tertiary care, LT center from February 2021 to December 2024. Patients were divided into alcoholic-liver disease (ALD) and non-alcoholic liver disease (non-ALD) groups. Clinical characteristics and components of the LT evaluation, including waitlist decision, were collected. Normality was assessed with the Shapiro-Wilk test. Categorical variables were compared using the Chi-square test and continuous variables utilized the Mann-Whitney U test given all were non-parametric. A multivariate logistic regression model utilizing significant variables on univariate analysis was created to evaluate predictors of placement on the LT waitlist; collinear variables with the SIPAT score were excluded. **Results:** One hundred and eighty-one patients met inclusion criteria, of which 102 (56%) patients had ALD and 79 (44%) had non-ALD. Patients with ALD tended to be younger (50 vs. 57 years, $p = 0.002$), male (68% vs 34%, $p < 0.001$), and more likely to be uninsured or insured by Medicaid (49% vs. 27%, $p = 0.002$). They also had higher SIPAT (26 vs. 16, $p < 0.001$) and MELD 3.0 (35 vs. 32, $p = 0.001$) scores. There was no difference between groups with respect to race, hospital length of stay, or LT evaluation outcome. ALD was positively predictive (OR 3.540, 95%CI 1.518-8.257, $p = 0.003$) of waitlist placement, while higher SIPAT scores were negatively predictive (OR 0.938, 95%CI 0.909-0.968, $p < 0.001$). **Conclusion:** Patients with ALD requiring expedited LT evaluation had a different demographic profile than non-ALD candidates, including presentation at a younger age, more severe liver disease, and higher SIPAT scores. However, the presence of ALD did not deter waitlist approval. These findings support recent literature noting excellent short-term survival in patients with ALD while also highlighting some of the challenges in ensuring equitable access to LT for non-ALD patients.

Table 1: Multivariate logistic regression for predictors of placement on transplant waitlist

Variable	Odds Ratio	95% CI	*p*
ALD	3.540	1.518–8.257	**0.003**
Age*	0.971	0.940–1.003	0.075
Female sex	1.583	0.762–3.289	0.219
MELD 3.0 score*	1.014	0.966–1.064	0.579
SIPAT score*	0.938	0.909–0.968	**<0.001**
Severe malnutrition	0.956	0.473–1.931	0.900
Medicaid/uninsured	1.046	0.498–2.196	0.906

*Represents odds ratio for each incremental 1 year or point.

3581 | MORTALITY, INTENSIVE CARE UNIT AND HOSPITAL LENGTH OF STAY IN PATIENTS UNDERGOING SIMULTANEOUS LIVER-KIDNEY TRANSPLANTATION COMPARED TO LIVER TRANSPLANTATION ALONE

Nazli Begum Ozturk[1] *Ahmed Aref*[1] *Usman Bin Hameed*[1] *Ewelina Niedzialkowska*[1] *Tatjana Blazin*[1] *Laith Jamil*[1], [1]*Beaumont Hospital, Royal Oak*

Background: Simultaneous liver-kidney transplantation (SLK) is the treatment of choice in patients with concomitant end-stage liver and kidney diseases. The number of patients undergoing SLK is rising in the United States. In this study, we aimed to compare the characteristics and outcomes of patients undergoing SLK compared to liver transplantation alone (LTA) at our transplant center. **Methods:** A retrospective analysis was performed of all adult patients who underwent LT or SLK at our transplant center between 2013-2023. Clinical, laboratory, histological, and follow-up data were obtained. Patients were be included to the study only once, thus excluded when a repeat transplant was done. The primary outcome was post-transplant mortality. Categorical variables are reported as numbers and percentages, and continuous variables are reported as means and standard deviation or median with interquartile range. Statistical significance was defined as $p < 0.05$. **Results:** Of all patients with ESRD, 37 patients (66.1%) underwent SLK, and 19 patients (33.9%) underwent LTA. Most common etiologies for patients underwent SLK were alcohol-associated liver disease (ALD) (29.5%), metabolic-dysfunction associated steatotic liver disease (MASLD) (23.0%), and hepatitis C virus (HCV) (9.8%); whereas for LTA those were ALD (23.6%), MASLD (16.3%), and hepatocellular carcinoma (12.3%). Patients who underwent SLK had a significantly higher MELD at listing (26.4 $\pm$8.62 vs 21.0 $\pm$9.62, $p = 0.0002$) and at LT (30.7 $\pm$8.46 vs 25.0 $\pm$9.49, $p = 0.0001$), more commonly had hepatic encephalopathy (78.7% vs 65.2%, $p = 0.0498$), and more commonly had DM (41% vs 25%,$p = 0.020$) compared to patients who underwent LTA. Post-transplant,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

patients who underwent SLK had longer ICU (9.0 (5.0-17.5) vs 5.0 (3.0-8.5), $p = 0.0001$) and hospital stay (16.0 (11.0-27.5) vs 12.0 (8.0-19.5), $p = 0.0003$) compared to patients who underwent LTA. There was no difference in overall survival in patients who underwent SLK vs LTA ($p = 0.6783$), and no survival difference in patients with ESRD that underwent SLK or LTA ($p = 0.6476$). Overall, 1-year survival was 98.3% in patients who had SLK compared to 94.3% in LTA, 3-year survival was 95.6% in SLK vs 90.0% in LTA, and 5-year survival was 81.4% in SLK vs 78.3% in LTA. **Conclusion:** Despite MELD at listing was significantly higher in SLK group, waitlist time was not significantly different in between both groups. Both ICU and hospital length of stays were significantly longer after SLK compared to LTA. Patient mortality was similar in patients underwent SLK and LTA. As the incidence of MASLD is increasing, the proportion of patients in need for SLK are expected to rise and the investigating the risk factors for survival would enhance the post-transplantation length of stay and overall survival.

3582 | A 10-YEAR RETROSPECTIVE SINGLE-CENTER STUDY ON VACCINATION STATUS OF PEDIATRIC LIVER TRANSPLANT RECIPIENTS

Stephanie Chau Nguyen[1] William Zhu[1] Udeme Ekong[2] Khalid Khan[2] Gabriel Gondolesi[2] Nada Yazigi[2],
[1]Georgetown University School of Medicine,
[2]Georgetown University Hospital

Background: Despite published guidelines requiring the administration of all age-appropriate immunizations, vaccine-preventable infections following transplantation remain common and are associated with increased morbidity, mortality, and graft injury. Amid rising vaccine hesitancy in the United States driven by a myriad of sociopolitical factors, it is increasingly important to assess the vaccination status and immunity of pediatric transplant recipients to guide evidence-based immunization strategies in this vulnerable population. **Methods:** A retrospective chart review was conducted on pediatric patients who underwent liver transplantation between 2014 and 2023. Variables assessed included pre-transplant vaccination status, serologic immunity at the time of transplant, and serologic titers one year post-transplant. The vaccines evaluated in this study included measles, mumps, and rubella; varicella; hepatitis A and B; diphtheria, tetanus, and pertussis; meningococcal; and pneumococcal vaccines. **Results:** Between 2014 and 2023, a total of 194 pediatric patients underwent liver transplantation at our center. Of these, 66 patients (34%) had no documented immunizations in their medical records. Among the 135 patients who were at least one year old at the time of transplant and thus eligible for serologic testing, 61 patients (45.2%) had no immunization titers documented at the time of transplantation, and 29 patients (21.5%) had no titers documented at either the time of transplant or at one year post-transplant. **Conclusion:** This retrospective review evaluated the impact of our current protocol on our ability to determine patients' immunity to common childhood vaccine-preventable diseases. Despite the protocol, our findings reveal that a substantial portion of patients did not have available vaccination records either at the time of transplant or one year post-transplant. This gap highlights the need for a more streamlined and integrated care pathway, as many patients currently must visit external sites, such as their pediatrician, to receive necessary immunizations. A more coordinated approach, such as administering vaccines in-office during transplant evaluations, may better protect immunosuppressed pediatric patients from vaccine-preventable infections.

3583 | IMPACT OF LIVER DISEASES ON DE-NOVO ALLOGENEIC LIVER TRANSPLANT OUTCOMES

Renuka Verma[1] Kamleshun Ramphul[2] Kaitlyn Gernhard[3] Himsikhar Khataniar[3] Leandro Sierra[4] Nikki Duong[5], [1]Kirk Kerkorian School of Medicine at UNLV, [2]Independent researcher, [3]Allegheny General Hospital, [4]Cleveland Clinic Foundation, [5]Stanford Health Care

Background: While liver transplant(LT) is a long-term treatment option for patients with end-stage liver disease(ESLD), the short-term complications based on its etiologies have not been well understood. We sought to explore further using the most extensive hospitalization data from the United States. **Methods:** Allogenic LT procedures, coded as a primary procedure, were studied from the National Inpatient Sample (2016-2022). We excluded patients with prior LTs, COVID-19, those under 18 years of age, and those with missing data. Our sample was stratified as: chronic hepatitis B (CHB), chronic hepatitis C(CHC), metabolic dysfunction-associated steatohepatitis(MASH), alcohol abuse(AA), primary biliary cholangitis(PBC), primary sclerosing cholangitis(PSC), and hepatocellular carcinoma(HCC). We removed patients who had more than one of these risk factors. Complications experienced among each group were compared via multivariable regression models. **Results:** In this study, we evaluated 27185 LT procedures. Around 48.17% were due to AA, 26.47% had MASH, 9.66% were HCC patients, 4.95% had PSC, 4.75% had CHC, 4.25% had PBC, and 1.77% had CHB. Patients with HCC were the oldest, while our youngest cohort consisted of those with PSC (Table 1a). Compared to those with AA, patients with CHB and HCC had higher odds of acute rejection during their current stay, while those with PSC and CHC had higher odds of LT failure. Events of acute kidney injury (AKI) were less common among patients with CHC, MASH, PBC, PSC, and HCC than those with AA. Meanwhile, MASH patients also reported fewer cases of sepsis than AA patients. The need for transfusion was less among PSC and HCC patients(vs AA). Odds of Clostridium difficile infection, postprocedural hematoma, and pulmonary embolism/deep venous thromboembolism during their current admission were comparable in all groups. In addition, in-hospital mortality and major adverse cardiac and cerebrovascular events (MACCE) did not differ among them(Table 1b). Patients with CHB reported the longest hospital stays, while PSC cases were discharged the earliest(Table 1a). **Conclusion:** Short-term in-hospital outcomes among LT patients differ based on etiology. Although the all-cause in-hospital mortality rates were comparable in our sample, we strongly advocate for further studies to understand their long-term survival outcomes.

Table 1a. Comparing the mean age, length of stay(LOS), and hospital charges

	Mean age (years)	Mean LOS (days)	Mean Hospital charge (USD)
Alcohol Abuse	51.6	21.6	679047.8
Chronic Hepatitis B	54.2	24.2	856702.9

3584 | IMPACT OF ACUTE HEART FAILURE ON OUTCOMES AFTER LIVER TRANSPLANTATION

umesh bhagat[1] ankit agrawal[1] mohamed Abdelbaky[2] faris hammad[1] archana kharel[1] archit garg[3] shalini tripathi[4] luisa recinos[5], [1]Cleveland clinic, [2]presbyterian hospital, [3]Saint peters university hopsital, [4]Cleveland clinict, [5]Saint peters university hospital

Background: Acute severe heart failure (AHF) developing after liver transplantation (LT) is a distinct entity with a poor prognosis. There is limited data regarding AHF in the postoperative period in liver transplant patients. This study aims to determine the incidence and adverse events of AHF in patients readmitted 30 days after LT. **Methods:** National Readmission Database (NRD) 2016-2021 was queried to identify LT patients. Patients readmitted after 30 days were divided into two cohorts: with and without new onset AHF. The primary outcome was all-cause mortality. Secondary outcomes included adverse events, ICU stay and respiratory failure. Statistical analysis was performed using Stata-Corp. 2021. **Results:** Of 43239 patients discharged post-LT, 12978 were readmitted after 30 days, of which 306 had VTE (2.3%). Patients with AHF had higher odds of mortality (aOR 4.37, 95% CI: 2.21–8.61, p <0.001), AKI (aOR 2.27, 95% CI: 1.54–3.34, p $<$ 0.001) ICU stay (aOR 3.93, 95% CI: 2.45–6.29, p $<$ 0.001) and respiratory failure (aOR 5.17, 95% CI: 3.35–7.97, p $<$ 0.001). **Conclusion:** Despite low incidence and poorly understood pathophysiology AHF in LT, it is associated with significant morbidity and mortality, emphasising the need for vigilant perioperative cardiac assessment and prompt management to improve post-transplant outcomes.

	Odds ratio	95% conf.-interval	P
Mortality	4.37	2.21 - 8.61	0.000
AKI	2.27	1.54 - 3.34	0.000
ICU	3.93	2.45 - 6.29	0.000
Acute respiratory failure	5.17	3.35 - 7.97	0.000

3585 | EPIDEMIOLOGIC DIFFERENCES IN HIGH-RISK CYTOMEGALOVIRUS MISMATCH BETWEEN ADULT AND PEDIATRIC LIVER TRANSPLANT (LT) RECIPIENTS

Vikram Raghu[1] James Squires[2] Kyle Soltys[3] Simon Horslen[3] George Mazariegos[2] Rakesh Sindhi[3], [1]University of Pittsburgh School of Medicine, [2]Children's Hospital of Pittsburgh, [3]UPMC Children's Hospital of Pittsburgh

Background: Cytomegalovirus (CMV) Donor-positive/Recipient-negative (D+/R-) serostatus has been implicated in delayed graft loss after solid organ transplantation, but little is known about its epidemiology in pediatric LT. We aimed to determine differences in D+/R- serostatus between pediatric and adult LT. **Methods:** In this cross-sectional study, isolated first-time pediatric (age <21 yrs) LT recipients were identified from the Scientific Registry of Transplant Recipients between 2014 and 2022. CMV serologic status was categorized by both donor and recipient positivity into four categories: D+/R-, D-/R+. D+/R+, and D-/R-. Least absolute shrinkage and selection operator (LASSO) identified predictors of CMV mismatch (Poisson regression) and graft and patient survival (Cox regression). **Results:** We identified 62,945 primary LT recipients (n = 4386, 7% pediatric). The overall high-risk CMV mismatch (D+/R-) rate increased from 21.1% in 2014 to 25.5% in 2022. Pediatric patients were more likely to be R- (63% vs 38%, $p<0.001$) but less likely to receive D+ grafts (50% vs 63%, $p<0.001$). Pediatric patients were 48% (95% CI: 38-60%, $p<0.001$) more likely to receive a CMV D+/R- transplant. Controlling for age, recipients with CMV D+/R- status had an increased risk of graft loss (HR 1.09, 95% CI 1.03–1.16, p = 0.004) and death (HR 1.06, 95% CI 1.00–1.13, p = 0.046) compared to other combinations (Figure). **Conclusion:** Pediatric recipients are at higher risk of CMV D+/R- transplant, which are associated with higher rates of graft loss and death. These results may have significant implications for the monitoring and treatment needs of these patients.

Figure. Graft and patient survival stratified by CMV status

3586 | EXPANDING THE DONOR POOL: SAFE RECOVERY IN LIVING LIVER DONORS OVER AGE 50

Hojung Park[1] Lauren Leung[1] Andrew Park[1] Rohan Rathi[1] Kyeong Ri Yu[1] Seung Duk Lee[1] Yuzuru Sambommatsu[1] Daisuke Imai[1] Aamir Khan[1] Muhammad Saeed[1] Amit Sharma[1] Adrian Cotterell[1] Marlon Levy[1] David Bruno[1] Vinay Kumaran[1], [1]Virginia Commonwealth University Medical Center

Background: Older age is often considered a contraindication for living liver donation. However, as global demand for liver transplantation rises, increasing the donor pool to include well-selected older individuals could improve transplant availability. This study compares the recovery of living liver donors aged > 50 to younger donors to evaluate the feasibility and safety of donations in this patient population. **Methods:** This retrospective cohort study analyzed 52 donors who underwent open or robot-assisted donor hepatectomy from February 2020 and December 2024 at a single tertiary care center. Patients were stratified into older donors (> 50 years, n = 10) and younger controls (n = 42). Data included demographics, surgical history, intraoperative characteristics, and postoperative outcomes. Primary endpoints included length of stay, postoperative complications (such as ileus, bile leak, and bleeding), liver function outcomes (measured by total bilirubin, ALT, AST, and INR), and incidence of liver dysfunction prior to discharge. **Results:** Older donors were more likely to have a history of prior abdominal surgery (90% vs 38.1%, p < 0.001). BMI was similar between groups (26.9 vs 27.6, p = 0.826), with no statistically significant difference. Intraoperative characteristics, including estimated blood loss, parenchymal transection time, warm ischemic time, and operative time showed no statistically significant differences. Postoperatively, ileus was the most common complication, occurring at a significantly higher rate in older donors compared to younger donors (50% vs. 35.7%, p = 0.045). Aside from a significantly lower peak INR in the older donors (1.5 vs 1.7, p = 0.046), there were no statistically significant differences in postoperative lab values at POD3, POD5, or peak between the groups. No older donors experienced liver dysfunction prior to discharge, whereas three younger donors did (0% vs 7.1%, p = 0.007). **Conclusion:** Older living liver donors (> 50 years) had similar intraoperative outcomes and liver function recovery to younger donors, despite higher rates of prior abdominal surgery and postoperative ileus. No older donors experienced liver dysfunction. These findings suggest that carefully selected older donors can safely undergo living liver donation.

Table 1. Patient demographics

	Older Donors (n=10)	Control (n=42)	p-value
Age, mean (sd)	54.4 (3.9)	37.9 (7.8)	<0.001

3587 | DIRECT BILIRUBIN-BASED MELD SCORE: IMPACT OF HEPATIC VS. EXTRA-HEPATIC HYPERBILIRUBINEMIA ON STAGING OF CIRRHOSIS

mete ucdal Yigit Berk Sahin[1] Ibrahim Sendur[1] Osman Dag[2] Yasemin Balaban[3], [1]Hacettepe University Faculty of Medicine, [2]Hacettepe University, Faculty of Medicine, [3]Hacettepe University

Background: The Model for End-Stage Liver Disease (MELD) score is based on total bilirubin, which may be affected by non-hepatic conditions such as hemolysis or Gilbert's syndrome. This may be confounding in assessment of liver dysfunction and cause over-staging of cirrhotic patients. The aim of this study was to evaluate the impact of using direct (conjugated) bilirubin (DB-MELD score) instead of total bilirubin on survival. **Methods:** This single-center retrospective cohort study included 826 cirrhotic patients diagnosed between January 2015–December 2020. Patients with missing survival data were excluded from the analysis. Three distinct groups emerged: double high (high MELD and high DB-MELD), intermediate (high MELD and low DB-MELD), and double low (low MELD and low DB-MELD). The median DB-MELD score was similar among patients in the low MELD group. Welch's ANOVA test for unequal variances(a) was used to analyze differences between follow-up durations with Bonferroni-corrected post-hoc analyses for multiple comparisons(b); chi-square test(c) was used for categorical data. Survival was estimated by the Kaplan–Meier method, and differences between curves were assessed by the log-rank test(d). Statistical significance threshold was $p < 0.05$. **Results:** The median MELD and DB-MELD scores were 20.0 and 19.8, respectively. There were 190 double high patients, 199 intermediate patients, and 437 double low patients. The respective survivals in these groups were 13.16 ± 0.52 months, 16.05 ± 0.66 months, and 18.57 ± 0.52 months ($F(2, 458.279) = 26.958$; $p < 0.001$[a]). The follow-up period of intermediate patients was 2.89 months longer than the double high group ($p = 0.011$; 95% CI 0.51–5.28[b]) and 2.52 months shorter than the double low group ($p = 0.008$; 95% CI –4.53 to –0.51[b]). Mortality rates during the study period were 68% for the double high group, 55% for the intermediate group, and 30% for the double low group ($\chi^2 = 87.24$; $p < 0.001$[c]). Survival analysis confirmed significantly better survival of patients with high MELD and low DB-MELD (log-rank $p < 0.001$[d]), validating DB-MELD's ability to identify a subgroup of patients with better survival among patients with high MELD scores. **Conclusion:** Improved survival was observed in patients with high MELD scores together with low DB-MELD scores compared to patients with both high MELD and DB-MELD scores. This suggests that DB-MELD may enhance prognostic stratification in cirrhotic patients beyond MELD. This significant mortality difference between patients with identical MELD scores but varying DB-MELD scores has clinical implications, not only for transplant listing decisions but also for the involvement of cirrhotic patients in clinical trials.

3588 | RELATIONSHIP BETWEEN POST-LIVER TRANSPLANT RELAPSE IDENTIFIED WITH PHOSPHATIDYLETHANOL (PETH) TESTING AND MORTALITY AMONG PATIENTS WITH ALCOHOL USE DISORDER

Humberto Gonzalez[1] Yara Dababneh[1] Sheri Trudeau[1] Christina Melkonian[1] Stuart Gordon[2] Mei Lu[2], [1]Henry Ford Health, [2]Henry Ford Health System

Background: Background: Phosphatidylethanol (PEth) testing—a sensitive, quantitative, and persistent biomarker for ethanol consumption—has replaced traditional blood tests for monitoring patients with alcohol use disorder (AUD) after liver transplant. We hypothesize that better detection of relapse may allow clinicians to intervene, resulting in improved outcomes for transplant patients. This preliminary study was performed to evaluate the relationship between mortality and positive PEth results after transplant. **Methods:** Methods: We used the Fisher exact test to compare time-to-event (mortality/last follow-up) by post-transplant PEth status (positive/ negative) as well as 12-month mortality among adult patients who received liver transplants secondary to AUD at a single integrated US health system between 2019–2022. Kaplan Meier curves were used to illustrate results. **Results:** Results: In a sample of 225 patients, 13 (6%) died during follow-up, including 2 who died at the time of surgery. After transplant, a total of 110 patients had negative tests, 86 were untested, and 29 patients (13%) had ≥1 positive test after transplant, indicating relapse. Those with positive post-transplant PEth results had significantly

higher mortality ($p = 0.04$ [0.03 after excluding patients without testing]) and 12-month mortality ($p = 0.3$). However, the effect became non-significant after adjusting for MELD score at transplant ($p = 0.09$). **Conclusion:** Conclusion: Our analysis suggests that alcohol use detected by PEth after liver transplant may be associated with increased mortality, supporting the need for early intervention. However, the low incidence of death in our sample limited our statistical power. Larger samples with longer follow-up are needed.

3589 | CLUSTERING RIGHT LOBE GRAFTS BASED ON ANATOMICAL COMPLEXITY USING UNSUPERVISED MACHINE LEARNING FOR DONOR HEPATECTOMY

Nishtha Singh[1] Erin Duggan[2] Angela Chen[3] Ellie Brandon[4] Carolyn Waite[4] Dustin Carpenter[4] Benjamin Samstein[4] Juan Rocca[4], [1]NewYork-Presbyterian/Weill Cornell Medical College, [2]NewYork-Presbyterian, CUIMC, NY, NY, [3]Weill Cornell Medicine, NewYork-Presbyterian, NY, NY, [4]Weill Cornell Medicine, NewYork-Presbyterian, NY, NY,

Background: The Minimally Invasive Living Donor Hepatectomy (MIS-DH) lacks a standardized framework to differentiate simple from complex grafts. Traditional classifications rely on arbitrary anatomical thresholds hindering reliable stratification, impacting surgical approach. Thus, we aim to develop a novel data-driven machine learning classification model for right lobe graft complexity using 2-step clustering, enabling objective preoperative stratification and surgical planning. **Methods:** A retrospective analysis of 49 right lobe MIS-DH (2018?2025) was performed at a single center. Due to limited sample size, bootstrapped datasets were generated to resample the data for improved stability and accuracy. Two-step clustering using SPSS was applied on continuous and categorical variables graft volume, future liver remnant (FLR), hepatic artery (HA), portal vein (PV), hepatic vein (HV), bile ducts (BD), and estimated blood loss (EBL) to differentiate simple and complex graft. Cluster performance was evaluated via BIC, silhouette score. Mann Whitney U- Test and chi-square were performed to validate the quality of final clusters. **Results:** The 500-bootstrap clustering model outperformed others (BIC = 3038.82, silhouette score = 0.3146), identifying 2 distinct clusters. Cluster 1 (57.8%), denoting complex grafts, had significantly lower FLR(34.6%) and higher EBL (490.5 mL) compared to Cluster 2(42.2%), which had FLR of 37.8% and EBL of 234 mL($p < 0.001$). Cluster1 includes all cases with 3BD, 3PV, 2HV/3HV, and 2HA significantly greater anatomical complexity ($p < 0.001$). Cluster 2 is dominated by type 2 PVs and single-structure variants, representing simpler graft. Further, Cluster1 was associated with younger age, higher weight, BMI, and graft volume ($p < 0.05$). Surgical approach varied significantly between clusters($p = 0.001$), with Cluster 1(Complex grafts) surgeries performed mostly via hybrid (n = 136) and robotic (n = 93)approach, whereas Cluster2 was evenly distributed across all surgical approaches. Despite anatomical and operative complexity, Cluster1 had fewer CD ≥ 3 complications($p = 0.04$), possibly due to enhanced surgical preparedness and technique selection. **Conclusion:** Unsupervised clustering of right lobe grafts based on combined anatomical and operative variables offers a novel reproducible, objective method to stratify graft complexity. The model reveals significant associations with surgical approach and outcomes, reinforcing its potential to enhance preoperative planning for surgical approaches and decision-making. Future directions include regression modeling for outcome prediction and integration into prospective donor evaluation algorithms.

Variable	Type	No of group
BD (Bile Duct)	Categorical	1BD, 2BD (trifurc/aberrRAHD/PD) 3BD(multiple sect duct/ lowBifurcs/ opNote)
HA (Hepatic Artery)	Categorical	1HA, 2HA(accessory/replaceRHA)
HV (Hepatic Vein)	Categorical	1 HV (RHV+V5+V8 drainingin MHV) 2HV(accessory V6/V7 or drain into IVC) 3 HV (3 in numbers/multibranches/opnote)
PV (Portal Vein)	Categorical	1 PV 2PV (2 veins or short RPV) 3PV (trifurcation+short RPV+multi sectors/opnote)
EBL (Estimated Blood Loss)	Continuous	Higher values suggest surgical complexity
FLR (Future Liver Remnant)	Continuous	Lower values indicate more complex grafts

3590 | LIVER TRANSPLANTATION SCHOLARLY WORKS: A FOCUSED BIBLIOMETRIC ANALYSIS USING THE LENS DATABASE

Hussam Almasri[1] Rahul Karna[2] John Bassett[3], [1]University of North Dakota, [2]University of Minnesota Medical Center, [3]Sanford Health

Background: Since the first human liver transplantation (LT) in 1963, there have been significant enhancements of various aspects of LT, including patient risk stratification, liver preservation, immunosuppression, and surgical techniques. LT is now performed routinely in many countries, with markedly improved outcomes compared to previous decades. These advancements are largely attributed to impactful, practice-changing research in the field. Here, we present a comprehensive bibliometric analysis of scholarly works in LT, focusing on those cited by patents. **Methods:** The Lens database was utilized to identify English-language scholarly articles related to LT. A focused search strategy using keywords was implemented to increase specificity. Document types, including preprints, datasets, and reference entries, were excluded. Scholarly works were categorized based on citation by patents or other scholarly works. Additional metadata, such as institution, country, and state of origin, were extracted. Due to the redundancy of non-specific documents when including abstracts, we updated the search strategy to be title-limited to ensure that we were primarily focusing on LT research, acknowledging that this might have resulted in the exclusion of a few relevant papers. **Results:** From 1890 to 2024, a total of 88,584 scholarly works related to LT were identified. Of these, 2,006 had been cited by patents, while 54,192 were cited by other scholarly works. The number of scholarly works in top-contributing journals has plateaued since 2019–2020. Scholarly works cited by patents peaked between 2003 and 2010, followed by a gradual decline. The top authors of patent-cited works primarily specialized in surgery, pathology, biology, and hepatology. The top institutions contributing to patent-cited works included the University of Pittsburgh, Harvard University, and the Mayo Clinic. The United States produced the highest number of total (19,293) and patent-cited (772) scholarly documents, followed by China with 5,667 and 112, respectively. Within the U.S., California, Pennsylvania, and Minnesota were the leading states for scholarly output. **Conclusion:** This bibliometric analysis highlights the progression and global distribution of impactful research in liver transplantation over more than five decades. Liver transplantation (LT) recipients have a 75% five-year survival rate, which necessitates innovation in this field to improve patient outcomes. The observed decline in patent citations since 2010 could be due to changes in research focus, patenting strategies, or the maturation of surgical techniques. The concentration of patent-cited works among U.S.-based institutions highlights the country's leadership in LT research. Identifying highly cited works and their sources offers valuable insights into research trends, helping to inform funding and collaboration priorities.

3591 | ROBOTIC CAUDATE LOBE RESECTION: A SYSTEMATIC REVIEW AND META-ANALYSIS OF PERIOPERATIVE AND POSTOPERATIVE OUTCOMES

Mohammad Abuassi[1] Ayham Hussein[2] Mahmoud Y Madi[3] Badi Rawashdeh[4] Kia Saeian[4] K Raj Prasad[4], [1]University of Central Florida, [2]Al-Balqa Applied University, Faculty of Medicine, [3]University of Texas Austin Dell Medical School, [4]Medical College of Wisconsin

Background: Caudate lobe resection is technically challenging due to its deep anatomical location and proximity to major vascular structures. Despite the growing adoption of minimally invasive techniques, data on robotic caudate lobectomy remain sparse, primarily limited to small case series. This study systematically evaluates the safety, feasibility, and outcomes of robotic caudate lobe resection to inform

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

practice and future guideline development. **Methods:** We conducted a systematic review and meta-analysis in accordance with PRISMA guidelines. A comprehensive search of PubMed, Scopus, Web of Science, and the Cochrane Library was performed through February 2025. We included studies reporting outcomes of isolated robotic caudate lobe resections. Data were extracted on intraoperative metrics (operative time, blood loss, transfusion) and postoperative outcomes (morbidity, major complications, length of stay). Pooled estimates were calculated using random-effects models for continuous outcomes and common-effect models for binary outcomes. Between-study heterogeneity was assessed using the I^2 statistic. Leave-one-out sensitivity analyses tested the robustness of results. Study quality and bias were assessed using the ROBINS-I tool. **Results:** Five studies comprising 110 patients were included. The pooled mean operative time was 184.3 minutes (95% CI: 153.0–215.6), and the estimated blood loss was 82.8 mL (95% CI: 31.5–134.0). The blood transfusion rate was 6.0% (95% CI: 2.5–13.5). Postoperative morbidity was 12.0% (95% CI: 2.7–40.0), and major complications were rare at 1.8% (95% CI: 0.5–7.0). The mean hospital stay was 4.3 days (95% CI: 2.6–6.0). Leave-one-out sensitivity analyses reinforced the stability of results, showing no significant change in pooled estimates upon exclusion of individual studies. Heterogeneity was substantial for operative time and hospital stay but minimal for complication rates. **Conclusion:** Robotic caudate lobe resection is a feasible and safe alternative to traditional approaches, demonstrating low blood loss, short hospital stays, and a favorable morbidity profile, including a remarkably low rate of major complications. These findings support the growing role of robotic platforms in minimally invasive liver surgery, potentially enhancing precision and reducing morbidity for complex resections. Further multicenter prospective studies are needed to validate these results and refine patient selection.

3592 | DE NOVO MALIGNANCY AFTER LIVER TRANSPLANTATION IN PATIENTS WITH AND WITHOUT HEPATOCELLULAR CARCINOMA: A PROPENSITY-MATCHED ANALYSIS

Mohammad Abuassi[1] Mahmoud Y Madi[2] Razan Aburumman[3] Badi Rawashdeh[4] Kia Saeian[4] K Raj Prasad[4], [1]UCF/HCA Florida North Florida Hospital, [2]University of Texas Austin Dell Medical School, [3]Henry Ford Hospital, [4]Medical College of Wisconsin

Background: Liver transplantation (LT) offers curative treatment for hepatocellular carcinoma (HCC) in carefully selected patients. However, long-term immunosuppression increases the risk of de novo malignancies, a growing cause of late post-transplant morbidity and mortality. While cancer risk in transplant recipients is well documented, limited data exist comparing post-transplant malignancy patterns between patients with and without pre-existing HCC. Given potential differences in immunologic profiles, oncogenic drivers, and surveillance intensity, understanding how HCC history influences de novo cancer risk is critical to guiding personalized post-LT care. **Methods:** We conducted a retrospective cohort analysis using the TriNetX US Collaborative Network, encompassing 68 healthcare organizations. Two propensity-matched cohorts of adult LT recipients were identified: those with HCC ($n = 7{,}595$) and those without ($n = 7{,}595$). Matching was based on demographics, viral hepatitis status, history of tobacco and alcohol use, and relevant comorbidities. Primary outcomes included the incidence of de novo malignancies and overall survival. Odds ratios (ORs) with 95% confidence intervals (CIs) and Kaplan-Meier survival analyses were used to compare groups. **Results:** LT recipients with HCC had significantly higher odds of developing bronchus and lung malignancies (OR 2.07, 95% CI 1.62–2.64, $p < 0.001$) and prostate cancer (OR 1.54, 95% CI 1.19–1.99, $p = 0.001$) compared to non-HCC recipients. Other cancer types including colon, pancreas, esophagus, stomach, larynx, and melanoma/skin cancers, showed no statistically significant differences. The incidence of post-transplant lymphoproliferative disorder (PTLD) was also comparable (OR 0.94, 95% CI 0.71–1.24, $p = 0.653$). **Conclusion:** Liver transplant recipients with pre-existing HCC were found to have a higher risk of developing bronchopulmonary and prostate cancers post-transplant. This may partly reflect differences in post-transplant surveillance intensity. These findings highlight the need for personalized oncologic surveillance, particularly for bronchopulmonary and prostate

3593 | LIVER FRAILTY INDEX: A VITAL SIGN IN A TRANSPLANT HEPATOLOGY CLINIC

Sahak Hovsepian[1] Amandeep Sahota[1] An Ly[1], [1]Kaiser Permanente Los Angeles Medical Center

Background: Frailty, characterized by reduced physiologic reserve due to impaired muscle function, is a key predictor of many adverse outcomes in patients with cirrhosis, namely increased waitlist mortality, post-transplant mortality, and functional decline. Furthermore, frail patients are at increased risk for hospital readmission, post-transplant hospitalization and post-transplant ICU stay. Traditional metrics fail to fully capture this risk. The Liver Frailty Index (LFI) is a validated, objective tool used to assess frailty in liver transplant candidates. Despite its clinical utility and ease of use, LFI implementation across hepatology clinics remains inconsistent, leaving many frail patients underdiagnosed and undermanaged. We aimed to describe how LFI is implemented, tracked, and used to guide care in a liver transplant clinic in an integrated health system to inform broader adoption of frailty screening in routine practice. **Methods:** We conducted an Institutional Review Board (IRB #12191) approved retrospective descriptive study of adult patients with cirrhosis seen in the liver transplant clinic at Kaiser Permanente Los Angeles Medical Center between January 1, 2023, and May 20, 2025. LFI was assessed at each clinic visit using standardized tests of grip strength, chair stands, and balance. Scores were calculated using the validated formula developed by University of California San Francisco and categorized as robust (LFI $<$ 3.2), pre-frail (LFI 3.2–4.4), or frail (LFI $\geq$ 4.5). LFI scores were documented and discussed with patients during clinic visits. All patients received frailty education, handouts on physical activity and diet, and those with elevated LFI scores were referred to physical therapy and nutrition services. **Results:** A total of 372 patients were included in the study. The average age of our population was 59.8 years and 60.5% of patients were male. LFI scores are reported as a histogram attached as an image (skewness = 0.68; kurtosis = 0.93) with a mean LFI of 3.43 $\pm$ 0.89, median of 3.35 (IQR 1.04) and a mode of 3.74. Based on their LFI scores, 10.9% of patients were frail, 45.9% pre-frail, and 43.2% of patients were robust. **Conclusion:** Our findings demonstrate that routine use of LFI in a community-based liver transplant clinic is feasible, effective, and supports targeted interventions such as physical therapy and dietician referrals. As a simple, validated, and prognostically meaningful tool, LFI should be standardized across all liver transplant clinics—including those in a unique position as non-transplant center—to stratify risk and guide pre-transplant optimization. Broader implementation of utilizing and tracking LFI scores over time can improve recognition of frailty, facilitate multidisciplinary care, and potentially enhance transplant readiness and outcomes for a particularly vulnerable patient population.

3594 | EXTERNAL VALIDATION OF MELD 3.0 PERFORMANCE IN A LATIN AMERICAN LIVER TRANSPLANT COHORT

Josefina Pages[1] Manuel Mendizabal[2] Federico Pinero[2] Graciela Castro-Narro[3] Alejandra Villamil[4] Fernando Cairo[5] Ignacio Roca[6] Nicolas Dominguez[6] Florencia Antinucci[7] Rodrigo Zapata[8] Julio Benitez Perez[9] Estefanía Liza Baca[10] Bertha Cardenas[11] Gustavo Pereira[12] Angelo Mattos[13] Iván López-Méndez[14] Aldo Torre[15] Marcelo Silva[16] Natalia Baumgartner Ayres[17] Carmen Alexandra Ginesta Frings[18], [1]Hospital Universitario Austral., [2]Hospital Universitario Austral, [3]Instituto Nacional de Ciencias Médicas y Nutrición " Salvador Zubiran", Mexico., [4]Hospital Italiano de Buenos Aires, Argentina, [5]HOSPITAL EL CRUCE, [6]Hospital El Cruce, Argentina, [7]Hospital Alemán, Argentina, [8]Clinica Alemana de Santiago/Facultad Medicina, Universidad del Desarrollo, [9]Complejo Asistencial Dr Sotero del Rio, Brasil, [10]Hospital Nacional Edgardo Rebagliati Martins, Peru., [11]Hospital Nacional Guillermo Almenara, Peru, [12]Hospital Federal de de Bonsucesso, Brasil, [13]Universidade Federal de Ciências da Saúde de Porto Alegre, Brasil, [14]Hospital Medica Sur Unidad de Hepatología y Trasplantes. Ciudad de México, México, [15]Centro Médico ABC, Mexico, [16]Hospital Universitario Austral, Argentina, [17]Irmandade Santa Casa de Misericórdia de Porto Alegre, Brasil., [18]Clinica Alemana

Background: The MELD 3.0 score has demonstrated superior discriminatory performance for predicting 90-day waitlist mortality among liver transplant (LT) candidates in the US. However, its performance remains unvalidated in regions with limited access to transplantation and high waitlist mortality. This study aimed to validate the MELD 3.0 in a Latin American cohort, coordinated by ALEH special interest group. **Methods:** We conducted a retrospective cohort study including adults LT candidates listed between January 2016 and December 2023 across five Latin American countries. Patients receiving MELD exception points were excluded. Baseline data were registered at listing. Continuous variables were transformed as per each original score´s specifications. A time-to-event analysis using Cox regression models was performed, with 90-day mortality as the primary outcome and LT as censored observation. Discriminative performance was assessed using Harrell´s c-index for MELD, MELD-Na and MELD 3.0. Net Reclassification Index (NRI) was also calculated. **Results:** We included 1,013 patients: mean age 51 years (±11.8); 41.4% females, and 25.8% obese. Ascites and encephalopathy were present in 58.1% and 38.3% of cases, respectively. Median laboratories values at listing were: Sodium 137 mEq/L (IQR 133–139), creatinine 0.8 mg/dL (IQR 0.65–1.05), total bilirubin 3.51 mg/dL (IQR 1.9–7.16), albumin 3.0 g/dL (IQR 2.55–3.4), and INR 1.5 (IQR 1.3–1.8). The most common causes of liver disease were autoimmune (23.7%), metabolic-associated steatotic liver disease (18.5%), and alcohol-related liver disease (17.2%). Median MELD score was 16.9 (IQR 13.3–21.1), MELD-Na 18.3 (IQR 14.6–24), and MELD 3.0 19.5 (IQR 15.1–24.8). At 90 days, 26.3% underwent LT and 66.8% remained on the waitlist. The mortality incidence was 29.4 deaths per 1,000 patient-months of follow up, with a cumulative mortality of 8.3% (95% CI 6.6–10.4%) at 3 months. Hazard ratios for 90-day mortality were: MELD 1.15 (95% CI 1.12-1.19), MELD-Na 1.16 (95% CI 1.13-1.20), and MELD 3.0 1.15 (95% CI 1.12-1.19). Harrell's c-index showed no significant differences (Table 1).NRI showed no significant improvement in risk reclassification using MELD 3.0. **Conclusion:** In a region showing high waitlist mortality, MELD 3.0 did not demonstrate superior predictive performance over MELD or MELD-Na. These findings underscore the need for regional validation of predictive models before implementation in transplant priorization policies.

Table 1: Discriminative Performance of MELD-Based Scores for Predicting 90-Day Waitlist Mortality

Model	Harrell's C-index	95% Confidence Interval	p vs MELD	p vs MELD-Na
MELD	0.809	0.76 – 0.86	—	—
MELD-Na	0.821	0.77–0.86	0.41	—
MELD 3.0	0.822	0.78 – 0.87	0.27	0.88
MELD 3.0 (no Alb)	0.822	0.78– 0.87	0.25	0.81

Note: All models evaluated at the time of listing. No statistically significant difference in discrimination was observed between scores.

Albenmousa[1] Bandar Aljudaibi[1] Saleh Alqahtani[1] Dieter Broering[1] Waleed Al Hamoudi[3], [1]KFSHRC, [2]Princess Noura University, [3]King Saud University/KKUH

Background: the presence of autoimmune markers is common in general population the absence of autoimmune diseases. The safety of accepting such individuals as living liver donors is unknown and the literature is lacking. We aim in the study to evaluate the safety of accepting such donors on donors themselves and recipients. **Methods:** Using our electronic medical record system, we retrospectively collected data of patients who underwent liver transplantation from January 2001 until December 2021 at King Faisal Specialist Hospital & Research Center (KFSH&RC) in Riyadh. We usually exclude candidates with evidence of an underlying autoimmune disease or high antibodies titers. We collected demographicdata for donors and recipients. For the donors, we collected the data of antinuclear (ANA), smooth muscles (ASMA) and mitochondrial antibodies (AMA). We also looked at the impact of positive autoimune antibodies on the recipient in term of development of rejection and graft and patient survival. **Results:** 206 donors had at least one positive autoantibodies. The median age of the donors was 28 and 67% were male. Forty-eight donors (23%) had positive ANA, 159 (77%) had positive ASMA and 7 (3.39%) had positive AMA. The patient survival was 90.1% at one year and 87.6% at 3 years. The survival was similar when compared to the cohort of 1600 recipients in our registry (90.1 % vs 92.3, p value 0.93) and (87.6% vs 88.4%, p value 0.9) at one and three years, respectively. Thirty-nine patients (19%) developed at least one episode of rejection. None of the donors developed long term complications. **Conclusion:** if carefully selected, it is safe to accept potential living donors with positive autoantibodies.

3597 | DEFINING WEIGHT TRAJECTORY AFTER LIVER TRANSPLANTATION USING GENERATIVE ARTIFICIAL INTELLIGENCE

Alexis Kim[1] Linxi Li[2] Reem Hamraz[3] Madison Nguyen[1] Rehan Razzaq[1] Vaishali Patel[1] Amon Ashgharpour[1] Idris Yakubu[1] Leslee Garland[1] Kavin Parmar[1] Mark Muthiah[4] Wen Hui Lim[4] Cheng Han Ng[4] Samarth Patel[5] Anh Bui[2] Mohammad Siddiqui[1], [1]Virginia Commonwealth University Health System, [2]Virginia Commonwealth University, [3]Integral University, [4]National University of Singapore, [5]Penn Medicine

Background: Better understanding of weight trajectories in liver transplant (LT) recipients is essential to improving clinical outcomes, however, current statistical approaches utilize aggregate data that does not account for unique patient trajectories. We utilized Generative Artificial Intelligence (GenAI) to identify factors that exist but are not observable (latent factors or LF) that result from limitation in current knowledge or statistical approach to model weight in LT recipients. **Methods:** Weight trajectories were modeled in 562 adult LT recipients with available weight data up to 36 months post-LT. Patients who died within 36 months post-LT, had multi-visceral transplants, or had incomplete follow-up data were excluded. Each weight trajectory was treated as an 8-dimensional vector, allowing us to convert longitudinal weight data into cross-sectional data. Multivariate analyses were also performed to determine the relationship between weight trajectories and clinical parameters. **Results:** The plotted weight trajectories represent complex data (Figure 1A) and conventional statistical approaches (Figure 1B) are not able to fully account for the individual patient-level data. Using GenAI, two discernable patterns, or latent factors were identified (LF_1 and LF_2), incorporating individual patient trajectories that explained 99% of the weight after LT (Figure 1C). Each patient's weight trajectory, thus, represented the combination of the LF_1 and LF_2. LF_1, the dominant latent factor, demonstrated rapid weight flux (increase or decrease) early after transplant (< 12 months), followed by gradual persistent weight gain for 36 months. LF_2 was less prevalent and demonstrated two distinct patterns: (A) initial weight gain in the first 12 months followed by weight loss and weight stabilization by 24-30 months, and (B) initial weight loss followed by rapid and continued weight gain after first 12 months post-LT. In multivariate analysis, MASH cirrhosis and male gender were the strongest clinical predictors of future

weight gain. **Conclusion:** Applying GenAI identified key weight gain trajectories in LT recipients that accounted for nearly all weight change observed following LT. Better understanding weight change in LT recipients can facilitate development of better risk mitigation strategies that can improve clinical outcomes.

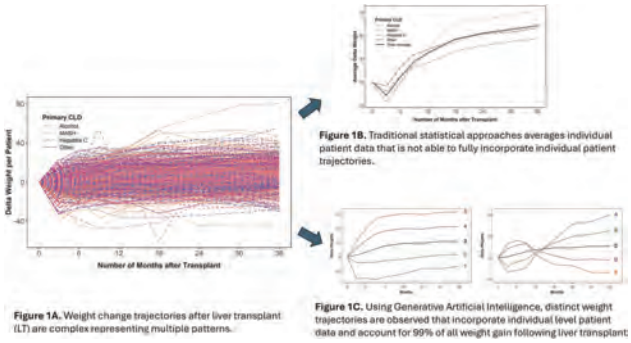

Figure 1A. Weight change trajectories after liver transplant (LT) are complex representing multiple patterns.

Figure 1B. Traditional statistical approaches averages individual patient data that is not able to fully incorporate individual patient trajectories.

Figure 1C. Using Generative Artificial Intelligence, distinct weight trajectories are observed that incorporate individual level patient data and account for 99% of all weight gain following liver transplant

3598 | PRE-LIVER TRANSPLANT CORONARY ARTERY DISEASE RISK IS ASSOCIATED WITH INCIDENCE OF ADVERSE CARDIOVASCULAR EVENTS AFTER LIVER TRANSPLANT: A SINGLE CENTER EXPERIENCE

Tanner Thornsberry[1] Joshua Musalia[1] Alexander Dile[1] Patricia Guzman Rojas[1] Askanda Osman[1] Matthew Still[1] April Gettelfinger[1] Victor Akinditan[1] Jordan Voss[1] Debra Yen[2] John Barnes[1] Jacob Ciricillo[1] Yeshika Sharma[3] Elizabeth Sprague[4] Nadia Alam[1] Clifford Ukarajit[1] Kyra Simmons[1] Edward Danso[5] Khurram Bari[1] Michael Schoech[1] Shimul Shah[6] Adam Myer[1] Kristina Lemon[1] Ralph Quillin[1] Alex Chang[1] Christine Haugen[1] Courtney Jones[1] Tiffany Kaiser[1] Luis Lara[1] Inuk Zandvakili[1] Bianca Wolmarans[1] Wei-Wen Hsu[1] Amoah Yeboah-Korang[1], [1]University of Cincinnati College of Medicine, [2]University of California San Francisco, [3]Baylor University Medical Center, [4]Gastroenterology Associates, [5]Greater Accra Regional Hospital, [6]Massachusetts General Hospital

Background: CVD is a leading cause of death after LT. Pre-LT CAD risk stratification guides pre-op optimization. Limited data exists on the relationship between pre-LT CAD risk stratification and adverse CV events (CVE) post-LT. The primary aim of this study was to examine the association between pre-LT CAD risk classification and post-LT CVE. **Methods:** Patients who had LT at a single center from 2012 to 2018 with follow-up through 2024 were reviewed. Pre-LT CAD risk groups were: low-risk (no CAD risk factors, age < 40, and ≥ 4 METs), intermediate risk (< 2 CAD risk factors, no diabetes, and no MASH), high risk (silent MI on ECG, new WMA on ECHO, new EF $< 50\%$, diabetes, MASH, or ≥ 2 CAD risk factors), and very high risk (prior CAD, PCI, MI, CABG, or CVD). CVD included CAD, CVA, PAD, or aortic atherosclerosis. CAD risk factors included: hypertension, hyperlipidemia, CKD, LVH, tobacco use, family history of early CAD, and age > 60. CVE was defined as hospitalization or death from MI or coronary revascularization, CHF, atrial fibrillation, ventricular arrhythmia, cardiac arrest, and stroke. **Results:** Among 576 LT recipients, 37.5% were female, mean age at LT 57 $\pm$ 10 years, 92.0% White. Primary indication for LT was MASH 29.9%, and alcohol 24.0%. Before LT, average BMI was 30 $\pm$ 6, tobacco use 51%, hypertension 46.5%, diabetes 36.5%, hyperlipidemia 22.1%, CAD 13.9%, CHF 7.1% and atrial fibrillation 5.0%. Pre-LT CAD risk groups included 7.3% low risk, 16.5% intermediate risk, 60.5% high risk, and 15.7% very high risk. By the end of 2024, 156 (27.1%) LT recipients had at least one CVE with 17 CV deaths. Most frequent CVEs were atrial fibrillation 10.2%, CHF 8.2%, cardiac arrest 5.6% and MI 5.4%. Incidence of CVE was 7.3% in low CAD risk, 19.4% intermediate risk, 29.2% high risk, and 39.3% very high risk. Compared to low CAD risk, CVE odds ratio in intermediate risk was 3.0 (95% CI 0.84, 10.97), high risk 5.23 (95% CI 1.58, 17.35), very high risk 8.21 (95% CI 2.35, 28.66). There was no significant difference in post-LT CV deaths between pre-LT CAD risk groups. **Conclusion:** Although most LT recipients were classified as high CAD risk pre-LT, the incidence of CVE was relatively low post-LT. Increasing pre-LT CAD risk was associated with significantly higher odds of post-LT CVE. Future studies should examine the impact of pre-LT CV interventions for high CAD risk on post-LT outcomes.

3599 | PATIENTS TRANSPLANTED FOR METALD CIRRHOSIS HAVE RATES OF METABOLIC DISORDERS POST-TRANSPLANT THAT ARE INTERMEDIATE BETWEEN MASLD AND ALCOHOL CIRRHOSIS

Mohammed Abourahma[1] Dinkar Ahuja[1] Ryan Meader[1] Irena Helenowski[2] Puja Brahmbhatt[1] Kartik Devgan[1] Michelle Lee[1] Emma Schnittka[1] Jonah Rubin[1] Steven Scaglione[1] Natasha Von Roenn[1] Eric Kallwitz[3] Scott Cotler[1], [1]Loyola University Medical Center, [2]Loyola University Chicago Stritch School of Medicine Center for Translational Research & Education, [3]Loyola University Health System

Background: Metabolic complications are common after liver transplantation (LT) and negatively affect outcomes. While post-transplant metabolic disorders are well-described in patients with MASLD, data are more limited for MetALD. We characterized and compared metabolic disorders pre-LT and post-LT among patients with MASLD, ALD, and MetALD. **Methods:** This retrospective study evaluated patients at a single center who underwent LT from 1/12-1/22 with cirrhosis related to MASLD, ALD, or MetALD according to recent criteria (Rinella ME et al., Hepatology 2023). HTN was defined by use of antihypertensive medication or elevated measurements, hyperlipidemia by statin use or abnormal lipid profile, obesity as BMI >30, and DM as HbA1c $>6.5\%$ or treatment with insulin or oral medications.

Results: 295 patients were included: ALD (n = 61), MASLD (n = 121), and MetALD (n = 113). Prior to LT, the MASLD group was older and had a higher percentage of female sex than the other two groups (all $p < 0.05$). In pairwise comparisons of pre-LT variables, the MASLD group had a higher rate of DM ($p < 0.05$) but similar rates of obesity, HTN, and hyperlipidemia compared to the MetALD group . The MetALD group had higher rates of obesity, DM, and HTN compared to ALD group (all $p < 0.05$), and a similar rate of hyperlipidemia. The rate of ascites, which affects BMI pre-LT was similar among groups. At 1-year post-LT, there were differences among groups in BMI, obesity, DM, HTN, and hyperlipidemia (Table). There was no difference in major cardiac events. Pairwise comparisons showed that at 1-yr post-LT, BMI, obesity, DM, HTN, and hyperlipidemia were more frequent in the MASLD group than in the MetALD group and more frequent in the MetAld group than in the ALD group (all $p < 0.05$). **Conclusion:** Metabolic disorders were more frequent in MetALD patients compared to those with ALD, but less common in MetALD compared to MASLD at 1-year post-LT. These findings emphasize the importance of early identification and management of metabolic risk factors in MetALD patients post-LT.

Characteristic	ALD (N = 61)	MASLD (N = 121)	MetALD (N = 113)	P-value
Age at Transplant (Mean ± SD)	52.55 (10.36)(n=59)	61.33 (8.20)(n=121)	56.60 (10.05)(n=113)	<0.001
Sex				<0.001
Female	21.43% (12/56)	46.61% (55/118)	22.32% (25/112)	
Male	78.57% (44/56)	53.39% (63/118)	77.68% (87/112)	
BMI at Transplant (Median, range)	26.33 (15.79, 41.50) (n=58)	32.16 (10.13, 52.00) (n=118)	30.48 (20.28, 52.97) (n=110)	<0.001
Metabolic Complications at 1 Year Post-Transplant				
BMI (Median, range)	26.68 (15.55, 35.95)(n=52)	31.11 (19.91, 49.30)(n=109)	29.40 (16.68, 51.41)(n=103)	<0.001
Obesity (BMI >30)	23.08% (12/52)	59.63% (65/109)	45.63% (47/103)	<0.001
Diabetes Mellitus	8.93% (5/56)	44.07% (52/118)	23.21% (26/112)	<0.001
Hypertension	12.50% (7/56)	75.42% (89/118)	39.29% (44/112)	<0.001
Hyperlipidemia	22.45% (11/49)	59.63% (65/109)	42.42% (42/99)	<0.001

Background: Milan criteria are robust and widely used to select patients for liver transplantation (LT) as they are strongly associated to pejorative histopathological (HP) features in hepatocellular carcinoma (HCC). Pre-transplant treatment may be needed to control cancer in the setting of organ shortage and it has shown to impact survival. The goal of this study was to evaluate whether treatments modalities impact the correlation between static morphological parameters and signs of aggressiveness of HCC. **Methods:** A retrospective monocentric series of 400 consecutive patients undergoing liver transplantation between Jan 2007 and Mar 2025 were included. The presence of vascular invasion (VI), poor differentiation (PD) and microsatellites (MS) was retrieved from the histopathological report. Only the viable tumors were considered to assess Milan status. Chi-2 test was used to correlate the presence of VI, PD and MS to Milan status on the explant in the whole population and in groups of patients according to number of preLT treatment line (< 3 or > 3), type of treatment (surgery, local ablation, radiotherapy, locoregional treatment) and timing of treatment (pre- or post-listing). Recurrence-free survival was calculated from the time of transplant to the first radiological examination showing sign of recurrence. **Results:** In the whole cohort, 93 patients (23%) were out of Milan on the explant. Pejorative HP parameters were identified in 116 patients (29%) (VI in 50 (13%), PD in 59 (15%) and MS in 31 (8%)). There was a significant correlation between all 3 pejorative HP parameters and Milan status in the whole population ($p < 0.0001$). However, in the 53 patients needing more than 3 treatments (13%), Milan status was no more correlated to VI ($p = 0.189$), PS ($p = 0.567$) and MS ($p = 0.099$). In the 140 patients undergoing local ablation (35%), there was no correlation between Milan status and presence of VI or MS ($p = 0.443$ and 0.056). The correlation between Milan status and pejorative HP parameters was significant in patients treated before listing ($p < 0.0001$) but not if treated after listing ($p = 0.128$). Patients having more than 3 treatments had a significantly shorter time to recurrence ($p = 0.001$). Interestingly, the 32 patients within Milan needing more than 3 treatments had a comparable survival to the patients out of Milan ($p = 0.655$). **Conclusion:** Multiple treatments may be necessary to control HCC before transplant but they may induce an increased risk of pejorative histopathological features independently from the morphological criteria usually considered for selection. **Disclosures:** Francois Faitot: Nothing to Disclose, Pietro Addeo: Nothing to Disclose, Camille Besch: Nothing to Disclose, Chloe Paul: Nothing to Disclose, Thierry Artzner: Nothing to Disclose, Baptiste Michard: Nothing to Disclose, Philippe Bachellier: Nothing to Disclose

3602 | LIVER GRAFT CHARACTERISTICS OF LOW-MELD (6-9) VERSUS HIGH-MELD (35+) RECIPIENTS: INSIGHTS FROM THE UNOS DATABASE

Mason Lai[1] Gabrielle Jutras[2] John Roberts[1] Jennifer Lai[1] Jin Ge[2], [1]UCSF, [2]University of California, San Francisco

Background: Waitlist mortality for MELD6-9 ("low-MELD") candidates is lower than for high MELD recipients (35+). Despite this, a significant proportion of LT occurs in patients with MELD6-9. Whether MELD 6-9 candidates may be receiving marginal quality livers compared to MELD35+ candidates ("high-MELD"), and whether this translates into poorer post-transplant outcomes is unknown. **Methods:** We analyzed 34,327 adults who underwent LT from a deceased donor between 2014-2024 from the UNOS database, along with potential organ offers from the Potential Transplant Recipient (PTR) database. The primary exposure was MELD < 9 compared to MELD35+ at the time of LT. MELD 20-24 recipients were also included for reference. Primary outcome was a composite of graft failure and death. We examined LT organ offers and acceptance decisions by differential MELD categories, specifically the donor risk index (DRI) and primary refusal codes. We generated Kaplan Meier curves for post-transplant survival and Cox models using discrete time-interval MELD categories. **Results:** Deceased donor characteristics varied by MELD category by age, (45 [MELD 6-9] vs 44 [MELD 20-24] vs 36 [MELD 35+]), DCD (21% vs 19% vs 2%), diabetes (17% vs 15% vs 8%), hypertension (40% vs 40% vs 26%), cold ischemic time (6.7 vs 5.7 vs 6.1 hours), and donor risk index (DRI, 2.3 vs 2.2 vs 1.8). Organs transplanted in MELD35+ were allocated on 3rd offer (median), versus 26th offer in MELD < 9 and 13th offer in MELD20-24. For organs transplanted into low-MELD, common refusal codes were donor age/quality, donor age, and unacceptable organ-specific test results. Late curve separation was seen in 5-year graft survival for MELD < 9 and MELD35+ (Figure), suggesting later worse survival in MELD < 9 recipients. In adjusted Cox regressions, higher DRI was associated with an increased hazard of graft failure (aHR1.24, 95%CI 1.14-1.34). Averaged over 5 years, compared with MELD35+, MELD < 9 did not show a differential hazard for graft failure (aHR0.95, 95CI 0.82-1.11. Compared with MELD35+, MELD < 9 had a lower hazard of graft failure in the first year (aHR0.71, 95%CI 0.60-0.85), and a higher hazard of graft failure between years 1-5 (aHR1.42, 95%CI 1.14-1.76). **Conclusion:** Low-MELD recipients are ultimately transplanted with deceased donors

with greater median numbers of prior offer declines, higher DRI, and higher donor comorbidity burden. This evidence suggests that poorer outcomes in low-MELD patients may be driven by donor quality.

3603 | COMORBIDITIES AND SURVIVAL IN LIVER TRANSPLANT RECIPIENTS

Lama Amer[1] Bandar Aljudaibi[1] Saleh Alqahtani[2] Dimitri Raptis[1] Ehab Abu-Farhaneh[3] Manhal Izzy[4] Dieter Broering[1] Tahir Mohamed[1] Maryam Abdulla[5] Waleed Haj Ahmed[5] Sayeda Mahma Fatimah Shamdi[5] Ahmed Tariq Alissa[5], [1]King Faisal Specialist Hospital & Research Center, [2]Johns Hopkins University, [3]University of Toronto, [4]Vanderbilt University Medical Center, [5]Alfaisal University

Background: Pre-liver transplant (LT) comorbidities significantly influence post-transplant outcomes, yet their cumulative impact on survival and graft function remains understudied. This study evaluates how the burden of pre-LT comorbidities correlates with mortality and graft failure in LT recipients. **Methods:** Data from LT adult recipients at a large tertiary center in the Middle East, were analyzed, focusing on diabetes mellitus, hypertension, obesity, renal impairment, and coronary artery disease (CAD). The aim of the study is to assess how comorbidities pre-LT affect post-LT survival. Statistical analysis was done using Cox proportional hazards regression for survival outcomes, chi-square tests for categorical comparisons, and multivariable models adjusted for age, sex, MELD-Na score, and HCC status. **Results:** A total of 745 adult LT were analyzed. Mean age at LT was 56 and 267 female patients constituted 37.1% of the cohort. Pre-LT comorbidities were prevalent: DM (46.9%), HTN (33.5%), obesity (33.5%), renal impairment (5.0%), and CAD (17.9%). While increasing comorbidity burden (1–4 conditions) showed no linear mortality risk (listed in table.1). However, specific comorbidities independently predicted outcomes. Heart failure conferred the highest mortality risk (HR 7.78, 95% CI 4.81–12.5, $p < 0.001$), followed by MELD-Na ≥ 30 (HR 2.01, CI 1.21–3.34, $p = 0.007$). DM, HTN, obesity, and personal history of CAD showed no significant associations (listed in table. 2). Sepsis caused 61.9% of deaths, disproportionately affecting recipients with metabolic comorbidities. **Conclusion:** Multimorbidity alone does not linearly predict post-LT mortality, but specific conditions—particularly heart failure and high MELD-Na—significantly elevate risk. These findings underscore the necessity of pre-transplant optimization of cardiovascular health and rigorous sepsis prevention in metabolically compromised recipients. Future studies should explore targeted interventions to mitigate risks associated with high-acuity comorbidities.

Table 1: Comorbidity Burden and Mortality

Number of comorbidities	Odd ratio (95% CI)	p-value
1	0.71(0.40-1.25)	0.238
2	0.81 (0.44– 1.47)	0.500
3	0.89 (0.48– 1.65)	0.717
4	0.22 (0.02– 1.67)	0.144

Table 2: Estimated Mortality Risk of Pre-LT Comorbidities

Comorbidity	Adjusted Hazard Ratio (HR)	95% CI	p-value
Personal CAD	1.04	0.58–1.88	0.88
Heart Failure	7.78	4.81-12.5	0.000
Diabetes Mellitus (DM)	0.75	0.46–1.21	0.24
Chronic Renal Impairment	1.72	0.79–3.79	0.17
Hypertension (HTN)	1.09	.66–1.79	0.72
Obesity	0.90	0.57–1.42	0.66
MELD-Na ≥30	2.01	1.21–3.34	0.007

3604 | INFECTIONS IN THE IMMEDIATE POST-LIVER TRANSPLANT PERIOD: INCIDENCE, MICROBIAL PROFILE, AND IMPACT ON EARLY MORTALITY

Radhika Nittala[1] Fathimathu Zahra[2] Mohamed Fawas[2] Sudheer Mohammed[2] Biju Chandran[3] Mathew Jacob[2] Charles Panackel[2], [1]Asian Institute of Gastroenterology, [2]Aster Medcity, Kochi, [3]Rajagiri Hospital, Kochi

Background: Liver transplantation is the definitive treatment for end-stage liver disease, hepatocellular carcinoma, and acute liver failure. Despite advancements in surgical techniques, immunosuppressive regimens, and perioperative care, the immediate post-transplant period remains a high-risk window for infectious complications. These infections significantly impact graft function, morbidity, and early mortality. This study aimed to evaluate the incidence, microbiological spectrum, infection sites, and the effect of early infections on 30-day mortality in liver transplant recipients **Methods:** We retrospectively analyzed 312 liver transplant recipients at our center. Patients who developed infections within 30 days post-transplant were included. These patients were stratified based on survival status at 30 days. Demographic data, microbial etiology, site of infection, presence of multidrug-resistant (MDR) organisms, preoperative infections, episodes of rejection, and reexploration rates were compared between survivors and non-survivors.
Results: Among 312 patients, 87.1% underwent living donor liver transplantation and 12.9% received grafts from deceased donors. Three patients underwent retransplantation. The overall 30-day mortality was 8.7%, with intracerebral hemorrhage, graft dysfunction, and infections being the primary causes. Infections were identified in 92 patients (29.5%) within 30 days post-transplant, including 12 with pre-existing infections. Bacterial infections predominated (93.5%), with *Klebsiella* spp. (43.5%) being the most frequent, followed by *E. coli* (16.3%). Fungal and viral infections accounted for 12% and 3.3% of cases, respectively. Bloodstream infections were most common (52.2%), followed by pulmonary and urinary tract infections (29.3% each). Notably, 31.5% of patients had infections involving multiple sites. MDR organisms were isolated in 50% of cases. Bloodstream infections, pulmonary involvement, multi-site infections, and fungal etiologies were significantly associated with non-survivors. The infection-related mortality rate within 30 days was 18.5%. **Conclusion:** Infections during the immediate post-liver transplant period are predominantly bacterial, with bloodstream infections being the most frequent and severe. The presence of MDR organisms and fungal infections significantly increases the risk of mortality. Despite advances in transplantation care, early infections remain a critical determinant of post-transplant outcomes and warrant robust preventive and management strategies.

Table 3 Comparison of survivors vs Non survivors having infections

	Survivors (%)	Non survivors (%)	p value
Number	75	17	
LDLT	70 (93.3)	15 (88.2)	.609
Blood stream infection	35 (46.7)	13 (76.5)	.033
Ascitic/Peritoneal infection	17 (22.7)	5 (29.4)	.543
Chest infection	15 (20)	12 (70.6)	<.005
Urine infection	26 (34.7)	1 (5.9)	.019
MDR	36 (48)	10 (58.8)	.592
Polymicrobial	17 (22.7)	6 (35.3)	.353
More than 1 site of infection	18 (24)	11 (64.7)	.003
Bacterial	71 (94.7)	15 (88.2)	.306
viral	1 (1.3)	2 (11.8)	.087
Fungal	5 (6.7)	6 (35.3)	.004
Rejection	12 (16)	2 (11.8)	1.00
Bile leak	57 (76)	16 (94.1)	.181
Peritonitis	12 (16)	0 (0)	.114
Pre op infection	10 (13.3)	2 (11.8)	1.0
Length of stay (days)	74	17	.010
Re-exploration	22 (29.3)	2 (11.8)	.221

3605 | THE AI AGENT IN THE ROOM: INFORMING OBJECTIVE DECISION MAKING AT THE TRANSPLANT SELECTION COMMITTEE

Bima Hasjim[1] Ghazal Azafar[2] Frank Lee[3] Tayyab Diwan[3] Shilpa Raju[2] Jed Gross[2] Aman Sidhu[2] Hirohito Ichii[1] Rahul Krishnan[2] Muhammad Mamdani[2] Divya Sharma[4] Mamatha Bhat[5], [1]University of California, Irvine, [2]University of Toronto, [3]Mayo Clinic, [4]York University, [5]Toronto General Hospital

Background: Transplantation is one of the few areas in medicine where the definitive treatment is rationed. Subjective decision-making pose challenges towards the transplant selection process. Large language

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

models (LLMs) through autonomous artificial intelligent (AI) agents have exciting implications in objective decision-making to solve complex problems, but there are gaps in the literature regarding its clinical applications. Thus, we examined the performance of a multidisciplinary selection committee of AI agents (AI-SC) in the liver transplant (LT) candidate selection process as a proof-of-concept towards objective decision-making. **Methods:** This was a hybrid cohort study of adult ($\geq$18-years-old) LT candidates between 2004-2023 from the Scientific Registry of Transplant Recipients (SRTR) database. The AI-SC consisted of four LLMs: transplant hepatologist, transplant surgeon, cardiologist, social worker, and medical scribe (Figure A). Patients receiving LT were retrospectively analyzed and, because the SRTR only contains patients who were already placed on the LT waitlist, a hypothetical cohort of patients with standard absolute contraindications to LT were generated to simulate cases of patients who would have been rejected from the waitlist. The AI-SC was tasked with classifying each patient as a valid transplant candidate if they 1) had no contraindication to LT, 2) were predicted to benefit from LT with $\geq$6-month survival or 3) $\geq$1-year survival. The temperature was set to a standard of 0.7 and variables $>$20% missingness were excluded to mitigate hallucinations. Cosine similarity index analysis identified the most prevalent variables used by each AI agent of the AI-SC in their decision making. **Results:** Of 8,412 patients, 83.6% were waitlisted and 16.4% had contraindications to LT. In this cohort, the 6-month and 1-year mortality rate was 4.0% and 7.5%, respectively. The AI-SC was able to accurately identify contraindications to LT (accuracy: 98.2%, 95%CI 97.9%-98.4%), and predict 6-month (94.9%, 95%CI 94.4%-95.3%) and 1-year (92.0%, 95%CI 91.4%-92.6%) survival (Figure B). Malignancy was the most common cause of death prior to 6-month (21.7%) or 1-year (28.5%) end points (false positive cases). The most common reason for rejection in false negative cases were tumors outside of the Milan Criteria (53.8% contraindications to LT; 53.8% 6-month survival; 60.9% 1-year survival). Each AI agent used different variables in their decision making and report generation, but indication for LT and recipient age were among the top 5 most important variables used by all members of the AI-SC. **Conclusion:** AI agents can be leveraged to simulate the LT-SC meetings and provide accurate, objective insights on patients who may or may not benefit from LT. Lessons learned from this study are a provocative step towards making the LT selection process more equitable and objective.

	Accuracy (95%CI)	Sensitivity (95%CI)	Specificity (95%CI)	Precision (95%CI)	Recall (95%CI)	F1-score (95%CI)
Contraindications to LT	98.17% (97.90%-98.44%)	1.00 (0.99-1.00)	0.91 (0.89-0.92)	0.88 (0.86-0.89)	1.00 (0.99-1.00)	0.99 (0.99-0.99)
6-month survival	94.88% (94.37%-95.29%)	1.00 (0.99-1.00)	0.75 (0.73-0.77)	0.94 (0.94-0.95)	1.00 (0.99-1.00)	0.97 (0.97-0.97)
1-year survival	92.00% (91.43%-92.56%)	1.00 (0.99-1.00)	0.86 (0.84-0.88)	0.91 (0.90-0.92)	1.00 (0.99-1.00)	0.95 (0.95-0.95)

3606 | ASSOCIATION BETWEEN RECIPIENT/DONOR CHARACTERISTICS AND LIVER STIFFNESS MEASUREMENT IN THE FIRST YEAR POST-LIVER TRANSPLANTATION

Clara Dibenedetto[1] Enrico Sguazzini[1] Michele Sagasta[1] Lucio Caccamo[1] Barbara Antonelli[1] Maria Francesca Donato[1] Pietro Lampertico[1], [1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Liver stiffness measurement (LSM) is widely used in the management of long-term liver transplantation (LT) recipients to non-invasively evaluate graft function. However, its clinical application in the early period post-LT needs further investigations. Our primary aim was to evaluate the relationship between LSM trend during the first 12 months post-LT and recipient/donor features at LT. **Methods:** This is a single centre retrospective study enrolling consecutive patients undergoing LT between 2015 and 2023. Deceased LT recipients within 6 months as well as those undergoing re-LT or without LSM were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

excluded. LSM was performed at 6 and 12 months by vibration-controlled transient elastography (Fibroscan, Echosens, Paris). We investigated the association between LSM > 8 kPa, defining presumptive graft damage, and donor/recipients features at LT. Chi-square and Student T-test were used to analyse categorical and continuous variables, respectively.
Results: 326 LT recipients were enrolled, median age 58 (18-72) years, 73% males.The major etiologies of liver diseases were viral hepatitis (54%) followed by Met-ALD (29%), immune-mediated (10%) and others (7%); 55% were transplanted for HCC, 8% of grafts were DCD and 100% of recipients undergone a CNI-based immunosuppressive regimen. Median LSM was 6.6 (2.5-30.5) kPa with 87 patients (27%) showing LSM > 8 kPa at 6 months and 6.1 (range 2.5-24.1, p = 0.02) kPa with 65 patients (20%) with LSM > 8 kPa at 12 months. By univariate analysis, among all the LT baseline features, including type of grafts (deceased cardiac donor, deceased brain donor, whole or split livers), donor (age, sex, body mass index, BMI) and recipients characteristics (aetiology, MELD, BMI, diabetes), only donor age was associated with LSM > 8 kPa both at 6 and 12 months (6-month OR = 1.04, 95%CI 1.02-1.05, p < 0.01; 12-month OR = 1.03, 95%CI 1.01- 1.06, p < 0.01). **Conclusion:** Our findings indicate that baseline recipient and graft characteristics do not significantly influence early trends in liver stiffness measurement (LSM) during the first year after liver transplantation, apart from donor age. These results suggest that the early increase in LSM observed in grafts from older donors is consistent with the well-established negative impact of advanced donor age on graft outcomes.

3607 | LONG-TERM OUTCOMES AFTER LIVER TRANSPLANTATION OF PATIENTS WITH HEPATITIS D VIRUS INFECTION IN A VERY HIGH-VOLUME TRANSPLANT CENTER

Muhammed Furkan Keser[1] Muhsin Murat Muhip Harputluoglu[2] Cihan Yurdaydin[3] Sezai Yilmaz[4], [1]Inonu University Medical Faculty Dept. of Gastroenterology, [2]Inonu University Liver Transpant Institute Malatya/ Türkiye, [3]Koc University Medical Faculty Istanbul/ Türkiye, [4]Inonu University Medical Faculty Liver Transplant Institute Malatya/Türkiye

Background: Although there are few studies reporting outcomes of patients with hepatitis D virus (HDV) infection after liver transplantation (1, 2), data on the long-term outcomes of patients with HDV recurrence are quite limited.
Methods: A total of 182 patients who underwent liver transplantation due to HDV in our center were retrospectively analyzed in terms of age, gender, transplantation type, pre-transplantation HBeAg, HBV-DNA, HDV-RNA, MELD-Na score, presence of hepatocellular carcinoma (HCC), antiviral treatment, post-transplantation HBsAg, Anti-HBs, HDV-RNA, HBV-DNA levels, survival, HCC, HBV and HDV recurrence, antiviral treatment, HBIG dose and duration, and follow-up duration. HDV-RNA positivity after transplantation was considered as HDV recurrence (HDVr). Factors that influence HDV recurrence were analyzed. Kolmogorov-Smirnov test, Fisher's Exact test, Mann-Whitney U tests were used where appropiate. Cumulative survival of patients with and without HDV recurrence was estimated by the The Kaplan-Meier method and compared with the log-rank test. P < 0.05 was accepted as significant . **Results:** A total of 12 patients had HDV recurrence, while 170 patients did not have HDV recurrence. Median follow-up was 85.00 (4-151) months in the HDVr group and 74.00 (6-196) months in the non-HDVr group. Median time to HDV recurrence was 12.00 (2-53) months. The 1, 3, 5, and 10-year survival rates were 91.6%, 83.3%, 83.3%, and 75%, and 98.2%, 93.5%, 91.1%, and 87.6% in patients with and without HDV recurrence, respectively (p < 0.001 by the Kaplan Meier method). In the HDVr group, one patient (8.3%) developed acute rejection. Post-transplant liver biopsy disclosed hepatitis in 3 patients and rejection in 1 patient in the HDVr group. The causes of mortality in the 4 patients with HDVr were sepsis in 2 patients, unknown cause at an external center in 1 patient, and one patient died during the big Türkiye earthquake in 2023. Pre-transplant HBV-DNA, post-transplant nucleos(t)ide analog (NA) use, hepatitis B immunoglobulin (HBIG) administration duration and dose significantly affected HDV recurrence (Table 1). **Conclusion:** Survival rates of patients with HDVr after transplantation were lower than those without recurrence but mortality etiologies make it unlikely to blame HDVr-induced liver disease for the shorter survival. HDVr was not associated with more severe liver disease. Inappropriate use of NAs and HBIG may affect HDV recurrence.

3608 | SEPSIS AS A LEADING CAUSE OF MORTALITY IN LIVER TRANSPLANT RECIPIENTS: A SINGLE-CENTER EXPERIENCE

abdullah alfhaid[1] Saleh Alqahtani[2] Maryam Abdulla[3] Waleed Haj Ahmad[4] Syeda Shamsi[4] Ahmad Alissa[5] Reem Alameer[3] Bandar Aljudaibi[3], [1]King Faisal Specialists Hospital and Reseach Centre, [2]Johns Hopkins University, [3]KIng Faisal Specialists Hospital and Research Centre, [4]Alfaisal Univeristy, [5]Alfaisal University

Background: Sepsis remains one of the most critical complications following liver transplantation (LT), frequently leading to mortality despite advances in surgical techniques and perioperative care. Its true burden and contributory factors remain undercharacterized in contemporary liver transplant cohorts. This study aims to evaluate the prevalence of sepsis-related mortality in liver transplant recipients and explore potential associations with metabolic and clinical risk factors. **Methods:** We conducted a retrospective analysis of 745 adult liver transplant recipients at a high-volume tertiary transplant center between January 2020 and December 2024. Sepsis was diagnosed based on physician documentation corroborated by clinical and microbiological evidence. Patients had a median age of 56.9 years, and 62.9% were male. Common comorbidities included diabetes (46.9%), hypertension (33.5%), obesity (33.5%), dyslipidemia (19.9%), and fatty liver disease (35.7%). MELD-Na scores were distributed as follows: ≤ 20 (49.8%), 21–29 (38.7%), and ≥ 30 (11.5%). Hepatocellular carcinoma (HCC) was present in 24.8% of recipients. Regarding transplant type, 114 patients (15.3%) received deceased donor liver transplants, while 631 (84.7%) received living donor liver transplants. Statistical analyses were conducted using Cox regression and Kaplan-Meier survival models to identify mortality predictors and sepsis-related trends. **Results:** Of 97 total deaths during the study period, 60 (61.9%) were attributed to sepsis, often accompanied by multisystem organ failure (41.2%). Despite their high prevalence, metabolic comorbidities—including diabetes, hypertension, obesity, and dyslipidemia—were not significantly associated with mortality. Additionally, a higher burden of comorbidities (ranging from 1 to 4) did not show a linear correlation with sepsis-related deaths. Post-LT dialysis was required in 8.6% of cases but was not an independent predictor of poor outcomes. The overall cohort survival rate was 86.9%. Importantly, a MELD-Na score ≥ 30 was significantly associated with increased mortality (HR 2.01, 95% CI 1.21–3.34, $p = 0.007$). **Conclusion:** Sepsis is the predominant cause of mortality among liver transplant recipients in our cohort, often presenting alongside multisystem organ failure. While metabolic comorbidities and dialysis were frequently observed, they did not independently predict mortality, indicating that further research is needed into immune response or microbiome-related risk profiles. Our findings underscore the importance of early recognition, standardized infection prevention measures, and risk stratification tools in improving post-LT outcomes. Future multicenter prospective studies should refine sepsis definitions and evaluate

3609 | SHOULD HBA1C LEVELS IMPACT CANDIDACY FOR LIVER TRANSPLANTATION? EVALUATING HBA1C CUTOFFS ON POST-LT OUTCOMES

Taylor Seacor[1] Garrick Gu[1] Charanpreet Sasan[1] Anita Krishnarao[2], [1]University of Massachusetts Chan Medical School, [2]Umass Memorial Medical Center

Background: Hemoglobin A1C (HbA1C) is a frequently used seromarker of glycemic control with implications for post-surgical outcomes. The validity of HbA1C remains unclear in patients with chronic liver disease, however, due to high erythrocyte turnover and splenic sequestration which may impact the accuracy and predictive value of HbA1C on outcomes after liver transplantation (LT). HbA1C levels are only variably incorporated into an assessment of LT candidacy at many centers since particular HbA1C cutoffs have not been established in regards to their potential impact on post-LT outcomes. We therefore sought to assess if there are specific HbA1C values above which post-LT outcomes are impacted including mortality, graft rejection, and hospital readmission. **Methods:** We collected data from a global de-identified database (TriNetX) and identified 9018 patients with an HbA1C recorded within 3 months prior to LT. Patients were stratified into cohorts based on a pre-LT HbA1C of $\leq 6.5\%$ or pre-LT HbA1C of $> 6.5\%$. Propensity score matching was used to control for etiology of cirrhosis, BMI, and prior exposure to GLP-1 agonists. Rates of mortality, graft rejection, and hospital readmission rates at 1 year following LT were assessed. Similar analyses were performed using an HbA1C cutoff of 8% as well as 10% with assessment of outcomes at 1 year. **Results:** When comparing the HbA1C of $> 6.5\%$ cohort to the HbA1C of $\leq 6.5\%$ cohort, no difference in mortality was noted at 1 year post-LT ([OR]: 1.08, $P = 0.23$). Similarly, there was no mortality difference noted using HbA1C cutoff values of $> 8\%$ or $> 10\%$. Comparing the HbA1C of $> 6.5\%$ cohort to the HbA1C of $\leq 6.5\%$ cohort, rates of graft rejection were lower in the HbA1C of $> 6.5\%$ cohort at 1 year post-LT ([OR]: 0.75, $P = 0.01$). No significant difference in graft rejection rates was observed using HbA1C cutoff values of $> 8\%$ or $> 10\%$. Comparing the HbA1C of $> 6.5\%$ cohort to the HbA1C of $\leq 6.5\%$ cohort, rates of hospital readmissions were reduced in the HbA1C of $> 6.5\%$ cohort 1 year post-LT ([OR]: 0.94, $P = 0.03$). This difference in hospital readmissions did not persist when stratifying cohorts by HbA1C cutoff values of $> 8\%$ or $> 10\%$. **Conclusion:** When comparing cohorts with pre-LT HbA1C cutoffs of above or below 6.5%, 8% and 10%; there were no demonstrated differences in mortality rates at 1 year after LT. Graft rejection and hospital readmission rates were marginally reduced in the HbA1C of $> 6.5\%$ cohort vs HbA1C of $\leq 6.5\%$ cohort at 1 year, an effect that may represent some degree of advantage from glycemic reserve in the immediate post-LT period. Patients with HbA1C values of $> 8\%$ or $> 10\%$ in the pre-LT period, however, did not have increased rates of rejection or readmission. HbA1C levels in pre-LT period therefore appear to have minimal impact on post-LT outcomes even at values suggestive of poor glycemic control. This data may be useful when attempting to utilize pre-LT HbA1C values to assess post-LT risk as part of LT candidate selection.

3610 | SAFETY AND FEASIBILITY OF IMMUNOTHERAPY POST LIVER TRANSPLANTATION– PROSPECTIVE MULTICENTERED STUDY OF A STANDARDIZED CLINICAL PRACTICE PROTOCOL

Kymberly Watt[1] Saurav Panda[1] Valeria Pierluissi Ruiz[1] Amanda Tapia[1] David Chaska[1] Hassan Azhari[2], [1]Mayo Clinic, [2]Memorial Sloan-Kettering Cancer Center

Background: Immune checkpoint-inhibitors (ICI) have improved cancer prognosis significantly, but their use has been avoided in liver transplant (LTr) recipients due to poorly characterized rejection risk based on sub-optimal data including case reports/series with highly variable immunosuppression approaches and followup that do not account for the learning curve. **Methods:** A standardized institutional clinical practice protocol was developed in 2021 and followed for LTr

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

immunosuppression management to fascilitate ICI therapy. Careful discussion of rejection risk was performed with every patient. Patients were followed with routine interval protocol lab testing including immunosuppression levels. Retrospective analysis of data was performed. **Results:** Of 18 LTr, 10 (56%) were male, 89% were white with a mean age 52.8(SD11.1) years. 11/18 had 3 or more failed cancer therapies before ICI. HCC (n = 5), lung (N = 3) and melanoma (N = 3) were the most common cancers treated.Time from first infusion to death was < 30days (N = 4), 30-60 days (N = 3), 61-90 days(N = 1), > 91 days(N = 6).All deaths were cancer related, reflecting the late stage of disease before ICI usage. ICI related toxicity occurred in 3 LTr; pneumonitis (N = 1,5.6%), myocariditis (N = 1,5.6%) and acute cellular rejection (N = 1,5.6%). This rejection related to inadequate everolimus level 3 weeks after first infusion. This patient experienced cholestatic allograft dysfunction and melanoma progression off ICI resulting in death 5 months after ICI due to sepsis in the setting of metastatic melanoma. Four patients continue on ICI thus far 131-236 days with stable allograft function and slow reduction in immunosuppression. 3/4 have partial cancer response and 1 with slowed progression of disease. **Conclusion:** ICI treatment in the immunosuppressed LTr is feasible with careful immunosuppression management and structured followup.Rejection occurred in 5.6%, a much lower rate than early uncontrolled experiences suggest. Patients were initially referred far too late in their disease to have benefitted from the ICI. With positive experience, patients are receiving ICI earlier in their treatment course and are experiencing treatment response. Demonstrating safety/feasibility should allow for earlier utilization of these agents, with a better impact on cancer prognosis. Optimizing rejection risk with cancer response requires ongoing study.

3611 | APPLICATION OF NEW STEATOTIC LIVER DISEASE NOMENCLATURE TO LIVER TRANSPLANT RECIPIENTS

Nicole Lulkin[1] Madison Nguyen[2] Alexis Kim[3] Rehan Razzaq[4] Vaishali Patel[2] Amon Asgharpour[5] Idris Yakubu[2] Anh Bui[2] Mohammad Siddiqui[2], [1]Virginia Commonwealth University School of Medicine, [2]VCUHS, [3]Virginia Commonwealth University Health System, [4]VCU Health System, [5]Virginia Commonwealth University

Background: Steatotic liver disease (SLD) has been widely adopted, and multiple studies have demonstrated its performance in the general population. The recognition of metabolic and alcohol-related liver disease (MetALD) has resulted in enhanced characterization of a phenotype that was previously overlooked. There is currently no data on application of SLD nomenclature to liver transplant (LT) recipients. Compared to the general population, the burden from metabolic diseases is considerably higher in LT recipients. Moreover, with an increasing number of transplants being performed for alcoholic liver disease (ALD) with higher risk of alcohol recidivism, it is important to understand how well the new nomenclature performs in LT recipients. **Methods:** We conducted a retrospective cohort study involving adult LT recipients who had quantification of liver fat via controlled attenuation parameter (CAP). Patients were classified into five groups: No SLD, metabolic-associated steatotic liver disease (MASLD), MetALD, ALD, and SLD not otherwise specified. Demographic, clinical, laboratory,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

and vibration controlled transient elastography (VCTE) variables were extracted from medical records. Alcohol use was quantified via patient history and phosphatidylethanol. **Results:** SLD was present in 247 (59%) patients (Fig. 1A). Patients transplanted for MASH cirrhosis were most likely to develop SLD post LT (Fig. 1B). Most patients with SLD had MASLD (n = 220), however, ALD and MetALD was present in 4.1% (n = 17) and 2.4% (n = 10) of LT recipients. Males and Caucasians were more likely to develop SLD. The severity of hepatic steatosis as measured by CAP was higher among patients with MASLD and ALD (Fig. 1C). Among patients transplanted for alcohol cirrhosis, 42% consumed some alcohol (15% severe, 10% moderate), however, only 28% of patients consuming any alcohol had SLD. Expectedly, the burden from metabolic comorbidities was considerably higher among patients who developed MASLD compared to MetALD and ALD (Fig. 1D). Biochemically, the serum aminotransferases (ALT, AST) were higher among patients with ALD and MetALD when compared to MASLD ($p < 0.01$ and $p = 0.035$, respectively), however, no differences in alkaline phosphatase, and bilirubin were noted. Patients with MASLD (GFR 77.5) and MetALD (73.0) had lower renal function ALD (88.0) and no SLD (82.0). **Conclusion:** The present study provides initial data with application of the novel SLD nomenclature to LT recipients with distinct clinical phenotypes. Additional studies are needed to link these phenotypes to clinical outcomes.

3612 | SLEEVE GASTRECTOMY IN LIVER TRANSPLANT RECIPIENTS IS SAFE AND EFFECTIVE: A PAIRED ANALYSIS

Jacob Bornstein[1] Tyler Lunow-Luke[2] Amy Shui[1] Garrett Roll[1] Andrew Posselt[1], [1]University of California, San Francisco, [2]University of California, Irvine

Background: Liver transplant recipients are at an increased risk of obesity due to post-transplant metabolic changes, and this in turn can increase the risk of allograft dysfunction and long-term graft deterioration. Laparoscopic sleeve gastrectomy (LSG) is an effective treatment for patients with obesity refractory to lifestyle and pharmacologic interventions, but many centers remain hesitant to perform LSG in liver transplant recipients due to perceived additional risk. This retrospective one-group pretest-posttest design study evaluates the safety and efficacy of LSG in severely obese patients who had previously undergone a liver transplant (LT). **Methods:** Medical records of 21 LT recipients who underwent LSG at our institution were evaluated for BMI, DM, and HTN at baseline (pre-LSG), 1-year [n = 20], and 5-year [n = 9] post-LSG. Paired t-tests were used to compare BMI, and Exact McNemar tests and Cohen's kappa coefficient were used to assess changes in DM and HTN prevalence. **Results:** Mean BMI reduction at 1-year post-LSG was 10.4 kg/m² (SD 4.2; $p < 0.001$) and was maintained (10.0 kg/m² (SD 5.0; $p < 0.001$) at the latest available time point. DM prevalence showed modest decreases at 1 year (57% [12/21] vs. 48% [10/21], $p = 0.50$) and at last follow-up (57% vs. 43% [9/21], $p = 0.25$). HTN status remained unchanged at both time points ($p > 0.99$). Kappa

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

coefficients indicated moderate to substantial agreement in DM and HTN classifications pre- and post-LSG. Within 5 years post-LSG, the only complication attributable to LSG was a subclinical anastomotic leak in one patient, which was successfully treated with endoscopy and dietary modification. There were no other complications directly attributable to LSG. **Conclusion:** LSG in LT recipients resulted in substantial BMI reduction and was not associated with significantly increased complications. While DM or HTN status did not show significant improvements during the study period, their prevalence and severity did not increase over time, as is often seen in post-LT patients. These findings support LSG as a safe and effective weight-loss option in LT recipients, though continued monitoring of metabolic outcomes is warranted.

3613 | IMPACT OF NON-VARICEAL UPPER GASTROINTESTINAL BLEEDING ON OUTCOMES AFTER LIVER TRANSPLANTATION

umesh bhagat[1] ankit agrawal[1] mohamed abdelbaky[2] Faris Hamad[1] archana kharel[1] prabhat kumar[3] shalini tripathi[1] luisa recinos[4], [1]Cleveland clinic, [2]Presbyterian Hospital, [3]Virginia Commonwealth university, [4]Saint peters university hospital

Background: Liver transplant (LT) is the only curative treatment for end-stage liver disease. Bleeding is a postoperative complication and a leading cause of morbidity and mortality post-LT. Although postoperative bleeding has been described in several clinical situations, data regarding non-variceal upper gastrointestinal bleeding (NVUGIB) after 30 days are lacking. We aim to assess the incidence and adverse events of NVUGIB diagnosed 30 days post-LT. **Methods:** National Readmission Database (NRD) 2016-2021 was queried to identify LT patients. Patients readmitted after 30 days were divided into two cohorts with and without new onset NVUGIB. The primary outcome was all-cause mortality. Secondary outcomes included adverse events, ICU stay and respiratory failure. Statistical analysis was performed using StataCorp. 2021. **Results:** Of 40,871 patients discharged post-LT, 12,227 were readmitted after 30 days, of which 392 had NVUGIB (3.2%). Patients with NVUGIB had higher odds of mortality (aOR 7.10, 95% CI: 3.35–15.06, p $<$0.001), vasopressor use (aOR 3.97, 95% CI: 1.96–8.04, p $<$ 0.001) ICU stay (aOR 3.80, 95% CI: 2.49–5.79, p $<$ 0.01) and respiratory failure (aOR 2.61, 95% CI: 1.67–4.10, p $<$ 0.001). **Conclusion:** Non-variceal upper gastrointestinal bleeding in liver transplant recipients is associated with significant morbidity and mortality, highlighting the importance of early identification, targeted prophylaxis, and multidisciplinary management to improve post-transplant outcomes

	Odds ratio	95% conf.- interval	P
Mortality	7.10	3.35- 15.06	0.000
Vasopressor use	3.97	1.96- 8.04	0.000
ICU stay	3.80	2.49- 5.79	0.000
arf	2.61	1.67- 4.10	0.000

3614 | EVALUATING THE PREDICTIVE ABILITY OF FIB-4 FOR IDENTIFYING FIBROSIS IN POST-LIVER TRANSPLANT ALCOHOL ASSOCIATED LIVER DISEASE

Adam Khalaf[1] Alessandra Martorella[1] Manotri Chaubal[2] Sungyoung Auh[3] Amol Rangnekar[1] Christine Hsu[3], [1]MedStar Georgetown University Hospital, [2]Georgetown University, [3]National Institutes of Health

Background: Return to alcohol use (AR) after liver transplantation (LT) contributes to progressive liver injury, and up to 54% develop cirrhosis within 10 years. Despite relapse rates nearing 25%

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

within 3-5 years post-LT, no standardized fibrosis surveillance strategies for post-LT patients currently exist. Liver biopsy remains the gold standard but is invasive. Noninvasive scores such as the Fibrosis-4 (FIB-4) index is commonly used in pre-LT populations, but its validity in post-LT patients needs further elucidation. We aim to evaluate the accuracy of FIB-4 in patients undergoing liver biopsy after LT. **Methods:** We conducted a single-center retrospective cohort study of 76 adult LT recipients transplanted for alcohol associated liver disease (ALD) from 2015 to 2022. All patients underwent for-cause liver biopsy and had laboratory data available at the time of biopsy, 30 ± 15 days and 90 ± 15 days before biopsy. Demographic, metabolic, and histologic data were collected. The primary outcome was biopsy-confirmed fibrosis. Outcomes included significant fibrosis (F2-F4) and advanced fibrosis/cirrhosis (F3-F4). Optimized cutoffs of FIB-4 were obtained by using Youden's J statistic. Also, we evaluated published cutoff values of 1.5 or 2.67. Diagnostic performance was assessed using area under the curve (AUC) with 95% confidence intervals, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). **Results:** A total of 76 adult post–LT patients transplanted for alcoholic liver disease underwent for-cause liver biopsies. In this cohort, 12 (16%) had F2–F4 fibrosis, 58% of which occurred within two years post-LT. AR was documented in 34.7% of the cohort (Table 1). Most patients were male (75%) and Caucasian (75%). When assessing FIB-4 at time of biopsy, 30, and 90 days prior, FIB-4 at 30 days prior best predicted F3–F4 fibrosis with the highest AUC of 0.649 (95% CI, 0.282–0.996) using an optimized cutoff of 4.14. This threshold yielded a sensitivity of 75%, specificity of 59.7%, NPV of 97.7%, and PPV of 9.4%. In contrast, published cutoffs (2.67 for F3–F4, 1.5 for F2–F4) had poor AUCs (0.52–0.54). However, FIB-4 ≥ 1.5 at time of biopsy was highly specific (89.3%) for predicting F2–F4 fibrosis, while FIB-4 ≥ 2.67 at time of biopsy and 30 days prior was highly specific for predicting F3–F4 fibrosis (96.1% and 97.1%, respectively). **Conclusion:** Currently, fibrosis surveillance post-LT is not standardized and varies across centers. FIB-4 in this study showed high specificity for F2–F4 and F3–F4 fibrosis at cutoffs of 1.5 and 2.67, respectively, but limited predictive accuracy. An optimized threshold of 4.14 improved performance for identifying F3–F4 fibrosis (AUC 0.65). This suggests that if FIB-4 > 1.5, then it should warrant further evaluation with transient elastography or biopsy. Our study suggests that fibrosis may occur rapidly post-LT, as the majority of patients developed F2-F4 fibrosis within 2 years of LT.

Category	Characteristic	Number (% of Total)

3615 | INTENT-TO-TREAT ANALYSIS OF LIVER TRANSPLANT (LIVING DONOR VS DECEASED DONOR) FOR HEPATOCELLULAR CARCINOMA IN THE UNITED STATES

Madeleine Wong[1] Hiroshi Sogawa[2] David Samson[3], [1]Stony Brook University Hospital, [2]Yale School of Medicine/Yale New Haven Hospital, [3]Westchester Medical Center

Background: Liver transplant is a key treatment for locoregional hepatocellular carcinoma (HCC) with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

cirrhosis. However, organ shortage and prolonged waitlist times serve as fatal barriers to deceased donor liver transplant (DDLT). Living donor liver transplant (LDLT) offers reduced waiting times, fewer waitlist dropouts, and liberalized transplant eligibility. While studies attempting to compare survival outcomes and HCC recurrence between LDLT and DDLT show mixed results, a few have used intention-to-treat (ITT) analysis for a more accurate comparison. We aim to conduct a nationwide ITT analysis of survival outcome between LDLT and DDLT for HCC in the United States. **Methods:** Clinicopathological and demographic data for HCC patients who underwent LT between 1985-2017 were retrospectively collected from the SRTR database. Two cohorts were formed: an ITT cohort (patients who were waitlisted/recipient for a DDLT vs. LDLT recipients) and a post-transplant cohort (recipients of DDLT vs. LDLT). Propensity score models using multivariable logistic regression were applied with LDLT as the dependent variable. The absolute standardized mean difference (ASMD) score quantified differences in each variable. Overlap weighting derived from the propensity scores was used to control confounding factors and achieve balance between both groups. Via Kaplan-Meier curves and median survival estimates, we analyzed survival outcomes between the waitlist/DDLT and LDLT groups in both cohorts. Hazard ratios from cox regression were also calculated. Between-group differences in median waitlist time was assessed using the Mann-Whitney U Test. **Results:** A total of 26,930 patients were identified from the SRTR database during the study period (262 LDLT and 26,668 DDLT). Prior to overlap weighting, LDLT patients were more likely to be female, aged $\geq$ 50 years, Asian, Black, on government insurance, have a BMI $\geq$ 30kg/sqm, had moderate encephalopathy, a history of portal vein thrombosis, MELD scores $\geq$ 20, and have abnormal bilirubin/creatinine levels. After the application of overlap weighting, the two donor type groups were remarkably well-balanced except for the presence of moderate encephalopathy or alpha fetoprotein values $\geq$ 20 ng/mL. In the ITT-cohort, LDLT had significantly higher survival of 11.35 years compared to the Waitlist/DDLT group of 8.28 years ($P < 0.000$). The median waitlist time of 6.1 months in the waitlist/DDLT group was significantly higher than the LDLT group with 5.2 months ($P < 0.005$). In the non-ITT analysis of overall survival, the DDLT group had medial survival of 10.94 years, but was still lower than the LDLT group of 11.04 years, although these findings were not significant ($P = 0.82$). **Conclusion:** LDLT patient survival was significantly better than DDLT patient survival for HCC in an ITT basis in the United States. This may be associated with significantly improved waitlist times in the LDLT group compared to the DDLT group.

3616 | PROGNOSTIC IMPACT OF COMBINED DIASTOLIC AND SYSTOLIC DYSFUNCTION WITH GLOBAL LONGITUDINAL STRAIN ON OUTCOMES IN LIVER TRANSPLANT RECIPIENTS

Ebehiwele Ebhohon[1] David Lee[2] Muhammad Hammami[1] Haytham Allaham[1] Zulqarnain Khan[1] Youngjae Cha[1] Adaobi Ahanotu[1] sabtain saroya[3] Michael Chang[1] Trent Johnson[1] Nathalie Urrunaga[4], [1]University of Maryland Medical Center, [2]University of Maryland School of Medicine, [3]Howard University School of Medicine, [4]University of Maryland, Baltimore

Background: Diastolic dysfunction, systolic dysfunction, and global longitudinal strain (GLS) abnormalities—have been identified as significant factors influencing patient outcomes. This study evaluates the composite impact of these three markers of cardiac dysfunction on liver transplant outcomes, focusing on mortality, inpatient rehabilitation needs, and overall hospital course in a cohort of patients from the University of Maryland Medical Center (2016–2018). **Methods:** The study cohort consisted of 274 liver transplant recipients with a mean age of 53.9 years, predominantly male (63.1%) and white (70.8%). Cardiac assessment revealed that systolic dysfunction was present in 24.8% of patients, diastolic dysfunction in varying grades in 27.4%, and the mean GLS value was -19.2 $\pm$ 3.71. Significant cardiac history, including coronary artery disease and atrial fibrillation, was noted

in 13.5% of patients. Outcomes were analyzed using a composite endpoint derived from these three measures, adjusted for age, sex, race, and BMI. **Results:** Post-transplant outcomes demonstrated that the composite cardiac endpoint significantly increased the likelihood of inpatient rehabilitation admission (HR: 2.13, 95% CI: 1.23–3.69, p = 0.007) (Table 2). Although trends towards extended ICU and total hospital stays were observed, these did not reach statistical significance. Mortality rates were unaffected by the composite cardiac endpoint (HR: 0.48, 95% CI: 0.16–1.47, p = 0.197)(Table2). **Conclusion:** These findings emphasize the nuanced role of cardiac dysfunction in influencing functional recovery and resource utilization post-liver transplant, highlighting the need for comprehensive pre-transplant cardiac evaluation and optimization in liver transplant candidates.

Table 2 Association between presence of Left and Right Diastolic Dysfunction[&] and Post-transplant Outcomes

	HR	95% CI	p-value
PTBS with Stent placed	1.30	0.63, 2.66	0.478
MACE	1.34	0.58, 3.10	0.495
ICU LOS	1.67	0.83, 3.40	0.153
Total Inpatient LOS	1.48	0.94, 2.34	0.092
Rehab Admission	**2.13**	**1.23, 3.69**	**0.007**
Mortality	0.48	0.16, 1.47	0.197

3617 | MELD-NA SCORE STRATIFICATION AND POST-LIVER TRANSPLANT OUTCOMES

Ahmad Alissa[1] Waleed Haj Ahmad[2] Maryam Abdulla[2] Saleh Alqahtani[3] Manhal Izzy[4] Syeda Shamsi[1] Bandar Aljudaibi[5], [1]Alfaisal Univeristy, [2]Alfailsal Univeristy, [3]Johns Hopkins University, [4]Vanderbilt University Medical Center, [5]King Faisal Specialists Hospital and Reseach Centre

Background: The Model for End-Stage Liver Disease-Sodium (MELD-Na) score is pivotal for liver transplant (LT) prioritization, yet its prognostic utility for post-LT complications remains incompletely defined. This study evaluates associations between MELD-Na stratification and post-LT survival, graft failure, and morbidity. **Methods:** Among 745 LT recipients, MELD-Na scores were categorized as ≤20 (49.8%), 21–29 (38.7%), and ≥30 (11.5%). Patients with acute liver failure and were non-cirrhotic were excluded from the analysis Outcomes included all-cause mortality, graft failure, sepsis, and cardiac events. **Results:** Higher MELD-Na scores correlated with increased mortality (MELD-Na ≥30: 13.0% vs. ≤20: 11.5%, *p* < 0.01) and graft failure (13.7% vs. 12.4%, *p* = 0.02). Sepsis was the leading cause of death (44/97 deaths, 45.4%), with a trend toward higher sepsis-related mortality in MELD-Na ≥30 (68.2% vs. ≤20: 58.1%, *p* = 0.04). Cardiac events (myocardial infarction: 2.6%, cardiac death: 1.6%) did not differ across MELD-Na groups. Lower MELD-Na (≤20) was associated with superior 1-year survival (89.2% vs. 76.7% in ≥30, *p* < 0.001). Renal impairment (GFR ≤60: 22.4%) was more prevalent in MELD-Na ≥30 (34.9% vs. ≤20: 18.1%, *p* = 0.01). **Conclusion:** MELD-Na ≥30 predicts higher mortality and sepsis risk, underscoring the need for tailored post-LT management in high-score recipients

3618 | IMPACT OF GRAFT REJECTION AND BILIARY COMPLICATIONS ON LIVER STIFFNESS MEASUREMENTS DURING THE FIRST YEAR AFTER LIVER TRANSPLANTATION

Michele Sagasta[1] Clara Dibenedetto[1] Enrico Sguazzini[1] Lucio Caccamo[1] Barbara Antonelli[1] Maria Francesca Donato[1] Pietro Lampertico[1], [1]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy

Background: Liver stiffness measurement (LSM) is a simple, non-invasive tool for long-term graft monitoring after liver transplantation (LT). The early post-LT period is often complicated by events that may impact LSM values, but this relationship has not been clearly studied. We aimed to evaluate the association between early (<12 months) post-LT complications and LSM changes. **Methods:** This single-center retrospective study included all consecutive LT recipients from 2015 to 2023. Patients who died within 6 months, underwent re-LT, or lacked LSM at 6 (T1) or 12 (T2) months were excluded. LSM was assessed by vibration-controlled transient elastography (Fibroscan®, Echosens, Paris). LSM >8 kPa was considered indicative of presumed graft damage. All rejection episodes were biopsy-proven. Categorical and continuous variables were analyzed using chi-square and t-test, respectively. **Results:** A total of 326 recipients were included (median age 58 years, range 18–72), 73% male. Pre-LT liver diseases included viral hepatitis (54%), Met-ALD (29%), immune-mediated (10%), and other etiologies (7%). LT was performed for HCC in 55% and for decompensated cirrhosis in 38% of patients.

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

All received calcineurin inhibitor-based immunosuppression. Median LSM was 6.6 kPa at T1 and 6.1 kPa at T2 ($p = 0.02$). LSM > 8 kPa occurred in 27% at T1 and 20% at T2. Rejection was reported in 22% at T1 and 3% at T2 while biliary complications in 17% and 9% and vascular complications in 12% and 1% at T1 and T2, respectively. CMV reactivation occurred in 27% exclusively within 6 months. The most common comorbidities were arterial hypertension (67%), steroid-induced diabetes (32%), and CKD grade > 3 (15%). At T1, LSM > 8 kPa was significantly associated only with graft rejection (37% vs 17%, $p < 0.01$). At T2, elevated LSM was significantly linked to biliary complications (15% vs 7%, $p = 0.03$) and CKD (25% vs 13%, $p = 0.02$). **Conclusion:** Elevated LSM during the first 6 months post-LT is mainly associated with graft rejection, while LSM increases observed in the second semester are more often linked to biliary complications and CKD. These findings support incorporating LSM into early post-LT monitoring to aid in the detection of graft-related complications.

3619 | DIRECT PERCUTANEOUS TRANSHEPATIC CHOLANGIOSCOPY VISUALIZATION FOR SAFE AND RADIATION-FREE REMOVAL OF BILIARY FOREIGN BODY: A MIGRATED NON-ABSORBABLE HEMOSTATIC CLIP

Tianhao Chen[1] Rongxing Zhou[1] Jingyi Zhang[1] Jie Zhang[1] Rui Chen[1], [1]West China Hospital of Sichuan University

Background: Clip migration is a rare but increasingly recognized complication following laparoscopic cholecystectomy (LC), which can lead to biliary obstruction and secondary stone formation. While endoscopic retrograde cholangiopancreatography (ERCP) is commonly used for foreign body extraction, its efficacy may be limited in cases where the object is firmly embedded. Percutaneous transhepatic cholangioscopy (PTCS) offers direct visualization and radiation-free access for biliary interventions. **Methods:** An 83-year-old man with a history of LC 6 years prior presented with right upper quadrant pain and recurrent fever. Imaging revealed a dilated common bile duct (CBD) with multiple stones. PTCS was performed via a percutaneous tract to facilitate stone removal. During the procedure, a foreign body resembling a "stubborn stone" was noted adherent to the upper CBD wall. After superficial stone removal, the object was identified as a non-absorbable hemostatic clip. A migrated clip may serve as a nidus for secondary common bile duct stone formationTo prevent ductal injury, two biopsy forceps were employed—one for stabilization and one for blunt dissection of surrounding tissue. **Results:** The embedded clip was successfully divided into three fragments and retrieved without damaging the bile duct. All residual stones were removed under direct cholangioscopic visualization. Final inspection confirmed an intact bile duct and no remaining foreign material. The reassembled fragments confirmed the complete retrieval of the hemostatic clip. The patient's postoperative recovery was uneventful, with no complications or discomfort reported. Removal of the underlying lesion may also help prevent recurrence of common bile duct stones. **Conclusion:** This case highlights the effectiveness and safety of PTCS in managing complex biliary foreign bodies, particularly those that are tightly adherent to the bile duct wall. Unlike ERCP, which may be limited by indirect visualization and anatomical constraints, PTCS offers direct endoscopic control, enabling precise dissection and foreign body retrieval without the use of fluoroscopy, thus avoiding radiation exposure for both patients and physicians. The identification of a migrated non-absorbable hemostatic clip as the nidus for stone formation underscores the importance of careful consideration regarding the use and placement of such clips during laparoscopic cholecystectomy. In conclusion, PTCS may be considered a valuable adjunct in the armamentarium for biliary interventions, particularly in managing complications related to surgical materials. Simultaneously, this case advocates for the judicious use of hemostatic clips and suggests further evaluation of absorbable alternatives or secure placement strategies to minimize the risk of migration and late biliary complications.

◆ 3620 | NEXT GENERATION GENE THERAPY FOR WILSON'S DISEASE: CLINICAL SAFETY AND EFFICACY OF LY-M003, A COPPER-RESPONSIVE AAV GENE THERAPY VECTOR

Andrew Lin[1] chaohui yu[2] Yi Chen[2] Chao Lu[2] Zhe Shen[2] Jianyong Wang[2] Yixiong Chen[3] Tianqi Jiang[1] Yuzhe Peng[3] Rihong He[3] Chenming Lu[3] Guofang Yan[3] Jian Wang[3] Juan Chen[3], [1]Lingyi Biotech Co., Ltd, [2]The First Affiliated Hospital of Zhejiang University, School of Medicine, [3]Lingyi Biotech co., ltd.

Background: Wilson disease (WD) is a rare autosomal recessive metabolic disorder caused by mutations in the ATP7B gene, leading to deficient ATP7B activity and progressive copper accumulation in the liver, brain, and kidney. LY-M003, an investigational AAV8-based gene therapy product, is designed to restore copper metabolism by delivering a modified miniATP7BLY protein. LY-M003 utilizes the Copper Responsive Engineering of ATP7B Expression (CREATE™) platform, which dynamically regulates protein expression in response to hepatic copper levels. This novel approach aims to enhance both efficacy and safety in the treatment of Wilson disease. **Methods:** A clinical study (NCT06650319) is currently underway at the First Affiliated Hospital of Zhejiang University, China, to evaluate the safety and efficacy of a single intravenous infusion of LY-M003 in patients with WD. Stable treated WD patients are eligible for enrollment, with the option to continue SoC therapy post-administration until clinical improvements are observed. A prophylactic immune supression regimen is administered to all participants. The study's primary objectives are to assess the safety and efficacy of escalating doses of LY-M003. Participants will undergo a 52-week post-treatment evaluation, followed by a four-year long-term follow-up phase. **Results:** Since September 2024, seven participants have received LY-M003, demonstrating a favorable tolerability profile across all dosage cohorts. No anti-drug antibodies (ADA) against ATP7B were detected, and no serious adverse events (SAEs) were reported. Mild elevations in liver enzymes were observed in some participants but were effectively managed with immune modulation therapy. Key therapeutic outcomes include: • Hepatic Copper Transport Restoration: Most participants exhibited significantly increased ceruloplasmin levels, with peak values exceeding 50% of the normal range in one patient, indicating reestablished hepatic ATP7B function. • Reduction in Chelation Therapy Dependence: Five out of seven participants successfully discontinued chelation therapy(cut off Apr 2025) following normalized urinary copper levels. Neurological and Psychiatric Symptom Improvement: Participants experiencing neurological and psychiatric manifestations showed functional improvements within three months, as evidenced by reductions in UWDRS scores related to writing ability, language skills, and motor function. **Conclusion:** LY-M003 is an innovative AAV8-based gene therapy for Wilson disease, currently under clinical investigation. Early clinical data across different dosage groups indicate a strong safety profile and promising therapeutic efficacy, with benefits observed in both peripheral and neurological symptoms. These findings highlight LY-M003's potential to revolutionize Wilson disease treatment, paving the way for a transformative therapeutic paradigm.

◆ 3621 | UX701 GENE THERAPY FOR WILSON DISEASE: RESULTS: FROM THE PHASE 1/2 PORTION OF CYPRUS^{2+}

Danny Bega[1] Jeff Bronstein[2] Hélder Cardoso[3] Russell Goodman[4] Sihoun Hahn[5] Paul Kwo[6] Craig Lammert[7] Valentina Medici[8] Andrew Muir[9] Nicole Davis[10] Serap Sankoh[10] Grace Wang[10] Andrew Grimm[10], [1]Northwestern University Feinberg School of Medicine, Chicago, IL, USA, [2]David Geffen School of Medicine at UCLA, Los Angeles, CA, USA, [3]Centro Hospitalar Universitário de São João, Alameda Prof. Hernâni Monteiro, 4200-319, Porto, Pt, [4]Massachusetts General Hospital, Boston, MA, USA, [5]Seattle Children's Hospital/Univ of Washington, [6]Stanford University Medical Center, [7]Indiana University Health, Indianapolis, IN, USA, [8]University of California Medical Center, [9]Duke University, [10]Ultragenyx Pharmaceutical, Inc.

Background: Wilson disease is a rare, progressive, genetic disorder of biliary copper (Cu) excretion due to pathogenic *ATP7B* variants. Hepatic manifestations can

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

include hepatitis, acute liver failure, chronic liver disease, and cirrhosis. Current standard of care (SOC) of Cu chelators and zinc can be burdensome, and compliance is challenging. UX701 is an investigational AAV9 gene therapy (GT) designed to restore ATP7B function in patients with Wilson disease. **Methods:** Cyprus^{2+} (NCT04884815) is a global, seamless Phase 1/2/3 first-in-human study of UX701 in adults with Wilson disease. In Phase 1/2 Cyprus^{2+}, subjects enrolled in 3 groups: 5.0X10^{12}, 1.0X10^{13}, and 2.0X10^{13} genome copies/kg. After UX701 administration, subjects were followed for at least 52 weeks during Stage 1 of Cyprus^{2+}. Key outcomes were changes from baseline in biomarkers of Cu metabolism, tolerance to discontinuing SOC medications, Patient Global Impression of Change (PGIC), and safety outcomes. **Results:** Five subjects were enrolled in each dose group (15 total). ATP7B transgene presence and mRNA expression in hepatocytes were observed by in-situ hybridization and confirmed with immunohistochemistry at 52 weeks, showing new ATP7B expression on the apical surface of hepatocytes (Figure 1). Five of 15 (33%) subjects showed biomarker improvement (total serum Cu, Ceruloplasmin [Cp]-bound Cu, and Cp concentration and activity). Eight of 15 (53%) subjects tapered and ultimately discontinued SOC through present analysis (median [range]: 44.5 [7-120] weeks). Subjects reported reduced disease severity with 10/15 (67%) reporting PGIC of $\geq$+1 at Week 52, and 8/15 (53%) reporting $\geq$+2. Of those who discontinued SOC, 6/8 (75%) reported PGIC improvement, with 5/8 reporting scores $\geq$+2. No patient who discontinued SOC reported worsening PGIC.

Safety data were consistent with the expected profile of AAV gene therapy, including transient asymptomatic liver enzyme elevations during the first 4 months following UX701 administration, which were responsive to corticosteroids. **Conclusion:** Cyprus^{2+} is the first systematic evaluation of long-term hepatic transgene expression in subjects receiving gene therapy. Durable changes in Cu homeostasis were observed along with new ATP7B apical expression. Most were able to discontinue SOC medications.

Additional long-term data are expected, including biliary Cu excretion. A fourth cohort with a higher dose and optimized immunomodulation regimen will be presented.

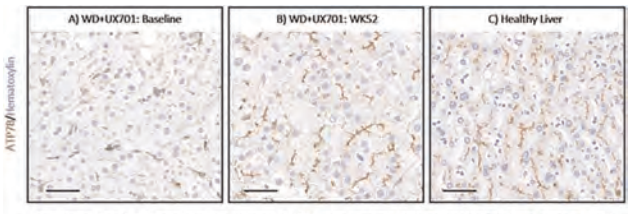

Figure legend: New ATP7B expression was observed at WK52 using immunohistochemistry staining of Liver biopsy with anti-ATP7B antibody. Representative images of ATP7B staining of A) baseline sample showed ATP7B+ Kupffer cells without apical surface staining of hepatocytes. B) the same subject showed new apical surface (canalicular membrane) staining of hepatocytes at WK52. C) a healthy control liver showed canalicular membrane staining of hepatocytes. Scale bars: 50μm

◆ 3622 | IN VIVO GENE EDITING THERAPY AS A TREATMENT FOR ALPHA-1 ANTITRYPSIN DEFICIENCY

Jeff An[1] Erin Spofford[2] Zsanett Jancso[2] April Hayes[2] Carol Cai[2] Guangde Li[2] Sudeepa Syamala[2] Tong Wu[2] Mugdha Bedekar[2] Sumanprava Giri[2] Sarah Ducat[2] Kenneth Ganley[2] Gulen Tonga[2] Tom Colace[2] Sherry He[2] Gang Sun[2] James Rottman[2] Anne Bothmer[2] Jane Wang[2] Cecilia Cotta-Ramusino[2] Michael Holmes[2] William Querbes[2], [1]Tessera Therapeutics, [2]Tessera Tx

Background: Alpha-1 antitrypsin deficiency (AATD) is an inherited autosomal recessive disorder that affects 1 in 2,000 to 3,500 newborns. It arises from mutations in the *SERPINA1* gene that encodes a serum protease inhibitor. Individuals homozygous for the E342K mutation (PI*ZZ genotype) account for 95% of AATD-related disease, leading to low serum AAT levels, accumulation of misfolded mutant Z-AAT protein, and clinical sequelae consistent with chronic obstructive pulmonary disease and liver disease. **Methods:** To develop a new class of therapy for AATD, we generated an RNA Gene Writer that is designed to correct the E342K mutation (PiZ allele) to wild- type in the *SERPINA1* gene. **Results:** LNP-RNA delivery of our RNA Gene Writers corrected this mutation in the NSG-PiZ mouse, a transgenic mouse model with ~20 copies of the mutation, where we precisely edited more than 90% of the hepatocytes, based on the assumption that 60% of liver cells are comprised of hepatocytes, after a single intravenous administration at 0.5 mg/kg. We also observed significant increases in serum AAT levels with no detectable circulating Z-AAT protein, restored neutrophil elastase inhibition, and reductions in protein aggregates in the liver with durable mutation correction and phenotypic rescue demonstrated for up to 10

weeks post-treatment. Separately, we generated a humanized mouse model with only two PiZ alleles to better approximate the efficacy of our product in patients with the homozygous PiZZ genotype. LNP-RNA delivery of our RNA Gene Writers achieved an estimated 82% correction of hepatocytes after a single low dose (0.1 mg/kg treatment in this mouse model). Finally, we evaluated RNA Gene Writer in cynomolgus macaques and showed that a single dose of 1.5 mg/kg LNP-RNA achieved an average of 76% editing of hepatocytes. Genomic assessments from treated NHPs showed LNP delivery of the RNA Gene Writers displayed high specificity of editing to the liver with only spleen showing quantifiable levels of editing above background (0.14%) among 30 additional tissues and biofluids tested. Importantly, editing was not detected in germline tissues, including testes and ovaries. Editing was also highly specific to the intended SERPINA1 locus, with no off-target activity detected by rhAmpSeq at other genetic loci. **Conclusion:** In summary, we demonstrated that our LNP formulated RNA Gene Writers efficiently edited the *SERPINA1* gene responsible for AATD in the liver of mice and NHP with a single administration at therapeutically relevant doses.

3623 | COPPER OVERLOAD RESHAPES THE HEPATIC IMMUNE LANDSCAPE IN WILSON&RSQUO;S DISEASE

Mugagga Kalyesubula[1] Som Dev[1] Andreas Patsalos[1] James Hamilton[1], [1]Johns Hopkins University School of Medicine

Background: Wilson's disease (WD) arises from ATP7B mutations that disrupt copper (Cu) homeostasis, resulting in hepatic Cu accumulation and progressive liver dysfunction. This pathological copper overload drives liver inflammation and fibrosis, with potential progression to liver failure, alongside a suppressed LXR signaling axis. The immunologic basis for liver inflammation and injury remains largely unknown. **Methods:** Single-nucleus RNA sequencing (snRNA-seq) was utilized in a WD mouse model to delineate the immunological landscape reshaped by Cu toxicity, followed by validation using immunofluorescence (IF) and RNAscope. *Atp7b*$^{-/-}$ mice and Heterozygote controls of the C57BL/6x129S6/SvEv background of 20 wk of age were employed in the study. The LXR agonist (T0901317 (Cayman Chemical, Ann Arbor, MI)) was administered to test its potential treatment effect in WD management. **Results:** Our analyses reveal that Cu overload reduces hepatocyte clusters and disrupts immune subset heterogeneity, leading to an expansion of distinct macrophage subsets, dendritic cells (DCs), and T cells, with an increase in pro-inflammatory and pro-fibrotic pathways. Furthermore, IF and RNA scope validation demonstrate a decrease in central hepatocytes and an increase in macrophages under copper overload. Strikingly, pharmacological activation of Liver X Receptor (LXR) using a synthetic agonist reverses these Cu-induced immune shifts. LXR treatment restores immune homeostasis by modulating key targets (*Mylip, Pltp, Il6, Il1b, Scd1*, and *Tnf*), attenuating inflammation, and reprogramming macrophages toward a reparative phenotype. **Conclusion:** These findings establish a novel link between Cu overload, immune dysregulation, and liver pathology in WD, highlighting LXR agonists as a potential therapeutic strategy to mitigate immune-driven hepatic damage in WD patients.

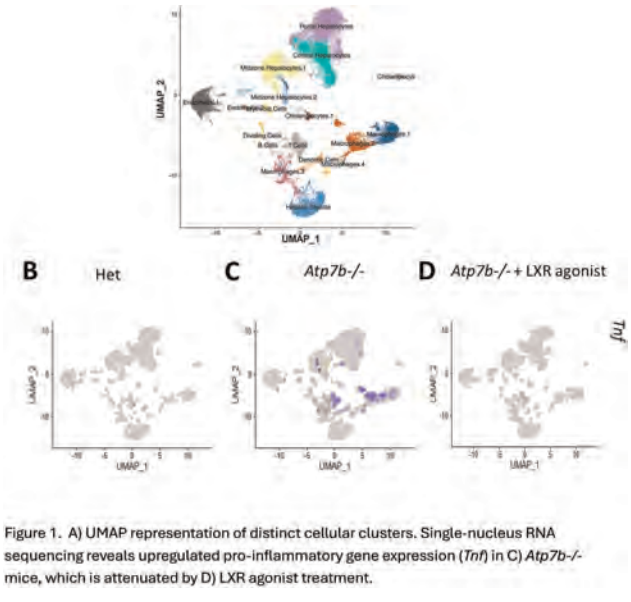

Figure 1. A) UMAP representation of distinct cellular clusters. Single-nucleus RNA sequencing reveals upregulated pro-inflammatory gene expression (*Tnf*) in C) *Atp7b-/-* mice, which is attenuated by D) LXR agonist treatment.

3625 | CRISPR-CORRECTED URINE-DERIVED STEM CELLS REVERSE WILSON'S DISEASE PHENOTYPES:A PATIENT-TAILORED TREATMENT STRATEGY

Jiaqi Li[1] Pengfei Yu[1] Jiateng Zhang[1] Huaibin Zou[1] Yu Chen[1] Zhongping Duan[1], [1]Beijing YouAn Hospital, Capital Medical University

Background: Wilson disease (WD), also known as hepatolenticular degeneration (HLD), is an autosomal recessive disorder caused by mutations in the ATP7B gene. Although liver transplantation can be curative, its clinical application is limited by donor shortages, immune-mediated graft rejection, and complications associated with long-term immunosuppression. To address critical unmet clinical needs in WD, we established an innovative autologous cell therapy platform by reprogramming WD patient-derived urine stem cells (USCs) into iPSCs, precisely correcting ATP7B mutations via CRISPR, and differentiating them into functional hepatocyte-like cells. **Methods:** USCs were reprogrammed into iPSCs via electroporation of non-integrating episomal plasmids carrying six factors: OCT4, SOX2, KLF4, l-MYC, Lin28, and sh-p53. We engineered an optimized CRISPR/Cas9 platform enabling precise homozygous correction of the pathogenic ATP7BR778L/R778L, generating genetically matched ATP7BWT/WT iPSC lines for functional rescue studies and therapeutic development. To facilitate comprehensive in vivo therapeutic assessment, we engineered a novel immunodeficient WD mouse model (ATP7B−/−; M-NSG) using CRISPR/Cas9 technology. The regulatory capacity of hepatic-like cells (HLCs) in improving liver function and copper metabolism in WD was systematically evaluated through in vitro functional validation and in vivo cell transplantation therapy. **Results:** We successfully isolated USCs from a 13-year-old patient with WD harboring a homozygous ATP7B p.R778L (c.2333G > T) mutation. USCs exhibited robust proliferation and maintained functionality over multiple passages in our optimized culture medium. iPSCs derived from the reprogramming of USC exhibit characteristics of stem cells and express multiple pluripotency markers, including OCT4, SOX2, NANOG, KLF4, FBX15, REX1, and others. Through optimization of sgRNA design, ssODN templates, and electroporation parameters, we achieved homozygous correction of the ATP7B c.2333G > T variant in iPSCs via CRISPR/Cas9 editing. Both uncorrected and genetically corrected iPSCs were robustly differentiated into HLCs. The WD model (ATP7B−/−; M-NSG) recapitulates key disease phenotypes, with biochemical profiling and histopathological analysis confirming characteristic pathological manifestations. Both in vitro and in vivo studies demonstrated that genetically repaired HLCs ameliorated liver function and reversed key pathological features including steatosis, hepatic fibrosis, and copper accumulation. **Conclusion:** The autologous cell therapy platform based on the non-invasive accessibility and broad therapeutic potential of USCs has demonstrated the feasibility of patient-specific USC generation, CRISPR/Cas9-mediated gene repair, and differentiation into functional hepatocytes, providing novel insights and ideas for the gene and cell therapy of Wilson's disease.

III, Madrid, Spain, [10]University Hospital Inselspital & University of Bern, Bern, Switzerland, [11]Institute for Clinical and Experimental Medicine, Prague, Czech Republic, [12]University Hospital Zürich, University of Zürich, Zürich, Switzerland, [13]Medical University of Vienna, Vienna, Austria, [14]Medical University Innsbruck, Innsbruck, Austria, [15]National Institute of Tuberculosis and Lung Diseases, Warsaw, Poland, [16]Paracelsus Medical University Salzburg, Salzburg, Austria, [17]Hannover Medical School, Hannover, Germany, [18]KU Leuven University Hospitals, Leuven, Belgium, [19]University of Barcelona, Barcelona, Spain, [20]University of Florida, Gainsville, United States, [21]University of Southern Denmark, [22]Beaumont Hospital, Dublin, Ireland, [23]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom

Background: Alpha-1 antitrypsin deficiency (AATD) is a prevalent rare genetic condition that increases the risk of lung and liver disease. We assessed the impact of metabolic factors, i.e. body mass index (BMI) and diabetes, on baseline liver parameters and the development of liver/lung endpoints. **Methods:** We collected an international, multi-centric Pi*ZZ cohort of 1,862 individuals from 17 different countries with severe AATD (Pi*ZZ), of whom 929 had a follow-up after a minimum of 6 months. At baseline, participants received a clinical evaluation, laboratory tests, and liver stiffness measurement (LSM) via transient elastography (Fibroscan®). Liver endpoints were defined as liver transplantation, liver-related mortality, and first hepatic decompensation, lung endpoints as lung transplantation and lung-related mortality. We compared the results with data from 16,715 Pi*MZ and 415,208 non-AATD (Pi*MM) individuals from the population-based UK Biobank. **Results:** At baseline, 64 Pi*ZZ participants had diabetes, 614 were overweight (BMI 25.0 - 29.9 kg/m²), and 295 obese (BMI $\geq$ 30 kg/m²). Participants with diabetes had significantly higher liver enzymes compared to those without. Surrogates of advanced fibrosis (APRI ³1.0 units / LSM ³15.0 kPa) were four to five times more frequent in subjects with diabetes (aOR = 3.7/5.0, p $<$ 0.01). Among normal-weight Pi*ZZ individuals, elevated transaminases were rare (9/12%), but more common in overweight (14/23%; aOR 1.7/2.1) and obese individuals (17/29%; aOR 2.2/3.1). During a median follow-up of 4.5 years, 56 Pi*ZZ participants experienced a liver and 55 a lung endpoint. Diabetic and obese Pi*ZZ subjects had an increased risk of hepatic endpoints (aHR = 4.1/5.7, p $<$ 0.001), whereas overweight status was associated with a decreased risk for lung endpoints (aHR = 0.3, p = 0.004). In the diabetic Pi*MZ and Pi*MM subcohorts from the UK Biobank, the ORs for elevated liver markers, advanced fibrosis, and hepatic endpoints were smaller than in the diabetic Pi*ZZ subcohort. Overweight was associated with a decreased (aHR = 0.6/0.8, p = 0.001) and diabetes with an increased risk (aHR = 2.1/2.3, p $<$ 0.001) for lung endpoints in Pi*MZ and Pi*MM subjects. **Conclusion:** Diabetes and obesity are associated with elevated liver markers and an increased risk of decompensation, independent of genotype, but their impact is most pronounced in Pi*ZZ individuals. These findings will inform patient counseling and risk stratification.

3627 | UNCOVERING THE CRITICAL ROLE OF CUPROPTOSIS IN WILSON DISEASE: IDENTIFICATION OF DIAGNOSTIC BIOMARKERS AND THERAPEUTIC TARGETS

Shan Tang[1] Sujun Zheng[1] Feng Ren[2] Wei Hou[1],
[1]Beijing Youan Hospital, Capital Medical University,
[2]Beijing Institute of Hepatology/Beijing Youan Hospital, Capital Medical University

Background: Wilson disease (WD) is an inherited disorder caused by ATP7B mutations, resulting in toxic copper accumulation primarily in the liver and brain. While copper-induced hepatotoxicity is a hallmark of WD, the mechanisms linking copper overload to liver injury remain unclear. This study aimed to investigate the role of cuproptosis—a copper-dependent form of regulated cell death—in WD pathogenesis and identify key cuproptosis-related genes (CRGs). **Methods:** We utilized ATP7B$^{-/-}$ mice and HepG2 cells to model WD. Liver injury was assessed histologically and biochemically. Transcriptomic analysis identified differentially expressed CRGs, followed by machine learning (LASSO, SVM-RFE) to identify key genes. Functional enrichment and protein validation were performed. Candidate biomarkers were evaluated in WD patient serum and confirmed in the mouse model. **Results:** ATP7B$^{-/-}$ mice showed marked hepatocellular injury with elevated AST, ALT, and LDH. Cuproptosis markers (FDX1, DLST, DLAT, LIAS) were upregulated in both liver tissue and HepG2 cells. Copper exposure decreased cell viability and increased LDH release—exacerbated by Elesclomol and alleviated by Tetrathiomolybdate. Transcriptomics revealed 14 CRGs; Lox, App, and Alb were identified as central hub genes. Machine learning highlighted Afp, Alb, Gpc1, Gls, and App as key diagnostic candidates, associated with copper homeostasis

and metabolic regulation. Serum Afp and Alb effectively distinguished WD from chronic hepatitis B. **Conclusion:** Cuproptosis contributes significantly to copper-induced liver injury in WD. Key mediators include Lox, Afp, Alb, Gpc1, Gls, and App, with Afp and Alb showing potential as diagnostic biomarkers. These findings offer new insights into WD pathogenesis and potential therapeutic targets.

3628 | COGNITIVE FUNCTION IN PATIENTS WITH WILSON DISEASE: PROSPECTIVE ANALYSIS FROM THE WILSON DISEASE REGISTRY STUDY

Michael Schilsky[1] Asim Ulcay[1] Hatice Maras[1] Sefa Keserci[1] Amar Patel[1] Susan Rubman[1] Regino Gonzalez-Peralta[2] Isabelle Mohr[3] Ayse Coskun[4] Uyen To[1] Kaitlin Maciejewski[5] Yanhong Deng[5] ZOE MARIÑO MENDEZ[6] Paula Zimbrean[1], [1]Yale University Medical Center, [2]AdventHealth for Children, [3]University Hospital Heidelberg, Heidelberg, Germany, [4]Creighton University, Omaha, Nebraska, [5]Yale University, [6]Hospital Clinic of Barcelona, Spain

Background: Few prospective data are available to assess cognition in patients with Wilson disease (WD). The Montreal Cognitive Assessment (MOCA) instrument is used to assess cognitive function and has several domains and standardized scoring methodology. From a possible total score of 30, <26 is considered abnormal, whereas ≥ 26 reflects normal cognition. Aims: to evaluate cognitive function in WD patients enrolled in the WD Registry (WDR) study using data at entry into the study, and longitudinally during follow-up. **Methods:** Cross-sectional (baseline at study entry) and longitudinal assessment of adult WD patients from the WDR with MOCA and neurologic (UWDRS) evaluations were performed. Patients were characterized as asymptomatic, hepatic, neurologic based on historical data at WD diagnosis. Repeated MOCA measurements were assessed by linear mixed models (ANCOVA) controlling for the time as the main confounder. Variables were expressed as mean (standard deviation).
Results: The cohort included 138 patients: 51% female, age 39y (14); time since WD diagnosis 15.8y (15); phenotype: hepatic 47%, neurologic 39%, asymptomatic 14%. For all patients, MOCA at baseline was 26.3 (3.1), with 44 (32%) patients scoring <26 [mean 22.9 (3)] (asymptomatic 21%, hepatic 30% and neurologic 37%). At baseline, MOCA negatively correlated with UWDRS ($r=-0.47$, $p=<0.001$, Pearson). Patients with lower cognitive function (MOCA <26) had significantly higher UWDRS scores ($p=0.0003$). Globally, MOCA increased by 1 point on average from enrollment to years 2 and 3 (both $p=0.001$), suggesting cognitive improvement could occur with treatment. In longitudinal analysis, adjusted for MOCA at enrollment, only those with baseline MOCA <26 scores presented significant improvements over time (years, 2, 3, 4 and 5, all $p<0.01$) with at least 1-point improvement year-over-year. When adjusting for phenotype, only the Hepatic group had significant changes in MOCA, ranging from 0.6 to 1.8 increase from baseline. **Conclusion:** MOCA was capable of detecting and quantifying the degree of cognitive impairment in our cohort of WD patients. Though most patients were unaffected (MOCA ≥ 26), in those with impairment (MOCA <26), the degree of altered cognition negatively correlated with higher UWDRS scores, suggesting CNS injury was worse in

more severely affected patients with neurologic disease. That cognition could improve significantly over time highlights the importance of early detection and treatment on WD patient outcomes.

3629 | PERFORMANCE OF VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY RELATIVE TO BIOPSY FOR LIVER FIBROSIS STAGING IN PATIENTS WITH ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED LIVER DISEASE AND A PI*ZZ GENOTYPE

Virginia Clark[1] Doneal Thomas[2] Gerald Lebovic[2] Flávia Soares Peres[3] Cláudia Ribeiro[3] Chitra Karki[4] Tami Nussbaum[4] Suna Park[4] Kaili Ren[4] May Hagiwara[4], [1]University of Florida, Gainesville, FL, USA, [2]IQVIA Real World Solutions, Mississauga, ON, Canada, [3]IQVIA Real World Solutions, Lisbon, Portugal, [4]Takeda Development Center Americas, Inc., Cambridge, MA, USA

Background: Alpha-1 antitrypsin deficiency-associated liver disease (AATD-LD) is caused by the protease inhibitor (Pi)*ZZ genotype. No study has validated vibration-controlled transient elastography (VCTE) relative to liver biopsy for the longitudinal assessment of liver fibrosis in patients (pts) with AATD-LD. The performance of VCTE versus liver biopsy for fibrosis staging in AATD-LD was assessed using data from the Alpha-1 Liver Fibrosis/Natural History Study, University of Florida (UoF). **Methods:** This longitudinal cohort study included pts with AATD-LD and a Pi*ZZ genotype (Nov 2013–Sept 2019). Liver fibrosis was assessed at baseline and Year 3 by liver biopsy (METAVIR fibrosis stage; interpreted by a single pathologist) and VCTE. Previously defined VCTE fibrosis stage thresholds were used: F1, $>$ 2.0–$\leq$ 7.1 kPa; F2, $>$ 7.1–$\leq$ 10.0 kPa; F3, $>$ 10.0–$\leq$ 15.0 kPa; F4, $>$ 15.0 kPa (Strnad P *et al. Hepatol* 2023;78:S1485). The performance of VCTE versus liver biopsy was determined according to the area under the receiver operating curve (AUC) and previously defined VCTE thresholds; for the UoF data, optimal cut-off values for VCTE were derived by maximizing Youden's J statistic (sensitivity + specificity – 1). Liver disease progression ($\geq$ 1 stage advancement in fibrosis), regression ($\geq$ 1 stage reduction in fibrosis) or stable disease (no change in fibrosis stage) were assessed. VCTE was considered reliable if there were $\geq$ 10 measurements with $\geq$ 60% success rate and an IQR/median value $\leq$ 30%; any VCTE was defined as all measurements. **Results:** The optimal F2 cut-off values were 6.3 at baseline and 6.1 at Year 3 for both reliable VCTE (AUC baseline 0.82; Year 3, 0.88) and any VCTE (AUC baseline 0.79; Year 3, 0.86). The optimal F3 cut-off value was 8.8 at baseline for both reliable VCTE (AUC 0.95) and any VCTE (AUC 0.94); at Year 3, the optimal cut-off value was 6.1 for reliable

VCTE (likely owing to the small sample size for F3; AUC 0.87) and 9.2 for any VCTE (AUC 0.86). Among pts with both liver biopsy and reliable VCTE results, 46 and 45 were staged by liver biopsy or reliable VCTE, respectively; at Year 3, 17 (37.0%) and 12 (26.7%) progressed, 21 (45.7%) and 22 (48.9%) were stable and 8 (17.4%) and 11 (24.4%) regressed, respectively (Figure A). Among pts with both liver biopsy and any VCTE, 50 and 49 were staged by liver biopsy or any VCTE, respectively; at Year 3, 17 (34.0%) and 15 (30.6%) progressed, 25 (50.0%) and 23 (46.9%) were stable and 8 (16.0%) and 11 (22.4%) regressed, respectively (Figure B). **Conclusion:** In this study on the performance of VCTE versus liver biopsy for fibrosis staging in adults with AATD-LD and a Pi*ZZ genotype, VCTE performed similarly to biopsy in staging F2/F3 fibrosis. The optimal cut-off values of VCTE-based staging for UoF data were slightly lower than predefined thresholds based on clinical practice. Findings should be interpreted with caution and validated in larger studies.

3630 | LIVER DISEASE PROGRESSION IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS WITH AND WITHOUT ALPHA-1 ANTITRYPSIN DEFICIENCY: RESULTS: FROM A RETROSPECTIVE COHORT STUDY IN THE USA

Suna Park[1] Sudhakar Manne[1] Kunali Ghelani[1] Chitra Karki[1] May Hagiwara[1] Tami Nussbaum[1] George Marek[2] Harmeet Malhi[2], [1]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [2]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, USA

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a chronic liver disease (LD) characterized by steatosis, hepatocyte injury, and inflammation. Alpha-1 antitrypsin deficiency (AATD) is a genetic disorder that can lead to liver fibrosis and cirrhosis and subsequent progression to end-stage LD/liver failure. Patients (pts) may have ≥ 1 LD etiology. Real-world evidence on LD progression in pts with MASH and AATD is limited. We aimed to evaluate LD progression in adults with MASH with and without AATD. **Methods:** This retrospective observational study included adults with MASH in the USA captured in Health Verity (Mar 2018–Sep 2024). Index date was defined as the earliest of either ≥ 2 diagnosis (dx) codes for MASH (ICD-10 K75.81) ≥ 90 days apart or ≥ 1 dx code for hepatic fibrosis (ICD-10 K74.0) preceded by ≥ 1 dx code for fatty liver (ICD-10 K76.0). Baseline period was defined as ≤ 180 days before index date. Eligible pts with MASH were considered to have cirrhosis if they had ≥ 1 dx code for hepatic cirrhosis (ICD-10 K74.6/60/69) ≤ 180 days before index date. Additionally, pts with AATD (≥ 2 dx codes for AATD [ICD-10 E88.01] ≥ 90 days apart or a laboratory serum AAT value < 120 mg/dL) and without AATD were identified and propensity score matched in a 1:2 ratio based on age, sex, race, and relevant key comorbidities. Standardized mean difference (SMD) was used to compare clinical features in pts with and without AATD (SMD > 0.1 is considered a notable difference). LD progression was defined as the earliest of either an advancement to cirrhosis or occurrence of LD-related clinical event. Kaplan–Meier analyses were used to assess time to LD progression and a log-rank test was performed. **Results:** Overall, 170,260 pts with MASH (3,766 with and 166,494 without AATD) were included.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

For pts with and without AATD, respectively, median (range) age at index date was 53 (18, 97) and 55 (18, 97) years, 52% and 60% were female, and 9% and 8% had cirrhosis at index date. A lower proportion of pts with than without AATD had diabetes and obesity (35% vs 41% for both comorbidites; $p < 0.0001$). After matching, 3,766 pts with and 7,532 pts without AATD were evaluated; of those, median (range) age was 53 (18, 97), 52% were female, and 8% had cirrhosis at index date. For all covariates, SMD was < 0.1 after matching. The probability of LD progression in pts with MASH was higher with than without AATD (Figure A). Among pts with MASH and cirrhosis at index date, median (95% confidence interval) time to LD progression was significantly shorter for pts with than without AATD (31 [23, 49] vs 48 [34, not estimable] months; $p < 0.05$; Figure B). **Conclusion:** In this matched cohort study, pts with MASH and AATD were more likely to have LD progression than pts with MASH alone, underscoring the incremental clinical burden associated with AATD. Testing for AATD in pts with MASH may guide treatment decisions and inform monitoring of LD progression.

3631 | SERUM MICRORNA SEQUENCING IDENTIFIED FAZIRSIRAN TREATMENT-RESPONSIVE MICRORNAS IN PATIENTS WITH ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED LIVER DISEASE AND A PI*ZZ GENOTYPE

Maria Paraskevopoulou[1] Ruixue Hou[1] Jen-Chieh Chuang[1] Loredana Cuccia[1] Susana Gonzalez[1] Tami Nussbaum[1] James Hamilton[2] Thomas Schluep[2] Pavel Strnad[3], [1]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [2]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, USA, [3]University Hospital RWTH, Aachen University, Aachen, Germany

Background: Alpha-1 antitrypsin deficiency (AATD) is a rare genetic disorder that can lead to AATD-associated liver disease (AATD-LD); the protease inhibitor (Pi)*ZZ genotype is associated with the most severe forms of disease. MicroRNAs (miRNAs) are post-translational regulators of gene expression that are emerging as potential biomarkers for the diagnosis and monitoring of liver disease. However, miRNA data in patients (pts) with AATD-LD are lacking. We aimed to detect treatment-responsive miRNAs and elucidate their function(s) in pts with AATD-LD treated with fazirsiran in the phase 2 AROAAT-2002 trial. **Methods:** In AROAAT-2002 (NCT03946449), pts with AATD-LD and a Pi*ZZ genotype received fazirsiran 100 mg or 200 mg on Day 1 and Week 4 and then every 12 weeks for 24 weeks or 48 weeks (Strnad P *et al. N Engl J Med* 2022;387:514–24). miRNAs in serum samples at baseline (BL) and after treatment were isolated and captured with RNA-seq or next-generation sequencing; miRNA expression was quantified with miRDeep2. Differential abundance and likelihood ratio test analyses were performed to identify altered miRNAs after fazirsiran treatment versus BL and temporal patterns of miRNA regulation. miRNAs were mapped to protein targets using *in silico* predicted and experimentally supported miRNA-target interactions (DIANA-microT/-TarBase). Serum Olink proteomics data from AROAAT-2002 (Chuang J-C *et al. J Hepatol* 2024;80:S698) were integrated with serum miRNA data to further define the potential functional link between fazirsiran-induced changes in miRNAs and proteins. **Results:** miRNA species were detected in serum samples from 13 pts at BL and post-treatment; the number of expressed miRNAs per sample ranged from 321 to 555. Differentially expressed miRNAs after fazirsiran treatment (Figure A) mapped to targets related to functional

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

pathways, including extracellular matrix (ECM) interactions, TGF-β pathway, ephrin signaling, phagocytosis and metabolism; 16 and 36 miRNAs showed a time-dependent decrease and increase, respectively (Figure B). The downregulated miRNA cluster included miRNA-15 family members involved in regulation of TGF-β signaling (mir-16, mir-122 and mir-195); the upregulated miRNA cluster included miRNA-29 family members involved in the induction of apoptosis of hepatic stellate cells (HSCs; mir-1, mir-29 and mir-200). Cross-referencing with serum Olink data revealed interactions between the upregulated miRNAs and corresponding downregulated ECM proteins such as COL3A1, CLEC11A, FN1 and ITGAV. **Conclusion:** Changes in miRNA expression suggest that there is reduced HSC activity in pts with AATD-LD treated with fazirsiran and support the potential clinical benefit of fazirsiran among pts with AATD-LD and a Pi*ZZ genotype. The utility of these miRNAs as potential non-invasive biomarkers for AATD-LD require validation in larger studies.

3632 | COMPARISON OF FERRISMART™ AND FERRISCAN™ FOR LIVER IRON QUANTIFICATION IN C282Y HOMOZYGOUS HAEMOCHROMATOSIS PATIENTS

Andrea Jasareno[1] Vanoo Jayasekeran[2] Timothy St Pierre[3] James Chen[2] John Olynyk[2], [1]Fiona Stanley Hospital, [2]Department of Gastroenterology, Fiona Stanley Hospital, [3]School of Physics, Mathematics, and Computing from The University of Western Australia

Background: Non-invasive MRI techniques are recommended as the method of choice for measurement of liver iron concentration (LIC). Regulatory authorities in Australia, the USA and Europe have approved use of FerriScan™ (an R2 relaxometry technique). Whilst accurate, this method requires trained personnel to conduct the analyses. A new automated method, called FerriSmart™, using a deep-learned algorithm based on the original FerriScan™ method has been developed. Validation of the accuracy of the new method against the original method in subjects with *HFE* C282Y homozygous haemochromatosis is limited. We compared LIC measurements in clinically well characterised C282Y homozygous subjects using both methods to determine the performance of FerriSmart™ compared with FerriScan™. **Methods:** LIC measurements were calculated from the same MRI scans using both the FerriScan™ and FerriSmart™ methods in 28 C282Y homozygous subjects. Measurements were compared using Bland-Altman analysis. **Results:** LICs, ranging between 0.8 to 38.6 Fe mg/g dry weight, were evaluated in 22 male and 6 female C282Y homozygous subjects, of mean age 49 ± 3 years. Bland-Altman analysis indicated a statistically significant difference between FerriSmart and FerriScan, with a geometric mean ratio of 0.91 (95% CI 0.85 to 0.98). Plot analysis showed heteroscedasticity as LIC increased (Figure 1). **Conclusion:** FerriSmart reports approximately a 9% lower LIC in C282Y homozygous subjects compared with FerriScan in this study. For comparison purposes, this bias is small relative to the known 19-40% coefficient of variation of LIC by chemical assay of liver biopsy in haemochromatosis.

3633 | UNDERSTANDING THE REAL-WORLD BURDEN OF WILSON&RSQUO;S DISEASE: A DECADE OF DATA FROM A MULTINATIONAL ANALYSIS

Do Han Kim[1] Donghyun Ko[2] Carlos Diola[3] Christina Lee[4] Frank Lukens[5] Pojsakorn Danpanichkul[6] Paul Kroner[7] Raffi Karagozian[4], [1]Department of Medicine, Mount Sinai Morningside and West, Icahn School of Medicine at Mount Sinai, [2]Department of Medicine, Bridgeport Hospital, Yale New Haven Health, Bridgeport, CT, USA, [3]Department of Medicine, Mount Sinai Morningside and West, New York, NY, USA, [4]Division of Gastroenterology and Hepatology, Tufts University School of Medicine, Boston, MA, [5]Division of Gastroenterology and Hepatology, Mayo Clinic Florida, Jacksonville, FL, [6]Texas Tech University Health Sciences Center, [7]Department of Gastroenterology, Riverside Health System, Newport News, VA

Background: Wilson's disease (WD) remains a diagnostic and therapeutic challenge in hepatology, given its variable trajectory and manifestations. While treatment can be life-altering, real-world data on the burden of hepatic and systemic complications are limited. Using a large, multi-national dataset, we aimed to characterize the clinical outcomes of WD to raise awareness for earlier recognition, risk stratification, and long-term management. **Methods:** We conducted a retrospective cohort study using population-based data from the TriNetX Global Collaborative Network. Patients with WD were identified by ICD-10 codes. The risk and incidence proportion of clinical outcomes were assessed from 2014 to 2024 using TriNetX analytics. **Results:** A total of 8,820 patients with WD were identified with a median follow-up time of 1,103 days (IQR: 2,322). The mean age was 43.1 years (SD:20.7) and 50.5% were female. The all-cause mortality rate was 10.8% (891/8,253). Acute kidney injury occurred in 9.5% (701/7,393), while hemolytic anemia in 0.8% (64/8,157). ICU admission was required in 9.7% (745/7,700) of cases. Rates of acute liver failure and orthotopic liver transplantation were 2.6% (201/7,858) and 2.7% (217/7,937), respectively. Hepatocellular carcinoma was identified in 0.9% (81/8,738). Liver biopsy was performed in 6.4% (563/8,808), and hepatic decompensation occurred in 15.0% (1,317/8,808). Emergency department visits and hospital admissions were frequent, occurring in 31.9% (2,812/8,808) and 44.7% (3,935/8,808) of patients, respectively. **Conclusion:** WD is a complex disease that frequently involves multiple organ systems beyond hepatic impairment. The variability in disease progression underscores the importance of an early detection strategy, especially in at-risk populations. Our findings support that despite the new advances in technology and treatment of WD, a significant number of patients experience substantial morbidity. Hence, these insights raise awareness for earlier recognition and long-term management in this subset of patients.

3634 | TRACKING IRON IN THE BRAIN: THE IMPACT OF CERULOPLASMIN VARIANTS ON NEURODEGENERATION

Marlene Panzer[1] Christoph Birkl[2] Elisabetta Indelicato[3] Bernhard Glodny[4] Maria Rosina Troppmair[5] Benedikt Schäfer[5] Christoph Scherfler[3] Elke Gizewski[6] Herbert Tilg[5] Heinz Zoller[5], [1]Department of Medicine I, Medical University of Innsbruck, [2]Department of Neuroradiology, Medical University of Innsbruck, Innsbruck, Austria, [3]Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria, [4]Department of Radiology, Medical University of Innsbruck, Innsbruck, Austria, [5]Department of Medicine I, Medical University of Innsbruck, Innsbruck, Austria, [6]Department of Neuroradiology/Neuroimaging Research Core Facility, Medical University of Innsbruck

Background: Aceruloplasminemia is a rare autosomal recessive disorder caused by mutations in the ceruloplasmin gene, leading to progressive iron accumulation in the brain, liver, and pancreas. Early biochemical hallmarks include low ceruloplasmin levels, hyperferritinemia, and reduced transferrin saturation, with neurological symptoms typically appearing between the ages of 40 and 60. This study aims to characterize the radiological and phenotypic patterns of aceruloplasminemia, with a particular focus on brain iron deposition and its impact on neurological function. Additionally, we aim to establish a patient registry to improve understanding of the phenotypic variability in aceruloplasminemia. **Methods:** We examined the clinical and radiological features of neurodegeneration in five patients with homozygous or compound heterozygous ceruloplasmin mutations and four heterozygous carriers. Demographic, biochemical, and clinical data were collected from patient records, and neurological impairment was assessed using the Unified Wilson Disease Rating Scale (UWDRS) and the Montreal Cognitive Assessment (MoCA). All participants underwent 3 Tesla MRI of the brain, including R2* relaxometry for iron quantification. Deep gray matter structures were segmented using FSL FIRST, and R2* values were analyzed. Brain volumetric measurements and R2* values were compared against sex- and age-matched healthy controls. **Results:** All patients presented with plasma ceruloplasmin concentrations below the lower limit of normal. Homozygous patients exhibited elevated ferritin levels, with four showing reduced transferrin saturation. Neurological presentation among homozygous patients ranged from asymptomatic to severe impairment, while all heterozygous individuals remained asymptomatic. MRI analyses revealed significantly increased R2* values, indicating iron overload in the basal ganglia, hippocampus, and nucleus accumbens in homozygous patients compared to heterozygous carriers and controls. Volumetric analysis showed pronounced atrophy in the cerebellum and deep gray matter, particularly in the putamen, globus pallidus, and thalamus. **Conclusion:** Our findings indicate that aceruloplasminemia is associated with a distinct pattern of brain iron accumulation, extending beyond the basal ganglia. The broad spectrum of neurological impairment suggests that factors beyond iron overload may contribute to disease severity. Furthermore, quantitative MRI proves to be a valuable tool for assessing neurodegeneration in aceruloplasminemia, offering potential for monitoring disease progression and exploring genotype-phenotype correlations.

3635 | TMED10 IS A NOVEL ATZ CARGO RECEPTOR AND THERAPEUTIC TARGET FOR LOWERING ATZ ACCUMULATION IN ALPHA-1 ANTITRYPSIN DEFICIENCY

Fabian Suri-Payer[1] Joseph Kaserman[2] Wei Chou Tseng[1] Juan Pablo[1] Andrew Wilson[2] Anna Greka[1], [1]Broad Institute of MIT and Harvard, [2]Boston University

Background: Alpha-1 Antitrypsin Deficiency (AATD) is a rare genetic disease caused by SERPINA1 variants which manifests as chronic liver and lung disease. There is currently no cure, and only supportive treatment available for AATD. The most common AATD allele, the Z allele (E342K, known as ATZ) – destabilizes AAT, making it prone to misfold and polymerize. ATZ accumulation within the endoplasmic reticulum (ER) of liver cells causes chronic liver disease, while the corresponding absence of protective AAT in the lung leads to lung disease. It remains unclear what decides the cellular fate of ATZ within the ER, and how this contributes to ATZ being insufficiently degraded in disease. Further understanding of the molecular mechanisms underlying ATZ trafficking is required for the identification and development of novel therapeutic targets and strategies. **Methods:** We conducted immunoprecipitation coupled with unbiased mass spectrometry to identify new potential regulators of ATZ in Huh7.5 cells. We then validated proteins of interest with pharmacological and genetic perturbation assessed by high-content imaging and native blotting in Huh7.5 cells and hepatocytes from patient-derived induced pluripotent stem cells (iHeps). Finally, we assess the therapeutic potential to ameliorate AATD disease progression in the Pi*Z mouse model. **Results:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

We identified 731 potential regulators of ATZ in Huh7.5 cells, including known regulators of ATZ trafficking. Our hit validation identified ATZ as a novel cargo of the transmembrane emp24 domain-containing proteins (TMEDs), a family of ER-Golgi resident proteins that act as cargo receptors for misfolded protein cargo in protein accumulation disorders. Crucially, we show that targeting TMED receptors lessens ATZ accumulation by up to 70% without affecting AAT secretion, in a mechanism dependent on TMED2 and TMED10. We are further exploring TMED-ATZ biology in iHeps and the Pi*Z mouse model. **Conclusion:** Here we identify TMED10 as a novel cargo receptor and regulator of the misfolding and disease-causing Z-variant of Alpha-1 Antitrypsin in endogenous models of AATD. Knockdown of TMED10 results in a significant reduction of intracellular ATZ accumulation without affecting secretion, suggesting a mechanism contributing uniquely to ATZ accumulation but not canonical trafficking. As chronic liver disease in AATD remains without treatments, targeting TMED10 may present a novel therapeutic target for preventing ATZ accumulation leading to liver disease.

3636 | PREDICTORS OF TESTING AND TEST POSITIVITY FOR ALPHA-1 ANTITRYPSIN DEFICIENCY IN PATIENTS WITH CIRRHOSIS IN A U.S. NATIONAL COHORT

Binu John[1] Dustin Bastaich[2] Andres Samos[3] Austen Hentschel[3] Sunny Sandhu[4] Raphaella Ferreira[5] Tamar Taddei[6] Brian Garnet[7] David Kaplan[8] Michael Campos[1] Bassam Dahman[2], [1]University of Miami and Miami VA, [2]Virginia Commonwealth University, [3]Herbert Wertheim College of Medicine, Florida International University, Miami, FL, [4]University of Miami - Jackson Memorial Hospital, [5]HCA HealthONE Sky Ridge Medical Center, Lone Tree, CO, [6]Yale University, [7]University of Miami, [8]University of Pennsylvania

Background: Alpha-1 antitrypsin deficiency associated liver disease (AATDLD) is a well-recognized genetic condition but may be undertested and underdiagnosed. Diagnosis of AATD is crucial for both genetic counselling, and for ensuring appropriate treatment options as new therapies continue to emerge. There is limited national data on rates of testing of AATD in patients with cirrhosis. Furthermore, the factors associated with higher rates of testing, as well as the test-positivity rates among those tested are mostly unknown.

The primary aim of this study was to examine the rates of testing of AATD in patients with cirrhosis, and patient and provider-level factors influencing AATD testing rates. The secondary aim was to identify factors associated with intermediate and severe AATD, in those who underwent testing. **Methods:** We included participants aged >18 years who had one inpatient or two outpatient ICD 9/10 code for cirrhosis with a first diagnosis of cirrhosis between January 2008 to December 2020 with follow up until 2/23/2023. An AAT value <100 mg/dl was used to define intermediate AATD, and a cut-off <57 mg/dL for severe AATD. AAT genotype or phenotypes were identified either from the extraction of a laboratory result comment, or a laboratory or clinical report mentioning alpha-1 antitrypsin genotype or phenotype using natural language processing. Patients with PiMS, PiMZ, and PiSS, PiSZ were considered to have intermediate disease, while those with PiSZ or PiZZ genotype/phenotypes were considered to have severe AATD.

We used logistic regression models to identify the patient, center and provider-level factors associated with AATD testing and those associated with test-positivity among those who were tested. **Results:** Of 126,210 patients with cirrhosis, 42,403 (33.6%) were tested for AATD, including 38,189 (30.3%) by AAT levels only, 1103 (0.8%) by genotype/phenotype only, and 3011 (2.4%) with both. Factors associated with higher AATD testing include specialist evaluation (adjusted Odds Ratio [aOR] 4.24, 4.06-4.42) and among individuals of White race. Older age at cirrhosis diagnosis (aOR per 5 years 0.92, 0.91-0.93), patients with COPD (aOR 0.36, 0.35-0.37), bronchiectasis (aOR 0.64, 0.54-0.75), and hepatic decompensation (aOR 0.33, 0.32-0.34), were less likely to be tested. When tested, veterans without an alternative cirrhosis etiology (aOR 4.49, 2.49-8.07), and with COPD (aOR 1.37, 1.03-1.82) were more likely, while older individuals (aOR per 5 years 0.85, 0.80-0.91), and those of black (aOR 0.23, 0.12-0.43), or hispanic race (aOR 0.40, 0.21-0.76), were less likely to have severe AATD. **Conclusion:** AATD testing rates in Veterans with cirrhosis is low, and patients at high risk are less likely to be tested. This calls for guidelines to emphasize universal AATD testing in patients with cirrhosis.

3637 | INTERIM RESULTS: OF THE INTERNATIONAL PHASE I/II GATEWAY GENE THERAPY TRIAL WITH VTX-801 CONDUCTED IN ADULT PATIENTS WITH WILSON DISEASE

Michael Schilsky[1] Frederick Askari[2] Thomas Sandahl[3] William Lee[4] Aftab Ala[5] Regino Gonzalez-Peralta[6] Valentina Medici[7] Sean Rudnick[8] Ulrich Lauer[9] Christoph Berg[10] Hartmut Schmidt[11] Sonia Valero[12] Jean Philippe Combal[13] Gloria Gonzalez-Aseguinolaza[14] Lorenzo D'Antiga[15] Bernard Benichou[13], [1]Yale University Medical Center, [2]University of Michigan Medical Center, [3]Aarhus University Hospital, [4]University of Texas Southwestern Medical Center, [5]Kings College Hospital, [6]AdventHealth for Children, [7]University of California Medical Center, [8]Atrium Health Wake Forest Baptist, [9]Medical University Hospital Tuebingen, Germany, [10]Medical University Hospital, Tuebingen, Germany, [11]University of Essen, Germany, [12]Vivet Therapeutics, Paris, France, [13]Vivet Therapeutics, Paris, France, [14]Vivet Therapeutics SL, Pamplona, Spain, [15]University of Bergamo, Italy

Background: Wilson Disease (WD) is a disorder of copper (Cu) homeostasis due to pathogenic variants in the ATP7B copper-transportergene that impair biliary Cu excretion and cause tissue Cu accumulation and reduced circulating ceruloplasmin (Cp). Limitations of management include treatment side effects, and poor adherence affecting long-term outcomes and survival. VTX-801 is a recombinant adeno-associated viral vector (rAAV) carrying a shortened *ATP7B* gene with a liver-specific promoter. Previous studies with VTX-801 in 6 to 12-week-old WD mice demonstrated restoration of biliary Cu excretion, increased levels of plasma Cp, reduced liver Cu, improved hepatic histology and 100% long-term survival. **Methods:** GATEWAY is an international phase I/II, open-label, 5-y follow-up, single dose-escalation study of VTX-801 in adults with WD (NCT04537377). This first-in-human study assessed safety, pharmacodynamics and efficacy of VTX-801. VTX-801 response at 3- or 9-month post-infusion was based upon ^{64}Cu pharmacokinetic assessments. **Results:** Results:: VTX-801 Cohort 1 (low dose) was completed (N = 2 patients), and Cohort 2 (intermediate dose) were treated (N = 2). One SAE was reported (DILI). Two patients had infusion-associated reactions managed with symptomatic treatment. All 4 had mild, resolving ALT increases following VTX-801 infusion without affecting liver function. One in Cohort 1 had a delayed, mild ALT elevation to 104 IU/l, and one in Cohort 2 had ALT elevation to 245 IU/l meeting criteria for DILI and had a liver biopsy; both resolved rapidly with a course of oral steroid treatment. Overall, insufficient VTX-801 response was observed, and standard of care treatment was not withdrawn. Follow-up liver biopsy at 1 y in a patient from Cohort 1 showed miniATP7B mRNA expression in up to 50% of hepatocytes, and an unscheduled biopsy after DILI in the Cohort 2 patient showed miniATP7B mRNA expression in up to 75% of hepatocytes. Available pharmacodynamic data for Cohorts 1 and 2 will be presented. **Conclusion:** Delivery of ATP7B is possible in human liver using AAV. VTX 801 transduction was successful, however changes in Cu parameters were subtherapeutic. Further study is needed to understand factors affecting the degree of functional transgene expression and its ability to increase biliary copper excretion and Cp levels in humans.

3638 | INTESTINAL-FAILURE ASSOCIATED LIVER DISEASE AND HEPATIC MANIFESTATIONS OF SHORT BOWEL SYNDROME: EXPLORING PREDICTORS OF DISEASE AND NATIONWIDE OUTCOMES

Michael Gianarakis[1] Adam Mikolajczyk[1] Robert Carroll[1], [1]University of Illinois Chicago

Background: Intestinal Failure-Associated Liver Disease (IFALD) is a progressive disease with high mortality in patients with short bowel syndrome (SBS) dependent on parenteral nutrition (PN). It encompasses a spectrum of hepatic manifestations including cholestasis, steatosis, cirrhosis, and portal hypertension (PHT). Risk factors include chronic PN use, remaining bowel length, choline and carnitine deficiency, recurrent sepsis, and cholelithiasis. We present the first nationwide study evaluating characteristics, outcomes, and predictors of hepatic disease in adults with SBS. **Methods:** We analyzed the Nationwide Inpatient Sample (2016–2020), identifying adult SBS hospitalizations stratified by the presence of liver disease (steatosis, cirrhosis, hepatic failure). Patients with primary hepatic disorders (viral, autoimmune, metabolic), alcoholic liver disease, and hepatic vessel thrombosis were excluded. Primary outcomes were mortality and complications including malnutrition, nutritional deficiencies, portal hypertension, cholelithiasis, sepsis and respiratory failure; secondary outcomes included predictors of liver disease. Multivariate regression was performed, adjusting for patient and hospital factors. **Results:** Among 119,750 weighted SBS hospitalizations, 7,630 (6.4%) had liver disease (steatosis $n = 4,610$; cirrhosis $n = 2,120$; hepatic failure $n = 1,865$) (Table 1). In patients with liver disease, in-hospital mortality rates were higher (8.6% vs. 2.1%, p-value < 0.001), mean length of stay was longer (11.2 vs. 8.5 days, $p < 0.001$) and admission costs were greater ($141,401 vs. $90,897 USD, $p < 0.001$) (Table 1). The mortality rate among patients with steatosis was similar to those without liver disease (2.93% vs 2.1%, $p = 0.1$). Independent predictors of steatosis/cirrhosis included female gender (aOR: 1.28, $p = 0.001$), malnutrition (aOR: 1.18, $p = 0.013$), fat-soluble vitamin deficiency (aOR: 1.68, $p < 0.001$), B12 deficiency (aOR: 1.89, $p = 0.014$), inflammatory bowel disease (IBD) (aOR: 1.34, $p = 0.001$), cholelithiasis (aOR: 1.75, $p < 0.001$), alcohol use (aOR: 1.99, $p < 0.001$), and obesity (aOR: 2.01, $p = 0.001$) (Table 1). Liver failure was associated with malnutrition (aOR 1.5, $p = 0.001$), PHT (aOR 3.3, $p < 0.001$), cholelithiasis (aOR 1.79, $p = 0.042$), sepsis (aOR 1.98, $p < 0.001$), and prior liver transplant (aOR 3.09, $p = 0.006$) (Table 1). **Conclusion:** This analysis highlights the significant

burden of hepatic complications in SBS, with IFALD markedly increasing mortality and healthcare utilization. Risk factors such as malnutrition, vitamin deficiencies, IBD, and cholelithiasis highlight the multifactorial pathogenesis of IFALD. Notably, sepsis and evidence of PHT strongly predicted progression to liver failure. These findings underscore the need for early monitoring for nutritional deficiencies and hepatic steatosis to mitigate progression and improve outcomes in this high-risk population.

Table 1 Demographics and clinical outcomes in patients hospitalized with SBS with and without diagnosis of hepatic disease. Multivariate logistic regression of predictors of steatosis/cirrhosis and liver failure.

Demographics	SBS without hepatic disease	SBS with hepatic disease	P-value

3639 | IMMUNE CELL EFFECTOR FUNCTION AND METABOLIC DYSREGULATION IN WILSON DISEASE: IMPLICATIONS FOR IMMUNE-METABOLIC CROSSTALK IN COPPER TOXICITY

Robert Hughes[1] Svetlana Lutsenko[1] James Hamilton[1], *[1]Johns Hopkins University*

Background: Wilson Disease is an autosomal recessive disorder caused by mutations in the gene encoding the copper transporter, ATP7B. Inactivation of ATP7B results in copper accumulation in various tissues including the liver, but clinical presentation and disease severity do not necessarily correlate with hepatic copper content. While the genetic cause of Wilson Disease is clear, the mechanism of disease remains only coarsely defined.

Prior work has demonstrated that a global *Atp7b* knockout mouse model recapitulates the hepatic phenotype of Wilson Disease (copper accumulation, ballooning hepatocytes, inflammation, fibrosis). Interestingly, however, when the *Atp7b* gene is specifically knocked out in hepatocytes, the inflammatory pattern is muted. In this study, we sought to better understand the effects of global loss of Atp7b on immune cell populations, and how this contributes to the persistent pro-inflammatory state in the liver. **Methods:** Immune cell populations were isolated from the bone marrow and spleen of 20 week old *Atp7b* global knockout (KO) and age-matched wild-type (WT) mice. These immune cell populations were then characterized by expression markers using flow cytometry, induced toward different activation states ex vivo, and their metabolic profiles assessed via Seahorse assay. **Results:** Macrophages derived from the *Atp7b* knockout (KO) mice demonstrated enhanced M1 polarization, as suggested by increased NOS2 expression (Figure 1A) and a trend towards enhanced basal ECAR via Seahorse assay (1B), when compared to macrophages derived from the WT mice. There was no significant difference in M2 polarization between the WT and KO-derived macrophages (1C), but the KO-derived M2 macrophages demonstrated a significantly increased maximum respiratory capacity (1D). In addition, there is enhanced activation of CD8+ and CD4+ T-cells derived from the KO mice, as evidenced by these populations being skewed toward a CD44 +CD62L- phenotype with significantly increased CD69 expression (1E, 1G). KO-derived effector T cells demonstrated a higher basal rate of oxygen consumption, higher basal rate of glycolysis, and non-mitochondrial respiration as determined by Seahorse assay (1F). Despite a more activated phenotype, however, there was reduced TNF production by KO-derived CD8+ T-cells (1E). **Conclusion:** Immune cells derived from the *Atp7b* knockout mice exhibit a pro-inflammatory predominant phenotype but demonstrate some signs of defective effector function, as evidenced by the reduced TNF production seen in CD8+ T cells. This could be due to an exhaustive effect of extracellular factors secreted by the diseased liver onto immune cells or an inherent defect within the immune cells due to a lack of functional Atp7b. Future

studies will focus on further characterizing the liver-resident and infiltrating immune cells as well as quantification of the copper content with these immune cell populations.

3640 | GENETIC DRIVERS OF LIVER CIRRHOSIS: THE ROLE OF SERPINA1 AND PNPLA3 VARIANTS IN DISEASE ONSET AND PROGRESSION

Sona Frankova[1] Mikolas Holinka[1] Svetlana Adamcova Selcanova[2] Lubomir Skladaný[2] Ondrej Fabian[1] Martin Kveton[1] Dusan Merta[1] Vera Adamkova[1] Jaroslav Hubacek[1] Veronika Pitova[1] Sarka Vesela[1] Tomas Hucl[1] Milan Jirsa[1] Jan Šperl[1], [1]Institute for Clinical and Experimental Medicine, Prague, Czech Republic, [2]F.D. Roosevelt Hospital Banska Bystrica, Slovakia

Background: Variant alleles *SERPINA1 Z* (alpha-1-antitrypsin (AAT) rs28929474) and *PNPLA3* G (patatin-like phospholipase domain-containing protein rs738409) are the most potent genetic risk modifiers of liver cirrhosis in chronic liver disease (CLD). We aimed to test the impact of concomitant carriage of these variant alleles on the progression of CLD of various aetiologies. **Methods:** The genotyping for *SERPINA1* rs28929474 and *PNPLA3* rs738409 was performed in the study group consisting of 1583 liver transplant candidates with cirrhosis of various aetiology: alcoholic 577 (ALD), metabolic dysfunction-associated 208 (MASLD), viral 264 (VIR), autoimmune and cholestatic 443 (AIH-CHOL), and metabolic 91 (MET) and in the group of 3,483 healthy population controls. Samples of explanted livers were immunostained for AAT aggregates. **Results:** The frequency of *SERPINA1* MZ heterozygotes (M means wildtype allele) was significantly higher ($p < 0.0001$) in the entire cirrhosis group (84 of 1583; 5.3%) than in controls (89 of 3483; 2.6%); OR 2.57; 95% CI 1.92–3.44 for liver cirrhosis. The frequency of *SERPINA1* MZ heterozygotes was significantly higher in the subgroups with ALD and MASLD cirrhosis (37 of 557; 6.4% and 23 of 208; 11.1%, respectively, $p < 0.0001$) than in controls; the frequency in the subgroups VIR, AIH-CHOL and MET did not differ vs. controls. The frequency of the *PNPLA3* G allele was significantly higher ($p < 0.0001$) in the entire cirrhosis group (880 of 1583; 55.6%) than in controls (1418 of 3402; 41.6%); OR 1.48; 95% CI 1.36–1.99 for liver cirrhosis. The G allele frequency was significantly higher only in the subgroups with ALD, MASLD and VIR cirrhosis (392 of 577, 67.9%; 133 of 208, 63.9% and 139 of 264, 52.7%; $p < 0.0001$ and $p = 0.0005$, respectively) than in controls. The frequency of the *PNPLA3* G allele was the same in cirrhotic patients carrying *SERPINA1* MM and MZ genotypes (824 of 1483, 55.6% vs. 50 of 84, 59.2%, N.S.). The *PNPLA3* genotype had no impact on the density and extent of AAT aggregates in the liver tissue of *SERPINA 1* MZ heterozygotes. *SERPINA1* MZ heterozygotes with ALD and MASLD were significantly younger (56.9 vs. 60 years, $p = 0.046$) and had a higher MELD score (17 vs. 15 points, $p = 0.0003$) at waitlisting, whereas the *PNPLA3* genotype had no impact on the age and MELD score at waitlisting. **Conclusion:** We conclude that both variant alleles increase the risk of liver cirrhosis in ALD and MASLD; however, *SERPINA1* MZ heterozygotes have more progressive chronic liver disease and need liver transplantation at a younger age.

3641 | LONGITUDINAL STUDY OF ACUTE HEPATIC PORPHYRIAS IN THE US: BASELINE FEATURES OF 400 SUBJECTS FROM THE PORPHYRIAS CONSORTIUM

Bruce Wang[1], [1]University of California San Francisco

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: The longitudinal study (LS) of the porphyrias is a NIH funded natural history study of the porphyrias in the United States. The goal is to assess the natural history, biochemical changes, therapeutic effects, and potential association with other medical conditions. To date more than 400 patients with acute hepatic porphyrias (AHP) have been enrolled, with some patients followed for more than 10 years. We previously described the baseline characteristics of the first 108 AHP patients. Here we provide an update to describe the baseline characteristics of more than 400 AHP patients. **Methods:** From 2009 to 2023, 404 patients of AHP were enrolled in the LS, including AIP (330 cases), VP (49 cases), HCP (24 cases), and ADP (1 case). Data including demographic characteristics (gender, race, ethnicity, family history), signs and symptoms, genetic testing, biochemical parameters (ALA, PBG, urine/serum creatinine, AST, ALT), as well as treatment history involving Hematin and Givosiran was entered into a centralized database. Selected features were compared to normal population values using various statistical analysis tools, including the Chi-Square test, T-test, and Pearson correlation. These analyses were performed within the SPSS Statistics 27.0.1 environment. **Results:** Among 404 patients in the study, 85% (345) were white, 80% (322) were females, and, mostly were diagnosed within ages of 33.1 ± 14.58. Patients were categorized based on their clinical presentation and frequency of attacks into 3 groups: recurrent (4 or more attacks annually), sporadic, and asymptomatic. Asymptomatic patients were further separated into those with abnormal ALA/PBG and those with normal ALA/PBG. We looked for clinical correlation between these groups with biochemical factors, DNA mutation, and diversity and severity of symptoms. The most common symptoms associated with acute attacks were abdominal pain, nausea, weakness, heartburn, and high blood pressure, and their incidences were significantly increased in porphyria compared to normal population as control. AHP diagnosis remains delayed, with a mean of 9 years after the onset of symptoms, though this is improved from our earlier report. Forty one percent (167) of patients have received intravenous Hematin, the majority of whom had recurrent acute attacks. Such a delayed diagnosis would significantly increase the occurrence of chronic medical conditions including chronic kidney disease with different stages (mean estimated GFR = 72.00) over the period before the diagnosis of porphyria. **Conclusion:** AHP remain undiagnosed for many years following the onset of symptoms. This delayed diagnosis can impact the quality of life and lead to the development of chronic medical conditions over time. A comprehensive understanding of the porphyria population in the United States can assist healthcare providers in achieving earlier diagnoses and implementing appropriate management strategies.

3642 | A NOVEL NOMOGRAM BASED ON COMMON CLINICAL INDICATORS FOR DIFFERENTIAL DIAGNOSIS OF INHERITED UNCONJUGATED HYPERBILIRUBINEMIA WITH HEMOLYTIC DISEASES

Haitian Yu[1] Meihan Li[1] Dacheng Sheng[1] Shan Tang[1] Jianxia Dong[1] Wei Hou[1] Sujun Zheng[1], [1]Department of Hepatology, Beijing YouAn Hospital, Capital Medical University, Beijing, China

Background: This study was designed to create and validate a nomogram model incorporating common clinical indicators to distinguish between unconjugated hyperbilirubinemia associated with UGT1A1 gene mutations and hemolytic diseases. **Methods:** We conducted a retrospective analysis of a cohort of patients diagnosed with unconjugated hyperbilirubinemia at Beijing YouAn Hospita, Capital Medical University from January 2022 to January 2025. Clinical and laboratory data from 379 subjects were extracted and participants were randomly assigned to training and validation groups in a 7:3 ratio. Significant variables associated with differential diagnosis were identified using least absolute shrinkage and selection operator regression(Lasso) and multivariate logistic regression models. Cutoff values derived from univariate receiver operating characteristic (ROC) curves were utilized to convert nonlinear continuous variables into binary categorical variables, establishing the diagnostic nomogram. The nomogram's predictive accuracy and clinical utility were evaluated in both the training and validation sets using ROC curves, calibration curves, and decision curve analysis(DCA). **Results:** A total of 317 patients with UGT1A1 gene mutation-associated unconjugated hyperbilirubinemia were enrolled, including 106 cases of Gilbert's syndrome and 11 cases of Crigler-Najjar type II. Additionally, 62 patients with hemolytic disease-associated unconjugated hyperbilirubinemia were included, comprising 36 cases of hereditary spherocytosis, 8 cases of autoimmune hemolytic anemia, 4 cases of hereditary stomatocytosis, 1 case of thalassemia, 1 case of BPGM gene mutation-related erythrocytosis, and 12 cases of unexplained hemolysis. Through variable selection using Lasso regression and logistic regression, four key variables were identified: abnormality of peripheral blood smear, hematocrit, red cell distribution width standard

deviation, and reticulocyte percentage. These variables were used to construct a differential diagnostic nomogram model with an optimal cutoff value of 126 points. The nomogram demonstrated excellent performance, with areas under the ROC curve of 0.99 (0.98–1.00) in the training set and 0.96 (0.88–1.00) in the validation set. Calibration curves showed good agreement between predicted and actual outcomes, with Hosmer-Lemeshow test p-values >0.05. DCA further confirmed the clinical utility of this nomogram. **Conclusion:** We successfully developed an effective nomogram model that can differentiate between UGT1A1 gene mutation-associated and hemolytic disease-associated unconjugated hyperbilirubinemia. This model significantly enhances the preliminary screening efficiency for patients with unconjugated hyperbilirubinemia.

3643 | ALPHA-1 FOUNDATION RESEARCH REGISTRY: COMPARISON OF LIVER-AFFECTED ALPHA-1 ANTITRYPSIN DEFICIENCY PATIENTS WITH PIZZ AND PIMZ GENOTYPES IN A UNITED STATES COHORT

Nadine Nuchovich[1] Alison Keaveny[1] Monica Goldklang[2] Jennifer Illarramendi[1] Randel Plant[1] Jeanine D'Armiento[2], [1]Alpha-1 Foundation, [2]Columbia University Irving Medical Center

Background: Alpha-1 Antitrypsin Deficiency (AATD) is a genetic condition characterized by accumulation of misfolded AAT protein in hepatocytes, leading to lung and liver disease. While the PiZZ genotype constitutes the largest burden of AATD liver disease, evidence suggests PiMZ genotype may also be at increased risk for liver complications highlighting the need to better understand the differences between these genotypes. **Methods:** The Alpha-1 Foundation (A1F) Research Registry is an online database of AATD patients in the United States and has enrolled over 4,100 participants from June 2019 to May 2025. We reviewed liver-affected participants with PiZZ and PiMZ genotypes who reported cirrhosis, MASH /MASLD, ascites, cholestasis, hepatopulmonary syndrome, portopulmonary hypertension, or bacterial peritonitis. **Results:** A total of 598 PiZZ participants reported to be liver-affected (mean age 52.6, +/- 17.99), along with 420 PiMZ (50.5, +/- 13.62). PiZZ participants were more likely to be tested for AATD due to lung symptoms (39.7% vs. 28.5% PiMZ), while both groups had similar rates for testing for liver symptoms (19.0% PiZZ vs 18.0% PiMZ). Although those with the PiZZ genotype had higher rates of reported cirrhosis (22.8%, vs. 9.2% PiMZ), rates of MASH/MASLD were similar in both groups (49.7% PiZZ, 50.4% PiMZ) as well as cholestasis (6.2% PiZZ, 5.9% PiMZ). Among liver-affected PiZZ participants, 53.6% reported additional diagnoses of COPD or emphysema. Augmentation therapy (42.1%) and use of oral or inhaled corticosteroids (42.4%) was notably higher compared to those with the PiMZ genotype (24.1%, 11.2%, and 30.5%, respectively). Fibroscan testing was performed on 24.8% of liver-affected PiZZ participants compared to liver-affected PiMZ's who reported 10.8%. Rates of alcohol consumption were noted in 22.1% of PiZZ individuals at least 2-3 times per week, compared to 17% of MZ's. **Conclusion:** Liver-affected PiZZ participants exhibited higher rates of lung disease and cirrhosis and had higher rates of Fibroscan elastography as compared to PiMZ participants. However, both genotypes exhibited comparable rates of MASH/MASLD and cholestasis. Alcohol and corticosteroid use were found to be higher in PiZZ participants and could contribute to higher rates of more severe liver disease. The A1F Research Registry is a useful tool for comparing AATD genotypes and has the capability to provide for a deeper dive into factors affecting disease burden and progression.

3644 | PXR DELETION PROMOTES HEPATOCELLULAR METABOLIC REPROGRAMING IN ATP7B$^{-/-}$ MICE

Clavia Wooton-Kee[1] Hari Yalamanchili[1] Vasanta Putluri[1] Nagireddy Putluri[1] David Moore[2], [1]Baylor College of Medicine, [2]University of California, Berkeley

Background: Wilson's disease (WD) is an autosomal recessive disorder caused by inactivating mutations in the copper (Cu^{++}) transporting P-type ATPase. Loss of Atp7b function prevents translocation of Cu^{++} into the trans-Golgi network and excretion into bile, resulting in oxidative stress, inflammation, mitochondrial dysfunction, fibrosis, cirrhosis, and liver failure. WD patients and *Atp7b*$^{-/-}$ mice have a progressive course of hepatocellular pathology, including regenerative hepatic nodule growth. Previously, we demonstrated that deletion of PXR in *Atp7b*$^{-/-}$ mice (DKO$^{Atp7b/PXR}$) worsened hepatocellular pathology and increased regenerative nodular growth relative to *Atp7b*$^{-/-}$ mice. To determine the factors that promote the accelerated pathology in DKO$^{Atp7b/PXR}$ mice, we tested the hypothesis that loss of PXR results in cellular signaling and metabolic reprograming in WD. Methods:: RNA-Sequencing and targeted metabolic analysis (fatty acids, bile acids, amino acids, glycolytic, TCA cycle, pentose phosphate metabolites) was performed with 12-month-old wild-type mice and nodule and normal adjacent liver tissues of *Atp7b*$^{-/-}$ and DKO$^{Atp7b/PXR}$ mice. Hepatic metabolites were measured with LC/MS quadrupole mass spectrometry. **Results:** Normal liver tissue of *Atp7b*$^{-/-}$ and DKO$^{Atp7b/PXR}$ mice shared transcriptomic pathways representing metabolism (PPAR signaling and fatty acid metabolism) and metabolic stress (cardiomyopathy pathways). Although normal liver tissue of *Atp7b*$^{-/-}$ and DKO$^{Atp7b/PXR}$ mice had similar transcriptomic and metabolic profiles, DKO$^{Atp7b/PXR}$mice had unique transcriptomic profiles associated with advanced metabolic reprogramming and immune activation, which agreed with greater hepatic accumulation of TCA cycle and glycolytic intermediates in normal liver tissues of DKO$^{Atp7b/PXR}$ vs. *Atp7b*$^{-/-}$ mice. Nodular liver tissue of *Atp7b*$^{-/-}$ mice had profound enrichment of immune disease pathways and associated metabolites (palmitoleic acid, docosahexaenoic acid, malate, betaine, and bile acids). Conversely, nodular liver tissue of DKO$^{Atp7b/PXR}$ mice had transcriptomic and metabolic (glutamine, and eicosatetraenoic acid) signatures associated with structural and tissue remodeling. **Conclusion:** In agreement with our previous findings of exacerbated hepatocellular pathology and nodular regeneration in DKO$^{Atp7b/PXR}$ vs. *Atp7b*$^{-/-}$ mice, DKO$^{Atp7b/PXR}$ mice display transcriptomic and metabolic signatures reflective of advanced metabolic stress and tissue remodeling in comparison with *Atp7b*$^{-/-}$ mice. These findings support previous work demonstrating that PXR has an essential role in mediating hepatocellular stress in WD and is a viable therapeutic target for the treatment of WD.

3645 | STRUCTURAL ANALYSIS AND PATHOGENICITY PREDICTION OF ATP7B GENE VARIANTS IN WILSON DISEASE

Minghui Sun[1] Lihua Yuan[1] Rui Hua[1] Yue Qi[1] Fang Xu[1] Hao Zhou[1], [1]The First Hospital of Jilin University, Changchun, China

Background: ATP7B gene testing enables precise diagnosis of Wilson's disease. However, emerging mutations of uncertain pathogenicity complicate clinical interpretation. This study aims to characterize the structural and functional impacts of these novel variants. **Methods:** Following informed consent, clinical data from 62 patients were collected and ATP7B genotyped. Novel variants of uncertain significance were functionally characterized via bioinformatics and in vitro minigene splicing assays. Statistical analysis of genotype-phenotype correlations was performed using SPSS 27.0. **Results:** A total of 48 mutations were identified across 17 exons, 5 introns, and the 5'UTR, with exon 8 harboring the highest mutation density. Eight novel mutations were discovered, four of which were classified as variants of uncertain significance. Following in silico prediction by REVEL and SpliceAI, two were deemed "deleterious," one "benign," and one predicted to disrupt splicing. Bioinformatics analysis of the top three exonic VUS characterized their sequence conservation, protein domains, transmembrane structure, and tertiary conformation. Minigene assays confirmed that intron 2 mutation c.1286-481A > G causes retention of a 136-bp intronic fragment containing a premature stop codon, resulting in truncated protein synthesis. Patients with p.R778L exhibited lower serum copper levels, while those without this mutation showed higher prevalence of loss-of-function (LOF) mutations. LOF mutation carriers were 68.4% male and had elevated ALP/GGT levels. Non-transmembrane domain mutations were associated with increased LOF frequency. p.E1173K was enriched in liver failure patients with age of onset $\leq$15 years. **Conclusion:** Of 48 identified mutations, 8 were novel. Bioinformatics and in vitro

minigene assays characterized structural changes in 4 novel variants of uncertain significance (VUS) and re-evaluated their pathogenicity. Additionally, correlations were found between p.R778L/LOF mutations and serum copper/liver function markers, with p.E1173K associated with severe clinical phenotypes.

3646 | LONGITUDINAL STUDY OF PSYCHIATRIC FEATURES AND DISEASE OUTCOMES IN WILSON DISEASE AT THE LARGEST UK PSYCHIATRIC CENTER

James Liu Yin[1] David Okai[2] Richard Thompson[3] Aftab Ala[1], [1]Kings College Hospital, [2]South London and Maudsley NHS Foundation Trust, [3]King's College London

Background: Wilson disease (WD) is a multi-systemic condition that can present with many different symptoms. Those that present with purely psychiatric presentation can have a longer time to diagnosis with irreversible symptoms.

South London and Maudsley NHS Foundation Trust (SLaM) is the largest provider of secondary mental health services in the UK and is the largest neuropsychiatric research centre in Europe.

We investigated the outcomes and progression of WD patients' psychiatric symptoms referred to a tertiary psychiatric hospital. **Methods:** We used national hospital episode statistics for the diagnosis of Wilson disease within the psychiatric cohort at SlaM and investigated outcomes and cause of death.

Using the validated natural language processing algorithm at SLaM within electronic patient records, able to detect 58 different psychiatric symptoms, we documented symptoms at presentation and then cumulatively across their follow up period. **Results:** In total 81 patients were identified as diagnosed with WD across the time-period with available electronic records.

At presentation patients reported anxiety (49%), cognitive impairment (49%), disturbed sleep (42%), tearful, hallucination, poor insight, mood instability, suicidal ideation, guilt and agitation. Cumulatively symptoms reported were of anxiety, cognitive impairment, disturbed sleep, hallucination, poor insight, tearful, suicidal ideation, paranoia, mood instability and agitation.

We found that the mortality rate of WD patients was 27%. The age range at death was 18 to 89 years with a mean time to death after referral of 83 months, with a range of 7 to 204 months. Gender and ethnicity variation within the cohort was similar to the overall WD distribution. **Conclusion:** Symptoms in our cohort at presentation and cumulatively were similar across patients. This provides evidence as to the common presenting psychiatric symptoms in WD, and over time these symptoms do not significantly change.

A higher than expected mortality rate was found within our patient cohort across a range of ages and time, this requires further investigation to better understand.

This work supports the evidence that psychiatric symptoms in WD are under recognised, often irreversible and may be linked to delay in diagnosis and premature death. It highlights the needs to crucially improve detection and diagnosis within this population. The data on mortality warrants further investigation to identify modifiable risks factors.

3647 | PERTINENCE OF NON-INVASIVE METHODS: FOR LIVER FIBROSIS ESTIMATION AND TO IDENTIFY PATIENTS AT RISK OF COMPLICATIONS IN WILSON&RSQUO;S DISEASE

Emanuela Vargiu[1] Alberto Civolani[1] Orazio Sorbello[1] Aurelia Poujois[2] Mickael Alexandre Obadia[2] Dominique DEBRAY[2] Ilias Kounis[3] Cyrille Feray[3] Audrey Coilly[3] Massimo Claudio Fantini[1] Rodolphe SOBESKY[3], [1]Gastroenterology Unit, AOU, Cagliari, Italy, [2]Service de Neurologie, Fondation Rothschild, Centre Maladie rare-Maladie de Wilson, Paris, France, [3]Centre Hépato-Biliaire, Hopital Paul Brousse, Université Paris-Sud, Villejuif, France

Background: Wilson's disease (WD) can lead to liver fibrosis and cirrhosis. Liver biopsy remains the gold standard to assess fibrosis but is invasive with possible sampling errors. In this context, non-invasive tests (NITs) appear to be useful and easily reproducible, however they have not been yet validated in WD. The aim of this study was to evaluate the diagnostic performance of transient elastography (TE) and other NITs in predicting liver fibrosis (LF) in patients with WD, using histological staging as the reference standard. **Methods:** We retrospectively analyzed 2 cohorts of adult patients with a confirmed diagnosis of WD. Patients were evaluated clinically, biologically and morphologically. We included patients who had a liver biopsy and non-invasive liver fibrosis assessment by NITs (TE, APRI, FIB4, GUCI, CDS, Lok Index) with a time interval between biopsy and NITs of less than 3 months. Spearman's coefficient was calculated for the correlation between METAVIR staging and NITs. The

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

AUROC was used to determine the predictive values of the quantitative variables. The performance of TE in predicting various clinical conditions was evaluated. **Results:** We retrospectively included 58 patients, with a mean age at WD diagnosis of 25.7 years (SD ± 11.4). All patients included in the study had liver involvement and 27 (46.55%) also presented neuro-psychiatric manifestations. There was a significant correlation between TE and METAVIR score ($p = 0.001$). The optimal thresholds identified for the diagnosis of cirrhosis was > 11.1 kPa (AUC 0.97, Se 100%, Sp 90%). For advanced fibrosis (F3) the cut-off was > 8.6 kPa, for mild/moderate fibrosis (F1) $\leq$ 7.9 kPa and $\leq$ 6.1 kPa for the absence of fibrosis (F0). We found a significant correlation between all the other NITs and F4 METAVIR staging: APRI: $\rho = 0.52$, $p < 0.0001$; FIB4: $\rho = 0.50$, $p < 0.0001$; GUCI: $\rho = 0.49$, $p < 0.0001$; CDS: $\rho = 0.57$, $p < 0.0001$; Lok Index: $\rho = 0.60$, $p < 0.0001$. The TE measurements could predict the risk of cirrhosis decompensation with ascites, using a threshold of 14 kPa (AUC = 0.83, Se 89%, Sp 78%). **Conclusion:** TE measurements correlate with METAVIR staging in WD patients and can identify different stages of LF and those at risk of cirrhosis decompensation. The other NITs appear to be useful tools in identifying or excluding cirrhosis supporting measurements at TE.

3648 | LIVER DISEASE PROGRESSION IN INDIVIDUALS WITH ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED GENOTYPES: INSIGHTS FROM A LARGE GENETIC DATABASE LINKED TO ELECTRONIC MEDICAL RECORDS IN THE USA

Lauren Petty[1] Grahame Evans[1] Xinruo Zhang[2] Jennifer Below[1] Kari North[2] May Hagiwara[3] Chitra Karki[3] Tami Nussbaum[3] Suna Park[3] Kaili Ren[3] Virginia Clark[4], [1]Vanderbilt Genetics Institute, Vanderbilt University Medical Center, Nashville, TN, USA, [2]Gillings School of Global Public Health, University of North Carolina, Chapel Hill, NC, USA, [3]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [4]University of Florida, Gainesville, FL, USA

Background: Alpha-1 antitrypsin deficiency (AATD) is a rare genetic disorder that can lead to liver and/or lung disease and is often underdiagnosed. This study used genetic information from a large electronic medical record (EMR)-linked biobank in the USA (BioVU) to evaluate progression of liver disease and associated clinical events and their potential predictors in individuals with AATD genotypes. **Methods:** A retrospective cohort of adults with AATD genotypes (protease inhibitor [Pi] MS/MZ/SS/SZ/ZZ) was identified using genetic data from BioVU among consented care recipients at Vanderbilt University Medical Center from 2018 to 2022. Based on their linked EMRs, individuals with one or more ICD-9/-10-CM code(s) for hepatic cirrhosis/fibrosis or one or more aspartate aminotransferase to platelet ratio index (APRI) score (calculated from laboratory measures within 3 months) were included and categorized at index as cirrhosis (APRI $>$ 1.5), fibrosis (APRI $>$ 0.43), or no fibrosis (APRI $\leq$ 0.43) (Wu T *et al. Aliment Pharmacol Ther* 2023;58:1075–85). A Kaplan–Meier analysis was conducted for liver disease progression to cirrhosis or a decompensating liver event. A Cox regression model was fit to assess time to liver disease progression using population characteristics as potential predictors. **Results:** In total, 6,804 individuals with an AATD genotype were included (mean age 52.3 years; 56.1% female; 93.1% White; 4.5% with lung disease), of whom 5.4%, 17.9%, and 76.7% had cirrhosis, fibrosis, and no fibrosis at index, respectively. The analytic cohort comprised 6,258 individuals, excluding those with evidence of liver decompensation on or before index date (median [interquartile range] follow-up: 5.2 [1.2–11.5] years). Time to liver disease progression is presented by index liver state (Figure A) or by AATD genotype (Figure B). Based on the Cox analysis, male sex, older age, Pi*ZZ genotype, use of augmentation therapy, and history of neonatal jaundice were all significantly ($p \leq 0.01$) associated with an increased rate of liver disease progression. Additionally, each of the incremental APRI score categories (referenced to APRI $\leq$ 0.43) was significantly ($p < 0.005$) associated with increased risk of liver disease progression: adjusted hazard ratio 1.33 (95% confidence interval 1.09–1.61), 2.56 (2.02–3.24), and 3.95 (2.84–5.50) for APRI 0.43 to $<$ 0.63, 0.63 to $<$ 1.50, and $\geq$ 1.5, respectively. **Conclusion:** This study leveraged genetic data with linked EMRs and provides evidence that patients carrying the Pi*ZZ genotype have the highest risk of liver disease progression, followed by Pi*SZ and other genotypes. Additionally, a higher APRI score at index was a strong predictor of liver disease progression, underscoring its value in identifying patients at higher risk for liver-related outcomes.

3649 | DIURNAL VARIATION IN BLOOD AMMONIA LEVELS IN PATIENTS WITH ADULT-ONSET TYPE II CITRULLINEMIA

Hiroaki Haga[1] Kyoko Hoshikawa[1] Tomohiro Katsumi[1] Keita Maki[1] Fumiya Suzuki[1] Fumi Uchiyama[1] Yoshiyuki Ueno[1], [1]Yamagata University

Background: Adult-onset type II citrullinemia (CTLN2) is a disorder characterized by neuropsychiatric symptoms such as impaired consciousness, abnormal behavior, and seizures, resulting from hyperammonemia and hypercitrullinemia caused by mutations in *SLC25A13*, which encodes citrin, a mitochondrial inner membrane transporter protein. Although the pathophysiology of CTLN2 has been described, there are few reports on the diurnal variation of blood ammonia levels in these patients. Based on our clinical experience with CTLN2 patients who exhibited normal fasting ammonia levels, we hypothesized that blood ammonia levels may show significant diurnal variation. This study aimed to investigate the diurnal fluctuations in blood ammonia levels in patients with CTLN2. **Methods:** We studied three hospitalized patients with CTLN2: a 50-year-old man, a 62-year-old man, and a 62-year-old woman. During hospitalization, patients were instructed to avoid snacks between breakfast, lunch, and dinner. Blood ammonia levels were measured at the following time points: 7:30, 9:00, 11:30, 13:00, 17:30, 19:00, and 22:00, both before and after meals and before bedtime. **Results:** In the 50-year-old male patient (Case 1), the citrulline concentration was 102.1 nmol/mL (normal: 17.1–42.6), with albumin 4.4 g/dL, total bilirubin 1.3 mg/dL, AST 33 U/L, ALT 47 U/L, ALP 235 U/L, γ-GTP 84 U/L, platelet count 19.6×10^4/μL, prothrombin time (PT) 92%, and ICG retention at 15 minutes of 9%. Blood ammonia levels at the designated time points were 100, 215, 411, 470, 121, 142, and 358 μg/dL, showing a maximum diurnal fluctuation of 370 μg/dL. The 62-year-old male patient (Case 2) had a citrulline concentration of 131.4 nmol/mL, albumin 3.4 g/dL, total bilirubin 1.2 mg/dL, AST 50 U/L, ALT 55 U/L, ALP 367 U/L, γ-GTP 96 U/L, platelet count 12×10^4/μL, PT 82%, and ICG (15 min) 8%. His ammonia levels were 44, 100, 121, 163, 79, 269, and 182 μg/dL, with a maximum variation of 225 μg/dL. The 62-year-old female patient (Case 3) showed a citrulline level of 486.4 nmol/mL, albumin 3.4 g/dL, total bilirubin 0.8 mg/dL, AST 36 U/L, ALT 37 U/L, ALP 352 U/L, γ-GTP 64 U/L, platelet count 19.6×10^4/μL, PT 120%, and ICG (15 min) 8%. Her blood ammonia values were 57, 94, 134, 136, 193, 125, and 203 μg/dL, with a maximum fluctuation of 146 μg/dL. In all three cases, fasting morning ammonia levels were within the normal range, and there was a clear tendency for levels to increase toward the evening. The magnitude of diurnal variation was considerable, with maximum differences of 370 μg/dL in Case 1, 225 μg/dL in Case 2, and 146 μg/dL in Case 3. **Conclusion:** Blood ammonia levels in CTLN2 exhibit marked diurnal variation, and some patients may show

normal values during early morning fasting, which could lead to missed diagnoses. Although ammonia levels tend to peak at night, measuring post-lunch ammonia levels in outpatient settings may be more useful for accurate diagnosis.

3650 | LIVER-HUMANIZED MICE REPOPULATED WITH HEPATOCYTES FROM A HEMOPHILIA B DONOR EXHIBIT DELAYED BLOOD CLOTTING AND HAVE A PHYSIOLOGIC RESPONSE TO GENE THERAPY CORRECTION OF HUMAN FIX

Devorah Goldman[1] Zoe Dimond[1] Riffat Ahmed[2] Robert Copenhaver[3], [1]Yecuris, [2]Yecuris Corp., [3]Yecuris Corporation

Background: Hemophilia B (HEMB), a single gene disorder affecting Factor IX (FIX), is an ideal target for gene therapies. In order to establish a relevant model for evaluating such therapeutics, primary hepatocytes from a patient with HEMB were evaluated for clotting defects and gene therapy correction in vivo in liver-humanized mice. **Methods:** Primary hepatocytes from a male HEMB donor carrying a pathogenic, missense mutation c.316 G > A (rs137852233) in FIX were transplanted into male FRG® mice on the NOD background (FRGN). This mutation converts a highly conserved Gly to Ser in the EGF1 domain of FIX and is associated with mild to moderate hemophilia B. Primary hepatocytes from a non-hemophilic human male donor were transplanted into male FRGN mice as a control. Donor performance and blood clotting in mice with human albumin levels of >4000 μg/mL, indicative of livers repopulated with $>70\%$ human hepatocytes, were compared. **Results:** Humanized mice repopulated with control donor cells ($n=3$) had average circulating human FIX (hFIX) levels of 1436ng/mL, whereas mice repopulated with the HEMB donor ($n=6$) had circulating hFIX levels of 647ng/mL. Measurement of partial thromboplastin time (PTT) in plasma samples from liver-humanized mice created with the control donor cells ($n=9$) revealed a mean PTT of 28.49 seconds. In HEMB liver-humanized mice ($n=9$), the average PTT was increased by 24% to 35.34 seconds. Thus, physiologically relevant defects in clotting could be modelled in liver-humanized mice reconstituted with a HEMB donor. To demonstrate that this model could be used to assess efficacy of gene therapies, HEMB mice were injected i.v with $2.5x10^{11}$ copies per mouse of a liver-tropic AAV expressing hFIX (AAVDJ-CAG-hFIX). One week after injection, increased expression of hFIX (14,266ng/mL) and a significant decrease in PTT (30.25s, $p<0.005$) was observed compared to untreated HEMB liver-humanized mice. Even without optimization of AAV-mediated correction, there was no significant difference in clotting time between HEMB liver-humanized mice that received hFIX gene therapy and mice that were liver-humanized with hepatocytes from a control donor. **Conclusion:** Our findings demonstrate that primary human hepatocytes from donors with genetic disease such as hemophilia B can successfully repopulate FRG mice, recapitulate physiologic disease pathologies, and be used to evaluate relevant in vivo therapeutic approaches.

3651 | HEPATIC OUTCOMES IN PORPHYRIA: AN UNDERSTUDIED AND UNDER EVALUATED COMPLICATION

Muhammad Saad Faisal[1] Razan Aburumman[1] Anju Pradeep[1] Minahil Fatima[1] Ammad Chaudhary[1] Abdulmalik Saleem[1] Muhammad Salman Faisal[1] Syed-Mohammed Jafri[2], [1]Henry Ford Hospital, Detroit, [2]Henry Ford Health System

Background: Porphyrias are rare metabolic disorders traditionally associated with cutaneous or neurovisceral manifestations. Porphyria Cutanea Tarda (PCT) and Erythropoietic Protoporphyria (EPP) are frequently linked to hepatic complications, including steatosis, cirrhosis, and liver failure. Although potentially severe, these complications remain under-evaluated and under-recognized. This study aims to evaluate factors associated with hepatology referral and to compare hepatic outcomes in porphyria patients based on whether they received hepatology care. **Methods:** We conducted a retrospective study of all patients diagnosed with EPP or PCT at our center. Following IRB approval, individual chart reviews were performed. Patients were divided into two groups: those seen by hepatology, forming the hepatology group (HG) and those not seen by hepatology, forming the control group (CG). Demographics, liver function tests, imaging findings, liver biopsy data, and transplant status were compared between the groups. **Results:** Of the 93 patients identified, 25 (27%) patients were evaluated by hepatology, formed the HG and 68 (73%) patients were not, forming the CG. There were no significant differences in gender, porphyria type, or alcohol use between the groups. A total of 20 (80%) patients in the HG and 56 (82.4%) in the CG were on porphyria

treatment (p = 0.767), with no significant differences in treatment modality. Patients in the HG had significantly higher mean ALT levels (70.3 vs. 37.3 IU/L, p = 0.03). While AST (80.2 ± 101.9 vs. 39.1 ± 31.3, p = 0.1005), ALP (96.4 ± 57.2 vs. 83.7 ± 36.0, p = 0.3811), and bilirubin (2.2 ± 3.0 vs. 1.2 ± 3.1, p = 0.212) levels were also elevated in this group, the differences were not statistically significant. Liver ultrasound (US) was more frequently performed in the HG (72% vs. 39.7%), with a higher frequency of cirrhosis (16% vs. 4.4%), steatosis (24% vs. 8.8%), and hepatic malignancy (8% vs. 0%) (p = 0.0074). Liver biopsies were more commonly performed in the HG (24% vs. 1.5%, p = 0.001), and 5 patients (20%) in this group underwent liver transplantation compared to none in the CG (p = 0.0003). For the patients in the HG, 10 (40%) were on active treatment for Hepatitis C, 2 (8%) were on bile acid sequestrants, and 1 (4%) was on steroids and ursodiol per hepatology recommendations. **Conclusion:** Porphyria patients who were evaluated by hepatology exhibited a significantly higher burden of hepatic complications, including cirrhosis, malignancy, and need for liver transplantation. These findings emphasize the importance of early hepatology referrals, particularly for patients with abnormal liver enzymes or imaging results. Greater awareness and multidisciplinary follow-up may improve detection, intervention, and outcomes of hepatic complications in porphyria.

3652 | UNDERSTANDING THE EXPERIENCE OF ADULTS WITH ALPHA-1 ANTITRYPSIN DEFICIENCY LIVER DISEASE: A CONCEPT ELICITATION INTERVIEW STUDY

Hafiz Oko-osi[1] Tiara Johnson[1] Michael Acquadro[2] Jack Brownrigg[3] Milena Anatchkova[2] Ebony Dashiell-Aje[1], [1]BioMarin Pharmaceutical Inc., Novato, CA, USA, [2]PPD™ Evidera™ Patient-Centered Research, Thermo Fisher Scientific, Wilmington, NC, USA, [3]BioMarin UK, London, UK

Background: Alpha-1 Antitrypsin Deficiency (AATD) is a genetic disease characterized by low serum level of alpha-1-antitrypsin (A1AT) and accumulation of A1AT polymers in the liver. There is very limited qualitative evidence describing the experience of individuals living with AATD liver disease (LD). This study aimed to describe the symptoms of AATD LD in adults and its associated impacts on functioning. **Methods:** Adults (≥ 18 years) with AATD LD and clinicians managing individuals with AATD LD located in the US participated in one-on-one, semi-structured, concept elicitation interviews. Participants were identified through a recruitment vendor. Interviews were conducted virtually and recorded. Deidentified transcripts of interview recordings were analyzed using qualitative analytic software (ATLAS.ti v22 [Scientific Software Development GmbH, Berlin]). **Results:** Twenty adults diagnosed with AATD LD and four clinicians were interviewed. Adults with AATD LD had a mean age of 61.4 years, were 70% female, and had a mean duration since diagnosis of 9.9 years; genotypes were protease inhibitor [Pi]-ZZ (n = 15), PiSZ (n = 3), and PiMZ (n = 2); fibrosis stages were F2 (n = 7), F3 (n = 2), F3/F4 (n = 2), F4 (n = 8), and unknown (n = 1). Clinicians had mean 23.5 years of AATD experience. Symptoms endorsed by at least 3 adults with AATD LD were shortness of breath (n = 6), cough (n = 5), pain in the upper right abdomen (n = 5), fatigue/weakness (n = 4), and fluid buildup in the abdomen (n = 3). Symptoms endorsed as worst symptoms were fatigue/weakness (n = 3), shortness of breath and pain in the upper right abdomen (n = 2 each). Adults with AATD LD endorsed impacts on emotional (n = 18),

physical (n = 15), and social function (n = 14), relationships (n = 12) and work (n = 9). Clinicians endorsed fatigue/weakness (n = 4) and itchy skin (n = 3) as the most frequently reported symptoms of AATD LD. Both symptoms were endorsed by clinicians (n = 2 each) as the worst symptom reported by individuals with AATD LD. Clinicians endorsed similar impacts as those reported by adults with AATD LD. **Conclusion:** This study offers critical insights into the experience of adults with AATD LD across three genotypes and fibrosis stages. Adults with AATD LD and clinicians endorsed similar symptoms and impacts. These findings demonstrate that AATD LD is a heterogenous disease with substantial symptom and impact burden on adults living with AATD LD.

Table 1. Summary of frequently endorsed symptoms and impacts of AATD LD

Concepts		Adults with AATD LD (N=20)		Clinicians (N=4)	
		Endorsed the concept N (%)	Endorsed as the worst/most bothersome concept* N (%)	Endorsed the concept N (%)	Endorsed as the worst/most bothersome concept* reported by patients N (%)
Symptoms	Shortness of breath	6 (30%)	2 (10%)	1 (25%)	0 (0%)
	Cough	5 (25%)	0 (0%)	0 (0%)	0 (0%)
	Pain in upper right abdomen	5 (25%)	2 (10%)	1 (25%)	1 (25%)
	Fatigue/weakness	4 (20%)	3 (15%)	4 (100%)	2 (50%)
	Fluid buildup in the abdomen (ascites)	3 (15%)	0 (0%)	3 (75%)	0 (0%)
	Swelling in lower extremities	2 (10%)	0 (0%)	0 (0%)	0 (0%)
	Itchy skin	2 (10%)	1 (5%)	3 (75%)	2 (50%)
	Migraine	2 (10%)	0 (0%)	0 (0%)	0 (0%)

3653 | METFORMIN TREATMENT TO IMPROVE MITOCHONDRIAL MORPHOLOGY AND FUNCTION IN A MOUSE MODEL OF WILSON DISEASE

Valentina Medici[1] Noreene Shibata[2] Isabel Snodgrass[2] Dohee Kim[3] John Newman[2] Aldo Vorkapich[2] Zoe Lee Greenblatt[2] Atena Tork[2] Jennifer Dang[2] Ieleen Li[2] Cecilia Giulivi[2], [1]University of California Medical Center, [2]University of California, Davis, [3]United States Department of Agriculture, Agricultural Research Service

Background: Wilson Disease (WD) is a genetic disorder caused by mutations affecting the *ATP7B* gene with consequent accumulation of copper in the liver and brain. Women with WD tend to experience more liver-related symptoms. WD is associated with liver mitochondrial dysfunction, suggesting that targeting the mitochondrial function could provide an effective treatment approach. The oral hypoglycemic agent metformin forms high-affinity pseudo-aromatic complexes with metals, including copper. We hypothesized that metformin could improve liver mitochondrial morphology in WD. **Methods:** We treated male (n = 5) and female (n = 5) *Atp7b* global knockout mice on a C57Bl/6 background (KO), a WD model, with 500 mg/kg/d metformin in their drinking water for 2 weeks. In samples collected before and after treatment, we analyzed mitochondrial structure and activity and mitochondria lipid mediator concentrations in the liver. **Results:** We implemented a scoring methodology to conduct a quantitative analysis of liver mitochondrial ultrastructure. The scores were analyzed by fitting them into a linear regression model to elucidate the contribution of sex, treatment, and their interaction. The analysis of mitochondrial scores indicated that sex ($P = 0.025$), treatment ($P = 0.0021$), and the sex × treatment interaction were significant. At baseline, females presented with worse liver mitochondrial scores than males ($P < .0001$). Metformin treatment resulted in improved scores for mitochondria from females compared to untreated females ($P < .0001$) and treated males ($P = 0.0473$). Quantification of the lipid vacuole areas revealed a significant sex effect ($P = 0.0299$) and a sex × treatment interaction ($P = 0.0412$). Compared to treated females, treated males showed increased size of lipid vacuoles in terms of area ($P < .0001$) and perimeter ($P = 0.019$). In females, metformin treatment improved mitochondrial overall morphology, the ratio of supercomplexes, and decreased lipid vacuole size compared to males treated with the same medication. Mitochondrial omega-6 oxylipins had a sex ($P = 0.010$), and a sex* treatment interaction ($P = 0.0003$). After metformin treatment, females' omega-6 oxylipins decreased to values similar to those of males (prostanoids and F2 isoprostane) or lower (hydroxy fatty acids). **Conclusion:** Metformin improves mitochondrial morphology and function in WD. This study highlights the importance of considering sex-based differences in the diagnosis and treatment of WD to improve patient outcomes.

3654 | EVALUATION OF NONINVASIVE TESTING FOR HEPATIC STEATOSIS: RESULTS: FROM THE MULTICENTER WILSON DISEASE REGISTRY INCLUDING YALE, AARHUS AND BARCELONA COHORTS

ZOE MARIÑO MENDEZ[1] Frederik Kirk[2] Uyen To[3] Asim Ulcay[3] Hatice Maras[3] Sefa Keserci[3] Regino Gonzalez-Peralta[4] Sanjiv Harpavat[5] Rima Fawaz[6] Alba Diaz[1] Kaitlin Maciejewski[3] Yanhong Deng[3] Thomas Sandahl[7] Michael Schilsky[3], [1]Hospital Clinic of Barcelona, Spain, [2]Aarhus University, Denmark, [3]Yale University, New Haven, CT USA, [4]AdventHealth for Children, [5]Texas Children's Liver Center - Baylor College of Medicine, [6]Yale University Medical Center, [7]Aarhus University, Aarhus, Denmark

Background: Hepatic steatosis due to copper induced mitochondrial toxicity is an early histological finding in Wilson Disease (WD). There is no reported data on the use of non-invasive tools for evaluating steatosis in WD. The Hepatic Steatosis Index (HSI) [calculated from AST/ALT ratio, BMI, presence of diabetes, and sex] identifies significant steatosis in liver biopsies (LB) from MASLD (cutoff >36). The elastographic Controlled Attenuation Parameter (CAP) detects moderate-severe steatosis in MASLD using a cutoff of ≥ 268 dB/m. Aims: to explore the accuracy of HSI and CAP in WD, using LB as the gold standard. **Methods:** Cross-sectional study of WD from registries at Yale, Aarhus and Barcelona with available LB. Clinical data were obtained from chart review. Steatosis in LB (according to NASH-CRN system) was graded as: 0, no steatosis; 1, mild 5-33%; 2, moderate 34-66%; or 3, severe $>66\%$. Moderate-severe steatosis (MSSt, $>33\%$) were considered together. HSI was calculated at the date of registry entry. Variables are expressed as median (IQR). The ROC curves for previously validated thresholds (HSI >36, CAP ≥ 268 dB/m) were calculated and optimal cutoffs determined by use of the Youden index. **Results:** We included 102 WD: 48% female, median age at LB 22.6y (12, 35[ZMM1]); median time from WD diagnosis 3m; 6 were diabetic; median BMI 22.8 kg/m^2. MSSt was present in 36 (35%) and was associated with higher BMI [26.1 (20.3, 30.5) vs 22.2 (19.9, 24.3), $p=0.021$]. HSI was available in 93 (91%) patients at a median time from LB of 11m; CAP was available in 29 patients (28%) close to time of LB. Although median HSI was significantly higher in MSSt vs non-MSSt (44.5 vs 36.9, $p=0.007$), the >36 threshold did not accurately predict MSSt (AUC 0.51). A higher HSI cutoff of 42.2 increased AUC to 0.67. CAP was also significantly higher in MSSt vs non-MSSt (324.5 vs 224 dB/m); the AUC was 0.80 for the ≥ 268 cutoff with a positive predictive value of 0.70 (0.35, 0.93). A cutoff of 292.5 dB/m increased AUC to 0.87. **Conclusion:** CAP with ≥ 292.5 cutoff improved the accuracy for detecting moderate or severe steatosis in patients with WD. HSI >36 was not accurate in predicting MSSt, though a higher cutoff did improve discrimination to a limited degree, possibly due to the different pathophysiology of steatosis in WD and greater delay in time from LB to HSI in this study. Further study is needed to determine whether MSSt impacts WD outcomes, and the best means for its non-invasive measurement.

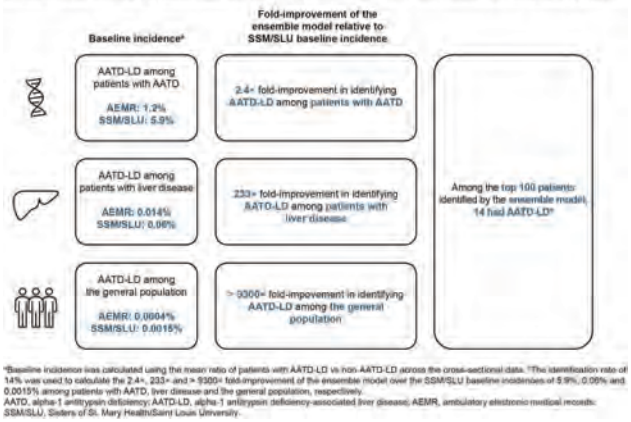
3655 | A CLINICAL DECISION SUPPORT TOOL FOR THE IDENTIFICATION OF PATIENTS AT RISK OF DEVELOPING ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED LIVER DISEASE: INTERIM RESULTS:

Jeffrey Teckman[1] Virginia Clark[2] Leslie Hinyard[3] Nadejda Leavitt[4] Suyin Lee[4] Amanda Sees[4] Chitra Karki[5] Suna Park[5] Kaili Ren[5] May Hagiwara[5] Rohit Loomba[6], [1]Saint Louis University School of Medicine, St. Louis, MO, USA, [2]University of Florida, Gainesville, FL, USA, [3]Saint Louis University School of Medicine, St. Louis, MO, USA; AHEAD Institute, St. Louis, MO, USA, [4]IQVIA, Plymouth Meeting, PA, USA, [5]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [6]University of California at San Diego, San Diego, CA, USA

Background: Alpha-1 antitrypsin deficiency (AATD)-associated liver disease (AATD-LD) is a rare genetic disorder that is underdiagnosed owing to its asymptomatic nature. To help clinicians identify patients (pts) at risk of developing AATD-LD, an artificial intelligence/machine learning-clinical decision support tool (AI/ML-CDST) was developed using data from the IQVIA US National Ambulatory Electronic Medical Records (AEMR) database. Here, we refine and validate the AEMR model (foundational), using electronic medical records from the Sisters of St Mary Health/Saint Louis University (SSM/SLU) database. **Methods:** The study comprised adults with ≥ 1 encounter for any medical activity in the SSM/SLU database (Oct 2015–Oct 2022). The positive cohort comprised pts with a recorded AATD diagnosis (dx) code (ICD-9/10 or SNOMED) and either a liver transplant or AATD-related liver condition. The negative cohort comprised all other pts. For each pt, cross-sectional (CS) data with 12-month lookback and outcome periods with 4-month shift were generated. Data were split into training and validation sets for model development and a hold-out set for independent evaluation. The foundational model was localized and refined using the SSM/SLU database (localized model). A combined 'ensemble' model was also generated. Model performance was assessed according to precision, area under the curve (AUC) and fold-improvement in pt detection over database records. **Results:** Overall, 1,883/77,000,000 (0.002%) and 274/6,200,000 (0.004%) pts in the AEMR and SSM/SLU databases, respectively, had AATD-LD. In CS data, baseline incidences of AATD-LD among the general population were 909/214,800,000 (0.0004%) in AEMR and 80/5,200,000 (0.0015%) in SSM/SLU. Among pts with AATD, more pts in the SSM/SLU than the AEMR database had AATD-LD (Figure; 5.9% vs 1.2%). At 15.0% recall, the ensemble model achieved the greatest precision (11.6%; AUC 0.84) versus the localized (4.9%; AUC 0.84) and foundational models (2.5%; AUC 0.83). Compared with incidence rates in the SSM/SLU database (Figure), the ensemble model achieved a 2.4×-, 233×- and > 9,300×-fold improvement in the rate of identification of pts with AATD-LD among pts with AATD, liver disease (LD), and the general population, respectively. Of the top 100 pts based on ensemble model score, 14 had AATD-LD: 6 had a prior AATD dx, 5 had a prior LD dx and 3 had no prior AATD/LD dx. The top five predictors in the ensemble model were AATD dx, LD dx, recency of gastroenterologist visit or AATD-LD dx, and White ethnicity. **Conclusion:** The ensemble model provided the best performance of the models evaluated, achieving a 233×- and > 9,300×-fold improvement in AATD-LD diagnosis versus incidence in pts with LD or the general population, respectively, in the SSM/SLU database. Prospective validation is in progress to support use of this AI/ML-CDST for the diagnosis of AATD-LD.

Writing support provided by E L Wescott, Oxford PharmaGenesis.

Figure. Incidence baselines for AATD-LD in the SSM/SLU and IQVIA US AEMR databases, and the performance of the ensemble model in identifying patients with AATD-LD among patients with AATD, liver disease and the general population



[a]Baseline incidence was calculated using the mean ratio of patients with AATD-LD vs non-AATD-LD across the cross-sectional data. *The identification rate of 14% was used to calculate the 2.4×, 233× and > 9300× fold-improvement of the ensemble model over the SSM/SLU baseline incidences of 5.9%, 0.06% and 0.0015% among patients with AATD, liver disease and the general population, respectively.
AATD, alpha-1 antitrypsin deficiency; AATD-LD, alpha-1 antitrypsin deficiency-associated liver disease; AEMR, ambulatory electronic medical records; SSM/SLU, Sisters of St. Mary Health/Saint Louis University.

3656 | PATIENT CHARACTERISTICS OF ADULT CYSTIC FIBROSIS LIVER DISEASE AND THE EFFECTIVENESS OF NONINVASIVE FIBROSIS TESTS IN DETERMINING DISEASE STATUS

Mehmet Eskiocak[1] Gamze Sonmez[2] Burak Elçi[3] Ibrahim Sendur[4] Bengi Öztürk[4] Oguz Karciooglu[3] Taylan Kav[4] Ebru Damadoglu[3] Yasemin Balaban[4] onur keskin[4], [1]Hacettepe University School of Medicine Department of Internal Medicine, [2]Hacettepe University School of Medicine, [3]Hacettepe University School of Medicine Department of Pulmonary Medicine, [4]Hacettepe University School of Medicine Department of Gastroenterology

Background: Adult cystic fibrosis-associated liver disease (CFLD) is a significant cause of morbidity and mortality in patients with cystic fibrosis (CF). However, a standard approach to CFLD screening and diagnostic criteria has not yet been defined. The aim of this study was to determine the prevalence of CFLD in a cohort of adult CF patients and to evaluate the effectiveness of noninvasive fibrosis tests in the diagnosis of CFLD. **Methods:** The study included 42 patients (23F/19M; mean age: 24.7 ± 5.7) diagnosed with CF and followed at the Pulmonology Department of Hacettepe University. All patients were examined in the Gastroenterology Clinic and underwent liver stiffness measurement (LSM) using transient elastography. Patients with LSM > 8 kPa were considered to have $\geq$F2 fibrosis, while patients with LSM > 10kPa in combination with ultrasonographic evidence of chronic liver disease were considered to have advanced chronic liver disease. Patients were stratified based on fibrosis severity, and clinical and biochemical parameters were compared between groups. **Results:** LSMs were detected as > 8 kpa in 11 (26%) patients (9F/2M; p:0.07), there were 7 (%16) diabetic patients and all had LSM > 8 kpa. Compared to those without fibrosis, patients with $\geq$F2 fibrosis had significantly elevated levels of ALT (63 ± 85 vs. 23 ± 10; p:0.01), AST (48 ± 31 vs. 24 ± 7;$p < 0.01$), and GGT (46 ± 56 vs. 19 ± 12;p:0.01), as well as reduced serum albumin levels (4.1 ± 0.4 vs. 4.4 ± 0.3;p:0.02). FIB4 (0.97 ± 0.6 vs. 0.5 ± 0.23; $p < 0.01$) and APRI values (0.71 ± 0.45 vs. 0.28 ± 0.15; $p < 0.01$) were found to be higher in the fibrosis group. Of the patients, 6 (14%) (5F/1M; p:0.19) had LSM > 10kPa and chronic liver disease findings in ultrasonographic examination, 5 of whom were diabetic ($p < 0.01$). GGT (58 ± 76 vs. 21 ± 13; $p < 0.01$) and INR (1.26 ± 0.1 vs. 1.09 ± 0.17; p: 0.03) levels were higher, serum albumin levels (3.97 ± 0.56 vs. 4.41 ± 0.3; $p < 0.01$) was lower and FIB-4 score was found to be higher (1.09 ± 0.27 vs 0.54 ± 0.27;p:0.002) in the advanced chronic liver disease group. Using a FIB-4 cut-off of 0.74, advanced fibrosis was identified with a sensitivity of 67% and specificity of 77% (Area under curve: 0.72). Although the APRI score was higher in the advanced fibrosis group, it did not reach statistical significance (0.61 ± 0.32 vs. 0.35 ± 0.30; p:0.06). **Conclusion:** In this cohort, 16% of CF patients had advanced fibrosis and 26% had $\geq$F2 fibrosis. 5 of 6 diabetic patients had advanced fibrosis. Due to the relatively young age of the population and preserved platelet counts even in advanced disease, the use of FIB-4 and APRI with the cut-off values in the literature may not be appropriate for fibrosis prediction.

Duong[3], [1]Allegheny General Hospital, [2]Lahey Health, [3]Stanford University

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) affects nearly one-third of adults and is the second leading cause for liver transplantation in the United States. Cardiovascular disease (CVD) is the primary driver of mortality in patients with MASLD, yet pharmacotherapy addressing cardiometabolic risk factors are scarce. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) address weight and hyperglycemia, but dual incretin agonists that also stimulate glucose-dependent insulinotropic polypeptide (GIP) receptors may confer additional benefits. Tirzepatide, the first GLP-1/GIP co-agonist has outperformed semaglutide for weight and glycemic control in clinical trials, however direct CVD data in MASLD are limited. **Methods:** Using the U.S. TriNetX network, we included adults ≥ 18 years with an ICD-10 code for fatty liver disease plus ≥1 metabolic risk factor (diabetes, obesity, hypertension, dyslipidemia) who first filled a prescription of tirzepatide or semaglutide from 1 Jan 2015 to 31 Dec 2021. We excluded other liver diseases, prior GLP-1 RA use, bariatric surgery, critical-care stay, liver transplant, previous major adverse cardiovascular events (MACE), or major liver outcomes. One-to-one propensity matching balanced age, sex, race, body-mass index (BMI), diabetes, hypertension, and dyslipidemia. The primary endpoint was 3-year composite MACE. Secondary endpoints were individual CV events, acute heart failure, all-cause mortality, all-cause hospitalization, and BMI change. **Results:** Of 15,538 eligible MASLD patients, 1,500 began tirzepatide and 14,038 semaglutide; matching produced 1,497 per cohort with similar baseline characteristics. Over three years, tirzepatide users had fewer MACE than semaglutide users (1.27% vs 4.08%; adjusted odds ratio [aOR] 0.30, 95% CI 0.18–0.51; p <0.0001). Myocardial infarction rates decreased by two-thirds (0.74% vs 2.00%; aOR 0.36, 0.18–0.72; p = 0.0028). Stroke and acute heart-failure rates were numerically lower but not significant. All-cause hospitalization decreased (21.31% vs 30.66%; aOR 0.61, 0.52–0.72; p <0.0001). Mortality was ≤0.67 % in both groups. BMI decreased more with tirzepatide (-4.1 kg m^{-2}) than with semaglutide (-2.2 kg m^{-2}; p < 0.001). **Conclusion:** Over a three-year period involving nearly 1,500 patients per cohort, tirzepatide was associated with a 70% reduction in MACE, fewer hospitalizations, and greater weight loss than semaglutide. These findings suggest that dual GLP-1/GIP receptor agonism provides superior cardiometabolic protection compared to GLP-1 monotherapy. Prospective head-to-head clinical trials are warranted to validate these cardiovascular and liver-related benefits and to guide optimal therapeutic strategies for this high-risk population.

Table 1: Three-Year Cardiovascular, Hospitalisation, Mortality, and Weight Outcomes After Propensity Matching

Outcome	Tirzepatide (n = 1,497)	Semaglutide (n = 1,497)	Adjusted OR	95 % CI	p-Value
Composite MACE	19 (1.27 %)	61 (4.08 %)	**0.30**	0.18–0.51	**< 0.0001**
Myocardial infarction	11 (0.74 %)	30 (2.00 %)	**0.36**	0.18–0.72	**0.0028**
Ischaemic stroke	≤ 10 (0.67 %)	14 (0.94 %)	0.71	0.32–1.61	0.41
Acute heart failure	≤ 10 (0.67 %)	16 (1.07 %)	0.62	0.28–1.38	0.24
All-cause hospitalisation	319 (21.31 %)	459 (30.66 %)	**0.61**	0.52–0.72	**< 0.0001**
All-cause mortality	≤ 10 (0.67 %)	≤ 10 (0.67 %)	1.00	0.42–2.41	1.00
BMI (kg m^{-2})	38.8 ± 7.65 → 34.7 ± 7.84	38.4 ± 7.59 → 36.2 ± 7.83	—	—	**< 0.001**

*MACE = major adverse cardiovascular events. ≤ 10 indicates suppressed cell counts for privacy compliance.

◆ 4002 | EFFICACY AND SAFETY OF TIME-RESTRICTED EATING IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Dae Won Jun[1] Ju Hyun Oh[2] Hyun Woo Oh[3] Hyo Young Lee[4] Eileen Yoon[4] Sang Bong Ahn[5] HA IL KIM[4], [1]Hanyang University, [2]Department of Internal Medicine, Bundang Medical Center, CHA University College of Medicine, Seoul, [3]Department of Internal Medicine, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicin, [4]Department of Internal Medicine, Hanyang University, Seoul, Korea, Rep. of South, [5]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, College of Medicine,

Background: Time-restricted eating (TRE) may improve weight loss, insulin resistance, and body composition, key factors in the pathophysiology of metabolic dysfunction-associated steatotic liver disease (MASLD). However, evidence in patients with MASLD is limited. This study aimed to evaluate the potential benefits of TRE in patients with overweight or obese MASLD. **Methods:** This 16-week randomized controlled trial included patients who were overweight or obese and had MASLD randomized into three groups in a 1:1:1 ratio: standard of care (SOC), calorie restriction (CR), and TRE. The primary endpoint was an improvement in hepatic steatosis, measured using magnetic resonance imaging proton density fat fraction. Changes in liver fibrosis, body composition, lipid profiles, glucose homeostasis, and sleep quality were also

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

analysed. This study is registered at ClinicalTrals.gov, NCT05579158. **Results:** Among the 337 participants randomized, 333 were included in the full analysis set (113 in SOC, 110 in CR, and 110 in TRE). After the 16-week intervention, hepatic steatosis significantly decreased in the TRE group (- 25.8%) than in the SOC group (0.7%, $p < 0.001$), with no significant difference between TRE and CR (- 24.7%, $p = 1.00$). The TRE group also showed greater reductions in body weight, waist circumference, and body fat mass compared to those of SOC, with similar changes between TRE and CR. No significant differences were observed between TRE and CR in liver stiffness, glucose homeostasis, or sleep quality. No serious adverse events were reported. **Conclusion:** TRE effectively reduces hepatic steatosis in MASLD, with comparable benefits on weight loss, body composition, and metabolic parameters as CR. This approach may serve as a practical dietary strategy for MASLD management.

◆ 4003 | DURABILITY OF RESMETIROM RESPONSE IN MASLD PATIENTS AFTER TWO YEARS OF TREATMENT IN MAESTRO-NAFLD-OLE

Naim Alkhouri[1] Rebecca Taub[2] Xiaomin Lu[2] Matthew Dauphin[3] Kathryn Lucas[4] Sam Moussa[5], [1]Summit Clinical Research, [2]Madrigal Pharmaceuticals, [3]Madrigal Pharmacueticals, [4]Lucas Research, [5]University of Arizona for Medical Sciences

Background: Resmetirom (RES) is approved for the treatment of patients with MASH and liver fibrosis. MAESTRO-NAFLD-1 (MN-1) (NCT04197479) was a randomized double-blind (DB) Phase 3 clinical trial of placebo (PBO) versus RES, a once-a-day oral selective thyroid hormone receptor ?? agonist, in which 972 MASLD patients identified non-invasively were randomized 1:1:1 to receive RES 80mg, 100mg or placebo for 52 weeks. MAESTRO-NAFLD-OLE NCT04951219 (MN-OLE) was a one year extension study in which 515 DB patients from MN-1 entered a second 52 weeks of treatment and received treatment for 52 weeks with RES. Efficacy was evaluated after two years of RES treatment (patients randomized to RES in MN-1) and one year of RES treatment in patients treated with PBO in MN-1. **Methods:** MN-1 is described [Nat. Med https://doi.org/10.1038/s41591-023-02603-1]. Inclusion requirements were 3 metabolic risk factors, FibroScan VCTE $\geq$5.5 kPa/CAP $\geq$280 dBm, MRI-PDFF $\geq$8%. After a treatment interruption of mean(SD) 120(84) days, 515 double-blind patients from MN-1 enrolled in MN-OLE, previous treatment in MN-1: n = 168, RES 80mg; 175, RES 100mg; 172, PBO. Enrolled MN-OLE patients received either 80mg or 100mg RES for the first 12 weeks and 100mg from weeks 12-52. PBO in MN-1 (blue line) was compared to same patients treated with RES in MN-OLE (figure, dashed blue line, baseline Day 1 MN-OLE). **Results:** At baseline in MN-1 the MN-OLE population (n = 515) was age 57 (11); female, 52%; hispanic 29%; BMI 35(6); type 2 diabetes 56%; hypertension 79%; dyslipidemia 77%; VCTE 7.4(4.7) kPa. RES treatment for a second year resulted in persistent effects on biomarkers, including lipids (mean [SE]) % change in LDL -15% [2%], ApoB -19% [1%], TRIGS -23% [2%]; liver enzymes (mean [SE] % change), ALT -25% [3%], AST -9% [4%], GGT -27% [3 %] i(baseline ALT $\geq$ 30IU/L); MRI-PDFF (median % reduction) -63%; and VCTE (median % reduction) -18% (baseline VCTE $\geq$ 7.2 kPa) (figure). Responses were similar in PBO from MN-1 treated for one year with RES in MN-OLE (solid blue line, year 1, PBO; dashed blue line, MN-OLE, year 2, RES). Adiponectin, a biomarker associated with fibrosis reduction, showed a mean % increase at one (16% [2%]) and 2 years (39% [4%]). The treatment gap between year 1 and 2 resulted in loss of effect on several biomarkers that was recovered with reinitiation of RES. RES was well-tolerated, reinitiation of RES therapy or uptitration to 100 mg at week 12 MN-OLE did not generally result in new or recurrent GI AEs. **Conclusion:** In a 52-week (extension of MN-1) Phase 3 clinical trial (MN-OLE) in patients with MASLD and high metabolic risk, RES treatment for a second year resulted in durable effects on biomarkers including reductions atherogenic lipids, VCTE, MRI-PDFF and improvements in markers of liver injury and fibrosis. PBO patients from MN-1 who received treatment with RES in MN-OLE showed an improvement in biomarkers with RES in MN-OLE compared to treatment with PBO in MN-1.

◆ 4004 | EMPAGLIFLOZIN REDUCES INCIDENT CIRRHOSIS, HEPATIC DECOMPENSATION, AND MORTALITY IN MASLD/MASH PATIENTS WITH DIABETES: A PROPENSITY-MATCHED ANALYSIS OF A MULTI-INSTITUTIONAL EHR DATABASE

Ludovic Saba[1] Thomas Cotter[1], [1]UT Southwestern Medical Center

Background: Randomized trials and meta-analyses have shown that the SGLT2 inhibitor, empagliflozin, reduces hepatic fat, improves liver enzymes, and ameliorates insulin resistance in metabolic dysfunction–associated steatotic liver disease (MASLD) and its inflammatory form, MASH, regardless of diabetes status. However, its effect on liver-related major clinical outcomes (e.g. incident cirrhosis, decompensation and mortality) is poorly understood. Thus, we examined these endpoints in a large, real-world MASLD/MASH population with type 2 diabetes (T2DM). **Methods:** Adults ≥18 years with MASLD/MASH (ICD-10 K76.0 or K75.81) and T2DM (E11.x) recorded in the TriNetX Research Network (2015-2024) were identified. Patients with competing liver diseases (e.g., alcoholic liver disease, viral or autoimmune hepatitis, primary biliary cholangitis, primary sclerosing cholangitis, hemochromatosis) or baseline cirrhosis were excluded. Exposure required an empagliflozin prescription ≥ 90 days after MASLD/MASH diagnosis; unexposed controls had no SGLT2 inhibitor use. Propensity-score matching (1:1, 17 covariates) generated two balanced cohorts (n = 69,385 each). Follow-up outcomes from day +1 through three years included incident cirrhosis (ICD-10 K74.60 or K74.69), first hepatic decompensation (ascites, variceal bleeding, jaundice or hepatic encephalopathy) and all-cause mortality. Risks were compared with risk ratios (RR, 95 % CI) and survival with Kaplan–Meier log-rank and hazard ratios (HR). **Results:** Baseline characteristics before and after matching are reported in Table 1. Median follow-up was 665 days in empagliflozin users and 544 days in controls. Empagliflozin was associated with a lower three-year risk of cirrhosis (0.5 % vs 0.9 %; RR 0.57, 95 % CI 0.50–0.65; $p < 0.0001$) and of composite decompensation (1.4 % vs 2.4 %; RR 0.61, 95 % CI 0.56–0.66; $p < 0.0001$) and of all-cause mortality (HR 0.39, 95 % CI 0.37–0.41; $p < 0.0001$). **Conclusion:** In this large, propensity-matched cohort of MASLD/MASH with T2DM, empagliflozin use halved the risk of incident cirrhosis, reduced early decompensation, and was associated with markedly better survival over three years. These real-world findings extend prior imaging-based studies and support prospective trials to confirm empagliflozin's potential to modify the clinical course of MASLD.

Table 1: Baseline Characteristics – Full vs Propensity-Matched Cohorts

Variable	All patients (N=578 480)				Propensity score-matched patients (N=138 770)			
	Non-Empagliflozin (n=508 637)	Empagliflozin (n=69 843)	p-value	Std Diff	Non-Empagliflozin (n=69 385)	Empagliflozin (n=69 385)	p-value	Std Diff

◆ 4005 | COMBINATION THERAPY IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS: GLP-1R AGONIST WITH OTHERS

Hui Li[1] Jiliang Zhang[1] Yan Zhou[1] Miao Yuan[1] Chen Liu[1] Luxia Wei[1] Xiuxiu Shen[1] Lijuan Jiang[1] Jing Li[1] Zhixiang Zhang[1] Qingyang Gu[1], [1]Wuxi AppTec

Background: Metabolic Dysfunction-Associated Steatohepatitis (MASH) is a progressive liver disease characterized by steatosis, inflammation, and fibrosis. Current therapeutic options are limited, necessitating the exploration of novel pharmacological interventions. This study evaluates the efficacy of GLP-1 receptor agonists, specifically Semaglutide, in combination with other agents such as MGL3196, GFT505, Efruxifermin, and Retatrutide in a murine MASH model. **Methods:** The study employed an HFD+CCl4 induced MASH mice model. A healthy control group receiving vehicle treatments, while MASH groups receiving vehicle, Semaglutide and combinations of Semaglutide with MGL3196, GFT505, Efruxifermin, or Retatrutide with specific dosages and administration frequencies tailored to each combination. After 6 weeks of treatment, endpoints included the assessment of hepatic steatosis, inflammation, and fibrosis on histological and molecular levels were taken and compared. **Results:** The combination therapies involving semaglutide demonstrated improvements in NAS score and liver fibrosis compared to the model group at different levels. Notably, the combination of Semaglutide with MGL3196 and Retatrutide showed relatively better therapeutic effects, suggesting a potential synergistic interaction between these agents. **Conclusion:** The findings indicate that combination therapies involving GLP-1 receptor agonists, particularly Semaglutide, with other pharmacological agents hold promise in the treatment of MASH, offering a potential strategy to address the complex pathophysiology of MASH.

◆ 4006 | JAMUN-DERIVED EXTRACELLULAR VESICLES RESTORE INTESTINAL HISTIDINE–ADIPONECTIN SIGNALING AND HEPATIC LIPID METABOLISM TO ATTENUATE HIGH CARB-HIGH FAT-INDUCED MASLD

Sukriti Baweja[1] P. Debishree Subudhi[2] Vibhuti R Jakhmola[2] Sakshi Bhatt[2] Ashmit Mittal[2] Anupama Kumari[2] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences, New Delhi, [2]Institute of Liver and Biliary Sciences

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is a metabolic disorder closely related to diet and the gut microbiota. Plant-derived edible extracellular vesicles (EEVs) are emerging as novel nutraceutical therapies. We evaluated the therapeutic efficacies of functional food derived EVs from, ginger (GinEx), turmeric (TurEx), carrot (CarEx), garlic (GarEx), and jamun (JamEx) in a diet-induced murine model of MASLD. **Methods:** EVs were isolated by differential ultracentrifugation and characterized using nanoparticle tracking analysis. Male C57BL/6J mice fed on high carb (32%) high fat (58%) diet for 20-weeks, followed by oral EV treatment (50nm-300nm; zeta potential: -17 ± -2.4mV; 4×10^4 particles/kg) for 3 or 6 weeks along with HFD diet. Metabolic assessment included body weight monitoring, insulin tolerance test (ITT), and oral glucose tolerance test (OGTT). Liver pathology was evaluated by H&E and Oil Red O staining. Biochemical markers and genes associated with inflammation, lipid metabolism, apoptosis, gut permeability were studied. Fecal metabolome was analyzed using mass spectrometry. **Results:** HFD-fed mice exhibited significant metabolic dysfunction, including weight gain ($p < 0.001$), insulin resistance ($p < 0.01$), and glucose intolerance ($p < 0.01$). EEV treatment significantly reduced body weight ($p < 0.05$) and improved insulin/glucose tolerance (ITT/OGTT AUC; $p < 0.05$ at week 23). By week 26 CarEx, GarEx, and JamEx significantly reduced macro- and micro-vesicular hepatic steatosis, serum ALT ($p < 0.002$), and AST ($p < 0.001$). These effects were associated with downregulation of intestinal TNF-α and IL-17α ($p < 0.02$) and upregulation of adiponectin ($p < 0.003$). While GarEx markedly reduced hepatic inflammation (TNF-α, IL-17α; $p < 0.001$), JamEx

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

showed the strongest effect on lipid metabolism, increasing hepatic leptin ($p < 0.05$) and decreasing resistin ($p < 0.04$). Fecal metabolomics (378 annotated compounds) in EV-treated mice resembled the control profile, with JamEx forming a distinct cluster. JamEx most strongly upregulated fecal histidine metabolism ($p = 0.03$), correlating with increased intestinal adiponectin, improved barrier integrity, reduced inflammation indicated favorable microbial colonization, collectively ameliorating MASLD. Conversely, GarEx upregulated fecal pantothenate–CoA biosynthesis and sphingolipid metabolism, enhancing CoA-mediated lipid metabolism and contributing to MASLD improvement. **Conclusion:** Edible EVs effectively mitigate HFD-induced MASLD by modulating lipid metabolism, inflammation, and gut barrier function. JamEx acts through histidine-mediated adiponectin induction to restore gut–liver axis homeostasis and MASLD amelioration. Other EEVs also help restore gut-liver altered metabolic milieu. Wider evaluation of EEVs is strongly recommended.

◆ 4007 | RANDOMIZED, PLACEBO CONTROLLED PHASE 1B TRIAL OF APL-18881, A NOVEL FGF21 AND GLP-1 BISPECIFIC DUAL RECEPTOR AGONIST, EVALUATING MEASURES OF METABOLIC AND LIVER HEALTH IN PATIENTS WITH TYPE 2 DIABETES AFTER 5 WEEKS OF TREATMENT

Matthew Cardinal[1] Rohit Loomba[2] Rachel Gurrell[1] Sanjay Aggwaral[1] Xiaoping Lee[3] Linfeng Guo[3] Can Xie[3] Jiangyu Yan[3], [1]Apollo Therapeutics Ltd, [2]University of California, San Diego, [3]Dongguan HEC Biopharmaceutical R&D Co., Ltd

Background: Fibroblast growth factor 21 (FGF21) and glucagon-like peptide 1 (GLP-1) receptor agonists are in development as single agents for the treatment of steatotic liver disease (SLD). APL-18881 (also HEC88473) is a bispecific FG21 and GLP-1 dual receptor agonist. APL-18881 is currently in development in a Phase 2 trial for the treatment of Type 2 Diabetes (T2D). **Methods:** HEC88473-DM-101 was a single-centre, randomized, double-blind, placebo-controlled Phase 1b trial to evaluate the safety, tolerability, PK, and PD of APL-18881. This multiple ascending dose trial was conducted in participants ($n = 60$) with T2D at dose levels of 5.1 mg, 15.3 mg, 30.6 mg, 45.9 mg, and 68.0 mg. Participants received APL-18881 on a QW schedule for 5 weeks. Those treated at doses $\geq$ 30.6 mg underwent a dose titration regimen, with the dose titrated up at 1 or 2-week intervals. Assessments included fasting blood glucose (FBG) and lipids, insulin, HbA1c, adiponectin, glucagon, ALT, AST, MRI-PDFF and FibroScan. Results of the trial have been published. Here we present data for the subset of participants with baseline MRI-PDFF $\geq$ 8% ($n = 32$). **Results:** In the overall population, APL-18881 dose-dependent changes in FBG, HbA1c and adiponectin were observed, along with trends in lipid and AST/ALT changes towards higher APL-18881 dose levels. Dose-dependent changes in MRI-PDFF ($p < 0.01$ at 30.6 mg and higher) and trends in liver stiffness were also observed.

Characteristics and results in the subset of T2D participants with baseline MRI-PDFF $\geq$ 8% are summarized in Table 1. There was at least a 15% placebo adjusted difference in the change from baseline (CFB) between the 30.6 mg (-42.3%), 45.9 mg (-45.2%) and 68.0 mg (-51.6%) APL-18881 dose groups, compared to placebo (-27.2%). The proportion of participants achieving $\geq$ 30% CFB in MRI-PDFF was significantly higher in these APL-18881 groups, compared to placebo ($p < 0.05$, $p < 0.10$, and $p < 0.01$ for 30.6 mg, 45.9 mg, and 68.0 mg, respectively). Reductions in liver stiffness (CAP) were also observed across the higher APL-18881 dose groups (CFB range -10.5% to -15.9%, vs. +2.5% for placebo). **Conclusion:** APL-18881 demonstrated robust dose-dependent improvement in measures of metabolic and liver health in a Phase 1b MAD trial in participants with T2D after 5 weeks of treatment. The effects observed on MRI-PDFF and liver stiffness support the potential of APL-18881 to be an effective therapeutic in SLD.

◆ 4008 | EFFICACY OF SAROGLITAZAR IN REAL WORLD PATIENTS WITH METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE WITH COMPENSATED ADVANCED CHRONIC LIVER DISEASE

Virendra Singh[1] Jahnvi Dhar[2] Upasna Rajput[2] Nitesh Bassi[2] sandeep kaur toor[2] Himanshu Gupta[2] Rashmeet Brar[2] Amandeep Singh[2], [1]Punjab Institute of Liver and Biliary Sciences, SAS Nagar, Punjab, [2]Punjab Institute of Liver and Biliary Sciences, SAS Nagar, Punjab, India

Background: Saroglitazar, a dual PPARα/γ agonist, is useful in management of metabolic dysfunction associated steatotic liver disease (MASLD) and diabetic dyslipidemia. The data on efficacy of saroglitazar on patients with compensated advanced chronic liver disease (cACLD) is sparse. Here we report the efficacy of saroglitazar in MASLD patients with cACLD. **Methods:** Patients diagnosed as MASLD with F4 fibrosis were started on saroglitazar (4 mg) and were prospectively evaluated for 24 weeks in a tertiary care hospital. Primary outcome was reduction in Liver stiffness measurement (LSM) at 24 weeks. Secondary outcomes were assessment of improvement in Alanine transferase and triglyceride. **Results:** A total of 236 patients with cACLD were enrolled in the study out of which 74 patients were finally included in the study. Mean age was 52.4 ± 10.7 with 73% male. Thirty-two (43%) patients were diabetic and 72 % patients had body mass index of more than 25. There was significant improvement of LSM from baseline (19.2 ± 3.3) to 24 weeks (15.6 ± 2.76) ($p < 0.001$). Significant reduction in ALT and triglyceride levels ($p < 0.001$) was also seen. There was no significant change in weight. All patients very well tolerated saroglitazar. **Conclusion:** Saroglitazar is effective in improving biochemical parameters of metabolic syndrome and LSM value in patients with cACLD. Patients with cACLD tolerate saroglitazar well without progression to decompensation.

◆ 4009 | OBESE PATIENTS ON GLUCAGON-LIKE PEPTIDE-1 INHIBITORS (GLP-1) HAVE LOWER RATES OF LIVER RELATED MORBIDITY COMPARED TO BARIATRIC SURGERY PATIENTS- A NATIONWIDE RETROSPECTIVE ANALYSIS

Rama Nanah[1] Ahmed Telbany[2] Nadeem Anwar[3],
[1]Vandalia Health/Charleston Area Medical Center, [2]University of New Mexico, [3]Vandalia health CAMC

Background: Metabolic dysfunction–associated steatotic liver disease (MALD) and obesity are closely associated disorders. Obesity is an independent predictor of hepatic steatosis. Furthermore, MASLD is a progressive disease that can result in liver fibrosis and cirrhosis. Weight loss is associated with improvement in MASLD and thus, liver outcomes. GLP-1 inhibitors are emerging as a safe and reasonable alternative to bariatric surgery in assisting weight loss. We hereby aim to examine liver outcomes among obese patients undergoing bariatric surgery vs GLP-1 inhibitors. **Methods:** This study is a retrospective cohort analysis utilizing TrinetX database, which aggregates real-time patient data from participating healthcare organizations. Adult obese patients were defined by body mass index (BMI) > 30. Bariatric surgery was defined by ICD-10 code for bariatric status or procedure codes for sleeve gastrectomy or gastric bypass in the past 10 years.

Cohort was divided into obese patients with bariatric status never on GLP-1 inhibitors vs obese patients on GLP-1 inhibitors, who never had bariatric surgery. The two cohorts were propensity score matched (PSM) for baseline demographics, age, sex, race, BMI and comorbidities. **Results:** Around 217,000 adult patients were identified on GLP-1 inhibitors with no prior bariatric surgery vs 77,000 who underwent bariatric surgery in the past 10 years. GLP-1 inhibitors group were older in age (52 vs 46 years old), less predominantly female (62% vs 80%) and more likely to have co-morbidities including hypertension (HTN) (72.5% vs 54.6%), hyperlipidemia (HLD) (59% vs 33%), diabetes (DM) (67.4% vs 26.5%), ischemic heart disease (22% vs 11%), liver fibrosis and cirrhosis (2.4% vs 1.4%), alcoholic liver disease (0.79% vs 0.62%), nicotine dependance (22% vs 11%) and cerebrovascular accidents (CVA) (12.7% vs 7.1%) compared to bariatric group respectively with otherwise comparable opioid use disorders and alcohol dependance.

After PSM, GLP-1 group had significantly lower odds ratio (OR) of liver cirrhosis (OR 0.42) and decompensations including ascites (OR 0.20), hepatic encephalopathy (OR 0.25) and esophageal varices (OR 0.39). Odds were also lower for alcoholic liver disease (OR 0.12), liver failure (OR 0.22), need for liver transplant (OR 0.34) and overall mortality (OR 0.32) compared to bariatric surgery group. **Conclusion:** Obese patients on GLP-1 inhibitors had more comorbidities compared to obese patients who underwent bariatric surgery but lower odds of liver related outcomes after PSM.

◆ 4010 | SAMARA: SEMAGLUTIDE TREATMENT IN THE REAL-WORLD FOR FIBROTIC MASH IN OBESITY AND T2DM

SEMAGLUTIDE VERSUS PLACEBO IN NIT-ASSESSED MASH: A REAL WORLD PRAGMATIC MULTICENTER RANDOMIZED PLACEBO-CONTROLLED TRIAL (SAMARA), *Rohit Loomba[1] Raj Vuppalanchi[2] Mandana Khalili[3] Muhammad Sheikh[4] Joseph Risser[5] Samuel Klein[6] Egbert Madamba[5] Seema Singh[5] Harris Siddiqi[5] Diana Cortez-Moreno[5] Darryl Contrano[5] Jenna Roulan[5] Heather Hofflich[5] Ruth Abeles[5] Eduardo Grunvald[5] Ricki Bettencourt[5] Feng He[5] Sonia Jain[5] Monica Tincopa[1] Lisa Richards[1] Veeral Ajmera[5]*

[1]University of California, San Diego, [2]Indiana University, [3]University of California, San Francisco, [4]Fresno Clinical Research Center, [5]University of California San Diego, [6]Washington University School of Medicine

Background: Semaglutide has been shown to be effective in a Phase 3 study among patients with biopsy-proven MASH and stage 2 or 3 fibrosis. However, liver biopsy assessment is not routinely used to determine candidacy for starting treatment in MASH in clinical practice. Therefore, we designed a pragmatic, real-world, multicenter trial to examine the clinical utility of non-invasive tests (NIT) in determining eligibility and treatment response in patients with suspected at-risk MASH who were randomized to semaglutide versus placebo. **Methods:** In this multicenter, randomized, double-blind placebo controlled trial, we screened 202 patients across 7 sites and randomized 55 patients to either Semaglutide 2.4 mg subcutaneously once a week or placebo in individuals who either had BMI $\geq$ 27 kg/m^2 or BMI $\geq$ 25 kg/m^2 and met ADA criteria for prediabetes or type 2 diabetes mellitus and a FAST score $\geq$ 0.5 (suggestive of at-risk MASH non-invasively) and LSM by VCTE $\geq$ 8 kPa who met AASLD criteria for MASLD. The primary outcome was a change in the FAST score. Secondary outcomes included changes in body weight, MRI-PDFF, ALT, and HbA1c. **Results:** The mean (SD) age, BMI and FAST at baseline was 48.8 (14) years, 40.2 (15) kg/m^2, 0.62 (0.12), respectively. 55% were women and 20% had T2DM. The mean (SD) VCTE, CAP and AST at baseline were 11.47 (3.23) kPa, 327 (38.8) dB/m and 51.7 (20.0) U/L respectively and did not differ between treatment groups. The mean (SD) duration of treatment was 6.5 (3.7) months and was similar between treatment groups [semaglutide 6.4 (3.7) months and placebo 6.5 (3.7) months]. The mean (SD) change in FAST from baseline to the end of treatment was significantly greater in the semaglutide group, at -0.28 (0.19), compared with placebo, at −0.12 (0.17), P = 0.002. More participants in the semaglutide group than in the placebo group achieved weight reductions of 5% or more (64% vs. 8.3%), at the end of treatment (P < 0.001). Semaglutide was better than placebo in achieving a clinically meaningful MRI-PDFF response ($\geq$30% reduction), 60% vs 17%, P = 0.047. Semaglutide led to a significantly greater reduction in ALT, AST, GGT, HbA1c, and LDL cholesterol (P < 0.05, Table). The most common side effects were gastrointestinal (GI), with 50 occurring in 50% of participants in the semaglutide group, compared to 35 in 41% of participants in the placebo group (P = 0.59). Four patients discontinued treatment early in the semaglutide group versus two in the treatment group P = 0.67 and one early termination was related to GI side effects in the semaglutide group. **Conclusion:** A real-world NIT-based screening approach for semaglutide treatment is feasible and effective. FAST, ALT, AST, and MRI-PDFF can monitor treatment responses. This study provides randomized controlled data to guide clinical practice for AASLD.

◆ 4011 | DENIFANSTAT ELICITED A SIGNIFICANT &GE;2-STAGE IMPROVEMENT IN FIBROSIS IN F3 MASH PATIENTS, AND IMPROVED LIVER FIBROSIS AND BIOMARKERS IN QFIBROSIS STAGE 4 MASH PATIENTS: SECONDARY ANALYSIS OF PHASE 2B FASCINATE-2 STUDY

Rohit Loomba[1] Wen-Wei Tsai[2] Shipra Vinod Gupta[2] Katharine Grimmer[2] Eduardo Martins[2] Pierre Bedossa[3] Dean Tai[4] Marie O'Farrell[2] George Kemble[2] Madhavi Rudraraju[5] Eric Lawitz[6] Jose Cobiella[7] Mary Rinella[8], [1]University of California, San Diego, [2]Sagimet Biosciences, [3]Liverpat, Paris, France, [4]HistoIndex, [5]Pinnacle Clinical Research, [6]Texas Liver Institute, [7]Global Research Associates, [8]The University of Chicago

Background: New therapies are needed for MASH cirrhosis, particularly those that treat liver fibrosis, the primary predictor of poor clinical outcomes. Denifanstat (TVB-2640), an oral fatty acid synthase (FASN) inhibitor, demonstrated significant improvements in fibrosis and MASH resolution, and prevented progression to cirrhosis in the Ph2b FASCINATE-2 study. AI-based digital pathology, an advanced tool that complements conventional histopathology, was used to identify a subpopulation of MASH patients with advanced fibrosis, defined as qFibrosis stage 4 (qF4), and to explore liver histology improvement with denifanstat in this subset. **Methods:** 168 patients with biopsy-

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

confirmed MASH and F2/F3 fibrosis were randomized 2:1 to once daily oral denifanstat (DENI) 50 mg or placebo (PBO) for 52 weeks. Pre- and post-treatment liver biopsy slides were read by a central pathologist using MASH CRN criteria. A separate unstained slide was evaluated by second harmonic generation (SHG) AI digital pathology (HistoIndex) to identify patients with baseline qF4 (DENI n = 13, PBO n = 3). All analyses of qF4 were post-hoc. **Results:** In F3 patients, by CRN scoring the response rate for fibrosis improvement by ≥ 2 stages without worsening of MASH was 34% (16/47) for DENI vs 4% (1/23) for PBO ($p = 0.0065$). In qF4 patients, by CRN the response rate for fibrosis improvement by ≥ 1 stage without worsening of MASH was 39% (5/13) for DENI, which 4 out of 5 had ≥ 2 stages improvement, vs 0% (0/4) for PBO ≥ 1 stage. By SHG digital pathology, the response rate for ≥ 1 qFibrosis stage regression was 85% (11/13) for DENI vs. 33% (1/3) for PBO. Several biomarkers were decreased by DENI in qF4 patients (mean change at week 52 from baseline):

- DENI -29% vs. +26% PBO, FibroScan (kPa)
- DENI -21% vs. +4% PBO, CAP (Db/m)
- DENI -45% vs. +9% PBO, FAST score
- DENI -34% vs. +14% PBO, MRI-PDFF (% liver fat)
- DENI -43% vs. +5% PBO, ALT
- DENI -37% vs. -1% PBO, AST
- DENI -0.3 vs. +0.0 PBO, ELF
- DENI -26% vs. +84% PBO, CK18 (M30)
- DENI -35% vs. +40% PBO, CK18 (M65). **Conclusion:** Denifanstat demonstrated a robust anti-fibrotic effect as measured by both conventional and AI-based digital pathology. Digital pathology identified a subpopulation of MASH patients with advanced baseline fibrosis (qF4), and denifanstat reduced fibrosis and multiple NIT biomarkers that indicate improvements in steatosis, inflammation and fibrosis in this subgroup. These findings support further clinical evaluation of denifanstat in MASH patients with advanced fibrosis, including compensated liver cirrhosis.

◆ 4012 | DA-1241, A GPR119 AGONIST, DEMONSTRATES HEPATOPROTECTIVE EFFECTS THROUGH IMPROVING INFLAMMATION AND METABOLISM IN THE LIVER: A 16-WEEK RANDOMIZED PLACEBO-CONTROLLED TRIAL IN PRESUMED METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH) PATIENTS

Rohit Loomba[1] Mi-Kyung Kim[2] Hyung Heon Kim[3] Yuna Chae[2] Robert Homolka[3] Ji Eun Lee[3] Kyunghyun Lee[2] Chris Fang[3] Sung-Jin Kim[2], *[1]University of California, San Diego, [2]Dong-A ST Co., Ltd., [3]MetaVia Inc.*

Background: DA-1241 is a potent and selective agonist for G protein-coupled receptor 119 (GPR119). Non-clinical studies have shown that GPR119 agonism may have direct therapeutic potential on not only hepatic steatosis but also inflammation and fibrosis, in the pathogenesis of MASH. This phase 2a trial (NCT06054815) evaluated the efficacy and safety of DA-1241 as a potential treatment for MASH, alone and in combination with a dipeptidyl peptidase 4 inhibitor (DPP4i) to augment endogenous glucagon-like peptide-1 action. **Methods:** Total 109 subjects with presumed MASH and qualifying baseline alanine transaminase (ALT) and imaging analysis were randomized to receive DA-1241 50 mg, DA-1241 100 mg alone, DA-1241 100 mg with a DPP4i, or placebo (PBO) in a 1:2:2:2 ratio, once daily for 16 weeks. The primary efficacy endpoint was the change from baseline in ALT after 16 weeks of treatment. **Results:** In the subgroup with $40 \leq$ ALT $<$ 200 U/L at baseline, DA-1241 treatment resulted in dose-dependent reductions in ALT, with the 100 mg dose demonstrating a significant decrease of 22.8 U/L at week 16 ($p < 0.05$ vs. PBO). Accordingly, plasma inflammatory (hs-CRP, CCL2) and fibrosis (TIMP1)-related parameters significantly decreased compared to PBO ($p < 0.05$). Cytokeratin 18, a marker of hepatocyte apoptosis, was significantly decreased by 30.5% ($p < 0.05$ vs. PBO). Additionally, the mean FibroScan-aspartate aminotransferase score improved from 0.559 to 0.371, indicating reductions in liver fibrosis and steatosis. Liver fat content decreased by 23.0 dB/m in Controlled Attenuation Parameter, along with a mean relative reduction of 19.9% in Magnetic Resonance Imaging-Proton Density Fat Fraction.

In plasma lipidomic profiles, administration of DA-1241 100 mg reduced both plasma glycerolipids (DG36:4, TG52:4) and glycerophospholipids (PE38:4, PE38:5), which are known to be pathogenic lipids ($p < 0.05$ vs baseline). Notably, on top of the hepatic effects, DA-1241 100 mg rapidly and markedly lowered mean hemoglobin A1c by 0.37, 0.41, and 0.54%p at week 4, 8, and 16 from the baseline of 6.99%, despite nearly half of them being non-diabetic ($p < 0.05$ vs. PBO). Additionally, co-administration with DPP4i augmented metabolic effects without body weight loss. **Conclusion:** DA-1241 is the first oral GPR119 agonist to demonstrate both hepatoprotective and glucose-regulating effects in presumed MASH patients. These findings support its further development as a potential monotherapy or combination therapy for MASH and metabolic disorders.

◆ 4013 | MACHINE-LEARNING ENABLED GENETIC DISCOVERY, IN VIVO VALIDATION, AND LIVER-SPECIFIC THERAPEUTIC TARGETING OF IRS1 IN MASLD

David Lloyd[1] Santhosh Satapati[1] Hari Somineni[1] Colm O'Dushlaine[1] Tanaya Walimbe[1] Arijit Bhowmick[1] Sumit Mukherjee[1] Vaishaali Natarajan[1] Chinmayi Kashyap[1] Anup Sarakki[1], [1]insitro

Background: Genetic discovery in metabolic dysfunction-associated steatotic liver disease (MASLD) has been limited by the lack of scalable, clinically relevant phenotypes. To address these limitations, we: (i) used machine learning (ML) to impute liver fat (LF) from widely available data modalities, increasing sample size; and (ii) improved the precision of the phenotype by adjusting for adipose tissue volume (ATV), increasing statistical power and identifying genes with direct effects in the liver. **Methods:** We applied ML to predict LF and ATV using four data modalities from the UK Biobank: magnetic resonance imaging (MRI; n = 25,474 participants), dual-energy X-ray absorptiometry (DXA, n = 48,494), plasma metabolites (n = 82,138), and blood-based and anthropometric markers (biomarkers; n = 262,927). We conducted a genome-wide association study (GWAS) of LF for each modality, adjusting for ATV. For top targets, we identified therapeutically optimised liver-targeted small-interfering RNAs (siRNAs) and assessed their efficacy in vitro and in vivo in mice and monkeys. **Results:** GWAS identified a total of 480 genetic loci, significantly expanding the genetic architecture of LF accumulation, including the first human association of FGF21. We observed strong genetic correlation between predicted LF content across

modalities (0.79 – 0.97) and with clinical MASLD (0.73 – 0.87), with multimodal hits having the highest concordance. We identified several novel genes involved in de novo lipogenesis (DNL), including IRS1, which was the strongest novel association ($p = 2 \times 10\text{-}82$ biomarker-imputed LF adjusted for ATV) and supported across all four modalities ($p < 5 \times 10\text{-}8$). We identified a potent, selective liver-targeted GalNAc-siRNA against IRS1 (IC50~0.04 nM) that completely suppressed lipid droplet accumulation in primary human hepatocytes. Treatment of diet-induced obese mice with a single dose (0.3 – 10 mg/kg) resulted in dose-dependent reduction in hepatic IRS1 expression (85% vs. vehicle) and hepatic triglycerides (45%), improved histologic NAS score (2.2 ± 0.2 vs. vehicle 4.3 ± 0.2, $p = 0.0002$), and suppressed DNL (59%) after one month. Treatment of cynomolgus monkeys (30 – 300 mg/kg) reduced hepatic IRS1 expression by up to 70% after 15 days, without impacting glucose homeostasis. **Conclusion:** IRS1 can be effectively targeted using a liver-targeted GalNAc-siRNA demonstrating efficacy and tolerability in preclinical models of MASLD.

◆ 4014 | COMPARATIVE RISK OF HEPATIC DECOMPENSATION AND HEPATOCELLULAR CARCINOMA AMONG ANTIDIABETIC THERAPIES IN PATIENTS WITH TYPE 2 DIABETES AND CHRONIC LIVER DISEASE

Ana Verma[1] Jonggi Choi[2] Eric Przybyszewski[3] Jiunn Song[3] Allison Carroll[3] Megan Michta[3] Erik Almazan[4] Tracy Simon[3] Raymond Chung[3], [1]Harvard Medical School, [2]Asan Medical Center, University of Ulsan. Massachusetts General Hospital, [3]Massachusetts General Hospital, [4]Brigham and Women's Hospital

Background: The comparative hepatic safety, or advantage, of second-line glucose-lowering therapies in patients with type 2 diabetes (T2DM) and chronic liver disease (CLD) remains uncertain. We evaluated the association of SGLT2 inhibitors (SGLT2i), GLP-1 receptor agonists (GLP-1RA), DPP-4 inhibitors (DPP4i), and sulfonylureas with the risk of hepatic decompensation and hepatocellular carcinoma (HCC) in this population. **Methods:** We conducted a multinational retrospective cohort study using electronic health records from Mass General Brigham (United States) and Asan Medical Center (Korea). Adults (≥ 18 years) with T2DM and CLD who newly initiated SGLT2i, GLP-1RA, DPP4i, or sulfonylurea therapy between 2013 and 2023 were included. Patients with prior HCC, decompensation, or liver transplantation were excluded. The primary outcome was incident hepatic decompensation; the secondary outcome was incident HCC. Inverse probability of treatment and censoring weighting (IPTW/IPCW) was applied to balance baseline covariates. Weighted Cox proportional hazards models were used to estimate hazard ratios (HRs) with 95% confidence intervals (CIs). **Results:** Among 21,951 eligible patients, MASLD was the predominant CLD etiology (70–93%), and baseline cirrhosis was present in 3.6–7.4% across groups. After weighting, covariate balance was achieved (standard mean difference, SMD < 0.1). A total of 692 hepatic decompensation events and 291 HCC cases occurred during follow-up. SGLT2i and GLP-1RA use were each associated with a significantly lower risk of hepatic decompensation when compared with sulfonylureas (HR for SGLT2i vs SU, 0.57; 95% CI, 0.35–0.92; HR for GLP-1RA vs SU, 0.68; 95% CI, 0.48–0.97). Similar protective associations were observed when DPP4i was used as the reference for SGLT2i (HR, 0.50; 95% CI, 0.31–0.81) and GLP-1RA (HR, 0.60; 95% CI, 0.42–0.85). No significant difference was observed between SGLT2i and GLP-1RA (HR, 1.20; 95% CI, 0.69–2.10), suggesting comparable effectiveness. For HCC, SGLT2i and GLP-1RA use were each associated with significantly lower risk compared with sulfonylureas (HR for SGLT2i vs SU, 0.47; 95% CI, 0.23–0.97; HR for GLP-1RA vs SU, 0.07; 95% CI, 0.03–0.19). **Conclusion:** In patients with T2DM and CLD, use of SGLT2i or GLP-1RA was associated with a significantly lower risk of hepatic decompensation and HCC compared to sulfonylureas and DPP4i. These findings support the preferred use of SGLT2i or GLP-1RA in this high-risk population.

◆ 4015 | VITAMIN E DOSING STUDY (VEDS) IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A RANDOMIZED-PLACEBO CONTROLLED TRIAL

Srinivasan Dasarathy[1] Emily Mitchell[2] Laura Wilson[2] Bilal Hameed[3] Brent Neuschwander-Tetri[4] Rohit Loomba[5] Ayako Suzuki[6] Liyun Yuan[7] Naga Chalasani[8] Jeanne Clark[9] Kris Kowdley[10] Arun Sanyal[11], [1]Cleveland Clinic, [2]Johns Hopkins University, [3]UCSF, [4]SLU, [5]University of California, San Diego, [6]Duke University, [7]University of Southern California, [8]Indiana University Medical Center, [9]Rutgers RWJ Medical School, [10]Liver Institute Northwest, [11]Virginia Commonwealth University

Background: The NASH CRN PIVENS study showed that 800 IU natural vitamin E (d-alpha-tocopherol) daily was more effective than placebo in resolving MASH. However, safety concerns with higher doses of vitamin E and lack of data on lower doses have limited its wide-scale use for treating MASH. The Vitamin E Dosing Study (VEDS) was a multicenter, randomized, placebo-controlled, dose-ranging trial to determine the efficacy and safety of lower doses of natural vitamin E on serum ALT levels over 24 weeks. **Methods:** Subjects $\geq$18 years with MASLD and controlled attenuation parameter (CAP) $>$280 dB/m and ALT $\geq$60 U/L were randomized to 24 weeks of once daily vitamin E (200, 400, or 800 IU [Pharmavite]) or placebo. Major exclusions were vitamin E or anticoagulant use and HbA1c $>$9.5%. Primary outcome was relative change from baseline in mean ALT at 24 weeks with the 3 doses of vitamin E vs placebo using analysis of covariance (ANCOVA). Secondary outcomes included changes in other liver tests, CAP and liver stiffness, and adverse events. **Results:** 200 participants were randomized. The 4 groups were well matched for sex (62% male), mean age (47.0 years), ALT (89 U/L), BMI (34.5 kg/m^2), and frequency of diabetes (31%) and dyslipidemia (48%). 192 patients (96%) completed the 24-week visit. All 3 doses of vitamin E significantly reduced mean ALT vs. placebo (-12%): 200 IU (-37%), 400 IU (-36%), and 800 IU (-36%) (all P $<$ .01) with no evidence of a dose response (Table 1). Reductions in ALT by $>$20% occurred in 43% on placebo vs 83% on 200 IU, 73% on 400 IU, and 75% on 800 IU of vitamin E. AST levels were also reduced in all vitamin E groups vs. placebo ($p < 0.01$), but changes in alkaline phosphatase, GGT, and BMI did not differ between vitamin E and placebo. While CAP scores and liver stiffness declined more in patients on vitamin E than placebo, the differences were not significant. Overall, adverse event rates were similar between the vitamin E and placebo groups. **Conclusion:** In MASLD patients, natural vitamin E at 200 IU once daily resulted in significant reductions in serum ALT levels similar to those treated with higher doses. After 24 weeks of treatment, there was a trend in improvements in liver fat and stiffness. Longer-term trials of natural vitamin E using doses of 200 IU and lower in patients with steatotic liver disease to evaluate its safety and efficacy further are warranted.

Table 1. Primary and secondary outcomes after 24 weeks of treatment (N=192)

	Placebo	Vitamin E 200 IU	Vitamin E 400 IU	Vitamin E 800 IU	P 200 IU vs. Plbo.	P 400 IU vs. Plbo.	P 800 IU vs. Plbo
N with Primary Outcome	46	49	49	48			
Primary Outcome: Relative change in ALT(U/L) (24 wks-BL) - %*	-12.2 (33.4)	-38.4 (31.9)	-36.3 (31.1)	-36.4 (43.1)	<0.0001	<0.0001	0.001
Secondary Outcomes– 24 wks-BL							
ALT % decrease ≥20%	20 (43%)	40 (82%)	36 (73%)	36 (75%)	0.0003	0.004	0.002
Mean change in ALT (U/L)	-12.4 (33.5)	-42.3 (42.4)	-43.5 (48.8)	-42.9 (58.5)	<0.0001	<0.0001	<0.0001
Mean change in AST (U/L)	-3.3 (20.3)	-22.1 (32.9)	-24.4 (46.4)	-23.7 (31.7)	<0.001	0.009	<0.0001
Mean change in GGT (U/L)	-19.8 (63.8)	-9.4 (47.1)	-25.1 (53.0)	-17.0 (27.4)	0.25	0.24	0.35
Mean change in Controlled Attenuation Parameter (CAP) (dB/m)	-11.2 (45.8)	-26.0 (46.3)	-9.0 (41.2)	-20.1 (47.3)	0.04	0.94	0.50
Mean change in Liver Stiffness Measure (LSM) (kPa)	0.4 (4.5)	-0.7 (4.7)	-1.2 (4.3)	-2.7 (7.5)	0.92	0.39	0.10
Mean change in BMI (kg/m2)	-0.2 (2.4)	-0.9 (2.7)	-0.6 (2.0)	-0.3 (1.7)	0.16	0.39	0.76

Data are mean (SD) or N(%).
*P values for mean change from baseline were calculated using ANCOVA, regressing change from baseline to 24 weeks on treatment group and clinical center. P values for categorical variables were calculated using the Cochran-Mantel-Haenszel chi-square test, stratified by clinic. Per protocol, complete case analysis used since <10% missing primary outcome.

◆ 4016 | SGLT2 INHIBITORS SUPPRESSED THE ONSET OF EXTRAHEPATIC CANCER COMPARED TO DPP4 INHIBITORS IN TYPE 2 DIABETIC PATIENTS WITH MASLD: A NATIONWIDE MEDICAL CLAIMS DATABASE STUDY IN JAPAN

Takumi Kawaguchi[1] Yoshiyuki Fujishima[2] Fusayo Io[2] Yuri Sato[2] Saeko Uchida[2] Yukiko Kitajima[2], [1]Kurume University School of Medicine, [2]Taisho Pharmaceutical Co., Ltd.

Background: Extrahepatic cancer is one of the main causes of death in patients with MASLD. Sodium-glucose transporter 2 inhibitors (SGLT2i), anti-diabetic medication, have been reported to improve MASLD in patients with type 2 diabetes mellitus (T2DM). We aimed to investigate the impact of SGLT2i on the incidence of extrahepatic cancer compared with dipeptidyl-peptidase 4 inhibitors (DPP4i) in T2DM patients with MASLD using a nationwide medical claims database in Japan. **Methods:** We conducted a retrospective cohort study using the Medical Data Vision database. From T2DM patients prescribed SGLT2i or DPP4i (n = 1,628,656), eligible patients were classified into SGLT2i (n = 4,204) and DPP4i (n = 4,204) groups after adjustment by propensity score matching using 67 covariates. Effects of SGLT2i on the incidence of cardiovascular events and extrahepatic cancer were compared to DPP4i during 12 months. **Results:** At baseline, both the SGLT2i and DPP4i groups had a mean age of 62 years and a same sex distribution. There was no significant difference in the use of other anti-diabetic medications between the SGLT2i and DPP4i groups. No significant differences were observed in HbA1c levels, ALT levels, or FIB-4 index between the two groups.

Outcomes: There was no significant difference in the incidence of cardiovascular events between the SGLT2i and DPP4i groups. However, SGLT2i significantly reduced the incidence of extrahepatic cancer compared to DPP4i (HR 0.5, 95%CI 0.30-0.84). Kaplan–Meier curve also demonstrated a significant reduction in the probability of extrahepatic cancer in the SGLT2i group compared to the DPP4i group. We further performed a stratified analysis to identify patients' characteristics associated with SGLT2i-caused suppression of the incidence of extrahepatic cancer. SGLT2i significantly suppressed the incidence of extrahepatic cancer in patients aged ≥65 years, ALT >30 U/L, FIB-4 index ≥1.3, eGFR <60 mL/min/1.73m^2, HbA1c <7.0%, and triglyceride ≥150 mg/dL. **Conclusion:** SGLT2i was more beneficial than DPP4i in suppressing the

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

incidence of extrahepatic cancer compared to DPP4i in T2DM patients with MASLD. This cancer-suppressing effect was more evident in patients with advanced age, hepatitis, liver fibrosis, chronic kidney disease, mild diabetes, and hypertriglyceridemia. Thus, SGLT2i may be beneficial to improve the prognosis of patients with T2DM and MASLD through inhibition of the onset of extrahepatic cancer.

◆ 4017 | EFFECT OF BARIATRIC SURGERY, GLP-1 RA, AND SGLT2I ON COMPOSITE LIVER EVENTS IN NON-CIRRHOTIC MASLD PATIENTS: A RETROSPECTIVE COHORT STUDY

Diwanshu Soni[1] Leith Ghani[1] Majd Aboona[1] Pooja Rangan[1] Derek Scholes[1] Chih-Hua Chung[1] Mark Wong[1] Karn Wijarnpreecha[2] Rohit Nathan[1] Moises Nevah Rubin[1] Michael Fallon[1] Farah Husain[1] Ma Ai Thanda Han[3], [1]University of Arizona College of Medicine - Phoenix, [2]University of Arizona College of Medicine-Phoenix, [3]University of Arizona College of Medicine Phoenix

Background: Globally, metabolic dysfunction-associated steatotic liver disease (MASLD) emerged as a leading cause of chronic liver disease, contributing to cirrhosis and its complications, hepatocellular carcinoma (HCC), and liver transplant. Bariatric surgery, GLP-1 receptor agonists (GLP-1 RA), and SGLT2 inhibitors (SGLT2i) have each demonstrated efficacy in reducing disease progression, however comparative analysis of their effects in composite liver events is lacking in the literature. This study compares these interventions' effect on the incidence of composite liver events in MASLD patients without cirrhosis at intervention. **Methods:** This multicenter retrospective cohort study conducted at Banner Health evaluated the effect of specific interventions on MASLD patients without cirrhosis at intervention, who were identified with ICD codes. The patients received the following interventions and were followed for at least 12 months post intervention: bariatric surgery, GLP-1 RA, SGLT2i, or combination therapies. Composite liver events were defined as follows: 1. New Onset of Cirrhosis, 2. LREs- ascites, hepatic encephalopathy, or esophageal varices, 3. Hepatocellular carcinoma (HCC), and 4. Liver transplant 12 months post intervention. Medication reconciliation was done to verify medication use, while bariatric procedures were confirmed via ICD codes. Competing risk analysis evaluated the incidence of liver events across treatment groups using bariatric surgery as reference, while adjusting for confounders. A Kaplan-Meier survival curve was generated to depict composite liver event free survival. **Results:** The study cohort comprised of 13,694 patients of which 4.8% underwent bariatric surgery, 45.6% received GLP-1 RA, 26.5% SGLT2i therapy, and 23.1% combination therapy. Among this cohort, multivariate and univariate analysis show bariatric surgery treatment group had statistically significant lower rates of composite liver events — new onset cirrhosis, LREs, HCC and liver transplant — 12 months post treatment compared to the GLP1-RA, SGLT2i and combination therapy groups (Table 1). Kaplan-Meier survival analysis demonstrated superior composite liver event free survival in the bariatric surgery group (Figure 1). **Conclusion:** The findings suggest that in MASLD patients without cirrhosis, bariatric surgery performs better than GLP1-RA, SGLT2i or combination therapy in lowering composite liver events 12 months post intervention even when adjusting for confounding factors. Future studies should use prospective cohort study design to investigate the mechanisms driving the impact of these therapies, strengthen temporal associations, and address retrospective cohort study limitations.

Table 1

Intervention	Composite Liver Events in Non-Cirrhotic MASLD Patients			
	HR (95% CI)	p-value	aHR (95% CI)	p-value
Bariatric Surgery	Reference			
Glucagon-Like Peptide-1 Agonist (GLP-1 RA)	3.28 (2.22-4.85)	0.000	2.25 (1.47-3.45)	0.000
Sodium-Glucose Cotransporter 2 Inhibitor (SGLT2i)	3.23 (2.15-4.88)	0.000	2.25 (1.43-3.54)	0.000
Combination Therapy	2.34 (1.58-3.45)	0.000	1.74 (1.13-2.66)	0.011

◆ 4018 | PRECLINICAL CHARACTERIZATION OF CVI-2742: A HIGHLY SELECTIVE, LIVER-TARGETED THR-β FULL AGONIST WITH ROBUST EFFICACY AND SAFETY IN MASH MODELS

Jingwen Liu[1] Dafang Zhong[2], [1]CVI Pharmaceuticals Shanghai Limited, [2]LVI Pharmaceuticals Shanghai Limited

Background: Thyroid hormone receptor beta (THR-β) selective agonists represent a breakthrough in metabolic dysfunction-associated steatohepatitis (MASH) treatment, with Resmetirom (MGL-3196) being the first FDA-approved THR-β agonist that avoids cardiac THR-α activation. Building on this, CVI-2742 is a next-generation, highly potent, liver-targeted THR-β full agonist designed to exhibit superior hepatic specificity and efficacy. This study comprehensively evaluates the preclinical profile of CVI-2742, including its in vitro potency, pharmacodynamic (PD) and pharmacokinetic (PK) properties, and toxicological safety, to establish its potential as a best-in-class therapeutic candidate for MASH. **Methods:** CVI-2742 was characterized through a series of in vitro and in vivo assays. In vitro efficacy was assessed using: (1) a cell-free coactivator binding assay, (2) a thyroid response element (TRE)-luciferase reporter assay in HEK293 cells, (3) an OATP1B1 co-expression reporter assay to evaluate liver transporter-mediated uptake, and (4) qPCR-based gene expression analysis in Huh-7 cells. In vivo efficacy was evaluated in a high-fat diet (HFD)-CCl4-induced DIO mouse model of MASH and a hyperlipidemic mouse model to assess lipid-lowering effects. PK studies included single- and multiple-dose assessments in mice, rats, and beagle dogs, with tissue distribution analyzed via LC-MS/MS. Liver targeting was further examined in mice, rats, and cynomolgus monkeys. Four-week repeat-dose toxicity studies were conducted in rats and dogs to evaluate safety margins. **Results:** CVI-2742 demonstrated potent THR-β agonism with an EC_{50} of 8.6 nM and 100% maximal T3 activity, while showing minimal THR-α activation (EC_{50} = 507 nM), yielding a 65-fold β-selectivity. OATP1B1 co-expression enhanced THR-β activation by 26-fold (EC50 = 13 nM vs. 333 nM without OATP1B1), confirming liver-specific uptake. In the HFD-CCl4 mouse model, C2742 resolved steatohepatitis and reduced fibrosis at a minimal effective dose (MED) of 0.5 mg/kg. In hyperlipidemic mice, it significantly lowered LDL-c (44.2%) and liver index (13.2%) at 0.17 mg/kg. Tissue distribution studies revealed exceptional liver targeting, with liver-to-plasma ratios of 37.9 (mouse), 58.2 (rat), and 54.9 (monkey). Toxicology studies in beagle dogs showed no adverse effects at 15 mg/kg (4-week dosing), indicating a safety window exceeding 60-fold. No histopathological abnormalities or organ weight changes were observed. **Conclusion:** CVI-2742 exhibits best-in-class potential as a liver-targeted THR-β full agonist, combining high potency, robust hepatic selectivity, and an outstanding safety profile. Its ability to ameliorate MASH pathology and dyslipidemia at low doses, coupled with favorable PK and toxicology data, strongly supports its advancement into clinical trials for MASH therapy.

◆ 4019 | A 5-WEEK TREATMENT WITH RETATRUTIDE STRONGLY REDUCES LIVER FAT CONTENT AND SHOWS MULTIPLE METABOLIC BENEFITS IN DIET-INDUCED OBESE MASH MOUSE AND HAMSTER MODELS

Francois Briand[1] Estelle Grasset[1] Natalia Breyner[1] Claire Bigot[1] Thierry Sulpice[1], [1]Physiogenex

Background: Retatrutide (RETA) is a novel GIP/GLP-1/glucagon receptors triple agonist that demonstrated significant body weight loss and liver fat reduction in patients with obesity. Our aim was to evaluate the effectiveness of RETA in diet induced obese MASH mouse and hamster models, two preclinical models that we routinely use for assessing new therapies targeting obesity and MASH. **Methods:** To induce obesity and MASH in both models, C57BL/6JRj male mice were fed a modified AMLN-diet for 35 weeks. Male golden Syrian hamsters were fed a 20-week free choice diet, which presents hamsters with a choice between control chow diet or high fat/cholesterol diet, and normal water or 10% fructose water. Both models were then treated with vehicle or RETA 15nmol/kg Q3D for 5 weeks. **Results:** In mice, RETA strongly reduced body weight by 31% ($p < 0.0001$ vs. vehicle) which was associated with significant reduction in fat and lean mass, a strong inhibition of food and water intake during the first days of treatment, and a significantly greater energy expenditure at the end of treatment. RETA significantly reduced fasting glycemia and plasma insulin, leading to a 69% lower HOMA-IR index of insulin resistance

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

($p < 0.0001$) and strongly reduced hepatic fatty acids, triglycerides and total cholesterol content (-66%, -75% and 45%, all $p < 0.001$). Although it did not reduce hepatic inflammation and portal fibrosis, histology analysis also showed a 2-fold lower steatosis score with RETA ($p < 0.0001$).
In hamsters, RETA altered food preference with greater chow diet intake and lower high fat/cholesterol diet and 10% fructose water intake. Compared with vehicle, the significant weight loss was associated with significant reduction in fat and lean mass, but the lean mass was not different after 5 weeks of treatment. RETA had no effect on bone density/microarchitecture as evaluated by μ-CT. RETA reduced HOMA-IR by 81% ($p < 0.0001$ vs. vehicle) and markedly improved dyslipidemia with significantly reduced plasma free fatty acids and triglycerides, lower VLDL- and LDL-cholesterol levels but unchanged HDL-cholesterol levels. As in mice, a 5-week treatment with RETA was not sufficient to reduce histopathological scoring, but there was a 50% reduction in hepatic triglycerides content ($p < 0.01$). **Conclusion:** RETA reduces liver fat content and shows multiple metabolic benefits in both mice and hamster models. Our preclinical setting will help to assess the efficacy of new therapies versus RETA as a reference. **Disclosures:** Francois Briand: Physiogenex: Employee, Physiogenex: Stock – privately held company, Estelle Grasset: Nothing to Disclose, Natalia Breyner: Nothing to Disclose, Claire Bigot: Nothing to Disclose, Thierry Sulpice: Nothing to Disclose

◆ 4020 | SAROGLITAZAR TREATMENT REDUCED SEVERITY OF MASLD PHENOTYPES BY LIPIDOMIC-BASED TEST OWLIVER IN SUBJECTS WITH MASLD IN A 16-WEEK PHASE 2 TRIAL

Cristina Alonso[1] Ibon Martinez-Arranz[1] Deven Parmar[2] Naga Chalasani[3] Samer Gawrieh[3], [1]Rubio Metabolomics, [2]Zydus Therapeutics INC, [3]Indiana University Medical Center

Background: Saroglitazar magnesium, a dual peroxisome proliferator activated receptor-α/γ agonist, improves ALT, liver fat content, insulin resistance, atherogenic dyslipidemia and reduces cardiovascular risk in patients with MASLD/MASH. OWLiver is a lipidomics-based test that allows non-invasive discrimination of different MASLD phenotypes [steatosis, MASH or MASH with significant fibrosis (at-risk MASH)]. This study aimed to evaluate the evolution of MASLD phenotypes in patients with MASLD treated with Saroglitazar based on the diagnostic panel OWLiver. **Methods:** OWLiver test was analyzed in 96 participants of the Evidences IV Phase 2 clinical trial that received different daily doses of Saroglitazar (1 mg, 2 mg or 4 mg) or placebo for 16 weeks (NCT03061721). The OWLiver test was used to further evaluate the efficacy of Saroglitazar on MASLD evolution from baseline to end of treatment (EoT) visits. The Z-test was used to assess differences in the proportion of patients with an improved or worsened diagnosis between arms. **Results:** At baseline, 73% of the analyzed patients had at-risk MASH, while the rest of patients were diagnosed with steatosis or MASH (13.5% of patients in each case) by OWLiver. On assessing the effect of interventions by comparing baseline and EoT diagnoses, most placebo-treated patients maintained their initial diagnosis (84%). Saroglitazar treatment led to favorable disease evolution in a 41% of patients, especially regarding 1mg [35% of subjects with improved diagnosis ($p = 0.016$ *vs.* Placebo), with no patients showing worsening (n.s.)] and 4mg doses [58% of improved diagnoses ($p < 0.001$ *vs.* Placebo) and no worsenings (n.s.)] (Figure: Sankey Plots). Saroglitazar 2mg patients showed both improved (29%) and worsened (14%) diagnoses (n.s. in comparison to Placebo). **Conclusion:** Most patients treated with Saroglitazar 4 mg regressed to less severe MASLD phenotypes after 16-weeks treatment. Evaluation of the effects of Saroglitazar on MASLD/MASH using OWLiver test provides further evidence supporting the beneficial effects of the intervention, especially the 4mg dose.

4021 | CARDIOMETABOLIC RISK FACTORS ARE HIGHLY PREVALENT AND UNDERTREATED IN MASLD WITH ADVANCED LIVER FIBROSIS-ANALYSIS OF A LARGE REGIONAL VETERANS' AFFAIRS COHORT

Suria Devarapalli[1] Srikanth Vallurupalli[1] Timothy Morgan[2] Ragesh Thandassery[1], [1]Central Arkansas Veterans Healthcare System & University of Arkansas Medical Science, [2]VA Long Beach Healthcare System

Background: Metabolic dysfunction associated steatotic liver disease (MASLD) is the most common chronic liver disease in the US. In this study, we analyzed the cardiometabolic risk characteristics of veterans with MASLD in South Central Veterans Affairs (VA) Health Care Network (VISN-16), a region with the highest obesity prevalence in the US. **Methods:** A retrospective cohort study was conducted using data from the Veterans Health Administration. We identified 315,578 veterans with MASLD for the fiscal year 2024 (alcohol liver disease excluded). Veterans with BMI above 30 (37.1%) and advanced liver fibrosis (3.3%) were included and those with decompensated cirrhosis excluded. Fibrosis-4 (FIB-4) score >2.67 was used to identify advanced liver fibrosis (age capped at 65 for FIB-4 calculation). To determine age related differences, patients were grouped based on age $\leq$ 65 and $>$ 65 years. Atherosclerotic cardiovascular disease (ASCVD) risk scores were calculated for those between 40 and 75 years of age. **Results:** 4107 veterans met inclusion criteria. Median age was 67 (61-72) years, 94.6% males, 72.4% Caucasian (17.9% African American). Median BMI was 33.5 (IQR 31.6-36.6). 51.2% had diabetes mellitus (DM) and 20.8% prediabetes. 35.8% had a diagnosis of cardiovascular disease (CVD), and 37.9% had metabolic syndrome as defined by the National Cholesterol Education Program ATP III ($\geq$ 3 criteria). As expected, veterans >65 years had higher prevalence of DM, CVD and higher 10-year ASCVD risk (Table 1). 61.4% were on HMG-CoA reductase inhibitors (statins). 56.1% had high ASCVD risk and 24.1% had intermediate ASCVD risk. Only 34.1% with high ASCVD risk received high intensity statin and 28.3% with intermediate risk received high intensity statin. 33.3% with high ASCVD risk and 45.8% with indeterminate ASCVD risk received no statins. A significant number of veterans with intermediate/high ASCVD risk, specifically those <65 years were not receiving statins. Similarly, when used, the intensity of statin therapy was often lower than that recommended for the degree of ASCVD risk. **Conclusion:** Statin treatment is significantly underutilized and underdosed in this high-risk advanced liver fibrosis cohort, likely reflecting the commonly held misconceptions regarding safety of statins in liver disease. System wide educational efforts are needed to improve ASCVD risk factor modification and adequate use of statins since CVD is the most important cause of death in MASLD.

Table 1

Comparison of veterans with MASLD and advanced liver fibrosis

4022 | TRANSCRIPTOMIC PROFILING IDENTIFIES STATIN-ASSOCIATED MODULATION OF AGING AND FERROPTOSIS PATHWAYS IN MASLD

David Umbaugh[1] Kuo Du[1] Rajesh Dutta[1] Liuyang Wang[1] Georgia Sofia Karachaliou[1] Manal Abdelmalek[2] Ayako Suzuki[1] Anna Mae Diehl[1], [1]Duke University, [2]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease, with aging as a key risk factor. Cellular senescence, a hallmark of aging, contributes to hepatic inflammation and fibrosis via the senescence-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

associated secretory phenotype (SASP). Ferroptosis, an iron-dependent form of regulated cell death, has also been implicated in liver injury and may intersect with aging-related processes in MASLD. While both senescence and ferroptosis have been linked to MASLD progression, the effects of statins on these pathways remain unclear. Age and sex influence MASLD risk and treatment response, yet their interactions with senescence and ferroptosis are poorly understood. In this study, we analyzed bulk RNA sequencing data from 368 obese patients with and without MASLD to investigate transcriptomic signatures of aging, senescence, and ferroptosis. We further assessed how statin use modulates these pathways across age (≤ 50 vs > 50 years) and sex (male vs female) strata to better understand context-specific effects of statin therapy. **Methods:** Gene signature scores were calculated using gene set variation analysis (GSVA) on bulk RNA-seq data. Pathway enrichment and differential expression analyses were performed by stratifying patients by age, sex, and through propensity score matching to adjust for demographic variables. **Results:** Across the full cohort, statin use was associated with increased cholesterol homeostasis and reduced gene signatures of cellular senescence, DNA damage, and oxidative stress–induced senescence. The most enriched pathways across all subgroups (old, young, male, female) included cholesterol biosynthesis, lipid homeostasis, the farnesyl diphosphate metabolic process, and SREBF/miR-33 regulatory networks. Hierarchical clustering revealed that transcriptomic profiles of males and older individuals were more similar, while those of younger patients more closely resembled females. Notably, in both male and female statin users, the ferroptosis signature positively correlated with age. **Conclusion:** Statin use is linked to reduced senescence and enhanced lipid homeostasis in MASLD, with effects consistent across subgroups. However, age- and sex-related differences in transcriptomic profiles, particularly in ferroptosis, suggest context-specific modulation of liver aging by statins.

4023 | INCRETIN MIMETIC THERAPY IN PATIENTS WITH MASLD IS ASSOCIATED WITH EARLY BODY COMPOSITION CHANGES WITH BLUNTING OF DIFFERENCES WITH LONGER-TERM TREATMENT

Oscar Shaver[1] Renwei Wang[1] Jessica Izenas[1] Olivia Popovich[1] Trevor Dean[1] Olivia Hansol Lee[1] Jian-Min Yuan[1] Jaideep Behari[1], [1]University of Pittsburgh

Background: Incretin mimetics benefit patients with metabolic dysfunction-associated steatotic liver disease (MASLD), promote weight loss and lower blood glucose. This study aimed to assess the impact of incretin mimetic therapy on body composition and muscle function in a cohort of patients with MASLD. **Methods:** The study prospectively enrolled 729 patients with MASLD from a subspecialty MASLD clinic in the mid-Atlantic U.S. between 2021 and 2025. Demographic and clinical data were collected at baseline and at Year 1 (Y1) follow-up. At each visit, subjects completed dietary and physical activity questionnaires. Hepatic steatosis and liver fibrosis stage were determined by Transient Elastography, body composition by bioelectrical impedance analysis, and muscle strength by a hand-held dynamometer. 61 of the 729 subjects were on incretin mimetic therapy (treated) for Type 2 diabetes beginning before baseline through Y1 visit. We compared this cohort to 61 subjects with MASLD not on incretin mimetic therapy who were matched by age (± 5 years), sex, and body mass index (BMI, ± 5 kg/m^2). **Results:** The treated and control cohorts were well matched at baseline (all p values = ns) for age (mean 57 years), sex (67% female) and race (97% vs 93% White), and similar in BMI (35.2 vs 35.7 kg/m^2), liver stiffness measurement (mean 11.1 vs 11.8 kPa), Fibrosis-4 index (1.4 vs 1.5), ALT (40 vs 36 U/L), platelet count (242 vs 250 x10^3/L), waist circumference (113 vs 116 cm), skeletal muscle mass (31 vs 33 kg), body fat mass (42 vs 43.6 kg), percent body fat (43 vs 42%), and hand grip strength (25.2 vs 25.7 kg). The change from the baseline to Y1 visit between the two cohorts was significant in muscle mass (-3.14 vs -1.06%, $p = .049$) and borderline significant in body weight (-3.41 vs -.89%, $p = .06$). In subgroup analysis, the change between treated and their matched controls was significant in BMI (-1.77 vs +.74 kg/m^2, $p < .01$), weight (-5.49 vs +1.33 kg, $p < .01$), muscle mass (-4.53 vs -.48%, $p < .01$), and body fat mass (-3.31 vs +1.59 kg, $p = .01$) among subjects with < 1 y of incretin mimetic therapy initiation prior to baseline (median total duration from initiation to Y1 visit was 1.4 years). Conversely, no significant change was observed among those treated for ≥ 1 years prior to baseline (median total duration 3.4 years). **Conclusion:** In patients with MASLD, significant body composition changes occurred in the first 1-2 years on incretin mimetic therapy but not afterward.

4024 | ANTISENSE-MEDIATED UPREGULATION OF HNF4α AS A POTENTIAL THERAPEUTIC STRATEGY FOR LIVER FIBROSIS

Lingdi Zhang[1] Terry Lin[1] Surendra Jian[1] Jian Li[1] Rich Thai[1] Lansha Peng[1] Xing xian Yu[1] Yanfeng Wang[1] Xuehai Liang[1], *[1]ARNATAR THERAPEUTICS INC*

Background: Hepatocyte nuclear factor 4 alpha (HNF4α) is a master regulator of hepatic gene expression and plays a critical role in maintaining metabolic homeostasis. Downregulation of HNF4A is observed in various metabolic disorders and contributes to disease pathogenesis. Although increasing HNF4α expression via mRNA or AAV delivery has demonstrated therapeutic benefit in NASH and fibrosis mouse models, there remains an unmet need for alternative strategies that can safely and effectively elevate HNF4α protein levels. **Methods:** We applied our Antisense-Coupled Translation Upregulation (ACT-UP1) platform to design antisense oligonucleotides (ASOs) targeting the 3′ UTR of *HNF4A* to enhance translational efficiency. Upregulation of HNF4α protein was assessed following ASO treatment in Hep3B cells or primary hepatocytes, with protein levels measured via Western blot or ELISA. In vivo, BALB/c mice received two subcutaneous ASO doses, and liver HNF4α protein level was analyzed by Western blot. In disease models, ASOs were administered weekly, followed by evaluation of HNF4α protein and disease-related markers through Western blot. The expression of downstream target genes was quantified using qRT-PCR. Tolerability studies were performed in BALB/c mice. **Results:** These ASOs enhanced HNF4α protein expression by approximately 50–150% in both human and murine cells. Importantly, HNF4α protein was increased after ASO treatment up to 2 fold in mouse liver. The upregulation of HNF4A in the liver in BALB/c mice can last at least 3 weeks. In different liver fibrosis mouse models, subcutaneous ASO administration increased hepatic HNF4α protein levels up to two-fold, accompanied by upregulation of HNF4α-regulated genes and improved disease phenotypes. **Conclusion:** These results indicate that ACT-UP ASO can increase HNF4A both in vitro and in vivo. The increased protein appeared functional. Given the advantages of ASO as a drug, these findings support ACT-UP1 ASO-mediated HNF4α upregulation as a novel therapeutic strategy for liver fibrosis and associated metabolic diseases.

4025 | RNA EDITING OF PNPLA3 I148M DECREASES HEPATOCYTE FAT CONTENT

Ginnie Yang[1] Chikdu Shivalila[1] Pachamuthu Kandasamy[1] Stearne Briem[1] Michael Byrne[1] Alyse Faraone[1] Naoki Iwamoto[1] Tomomi Kawamoto[1] Richard Looby[1] Frank Favaloro[1] Stephany Standley[1] Suma Veeramachineni[1] Hailin Yang[1] Yuan Yin[1] Hui Yu[1] Genliang Lu[1] Chandra Vargeese[1] Erik Ingelsson[1], *[1]Wave Life Sciences*

Background: The *PNPLA3 I148M* variant disrupts PNPLA3 function and hepatic lipid metabolism and is associated with substantially increased risk of liver disease, including MASH and hepatic steatosis. We have developed RNA editing oligonucleotides, or AIMers, that are designed to edit *PNPLA3 I148M* transcripts and restore functional protein. Emerging evidence showing that PNPLA3 plays an important role in hepatic lipid metabolism suggests that an RNA editing approach that restores PNPLA3 protein function may be preferable to silencing *PNPLA3* expression to treatment. **Methods:** We synthesized GalNAc-conjugated chemically modified AIMers to edit the I148M variant using endogenous adenosine deaminase acting on RNA (ADAR) enzymes. GalNAc-AIMer editing efficiency was quantified in concentration-response experiments in human primary hepatocytes. The impact of editing or silencing (with GalNAc-siRNA) on intracellular lipid droplet density was evaluated using the human HEPATOPAC system. Transgenic mice expressing human wild-type *PNPLA3* (148I) were dosed subcutaneously with GalNAc-AIMers, and tissue concentrations in liver were quantified by ELISA after one week. **Results:** We evaluated chemically modified PNPLA3 GalNAc-AIMers in human homozygous *PNPLA3 I148M* primary hepatocytes. The most effective AIMers directed potent (EC_{50} ~15 nM) and efficient (>60%) editing of *PNPLA3* transcripts. In a human HEPATOPAC system with homozygous I148M hepatocytes, PNPLA3 GalNAc-AIMers significantly decreased lipid droplet density (>50%) compared to mock treatment or a GalNAc-siRNA designed to silence expression of *PNPLA3* ($p < 0.0001$). In a human HEPATOPAC system with homozygous wild-type *PNPLA3* hepatocytes, GalNAc-siRNA-mediated silencing significantly increased lipid

droplet density (3 to 5-fold, $p < 0.001$) compared to controls, consistent with PNPLA3 playing an important role in lipid homeostasis. In mice expressing wild-type *PNPLA3*, GalNAc-AIMers dosed subcutaneously reached 500-1,000 mg/g in liver, concentrations expected to yield substantial RNA editing based on experiments in hepatocytes. **Conclusion:** These data demonstrate that AIMers supporting potent and efficient *PNPLA3 I148M* editing decrease fat content in hepatocytes, and editing to restore PNPLA3 function outperforms *PNPLA3* silencing. Overall, these data support continued advancement of AIMers for the treatment of *PNPLA3 I148M* liver disease.

4026 | COVID-19 VACCINE LOWERS THE RISK OF ADVERSE HEPATIC OUTCOMES IN PATIENTS WITH NAFLD: A POPULATION-BASED COHORT STUDY

Hang Dong[1] Xiude Fan[1], [1]Shandong Provincial Hospital

Background: Non-alcoholic liver disease (NAFLD) affects approximately 30% of the global population. However, approved pharmacological interventions are still lacking. COVID-19 can cause liver injury, aggravate metabolic disorders, and increase the mortality rate of NAFLD. Previous studies have demonstrated that the COVID-19 vaccine has cardiovascular benefits beyond the prevention of COVID-19. However, there remains a lack of clinical evidence regarding whether the COVID-19 vaccine can improve the prognosis of NAFLD. **Methods:** This retrospective cohort study was conducted based on the Optimum Patient Care Research Database (OPCRD), an electronic medical record database covering 22% of the population of the UK, and includes information on demographics, diagnoses, and prescriptions. According to the prescriptions, patients with NAFLD were divided into the COVID-19 vaccinated group and the non-vaccinated group. The primary outcome was severe NAFLD, which was defined as a composite outcome, including chronic hepatitis, cirrhosis, hepatocellular carcinoma, and liver failure. The Cox proportional hazards model was used to adjust for the confounding factors, including age, gender, BMI, smoking status, drinking status and metabolic disorders. **Results:** A total of 82,360 patients with NAFLD were included in the study (mean [SD] age, 55.3[26.8] years; 40,324[49.0%] females). Among them, 31,154(37.8%) were COVID-19 vaccine recipients and 51,206(62.2%) were non-recipients. During the median follow-up of 3.9 years, the incidence of severe NAFLD in the vaccinated group (1.5%) was significantly lower than that in the non-vaccinated group (4.5%), with a hazard ratio (HR) of 0.48 (95% CI: 0.44 - 0.54) after adjustment for confounding factors. Compared with the non-vaccinated group, the vaccinated group had a lower incidence of hepatitis (0.3% vs 1.4%; HR: 0.25 [0.19 - 0.31]), cirrhosis (1.2% vs 3.0%, HR: 0.57 [0.50 - 0.64]), hepatocellular carcinoma (0.1% vs 0.3%, HR: 0.76 [0.49 – 1.18]), and liver failure (0.1% vs 0.5%; HR: 0.26 [0.17 - 0.39]). The subgroup analysis showed that the vaccinated group was associated with a lower risk of severe NAFLD in male (HR: 0.47 [0.41 - 0.55]), female (HR: 0.41 [0.35 - 0.48]), the elder subgroup(HR: 0.53 [0.46 - 0.61]), and the younger subgroup (HR: 0.36 [0.30 - 0.43]). **Conclusion:** The COVID-19 vaccine may have potential benefits in improving the prognosis of NAFLD.

4027 | LOWER LIVER STIFFNESS AMONG ADULTS WITH TYPE II DIABETES AT RISK OF MASLD IS INDEPENDENTLY ASSOCIATED WITH STATIN USE: ANALYSIS OF A PROSPECTIVE COHORT OF 548 INDIVIDUALS

Monica Tincopa[1] Suruchi Ramanujan[2] Lisa Richards[1] Egbert Madamba[2] Seema Singh[2] Harris Siddiqi[2] Veeral Ajmera[1] Rohit Loomba[1], [1]University of California, San Diego, [2]UCSD

Background: Individuals with type 2 diabetes (T2DM) are at high risk of developing metabolic dysfunction-associated steatotic liver disease (MASLD). T2DM is also a risk factor for higher disease severity in MASLD. Prior data have shown potential benefit of statin therapy on MASLD prevalence and severity, though results are conflicting. The aim of this study was to determine the association of statin use on MASLD prevalence and severity using advanced MRI biomarkers in a prospective, well-phenotyped cohort of adults with T2DM. **Methods:** This prospective study enrolled adults age $\geq$ 50 years with T2DM recruited from primary care and endocrinology clinics. Participants underwent a standardized clinical research visit with vibration controlled transient elastography (VCTE) with controlled

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

attenuation parameter (CAP) and magnetic resonance imaging with proton density fat fraction (MRI-PDFF) and MR elastography (MRE). A subset completed genetic testing. Participants with alcohol intake exceeding AASLD guidance for MASLD were excluded. MASLD was defined as MRI-PDFF of $\geq 5\%$. Univariate and multivariate regression analyses were performed to assess the impact of statin use on MASLD prevalence and severity. **Results:** 548 patients (34.4% male, 43% Hispanic) with T2DM were included. The median age was 65 years (95% CI 57-70) and body mass index (BMI) was 30.7 (95% CI 27.4-34.3) kg/m2. In the overall cohort, 363 (66%) were on statins and 361 (N = 65.8%) had MASLD. Individuals on statins were older (66 vs 62 years), had higher prevalence of hypertension (64 vs 55%), and lower prevalence of TM6SF2 high risk variants. Among those with MASLD, individuals on statins were also more likely to be on glucagon-like peptide 1 (GLP1s) receptor agonist. On multivariate analysis accounting for difference in baseline characteristics by statin use, individuals on statins had lower liver stiffness measurement (LSM) on MRE compared to those not on statins (coefficient -0.34, 95% CI -0.66, -0.03, $p = 0.03$) (Table). In the MASLD subset, after accounting for baseline covariates, statin use was not independently associated with markers of MASLD severity. **Conclusion:** In a well-phenotyped, prospective cohort of adults with T2DM, statin use was independently associated with lower LSM on MRE, indicating a potential liver-specific benefit of statins in T2DM. Future randomized controlled trials assessing the independent impact of statin therapy on reducing MASLD prevalence and severity in T2DM are needed.

Table. Association of Statin Use with MASLD Prevalence and Severity Among Adults with T2DM

Overall Cohort N= 548	Unadjusted OR or coefficient	P value	Multivariate Model* OR or coefficient	P value
VCTE CAP	-1.55 (-11.6-8.5)	0.76	-0.20 (-15.30-14.89)	0.97
MRI PDFF	-1.67 (-3.0, -0.27)	**0.02**	0.22 (-1.79-2.24)	0.82

4028 | EFFICACY OF GLP-1 RECEPTOR AGONISTS IN IMPROVING LIVER ENZYMES, METABOLIC INDICES, AND FIBROSIS SURROGATES IN NON-ALCOHOLIC FATTY LIVER DISEASE: A META-ANALYSIS

Madia Ahad[1] Anwar Uddin[1] Aisha Elamin[1] Rafat Uddin[1], [1]Suny Downstate Medical Center

Background: Fatty liver disease tied to metabolic dysfunction, historically called non-alcoholic fatty liver disease (NAFLD), affects a growing number of adults. Although recently renamed metabolic dysfunction–associated steatotic liver disease (MASLD), most studies, including those in this analysis, still use NAFLD. For consistency, we use NAFLD throughout. GLP-1 receptor agonists (GLP-1 RAs), initially developed for type 2 diabetes, also promote weight loss and reduce liver enzymes. Given NAFLD's strong ties to insulin resistance and obesity, GLP-1 RAs are being evaluated as a potential treatment. This meta-analysis compiles existing data to assess their impact on liver enzymes, insulin resistance, metabolic outcomes, and fibrosis surrogates in adults with NAFLD. **Methods:** We included randomized controlled trials and large-scale cohort studies evaluating GLP-1 receptor agonists in adults with NAFLD. Eligible studies reported at least one of the following: ALT, AST, body weight, HOMA-IR, HbA1c, non-invasive fibrosis scores (FIB-4, NAFLD Fibrosis Score), or liver outcomes (cirrhosis, liver failure, or liver-related mortality). Four studies were included: a phase II RCT (Newsome et al., NEJM), two meta-analyses (Ghosal et al., Zhu et al.), and a retrospective cohort (Yen et al.). Pooled estimates were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

calculated using weighted mean differences (WMD) or adjusted hazard ratios (aHR) with 95% confidence intervals via a random-effects model (DerSimonian–Laird). Heterogeneity was assessed with I^2 and τ^2; publication bias was evaluated with a funnel plot for ALT. **Results:** GLP-1 receptor agonists were associated with consistent improvements in liver enzymes and metabolic indices. ALT decreased by −7.93 U/L (95% CI: −13.44 to −2.42) and AST by −5.29 U/L (95% CI: −9.04 to −1.55), with moderate-to-high heterogeneity (I^2 = 69.9% and 72.5%). Weight dropped by −3.56 kg, HOMA-IR by −1.62, and HbA1c by −0.43%, all with low heterogeneity (I^2 < 15%). Benefits were consistent across trials and real-world data. Only one study (Newsome et al.) reported biopsy-confirmed fibrosis improvement, which was not pooled. Non-invasive scores (FIB-4, NAFLD Fibrosis Score) from Zhu et al. showed no significant change. In the Yen cohort, GLP-1 RAs were not linked to reduced cirrhosis or liver failure but were associated with lower liver-related mortality (aHR 0.32, 95% CI: 0.13 to 0.75). Heterogeneity in ALT and AST likely reflects differences in study design, duration, population, and GLP-1 agent. Trial overlap was minimized across meta-analyses (Ghosal and Zhu), and pooled estimates remained consistent. The ALT funnel plot appeared symmetric, suggesting no major publication bias. **Conclusion:** GLP-1 receptor agonists improve liver enzymes, glycemic control, and metabolic parameters in adults with NAFLD, but their effect on fibrosis remains unclear. Further long-term trials with biopsy-confirmed outcomes and advanced liver endpoints are needed.

Table 1. Summary of Pooled Clinical and Metabolic Outcomes from Studies of GLP-1 Receptor Agonists in NAFLD

4029 | PRESCRIBING PATTERNS OF STATINS IN DECOMPENSATED CIRRHOSIS: A MULTI-CENTER COHORT STUDY

Rishaan Sharma[1] John McMichael[1] Xaralambos Zervos[2] Kalyan Bhamidimarri[2] Nicholas Ruthmann[1] Omar Sims[1] William Carey[1] Shilpa Junna[1], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic Florida

Background: Statins are increasingly prescribed for their liver-specific benefits, with a notable preference for lipophilic agents. However, detailed insights into prescribing patterns—including statin type and dose—remain limited. This study aimed to characterize statin use in patients with advanced liver disease listed for liver transplantation. **Methods:** This was a multi-center retrospective cohort study (Cleveland Clinic OH and FL) evaluating statin use for ≥60 days prior to liver transplant listing in patients with decompensated cirrhosis between January 2000 and October 2023. Exclusion criteria included age <18, acute liver failure, and multi-organ transplantation. Data collected included statin type, dose, and start/stop dates. Chi-square testing was used to assess distributions across statin type and dose. **Results:** Among 4,906 liver transplant candidates, 277 (5.6%) were prescribed statins through LT listing. Atorvastatin was the most commonly used (50.9%), followed by simvastatin (24.2%), pravastatin (12.3%), rosuvastatin (10.1%), lovastatin (2.2%), and pitavastatin (0.4%) ($p < 0.001$). Lipophilic statins were used in 77.6% of cases, while hydrophilic statins accounted for 22.4% ($p < 0.001$).

Statin dosage also varied significantly ($p < 0.001$): 3.2% were prescribed <10 mg, 63.9% received 10–20 mg, 27.8% were on 20–40 mg, and 5.1% were prescribed 40–80 mg daily. **Conclusion:** Statins are actively prescribed in patients with decompensated cirrhosis awaiting transplantation, despite prior concerns about hepatotoxicity. The clear predominance of lipophilic statins reflects existing evidence supporting their potential benefits in cirrhosis. These findings emphasize the need for prospective studies to better define the optimal statin type and dosage in this high-risk population.

n=4,906	Statin users (n=277, 5.60%)	P value:

4030 | ALTERNATIVE LIPID MANAGEMENT IN MASLD: CARDIOVASCULAR ADVANTAGES AND LIVER RISKS OF BEMPEDOIC ACID COMPARED TO STATINS

Mohamad-Noor Abu-Hammour[1] Barish Eren[1] Mohammad Alabbas[1] Mohamad Mahdi Osman[1] Leandro Sierra[1] Hussam Kawas[1] Walid Hazem[2] Omar Sims[1] Dian Chiang[3], [1]Cleveland Clinic Foundation, [2]University Hospitals, [3]Cleveland Clinic

Background: Metabolic-associated steatotic liver disease (MASLD) patients are at elevated risk for cardiovascular and hepatic complications. Statins are commonly utilized for their cardioprotective benefits; however, tolerability issues drive the need for alternative lipid-lowering therapies like bempedoic acid. This study compares outcomes in MASLD patients treated with bempedoic acid versus high-intensity (HI) statins. **Methods:** Utilizing the TriNetX global research network, a retrospective cohort analysis identified adult patients ($\geq$18 years) diagnosed with MASLD receiving either bempedoic acid (n = 479) or HI statins (atorvastatin 40-80 mg or rosuvastatin 20-40 mg, n = 479). Cohorts were balanced through propensity score matching on demographics, comorbidities, medications, and laboratory values. Outcomes assessed included major adverse cardiovascular events (MACE), all-cause mortality (ACM), hospitalizations (ACH), progression to cirrhosis, hepatocellular carcinoma (HCC) development, drug-induced liver injury (DILI), and liver enzyme (ALT and AST) levels over a 3-year follow-up. **Results:** After propensity matching, the bempedoic acid cohort was associated with significantly lower risk of MACE (13.2% vs. 18.8%; HR 0.645, 95% CI 0.467-0.890, p = 0.015) and ACH (16.1% vs. 23.8%; HR 0.618, 95% CI 0.463-0.826, p = 0.001) compared to the HI statin cohort. No significant differences were observed for ACM, cirrhosis progression, HCC incidence, stroke, or heart failure. However, DILI occurred exclusively in the bempedoic acid group (2.1%, p = 0.001). Liver enzymes (ALT, AST) were similar between groups at 3 years. **Conclusion:** In MASLD patients, bempedoic acid use was associated with fewer cardiovascular events and hospitalizations compared to HI statins, but with a notable risk for drug-induced liver injury. These findings highlight the potential benefits and risks of bempedoic acid as an alternative lipid-lowering therapy in MASLD, necessitating careful patient selection and monitoring.

4031 | VARIATION IN PLACEBO RESPONSE OF RANDOMISED CONTROLLED TRIALS EVALUATING GLP-1 RECEPTOR AGONIST ACTIVITY ON METABOLIC-DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE

Katie Denver[1] Timothy Jobson[2] Kushala Abeysekera[3], [1]Predictive Health Intelligence, [2]Somerset NHS Foundation Trust, [3]Bristol University

Background: Drugs with GLP-1 receptor agonists activity (GLP-1 RAs) are unlicensed but have shown promising benefits for metabolic dysfunction–associated steatotic liver disease (MASLD). Trials have shown a major benefit with disease resolution rates ranging from 36%-63%, with a significant benefit over placebo. MASLD also responds to diet and exercise and results in treatment arms are likely to be additive to those seen with lifestyle changes in trials. To replicate the impressive drug benefits seen in clinical trials it will be important to achieve the lifestyle related responses as represented by the placebo groups. In MASLD trials the placebo responses were as high as 34%. We looked at a range of GLP-1 study placebo arms to understand variation and identify barriers to real world responses. **Methods:** Studies were identified from clinical trial and publication databases, and conference proceedings. There were 2 distinct types – a) biopsy-based studies looking for resolution of MASH without worse fibrosis or improved fibrosis without worse inflammation) and b) liver fat storage / inflammation assessed non-invasively. Placebo responses were compared across all trials, and by category. Where available, trial protocols were reviewed to identify potential non-pharmacological interventions that contributed to MASLD resolution. **Results:** 10 randomised controlled phase 2b and 3 studies were found with a median of 30 (IQR 44) patients in placebo arms. Placebo responses showed statistically significant variability (0% to 34.1%; n = 10 p < 0.001). Pooled data from biopsy and non-biopsy studies (n = 6, n = 4) showed that placebo response in biopsy studies (25%) was 5 times higher than those relying on non-invasive testing (5%) (P < 0.001). While the end points being compared here are different, further evidence for

reduced placebo responses came from CT1 measurements in a non-invasive trial – showing no reduction - compared to steatohepatitis resolution in biopsy trials. Inclusion of biopsies appeared to be a significant factor driving placebo responses. **Conclusion:** Patients in placebo arms in MASLD GLP-1 studies achieved much higher response rates when biopsy was part of the protocol. Patients may be more motivated to engage with lifestyle measures when having serial liver biopsies. Placebo responses in non-invasive studies were near zero. In real world use, outcomes from GLP-1 RAs may fall short of responses seen in trials, as the baseline lifestyle changes will be unlikely to match those seen in biopsy studies.

4032 | DECREASED SERUM CONCENTRATIONS OF PRO-INFLAMMATORY OXYLIPINS IN MASH PATIENTS TREATED WITH ICOSABUTATE (ICONA STUDY)

David Fraser[1] Cristina Alonso[2] Sophie Jeannin[3] Hilde Steineger[3] Tore Skjæret[3] Alejandro Montilla[4], [1]NST, [2]Rubio Metabolomics, S.L.U., [3]Northsea Therapeutics, [4]Rubio Metabolomics

Background: Treatment for 52 weeks with icosabutate, an oral free fatty receptor 1 and 4 agonist, has recently demonstrated significant anti-inflammatory and anti-fibrotic effects in F1-F3 MASH patients (ICONA study, NCT04052516). Icosabutate has also been shown to markedly reduce hepatic oxidative stress and MASH-associated oxylipins [oxidised PUFAs, including oxidised phospholipids (oxPLs)] in multiple fibrosing murine MASH models. To assess whether these findings may translate to humans, we compared serum levels of oxylipins in MASH patients treated with either icosabutate or placebo as part of the ICONA study. **Methods:** Serum samples were collected at 52 weeks (study end) in MASH patients participating in the ICONA trial. Sample collection and storage were performed in accordance with a pre-defined protocol for lipidomic analysis. A total of 31 oxylipins, in addition to oxPLs, were quantified by UHPLC-MS/MS. Univariate statistical analyses included the assessment of data normality by the Shapiro-Wilk test, and the calculation of group fold changes and unpaired p-values for placebo vs. 600 mg icosabutate was performed. **Results:** Serum samples were collected from 44 and 45 patients treated with 600 mg icosabutate or placebo respectively. Significantly lower levels of multiple oxylipins and oxPLs were observed in the icosabutate treated patients versus placebo, primarily in arachidonic acid (AA) derived oxylipins (Figure). Five of 6 AA-derived hydroxyeicosatetraenoic acid (HETE) species were significantly reduced (8-, 9-, 11-, 15- and 20-HETE) in icosabutate treated patients, with the most pronounced decrease seen for 20-HETE [-0.68 $\log_2$ (fold-change), $p < 0.001$ vs. placebo]. Marked and significant decreases in oxidized eicosatrienoic acids (DiHET, DHET) were also observed, in addition to linoleic acid-derived species (5,6-DiHETE and 8,15-DiHETE, and 9,10-EpOME). Interestingly, despite lack of incorporation into phospholipid membranes, treatment with icosabutate was also associated with significantly lower oxPLs [-0.54 $\log_2$ (fold-change), $p < 0.001$ vs. placebo]. **Conclusion:** Treatment with icosabutate for 52 weeks was associated with markedly lower serum concentrations of multiple MASH associated oxylipins, in particular HETEs and oxPLs. These findings in patients confirm hepatic changes observed in pre-clinical MASH models, indicating that icosabutate is potently reducing both enzymatic (LOX/COX/CYP450) and non-enzymatic (oxidative stress) oxidation of PUFAs in MASH patients. Reductions in oxylipins, in particular oxPLs for which a causal role has been established in pre-clinical MASH models, may underlie the improvements in fibrosis observed in patients treated with icosabutate.

4033 | MRI-PDFF ≥ 70% REDUCTION WAS ASSOCIATED WITH FIBROSIS IMPROVEMENT WITH TIRZEPATIDE: POST-HOC ANALYSIS OF THE SYNERGY-NASH PHASE 2B TRIAL

Rohit Loomba[1] Mark L. Hartman[2] Yuanyuan Tang[2] Bram Brouwers[2] Arun Sanyal[3], [1]University of California, San Diego, [2]Eli Lilly and Company, Indianapolis, IN, USA, [3]Virginia Commonwealth University

Background: Magnetic resonance imaging-proton density fat fraction (MRI-PDFF) is a quantitative biomarker of liver fat content and a reduction in MRI-PDFF by at least ≥ 30% is associated with resolution of MASH in MASH trials. However, there are limited data whether a greater MRI-PDFF reduction may be associated with fibrosis improvement in MASH. Tirzepatide, a GIP/GLP-1 agonist, improved both MASH resolution and fibrosis in the SYNERGY-NASH phase 2B trial in patients with MASH and fibrosis stages 2 and 3 (NCT04166773; Loomba et al NEJM 2024). The aim of this post hoc analysis was to examine the association between 30%, 50% and 70% relative reduction in MRI-PDFF and fibrosis improvement in this trial. **Methods:** Among randomized 190 participants, 116 had both evaluable liver-biopsy and MRI-PDFF results at week 52. The outcome of interest was ≥ 1 stage improvement in fibrosis without worsening of MASH. The proportion of participants achieving this endpoint (fibrosis responders) was evaluated by whether the MRI-PDFF reduction thresholds of 30%, 50% and 70% were met and compared using the Chi-square test. All treatment groups were pooled for this analysis. **Results:** The mean percent reduction from baseline at week 52 in MRI-PDFF ranged from 49.7% to 63.8% across the three tirzepatide dose arms (5 mg, 10 mg and 15 mg) compared with 2.6% in the placebo group ($p < 0.001$ for all tirzepatide doses versus placebo). Among 80 participants achieving a ≥30% reduction in MRI-PDFF, the proportion of fibrosis responders did not differ significantly from that observed in the 36 participants not meeting the 30% threshold for MRI-PDFF reduction (53.8 vs 41.7%, $p = 0.23$). Similarly, the proportion of fibrosis responders did not differ significantly among those meeting ($n = 66$) versus those not meeting ($n = 50$) the ≥50% MRI-PDFF reduction threshold (57.6 vs 40.0%, $p = 0.06$). However, among participants achieving a ≥70% reduction in MRI-PDFF ($n = 40$), 65.0% met the endpoint of fibrosis improvement without worsening of MASH; a significantly lower ($p = 0.02$) proportion of fibrosis responders was observed (42.1%) if the ≥70% reduction in MRI-PDFF was not achieved ($n = 76$). None of the participants in the placebo group achieved 70% reduction in MRI-PDFF. **Conclusion:** In this post hoc analysis of the SYNERGY-NASH trial, a super response rate of 70% relative reduction in liver fat assessed by MRI-PDFF was associated with a higher rate of fibrosis improvement with tirzepatide treatment.

4034 | SGLT2 INHIBITORS AND RISK OF LIVER FIBROSIS PROGRESSION IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AND TYPE 2 DIABETES

Daniel Fulop[1] Jonggi Choi[2] Eric Przybyszewski[1] Jiunn Song[1] Allison Carroll[1] Megan Michta[1] Erik Almazan[3] Tracey Simon[1] Raymond Chung[1], [1]Massachusetts General Hospital, [2]Asan Medical Center, University of Ulsan College of Medicine, [3]Brigham and Women's Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a growing cause of cirrhosis and its complications. Given the strong link between MASLD and type 2 diabetes (T2DM), evaluating whether antidiabetic agents such as sodium-glucose cotransporter-2 inhibitors (SGLT2i) reduce liver fibrosis progression is of clinical interest. This study examined the association between SGLT2i use and both liver fibrosis progression and its complications in patients with MASLD and T2DM. **Methods:** We conducted a target trial emulation study using a retrospective, active comparator, new-user design among adults $\geq$18 years old with MASLD, T2DM, and low/intermediate Fibrosis-4 index (FIB-4 $\leq$2.67) who initiated either a SGLT2i or dipeptidyl peptidase-4 inhibitor (DPP-4i) at Mass General Brigham or Asan Medical centers between January 1, 2013 and December 31, 2023. Patients with prior cirrhosis, hepatic decompensation, hepatocellular carcinoma (HCC), or liver transplantation were excluded. Propensity score matching accounted for differences in demographic, clinical, laboratory, and treatment characteristics. The primary outcome was progression to a high risk for advanced fibrosis category (FIB-4 $>$ 2.67) confirmed on $\geq$2 occasions within 1 year to ensure robustness. The secondary outcome was development of major adverse liver outcomes (MALO), a composite endpoint comprising incident cirrhosis, decompensation events, HCC, and liver transplant. Time-to-event analyses were conducted using Cox proportional hazards models and cumulative incidence curves were constructed. **Results:** From the eligible cohort of 16,901 adults, SGLT2i users were matched 1:1 to DPP-4i users yielding 2,571 matched pairs (n = 5,142) with well-balanced baseline characteristics (all standardized mean differences $<$ 0.1). During a median follow-up of 3.7 years, FIB-4 progression occurred at a rate of 4.44 per 100 person-years in DPP-4i users and 3.46 per 100 person-years in SGLT2i users. SGLT2i use was significantly associated with a lower risk of FIB-4 progression compared to DPP-4i use (hazard ratio [HR], 0.78; 95% confidence interval [CI], 0.67–0.89; p $<$ 0.001). No significant difference was observed in the incidence of MALOs. In subgroup analyses stratified by concurrent medication use, the inverse association between SGLT2i use and FIB-4 progression remained consistent among users of putative chemopreventive agents including metformin (n = 1,641; HR, 0.81; 95% CI, 0.68–0.97; p = 0.021), statins (n = 1,780; HR, 0.79; 95% CI, 0.67–0.93; p = 0.005), and aspirin (n = 1,186; HR, 0.84; 95% CI, 0.70–1.01; p = 0.059), although the latter did not reach statistical significance. **Conclusion:** SGLT2i use was associated with a lower risk of fibrotic progression compared to DPP-4i use in adults with MASLD and T2DM. Prospective studies are needed to confirm this association in MASLD.

Chung[1], [1]Massachusetts General Hospital, [2]University of Ulsan, Asan Medical Center, [3]Brigham and Women's Hospital

Background: Fibrosis progression is a key determinant of liver-related outcomes in metabolic dysfunction-associated steatotic liver disease (MASLD). However, large-scale data on GLP1-RA use and risk of fibrosis progression is limited in real-world healthcare settings. **Methods:** We conducted a target trial emulation using electronic health record data from the Mass General Brigham network via the Research Patient Data Registry, identifying patients from 2010 to 2023. We included adults aged 18–80 years with type 2 diabetes (T2DM) and MASLD and low-to-intermediate fibrosis risk (FIB-4 score less than 2.67). We additionally excluded patients with a prior diagnosis of cirrhosis, liver-related decompensation, hepatocellular carcinoma (HCC), liver transplant, or prior use of GLP-1RA/DPP4 inhibitor (DPP4i) before the index date. DPP4i served as the active comparator and reference group to evaluate the effect of GLP-1RA.

Among 18,439 initially eligible patients, exclusion criteria and subsequent 1:1 propensity score matching yielded 4,476 patients, equally split across arms of newly initiated GLP-1RA or DPP4i. Covariates for matching included demographics, diabetes-related comorbidities, laboratory values, fibrosis-related indices, healthcare utilization, and concurrent medications.

The primary outcome was FIB-4 progression, defined as transition from low/intermediate to high-risk (FIB-4 >2.67) confirmed on at least two occasions within one year. The secondary outcome was development of a MASLD-associated liver outcome (MALO), defined as new cirrhosis, decompensation, HCC or liver transplant.

Results: During a median follow-up of 4.3 years, FIB-4 progression occurred at a rate of 4.29/100 person-years (PY) in the DPP4i group and 3.25/100 PYs in the GLP-1RA group. GLP-1RA use was associated with a significantly lower risk of FIB-4 progression (hazard ratio [HR]: 0.75, 95% confidence interval [CI]: 0.65–0.87, $p < 0.001$). No significant difference was observed in secondary liver-related outcomes. In stratified subgroup analyses among aspirin ($n=1,269$), statin ($n=1,840$), and metformin users ($n=1,751$), GLP-1RA use consistently showed a lower risk of FIB-4 progression with a HR of 0.74 (95% CI 0.62–0.88), 0.74 (95% CI 0.63–0.86), and 0.67 (95% CI 0.57–0.80), respectively. **Conclusion:** GLP-1RA use was associated with a lower incidence of liver fibrosis progression compared to use of DPP4i among patients with MASLD and T2DM, supporting the role of this medication in modifying outcomes in MASLD.

4036 | SEMAGLUTIDE IMPROVES MARKERS OF CARDIOVASCULAR RISK IN PEOPLE WITH HIV AND MASLD: THE SLIM LIVER STUDY

Jordan Lake[1] Doug Kitch[2] Amy Kantor[2] Cristina Alonso[3] Pablo Belaunzaran-Zamudio[4] Carl Fichtenbaum[5] Todd Brown[6] Fred Sattler[7] Kristine Erlandson[8], [1]UTHealth Houston, [2]Harvard T.H.Chan School of Public Health, [3]OWL Metabolomics, [4]NIH/NIAID, [5]University of Cincinnati, [6]Johns Hopkins University, [7]University of Southern California, [8]University of Colorado Denver-Anschutz Medical Campus

Background: We previously reported that, among with people with HIV (PWH) and metabolic dysfunction-associated steatotic liver disease (MASLD), the glucagon-like peptide-1 receptor agonist semaglutide (SEMA) improved weight, intra-hepatic triglyceride (IHTG) content, insulin resistance (IR), glucose and triglycerides (TG); here we report novel lipidomic, lipoprotein and glycoprotein profiling pre-/post-SEMA. **Methods:** PWH at least 18 years old on suppressive antiretroviral therapy (ART) with $>5\%$ IHTG on MRI-PDFF received SEMA 1mg subcutaneously per week for 24 weeks. Those with >2.27 kg weight loss had serum lipidomic, lipoprotein and glycoprotein profiling at OWL Metabolomics. Wilcoxon signed-rank tests and Spearman's rank correlations were performed. **Results:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Of 36 participants: median age was 52 years, BMI 34 kg/m^2, 39% Hispanic, 28% Black, 45% female and 77% integrase strand transfer inhibitor-based ART. Lipidomics: SEMA reduced TG and diglycerides, especially polyunsaturated species, reduced sphingomyelins and increased some bile acids (deoxycholic acid and chenodeoxycholic acid) and phosphatidylcholines, Table 1. Non-esterified fatty acids generally did not change. Lipoproteins: Cardiovascular disease (CVD)-linked species (total TG, VLDL-TG, HDL-TG, HDL-TG/HDL-C, Remnant-C and VLDL particle number) decreased; LDL particle size and large HDL-P increased. Glycoproteins: 69% and 53% of participants had elevated baseline GlycA and GlycB, CVD-associated markers of systemic inflammation. While no overall glycoprotein changes were observed, 56% with elevated baseline Glyc A had a reduction and 32% of those normalized; 41% with elevated Glyc B had a reduction and 42% normalized. Changes in total glycoprotein and GlycA correlated with changes in IL-6 ($r = -0.43$, $p = 0.01$) and leptin ($r = 0.50$, $p = 0.002$). Lipoprotein and glycoprotein concentrations generally did not correlate with baseline or change in weight, IHTG or IR. **Conclusion:** Among PWH and MASLD, lipidomic changes with SEMA suggest reduced lipotoxicity and hepatic insulin resistance, consistent with MASLD improvement. Significant reductions in CVD risk-associated lipoprotein and glycoprotein species were observed that did not correlate with changes in weight, IHTG or IR, suggesting an independent mechanism. Larger studies with clinical endpoints are needed to optimize CVD risk reduction in PWH and MASLD.

Table 1. Changes in and Success of Achieving Lipid Goals Before and After Semaglutide. (Based on European Society of Cardiology/European Atherosclerosis Society Guidelines for the Management of Dyslipidaemias, 2019)

Lipoprotein	Goal Concentration	Median (Q1, Q3) 24-W change	Not at Goal Week 0	Newly at Goal Week 24
Total Cholesterol (C) (mg/dL)	<200	-4.72 (-13.7, 4.58) p=0.11	53%	17%

4038 | THERAPEUTIC FAILURES WITH SEMAGLUTIDE - LESSONS DRAWN FROM OBESITY AND TYPE 2 DIABETES MELLITUS TRIALS

Donghyun Ko[1] Do Han Kim[2] Faith Xin Ning Tan[3] Glenn Ho[3] Pojsakorn Danpanichkul[4] Mazen Noureddin[5] Mark Muthiah[3] Mohammad Siddiqui[6] Cheng Han Ng[7], [1]Bridgeport Hospital, Yale New Haven Health, [2]Department of Medicine, Mount Sinai Morningside and West, Icahn School of Medicine at Mount Sinai, [3]Yong Loo Lin School of Medicine, [4]Department of Medicine, Texas Tech University Health Sciences Center, Lubbock, TX, USA, [5]Houston Methodist Hospital, [6]Division of Gastroenterology, Hepatology and Nutrition, Section of Hepatology, Virginia Commonwealth, [7]Division of Gastroenterology and Hepatology, Department of Medicine, National University Hospital,

Background: Semaglutide, a glucagon-like-peptide-1 receptor agonist (GLP1-RA), has gained increasing popularity for its efficacy in glycemic control, weight reduction, cardiovascular outcomes, and metabolic dysfunction-associated steatotic liver disease outcomes. Although numerous randomized clinical trials (RCTs) have analyzed its benefit, studies assessing the overall outcomes are still lacking. This study aims to evaluate the rate of failure to achieve therapeutic endpoints across a broad patient population. **Methods:** Medline (Ovid) and Embase databases were searched to include RCTs reporting weight reduction and hemoglobin A1c (HbA1c) reduction associated with weekly administration of semaglutide in obesity and type 2 diabetes mellitus (T2DM), respectively. Proportions from the semaglutide arm of each RCT were extracted, and the Copper Pearson method was conducted to obtain the pooled proportion with its respective confidence interval. Studies that reported outcomes in metabolic dysfunction-associated steatohepatitis (MASH) spectrum were analyzed separately. **Results:** A total of 32 RCTs were included. Overall, 33%, 65%, 64%, and 75% of patients treated with semaglutide did not achieve $\geq$ 5%, $\geq$10%, $\geq$15%, and $\geq$20% weight reduction, respectively. In the group without T2DM, 14%, 30%, 50%, and 70% did not achieve $\geq$ 5%, $\geq$10%, $\geq$15%, and $\geq$20% weight reduction,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

respectively. In the group with T2DM, 46%, 80%, 90%, and 95% did not achieve ≥ 5%, ≥10%, ≥15%, and ≥20% weight reduction, respectively. In terms of HbA1c, 22% and 38% of patients treated with semaglutide did not achieve HbA1c ≤7% and ≤6.5%, respectively. Lastly, 61% and 87% of patients with MASH and MASH cirrhosis, respectively, did not achieve ≥ 1 stage improvement in fibrosis NASH CRN. **Conclusion:** Semaglutide has shown tremendous progress in the treatment of metabolic disease, and its effect has been well proven in promoting weight reduction, HbA1c reduction, and improving cardiovascular as well as hepatic outcomes. While the use of semaglutide is encouraged to provide these benefits to the patient, it is important to note that some degree of therapeutic failure is expected.

4039 | SURVODUTIDE IMPROVED LIVER HISTOLOGY IN PEOPLE WITH MASH AND MODERATE-TO-SEVERE FIBROSIS REGARDLESS OF AGE, SEX, ETHNICITY, OR TYPE 2 DIABETES: SUBGROUP ANALYSIS OF A RANDOMIZED PHASE 2 TRIAL

Naim Alkhouri[1] Jörn Schattenberg[2] Elisabetta Bugianesi[3] Vincent Wai-Sun Wong[4] Mandy Fraessdorf[5] Samina Ajaz Hussain[6] Renee Marshall[7] Ramy Younes[6] Arun Sanyal[8], [1]Summit Clinical Research, [2]Department of Internal Medicine II, University Medical Center Homburg, Homburg & Saarland University, [3]University of Turin, [4]Department of Medicine and Therapeutics, The Chinese University of Hong Kong, [5]Boehringer Ingelheim Pharma GmbH & Co. KG, [6]Boehringer Ingelheim International GmbH, [7]Boehringer Ingelheim Pharmaceuticals, Inc., [8]Virginia Commonwealth University

Background: Survodutide is a glucagon receptor/glucagon-like peptide-1 receptor (GCGR/GLP-1R) dual agonist in phase 3 trials for treatment of metabolic dysfunction-associated steatohepatitis (MASH) and obesity. In a phase 2 trial in people with biopsy-confirmed MASH and F1–F3 liver fibrosis, survodutide improved both steatohepatitis and liver fibrosis. We evaluated its efficacy in clinically important subgroups. **Methods:** This 48-week, multinational, double-blind trial (NCT04771273) randomized 295 people aged 18–80 years with biopsy-proven MASH (Non-alcoholic fatty liver disease Activity Score [NAS] ≥ 4) and liver fibrosis stage F1–F3 to once-weekly subcutaneous placebo or survodutide, escalated over ≤ 24 weeks to maintenance doses of 2.4, 4.8, or 6.0 mg. Endpoints included: resolution of MASH (absence of ballooning [score of 0], no or mild inflammation [score of 0 or 1], and possible steatosis [score of 0 to 3]) without worsening of fibrosis; improvement in fibrosis (≥ 1 stage decrease) without worsening of MASH; % change in liver fat content (LFC) by magnetic resonance imaging–proton density fat fraction; absolute change in Enhanced Liver Fibrosis (ELF™) score; and % change in N-terminal propeptide of type III collagen (PRO-C3). We analyzed these endpoints post hoc by age (<65/≥ 65 years), sex (male/female), ethnicity (Hispanic/Latino or not), and presence or absence of type 2 diabetes (T2D) in participants with F2–F3 fibrosis who received ≥ 1 dose of trial drug and had baseline and end of treatment biopsies (n = 170). **Results:** At baseline, 138 (81.2%) participants were aged <65 years, while 85 (50.0%) were female, 48 (28.2%) Hispanic/Latino, and 71 (41.8%) had T2D. Resolution of MASH without worsening of fibrosis, and improvement in fibrosis without worsening of MASH, occurred in more of the survodutide groups than the placebo group across subgroups based on age, sex, ethnicity, and T2D (Figure). Similarly, survodutide was associated with larger reductions in LFC, ELF™ score, and PRO-C3 level across these subgroups. **Conclusion:** Survodutide reduced MASH, fibrosis, and LFC across participant subgroups in this phase 2 trial, suggesting consistent benefits of this GCGR/GLP-1R dual agonist in different patient populations. There was no difference in MASH resolution based on age, sex, ethnicity, or T2D —and no difference in fibrosis improvement based on age, sex, or ethnicity, although response rate was possibly lower in those with T2D.

4040 | TARGETING NUCLEAR PROTEIN IMPROVES NAFLD ACTIVITY SCORE AND SHOWS ANTIFIBROTIC AND HEPATOPROTECTIVE EFFECTS SUPERIOR TO LANIFIBRANOR IN THE GAN DIET-INDUCED OBESE AND BIOPSY-CONFIRMED MOUSE MODEL OF MASH

Jacob Nøhr-Meldgaard[1] Michael Feigh[2] Stefan Hoenow[3] Kristoffer Voldum-Clausen[1] Susanne Pors[1] Christopher Shepard[4], [1]Gubra A/S, [2]Gubra, [3]NuLa Therapeutics, [4]Apollo Health Ventures

Background: NLT-101 is a first-in-class compound that functions by proximity engagement with a target in the nuclear envelope that mediates its activity. NLT-101 is in preclinical development for metabolic dysfunction-associated steatohepatitis (MASH) and fibrosis driven indications. The present study aimed to investigate the therapeutic benefits of NLT-101 on metabolic, biochemical, histopathological and transcriptome profile in the translational GAN diet-induced obese (DIO) and biopsy-confirmed mouse model of MASH with liver fibrosis. Lanifibranor, a late-stage clinical candidate (Ph3) for the treatment of patients with MASH and liver fibrosis, was included for comparison. **Methods:** Male C57BL/6 mice were fed the GAN diet high in fat, fructose and cholesterol for 36 weeks prior to study start. A liver pre-biopsy was collected 4 weeks before treatment start. Only GAN DIO-MASH mice with biopsy-confirmed NAFLD Activity Score (NAS ≥ 5) and fibrosis (stage F2-F3) were included and stratified into treatment groups ($n = 16$ per group). Mice were administered once daily oral vehicle, NLT-101 (30 (low) and 60 (high) mg/kg), lanifibranor (30 mg/kg) for 12 weeks. Histopathological pre-to-post individual assessment of NAS and fibrosis stage was performed. Other terminal endpoints included quantitative liver histology, blood and liver biochemistry in addition to RNAsequencing-Bioinformatic analysis. **Results:** NLT-101 demonstrated vehicle-corrected weight loss of 25% (low) and 30% (high) after 12 weeks of treatment, which was comparable with lanifibranor (34%). High dose NLT-101 resulted in a 4-point improvement in NAS in 30% of the animals, driven by reduction in steatosis and lobular inflammation score. A 2-point improvement was observed in 95% of the animals ($p < .001$). High dose NLT-101 showed distinguishably better effects compared to lanifibranor. NLT-101 showed superiority towards lanifibranor for plasma transaminases lowering and comparable effects on plasma total cholesterol. Benefits on NAS were supported by quantitative liver histology on steatosis (hepatocytes with lipids, liver lipids) and marker of inflammation (galectin-3). No treatments improved fibrosis stage, however improvement in histological markers for fibrosis (PSR, Col1a1) and hepatic stellate activation (α-SMA), indicating effect on fibrogenesis was numerically superior for NLT-101 compared to lanifibranor. Finally, all treatments induced significant gene regulation and suppressed genes involved in extracellular matrix and inflammation pathways. **Conclusion:** NLT-101 treatment improved metabolic, biochemical and histopathological parameters of MASH, including hepatic transcriptomic profile, in the GAN DIO-MASH mouse model. Notably, NLT-101 treatment dose-dependently improved NAFLD Activity Score superior to late-stage clinical candidate lanifibranor, introducing NLT-101 as a promising first-in-class treatment for MASH.

4041 | TIRZEPATIDE REDUCES TUMOR BURDEN IN THE GAN DIET-INDUCED OBESE AND BIOPSY-CONFIRMED MOUSE MODEL OF MASH-HCC WITH ADVANCED FIBROSIS

Jacob Nøhr-Meldgaard[1] Michael Feigh[2] Nicolas Eskesen[1] Susanne Pors[1] Henrik Hansen[1], [1]Gubra A/S, [2]Gubra

Background: The GLP-1: GIP receptor dual agonist Tirzepatide, approved for the treatment of obesity and type 2 diabetes, has demonstrated therapeutic efficacy on clinical endpoints in a recent phase 2 clinical trial (SYNERGY-NASH) in patients with metabolic-dysfunction associated steatohepatitis (MASH) and liver fibrosis (Loomba et al.; NEJM; 2024). The present study aimed to evaluate therapeutic efficacy of tirzepatide on clinical endpoints and outcome in the GAN (Gubra-Amylin NASH) diet-induced obese (DIO) mouse model of MASH with advanced fibrosis and hepatocellular carcinoma (HCC). **Methods:** Male C57BL/6J mice were fed the GAN diet high in fat, fructose, and cholesterol for extended 52 weeks prior to study start. Only animals

with liver biopsy-confirmed NAFLD Activity Score (NAS ≥ 5) and advanced fibrosis (stage F3) were included and stratified into treatment groups. DIO-NASH-HCC mice received (SC, QD) vehicle (n = 15) or tirzepatide (10 nmol/kg, n = 17) for 14 weeks. Vehicle-dosed chow-fed C57BL/6J mice (n = 9) served as lean healthy controls. Untreated DIO-MASH-HCC mice (n = 12) were terminated at baseline. Tumor histopathological evaluation was performed by an expert pathologist. Pre-to-post liver biopsy histopathology was performed for within-subject evaluation of NAFLD Activity Score (NAS) and fibrosis stage. Additional endpoints included blood and liver biochemistry and quantitative liver histology. **Results:** Compared to baseline, DIO-MASH-HCC mice demonstrated progressive tumor burden over the 14-week study period. Tumors showed consistent architectural and cytologic features of HCC with a marked lack of reticulin trabecular framework in addition to diffuse/reduced glutamine synthetase staining, representing standard diagnostic criteria for HCC, and with tumors clearly demarked by extensive Ki67 expression (proliferative phenotype). Notably, tirzepatide completely prevented progression in tumor burden and reduced histological marker for hepatocellular proliferation (Ki67). Concurrently, tirzepatide improved hallmarks of MASH, including hepatomegaly, transaminases (ALT/AST), plasma and liver lipids (TG/TC), in addition to histopathological NAS (≥ 2 point improvement). In agreement, tirzepatide reduced quantitative histological markers of steatosis (lipids, hepatocytes with lipid droplets) and inflammation (CD45, galectin-3). Tirzepatide did not improve fibrosis stage, albeit reduces clinical-derived plasma fibrosis markers (TIMP-1, PIIINP) and histological marker for hepatic stellate cell activation (α-SMA), indicating anti-fibrogenic action. **Conclusion:** This is the first study to demonstrate that tirzepatide reduces tumor burden and improves clinical biomarkers and histopathological endpoints for NAFLD Activity Score in a preclinical translational diet-induced obese mouse model of MASH-driven HCC with advanced fibrosis.

4042 | EFFICACY RESPONSE IN SUBGROUPS OF PARTICIPANTS IN ESSENCE DEMONSTRATE THAT SEMAGLUTIDE IS EFFECTIVE IN IMPROVING LIVER FIBROSIS ACROSS A DIVERSE POPULATION

Mary Rinella[1] Manal Abdelmalek[2] Elisabetta Bugianesi[3] Anna Cali[4] Laurent Castera[5] Mette Kjær[4] Jacob George[6] Wah Kheong Chan[7] Niels Krarup[4] Michelle Long[4] Philip Newsome[8] Claudia Oliveira[9] George Papatheodoridis[10] Ahsan Shoeb[4] Salvatore Petta[11] Michael Roden[12] Arun Sanyal[13] Yusuf Yilmaz[14] Vlad Ratziu[15], [1]Division of Gastroenterology, Hepatology and Nutrition, University of Chicago, Chicago, IL, USA, [2]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, Minnesota, USA, [3]Department of Medical Sciences, University of Turin, Turin, Italy, [4]Novo Nordisk A/S, Copenhagen, Denmark, [5]Université Paris Cité, INSERM UMR1149, Centre de Recherche sur l'Inflammation, Paris, France, [6]Westmead Institute for Medical Research, Westmead Hospital, University of Sydney, NSW, Australia, [7]Department of Medicine, Faculty of Medicine, University of Malaya, Malaysia, [8]School of Immunology & Microbial Sciences, Foundation for Liver Research and King's College Hospital, [9]Hospital das Clínicas (LIM07) da Faculdade de Medicina da Universidade de São Paulo, São Paulo, [10]Medical School of National and Kapodistrian University of Athens, General Hospital of Athens, [11]Sezione di Gastroenterologia, PROMISE, University of Palermo, Italy, [12]Medical Faculty and University Hospital Düsseldorf, Heinrich Heine University Düsseldorf, Düsseldorf, [13]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, VCU School of Medicine, Richmond, [14]School of Medicine, Recep Tayyip Erdoğan University, Rize, Turkey, [15]Sorbonne Université,Hospital Pitié-Salpêtrière, INSERM UMRS 1138 CRC, Paris, France

Background: In part 1 of the phase 3 ESSENCE trial (NCT04822181), once-weekly subcutaneous semaglutide 2.4 mg demonstrated significant improvement in liver fibrosis and resolution of steatohepatitis over 72 weeks versus placebo in participants with MASH and liver fibrosis (stage 2 or 3). Histological benefits were reflected in improvements of pre-specified non-invasive tests (NITs). The aim of this secondary analysis was to evaluate if the efficacy of semaglutide in the combined histologic endpoint of resolution of steatohepatitis and improvement in liver fibrosis and fibrosis-related NITs differed across age, sex, race and ethnicity subgroups. **Methods:** The first 800 randomized participants were stratified by race (Asian vs. non-Asian), ethnicity (Hispanic or Latino vs Non-Hispanic or Latino), sex (male and female) and age (<45, ≥ 45–64 and ≥ 65 years). Participants were evaluated for the combined histologic endpoint of resolution of steatohepatitis and improvement in liver fibrosis, and fibrosis-related NITs (a decrease of $\geq 25\%$ from baseline in liver stiffness measurement by vibration-controlled transient elastography [VCTE LSM], or a decrease of ≥ 0.5 units from baseline in enhanced liver fibrosis [ELF] score). A Cochran–Mantel–Haenszel test stratified by baseline diabetes status and baseline fibrosis stage was conducted. Missing data were handled by multiple

imputation informed by data from placebo participants. **Results:** Asian participants (n = 216) showed treatment benefits with semaglutide vs placebo across all outcomes (estimated difference in responder proportions for combined histology: 16.9% [95% CI: 4.7; 29.0], ELF 35.2% [95% CI: 22.3; 48.0], VCTE LSM ≥25% 24.3% [95% CI: 9.2; 39.6]), as did non-Asians (n = 576) (combined histology 16.6% [95% CI: 9.18; 23.93], ELF 28.4% [95% CI: 20.0; 36.8], VCTE LSM ≥25% 23.5% [95% CI: 13.3; 33.6]). Semaglutide demonstrated consistent treatment benefits vs placebo for non-Hispanic/Latino participants (n = 632) (combined histology 17.9% [95% CI: 10.91; 24.9], ELF 32.2% [95% CI: 24.4; 40.0], VCTE LSM ≥25% 27.0% [95% CI: 17.7; 36.3]); more modest effects were observed in Hispanic or Latino participants. Males (n = 343) and Females (n = 457) both showed treatment benefits for combined histology and ELF (Figure), along with VCTE LSM ≥25% (24.3% [95% CI: 12.0; 36.5] and 23.7% [95% CI: 12.2; 35.2], respectively). Across <45 (n = 126), ≥45–64 (n = 472) and ≥65 years (n = 202) subgroups, consistent treatment benefits for semaglutide were observed for combined histology and ELF (Figure); VCTE LSM ≥25% improvement was better demonstrated among patients aged ≥45 years. **Conclusion:** Semaglutide demonstrated consistent efficacy across multiple subgroups for histologic and liver fibrosis-related NIT responder endpoints. These data support the benefits of semaglutide across a diverse population for the treatment of MASH with stage 2 or 3 fibrosis.

4043 | COMPARATIVE SYSTEMATIC REVIEW AND META-ANALYSIS: EFFICACY OF EMPAGLIFLOZIN VERSUS DAPAGLIFLOZIN IN MANAGING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Vikash Karmani[1] Ruchir Paladiya[2] Krishan Joshi[3] Vikash Kumar[4] Aalam Sohal[4] Neil Parikh[5], [1]Jinnah Singh Medical University, [2]University of Connecticut Health Center, [3]California University Health Sciences University, [4]Creighton University, [5]Hartford Hospital

Background: The use of sodium-glucose cotransporter-2 inhibitors in patients with Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) has received increasing attention. This systematic review and meta-analysis were conducted to assess and compare the effectiveness of empagliflozin and dapagliflozin as potential treatments for patients with MASLD. **Methods:** We conducted a systematic review and meta-analysis in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. We searched the PubMed and Cochrane Central Register of Controlled Trials (CENTRAL) databases from their inception through December 2023. The outcomes evaluated

included hepatic enzymes—alanine aminotransferase (ALT) and aspartate aminotransferase (AST)—as well as body mass index (BMI), body weight, and serum lipid profile parameters: high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), and triacylglycerol (TAG). We calculated the standard mean difference (SMD) with a 95% confidence interval (CI) for continuous outcomes across all studies and applied a random-effects model for data synthesis, regardless of heterogeneity. Heterogeneity was assessed using the I^2 statistic. **Results:** We screened 1028 articles and included 7 randomized controlled trial studies (515 patients). Dapagliflozin exhibited a statistically significant decrease in both weights (SMD: −0.30, 95% CI:−0.60 to −0.01, $I^2 = 36$, $p = 0.04$) as well as BMI ((SMD: −0.64, 95% CI: −0.97 to -0.30, $I^2 = 49\%$, $p = 0.0002$), an increase in HDL-C levels (SMD: 1.26, 95% CI: 0.01 to 2.50, $I^2 = 92\%$, $p = 0.05$), and an insignificant change in LDL-C ($p = 0.38$) and TAG ($p = 0.45$). Conversely, Empagliflozin exhibited statistically non-significant reductions in body weight ($p = 0.56$), BMI ($p = 0.28$), HDL-C levels ($p = 0.40$), LDL-C ($p = 0.15$), and TAG ($p = 0.35$). Regarding hepatic enzymes, the changes observed in ALT levels for dapagliflozin and empagliflozin were non- significant, with p-values of (0.22) and (0.50), respectively. Similarly, there were non-significant changes in AST levels, with p-values of (0.08) for dapagliflozin and (0.07) for empagliflozin. **Conclusion:** Our results suggest that dapagliflozin treatment is more effective than empagliflozin in patients with MASLD, as evidenced by a significant reduction in weight and BMI, along with a noteworthy increase in HDL-C levels. Further prospective clinical data is needed to corroborate these findings.

4044 | PHARMACOLOGICAL TARGETING OF IKKA FOR RESOLUTION OF STEATOSIS, INFLAMMATION, AND FIBROSIS: A MECHANISTIC DISTINCT DEVELOPMENT OF HPN-01 FOR MASH

Belle Wang[1] Yongmei Li[1] Ke Li[1] T Jake Liang[2] Qisheng Li[1], [1]Hepanova, Inc., [2]National Institute of Diabetes, Digestive

Background: The pathogenesis of metabolic dysfunction-associated steatohepatitis (MASH) involves a multifactorial interplay among hepatic steatosis, inflammation, and fibrogenesis, yet few therapeutic agents effectively target all three processes. **Methods:** HPN-01 is a novel, orally bioavailable small-molecule inhibitor of IKKα (IκB kinase alpha), developed to modulate key pathogenic pathways driving MASH and its progression to hepatocellular carcinoma (HCC). Here, we describe the mechanistic basis and preclinical efficacy of HPN-01, with supporting early-phase clinical safety data. **Results:** KKα is activated in hepatocytes by metabolic, inflammatory and infectious stimuli, including obesity, insulin resistance, and HCV infection. Phosphorylated IKKα translocates to the nucleus, promoting transcriptional activation of sterol regulatory element-binding proteins (SREBP-1/2), thereby enhancing de novo lipogenesis through NF-κB-independent mechanisms. Knockdown of IKKα or pharmacologic inhibition via HPN-01 suppresses lipogenic gene expression and lipid droplet accumulation. In an STZ + high-fat diet-induced MASH model, HPN-01 treatment significantly reduced hepatic steatosis.

HPN-01 also attenuates hepatic inflammation by inhibiting IKKα-mediated NF-κB signaling, resulting in reduced serum ALT/AST and histologic inflammation scores in the mouse model. Composite MASH activity scores, incorporating steatosis, lobular inflammation, and ballooning, were significantly improved. Beyond inflammation, HPN-01 suppresses fibrogenic pathways regulated by IKKα, leading to reduced hepatic collagen content and fibrosis scores following a five-week treatment.

Furthermore, in a murine model that recapitulates the progression of MASH to HCC, HPN-01 markedly decreased serum alpha-fetoprotein (AFP), HCC formation and overall tumor burden. **Conclusion:** HPN-01 is currently under evaluation in a U.S. Phase I clinical trial in healthy volunteers. Preclinical toxicology and initial clinical data indicate a favorable safety profile. Collectively, these findings position HPN-01 as a mechanistically distinct, first-in-class therapeutic candidate capable of addressing the multifaceted pathobiology of MASH and preventing HCC development.

4045 | GLUCAGON-LIKE PEPTIDE 1 RECEPTOR AGONIST, SEMAGLUTIDE, REDUCES METABOLIC AND ALCOHOL-ASSOCIATED LIVER DISEASE (METALD)

Ramesh Bellamkonda[1] Sundararajan Mahalingam[1] Ojeshvi Ethiraj[1] Sathish kumar Perumal[2] Ramachandran Rajamanickam[2] Carol Casey[3] Kusum Kharbanda[2] Karuna Rasineni[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Veterans Affairs Nebraska-Western Iowa Health Care System, Omaha, NE, [3]University of Nebraska Medical Center

Background: Steatotic liver disease (SLD), which affects over 35% of the global population, is driven by high-caloric diet intake/obesity, excessive alcohol consumption, or a combination of both. The co-occurrence of obesity and chronic alcohol use significantly increases the risk of progressive liver injury and liver failure. Our lab's previous research has demonstrated that disruptions in metabolic hormone levels from chronic alcohol exposure or a high-caloric diet intake play a causative role in the development of metabolic-associated fatty liver disease (MASLD) and alcohol-associated liver disease (ALD), respectively. We and others have further reported that glucagon-like peptide 1 (GLP-1), an incretin, improves metabolic homeostasis and reduces hepatic fat accumulation in both MASLD and ALD. Building on this knowledge, our study aimed to investigate the effects of semaglutide, a GLP-1 receptor agonist, in an experimental mouse model of metabolic and alcohol-associated liver disease (MetALD), an emerging form of SLD resulting from diet-induced obesity and alcohol consumption. **Methods:** To replicate the features of MetALD, two-month-old mice were given 15% alcohol (gradual ramp-up over a 10-day period) in their drinking water along with an ad libitum access to Western diet [ResearchDiets D12079B]. The control group was fed a chow diet. After 12 weeks of this feeding regimen, a subset of MetALD mice received semaglutide (60 μg/kg BW/every other day for 4 weeks) while continuing their respective diet. At the end of the treatment period, the animals were fasted for 6 hours and underwent a glucose tolerance test. The following day, the animals were euthanized, and blood and tissue samples were collected for analysis. **Results:** Semaglutide (SG) treatment moderately reduced body weight in the MetALD groups. SG-treated MetALD mice showed a reduced adipose/body weight ratio, insulin resistance, serum AST, ALT, endotoxin, NEFA, and cholesterol compared to the untreated MetALD group. Additionally, SG treatment reduced hepatic steatosis, inflammation, and hydroxyproline content in the MetALD group. The hepatic S-adenosylmethionine (SAM):S-adenosylhomocysteine (SAH) ratio reflective of the methylation potential, was significantly reduced in the MetALD group compared to the control group; SG treatment significantly improved this ratio by increasing SAM levels. **Conclusion:** These results strongly suggest that semaglutide reduces MetALD pathology by improving insulin sensitivity, hepatic SAM levels, and gut permeability.

4046 | DISCOVERY OF SIRNA THERAPEUTICS TARGETING PNPLA3 I148M FOR THE TREATMENT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Chuan He[1] Chunxue Zhou[2] Huaye Pan[1] Xiaowei Sun[2] Rongyao Zhu[1] Haixia Yu[2] Xu Yang[1] Xiaochen Xu[2] Xiaobei Wang[1] Xiaochuan Cai[2] Shiyu Wang[2] Dongzhou Liu[1], [1]Hangzhou Zhongmei HuaDong Pharmaceutical CO. LTD, [2]sanegenebio

Background: The PNPLA3 I148M variant (rs738409) represents a critical genetic determinant of MAFLD/MASH pathogenesis, driving disease progression through gain-of-function effects on hepatic lipid metabolism. This mutation impairs triglyceride hydrolysis while promoting lipotoxic injury and fibrogenesis, creating an urgent need for therapies in this high-risk population. We developed a GalNAc-conjugated siRNA to address this unmet clinical need. **Methods:** GalNAc-siRNA sequences targeting PNPLA3 were rationally designed, and the IC50 efficacy was determined by high-

throughput screening in Huh-7 cells. The lead compounds were optimized using primary hepatocyte assays and whole-transcriptome off-target profiling. In vivo validation included humanized PNPLA3 I148M knock-in mice and cynomolgus monkeys. Comprehensive repeat-dose toxicology evaluations were conducted in both rodent and non-rodent species to establish the therapeutic safety window. **Results:** In in vivo studies where human PNPLA3 was expressed exogenously in the mouse liver, the top-performing compound achieved more than 85% target mRNA knockdown following single-dose administration, and exhibited favorable dose-dependent responses in multiple-dose regimens. In humanized PNPLA3 I148M knock-in mice, RNAi treatment resulted in sustained silencing activity and maintained target suppression 4 weeks after dosing. In cynomolgus monkey pharmacodynamic studies, more than 80% target mRNA silencing was achieved after 4 weeks and persisted through 12 weeks after a single subcutaneous dose. In in vivo safety studies, the test article showed good tolerability in both rodent and non-rodent species. **Conclusion:** Based on established delivery and screening platforms, we have identified a series of potent and durable PNPLA3-targeting molecules. GalNAc-PNPLA3 siRNA demonstrates exceptional liver targeting, deep and durable silencing, and favorable safety profiles. Taken together, these data support its advancement as preclinical candidate compounds (PCCs) for MAFLD/MASH precision therapy, especially for PNPLA3 I148M homozygous patients. The IND-enabling studies are planned.

4047 | EFFICACY AND SAFETY OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOHEPATITIS AND HEPATIC FIBROSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS WITH TRIAL SEQUENTIAL ANALYSIS

Eliabe Abreu[1] Rafael Borges[2] Luiza Paula[2] Ana Conegundes[2] Jefferson Martins[3] Marcelo Martins[4] Giovanni Gosch Berton[5] Alladin Dahbour[6] Erica Holanda[7] Manal Abdelmalek[1], [1]Mayo Clinic Rochester, [2]Federal University of Minas Gerais, [3]Federal University of Pará, [4]Federal University of Ouro Preto, [5]University of Passo Fundo, [6]Indiana University, [7]University Center Christus

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease. Metabolic dysfunction-associated steatohepatitis (MASH), the progressive form of MASLD, is a risk factor for progressive hepatic fibrosis and cirrhosis. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have revolutionized the treatment of obesity and diabetes; however, the role of GLP-1 RAs in the treatment of MASH with moderate-to-advanced (F2-F3) hepatic fibrosis, those 'at-risk' for adverse clinical outcomes, remains under investigation. This systematic review and meta-analysis evaluate the efficacy and safety of GLP-1 RAs in patients with MASH with fibrosis. **Methods:** We systematically reviewed and analyzed all randomized controlled trials (RCTs) from PubMed, Embase, and Cochrane databases about GLP-1 RAs and MASH. Primary outcomes included MASH resolution without worsening fibrosis or fibrosis improvement without worsening of MASH as defined by NASH CRN grading /staging criteria. Secondary outcomes included adverse events (AE), laboratory, and anthropometric data. Trial Sequential Analysis (TSA) was performed for the primary outcomes and used to assess evidence sufficiency and control random errors in the meta-analysis. **Results:** Six RCTs (1,480 patients, mean follow-up: 150.8 weeks) were included. GLP-1 RAs were superior to placebo on histologic improvement of fibrosis without worsening MASH (RR 1.66; 95%CI 1.37-2.02, $p < 0.001$; $I^2 = 0\%$) and histological resolution of MASH without worsening of fibrosis (RR 2.69; 95%CI 1.65-4.39, $p < 0.001$; $I^2 = 66.3\%$). Patients treated with GLP-1 RAs reported higher rates of treatment-emergent gastrointestinal adverse events, but no significant differences in serious AE in GLP-1 RA versus placebo groups were observed. GLP-1 RAs improved hepatic aminotransferases, MRI-PDFF, HbA1c, serum lipids, blood pressure, and anthropometric parameters in RCTs of MASH with F2-F3 fibrosis. The TSA showed an adequate sample size and evidence unlikely to change with additional studies. **Conclusion:** GLP-1 RAs improve cardiometabolic risk factors in patients with MASH while also lending improvement and/or resolution of MASH and MASH-associated hepatic fibrosis. Ongoing studies will define whether these surrogate endpoints will translate into a decrease in liver- and all-cause morbidity and mortality in patients with 'at-risk' MASH.

4048 | BETAINE REDUCES HEPATIC INFLAMMATION AND FIBROSIS IN A PRE-CLINICAL MOUSE MODEL OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Izabela Hawro[1] *Sara Osorio-Valencia*[1] *Grace Guzman*[1] *Kusum Kharbanda*[2] *Mercedes Del Rio-Moreno*[1] *Rhonda Kineman*[1], [1]*University of Illinois at Chicago,* [2]*University of Nebraska*

Background: Dysregulated hepatic methionine metabolism and increased homocysteine (Hcy) levels may promote hepatic inflammation and fibrosis. In hepatocytes, betaine-homocysteine S-methyltransferase (BHMT) reduces Hcy levels by utilizing betaine as a methyl donor to convert Hcy into methionine. We have shown that diet-induced metabolic dysfunction-associated steatohepatitis (MASH) reduces hepatic *Bhmt* expression and increases Hcy levels in male mice. Furthermore, we have reported that the knock-out of peroxisome proliferator-activated receptor gamma (*Pparg*) in hepatocytes ($Pparg^{\Delta Hep}$) increased hepatic *Bhmt* expression, reduced Hcy levels, and improved liver histology in mice with diet-induced MASH. Here, we sought to determine whether betaine supplementation reduces pre-established MASLD induced with fructose in the drinking water and high-fat and cholesterol diet (HFC+Fr) in both control and $Pparg^{\Delta Hep}$ mice. **Methods:** We fed male *Pparg*-floxed mice with a HFC+Fr diet for sixteen weeks to induce obesity, insulin resistance, and MASLD. Then, we generated control and $Pparg^{\Delta Hep}$ mice with AAV8-TBG-Null or AAV8-TBG-Cre injections, respectively. Half of the HFC+Fr-fed mice were supplemented with 1% betaine in the drinking water for eight additional weeks. **Results:** The HFC+Fr diet promoted dyslipidemia and insulin resistance, and increased body weight, plasma ALT levels, liver weight, steatosis, MASLD activity score (MAS), and fibrosis. $Pparg^{\Delta Hep}$ did not reduce body weight or adipose tissue mass, but increased plasma insulin levels in obese mice, which might be indicative of worsened insulin resistance. However, $Pparg^{\Delta Hep}$ improved liver health by reducing liver weight, steatosis, and plasma ALT levels. Furthermore, $Pparg^{\Delta Hep}$ reduced hepatic Hcy level, and increased S-adenosylhomocysteine, as well as the expression of key hepatic methyltransferases: *Mat1a*, *Pemt*, *Gnmt*, *Cbs*, and *Bhmt*. Of note, although betaine reduced liver weight in HFC+Fr-fed control mice, it did not alter the Hcy level or the MAS score. However, betaine was able to reduce the hepatic inflammation score and MAS in $Pparg^{\Delta Hep}$ mice (See Figure). This positive effect of betaine on the liver was associated with a dramatic reduction in fibrosis, as indicated by reduced gene expression of *Col1a1*, *Mmp13*, and *Timp1*, as well as decreased COL1A1 protein levels in both control and $Pparg^{\Delta Hep}$ mice (See Figure). In addition, betaine consistently reduced the expression of *Tnfa*, *Ccl2*, *Cd8a*, and *IL-17a* in the liver of both control and $Pparg^{\Delta Hep}$ mice (See Figure). **Conclusion:** Taken together, betaine had a robust and positive effect on the liver because it reduced hepatic inflammation and fibrosis in a mouse model with pre-established MASLD. This effect was enhanced by increased *Bhmt* expression in hepatocytes of $Pparg^{\Delta Hep}$ mice.

4049 | FIBROSIS REGRESSION WITH RESMETIROM: EARLY OBSERVATIONS IN REDUCING FIBROSIS IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Rachel Patel[1] Corey Savard[2] Cristina Angelo[2] She-Yan Wong[3] Adam Peyton[4], [1]Lehigh Valley Health Network, [2]Lehigh Valley Health Network / Division of Gastroenterology, [3]Thomas Jefferson University Hospital, [4]Eastern Pennsylvania Gastroenterology & Liver Specialists

Background: Metabolic dysfunction-associated steatohepatitis (MASH) with fibrosis is a leading cause of progressive liver disease, with limited effective pharmacotherapies. Resmetirom, a novel medication, has shown potential in clinical trials to reduce hepatic fibrosis. We aim to evaluate real-world outcomes of Resmetirom using FibroScan-derived liver stiffness measurements (LSMs) in patients with biopsy-confirmed or clinically suspected MASH with fibrosis. **Methods:** We conducted a prospective observational study of patients with MASH and fibrosis who began Resmetirom at Lehigh Valley Health Network between April–October 2024. Inclusion criteria: (1) age ≥18 years; (2) MASH with fibrosis confirmed by FibroScan or biopsy; (3) Resmetirom initiation during enrollment. Common metabolic comorbidities (e.g., diabetes, hypertension, hypertriglyceridemia, obesity) were not exclusionary. One patient was excluded post-enrollment due to financial inability to start therapy. Of 26 enrolled, 25 completed baseline assessment. Collected data included fibrosis stage, comorbidities, and GLP-1 receptor agonist use. Follow-up LSMs were planned ~12 months post-initiation. At submission, post-treatment LSMs were available for seven patients. Adverse events were monitored during treatment. Full cohort data are expected by the AASLD Liver Meeting 2025. **Results:** Among 25 patients initiating therapy, baseline fibrosis ranged F2–F4; 72% began at F3. The cohort was 64% female with a median age of 62. Comorbidities included diabetes (60%), hypertension (60%), obesity (76%), and hypertriglyceridemia (68%). Six patients (24%) were on GLP-1 receptor agonists at baseline. Among seven patients with follow-up LSMs: five demonstrated at least one-stage fibrosis regression (from F2–F4 to F0–F1), two remained stable and none showed fibrosis progression. Adverse events were minimal—two reported self-limited diarrhea, with no therapy discontinuations. Final statistical analysis, including paired pre- and post-treatment LSM comparisons, will be completed once follow-up for the full cohort is available. **Conclusion:** Preliminary findings suggest that Resmetirom may be associated with fibrosis regression in patients with MASH. Real-world safety and tolerability appear favorable to date. As additional post-treatment data are collected, we anticipate further insight into the potential for Resmetirom to promote fibrosis regression and improve liver stiffness measurements in this population. Full cohort analysis will be presented upon completion of ongoing data collection.

4050 | BEYOND BODY WEIGHT CONTROL: TRANSCRIPTOMIC ANALYSIS REVEALS ADDITIONAL BENEFICIAL EFFECT OF GIPR/GLP-1R AGONISTS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS THERAPY

Hui Li[1] Jiliang Zhang[1] Jingxuan Yan[1] Yan Zhou[1] Miao Yuan[1] Chen Liu[1] Luxia Wei[1] Xiuxiu Shen[1] Lijuan Jiang[1] Zhixiang Zhang[1] Qingyang Gu[1], [1]Wuxi AppTec

Background: Metabolic Dysfunction-Associated Steatohepatitis (MASH) poses a significant global health challenge. The lack of regulatory-approved MASH medications underscores the critical need for innovative treatments. Various gastric inhibitory polypeptide receptor (GIPR) and glucagon-like peptide-1 receptor agonists (GLP-1RAs) are undergoing clinical trials at different stages for MASH, potentially providing new avenues for MASH therapy. Semaglutide (SEM) and Tirzepatide (TZP) are both under clinical investigation for MASH therapy, with promising therapeutic potential.

This study aimed to investigate the differential responses to SEM and TZP at the transcriptional level in MASH mice. Additionally, this study also examined the mechanism of action of SEM and TZP beyond satiety and food consumption regulation by introducing corresponding dietary restriction groups. **Methods:** MASH mice were either treated with SEM or TZP for 6 weeks. Meanwhile, a dietary restriction control groups for each drug were set respectively. Transcriptional profiling then was done with liver samples collecting from each group. **Results:** In this study, SEM and TZP both exhibited a significant reduction in the NAS score in MASH murine models, though with no substantial changes in liver fibrosis scores. The transcriptomic analysis of the HDF+CCl4 MASH model, effectively replicating human MASH histopathology, revealed significant perturbations in lipid metabolism, xenobiotic metabolism, inflammation, extracellular matrix regulation, retinol metabolism, and PPAR signaling pathways. On a molecular level, SEM and TZP demonstrated overlapping effects on pathways such as steroid biosynthesis, PPAR signaling regulation, and arachidonic acid and retinol metabolism. Notably, both SEM and TZP showed distinctive modulation effects on retinol metabolism, PPAR signaling, and other inflammatory pathways compared to their respective dietary restriction controls. **Conclusion:** These findings suggest additional beneficial effects beyond food intake regulation for SEM and TZP, emphasizing their therapeutic potential for MASH and underscore the importance of delineating the molecular mechanisms driving these beneficial effects in MASH treatment to fully harness the therapeutic potential of SEM and TZP.

4051 | REAL WORLD RESMETIROM 6-MONTH FOLLOW UP DATA

Nadia Blessing Benjamin Robinson[1] Phoebe Shackelford[2] Nicole Cowgill[1] Jake McCarty[2] Neel Ravela[2] Andrew deLemos[1] Niharika Samala[2], [1]Wake Forest University Atrium Health, [2]Indiana University

Background: Metabolic dysfunction associated steatohepatitis (MASH) is the second leading cause of liver transplantation in the United States. In March 2024, the FDA conditionally approved resmetirom, a thyroid hormone receptor-b agonist for MASH with stage 2/3 fibrosis. Follow up data on patients on resmetirom for at least 6 months are needed. **Methods:** We report retrospective study of the patients approved to start resmetirom between March 14, 2024 and November 19, 2024, ensuring at least 6-months on medication, at two academic health centers- Indiana University Health (IUH) (N = 111) and Atrium Health and Wake Forest University (AHWF) (N = 33). Once approved patients were provided laboratory orders and clinic visit at 6 month follow up. Early experience with resmetirom in a portion of the study cohort was described in an earlier publication. **Results:** A total of 148 patients received resmetirom for at least 6 months, 69% females, 94% White, and 4% Hispanic with mean age of 52.8 $\pm$ 13.6 years and mean BMI of 37 $\pm$ 8Kg/m^2. Type 2 diabetes was seen in 50% and hypothyroidism in 27% of the cohort. All patients had health insurance - Medicare in 28% (42), Medicaid in 11% (17) and private in 60% (89). Median time from treatment approval to actual start was available in 69% of the cohort and was 26 $\pm$ 30 days. Additionally, 48% (63) were on GLP-1 R agonists, 39% (51) on statins and 32% (45) were on vitamin E. Of 132 (88%) who started the treatment, 17% (22) discontinued treatment within 6 months of initiation, of which 82% (18) were related to side effects, 3 could not afford the medication and 1 opted to participate in a clinical trial. There were no further discontinuations at 6 months follow up visits. Side effects were seen in 36 (27%) early in course of medication exposure – diarrhea in 16 (44%), abdominal pain/discomfort in 9 (25%), nausea or vomiting in 6 (17%), itching or rash in 6 (17%), and dizziness or headache in 4 (11%). Of those who continued the medication (n = 110), mean ALT at 6-months (n = 98) was lower than at baseline (44 $\pm$ 36 U/L vs. 56 $\pm$ 53 U/L, $p < 0.009$). Follow up liver stiffness measurement was only seen in 39 patients, with no significant difference from baseline (13.9 $\pm$ 7kPa vs. 12 $\pm$ 8kPa, $p = 0.3$). **Conclusion:** Most patients tolerated resmetirom well, with only 17% discontinuations, mostly related to side effects, which presented early in medication exposure, within 6 months. Compared to baseline, ALT was significantly lower after 6 months of treatment with resmetirom.

4052 | RESMETIROM IMPROVES MORTALITY, LIVER AND CARDIO-RENAL-METABOLIC (CRM) OUTCOMES IN INDIVIDUALS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE IN ROUTINE CLINICAL PRACTICE

Vinay Jahagirdar[1] Kavin Parmar[1] Neha Shah[1] Amon Asgharpour[1] Velimir Luketic[1] Ekaterina Smirnova[1] Juan Pablo Arab[1] Arun Sanyal[1], [1]Virginia Commonwealth University

Background: Resmetirom is conditionally approved for the treatment of metabolic dysfunction-associated steatohepatitis (MASH) with fibrosis based on histological improvement in clinical trials. Its benefits on liver and cardio-renal-metabolic (CRM) outcomes, that are competing threats to life, are unknown. The aim of this study was to evaluate the impact of resmetirom on liver- and CRM-outcomes. **Methods:** Patients with MASLD who received resmetirom were included along with controls matched for age, race, sex, BMI, type 2 diabetes mellitus (T2DM), smoking status, prior known coronary artery disease (CAD), chronic kidney disease (CKD), LDL-cholesterol (LDL-C), alcohol use and GLP-1 use. The key outcome measures included 5-point major cardiovascular adverse events (MACE), major adverse liver outcomes (MALO) (ascites, overt hepatic encephalopathy, variceal hemorrhage), new onset hypertension, CKD, T2DM and death. The period of observation was up to 1 year since the drug was only recently approved. Those with events prior to start date were excluded for specific outcome analyses. Proportions of patients with outcomes and Kaplan Meier estimates of time to outcomes were analyzed. **Results:** A total of 1304 individuals each with MASLD who received resmetirom and matched controls were identified; 27% were on a GLP-1 agonist. Baseline demographics included (mean or %): age-56 yrs., white-74%, T2DM-46% while laboratory data were (resmetirom vs control): AST-44 vs 33 IU/l, Bilirubin-0.6 vs 0.7 mg/dl, platelets- 237 vs 247K/mm3, A1C- 6.2 vs 6.4%, LDL-C-92 vs 96 mg/dl. Resmetirom (vs control) improved mortality (absolute risk (AR): 0.7 vs 2%, $p < 0.0009$, Odds ratio (OR) 0.31 95% CI (0.2-0.6), time to death ($p < 0.003$ logrank). It improved MACE (AR): 0.74 vs 3.1% $p < 0.0001$, OR: 0.23 (0.11-0.47) and time to MACE (logrank $p = 0.008$), MALO: (AR: 1 vs 2.2%, $p < 0.01$, OR: 0.45 (0.24-0.85) without affecting time to outcome. It improved other CRM outcomes also: new onset CKD: AR: 0.9 vs 2.9%, $p = 0.0001$, OR:0.3 (0.15-0.55), new onset hypertension: (AR: 4.7 vs 13.3%, $p < 0.00001$, OR:0.32 (0.2-0.5) and new onset T2DM (AR: 4.5 vs 7.4%, $p = 0.01$, OR: 0.6, 0.4-0.9). It did not affect overall cancer incidence (AR: 0.8 vs 0.9%, p = NS). These benefits were independent of statin use or weight change. **Conclusion:** In a real-world clinical practice, resmetirom improved mortality, liver and CRM outcomes in patients with MASLD.

4053 | HARNESSING THE PERIPHERAL SEROTONIN SIGNALING: NON-PSYCHEDELIC PSILOCIN ANALOGUES DESIGNED FOR THE TREATMENT OF MASLD

Sara De Martin[1] Martina Colognesi[1] Daniela Gabbia[1] Anna Signor[1] Giovanna Finzi[2] Lucia Centofanti[3] Ilaria Goggi[3] Marco Banzato[1] Alessandro Cadore[1] Camillo Morano[3] Michele Dei Cas[3] Carla Perego[3] Alessandra Galli[3] Stefano La Rosa[4] Rita Paroni[3] Stefano Comai[1] Paolo Manfredi[5] Franco Folli[1] Andrea Mattarei[1] Gianfranco Pasut[1], [1]University of Padova, [2]Azienda Socio Sanitaria Territoriale (ASST) dei Sette Laghi, Varese, Italy, [3]University of Milan, [4]University of Insubria, [5]MGGM Therapeutics

Background: In a diet-induced model of MASLD, chronic low dose psilocybin reduced liver steatosis, limited body weight (BW) gain, and improved glucose and lipid homeostasis. Psilocybin is the prodrug of psilocin, a serotonin analogue that binds 5-HT receptors (5-HTRs) in both the CNS and peripheral tissues. We hypothesized that a gastrointestinal (GI)-targeted, CNS-sparing, psilocin derivative might retain metabolic benefits without psychedelic effects. **Methods:** A library of psilocin conjugates with polyethylene-glycols (PEGs) of different length (4, 6, 8, 10 monomers) was designed, synthetized and pharmacologically profiled using FLIPR assay in CHO-cells overexpressing 5-HT2A, 2B or 2C receptors. A standard toxicology evaluation was performed in rats. PK analyses were performed in C57BL6J mice by measuring drug concentration in plasma, liver and brain by LC-MS. Head-twitch response (HTR) in mice was tested at increasing doses. The metabolic effects of 12 weeks of daily oral gavage with 0.05 mg/kg psilocybin, PEG-8-psilocin (equiv. dose) or placebo were tested in mice ($n = 10$ per group) fed on high fat (60% kcal from fat) and high fructose (30% in drinking water) diet (HFHFD) for 5+12 weeks. Mice fed with standard diet were included as healthy controls. Liver steatosis was evaluated by H&E and ORO staining. Hepatic lipids were evaluated by LC-MS/MS untargeted lipidomic analysis. An oral glucose tolerance test was performed before sacrifice. Pancreas ultrastructure was evaluated by transmission electron microscopy. **Results:** PEG-8 psilocin was identified as the lead candidate due to its low oral bioavailability and negligible brain exposure. It maintained psilocin-like activity at 5-HT2 receptors, was well-tolerated in rats, did not elicit HTR.Chronic treatment with PEG-8-psilocin, similarly to psilocybin, resulted in marked reduction of liver steatosis and significantly reduced BW gain vs healthy mice ($p < 0.01$ for PEG-8 psilocin and $p < 0.05$ for psilocybin). At lipidomic analysis, PEG-8-psilocin restored hepatic di- and triglycerides, increased by HFHFD, back to healthy control levels, with a stronger effect than psilocybin. Furthermore, PEG-8-psilocin normalized glucose tolerance curves and improved pancreatic β-cell ultrastructure, as evidenced by insulin granule number and morphology. **Conclusion:** In this MASLD mouse model, the GI-targeted, brain-impermeable, psilocin derivative PEG-8-psilocin significantly reduced liver steatosis and improved key metabolic parameters, supporting the role of gastrointestinal 5-HTRs as likely mediators of the metabolic benefits observed with both psilocybin and PEG-8-psilocin.

CIBEREHD, [2]Liver Vascular Biology, IDIBAPS - Hospital Clínic de Barcelona - CIBEREHD, [3]Hospital Clínic de Barcelona, [4]Hospital Clínic de Barcelona - CIBEREHD

Background: Liver fibrosis is a major contributor to chronic liver disease, currently lacking effective pharmacological therapy. Understanding extracellular matrix (ECM) remodeling is essential for characterizing fibrosis progression and resolution. Precision-cut liver slices (PCLS) represent a valuable ex vivo tool, maintaining native liver architecture and enabling multicellular ECM assessment. However, traditional static cultures limit slice viability and induce phenotypic drift, constraining long-term studies. This work aimed to establish a novel human 3D liver model using PCLS cultured in a microfluidic device that preserves tissue viability, architecture, and cirrhotic phenotype for up to 7 days, and to assess liraglutide's antifibrotic effects within this system. **Methods:** Human PCLS from cirrhotic explant livers (ALD and MetALD etiologies) were cultured under conventional or microfluidic conditions ($n = 5$ per group). Viability, necrosis, sinusoidal fibrosis, and liver function were evaluated at 24h, 72h, and day 7. Expression of LSECs, HSCs and macrophages specific phenotypic markers was assessed by qPCR, and cellular interactions were visualized by immunofluorescence co-localization of vimentin (HSC marker) and endomucyn (LSEC marker). Cirrhotic PCLS were treated with liraglutide (200 μM) or vehicle (PBS) for 7 days ($n = 6$–7 slices/condition), and fibrogenic profile was analyzed at the transcript, protein and histological levels. **Results:** Microfluidic-cultured PCLS showed markedly reduced necrosis (−59%), sinusoidal fibrosis (−33%), and release of LDH, ALT, and AST at day 7 compared to static culture. Albumin secretion increased under flow at 24 h (+52%). Cirrhotic phenotypes of LSECs, HSCs, and macrophages were better retained within the device, with maintenance of HSC–LSEC interaction. Liraglutide treatment significantly reduced mRNA expression of ACTA2 (−65%), COL1A1 (−69%), and PDGFRB (−61%), alongside protein reductions in α-SMA (−41%), VIM (−51%), and COL1A1 (−56%), which were associated with an improvement in Sirius-Red stained area (-24%), altogether consistent with HSC deactivation and ECM remodeling. All $p < 0.05$. **Conclusion:** This study introduces a robust human 3D liver model based on microfluidic-cultured PCLS, preserving tissue integrity and cellular phenotypes up to 7 days. Furthermore, it demonstrates liraglutide's ability to deactivate HSCs and remodel ECM in human cirrhotic liver tissue. This platform offers a physiologically relevant and translationally meaningful system for antifibrotic drug evaluation, bridging experimental research with clinical application.

4055 | EFFECTS OF PEMAFIBRATE ON IMPROVEMENT AND RECURRENCE IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Takamasa Ohki[1], [1]Shioda Memorial Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a liver condition closely associated with metabolic syndrome and frequently accompanied by dyslipidemia. Pemafibrate (PEM), a selective peroxisome proliferator-activated receptor alpha modulator (SPPARMα), exerts a strong triglyceride-lowering effect and has also been reported to improve alanine aminotransferase (ALT) levels and hepatic steatosis. However, as MASLD is primarily driven by lifestyle factors, recurrence after improvement is a concern. This study aimed to evaluate the therapeutic effect of PEM and the recurrence of abnormal ALT levels in MASLD patients with dyslipidemia. **Methods:** A total of 127 MASLD patients with dyslipidemia who were prescribed PEM between July 2019 and October 2024 were retrospectively analyzed. The primary outcome was normalization of ALT levels, defined as ≤ 30 IU/L. The secondary outcome was recurrence, defined as ALT returning to ≥ 31 IU/L on two consecutive measurements after normalization. Factors associated with ALT normalization and recurrence were also analyzed. **Results:** Among the 127 patients, 96 (76%) were male, the median age was 55 years, and the median BMI was 27.8 kg/m². Diabetes mellitus was present in 62 patients (49%). The median baseline ALT was 64 IU/L, triglycerides were 289 mg/dL, and the median PEM treatment duration was 21 months. At 12 months, ALT decreased to a median of 37 IU/L and triglycerides to 190 mg/dL, both showing significant improvement ($P < 0.01$). ALT normalization

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

was achieved in 73 patients (57%). The cumulative normalization rates were 37% at 6 months, 50% at 12 months, and 65% at 24 months. In univariate analysis, only age was significantly associated with ALT normalization (HR 1.02, P = 0.048). Among the 73 patients with normalized ALT, 13 (18%) experienced recurrence. The cumulative recurrence rates were 7% at 6 months, 20% at 12 months, and 20% at 24 months. **Conclusion:** PEM therapy led to normalization of ALT levels in approximately half of MASLD patients with dyslipidemia. However, about 20% experienced recurrence, highlighting the importance of sustained lifestyle modification alongside pharmacotherapy.

4056 | GENIPIN 1-β-D-GENTIOBIOSIDE ALLEVIATES MASH BY INHIBITING HEPATIC PP2A ENZYMATIC ACTIVITY

Xin Xin[1] Cheng Chen[1] Xu Xiao[1] Chen Zou[1] Qinmei Sun[1] Cen Xie[2] Yiyang Hu[1] Feng Qin[1], [1]Shuguang Hospital affiliated to Shanghai University of Tradional Chinese Medicine, [2]Shanghai Institute of Materia Medica, Chinese Academy of Sciences

1. **Background:** Genipin 1-β-D-gentiobioside (GG) is a key bioactive component derived from the herb Gardenia jasminoides. This study aims to investigate the therapeutic potential of GG in treating metabolic-associated steatohepatitis (MASH) and to elucidate its underlying pharmacological mechanisms. **Methods:** The anti-MASH effects of GG were evaluated using two murine models induced by a high-fat, high-carbohydrate (HFHC) diet and a methionine/choline-deficient (MCD) diet, as well as a rat model induced by a high-fat diet (HFD).
2. *In vitro* studies utilized free fatty acid (FFA)-induced THLE2 cells and primary hepatocytes to assess lipid accumulation and inflammation.
3. Potential GG-binding proteins were identified through HuProt protein microarray screening and pull-down mass spectrometry. Binding interactions were validated using surface plasmon resonance (SPR), drug affinity responsive target stability (DARTS), and cellular thermal shift assay (CETSA). Phosphoproteomic profiling was employed to identify downstream effectors of the GG target protein.
4. *In vivo* and *in vitro* liver-specific gene editing models were used to confirm the mechanistic role of GG in MASH. **Results:** GG significantly reduced hepatic lipid accumulation, inflammation, and early-stage fibrosis in MASH animal models. *In vitro*, GG effectively mitigated FFA-induced lipid deposition in hepatocytes.

1. Combined analyses identified protein phosphatase 2A (PP2A) as a direct binding target of GG, with strong binding affinity confirmed by SPR (KD = 7.99 × 10^{-6} M). Notably, while GG did not alter PP2A expression levels, it significantly inhibited its enzymatic activity, which was upregulated under metabolic stress conditions.
2. Phosphoproteomic analysis identified acetyl-CoA carboxylase 1 (ACC1), a key enzyme in de novo lipogenesis, as a downstream substrate of PP2A. Co-immunoprecipitation confirmed the interaction between PP2A and ACC1. GG-mediated inhibition of PP2A activity led to increased phosphorylation of ACC1, suppressing its lipogenic activity.
3. Hepatocyte-specific deletion of PP2A *in vivo* and *in vitro* abolished the therapeutic effects of GG, confirming PP2A as a critical mediator of GG's action against MASH. **Conclusion:** GG alleviates MASH by inhibiting hepatic PP2A enzymatic activity, thereby enhancing ACC1 phosphorylation and suppressing *de novo* lipogenesis. These findings highlight GG as a promising therapeutic candidate for MASH treatment.

4057 | IMPACT OF LEVOTHYROXINE ON PROGRESSION TO AND COMPLICATIONS OF CIRRHOSIS IN MASH

Abhinav Rao[1] Don Rockey[1], [1]Medical University of South Carolina

Background: Resmetirom, a liver-targeted thyroid hormone receptor-β (THR-β) agonist, used to treat MASH, shares a similar mechanism of action with levothyroxine, a nonselective (THR-α/β) receptor agonist used to treat hypothyroidism. Given the potential effect of levothyroxine on THR-β, we hypothesized that it may have beneficial effects in MASH patients. **Methods:** We used TriNetX to examine patients aged ≥18 years with MASH treated with levothyroxine from 1/1/16-1/1/25. Patients prescribed levothyroxine (levothyroxine group) were compared to those not receiving them (control group). Patients with previous cirrhosis or liver transplant were excluded. To control for disease severity and underlying comorbidities, propensity score matching (PSM) was performed. **Results:** Of 109,268 patients with MASH, 17,629 (16%) received levothyroxine. Following PSM, we examined 15,076 patients in each group. MASH patients with or without levothyroxine treatment were predominantly White females, with a mean [SD] bilirubin, INR, and creatinine of 0.6 [0.7], 1.1 [0.4], and 0.9 [1.2], respectively. Comorbidities, BMIs and MASH therapies including GLP-1s, SGLT-2s, and statins were similar in both groups. Over a mean [SD] follow-up of 2.8 [1.8] years, patients receiving levothyroxine had a similar rate of progression to cirrhosis (HR:1.08;95% CI:0.97–1.21;p = 0.16) as patients not on levothyroxine. In patients who developed cirrhosis, those receiving levothyroxine had a small, but statistically significantly higher risk of developing any portal hypertensive complication (HR:1.33;95% CI:1.18–1.49; p < 0.001) than those not receiving levothyroxine. **Conclusion:** MASH patients prescribed levothyroxine had a similar rate of progression to cirrhosis and a slightly higher rate of portal hypertension complications than those not prescribed levothyroxine.

Table 2. Clinical Outcomes

Outcomes (%)*	Levothyroxine (N = 15,076)	No Levothyroxine (N = 15,076)	HR (95% CI)	P value (Log-Rank)
MASH Cirrhosis	698 (4.6)%	579 (3.8%)	1.08 (0.97-1.21)	NS
Any portal hypertensive complication	698 (4.6)%	484 (3.2%)	1.33 (1.18-1.49)	<0.001
Ascites	251 (1.7%)	201 (1.3%)	1.14 (0.95-1.38)	NS

4058 | REALWORLD USE PATTERNS OF RESMETIRON IN PATIENTS WITH MASH: ANALYSIS OF A NATIONAL COHORT

Tatyana Kushner Kate Solpari[1] Scarlet Yang[1] Stephanie Rutledge[1] Allysa Saggese[1] Adam Buckholz[1] Sonal Kumar[1], [1]Weill Cornell Medicine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

Background: Resmetiron was FDA approved for use in MASH with advanced fibrosis in March 2024. We evaluated current prevalence and predictors of resmetiron use in a national realworld cohort. **Methods:** We performed a population-based retrospective study of individuals with a prescription for resmetiron compared to individuals with a diagnosis code for metabolic dysfunction associated steatohepatitis (MASH) not on resmetiron based on ICD10 code K75.81 from 2000-2025 using the TriNetX research network, which contains deidentified electronic health record data from 100 U.S. health care organizations. Prevalence and predictors of resmetiron prescriptions were assessed. **Results:** We identified a total of 1638 individuals with a prescription for resmetiron, compared to a total of 247155 individuals with a diagnosis code for MASH who were not on resmetiron. Interestingly, only 66% of individuals on resmetiron had a diagnosis code for MASH in their medical record. A total of 24 health system providers had records of prescriptions of resmetiron. Individuals on resmetiron were lower age and more likely to be White and Asian compared to individuals with MASH not on resmetiron ($P < 0.05$), see Table 1. They were also more likely to have a diagnosis of obesity, type 2 DM, and hyperlipidemia ($p < 0.05$). Interestingly, 59% had a diagnosis code for hepatic fibrosis (compared to 20% in non-resmetiron group, $p < 0.0001$). Of note, 22% had a diagnosis of cirrhosis (compared to 41% in MASH comparison group). Among patients on resmetiron, 27% also had a prescription for semaglutide, 16% for tirzepatide; 32% were on atorvastatin. Patients on resmetiron had mean follow up of 128 days (SD 108). A total of 5% of individuals in both groups had a diagnosis of alcohol related disorders. **Conclusion:** Resmetiron is still uncommonly prescribed nationally, with a small number of health systems currently prescribing it. Patient characteristics of resmetiron group reflect high burden of metabolic comorbidities, with over 25% also being on glp-1 therapies. Relatively high rates of prescriptions among people with diagnosis of cirrhosis suggests off label prescribing practices. Given current short duration of real-world follow up of patients on resmetiron, longer follow up is needed in order to assess influence on disease outcomes in the real world.

Table 1. Characteristics of patients on resmetiron compared to control MASH population not on resmetiron.

	Individuals on Resmetiron (n=1638)	Individuals with MASH not on Resmetiron (n=253797)	P value
Demographics			
Age (mean, SD)	56.8 (13.7)	61 (15)	<0.0001
Female (n, %)	954 (60%)	137470 (54%)	<0.001
Hispanic	640 (40%)	106479 (42%)	0.114

4059 | SEMAGLUTIDE-INDUCED WEIGHT LOSS IS THE MAIN DETERMINANT FOR THE IMPROVEMENT OF HEPATIC BIOCHEMISTRY AND ELASTOGRAPHIC REPEATED MEASUREMENTS WITH FIBROSCAN® IN PATIENTS WITH T2DM AND MASLD

Savvoula Savvidou[1] Electra Avgousti-Varela[1] Aikaterini Damianakou[1] Miltos Chalkias[1] Ioannis Stergiou[1] Georgios Petridis[1], [1]"G.GENNIMATAS" General Hospital of Thessaloniki

Background: Semaglutide is currently being investigated for its effectiveness in MASLD (anticipated ESSENCE trial results), even though recent studies have concluded on its usefulness in MASH-related cirrhosis. Aim of this study was to examine the effect of semaglutide on hepatic parameters of patients with T2DM and MASLD in real-world clinical practice, and to further assess the significance of weight loss during treatment. **Methods:** In consecutive patients with T2DM and MASLD, hepatic biochemistry, non-invasive score of FIB-4 (= age x AST / platelets x $\sqrt{}$ALT), and elastographic measurements with FibroScan® mini+430 (Echosens, Paris) of liver stiffness (LSM) and Controlled Attenuation Parameter (CAP) were recorded before and after treatment with semaglutide. All participants had ultrasonographic evidence of fatty liver, while respective

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

CAP measurements exceeded 220 dB/m. Differences (Δ) were calculated as % percentages of (final – baseline) / baseline values. For within group comparisons, Wilcoxon Signed Ranked test for related samples was performed, while the effect of weight loss was investigated statistically with MANCOVA. **Results:** A total of 111 patients were investigated: 31 males (27.9%), mean age 56.4 ± 9.7 years-old, BMI 32.7 ± 6.3 kg/m^2, median HbA1c 5.8% (IQR 5.6-6.2). Prevalence of metabolic factors: dyslipidemia 66.7%, obesity 64.9%, arterial hypertension 74.8%. Semaglutide (0.5-2.4mg/week sc.) was administered for a median of 12 months (IQR 6.6-17). Baseline lab: AST 26U/L (IQR 19-47), ALT 31U/L (IQR 22-81), γGT 45U/L (IQR 22-73), FIB-4 1.09 (IQR 0.78-1.38). Thirty-three patients (29.7%) had AST and/or ALT above upper limit of normal (ULN), and 35 (31.5%) FIB-4 > 1.30 (cut-off for intermediate/high-risk of advanced hepatic fibrosis). Apart from an overall drop in HbA1c of 5.6% (IQR 1.6-8.6) and weight loss of 10% (IQR 3.2-19.6), statistical significant reductions were recorded in liver enzymes, and elastographic parameters [GRAPH].
Improvements in AST, ALT, γGT, LSM and CAP correlated independently to weight loss and semaglutide treatment duration (Pearson correlation, $p < 0.001$). In multivariate analysis of covariance, weight loss was found to be associated with Δ_ALT ($p = 0.016$), Δ_AST ($p = 0.001$), Δ_LSM ($p = 0.030$) and Δ_CAP ($p = 0.001$), irrespective of treatment duration and baseline FIB-4 score. **Conclusion:** In this cohort of T2DM/MASLD patients with baseline satisfactory glycemic control, semaglutide-induced weight loss led to significant improvements of all hepatic parameters (biochemistry, liver stiffness and steatosis assessed with CAP), even in MASLD patients with baseline liver enzymes within normal. This study supports the advantages of semaglutide administration in T2DM patients with concomitant MASLD of any stage.

4060 | KEY INTERACTION BETWEEN ASPIRIN, MEDITERRANEAN DIET AND MORTALITY IN HIGH-RISK MASLD: ANALYSIS OF NHANES 2011-2018

Tsubasa Tsutsumi[1] Mary Rinella[2] Takumi Kawaguchi[1] Sarah Kolb[3] Hee Yeon Kim[3] Dejan Micic[4] Matthew Odenwald[3] Edwin Mcdonald[3] Michael Charlton[5], [1]Kurume University School of Medicine, [2]The University of Chicago, [3]University of Chicago, [4]University of Chicago Medical Center, [5]Madrigal Pharmaceuticals

Background: The benefit–risk profile of low-dose aspirin (ASA) in individuals with metabolic dysfunction–associated steatotic liver disease (MASLD) remains uncertain. The extent to which dietary patterns modulate this relationship is largely unexplored. We examined whether degree of adherence to the Mediterranean-style diet, assessed by Mediterranean diet score (MDS) modifies the impact of ASA use on all-cause mortality in patients with MASLD in a nationally representative cohort. **Methods:** We analyzed 4,541 adults (median follow-up 4.8 years) from NHANES 2011–2018 with linked mortality data. MASLD was defined by US-FLI > 60 and at least one cardiometabolic risk factor; habitual ASA use was self-reported. A 24-h dietary recall–derived MDS was categorized into tertiles (Low, Mid, High). Cox models accounting for complex survey design included ASA, MASLD, MDS, all lower-order terms, and the ASA × MASLD × MDS interaction. Covariate adjustment was stepwise: Model 0, unadjusted; Model 1, demographics (age, sex, race/ethnicity, marital status, education, poverty index); Model 2, Model 1 plus smoking, cancer history, and cardiovascular disease. The outcome was all-cause mortality. **Results:** In the fully adjusted survey-weighted model, the three-way interaction (ASA × MASLD × MDS) reached statistical significance ($p = 0.02$). In crude analysis, participants prescribed prophylactic ASA, who inherently carried higher baseline cardiovascular risk, showed elevated mortality (HR 6.51, 95 %CI 3.32–12.75). This excess risk was attenuated after demographic adjustment (HR 2.35) and became non-significant in the fully adjusted model (HR 2.07, 0.95–4.52), indicating substantial confounding rather than a harmful pharmacologic effect. MASLD itself doubled mortality risk (HR 2.32, 1.18–4.58). Diet quality showed no association with mortality in participants without MASLD (Mid vs Low 95% CI 0.81–2.74; High vs Low 95%CI 0.51–1.66). In contrast, among MASLD participants a High MDS reduced mortality by 68 %—interaction-derived HR 0.32 (95% CI 0.12–0.87)—whereas a Mid-level score was essentially neutral

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

(combined HR ≈ 0.82). Among patients with MASLD using ASA, diet quality displayed a non-linear pattern. Using the low-MDS subgroup as reference (combined HR = 1.49), mid-level adherence of MDS was neutral (HR 1.37, 95 % CI 0.68–2.76), whereas high adherence tended to reduce mortality (HR 0.68, 0.32–1.42) although not statistically significant. **Conclusion:** In patients with MASLD, diet quality modulates aspirin's impact in a threshold-like fashion: high MDS tends to attenuate mortality, whereas both low (non-adherence) and mid-range scores show no clear benefit. These findings highlight the need for diet-informed, personalized aspirin prophylaxis and for prospective studies that minimize indication bias.

4061 | LUSEOGLIFLOZIN REDUCED CVD RISK BY IMPROVING BLOOD PRESSURE AND HDL CHOLESTEROL LEVELS IN DIABETIC PATIENTS WITH MASLD: A POOLED META-ANALYSIS OF PHASE III CLINICAL TRIALS USING A CAUSAL INFERENCE ANALYSIS

Takumi Kawaguchi[1] Hiromitsu Kajiyama[2] Hironori Yamaguchi[3] Yutaka Seino[4], [1]Kurume University School of Medicine, [2]2. Taisho Pharmaceutical Co., Ltd., [3]Taisho Pharmaceutical Co., Ltd., [4]Kansai Electric Power Hospital

Background: Luseogliflozin, a sodium-glucose cotransporter 2 inhibitor, potentially exerts pleiotropic effects on the heart and liver. We aimed to investigate the effects of luseogliflozin on cardiovascular disease (CVD) risk in diabetic patients with MASLD by a pooled meta-analysis of phase III clinical trials. Furthermore, we investigated the direct causal interactions between changes in CVD risk and cardiometabolic risk factors (CMRFs) by luseogliflozin. **Methods:** In this pooled meta-analysis, we enrolled diabetic patients with MASLD who participated in phase III clinical trials of luseogliflozin (luseogliflozin group n = 259; placebo group n = 153). The primary outcomes were changes in the Framingham Risk Score (FRS) and the classification of FRS (high, intermediate, low risks) after 24

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

weeks. We also investigated the direct causal interactions between changes in FRS and CMRFs affected by luseogliflozin using a directed acyclic graph. **Results:** At the baseline, there were no significant differences in FRS and the classification of FRS between the luseogliflozin and placebo groups. No significant differences were also observed in any CMRFs between the two groups. Primary outcomes: Luseogliflozin significantly decreased FRS compared to placebo after 24 weeks (FRS 0.00 vs. -0.53 points, $P = 0.0039$). Luseogliflozin also significantly improved the classification of FRS compared to placebo (improvement in the classification 5.0% vs. 12.0%, $P = 0.0187$). There was no significant difference in changes in triglycerides and total cholesterol levels between the two groups. In contrast, luseogliflozin significantly improved body mass index (-0.1 vs. -0.7, $P < 0.0001$) and levels of HbA1c (0.17% vs. -0.44%, $P < 0.0001$), blood pressure (0.0 vs. -3.7 mmHg, $P = 0.0178$), and HDL-cholesterol (1.5 vs. 3.4 mg/dL, $P = 0.0106$) compared to placebo. The directed acyclic graph revealed that the improvement of FRS was directly caused by the changes in blood pressure and HDL-cholesterol levels, but not by other CMRFs induced by luseogliflozin. **Conclusion:** This pooled meta-analysis demonstrated that 24-week treatment with luseogliflozin improved FRS in diabetic patients with MASLD. Furthermore, the improvement in CVD risk was directly caused by the improvement of blood pressure as well as HDL-cholesterol levels. Thus, luseogliflozin may be useful for reducing CVD risk through the improvement of circulatory dynamics and lipid metabolism in diabetic patients with MASLD.

4062 | UNCOUPLER SKQ1 INDUCES WEIGHT LOSS AND NORMALIZES LIVER FUNCTION IN DIO RABBITS

Anton Petrov[1] Maksim Skulachev[2] Ivan Senin[2],
[1]Mitotech, [2]Mitolab

Background: SkQ1 is a small molecule that accumulates in mitochondria with high specificity and can stimulate mitochondrial uncoupling at much lower doses than conventional uncouplers. Antioxidant properties of SkQ1 provide additional protection against ferroptosis in liver tissue, which was demonstrated in animal models of both obesity and MASH. With combined potential effect of weight loss via uncoupling mechanism and positive impact on the liver SkQ1 may be ideal candidate for the next-generation treatment of MASH. **Methods:** In our first study study, to examine the effects of SkQ1 in DIO rabbit model of obesity, female NZW rabbits were exposed to the high fat diet for circa 14 weeks. SkQ1 was administered orally at low, medium and high doses QD. GLP-1 agonist treatment was administered at 0.03 mg/kg subcutaneously once every three days. The treatment window was approximately 8 weeks. Animals were monitored daily for body wight and weekly for food intake. Rabbit plasma was analyzed for ALT/AST and lipid levels at the end of the study to assess liver function.

To evaluate the effect of SkQ1 in STAM model of MASH, male C57BL/6J mice were subcutaneously injected with a low dose of streptozotocin solution 2 days after birth and were fed with high fat diet after 4 weeks of age. SkQ1 was administered at the dose of 2 mg/kg BID for four weeks. **Results:** In DIO rabbit study, all SkQ1 treatments demonstrated significant dose-dependent weight loss in the first part of the experiment. At the highest dose SkQ1 monotherapy induced 27% weight loss in DIO rabbits over approximately nine weeks of treatment ($p < 0.001$). Plasma lipids were also significantly reduced pointing to normalization of liver function. In the second part of the experiment, we used GLP-1 agonist injections to induce rapid weight loss in DIO rabbits over the course of two weeks. After two weeks of GLP-1 treatment, GLP-1 treatment was withdrawn, and oral SkQ1 treatment was introduced instead. SkQ1 treatment was able to prevent weight re-gain normally occurring when GLP-1 treatment is stopped in animal models and in human patients.

In the STAM model study no weight loss was observed, as in that model MASH was induced in lean animals. The study demonstrated SkQ1-induced reduction of both steatosis and ballooning in the liver ($p < 0.05$ vs. vehicle for both), as well as reduction of the combined NAFLD activity score ($p < 0.01$ vs. vehicle). Interestingly, these effects were accompanied by a significant reduction in fibrosis grade in the liver ($p < 0.05$ vs. vehicle). **Conclusion:** The two studies highlighted SkQ1 potential as a candidate for next-generation treatment of obesity and comorbidities both as a monotherapy and in a combination with GLP-1 agonists.

4063 | EVALUATING ANTIDEPRESSANT CHOICE: TCAS VS SSRIS IN MASLD PATIENTS WITH COMORBID MAJOR DEPRESSIVE DISORDER

Saad Ahmed[1], [1]Northwell Health NS-LIJ

Background: MASLD has been on the rise in recent years and it's link to diabetes, hypertension, and obesity is well known. However, depression is also noted to be prevalent among patients with MASLD. Specifically, it is estimated that 20% of patients with MASLD also suffer from MDD. SSRIs have long been established as the first line treatment for patients with MDD. Morever, there is evidence TCAs play a role in mitigating liver fibrosis. However, the literature is sparse in comparing the effect of TCAs and SSRIs for patients with MASLD and MDD. Thus, our project examined the effects of each class of these medications in patients with both MASLD and MDD in progression to cirrhosis, HCC, and mortality. **Methods:** This was a retrospective cohort study conducted using the TriNetX database and the US Collaborative Network, which includes healthcare information records from 60 healthcare organizations. Two cohorts were generated for patients with both MASLD and MDD and they were assigned to a group with treatment with either SSRIs or TCAs. These cohorts were propensity matched to age of diagnosis, sex, race, and metabolic comorbidities of hyperlipidemia, hypertension, and obesity. This generated two cohorts each with 291,573 patients and were examined for risk and Kaplan-Meier analysis. **Results:** At the end of the 20 year period, 10,030 patients in the TCA group (3.7%) and 11,076 in the SSRI group (4%) experienced cirrhosis. This corresponded to a risk difference of 0.3% ($p = 0$) with a risk ratio of 0.906 (95% CI 0.882, 0.930). Next, 1,361 patients in the TCA group (0.5%) and 1,484 patients in the SSRI group (0.05%) advanced to HCC. The risk ratio was 0.917 (95% CI 0.852, 0.987). Lastly, 26,270 patients in the TCA group (9%) and 27,044 in the SSRI group (9.2%) experienced mortality. This yielded a risk difference of 0.2% ($p = 0$) and a risk ratio of 0.972 (95 CI 0.956, 0.987). **Conclusion:** We found the use of TCAs was associated with a lower risk of progression to cirrhosis, HCC, and overall morality when compared to SSRI use. Although these differences were not robust, they were significant. It is thought the increased serotonergic effects of SSRIs can contribute to lipogenesis and hepatic steatosis. SSRIs have also thought to be associated with increased mitochondrial dysfunction and generation of reactive oxygen species. Similarly, TCAs may reduce liver fibrosis due to optimizing endoplasmic reticulum functioning and autophagy. This is consistent with other studies, including one that found TCAs can reduce liver fibrosis in patients with Hepatitis C when compared to SSRI use. Ultimately, our study is unique as we compared the effects of TCAs and SSRIs for patients with MASLD and MDD. Further investigation should be done to explore the mechanism of these findings. More weight should be given to using TCAs for such patients, especially when SSRIs are intolerable, while balancing side effect profiles.

4064 | SUPERIOR HEPATOPROTECTIVE EFFECTS OF OPK-88006, A NOVEL GLP-1/GLUCAGON RECEPTOR DUAL AGONIST, TO SEMAGLUTIDE AND SURVODUTIDE IN THE GAN DIET-INDUCED OBESE AND BIOPSY-CONFIRMED MOUSE MODEL OF MASH

Jacob Nøhr-Meldgaard[1] Michael Feigh[2] Jane Hsiao[3] Kristian Pedersen[1] Susanne Pors[1] Martin Rønn Madsen[1] Grzegorz Maciag[1] Miri Gerzon-Zakar[3] Tony Cruz[3] Amit Rivkin[3] Laura Moschcovich[3], [1]Gubra A/S, [2]Gubra, [3]Opko Health Inc.

Background: OPK-88006, a novel GLP-1/Glucagon receptor dual agonist, is in preclinical development for metabolic disease including obesity and metabolic dysfunction-associated steatohepatitis (MASH). The present study aimed to investigate the therapeutic benefits of OPK-88006 on metabolic, bichemical, histopathological and transcriptome profile in the translational Gubra Amylin NASH (GAN) diet-induced obese and biopsy-confirmed mouse model of MASH with liver fibrosis. The late-stage clinical candidates semaglutide (GLP-1) and survodutide (GLP-1/Glucagon) for the treatment of patients with MASH and liver fibrosis, were included for comparison. **Methods:** Male C57BL/6 mice were fed the GAN diet high in fat, fructose and cholesterol for 38 weeks prior to study start. A liver pre-biopsy was collected 4 weeks before treatment start. Only GAN DIO-MASH mice

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with biopsy-confirmed NAFLD Activity Score (NAS ≥ 5) and moderate/advanced fibrosis (stage F2-F3) were included and stratified into treatment groups (n = 16-18 per group). Mice were administered once daily subcutaneous vehicle, semaglutide (30 nmol/kg), survodutide (10 (low) and 15 (high) nmol/kg) and OPK-88006 (10 (low) and 20 (high) nmol/kg) for 12 weeks. Histopathological pre-to-post individual assessment of NAS and fibrosis stage was performed. Other terminal endpoints included quantitative liver histology, blood and liver biochemistry in addition to RNAsequencing-Bioinformatic analysis. **Results:** GAN DIO-MASH mice demonstrated robust vehicle-corrected weight loss of approx. 12%, 24% and 26% after 12 weeks of OPK-88006 (high), semaglutide and survodutide (high) treatment, respectively. All treatments similarly improved hepatomegaly, plasma transaminases and plasma lipids levels. All treatments promoted a 1-point significant improvement in NAS, predominantly driven by reduction in steatosis score, albeit only OPK-88006 induced 2-point significant improvement in NAS. Benefits on NAS were supported by quantitative liver histology on steatosis (hepatocytes with lipids, liver lipids) and marker of inflammation (galectin-3). No treatments improved fibrosis stage, however reduced markers for fibrosis (TIMP-1 PIIINP) and hepatic stellate activation (α-SMA), indicating effect on fibrogenesis. Finally, all treatments induced significant gene regulation and suppressed genes involved in extracellular matrix and inflammation pathways. **Conclusion:** OPK-88006 treatment improved metabolic, biochemical and histopathological parameters of MASH, including hepatic transcriptomic profile, in the GAN DIO-MASH mouse model. Notably, OPK-88006 treatment improved NAFLD Activity Score superior to late-stage clinical candidates semaglutide and survodutide, introducing OPK-88006 as a promising treatment for MASH.

4065 | TREATMENT WITH SGLT2 INHIBITORS IS ASSOCIATED WITH A REDUCTION IN ESOPHAGEAL AND GASTRIC VARICES IN PATIENTS WITH CIRRHOSIS

Siham Abdelgani[1] Sasha Tverski[1] Oren Shibolet[1] Helena Katchman[1], [1]Tel-Aviv Sourasky Medical Center, Faculty of Medicine, Tel-Aviv University

Background: Clinically significant portal hypertension (CSPH) is associated with substantial morbidity and mortality. Currently, only nonselective beta-blockers have been shown to reduce portal pressure. Recent reports suggest that sodium-glucose cotransporter 2 (SGLT2) inhibitors may have a beneficial effect on portal hypertension. **Methods:** We aimed to evaluate the effect of SGLT2 inhibitors on esophageal and gastric varices as a surrogate marker for portal hypertension.

We retrospectively reviewed the medical records of cirrhotic patients followed in our Liver Unit between 2016 and 2025. Forty-three patients who met the Baveno VII criteria for CSPH (liver stiffness > 15 kPa and platelet count $< 150 \times 10^9$/L) were included. Of these, 28 patients were treated with SGLT2 inhibitors for various indications, while 15 served as matched controls without treatment. Thirty-six participants underwent at least two surveillance endoscopies. Data were analyzed using SPSS version 27. **Results:** The majority of patients had cirrhosis due to metabolic-associated steatohepatitis (MASH). The mean follow-up period was four years. The treatment and control groups were comparable in terms of cirrhosis severity and beta-blocker use (60%), with a mean age of 66 years and BMI of 27. The SGLT2 group had higher rates of diabetes (96% vs. 73%), chronic kidney disease (42% vs. 13%), and GLP-1 receptor agonist use (67% vs. 33%). Variceal ligation was performed in 9 patients (32%) in the treatment group and 4 patients (26%) in the control group.

Esophageal or gastric varices were present in 15 of 28 patients (53%) in the treatment group, compared to 11 of 15 (73%) in the control group (p = NS). Treatment with SGLT2 inhibitors was associated with either stability or a reduction of at least one grade in varices in 21 patients (95.5%) versus 7 patients (50%) in the control group (p = 0.03). Variceal progression occurred in only 1 patient (4.5%) in the SGLT2 group compared to 7 patients (50%) in the control group (p = 0.03). The risk of variceal progression was significantly higher in the control group (OR = 20.8; 95% CI, 2.1–200). **Conclusion:** We demonstrated that SGLT2 inhibitors treatment in cirrhotic patients was associated with improvement or stabilization of esophageal and gastric varices, suggesting a potential reduction in portal hypertension. A prospective interventional trial is warranted to validate these findings and further explore the underlying mechanisms

4066 | SHARED AND DISTINCT PATHWAYS IN STEATOTIC LIVER DISEASE SUBCATEGORIES: UNVEILING THE ROLE OF GUT HORMONES

Sundararajan Mahalingam[1] Ramesh Bellamkonda[1] Ojeshvi Ethiraj[1] Srilaasya Nedunoori[1] Carol Casey[1] Kusum Kharbanda[2] Karuna Rasineni[1], [1]University of Nebraska Medical Center, Omaha, NE, [2]Veterans Affairs Nebraska-Western Iowa Health Care System, Omaha, NE

Background: Steatotic liver disease (SLD) affects more than 35% of the global population and is primarily driven by obesity, chronic alcohol use, or a combination of both. While the pathophysiological mechanisms of metabolic dysfunction-associated liver disease (MASLD) and alcohol-associated liver disease (ALD) are relatively well-characterized, a critical gap exists in our understanding of metabolic and alcohol-associated liver disease (MetALD). This emerging condition results from the co-occurrence of diet-induced obesity and alcohol consumption. Understanding its distinct pathological mechanisms and potential therapeutic targets is crucial. Leveraging our expertise in differentiating MASLD and ALD and our knowledge of the role of gut hormones in ALD, this study aimed to distinguish the shared and unique pathological mechanisms among these three SLD subcategories, with a particular focus on gut hormones and organ crosstalk. **Methods:** We established experimental mouse models for MetALD (Western diet (ResearchDiets D12079B) + 15% alcohol in drinking water), ALD (chow diet + 15% alcohol in drinking water), and MASLD (Western diet + regular water). This feeding regimen was maintained for 16 weeks. At the end of the treatment, the animals underwent a 6-hour fast followed by a glucose tolerance test. The next day, the animals were euthanized, and blood and tissue samples were collected for further analysis. **Results:** Despite histological similarities, we identified key differences in metabolism-related events between these SLD subcategories, particularly in hormone levels. Mice in the MASLD group exhibited high serum insulin and low levels of two gut hormones, GLP-1 and ghrelin, whereas the ALD group showed the opposite pattern. Differences were also observed in hepatic methionine metabolism between these two models. Additionally, increased adipose lipolysis was observed only in the ALD group. Interestingly, mice with MetALD displayed higher insulin resistance and more pronounced liver inflammatory changes compared to those with MASLD or ALD. Moreover, MetALD mice showed increased serum levels of ghrelin and GLP-1, characteristics typically associated with chronic alcohol consumption. Unique features such as apoptosis and cell death were observed only in MetALD mice. **Conclusion:** These findings strongly suggest that MetALD pathogenesis is influenced by a complex interplay of shared and unique pathways from both ALD and MASLD. This underscores the need for targeted research to develop effective treatments for MetALD.

Background: Metabolic dysfunction-associated steatohepatitis (MASH) involves hepatic steatosis with inflammation and hepatocellular injury, often progressing to fibrosis. In March 2024, the United States (US) Food & Drug Administration approved resmetirom as the first therapy for MASH patients with moderate to advanced liver fibrosis. Given its recent approval, real-world evidence on resmetirom use remains limited. This analysis describes US patients prescribed resmetirom and their treatment patterns following initiation. **Methods:** This was a descriptive, retrospective analysis of adults with ≥ 1 paid claim for resmetirom (first paid claim = index date) on or after 3/14/2024 in the Optum® de-identified Market Clarity data (study period: 3/14/2023–12/31/2024). Patients in the 12-month pre-index period coded with cirrhosis-related complications, ≥ 1 diagnosis for non-MASH liver conditions, or heavy metal exposure were excluded. Baseline demographic and clinical characteristics were summarized. Treatment patterns, including duration; persistence; discontinuation (>45-day gap); restart; and adherence (proportion of days covered [PDC]) were described. **Results:** In total, 341 patients met study inclusion criteria. Results are presented in Table 1. Mean (SD) patient age was 60.6 yrs (12.5); 210 (61.6%) were female and 237 (69.5%) were White. Most patients had commercial insurance (39.6%) or Medicare (54.8%); only 5.6% were Medicaid beneficiaries. Based on BMI, 5.5% were normal/underweight, 15.3% were overweight, and 79.2% were obese. Mean (SD) BMI among the 78 patients with continuous BMI reported was 32.9 (6.5) kg/m^2. Almost half (46.9%) of patients had type 2 diabetes mellitus. Many (42.2%) patients used at least one GLP-1 during the baseline period and 61.9% used statins. Overall, 98.2% of patients were persistent. Over half (57.8%) had ≥ 3-month follow-up; of these, 97.0% remained persistent, and all who discontinued later restarted resmetirom. Mean (SD) PDC was 0.84 (0.24) at 3 months and 0.75 (0.30) at 6 months. **Conclusion:** This study provides an early look at real-world resmetirom use in the US. Half of the patients treated with resmetirom were obese, and nearly half had diabetes. Adherence was high, with most patients remaining persistent for at least three months. Future studies with longer follow-up are needed to evaluate clinical outcomes in real-world resmetirom users.

Table 1. Baseline demographics and clinical characteristics

	Resmetirom Cohort (N = 341)
Baseline Demographic Characteristics	
Age, years	
Mean (SD)	60.6 (12.5)
Sex, n (%)	
Female	210 (61.6)
BMI, continuous, kg/m^2	
Mean (SD)	32.9 (6.5)

4068 | ENHANCED SCREENING EFFICIENCY: OVER 90% PREVALENCE OF F2–F4 FIBROSIS IN PNPLA3 HOMOZYGOUS PARTICIPANTS WITH MASH IN THE AZD2693 FORTUNA PHASE 2B STUDY

Rohit Loomba[1] Atsushi Nakajima[2] Marco Arrese[3] Elisabetta Bugianesi[4] Linda Wernevik[5] Mathias Liljeblad[5] Weier Qi[6] Ola Fjellström[5] Anna Ramne[5] Anna Rudvik[6] Janeli Sarv[6] James Sherwood[7] Javier Armisen[7] Lars Hansen[6] Vincent Wong[8], [1]University of California, San Diego, [2]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [3]Escuela de Medicina, Pontificia Universidad Católica de Chile, Santiago, Chile, [4]University of Turin, Turin, Italy, [5]AstraZeneca, Gothenburg, Sweden, [6]AstraZeneca, Gaithersburg, USA, [7]AstraZeneca, Cambridge, UK, [8]The Chinese University of Hong Kong, Hong Kong

Background: High biopsy screen-failure rate to identify participants with significant fibrosis is common in metabolic dysfunction-associated steatohepatitis (MASH) clinical trials. AZD2693 is an anti-sense oligonucleotide designed to silence hepatic PNPLA3 mRNA expression under development for treating MASH with fibrosis. **Methods:** The FORTUNA Phase 2b study (NCT05809934) is designed to evaluate the safety, tolerability, and efficacy of AZD2693 in participants who have non-cirrhotic MASH with fibrosis and are homozygous for the *PNPLA3* 148M risk allele over a 52-week treatment period. Primary and secondary endpoints are the histological resolution of MASH without worsening of fibrosis and the improvement of histological fibrosis without worsening of MASH. **Results:** Out of 2479 participants screened, a total of 217 (9%) were randomized. Homozygous carriers eligible for biopsy (N = 363) had a mean (SD) age of 53 (13) years; 53% were female, mean (SD) BMI of 32 (6) kg/m^2 with 31% exhibiting type 2 diabetes and 54% with at least one associated cardiometabolic disease (e.g. hypertension, dyslipidemia). The main reason for screen failure (SF) was participants who were not homozygous carriers for the *PNPLA3* rs738409 148M risk allele, with a SF rate of 74%. Among the 363 biopsies from homozygous carriers, 5 (1%) had F0 and 30 (8%) had F1 fibrosis, while the remaining of the homozygous carriers (91%) had significant fibrosis (184 (51%) had F2; 111 (31%) had F3 and 34 (9%) had cF4). Overall SF due to biopsy criteria was 36%. **Conclusion:** In this study, homozygosity for the *PNPLA3* rs738409 148M risk allele enhanced clinical biopsy-screening efficiency for participants with significant F2–F4 fibrosis.

4069 | PRESCRIBING PATTERNS AND CLINICAL CHARACTERISTICS OF RESMETIROM RECIPIENTS: REAL-WORLD INSIGHTS

Vinay Jahagirdar[1] Kaanthi Rama[1] Amon Asgharpour[1] Richard Sterling[1] Arun Sanyal[1] Juan Pablo Arab[1],
[1]Virginia Commonwealth University

Background: Resmetirom was conditionally approved in March 2024 for the treatment of metabolic dysfunction-associated steatohepatitis (MASH) with F2-F3. The aim of this study was to evaluate real-world prescribing patterns, patient characteristics, and early biochemical trends among adults initiated on resmetirom. **Methods:** Data were obtained from the TriNetX U.S. Collaborative Network, to identify adults prescribed resmetirom between 3/2024 and 4/2025. Data were extracted on demographics, diagnoses, procedures, medications, most recent laboratory values and vital signs recorded within the preceding 24 months. Changes in weight, BMI, and liver enzymes (ALT, AST) were assessed at baseline, 1–90 days, and beyond 90 days. Continuous variables were summarized using means with standard deviations (SD) or medians with interquartile ranges (IQR). Differences in repeated measures across timepoints were assessed using repeated measures ANOVA, with a p-value <0.05 considered statistically significant. **Results:** A total of 1,438 patients were prescribed resmetirom (mean age 57 $\pm$ 13 years); females were more prevalent in the 80 mg group (70%), while males predominated in the 100 mg group (57%) (Fig A). Most patients were White (74%) and geographically clustered in the southern U.S. (46%) (Fig B). The most common comorbidities included dyslipidemia (69%), hypertension (65%), obesity (64%), type 2 diabetes (49%). Co-prescription of GLP-1 receptor agonists was common, including semaglutide (27%) and tirzepatide (15%), with higher use in the 100 mg group.

ALT and AST levels increased modestly from baseline to 1–90 days (ALT: 49.7 $\rightarrow$ 58.4 U/L; AST: 40.5 $\rightarrow$ 44.8 U/L), followed by improvement beyond 90 days (ALT: 45.6 U/L; AST: 37.0 U/L). These changes were statistically significant (ALT: $p=0.03$; AST: $p=0.01$). In contrast, weight and BMI remained stable over time (baseline BMI: 33.9 $\pm$ 7.6; >90 days: 33.7 $\pm$ 7.5; $p=0.72$ for BMI, $p=0.89$ for weight) (Fig C). **Conclusion:** In this national real-world cohort, resmetirom was more frequently prescribed to females and individuals with cardiometabolic comorbidities. Frequent co-prescription with GLP-1 receptor agonists reflects integrated management of metabolic disease. A transient but statistically significant rise in liver enzymes was observed in the first 90 days, followed by improvement beyond 3 months, while anthropometric measures remained unchanged. Longer-term follow-up will be important to evaluate sustained biochemical response, weight trends, and treatment durability over time.

4070 | SAFETY PROFILE AND ADVERSE EVENTS OF RESMETIROM: PHARMACOVIGILANCE ANALYSIS OF THE FDA ADVERSE EVENTS REPORTING SYSTEM (FAERS) DATABASE

Marina Takawy[1] Mary Rinella[2] Naim Alkhouri[3] Meena Bansal[4] Mazen Noureddin[5] Rebecca Taub[6] Manal Abdelmalek[7], [1]Rochester Regional Unity program, [2]The University of Chicago, [3]Summit Clinical Research, [4]Icahn School of Medicine at Mount Sinai (ISMMS), [5]Houston Methodist Hospital, [6]Founder of Madrigal Pharmaceuticals, [7]Mayo Clinic Rochester

Background: Metabolic dysfunction associated steatohepatitis (MASH) is a leading cause of chronic liver disease contributing to the rise in cirrhosis, liver cancer and need for liver transplantation. While lifestyle modification to improve cardiometabolic risk factors remains foundational, it may be insufficient in those with advanced fibrosis. Resmetirom (Rezdiffra™), a selective thyroid hormone b-receptor agonist, is the first FDA-approved drug for patients with moderate-to-severe MASH without cirrhosis. In the phase 3 MAESTRO NASH, resmetirom was superior to placebo in MASH resolution and fibrosis improvement. Diarrhea and nausea were most frequent adverse events (AEs) compared to placebo. The incidence of serious AEs (SAEs) was similar across trial groups in the 80 mg, 100 mg and placebo group (10.9%, 12.7% and 11.5%, respectively). The aim of this study is to analyze the real-world reported AEs of resmetirom as compared to those in MAESTRO NASH. **Methods:** A retrospective analysis of the public FDA Adverse Events Reporting System (FAERS) Database of resmetirom use (March 14, 2024-March 31, 2025) and reported AEs attributable to its use was performed. **Results:** 390 AEs were reported with resmetirom, 294 (75%) non-serious, and 96 (25%) SAEs. The majority of reported AEs (93%) were solicited through a Sponsor-supported pharmacovigilance program. Consistent with the MAESTRO study results, the most common real-world treatment emergent AEs were nausea (23.1%) and diarrhea (18.2%). Elevations of aminotransferases and elevated bilirubin were observed in 19.5% and 6.7%, respectively. Of the SAEs, 29 (7.4%) were hospitalizations, 1 (0.3%) life-threatening, 1 (0.3%) requiring surgical intervention and 8 deaths [cause unknown (n = 4), liver failure (n = 1), sepsis with multi-organ failure (n = 2) and ventricular fibrillation (n = 1)] were reported. Three SAEs occurred in the setting of malignancies (pancreas, renal and liver). The liver-related death was attributed to off-label use of drug not in accordance with FDA label. **Conclusion:** To date, post-marking safety reporting of resmetirom (Rezdiffra™) suggests a safety profile comparable to that observed in the phase 3 MAESTRO study when prescribed in accordance with the FDA-approved label. To minimize the risk of SAEs, due diligence should be made in patient selection and risk stratification to exclude those with cirrhosis and/or other serious co-morbid conditions prior to prescribing resmetirom for patients with MASH.

4071 | BEYOND THE LIVER,IMPACT OF MASLD TREATMENT ON SUBCLINICAL ATHEROSCLEROSIS AND CARDIOMETABOLIC RISK: A SYSTEMIATIC REVIEW AND META-ANALYSIS

Eunice Omeludike[1] Sarpong Boateng[2] Abdul-Rahaman Ottun[3] Ooreoluwa Fasola[4] Cherechi Nwabueze[5] Eunice Aregbesola[6] Babajide Obidigbo[7] Chukwuka Elendu[8] Papa Beeko[3] Samuel Acheampong[3] Chisom Nwaneki[9], [1]Piedmont Athens Regional Medical Centre, [2]Yale New Haven Health, Bridgeport Hospital, [3]Piedmont Athens Regional Medical Center, [4]Texas Tech University Health Sciences Center-Permian Basin, [5]John H. Stronger Jr Hospital of Cook County, [6]University of Missouri, Columbia, [7]York and Scaborough NHS Foundation Trust, [8]Federal University Teaching Hospital, Owerri, [9]Saint Peters University Hospital, New Brunswick, NJ

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is associated with elevated cardiovascular risk, but the impact of MASLD-targeted interventions on subclinical atherosclerosis and cardiometabolic risk markers remains unclear. Our systematic review and meta-analysis aimed to evaluate the impact of MASLD treatment on markers of subclinical atherosclerosis and cardiometabolic risk, synthesizing current evidence to inform clinical management. **Methods:** We conducted a systematic review and meta-analysis of randomized controlled trials and cohort studies assessing lifestyle or pharmacologic interventions for MASLD and reporting outcomes on subclinical atherosclerosis including carotid intima-media thickness(CIMT), pilse wave velocity(PWV), coronary artery calcium and/or cardiometabolic risk (e.g., HOMA-IR, blood pressure, lipid profile). Searches were run across five major databases and clinical trial registries through March 15, 2025. Data extraction, bias assessment (Cochrane RoB 2.0, Newcastle-Ottawa Scale), and synthesis followed PRISMA guidelines. Meta-analyses used random-effects models. **Results:** Out of 4,276 records, 38 studies (n = 5,422 participants) met inclusion criteria. Interventions included GLP-1 receptor agonists (8 studies), SGLT2 inhibitors (6), pioglitazone (9), omega-3 fatty acids (3), and lifestyle modifications (12). GLP-1 RAs significantly reduced CIMT (MD – 0.09 mm; 95% CI –0.13 to –0.05) and HOMA-IR (MD –2.3; 95% CI –3.0 to –1.6). Lifestyle changes and SGLT2 inhibitors showed similar benefits on HOMA-IR and lipid profiles, though SGLT2 data on atherosclerosis markers were less consistent. Table illustrates pooled effect sizes, MASLD therapies significantly improved markers of cardiovascular risk (see Table). Results were consistent across pharmacologic and lifestyle interventions, with GLP-1 RAs and SGLT2 inhibitors showing the most robust dual benefit. **Conclusion:** Our findings support the beneficial impact of MASLD-targeted interventions—especially GLP-1 RAs and lifestyle changes—on surrogate markers of cardiovascular risk. Improvements in CIMT, HOMA-IR, LDL-C, and systolic blood pressure suggest that integrated management of MASLD may concurrently mitigate early cardiovascular disease risk. Meta-regression highlighted baseline BMI and age as moderators of treatment effect. Publication bias was minimal, and GRADE certainty was rated moderate to high for primary outcomes. Further longitudinal and comparative trials are warranted to confirm these effects and guide clinical strategies targeting the hepatic-cardiovascular interface in MASLD.

Table 2. Pooled Effects of Interventions on Key Cardiometabolic Outcomes

Outcome	Intervention Type	No. of Studies	Mean Difference (95% CI)	I^2 (%)
Carotid Intima-Media Thickness (CIMT)	GLP-1 RAs	6	–0.09 mm (–0.13 to –0.05)	58
	SGLT2 inhibitors	4	–0.07 mm (–0.12 to –0.02)	61
	Lifestyle interventions	5	–0.05 mm (–0.09 to –0.01)	66
HOMA-IR	GLP-1 RAs	7	–2.3 (–3.0 to –1.6)	54
	SGLT2 inhibitors	5	–1.8 (–2.5 to –1.1)	63
	Lifestyle interventions	6	–1.5 (–2.1 to –0.9)	72
LDL Cholesterol (mg/dL)	GLP-1 RAs	5	–14.2 (–19.1 to –9.3)	49
	SGLT2 inhibitors	4	–11.6 (–17.0 to –6.1)	57
	Lifestyle interventions	6	–12.4 (–18.2 to –6.7)	60
Triglycerides (mg/dL)	Pharmacologic (mixed)	7	–15.9 (–22.4 to –9.4)	64
Systolic Blood Pressure (mmHg)	All interventions	9	–4.6 (–6.8 to –2.4)	52

Background: Resmetirom (Rezdiffra™) is a thyroid hormone receptor β-selective agonist conditionally approved in the United States in March 2024 for the treatment of noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH) with moderate to advanced fibrosis. This study describes baseline characteristics, medication use, and 6-month real-world effectiveness based on changes in non-invasive fibrosis markers among patients initiated on resmetirom in routine gastroenterology care. **Methods:** This retrospective cohort study used electronic medical records from the Latica real-world gastroenterology data repository. Adults with ≥1 prescription for resmetirom between January 2023 and April 2025 and ≥6 months of follow-up were included. The index date was the first recorded resmetirom prescription. Baseline characteristics were assessed during the 12 months prior to the index date. Demographics, comorbidities, medication use, and laboratory values (aspartate aminotransferase [AST], alanine aminotransferase [ALT], platelet count, and Fibrosis-4 [FIB-4] index) were evaluated at baseline and at 6-month follow-up, where available. **Results:** Of 848 patients who initiated resmetirom, 347 (40.8%) had documented ≥6 months of follow-up and were included in the analysis. The median duration of pre-treatment data was 3.4 years (IQR: 0.7–7.3). The mean age was 59.1 years (SD: 12.5); nearly half were aged 45–64 and 15% were ≤44. The cohort was predominantly female (56%), from Florida (63%), and 41% identified as White. All patients had commercial insurance, and 43% were also Medicare enrollees. At baseline, mean BMI was 33.8 (SD: 6.5), with 69.5% classified as obese, 23.1% overweight, and 6.3% with BMI <25. The most common comorbidities were hypertension (71.2%), hyperlipidemia (65.1%), and type 2 diabetes (53.9%). At baseline, GLP-1RA use was observed in 23.3% of patients, with semaglutide being the most prescribed (11%). Thirteen percent of patients had concomitant GLP-1RA use that began prior to resmetirom initiation and continued through follow-up, most commonly with semaglutide (7%). Among those with values at baseline and follow-up, median AST declined from 32.0 to 28.5 U/L in statin users (n = 41) and from 44.0 to 32.0 U/L in non-users (n = 44). Similarly, ALT declined from 39.0 to 39.0 U/L in statin users and from 53.0 to 37.5 U/L in non-users. FIB-4 scores decreased from 1.8 to 1.6 (n = 32), while platelet counts remained stable (median 198.5 to 198.0, n = 38). **Conclusion:** In this real-world cohort, patients initiating resmetirom commonly had obesity, cardiometabolic comorbidities, and prior GLP-1RA use. Modest improvements in non-invasive fibrosis markers were observed over 6 months, supporting early real-world effectiveness of resmetirom in routine clinical practice. Ongoing follow-up and cohort expansion are needed to confirm long-term effectiveness.

4074 | ANALYSIS OF BIOMARKERS PRO-C3 AND ELF COMPONENTS IN BASELINE MASH/MASLD AND MASH CIRRHOSIS PATIENTS; CORRELATIONS BETWEEN CHANGE IN PRO-C3 AND ELF IN RESMETIROM-TREATED PATIENTS FROM THE MAESTRO-NASH TRIAL

Meena Bansal[1] Rebecca Taub[2] Hang Zhang[2] Dominic Labriola[2] James Hennan[2] Suneil Hosmane[2] Mazen Noureddin[3], [1]Icahn School of Medicine at Mount Sinai (ISMMS), [2]Madrigal Pharmaceuticals, [3]Houston Methodist Hospital

Background: Resmetirom (RES) is approved for the treatment of adults with MASH and liver fibrosis by the accelerated approval pathway based on improvements in MASH and fibrosis. Non-invasive tests including ELF and PRO-C3 have been used to characterize fibrosis stage in MASH and predict liver outcomes. RES reduces ELF and its components P3NP and TIMP-1 but not hyaluronic acid (HA) ((N Engl J Med 2024;390:497-509). This study

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

evaluated baseline ELF and its individual components, TIMP-1, P3NP and hyaluronic acid (HA) according to biopsy fibrosis stage; in MAESTRO-NASH (NCT03900429) correlations between baseline and Week-52 ELF/P3NP and PRO-C3 and the effect of RES compared with placebo (PBO) on PRO-C3 and P3NP/ELF were determined. **Methods:** ELF and ELF components were determined by a central laboratory in biopsy proven cohorts from MAESTRO-NASH and MAESTRO-NAFLD-1 (NCT04197479): F0 (N = 51), F1a/1c (N = 126), F1b (N = 126), F2 (N = 356), F3 (N = 540), and F4 (N = 107)). PRO-C3 analyses were assessed in MAESTRO-NASH F1b/F2/ F3 using the ELISA GEN2 assay. ANCOVA was used for comparisons between RES 80 or 100 mg vs. PBO in PRO-C3 and ELF change from baseline at week 52 (wk52CHG). Mean difference with 95% CI and nominal p-values were obtained from the ANCOVA. Scatterplots and Spearman's correlations with 95% CIs assessed P3NP/ELF and PRO-C3 both at baseline and wk52CHG. **Results:** In biopsy confirmed MASH, ELF increased from mean 9.4-9.6 (F0-F2), 10.0 (F3),10.6 (F4). Components TIMP1 and P3NP did not increase between F0 and F2, increased by 20% between F2 and F3/F4. HA was variable and higher in diabetics (F0 to F2) and increased 1.9 fold between F3 and F4, explaining the increase in ELF in F4 patients (Figure). Baseline P3NP and ELF were correlated with baseline PRO-C3 (0.563 and 0.458, respectively). At week 52, PRO-C3 wk52CHG for RES 100mg -23.05 (4.76), 80mg, -17.93 (4.61), PBO, -0.19, (4.07) with mean difference (95% CI) in PRO-C3 wk52CHG, 80mg and PBO, -16.9 (-27.0, -6.76), p = 0.0011; 100mg and PBO, -22.1 (-32.3, -11.84, p < 0.0001). Larger reductions in PRO-C3 mean (SD) in the RES arms were observed in F3 patients: 80 mg,-22.42 (6.38); 100mg, -27.42 (6.72); PBO, -0.50 (5.46). Wk52CHG in P3NP was positively associated with wk52CHG in PRO-C3, 0.557, 0.548 and 0.524 for 100mg, 80mg and PBO; respectively. A correlation was observed between wk52CHG for ELF and PRO-C3, 0.483, 0.484 and 0.487 for 100mg, 80mg and PBO, respectively.

Conclusion: The increase in ELF in F3/F4 patients is explained by the increase in HA, an extracellular matrix protein made outside the liver and cleared from blood by liver sinusoidal endothelial cells that are dysfunctional in F4. PRO-C3 and P3NP, markers of liver fibrosis, were correlated and significantly reduced by RES vs PBO; the reduction was more pronounced in F3 patients. Evaluation of changes in ELF with treatment should include assessment of individual ELF components.

4075 | COMPARATIVE EFFECTIVENESS OF LIRAGLUTIDE VERSUS SEMAGLUTIDE ON CLINICAL OUTCOMES IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH): A REAL-WORLD TWO-YEAR RETROSPECTIVE COHORT STUDY

Aditya Sood[1] Nathaniel Herman[2] Stephanie Chain[1] Saad Ahmed[1] Alex Chang[3] Sanjaya Satapathy[1], [1]Northwell, New Hyde Park, NY, [2]Stony Brook School of Medicine, [3]Brown University

Background: Real-world data directly comparing clinical outcomes of Liraglutide and Semaglutide in patients with MASH over extended follow-up periods remain limited. **Aim:** To compare 1- and 2-year risks of major adverse liver outcomes (cirrhosis, hepatocellular carcinoma [HCC], mortality) and safety events (pancreatitis, gallbladder/biliary disease) among MASH patients initiating Liraglutide vs. Semaglutide. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network, a large U.S. electronic medical record database. Adults with MASH (ICD-10: K75.81), confirmed by imaging (e.g., elastography) or liver biopsy, initiating Liraglutide (N = 697) or Semaglutide (N = 4,385) were identified. Propensity score matching (1:1, 696 pairs, 19 covariates) was performed. Outcomes were assessed at 1 and 2 years using logistic regression for risk ratios and Cox proportional hazards models for hazard ratios. This study used de-identified data, was exempt from IRB approval, and adhered to the Declaration of Helsinki. **Results:** After matching, no significant differences were observed between the Liraglutide and Semaglutide cohorts for any outcome. Two-year hazard ratios (HR [95% CI]) were: • Cirrhosis: HR 1.19 (0.73–1.93), $p = 0.45$. • HCC: HR 1.31 (0.47–3.69), $p = 0.997$. • Mortality: HR 1.23 (0.55–2.75), $p = 0.465$. • Pancreatitis: HR 1.01 (0.41–2.48), $p = 0.555$. • Gallbladder/biliary disease: HR 0.86 (0.52–1.44), $p = 0.806$. One-year risk ratios and event counts were similarly non-significant across all outcomes. Time course was restricted to two years based on limitations on length of real-world semaglutide data availability. **Conclusion:** In this large, real-world cohort of MASH patients, initiation of Liraglutide or Semaglutide was associated with comparable 1- and 2-year risks of cirrhosis, HCC, mortality, and key safety events. These findings suggest that short-term choice between these GLP-1 receptor agonists may be guided more by individualized clinical factors rather than differential risk of hepatic or safety outcomes.

Table: Comparative Risk of Clinical Outcomes in MASH Patients Treated with Liraglutide vs. Semaglutide

Outcome	1-Year Risk Ratio (95% CI)	p-value	2-Year Hazard Ratio (95% CI)	p-value	Event Count (Lira vs. Sema)
Cirrhosis	1.20 (0.67–2.15)	0.758	1.19 (0.73–1.93)	0.450	38 vs. 29
Hepatocellular Carcinoma (HCC)	1.01 (0.42–2.40)	0.989	1.31 (0.47–3.69)	0.997	<10 vs. <10
All-Cause Mortality	1.00 (0.42–2.38)	0.997	1.23 (0.55–2.75)	0.465	15 vs. <10
Acute Pancreatitis	1.03 (0.43–2.45)	0.951	1.01 (0.41–2.48)	0.555	<10 vs. <10
Gallbladder/Biliary Disease	0.80 (0.42–1.53)	0.497	0.86 (0.52–1.44)	0.806	29 vs. 29

4076 | PRESCRIBING PATTERNS OF GLP-1 RA ACROSS STEATOTIC LIVER DISEASE PHENOTYPES

Natalia Salinas Parra[1] Dilara Hatipoglu[1] David Kaplan[2] Nadim Mahmud[1], [1]Hospital of the University of Pennsylvania, [2]University of Pennsylvania

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RA) have emerged as valuable therapeutic options for weight loss and metabolic comorbidities. Real-world utilization has not been studied in patients with cirrhosis under the new steatotic liver disease (SLD) nomenclature, which includes MASLD, MetALD, and ALD. Understanding prescribing patterns is valuable as patients with MetALD may benefit from GLP-1RA but may not be managed accordingly. We investigated the independent effect of SLD phenotype on GLP-1RA prescription in a national cohort of patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2025 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, Inc. Unauthorized reproduction of this article prohibited.

with cirrhosis in the Veteran's Health Administration (VHA). **Methods:** This was a retrospective cohort study in adult patients with incident cirrhosis related to MASLD, ALD, or MetALD, identified using established algorithms; the date of cirrhosis diagnosis was the index date. Those with prior GLP-1RA prescriptions were excluded. Demographic, body mass index, comorbidity data, and all GLP-1RA prescriptions in the VHA were obtained. Adjusted Fine and Gray competing risk regression and cause-specific hazards models were fit to evaluate cumulative incidence and the independent association between SLD phenotype and GLP-1RA prescription, treating death as a competing event (Figure panel A). An interaction between SLD phenotype and era (pre/post 2021) was also evaluated. **Results:** A total 97,357 patients were included. Of these, 58.4% had MASLD, 28.4% had ALD, and 13.2% had MetALD. Patients were predominantly male and white. Diabetes was more prevalent in MASLD (69.8%) and MetALD (70.8%) versus ALD (40.9%). Over a median follow-up time of 33.5 months (IQR 9.7, 71.1), 3,710 patients were newly initiated on GLP-1RA agents. In Fine and Gray models adjusted for *a priori* confounders, patients with MASLD had a significantly higher cumulative incidence of GLP-1 RA initiation through 5 years ($p < 0.001$), around 2.3%, versus MetALD and ALD at approximately 1.2%. In cause-specific hazards models, MASLD patients were significantly more likely to receive GLP-1 RA medications (HR 1.79, 95% CI 1.60-2.01) relative to ALD patients; there was no difference in MetALD versus ALD patients (HR 0.94, 95% CI 0.82-1.09). There was a significant interaction between SLD phenotype and era ($p < 0.001$), with MASLD patients more likely to receive GLP-1RA prescription post-2021 relative to other SLD phenotypes (Figure panel B). **Conclusion:** In this large VA cohort, overall GLP-1RA utilization was low among patients with cirrhosis and SLD. Patients with MASLD had higher GLP-1RA use than those with MetALD or ALD. Despite the substantial metabolic burden of patients with MetALD, they are no more likely than patients with ALD to be initiated on GLP-1RA. Notably, the era effect post-2021 following expanded FDA indications for GLP-1RA for weight loss was associated with increased relative GLP-1RA use in MASLD versus ALD.

4077 | GLP-1 RECEPTOR AGONIST THERAPY REDUCES FIB-4 INDEX IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Anderson Huang[1] Jonathan Weng[1] Tamiru Berake[1] Sarah Chen[1] Brian Yan[1] Raffi Karagozian[1], [1]Tufts Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects one-third of the global population and is a prominent driver of liver-related morbidity. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have demonstrated potential in improving MASLD-related outcomes, including lowering liver enzyme levels, reducing intrahepatic fat content, and improving histologic features of steatohepatitis. However, their effect on hepatic fibrosis remains unclear. This study aims to evaluate the impact of GLP-1 RA therapy on liver fibrosis, utilizing the validated fibrosis-4 (FIB-4) index as a non-invasive marker of fibrosis severity. **Methods:** In this retrospective cohort study, we identified patients diagnosed with MASLD who were treated with GLP-1 RAs at a large academic medical center between 2020 and 2024. Inclusion criteria consisted of a baseline FIB-4 index of 1.3 or greater—indicating at least intermediate risk for hepatic fibrosis—and at least two GLP-1 RA prescriptions within a 90-day window. Patients with cirrhosis or alcohol use disorder were excluded. FIB-4 index was calculated as: (Age [yr] × AST [U/L]) / (platelets [K/mcL] × (ALT [U/L]) ^ 0.5). Values were collected at treatment initiation and 12 months later. One-tailed paired *t*-tests were performed to test for a post-treatment reduction in FIB-4 index. We similarly assessed differences in the secondary outcomes, which included the components of the FIB-4 index, body mass index (BMI), and hemoglobin A1c (A1c). **Results:** Of 229 MASLD patients exposed to GLP-1 RAs, 29 had a baseline FIB-4 index of 1.3 or greater. At GLP-1 RA initiation, the mean age was 62.0 years and mean BMI was 37.5 kg/m^2. GLP-1 RAs were prescribed for type 2 diabetes in 18 patients (62%) and for obesity in 11 patients (38%). At 12 months, mean FIB-4 index decreased by 0.21 (95% CI, -0.38 to -0.05; $p = 0.019$). Significant reductions were also observed in AST (-15.8 U/L), ALT (-21.9 U/L), BMI (-2.6 kg/m^2), and A1c (-1.1%; all $p < 0.001$) (Table 1). **Conclusion:** In MASLD patients with at least intermediate risk for hepatic

fibrosis, GLP-1 RA therapy was associated with a significant reduction in FIB-4 index over one year, alongside improvements in liver enzymes, weight, and glycemic control. These findings support a potential antifibrotic role for GLP-1 RAs.

Table 1. Mean values of primary and secondary outcomes at baseline and after 12 months of GLP-1 RA therapy. Abbreviations: SD, standard deviation; CI, confidence interval.

	Pre-exposure (SD)	Post-exposure (SD)	Difference (95% CI)	P-value
FIB-4	1.94 (0.61)	1.73 (0.62)	-0.21 (-0.38, -0.05)	0.019
AST (U/L)	48.9 (22.4)	33.1 (17.4)	-15.8 (-22.3, -9.3)	< 0.001
ALT (U/L)	60.3 (34.3)	38.4 (27.0)	-21.9 (-30.8, -13.0)	< 0.001
Platelets (K/mcL)	212.2 (51.1)	215.3 (57.6)	3.1 (-4.9, 11.1)	0.742
BMI (kg/m^2)	37.5 (7.0)	34.9 (6.8)	-2.6 (-3.7, -1.5)	< 0.001
A1c (%)	7.4 (1.8)	6.3 (1.0)	-1.1 (-1.5, -0.6)	< 0.001

4078 | ONLINE CERTIFIED MEDICAL EDUCATION IMPROVED COMPETENCE AND CONFIDENCE IN MANAGING METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Shari Dermer[1] Briana Betz[1] Julie Schrand[1], [1]Medscape Education

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a common cause of liver disease whose prevalence is increasing along with the rise in metabolic syndrome. The aim of this study was to examine the role of case-based online continuing medical education (CME) on competence and confidence in risk stratification and treatment selection for patients with MASH. **Methods:** Learners participated in an online activity on MASH that featured video and synchronized slides. A repeated pairs pre-/post-assessment study included 3 multiple choice competence questions and a confidence assessment question. Chi-squared test ($P < .05$) assessed educational effect. The educational activity launched on May 31, 2024, and data were collected on May 15, 2025. **Results:** We report on data from gastroenterologists/hepatologists (n = 221 pre; n = 151 post) who participated in the online CME activity. Among these learners 40% self-reported as practicing in hepatology. Data are presented as % pre vs %post education.

- Selection of noninvasive tests (NITs) to identify patients with liver fibrosis increased by 12% following education (23% pre/45% post; $p < .05$)
- Evidence-based management of patients at low risk of MASH as determined by FIB-4 and VCTE increased by 15% after education (47% pre/62% post; $p < .05$)
- Selection of evidence-based liver-directed treatment for patients with MASH increased by 16% (56% pre/72%; $p < .05$)
- 12% had a measurable increase in confidence in tailoring MASLD/MASH management strategies based on patients' risk factors (20% pre/32%; $p < .05$). **Conclusion:** Online case-based CME resulted in increased competence and confidence regarding the risk stratification and management of MASH. The results from this study also indicate that gastroenterologists and hepatologists would benefit from additional education to help improve the care of individuals with MASH.

4079 | THE LIPID SYNTHESIS INHIBITORS ACC (FIRSOCOSAT) AND DGAT2 (ERVOGASTAT) REDUCE TRIGLYCERIDE CONTENT INDEPENDENTLY, BUT ONLY ERVOGASTAT ALSO REDUCES FIBROSIS BIOMARKERS IN HUMAN LIVER SPHEROIDS

Francisco Verdeguer[1] Philipp Vonschallen[1] Jesus Glaus[1] Radina Kostadinova[1] Joel Zvick[1], [1]InSphero

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive severe disease characterized by hepatic lipid accumulation, inflammation, and fibrosis which lacks any approved drug therapy. Novel approaches to identify therapeutic candidates that predict clinical responses are needed. Human pre-clinical models, including organoids/spheroids, are powerful models for drug testing and discovery. Pre-clinical models combining fast, robust, high-throughput compatible and predictive outputs are still a limiting factor to identify novel clinical therapies. We aimed at performing a comparison of the efficacy of existing clinical

candidates for MASH using a human-derived 3D spheroid model. **Methods:** We used human-derived 3D spheroid model, containing primary human hepatocytes, Kupffer cells, liver endothelial cells, and stellate cells from healthy donors to induce a MASH phenotype. We screened simultaneously for the toxicity and MASH efficacy of 20 current clinical candidates in a dose-dependent manner. We selected secreted lactate dehydrogenase (LDH), intracellular triglycerides (TGs) and secreted pro-collagen 1 (PC-1) as surrogate markers of cytoxicity, steatosis and fibrosis. LDH was measured at day 3, 5, 7 and 10, TGs at day 10 and PC-1 at day 7 and 10. **Results:** Incubation with a MASH-inducing cocktail for 10 days lead to the recapitulation the main hallmarks of MASH including steatosis, and fibrosis by 10 fold increase of triglyceride levels and PC-1 secretion compared to healthy control. The DGAT2 inhibitor Ervogastat and ACC inhibitor Firsocostat did not show any significant elevation of LDH secretion. Both compounds showed a 25.3% (p-value < 0.01) and 35% decrease (p-value < 0.0001) of triglyceride content versus healthy control respectively. However, only Ervogastat showed a 24.8% reduction PC-1 at 6.3 micromolar (p-value < 0.05). **Conclusion:** We show a robust platform for MASH drug candidates and identify the DGAT2 inhibitor as a clinical candidate improving steatosis and fibrosis in human liver spheroid model. This data show that supressing steatosis would result in fibrosis prevention.

4080 | NONINVASIVE INITIATION AND MONITORING OF THE THERAPY WITH TNR-BETA AGONIST RESMETIROM (RT) USING LIVERFAST (LFAST), FIB-4 AND VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY (VCTE, FIBROSCAN) IN PATIENTS WITH MASH

Jeevin Sandhu[1] Shaheen Mehrara[2] Mona Munteanu[3] Mangesh Pagadala[4] Ashwini Mehta[5] Juan Manuel Munoz Perez[3] Obinna Okolo[6] Parker Woods[7] Parvez Mantry[2], [1]Methodist Dallas Medical Center, [2]Methodist Dallas Medical Center, Division of Hepatology, Dallas, United States, [3]Fibronostics, [4]Methodist Dallas Medical Center, Division of Hepatology, Dallas, TX, United States, [5]Methodist Dallas Medical Center, Division of Hepatology, Internal Medicine, Dallas, TX, United Stat, [6]Methodist Dallas Medical Center, Liver Institute, Dallas, TX, United States, [7]Methodist Dallas Medical Center, Liver Institute, Dallas, TX, United States

Background: The RT impact using non-invasive tests (NITs) in real-life patients has not been assessed. LFAST is a blood-based AI-test that generates scores (0.00-1.00) proportional to the severity of fibrosis (F), activity (A), and steatosis (S), useful for initiating and for monitoring RT. The aims were to assess the dynamic of LFAST, FIB-4 and VCTE in monitoring patients on RT [mean change and fibrosis progression rate (PR) from baseline to repeated NIT]. **Methods:** Patients on RT with baseline (t0) and repeated (t1) LFAST, VCTE and FIB4 have been included retrospectively. NITs dynamics have been assessed using Kaplan Meier non-parametric statistics censored at -10% PR occurrence from t0, Tukey-Kramer Multiple-Comparison Test (repeated measurements ANOVA), descriptive and subgroup analysis (dose and GLP-1 receptor agonists (GLP-1RA) analysis. **Results:** 86 patients have been eligible without RT discontinuation (61.4% 80mg-dose), 39% male, 47% T2D, 40% on GLP-1RA, mean(se) age 61.5(1.3), BMI 32.6(0.7), ALT 45(3), FIB4 1.78(0.14). Using LFAST and VCTE, the baseline prevalence of F2F3 were 63% and 44%. Median (max) delays (months) t0-to-t1 were 3.4 for LFAST and 2.23 for FIB4. 60% patients had t0-FIB4 ≥ 1.3 and 50 patients already had t1-FIB4, without significant change from t0 (1.75vs1.60, Fig.1b), ALT (45vs41)or AST (40vs36), platelets count (232vs241*109), all p = ns. In 9 patients with repeated VCTE there were no significant changes (9.2 vs 10.7KPa). 40 patients achieved t1-LFAST: median fibrosis (0.49 vs 0.39,$p < 0.001$, Fig 1a), steatosis (0.48 vs 0.40,$p < 0.05$, Fig. 1c), activity (0.42 vs 0.44,p = ns). The median (range) PR t0-to-t1 per month were: FIB4 -0.0007 (-9.8;1.5), LFAST fibrosis -0.02 (-0.79;0.23) and steatosis -0.005 (-1.33;0.17). LFAST fibrosis At 3.6months of RT, LFAST PR of -10% or lower from t0 has been achieved more. with the 80mg group than 100mg (54.6% vs 27.3%, Cox Mantel $P < 0.05$). (Fig 1d) Similar PR were observed with FIB-4 and LSTAT according to the GLP-1RA therapy. The significant decreases t0-to-t1 in total cholesterol have not impacted the Apolipoprotein A1 [132 vs 147mg/dl] or LFAST score. **Conclusion:** Initiation of RT based on assessment of patients using LFAST, FIB4 (fibrosis only) and VCTE is efficient and allows further non-invasive monitoring. A rapid trend in fibrosis and steatosis improvement was observed, mainly in the 80mg RT group. LFAST is an efficient monitoring tool not impacted by RT-induced drop in cholesterol.

4081 | LOWER RISK OF NON-LIVER MORTALITY AND COMPLICATIONS IN GLP-1RA AND/OR SGLT2I USERS WITH MASLD: A SYSTEMIC REVIEW AND META-ANALYSIS

Jie Wang[1] Taotao Yan[1] Xiangrong Gao[1] Haruki Uojima[1] Michael Le[1] Ramsey Cheung[1] Mindie Nguyen[2],
[1]Division of Gastroenterology and Hepatology, Stanford University Medical Center, Palo Alto, Californ, [2]Stanford University Medical Center

Background: Metabolic dysfunction associated steatotic liver disease (MASLD) has become the leading cause of chronic liver disease worldwide. Glucagon-like peptide-1 receptor agonist (GLP-1RA) and sodium–glucose cotransporter-2 inhibitors (SGLT2i) have shown hepatoprotective signals such as improvement of liver enzymes, hepatic inflammation and fibrosis. However, data on their impact on long-term clinical events such as mortality (liver and non-liver related) as well as specific liver (e.g. cirrhosis, decompensation, hepatocellular carcinoma [HCC], liver transplant) and non-liver (e.g. cardiovascular, non-liver cancer) complications remain sparse. Using a systematic review and meta-analytic approach, we aimed to compare the risk of liver and non-liver related complications and mortality between GLP-1RA and/or SGLT2i users and their nonusers counterparts. **Methods:** We searched PubMed, Embase, Web of Science, Scopus, and Cochrane Library for studies reporting long-term adverse clinical outcomes of patients with MASLD who received GLP-1RA and/or SGLT2i and those who did not receive either medications from inception to Jan 23, 2025. Long-term adverse clinical outcomes include mortality (overall, liver-related and non-related), liver-related events (cirrhosis, decompensation, HCC, liver transplant or combination of) and non-liver related events (major adverse cardiovaslular events [MACE], myocardial infarction, stroke, heart failure and non-liver cancer). We used a randoms effect model to estimate the hazard ratio relating GLP-1RA and/or SGLT2i use with adverse clinical events. **Results:** We initially identified 7,228 studies and 66 were retrieved for full-text review after title and abstract review. Finally, 18 eligible studies involving 1,152,344 patients with MASLD (568,568 GLP-1RA and/or SGLT2i users, 583,776 nonusers) were included in study analysis. Therapy with GLP-1RA and/or SGLT21 use was associated with lower risks of all-cause mortality (hazard ratio [HR] 0.61, 95%CI 0.48–0.79), liver-related mortality (0.61, 0.45-0.84), adverse liver events (0.77, 0.69-0.87), as well as non-liver events such as stroke (0.61, 0.44–0.84) and heart failure (0.90, 0.86–0.94). **Conclusion:** Treatment with GLP-1RAs and/or SGLT2is is associated with significant long-term reductions in both hepatic and extra-hepatic complications and mortality in patients with MASLD. These data support the incorporation of these agents into comprehensive MASLD management.

4082 | DIGOXIN USE AND CLINICAL OUTCOMES IN MASLD AND MASH: A REAL-WORLD RETROSPECTIVE COHORT STUDY

Yazan Al Jabiri[1] Mohammad Aldiabat[1] Sura Issa[2] Thabet Qapaja[1] Kamran Qureshi[3] Wing-Kin Syn[3], [1]Washington University in saint louis, [2]Jordan University, [3]Saint Louis University School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and its progressive form, metabolic dysfunction-associated steatohepatitis (MASH), are increasingly prevalent causes of chronic liver disease. Preclinical studies have identified digoxin as a potential hepatoprotective agent through inhibition of the PKM2–HIF-1α signaling pathway, leading to reductions in hepatic steatosis, inflammation, and mitochondrial dysfunction in murine models. To date, no clinical studies have assessed the real-world effects of digoxin on MASLD or MASH outcomes in human populations. We conducted a retrospective cohort analysis to assess the association of digoxin use with clinical outcomes in patients with MASLD or MASH and concurrent heart failure or arrhythmia. **Methods:** This retrospective cohort study utilized the TriNetX US Collaborative Network, comprising data from 67 healthcare organizations. Adults (≥18 years) with MASLD or MASH and comorbid heart failure or arrhythmia—with left ventricular ejection fraction (LVEF) between 30–70%—were identified and stratified by digoxin use. Propensity score matching (1:1) was performed to balance cohorts based on LVEF, metabolic and cardiovascular comorbidities, MELD score components, metabolic-related labs, and anticoagulant use. Outcomes over a 10-year period included cirrhosis, all-cause mortality, hepatic encephalopathy (HE), hepatocellular carcinoma (HCC), liver transplantation (LT), spontaneous bacterial peritonitis (SBP), hospitalization, emergency department (ED) visits, and MASH occurrence. Hazard ratios (HRs), 95% confidence intervals (CIs), and P-values were reported. **Results:** In the matched MASLD cohort (n = 3,159 per group), digoxin use was associated with increased risks of cirrhosis (HR 1.351, $p < 0.001$), mortality (HR 1.637, $p < 0.001$), hospitalization (HR 1.524, $p < 0.001$), and ED visits (HR 1.229, $p < 0.001$). No significant differences were observed in HE, variceal bleeding, HCC (HR 0.802, $p = 0.469$), LT (HR 2.625, $p = 0.090$), or SBP (HR 1.414, $p = 0.323$). In the matched MASH cohort (n = 669 per group), digoxin use was associated with increased mortality (HR 1.291, $p = 0.008$), hospitalization (HR 1.391, $p < 0.001$), ED visits (HR 1.177, $p = 0.022$), and SBP (HR 2.363, $p = 0.010$), with no significant differences in cirrhosis, HE, variceal bleeding, HCC, or LT. **Conclusion:** In this real-world retrospective study of patients with MASLD or MASH and concurrent heart failure or arrhythmia, digoxin use was associated with significantly higher risks of mortality, hospitalization, and ED visits. In the MASH cohort, it was also linked to increased risk of SBP. No significant associations were observed with HE, variceal bleeding, HCC, or LT. These findings highlight the need for prospective studies to clarify the clinical utility, safety profile, and appropriate patient selection for digoxin in individuals with MASLD or MASH. This presentation discusses investigational, unlabeled use of digoxin for MASLD and MASH

4083 | INHIBITION OF THE PROSTAGLANDIN-DEGRADING ENZYME 15-PGDH AMELIORATES MASH-ASSOCIATED APOPTOSIS AND FIBROSIS IN MICE

Utibe-Abasi Udoh[1] Mathew Schade[1] Jacqueline Sanabria[1] PRADEEP KUMAR RAJAN[1] Rodrigo Aguilar[1] Micheal Andryka[1] Alexei Gorka[1] Sandrine Pierre[1] Juan Sanabria[1], [1]Marshall University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects more than 30% of the world population. Progression to its inflammatory state- metabolic dysfunction-associated steatohepatitis (MASH) is associated with increasing liver fibrosis, leading to end-stage liver disease (ESLD) and hepatocellular carcinoma (HCC). SW033291, an inhibitor of 15-PGDH (PGE2 degradation enzyme) has been shown to increase in vivo regeneration of liver parenchyma and ameliorates oxidative stress and inflammation. We hypothesized that SW033291 abrogates MASH progression through a paucity of the initial apoptotic switch restoring physiological collagen microenvironment. **Methods:** Plasma non-targeted metabolomics was measured by LC-MS/MS in a diet-induced MASH-mouse model at 24 weeks (24W). Liver morphology and apoptotic activity were quantitated by the NAS score and TUNEL assay, respectively. Statistical analyses (Control = NMC, HFD and HFD+SW03321) were determined by ANOVA/Principal Component Analysis (PCA) using GraphPad, or SPSS / R-Lab. Statistical significance was set at $p < 0.05$, n = 7/group. All mice used in this study were 7 weeks old (at start of experiment) female C57BL/6J strain. **Results:** The SW033291 group showed a significant decrease in total body fat, cellular oxidative stress and inflammation, and an increase in total lean mass with improved insulin resistance compared with the HFD group ($p < 0.05$). In addition, SW033291 significantly decreased GS:SG, citric acid and corticosterone, NAS score (9.4 ± 0.2 vs. 6.2 ± 0.1), liver

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

fibrosis score (1.3 ± 0.5 vs. 0.25 ± 0.1), and apoptotic activity (43.9 ± 4.6 vs. 0.38 ± 0.1%, $p < 0.05$) when compared to HFD at 24W. **Conclusion:** Inhibition of 15-PGDH normalizes the metabolic and morphological disturbances during experimental MASH progression with a paucity of the initial apoptotic switch, restoring normal collagen architecture. SW033291 warrants further investigation for clinical translation.

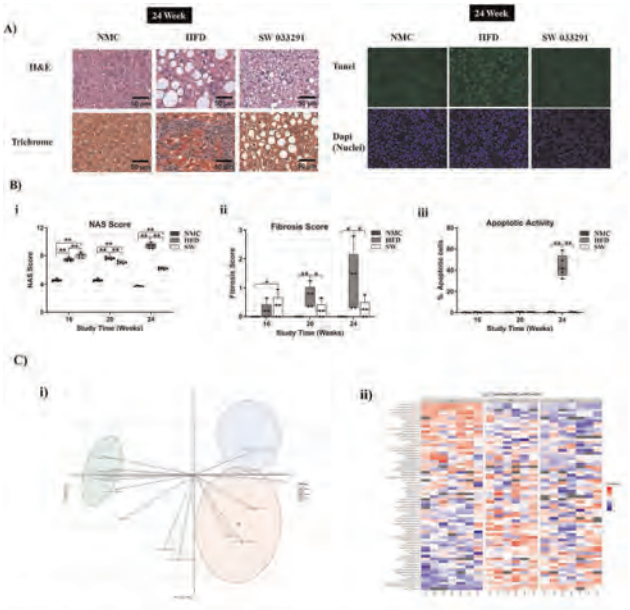

Fig 1. **(A)** *Liver Morphology of MASH at 24W, using H&E, Trichrome, and TUNEL staining techniques.* Observe the pronounced steatosis, fibrosis, and apoptosis in the HFD mice compared to both the NMC and SW033291-treated mice. **Bi-iii)** *NAS score, fibrosis and apoptotic activity in NMC vs. HFD vs. SW033291-treated mice.* Notice the significant reduction in the NAS and fibrosis scores and apoptotic activity in the SW03329-treated group vs. HFD and NMC groups (** $p < 0.01$, * $p < 0.05$). **C)**. *PCA plots of plasma Non- targeted Metabolomics in the MASH mice.* **i)** Biplot of principal component scores (points) and variable loadings (arrows); **ii)** Heat map displaying discrimination in metabolites in mice serum (NMC vs. HFD vs. SW033291). **NMC** = Normal mouse chow group, **HFD**= High fat diet group, **SW033291**= SW033291-treated group.

4084 | COMBINATION THERAPY WITH RESMETIROM AND GLP-1 RECEPTOR AGONISTS DEMONSTRATES SUPERIOR EFFICACY IN REDUCING LIVER FIBROSIS IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS: A REAL-WORLD MULTI-COHORT ANALYSIS

Kate Solpari Allysa Saggese[1] Scarlet Yang[2] Jessica Siguencia[2] Tatyana Kushner[2] Reem Sharaiha[2], [1]Weill Cornell Medicine, [2]Weill Cornell Medical College

Background: Resmetirom, a selective thyroid hormone receptor-beta agonist, was approved by the FDA in March 2024 as the first treatment for noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH) with moderate to advanced fibrosis. While glucagon-like peptide-1 receptor agonists (GLP-1RA) have shown promise in MASH, combining these agents with resmetirom may offer complementary mechanisms—with GLP-1RAs targeting extrahepatic metabolic pathways and resmetirom addressing intrahepatic mechanisms. This real-world study compared outcomes in MASH patients treated with resmetirom plus GLP-1RAs versus resmetirom monotherapy. **Methods:** Using the TriNetX research network, we conducted a retrospective cohort analysis of adults (≥ 18 years) with MASH initiated on resmetirom between March 2024 and May 2025. Patients were stratified into two cohorts: resmetirom plus GLP-1RA combination therapy versus resmetirom monotherapy. Propensity score matching (1:1) was performed based on demographics, comorbidities (including type 2 diabetes and obesity), and baseline medications. Primary outcomes included progression to fibrosis, and composite fibrosis and cirrhosis risk. Secondary outcomes included ALT/AST normalization and lipid profiles. Kaplan-Meier survival analysis and risk ratios were calculated. **Results:** The initial cohort included 224 patients receiving combination therapy and 419 receiving resmetirom monotherapy. After propensity score matching, 132 patients remained in each group with well-balanced baseline characteristics (mean age 56.5 vs 58.0 years, 62.1% vs 65.2% female, 68.2% hypertension, 55.3% vs 56.8% diabetes). At a median follow-up of 130 days, combination therapy demonstrated significantly lower risk of fibrosis progression compared to monotherapy (25.0% vs 38.6%, RR 0.65, 95% CI 0.45-0.93, p = 0.017). Patients in the combination therapy arm experienced significantly less progression to fibrosis over time, as demonstrated by the Kaplan-Meier analysis (hazard ratio 0.521) (Figure 1). The composite endpoint of fibrosis/cirrhosis was also reduced (27.3% vs 40.2%, RR 0.68, 95% CI 0.48-0.96, p = 0.027). No significant differences were observed in ALT normalization (50.0% vs 47.6%, p = 0.879) or AST normalization (35.7% vs 35.7%, p = 1.0). Lipid profiles showed no significant differences between groups. **Conclusion:** In this real-world analysis, combination therapy with resmetirom and GLP-1RAs demonstrated superior efficacy in reducing fibrosis progression compared to resmetirom monotherapy in patients with MASH. These findings support the complementary mechanisms of action hypothesis, with GLP-1RAs addressing upstream metabolic dysfunction and resmetirom targeting intrahepatic pathways. Prospective randomized trials are needed to confirm these promising real-world findings and establish optimal combination strategies for MASH management.

4085 | AI-POWERED HISTOLOGY ANALYSIS OF HARMONY REVEALS EFRUXIFERMIN-DRIVEN CHANGES IN THE LIVER MICROARCHITECTURE IN F2/F3 MASH

Jörn Schattenberg[1] Vlad Ratziu[2] Ylaine Gerardin[3] Lara Murray[3] Christina Jayson[3] Robert Egger[3] Geetika Singh[3] Jacqueline Brosnan-Cashman[3] Doreen Chan[4] Jimmie Zhang[4] Erica Fong[4] Brittany De Temple[4] Matthew Minerva[4] Mark Burch[4] Kimberly Barrett[4] Reshma Shringarpure[5] Erik Tillman[4] Timothy Rolph[4] Andrew Cheng[4] Kitty Yale[4] Mazen Noureddin[6],

Background: In Phase 2b trials for metabolic dysfunction-associated steatohepatitis (MASH), Efruxifermin (EFX) reversed cirrhosis in participants (pts) with F4 MASH (SYMMETRY) and improved fibrosis without worsening MASH in pts with F2-F3 disease (HARMONY). An opportunity remains to understand EFX-induced changes at the structural, cell, and tissue level. Here, we conducted a retrospective analysis of HARMONY (NCT04767529) using Liver Explore[1], an AI-powered tool for the comprehensive characterization of liver microarchitecture, to assess liver histology changes that occur with EFX. **Methods:** In HARMONY, pts (N = 128) were randomized to placebo (Pbo), 28 mg EFX (EFX-28), or 50 mg EFX (EFX-50), and biopsies were taken at baseline (BL), week 24 (w24), and week 96 (w96). Hematoxylin and eosin-stained whole slide images of biopsies from all study arms and timepoints were analyzed using Liver Explore to detect, classify, and quantify liver tissue regions, cells, and fibrosis subtypes. For each study arm, fold changes in each feature from BL to w24 and w96 were calculated and compared to Pbo using ANCOVA. **Results:** Eight Liver Explore features relevant to MASH were selected to measure changes from BL at w24 and w96 (Figure 1). At wk24, we observed treatment-specific reductions from BL in early-stage fibrosis (-40% EFX-28; -44% EFX-50), hepatocellular ballooning (-85%; -95%) and steatotic hepatocytes (-49%; -70%). Macrophages (-17%) and total immune cells (-15%) were reduced in EFX-50, and normal hepatocytes increased at both doses (40% EFX-28; 71% EFX-50) at wk24. These improvements were largely sustained at wk96, with macrophages and total immune cells showing improvement in EFX-28, as well. While not significant at wk24, total and advanced fibrosis improved at wk96, with a 59% reduction in advanced fibrosis in EFX-50. These results reveal dose- and time-dependent effects of EFX: histologic features related to MASH disease activity, inflammation, and early-stage fibrosis resolve most quickly, while resolution of advanced fibrosis requires a longer EFX duration and higher dose. **Conclusion:** Liver Explore analysis of HARMONY revealed improvements in histologic features related to MASH disease activity and fibrosis severity beyond categorical scoring. These results highlight the multimodal and antifibrotic nature of EFX as a MASH therapeutic and corroborate the improvements observed by conventional histology in HARMONY.

4086 | A BISPECIFIC ANGPTL3-DGAT2 SIRNA FOR CONCURRENT TREATMENT OF BOTH HEPATIC STEATOSIS AND ATHEROSCLEROTIC CARDIOVASCULAR DISEASE

Michael Khan[1] Gerda Gasiunaite[1] Mitchell Geer[1] Dan Mitchell[1] Owen Cox[1] Antonio Vidal-Puig[2] Stella Pelengaris[1], [1]Argonaute RNA Ltd, [2]University of Cambridge

Background: Hepatic steatosis is a well-established risk factor for severe diseases of the liver. Moreover, not only is hepatic steatosis a risk factor for atherosclerotic cardiovascular disease (ASCVD) *per se*, but recent studies demonstrate that otherwise promising treatments for liver complications, such as targeting *PNPLA3*, can increase ASCVD risk factors, particularly atherogenic LDL-C. Conversely, treatments for Residual Risk (RR) of ASCVD, targeting triglyceride-rich lipoproteins or ApoB, are associated with the development of hepatic steatosis. There is, therefore, an urgent need for new synergistic therapies to prevent or improve both hepatic steatosis and risk of ASCVD.

We present our approach, which utilises a proprietary Argonaute platform technology for the simultaneous silencing of two or more hepatocyte target genes using a single, multi-valent molecular entity. Data will be presented to confirm that the Argonaute therapy remains intact until linker cleavage in the hepatocyte endosomal compartment. Next, the effect of simultaneous bispecific silencing of *Angptl3* and *Dgat2* in a diet-induced obese (DIO) mouse model *in vivo* will be discussed. **Methods:** Bispecific *ANGPTL3-DGAT2* siRNAs were designed, developed and administered to DIO mice at 4, 10 and 20 mg/kg doses *in vivo* by a single subcutaneous injection. Changes in plasma lipids, hepatic mRNA and hepatic lipid profile were assessed at 7-, 21- and 42-day time points. Controls included equivalent doses of monospecific siRNAs, vehicle and a control siRNA. **Results:** Administration of a single dose of a bispecific siRNA targeting *ANGPTL3* and *DGAT2* produced a robust ($>90\%$) and sustained reduction in mRNA for both target genes. The therapy was safe and well-tolerated, with no markers of liver toxicity. Comprehensive lipidomic analyses confirm substantial reductions in hepatic steatosis (-50%), extending to liver diacylglycerols as well as triacylglycerols, and without accumulation of hepatotoxic precursors or contributors to insulin resistance. Moreover, there was a marked reduction in genetically validated genes implicated in MASLD/MASH, including a 70% reduction in the apical risk factor *Pnpla3*. Notably, there was a profound concurrent reduction in atherogenic plasma lipids, including LDL-C (-70%) and triglycerides (-38%). **Conclusion:** These results justify further development of bispecific *ANGPTL3-DGAT2* siRNAs for the prevention and treatment of MASLD/MASH, as well as for RR of ASCVD and cardiometabolic disease more broadly.
