2389 | EVALUATION OF ALBUMIN-DERIVED RATIOS IN PREDICTING 30-DAY MORBIDITY AND MORTALITY IN HBV- AND MASLD-RELATED CIRRHOSIS: A COMPARATIVE ANALYSIS WITH MELD 3.0

Derya Emel Baki[1] Elvan Isık[2] Ilker Turan[2] Fulya Gunsar[2] Zeki Karasu[2], [1]Ege University Faculty of Medicine Hospital, [2]Ege University Faculty of Medicine Hospital Department of Gastroenterology

Background: Liver cirrhosis due to HBV or MASLD remains a major global health concern with high short-term mortality. While MELD-based scoring systems are widely utilized for prognostic assessment, albumin-derived biochemical ratios have recently emerged as promising supplementary markers. This study aimed to evaluate the predictive value of albumin-derived ratios—particularly blood urea nitrogen-to-albumin ratio (BAR) and red cell distribution width-to-albumin ratio (RAR)—in comparison with the MELD 3.0 score for 30-day and 60-day mortality in patients with HBV- or MASLD-related decompensated cirrhosis. **Methods:** This retrospective cohort study included 210 patients who were hospitalized with HBV- or MASLD-related decompensated cirrhosis between April 2019 and April 2024. Clinical, demographic and laboratory data were systematically retrieved from institutional medical records. MELD 3.0 scores and albumin-derived ratios were calculated for each patient. Receiver operating characteristic (ROC) curve and logistic regression analyses were conducted to assess independent predictors and discriminatory performance. **Results:** The 30-day and 60-day mortality rates were 32.9% and 40.0%, respectively. In multivariate analyses, MELD 3.0 (OR = 1.098, p = 0.023), BAR (OR = 1.057, p = 0.018), RAR (OR = 1.295, p = 0.046) were independent predictors of 30-day mortality. BAR showed the highest predictive power with an AUC of 0.834, followed by MELD 3.0 (AUC = 0.805) and RAR (AUC = 0.766). A combined predictive model incorporating MELD 3.0, BAR, and RAR yielded an AUC of 0.857, with 82.6% sensitivity and 75.5% specificity. **Conclusion:** BAR and RAR are strong, independent predictors of short-term mortality in decompensated cirrhotic patients, with prognostic utility beyond the MELD 3.0 score. The integration of albumin-derived ratios into existing models enhances risk stratification and may contribute to more personalized management strategies in HBV- and MASLD-related cirrhosis.

2390 | MODERATE ALCOHOL CONSUMPTION AND LIVER-RELATED EVENTS IN MASLD: THRESHOLDS AND LONGITUDINAL EFFECTS

Hanah Lee[1] Jae Yoon Jeong[2] Young Youn Cho[1] Hyung Joon Kim[1] Hwi Young Kim[3], [1]Chung-Ang University Hospital, [2]Ewha Womans University Mokdong Hospital, [3]University of Nebraska Medical Center

Background: Although several studies have suggested potential health benefits of low-volume alcohol consumption, findings remain controversial, particularly in patients with liver disease. This nationwide study investigated the association between varying alcohol intake levels and the risk of liver-related events (LREs) in individuals with steatotic liver disease (SLD). **Methods:** We analyzed data from 2,951,003 adults aged 40–64 years in the Korean National Health Insurance Service database who underwent health examinations between 2009 and 2010. Hepatic steatosis was defined by a Fatty Liver Index ≥30, and SLD was classified according to established criteria. Alcohol intake was categorized as none, very low (1–49 g/week), low (50–99 g/week), moderate (100–139 g/week in women, 100–200 g/week in men), high (140–350

g/week in women, 210–420 g/week in men), and heavy (>350 g/week in women, >420 g/week in men). We evaluated the impact of baseline alcohol intake and 4-year longitudinal changes in consumption on long-term LRE risk among individuals with SLD. **Results:** During a median follow-up of 14 years, incidence rates of LREs per 100,000 person-years were 132.7 in the non-SLD group and 493.7, 435.7, 439.8, and 446.8 in MASLD groups with no, very-low, low, and moderate alcohol intake, respectively. Compared with the MASLD group with none-to-low alcohol intake (0–99 g/week), moderate alcohol intake was associated with a significantly increased risk of LREs in both multivariable-adjusted (adjusted sub-distribution hazard ratio [aSHR] = 1.035; 95% CI 1.011–1.059; P = 0.003) and IPTW-adjusted models (aSHR = 1.071; 95% CI 1.057–1.084; P < 0.001). Sex-specific analyses showed a lower risk threshold in women than in men. In men, significant risk elevation was observed only at moderate intake (aSHR = 1.036; 95% CI 1.009–1.064; P = 0.009), whereas women demonstrated increased risk beginning at low-volume intake (aSHR = 1.093; 95% CI 1.022–1.169; P = 0.009) and continuing at moderate intake (aSHR = 1.122; 95% CI 0.997–1.264; P = 0.057). Longitudinal analysis showed that progression to moderate alcohol intake was associated with higher LRE risk than sustained low-volume drinking (HR 1.393–1.509 for progression to moderate intake vs. HR 1.141–1.295 for maintaining or shifting within the low-volume range). Among individuals initially in the moderate alcohol group, LRE risk remained similarly high regardless of whether alcohol intake decreased or remained unchanged (HR 1.290–1.450 for reduction to low-volume vs. HR 1.312 for maintaining moderate volume). **Conclusion:** In this nationwide cohort, moderate alcohol intake was associated with increased LRE risk in individuals with MASLD, with a lower risk threshold in women. Longitudinal increases in alcohol intake were also associated with higher risk.

Risk of liver-related events
(vs. MASLD without any alcohol group)

Population group	Events	Person-yrs	IR	Hazard ratio (95% confidence interval)					
				Model 1		Model 2		Model 3	
Liver-related event									
MASLD without any alcohol	28,979	5,960,918	493.7	1.00	(Reference)	1.00	(Reference)	1.00	(Reference)
MASLD with very-low alcohol	5,725	1,313,837	435.7	0.93	(0.90–0.95)	0.97	(0.94–1.00)	0.99	(0.97–1.02)
MASLD with low alcohol	7,920	1,800,102	439.8	0.94	(0.91–0.96)	0.99	(0.97–1.02)	1.00	(0.98–1.03)
MASLD with moderate alcohol	10,716	2,398,626	446.8	0.95	(0.93–0.97)	1.03	(1.01–1.06)	1.04	(1.01–1.06)

*Incidence rate per 100,000 person-years
Model 1: unadjusted
Model 2: adjusted for age and sex.

2391 | DEVELOPMENT OF A CLINICALLY SCALABLE CIRCULATING MICRORNA ASSAY FOR LIVER FIBROSIS STAGING IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Haleigh Parker[1] Byung-In Lee[1] Chang Han[1] Trevor Hoang[1] Gordon Vansant[1] Shuguang Huang[1] Yipeng Wang[1], [1]LuminoDx Inc.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects 30–35% of U.S. adults and can progress to metabolic dysfunction-associated steatohepatitis (MASH), fibrosis, cirrhosis, and liver failure. Liver biopsy is the gold standard for fibrosis staging but is invasive and costly. Current noninvasive methods have limitations in accuracy and accessibility. Circulating microRNAs (miRNAs) are promising biomarkers due to their stability and role in liver fibrogenesis. We developed a multiplex circulating miRNA assay using a proprietary one-step RT-qPCR workflow for noninvasive fibrosis assessment in MASH patients. **Methods:** A proprietary one-step RT-qPCR workflow was developed for multiplex circulating miRNA detection targeting miR-34a, miR-99a, miR-192, miR-223, miR-122, and endogenous control miR-23a. Analytical performance, including quantification range, sensitivity, and specificity, was evaluated using synthetic miRNA mimics. Plasma samples were collected from obesity controls without MASLD/MASH, MASLD patients, and MASH patients with different fibrosis stages. A total of 200 µL plasma per patient was used for miRNA isolation and RT-qPCR analysis. Relative miRNA expression was normalized to miR-23a. Algorithms were developed to differentiate low fibrosis (F0/F1) from moderate-to-advanced fibrosis (F2+) MASH patients and to distinguish MASLD from MASH. Clinical performance was evaluated using leave-one-out cross-validation (LOOCV). **Results:** Analytical validation demonstrated robust performance for all targeted miRNAs suitable for clinical use. Twenty-three patients were included: 3 obesity controls, 7 MASLD patients, 7 MASH F0/F1 patients, and 6 MASH F2+ patients. Differential expression patterns of miR-34a, miR-99a, miR-192, miR-223, and miR-122 were observed among groups. Using LOOCV, the multiplex miRNA model distinguished MASH F0/F1 from F2+ patients with 92.3% accuracy (95% CI: 0.64–0.998), 87.5% positive predictive value, and 100% negative predictive value. Significant correlations were observed between transient elastography liver stiffness measurements and circulating miRNA levels, including miR-34a (r = -0.71), miR-122 (r = -0.65), and miR-192 (r = -0.57). **Conclusion:** This preliminary study demonstrates the potential utility of a multiplex circulating miRNA RT-qPCR assay for noninvasive liver fibrosis staging in MASH patients. The assay showed robust analytical performance and promising discrimination between early-stage and clinically significant fibrosis. Correlations between circulating miRNAs and liver stiffness

2392 | WAIST-TO-HEIGHT RATIO OUTPERFORMS BMI IN IDENTIFYING HEPATIC AND METABOLIC COMORBIDITIES AND PREDICTING DISEASE COURSE IN CROHN'S DISEASE

Sandra García-Mateo[1] Coral Rivas-Rivas[2] Samuel Martinez-Dominguez[1] sergio García-Mateo[1] Maria del Henar Ruiz Saez[3] Inmaculada Sanchez Ojeda[3] Maria Escuin[1] Monserrat Rivero[4] Maria Jose Garcia[4] Beatriz Gallego[1] Marta Pascual[4] Carla Gargallo[1] Antonio Cuadrado[4] Fernando Gomollon[1] Maria Teresa Arias-Loste[3], [1]Hospital Clínico Universitario Lozano Blesa. Instituto Investigación Sanitaria de Aragon. CIBERehd, [2]Clinical and Translational Research Group in Digestive Diseases, IDIVAL. Santander, Spain, [3]Clinical and Translational Research Group in Digestive Diseases, IDIVAL. Santander. Spain, [4]Clinical and Translational Research Group in Digestive Diseases, IDIVAL

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic syndrome (MS), and liver fibrosis are increasingly recognized comorbidities in Crohn's disease (CD). Body mass index (BMI) fails to adequately capture central adiposity, potentially underestimating hepatic and metabolic risk. Waist-to-height ratio (WHtR) is a simple anthropometric marker of central adiposity, but its utility for identifying liver-related and metabolic comorbidities and predicting CD course remains unexplored. **Methods:** Prospective multicenter cohort study including CD patients in clinical remission from two Spanish tertiary hospitals. Baseline BMI, WHtR, and prevalence of MASLD (CAP > 248 dB/m plus ≥ 1 metabolic criterion), MS (NCEP-ATP3), and significant liver fibrosis (liver stiffness > 8 kPa) were assessed. Relapses, steroid use, and treatment modifications were recorded over follow-up. **Results:** A total of 641 CD patients were included (median follow-up 36 months). MASLD was present in 41.2%, MS in 21.5%, and significant liver fibrosis risk in 10.9%. WHtR ≥ 0.50 was detected in 74.6% of patients, including > 50% of those with normal BMI. WHtR demonstrated markedly higher sensitivity than BMI for detecting MASLD (96.2% vs. 85.6%; p < 0.001), MS (99.2% vs. 86.2%; p < 0.001), and significant liver fibrosis (84.2% vs. 68.5%; p < 0.001). Regarding disease course, elevated WHtR was independently associated with increased risk of relapse (aHR 1.518; 95%CI 1.004–2.296), steroid use (aHR 1.774; 95%CI 1.004–3.136), and treatment modification (aHR 1.674; 95%CI 1.111–2.523), whereas BMI showed no significant associations. **Conclusion:** WHtR outperforms BMI in identifying hepatic and metabolic comorbidities in CD, and independently predicts adverse disease course. Its routine use may improve risk stratification and facilitate early detection of metabolically vulnerable patients, including those misclassified by BMI.

Comorbidities	BMI ≥30 Crohn's disease	WHtR ≥ 0.5 Crohn's disease	P value
MASLD			
Sensitivity	85.6%	96.2%	
Specificity	71.3%	39%	**<0.001**
NLR	-1.18	-2.44

2393 | SOLUBLE TREM2 PREDICTS POST-TRANSPLANT MASH RECURRENCE AND REFLECTS SCAR-ASSOCIATED MACROPHAGE EXPANSION RATHER THAN ENHANCED PROTEOLYTIC SHEDDING

Zhihao Li[1] Kai-Philipp Seeger[1] Xingxing Zhu[1] Yawen Dong[1] David Pereyra[1] Byron Smith[1] Tayyab Diwan[1] Kymberly Watt[1] Timucin Taner[1] Patrick Starlinger[1] Hu

Zeng[1] Julie Heimbach[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatohepatitis (MASH) recurs in up to 25% of liver transplant (LT) recipients, yet reliable predictors are lacking. Soluble triggering receptor expressed on myeloid cells 2 (sTREM2) correlates with MASLD severity, but whether its elevation reflects ADAM10/17-mediated proteolytic shedding or scar-associated macrophage (SAMac) expansion is unresolved. We evaluated a longitudinal sTREM2 index as a biomarker for post-LT MASH recurrence and integrated single-cell and proteomic data to define the underlying mechanism. **Methods:** Consecutive adult LT recipients with MASH at Mayo Clinic Rochester (2010–2022) with stored plasma were included. sTREM2 was measured at baseline, 4 and 12 months by ELISA, and the sTREM2 index (12-month/baseline ratio) was tested against FIB-4 and NFS for predicting 3-year MASH recurrence, defined as MRE liver stiffness ≥ 3 kPa. Logistic and Cox models were adjusted for recipient age, BMI, and diabetes. To define cellular mechanism, we re-analyzed human liver scRNA-seq (GSE136103; 45,328 cells, 8 populations) and two independent liver proteomics cohorts spanning the MASLD spectrum. **Results:** Of 140 recipients (median age 60, BMI 31.8, 63.6% diabetes), 43 (30.7%) developed MASH recurrence. sTREM2 declined uniformly at 4 months, then rebounded to near-baseline in the recurrence group (median index 1.10) versus remaining suppressed in non-recurrence (0.54; $p < 0.001$). The sTREM2 index discriminated recurrence with AUC 0.713, outperforming FIB-4 (0.431; DeLong $p < 0.001$) and NFS (0.608; $p = 0.074$); adjusted OR 1.68 (95% CI 1.17–2.42; $p = 0.005$, Fig.1A&B). Adding the index to a clinical base raised AUC from 0.543 to 0.722 ($p = 0.002$). The index was also independently associated with post-transplant diabetes (aOR 1.45; $p = 0.011$), and a Youden-dichotomized high index predicted worse graft survival (log-rank $p = 0.024$, Fig.1C). Mechanistically, scRNA-seq revealed a 2.3-fold expansion of TREM2-high SAMac in cirrhotic livers with per-cell TREM2 upregulation ($\log_2FC = 1.54$, Fig.1D), while ADAM10/ADAM17 were unchanged across 8 cell types — confirmed at the protein level in both proteomics cohorts. Cell-cycle distribution was unchanged ($p = 0.399$), excluding proliferation; instead, stellate (CCL2/CXCL12) and endothelial (CX3CL1) chemokine axes were upregulated (Fig.1E), identifying monocyte recruitment as the driver of SAMac accumulation, with recruited cells reprogrammed toward oxidative phosphorylation and lipid handling. **Conclusion:** The sTREM2 index is a novel non-invasive biomarker for post-transplant MASH recurrence outperforming conventional fibrosis indices. Elevated circulating sTREM2 reflects chemokine-driven SAMac recruitment rather than enhanced proteolytic shedding. This positions sTREM2 as an actionable post-LT surveillance tool and the CCL2/CXCL12/CX3CL1 axes as therapeutic targets.

Figure 1

(A) Distribution of $\log_2$-transformed sTREM2 index (12-month/baseline ratio) by recurrence status. Individual data points, half-violin density, and mean ± 95% CI (black diamond and error bars) are shown. The dashed line indicates no change from baseline. P-value from Welch's t-test. (B) ROC curves comparing the sTREM2 index, FIB-4, and NFS as standalone predictors. (C) Kaplan-Meier curve for graft survival stratified by sTREM2 index (High vs. Low) using a Youden-optimized cutoff derived from the primary endpoint (MASH recurrence). P-values from log-rank test. Number at risk shown below each curve. (D) Reanalysis of scRNA-seq data from healthy (n = 5) and cirrhotic (n = 2, MASLD etiology) human livers (GSE136103). Proportion of SAMac among myeloid cells in healthy and cirrhotic livers. SAMac were defined by a module score > 0.1 based on the TREM2/CD9/SPP1/LGALS3 signature. (E) Heatmap of $\log_2$ fold change (cirrhotic vs healthy) for monocyte recruitment chemokines in non-macrophage cell types. Hepatic stellate cells show significant upregulation of CCL2 and CXCL12, and endothelial cells show upregulation of CX3CL1, indicating selective activation of monocyte homing axes in the fibrotic microenvironment.

2394 | POC-HRM: A POINT-OF-CARE HIGH-RISK MASLD MACHINE LEARNING FRAMEWORK FOR RISK STRATIFICATION AND ENRICHMENT FOR SYNERGY OUTCOMES TRIAL SCREENING

Winston Dunn[1] Naim Alkhouri[2] Elizabeth Brombosz[3] Gražina Binkauskiene[3] Rashmee Patil[4] Rohit Puskoor[5] David Huang[6] Nirupama Esther Jerome[5] John Poulos[7] Alaa Abousaif[8] Aasim Sheikh[9] Alma Laura Ladrón de Guevara[10] Marcelo Kugelmas[11] Mousab Tabbaa[12] Sam Moussa[13] Vlad Ratziu[14] Meena Bansal[15] Jörn Schattenberg[16] Mazen Noureddin[17], [1]University of Kansas Medical Center, [2]Summit Clinical Research, [3]Summit Clinical Research Solutions, [4]Pinnacle at San Antonio, Summit Clinical Research Solutions, [5]Pinnacle at Austin, Summit Clinical Research Solutions, [6]Houston Research Institute – Main, [7]Coastal Research Institute, [8]Providence St. Joseph Hospital-Orange, [9]GI Specialists of Georgia, [10]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [11]South Denver Gastroenterology, [12]Clinical Research Institute of Ohio, [13]Adobe Clinical Research, [14]Service D' Hepatogastroenterologie (FR), [15]Icahn School of Medicine at Mount Sinai (ISMMS), [16]Saarland University Medical Center, [17]Houston Methodist Hospital, Houston Research Institute, Summit Clinical Research Solutions

Background: The SYNERGY Outcomes trial targets patients with high-risk MASLD (HRM) defined by elevated LSM and ELF score. Identifying eligible patients remains challenging because VCTE and ELF testing are costly, not universally available, and frequently result in screen failure. We aimed to develop a point-of-care machine (POC) learning framework using routinely available laboratory and clinical variables to stratify patients into lower- and higher-probability groups for SYNERGY Outcomes eligibility prior to VCTE and ELF testing. **Methods:** HRM was defined according to SYNERGY Outcomes inclusion criteria. The derivation cohort included a multi-center cohort of 5249 patients, of whom 1459 (27.8%) met HRM criteria. The external validation cohort included 4336 patients from non-overlapping centers, of whom 1287 (29.7%) met criteria. Extreme gradient boosting machine learning models predicted lower- and higher-risk MASLD phenotypes using routinely available clinical and laboratory variables. SHAP analysis ranked variable importance and identified reduced point-of-care models. Optimized probability thresholds were selected using the Youden index. **Results:** SHAP analysis identified platelet count, GGT, AST, ALT, globulin, hemoglobin A1c, age, height, and weight as the top-ranking variables. The POC-HRM rule-in model demonstrated an AUC of 0.766 (95% CI 0.752-0.780) in external validation, outperforming SAFE at 0.750 (95% CI 0.736-0.765) and FIB-4 at 0.731 (95% CI 0.717-0.746). At the optimized threshold, sensitivity was 68.5% and NPV was 70.4%, compared with 63.8% and 67.8% for SAFE, and 63.9% and 66.9% for FIB-4, at a cutpoint of 1.25 and 107 respectively. The rule-out model demonstrated an AUC of 0.792 (95% CI 0.775-0.809), outperforming SAFE (0.777; 95% CI 0.760-0.794) and FIB-4 (0.763; 95% CI 0.746-0.781). At the optimized threshold, specificity was 75.4% and PPV was 44.4%, compared with 73.7% and 42.7% for SAFE, and 73.4% and 42.0% for FIB-4, at a cutpoint 1.49 and 132, respectively. **Conclusion:** A POC machine learning framework using routinely available laboratory and clinical variables successfully stratified patients into rule-in and rule-out groups for SYNERGY Outcomes eligibility prior to VCTE and ELF testing. Compared with SAFE and FIB-4, the framework demonstrated improved exclusion performance in lower-risk patients and superior enrichment capability in higher-risk patients. This strategy may improve screening efficiency using variables readily available in routine clinical practice.

Model	Threshold	AUC	95% CI Lower	95% CI Upper	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
Rule-in Threshold								
POC-HRM	0.406	0.766	0.752	0.780	68.5	71.3	69.4	70.4
FIB4	1.25	0.731	0.717	0.746	63.9	69.2	66.4	66.9
SAFE	107	0.750	0.736	0.765	63.8	72.5	68.8	67.8
Rule-out Threshold								
POC-HRM	0.226	0.792	0.775	0.809	69.0	75.4	44.4	89.5

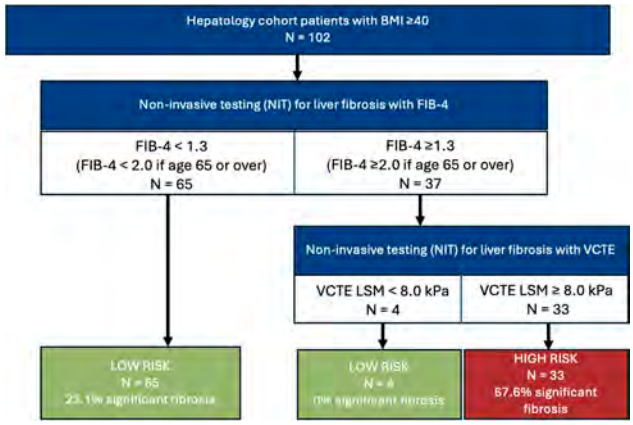
2395 | RISK STRATIFICATION OF MASLD IN PATIENTS WITH BMI ≥40: PERFORMANCE OF FIB-4 AND VCTE WITHIN THE 2026 AGA CLINICAL CARE PATHWAY



Abigail Tami[1] Fady Gendy[1] Mustafa Shah[1] G. Craig Wood[1] Meredith Lewis[1] Andrea Berger[1] Samantha Service[1] Christopher Still[1] Alberto Unzueta[1], [1]Geisinger Medical Center

Background: Non-invasive liver disease assessments (NILDA) such as FIB-4 and vibration

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

controlled transient elastography (VCTE) are useful in the risk stratification in MASLD. In individuals with BMI ≥ 40, the accuracy of FIB-4 and VCTE in predicting significant fibrosis has not been completely characterized. This study evaluates the performance of FIB-4 and VCTE within the 2026 AGA multi-step MASLD clinical care pathway in two obesity class III cohorts using liver biopsy as the reference standard. **Methods:** This retrospective study utilized two institutional data registries composed of all patients who underwent liver biopsy between 2016-2021. The study included those with BMI ≥ 40 kg/m^2 who either had a wedge liver biopsy at the time of bariatric surgery (bariatric cohort) or were referred to hepatology clinic (hepatology cohort). Patients with alternate liver disease etiologies were excluded. Among those with FIB-4 data across both cohorts, the prevalence of significant fibrosis (≥ F2 fibrosis) was outlined in those labeled as low- and high- risk by the initial steps of the AGA clinical care pathway. In hepatology patients with both FIB-4 and VCTE data, the multi-step approach of the pathway was applied and validated. **Results:** A total of 1,495 patients (mean BMI 47.4 kg/m²) were included, and 1,402 (93.8%) patients had FIB-4 values. Most patients were female (77.2%) with a mean age of 43.8 ± 11.9 years. Within the bariatric cohort, 112 (10.0%) patients had a high- risk FIB-4 (≥ 1.3 or ≥ 2.0 for Age > 65), and significant fibrosis (≥ F2) was present in 90 (8.0%) of patients based on liver biopsy. Within the hepatology cohort, 92 (32.9%) patients had a high- risk FIB-4, and significant fibrosis was present in 104 patients (37.1%). Within the bariatric cohort, 94.5% of patients with a low-risk FIB-4 (< 1.3) had no fibrosis on liver biopsy, compared to 73.4% in the hepatology cohort. Multi-step risk stratification in the clinical care pathway was applied among hepatology referred patients with both FIB-4 and VCTE data (N = 102). Using FIB-4 alone, 65 patients were labeled as low-risk, with 23.1% having ≥ F2 fibrosis on their liver biopsy. After applying both FIB-4 and VCTE, none of the low-risk patients had ≥ F2 fibrosis. In the high-risk group, 67.6% had ≥ F2 fibrosis histologically. **Conclusion:** In patients with BMI ≥ 40, FIB-4 performance varied by clinical setting. Using liver biopsy data, a low-risk FIB-4 < 1.3 correctly identified a higher proportion of those in the bariatric cohort, which may better represent a primary care population. Among those referred to hepatology care, a high percentage of misclassification was observed in the application of the AGA multi-step MASLD clinical care pathway. These results further support an expanded combination of NILDA in populations with a higher pre-test probability of significant fibrosis.

2396 | INTEGRATING AN ENHANCED LIVER FIBROSIS (ELF)-BASED RISK STRATIFICATION PATHWAY FOR AT-RISK MASH FIBROSIS IN DIABETES CLINICS: A FEASIBILITY PILOT

Larissa Lushniak[1] Anastasia-Stefania Alexopoulous[1] Alice Parish[2] Donna Niedzwiecki[2] Michael Canos[1] Michelle Ponder[1] Kathryn O'Donnell[1] Amreen Dinani[1], [1]Duke University School of Medicine, [2]Duke University

Background: Patients with type 2 diabetes (T2D) are at risk for metabolic dysfunction-associated steatohepatitis (MASH), advanced fibrosis, cirrhosis, and liver cancer. There is consensus among multiple societies to screen for at-risk MASH (i.e., MASH and ≥ F2 liver fibrosis) in all with T2D. The first step in screening is calculating a FIB-4 score, followed by transient elastography (TE) or serum Enhanced Liver Fibrosis (ELF) test in those with FIB-4 ≥1.3. ELF is a blood test that can be easily drawn alongside other labs as part of routine T2D care. The goal of this pilot was to examine the feasibility of integrating an ELF-based care pathway in T2D clinics to identify at-risk MASH. **Methods:** We conducted a prospective feasibility pilot with 3 Endocrinologists across 3 clinics at a tertiary care center. Each Endocrinologist was educated about at-risk MASH and the use of ELF. They were asked to implement an ELF-based care pathway in their T2D practice between 10/2024 and 10/2025. The protocol consisted of an initial FIB-4 calculation followed by an ELF test if FIB-4 was ≥ 1.3 (or ≥ 2.0 if ≥ 65 years of age). Hepatology referral was recommended for ELF ≥ 9.5.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Feasibility and outcome data were collected. **Results:** Analysis includes 33 patients with T2D for whom the ELF-based care pathway was implemented. Demographics are described in Table 1. Median age was 66 years (IQR 55, 71), 51% were female, 6% were Latino/a, 67% White, and 30% Black. Median HbA1c was 7.6% (IQR 6.8, 8.6), median FIB-4 was 1.8 (IQR 1.5, 2.6), and 36% were on GLP-1 receptor agonist therapy. Deviation from the care pathway occurred twice; in both cases, referral to Hepatology was placed despite ELF < 9.5. The majority of the patients (n = 31/33, 94%) had ELF drawn within 1 day. The median ELF value was 9.9 (IQR 9.3, 10.6). Two-thirds (n = 22/33, 67%) were referred to Hepatology. Median time from ELF result to referral was 8 days (IQR 3, 26). Of the 22 referrals, 13 completed Hepatology evaluation, 7 had future appointments, and 4 remained unscheduled. Of the 10 who saw Hepatology and underwent TE or MR elastography (MRE), 4 had cirrhosis (F4), 2 had significant fibrosis (F2/F3), and 4 had minimal fibrosis (< F2). **Conclusion:** Our ELF-based care pathway for identifying at-risk MASH was feasible to implement in Endocrinology clinics and resulted in high-quality Hepatology referrals. Among patients with indeterminate FIB-4 scores (> 1.3) who were evaluated by Hepatology, 60% were identified as having at-risk MASH or cirrhosis, highlighting the clinical utility of this approach for detecting advanced liver disease that may otherwise remain underrecognized. Comparison to a matched control cohort of patients managed by endocrinologists not participating in the ELF stratification initiative is ongoing.

Background: MASLD may progress to advanced fibrosis and cirrhosis, the stage of liver fibrosis (LF) being the main determinant of liver-related clinical outcomes in MASLD. Aiming to overcome the limitations of noninvasive tests for LF assessment, the Metabolic Dysfunction–Associated Fibrosis 5 (MAF-5) score was developed. This study aims to evaluate the accuracy of MAF-5 score in patients with MASLD in a Brazilian multicenter cohort. **Methods:** This was a multicenter, cross-sectional, retrospective study conducted at 10 referral centers in Hepatology across Brazil. Individuals older than 18 years, with diagnosis of biopsy-confirmed MASLD, and complete data for calculation of MAF-5 were included. The primary outcome was to evaluate the performance of the MAF-5 score in the assessment of LF in individuals with MASLD. MAF-5 score was calculated as follows, and classified as low (<0), intermediate (0–1), and high risk (>1) for LF. MAF-5 = $-11.3674 + WC \times 0.0282 - BMI \times 0.1761 + WC \times BMI \times 0.0019 + 2.0762$ (if T2DM) + $\ln(AST) \times 2.9207 -$ platelets $\times 0.0059$ Diagnostic performance was evaluated by AUROC. A p-value <0.05 was considered statistically significant, while an AUROC >0.7 was considered adequate. **Results:** The sample consisted of 1,115 individuals, with a mean age of 47.99 ± 18.7 years, predominantly women (n = 813; 72.9%). A high prevalence of comorbidities was observed, including diabetes mellitus (n = 454; 40.7%) and systemic arterial hypertension (n = 586; 52.6%). Liver biopsy showed that 511 patients (45.8%) had no fibrosis (F0), whereas 604 (54.2%) presented some degree of fibrosis: 350 (31.4%) with F1, 93 (8.3%) with F2, 110 (9.9%) with F3, and 51 (4.6%) with F4. The performance analyses of the MAF-5 score under different scenarios are presented in Table 1. Statistical significance was found when advanced fibrosis (F3 and F4) or cirrhosis (F4) were considered as outcome variables (p = 0.002 and p = 0.013, respectively), although with low AUROC values (0.574 and 0.589, respectively). When the sample was stratified according to the presence of grade II obesity (BMI ≥ 35) or not, all p-values were statistically significant. MAF-5 score performed better in groups with BMI <35 across all fibrosis stages (F1 to F3). Among cirrhotic patients (F4), the score performed better in individuals with obesity grade II.When the population was stratified into older (age $\geq$ 60 years) people or not, a moderate predictive performance for advanced fibrosis (F3–F4; AUROC = 0.778; p < 0.001) and high predictive performance for cirrhosis (F4; AUROC = 0.856; p < 0.001) was observed only in the older people group. **Conclusion:** In this sample, MAF-5 showed better performance for the diagnosis of advanced fibrosis (F3-F4) and cirrhosis (F4) in older population. Also, there was a tendency of good performance, with statistical relevance, when the sample were divided in above or below BMI 35Kg/m².

Table 1. Areas under the ROC Curve for different Scenarios

Grouping	State Variable	AUROC	p-value	CI 95% Lower limit	CI 95% Upper limit

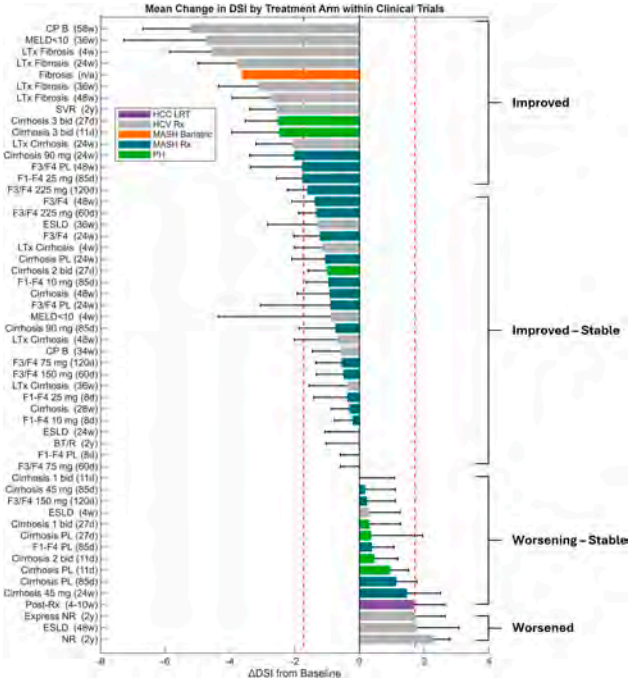
2398 | DISEASE SEVERITY INDEX DETECTS DYNAMIC CHANGES IN LIVER FUNCTION ACROSS THERAPEUTIC INTERVENTIONS AND LIVER DISEASE ETIOLOGIES



Eric Lawitz[1] Michael McRae[2] Joanne Imperial[3] Gregory Everson[4], [1]The Texas Liver Institute, [2]Custom DX Solutions LLC, [3]HepQuant LLC, [4]HepQuant

Background: Responsiveness to therapeutic intervention across diverse disease etiologies has not been systematically characterized. The Disease Severity Index (DSI) is a measure of global liver disease severity from 0 (healthy) to 50 (severe

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

dysfunction) derived from the noninvasive oral cholate challenge test (OCCT). This analysis evaluated the changes in DSI relative to baseline in response to therapeutic interventions. **Methods:** Data from 14 clinical trials were analyzed, comprising 1258 tests from 473 subjects. The OCCT involved oral administration of deuterium-labelled (d4-) cholate, blood sampling at 20 and 60 minutes, and quantification of the d4-cholate by LC-MS/MS. Test parameters, including DSI, were calculated for each subject. The minimum detectable difference (MDD), which is the smallest difference between treatment and control group that can be detected with statistical significance, was ±1.7 for DSI based on prior within-individual reproducibility studies (McRae et al. 2024). For each treatment arm, the mean change from baseline in DSI (ΔDSI) was calculated. Treatment response was categorized relative to the MDD as improved ($\Delta DSI \leq -1.7$), stable/improved ($-1.7 < \Delta DSI \leq 0$), stable/worsened ($0 < \Delta DSI \leq 1.7$), or worsened ($\Delta DSI > 1.7$). **Results:** The trials represented primarily subjects with HCV and MASH and represented a broad spectrum of disease severity, ranging from fibrosis to cirrhosis to end-stage liver disease (ESLD) (Figure). Among 54 treatment groups, 14 (26%) improved, 25 (46%) were stable/improved, 12 (22%) were stable/worsened, and 3 (6%) worsened. The largest improvements in liver function occurred in HCV treatment arms receiving antiviral therapy, consistent with viral eradication. Substantial improvement was also observed in subjects with fibrotic MASH who underwent bariatric surgery (ΔDSI −3.6). The OCCT detected rapid functional improvement within 27 days in subjects with Child-Pugh A cirrhosis treated with the highest dose of avenciguat, a soluble guanylate cyclase activator for treatment of portal hypertension (3 mg twice daily; ΔDSI −2.5). Among MASH treatment cohorts, 19 of 24 (79%) were improved or stable/improved. Hepatotoxicity (ΔDSI of +1.7) was observed in patients undergoing locoregional therapy for hepatocellular carcinoma (HCC). Worsening DSI was observed in antiviral nonresponders (NR) and patients with ESLD prior to liver transplantation. **Conclusion:** DSI is a dynamic, sensitive indicator of liver function that detects both improvement and worsening across diverse liver disease etiologies, severities, and therapeutic modalities. Incorporation of DSI into clinical trials as a continuous functional endpoint may enable earlier detection of treatment response, support adaptive trial designs, and reduce required sample sizes by providing a quantitative functional endpoint.

2399 | BLOOD METAL EXPOSURE AND ADVANCED FIBROSIS IN MASLD: NATIONAL EVIDENCE FROM NHANES 2017–MARCH 2020

Serene John[1] Madhu Babu Adusumilli[2] Pragathi Munnangi[3] Sri Ram Charan Gundapaneni[2] Jagadish Koyi[4] Mounika Kotte[5] Hardik Dineshbhai Desai[6], [1]Detroit medical center, Detroit, Michigan, 48201, [2]UCF/HCA Florida Ocala Hospital, Ocala, Florida, United States, 34471, [3]BronxCare Health System , Bronx , New York - 10457, [4]Integris Health, Oklahoma City, Oklahoma. USA. 73112, [5]Drmounikakotte@gmail.com, [6]AB Plus Specialty Hospital, Ahmedabad, Gujarat, India

Background: Environmental metal exposure may influence metabolic dysfunction and liver injury, but its association with advanced fibrosis in MASLD remains unclear. We examined blood metal exposure and VCTE-defined advanced fibrosis among U.S. adults with MASLD. **Methods:** We analyzed NHANES 2017–March 2020 adults aged ≥20 years with valid VCTE and blood metal data. MASLD was defined as CAP ≥285 dB/m plus ≥1 cardiometabolic risk factor, excluding heavy alcohol use and hepatitis C. Advanced fibrosis was defined as LSM ≥9.7 kPa. Blood lead, cadmium, mercury, selenium, and manganese were assessed by quartiles and log2-transformed continuous levels. Survey-weighted logistic regression adjusted for demographics, socioeconomic factors, BMI, diabetes/prediabetes, hypertension, smoking, and alcohol intake. **Results:** Among adults with MASLD and blood metal data, the final analytic sample included 2,382 participants, representing 66.2 million U.S. adults. VCTE-defined advanced fibrosis was present in 11.6%, corresponding to approximately 7.7 million U.S. adults. Across quartiles, advanced fibrosis prevalence did not show a positive dose-response pattern for lead, cadmium, selenium, or manganese. For mercury, advanced fibrosis prevalence decreased from 16.1% in Q1 to 8.3% in Q4. In fully adjusted models, each doubling in blood mercury was associated with lower odds of advanced fibrosis, OR 0.81, 95% CI 0.72–0.92, p = 0.0007. Lead was not significantly associated with advanced fibrosis, OR 0.93, 95% CI 0.76–1.16, p = 0.53. Cadmium showed no independent association, OR 1.01, 95% CI 0.85–1.19, p = 0.95. Selenium was also not significant, OR 0.76, 95% CI 0.35–1.64, p = 0.48, and manganese showed a non-significant positive association, OR 1.23, 95% CI 0.87–1.72, p = 0.24. These findings suggest that among measured blood metals, mercury demonstrated the strongest exposure–fibrosis signal, whereas other metals were not independently associated with advanced fibrosis after multivariable adjustment. **Conclusion:** In this nationally representative VCTE-based analysis of U.S. adults with MASLD, lead, cadmium, selenium, and manganese were not independently associated with advanced fibrosis. Higher blood mercury was associated with lower observed fibrosis odds, likely reflecting dietary, seafood-related, or socioeconomic exposure patterns rather than direct biological protection. Environmental exposure profiles in MASLD should be interpreted alongside metabolic and social determinants of fibrosis risk.

Madamba[1] Michael Middleton[1] Richard Ehman[2] Kevin Glaser[2] Yuan Le[2] Jiahui Li[2] Meng Yin[3] Yesenia Covarrubias[1] Mustafa Bashir[4] Scott Reeder[5] Bachir Taouli[6] Rohit Loomba[1] Claude Sirlin[1], [1]University of California, San Diego, [2]Mayo Clinic Rochester, [3]Mayo Clinic, [4]Duke University, [5]University of Wisconsin, Madison, [6]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: 3D magnetic resonance elastography (MRE) analyzes wave motion in three dimensions, theoretically enabling more accurate and precise liver stiffness (LS) quantification than 2D MRE. Free-breathing (FB) 3D spin-echo EPI (SE-EPI) MRE is an ~3: 50 min investigational alternative to conventional breath-hold (BH) 3D SE-EPI MRE, which can take over 4 minutes to acquire due to its six separate required breath-holds with pauses between. FB 3D MRE uses the same 32-slice pulse sequence design at 60Hz as BH 3D MRE but increases the TR from ~1600ms to ~3200ms, increases the number of phase offsets from 3 to 12, and uses temporal averaging. This increases the signal-to-noise ratio (SNR), reduces motion artifacts, and can be used when patients have difficulty suspending respiration. We sought to assess reproducibility between FB 3D MRE and BH 3D MRE for quantifying LS at 3T in adults with chronic liver disease (CLD). **Methods:** This prospective, single-center study enrolled adults with known or suspected CLD who received same-day FB and BH 3D SE-EPI MRE exams. Images were acquired at 60Hz on a GE 3T system with a 448-mm field-of-view reconstructed to a 128x128 final matrix. Expert analysts placed regions of interest (ROIs) on 4 of 32 slices, centered in the liver and approximately 10mm apart, in areas of planar wave propagation and recorded LS and cumulative ROI size (cROI). Exams were scored successful if cROI $\geq$ 300 pixels (Px). Success rate (SR) of each method was calculated. cROI (paired t-test) and SR (McNemar's test) were compared between methods. Inter-method reproducibility for quantifying LS was assessed by Bland-Altman analysis, yielding bias and its significance, limits of agreement (LoA), proportional reproducibility coefficient (RDC%), and intraclass correlation coefficient (ICC) with 95% confidence intervals (CIs). **Results:** This study included 62 participants (34 female; mean age 59 ± 12 yrs; mean body mass index 30 ± 6 kg/m^2). Median (range) cROIs were 3,201 (553-10,210) Px for FB 3D MRE and 2,611 (494-5,716) Px for BH 3D MRE ($p = 0.003$). The SR of FB (98%) and BH (94%) 3D MRE were similar ($p = 0.371$). In 57 participants, both methods were successful. In these, mean LS (range) was 4.6 (2.0-11.7) kPa for FB 3D MRE and 4.4 (2.0-11.2) kPa for BH 3D MRE. Bias (p-value), LoA, RDC%, and ICC (95% CI) were: 0.2 kPa ($p = 0.006$), (-0.7 kPa, 1.0 kPa), 16.5%, and 0.967 (0.939, 0.982), respectively. **Conclusion:** In adults imaged at 3T, FB 3D MRE agreed with BH 3D MRE for quantification of LS, with precision metrics akin to test-retest repeatability of BH 3D-MRE in prior studies, larger cROIs, and negligible bias. FB 3D MRE provides an attractive alternative to BH 3D MRE, especially for those who have difficulty suspending respiration.

2401 | LIVERFAST IN SEQUENTIAL COMBINATION WITH VIBRATION CONTROLLED TRANSIENT ELASTOGRAPHY (VCTE) OUTPERFORMS FIB-4 AND VCTE FOR IDENTIFYING ADVANCED FIBROSIS (≥F3) IN PATIENTS WITH MASLD

Mona Munteanu[1] Marie Decraecker[2] Jean-Baptiste Hiriart[3] Marie Irles-Dèpe[3] Jenny Yu[4] Ronald Quiambao[5] Amon Asgharpour[6] Juliette Foucher[7], [1]Fibronostics US Inc., New Orleans, LA, US, [2]Hôpital Haut Lévêque, Pessac, Bordeaux University Hospital, Bordeaux, France, [3]Hôpital Haut Lévêque, Pessac, France, Bordeaux University Hospital, Bordeaux, Fran, [4]Fibronostics U.S., Inc., New Orleans, Lousiana, USA., [5]Fibronostics U.S., Inc., New Orleans, Lousiana, USA, [6]Virginia Commonwealth University, [7]Hôpital Haut Lévêque, Pessac, France, Bordeaux University Hospital, Bordeaux, France

Background: AASLD clinical practice guidelines recommends FIB-4 followed by VCTE for the detection of ≥F3 stages. LIVERFAST (Fibronostics U.S.,Inc., New Orleans, US) is a novel blood-based test reimbursed in US to identify liver fibrosis. The study aimed to compare the performance, efficacy of LIVERFAST and FIB-4, sequentially with VCTE, and to assess the and need to VCTE referral for the identification of ≥F3 fibrosis in the overall MASLD population and in the subgroup of patients with type 2 diabetes (T2DM). **Methods:** Cross-sectional retrospective study including MASLD patients from a tertiary hepatology center with contemporary LIVERFAST, FIB-4, VCTE, and liver biopsy within 6-month. Performances were assessed using sensitivity, specificity, PPV, NPV, and number needed to diagnose (NND), number of refferals for a second assessment. VCTE with IQR < 30% of median value, 10 valid measurements and success rate ≥ 60% were included. The following cutoffs have been tested for VCTE, 8 and 12 kPa, for FIB-4 2.67 and 1.3 and for LIVERFAST 0.52. **Results:** LIVERFAST outperformed FIB-4 for identifying ≥F3 fibrosis, showing almost twice higher sensitivity and higher NPV at the rule-in FIB-4 cut-off (>2.67) and higher specificity and PPV at the recommended rule-out cut-off (≥1.3 [2.0]). The combination LIVERFASt and VCTE achieved higher PPV (90.4%) than FIB-4 and VCTE (76%) with similar NPV. LIVERFASt identified almost twice more of ≥F3 cases as FIB-4 at the rule-out >2.67 cut-off, NNDs 4.56 vs 7.98, respectively. LIVERFAST identified a similar number of ≥F3 cases as FIB-4 at the recommended rule-out ≥1.3 [2.0] cut-off with a lower number of required VCTEs referrals of 187 vs 243 ($p < 0.001$), respectively. Similar results have been observed in the T2DM subanalysis with a with a lower number of required VCTEs referrals of 118 vs 146 ($p < 0.01$), respectively. **Conclusion:** LIVERFASt outperformed FIB-4 and its integration into MASLD pathways may enhance screening efficiency, including in high-risk T2DM patients.

Figure 1. Sequential approach with LIVERFAST ≥F3, FIB-4 >2.67 cut-off and recommended FIB-4≥1.3 (2) followed by VCTE >12 KPa, high risk for ≥F3 in the overall population.

2402 | INDIVIDUALS UNDERGOING JOINT REPLACEMENT ARE AT RISK FOR UNRECOGNIZED ADVANCED LIVER DISEASE

Krishan Puri[1] Alina Puri[2] Nancy S. Reau[3] Rajeev Puri[4], [1]The University of Illinois Observatory, Urbana, United States, [2]Lincolnway East High School, Frankfort, IL, [3]Rush University Medical Center, Chicago, United States; [4]Ibji, Kankakee, United States

Background: Cirrhosis makes joint replacement surgery riskier due to an increased risk for complications. Chronic liver disease (CLD) is common in the United States with metabolic dysfunction associated steatotic liver disease (MASLD) affecting 1 out of every 3 adults and more than 80% of adults living with type 2 diabetes. Most people with CLD are unaware that they are at risk for liver disease and up to 75% of people with liver cirrhosis are unaware of their condition. Older adults with metabolic disease are at highest risk for advanced disease from MASLD and are also impacted by osteoarthritis leading to evaluation for joint replacement. Non-invasive tools such as FIB4 can be used to identify people at risk for advanced liver disease, even when they are unaware of their risk. A FIB4 score > 2.67 is associated with risk for advanced liver disease and > 3.25 has a positive predictive value of 65% for advanced fibrosis. Primary aim is to evaluate for unrecognized advanced liver disease in a population of individuals undergoing joint surgery. Secondary aim to see if this impacts perioperative outcome. **Methods:** Retrospective chart review of patients undergoing joint replacement surgery over a 12-month period with at least 6 months post-surgical follow-up. Data collection will include demographics (age, sex), comorbid conditions (T2DM, HTN, Liver disease), BMI, and preoperative blood work (CBC, CMP) to allow calculation of FIB4. Post-operative outcomes will be assessed, including infection and dislocation. **Results:** 403 consecutive total joint patients were reviewed. No patient had known cirrhosis. 12 were eliminated for inadequate labs to calculate FIB4. Avg Age 69 (58-81), 61% TKI (total knee implant), 39% THI (total hip implant), 52% male, Avg BMI 33.9 (28-39), 30% T2DM, 62% HTN. 25% had a calculated FIB4 > 2.67 and 8% with FIB4 > 3.25. There were no post-operative dislocations or joint infections. Elevated FIB4 did not correlate with T2DM. **Conclusion:** In this population of individuals enriched with risk factors for MASLD, 25% had a FIB4 that suggested they were at high risk for advanced liver disease and 8% with a score concerning for very high risk. Not only is this an opportunity to identify patients at risk for surgical complications it is also an excellent opportunity to identify individuals at risk for liver related morbidity and mortality.

2403 | ULTRASOUND-DERIVED FAT FRACTION (UDFF) AND AUTOMATED POINT SHEAR WAVE ELASTOGRAPHY (AUTO PSWE) FOR NON-INVASIVE STEATOSIS QUANTIFICATION AND LIVER FIBROSIS STAGING

Christian Sebesta[1] Nina Dominik[1] Georg Kramer[1] Benedikt Hofer[1] Paul Thöne[1] Marlene Hintersteininger[1] Mathias Jachs[1] Lukas Hartl[1] Lorenz Balcar[1] Philipp Schwabl[1] Benedikt Simbrunner[1] Georg Semmler[1] Michael Trauner[1] Mattias Mandorfer[1] David Bauer[1] Thomas Reiberger[1], [1]Medical University of Vienna

Background: Modern ultrasound platforms allow the measurement of liver stiffness (LSM) and hepatic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

steatosis quantification such as by ultrasound derived fat fraction (UDFF). Validating these ultrasound-based parameters against vibration controlled transient elastography (VCTE), the current non-invasive reference standard may support their implementation in routine clinical practice. **Methods:** In this prospective study, patients with suspected liver disease underwent same-day non-invasive assessment on two elastography platforms. LSM was measured by Auto point shear wave elastography (auto pSWE) on a Siemens ACUSON Sequoia system, which also enabled acquisition of UDFF. Participants additionally underwent LSM by VCTE with continuous controlled attenuation parameter (cCAP). VCTE-derived LSM thresholds of ≥15 kPa and ≥25 kPa were used to define advanced chronic liver disease (ACLD) and clinically significant portal hypertension (CSPH), respectively. Steatosis grades were defined according to cCAP thresholds, with ≥S1 steatosis defined as cCAP ≥248 dB/m and severe steatosis (≥S3) as cCAP ≥280 dB/m. **Results:** The study included 111 patients with suspected liver disease. Median age was 51 years, 76% were male, and the most common etiology was steatotic liver disease (46%). Overall, 49 patients (44%) fulfilled criteria for ACLD and 25 (23%) for CSPH. Median VCTE-LSM was 9 kPa, while median Auto pSWE-LSM was 6 kPa. Median cCAP was 250 dB/m. Any steatosis (≥S1) was present in 49 patients (51%), and S3 steatosis in 33 patients (34%). Median UDFF was 6%. UDFF showed a moderate correlation with cCAP ($r = 0.50$, $p < 0.001$) and provided moderate diagnostic performance for steatosis staging, with AUCs of 0.79 for ≥S1 and 0.83 for S3 steatosis. Optimized UDFF thresholds for excluding ≥S1 steatosis were at <5% (NPV 88%), for identifying S3 at >15% (PPV 70%).Auto pSWE-LSM demonstrated a strong correlation with VCTE-LSM ($r = 0.76$, $p < 0.001$). However, Bland–Altman analysis indicated a systematic underestimation of LSM by Auto pSWE compared to VCTE, with a mean bias of −10.5 kPa and greater divergence at higher VCTE-LSM values. For liver disease staging, Auto pSWE-LSM showed good discrimination for ACLD (AUC 0.79, 95% CI 0.70–0.88) and excellent discrimination for CSPH (AUC 0.87, 95% CI 0.77–0.96). Optimized cutoffs supported the use of Auto pSWE-LSM <4.0 kPa to rule out ACLD (NPV 79%) and >10.3 kPa to rule in CSPH (PPV 65%). Incorporating platelet count further improved diagnostic performance, increasing the AUC to 0.88 for ACLD and 0.94 for CSPH. **Conclusion:** UDFF demonstrated good performance for hepatic steatosis quantification, with values <5% excluding any steaotosis (≤S1) and >15% identifying severe steatosis (≥S3). Auto pSWE yielded systematically lower LSM values than VCTE especially at higher VCTE-LSM strata, thus, further studies investigating the value of Auto pSWE-LSM for non-invasive ACLD and CSPH assessment are needed.

2404 | CORRELATION BETWEEN LIVER ELASTOGRAPHY AND THAI CARDIOVASCULAR RISK IN PATIENTS WITH MASLD WITH OR WITHOUT CHRONIC HBV INFECTION

Itsara Bunupuradah[1], [1]Faculty of Medicine Ramathibodi Hospital, Mahidol University

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is strongly associated with increased cardiovascular (CV) risk, which is a leading cause of mortality. Conversely, chronic hepatitis B (CHB) infection alters hepatic lipid metabolism and may have a protective effect against atherosclerosis. This study aimed to evaluate the correlation between vibration-controlled transient elastography (VCTE) parameters (LSM and CAP), non-invasive fibrosis scores (FIB-4 and MAF-5), and the Thai CV risk score in MASLD patients with or without CHB. **Methods:** A retrospective cross-sectional study was conducted at Ramathibodi Hospital between January 2023 and December 2024, including 234 MASLD patients aged 35–70 years (128 with MASLD alone and 106 with MASLD plus CHB). All patients underwent VCTE and 10-year Thai CV risk score assessment. Patients with HCV infection, HIV infection, significant alcohol use, or established ASCVD were excluded. Data were analyzed using Spearman's rank correlation and multivariable logistic regression. **Results:** Most patients in both groups presented with early-stage fibrosis (predominantly F1). Compared with the MASLD-alone group, the MASLD plus CHB group had significantly lower BMI (27.8 vs 26.3 kg/m², $p = 0.029$), lower prevalence of hypertension (53.9% vs 39.6%, $p = 0.025$), and lower CAP values (292 vs 274 dB/m, $p = 0.031$). VCTE parameters (LSM and CAP) demonstrated no significant correlation with the Thai CV risk score in either group. Conversely, non-invasive fibrosis scores (FIB-4 and MAF-5) showed significant positive correlations with the Thai CV risk score (all $p < 0.001$). Multivariable analysis identified higher HbA1c (adjusted OR 1.54, $p = 0.019$) and reduced renal function (CKD stage ≥ 2; adjusted OR 4.10, $p < 0.001$) as independent predictors of intermediate-to-very-high Thai CV risk score. **Conclusion:** VCTE parameters (LSM and CAP) were not correlated with the Thai CV risk score in this MASLD cohort with predominantly early-stage fibrosis. However, non-invasive fibrosis scores (FIB-4 and MAF-5) were significantly correlated with Thai CV risk score. These findings suggest that VCTE alone may not adequately reflect cardiovascular risk score in early-stage fibrosis, highlighting the importance of comprehensive multimodal assessment.

2405 | HEPASCORE ALONE MATCHES A TWO-STEP FIB-4 AND FIBROSCAN ALGORITHM FOR DETECTION OF SIGNIFICANT FIBROSIS IN METABOLIC ASSOCIATED STEATOTIC LIVER DISEASE: IMPLICATIONS FOR COMMUNITY SCREENING

Dewruwan Gammanpila[1] Angus Jeffrey[2] Chloe Attree[1] Michael Wallace[2] George Garas[3] Zhengyi Wang[1] Gerry MacQuillan[2] Gary Jeffrey[2] Leon Adams[4], [1]Sir Charles Gairdner Hospital, [2]Sir Charles Gairdner Hospital, University of Western Australia, [3]University of Western Australia, Sir Charles Gairdner Hospital, [4]University of Western Australia

Background: Current guidelines recommend sequential non-invasive testing with FIB-4 followed by liver stiffness measurement (LSM) by Fibroscan to screen for significant hepatic fibrosis (F2–F4) in metabolic associated steatotic liver disease (MASLD). We compared the diagnostic accuracy of Hepascore, a composite serum biomarker for hepatic fibrosis, against FIB-4 combined with Fibroscan for identifying significant fibrosis on liver biopsy. **Methods:** A retrospective analysis of 101 patients with biopsy-proven

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

MASLD using NASH CRN fibrosis staging as the reference standard was performed. Four triage pathways were compared: Pathway A (FIB4 ≥1.3 → LSM ≥8 kPa; guideline-recommended), Pathway B (Hepascore >0.6 → LSM ≥8 kPa), Pathway C (Hepascore >0.5 → LSM ≥8 kPa), and Pathway D (Hepascore >0.5 alone). AUROC of FIB-4, Hepascore and LSM for F2–F4 fibrosis prediction were compared by DeLong's method. The diagnostic performance of each pathway was compared with referral rates compared using McNemar's test. **Results:** The cohort had a mean age 53 ± 12 years, 60% were female with a mean BMI of 37 ± 8 kg/m². Significant fibrosis (F2–F4) was present in 45.5% (46/101). All three markers demonstrated equivalent discriminative ability: AUROC 0.804 (95% CI 0.718–0.891) for Hepascore, 0.793 (0.705–0.880) for LSM, and 0.788 (0.701–0.874) for FIB4 (all comparisons p > 0.05). Despite equivalent AUROCs, all Hepascore pathways demonstrated lower false positive rates (6–11% vs 16%) and higher PPV (82–86% vs 76%) than Pathway A. Pathways B and C required fewer Fibroscans than Pathway A (21 and 28 vs 38; p = 0.001 and p = 0.04), though with lower sensitivity (39–52% vs 63%). Pathway D referred an equivalent number as Pathway A (34 vs 38; p = 0.46) with superior specificity (89% vs 84%), higher PPV (82% vs 76%), lower false positive rate (11% vs 16%), and similar sensitivity (61% vs 63%) without requiring Fibroscan (**Table 1)** . **Conclusion:** Hepascore, FIB-4, and LSM demonstrated equivalent overall discriminative ability by AUROC, however Hepascore >0.5 alone showed similar diagnostic performance to the two-step FIB-4 and Fibroscan algorithm with slightly better predictive ability and no Fibroscan requirement. Hepascore based screening may reduce community Fibroscan demand and identify MASLD patients with significant fibrosis requiring treatment where Fibroscan is not available.

Table 1 — Diagnostic performance of referral pathways for significant fibrosis detection in MASLD (n = 101)

	Pathway A FIB4 ≥1.3 → LSM ≥8	Pathway B Hepascore >0.6 → LSM ≥8	Pathway C Hepascore >0.5 → LSM ≥8	Pathway D Hepascore >0.5 alone
Referral rate				
Referral rate	38 (37.6%)	21 (20.8%)	28 (27.7%)	34 (33.7%)
vs Pathway A	—	p = 0.001	p = 0.041	p = 0.465
Diagnostic performance				
Sensitivity	63.0%	39.1%	52.2%	60.9%
Specificity	83.6%	94.5%	92.7%	89.1%
Accuracy	74.3%	69%	74.3%	76%
PPV	76.3%	85.7%	85.7%	82.4%
NPV	73.0%	65.0%	69.9%	73.1%

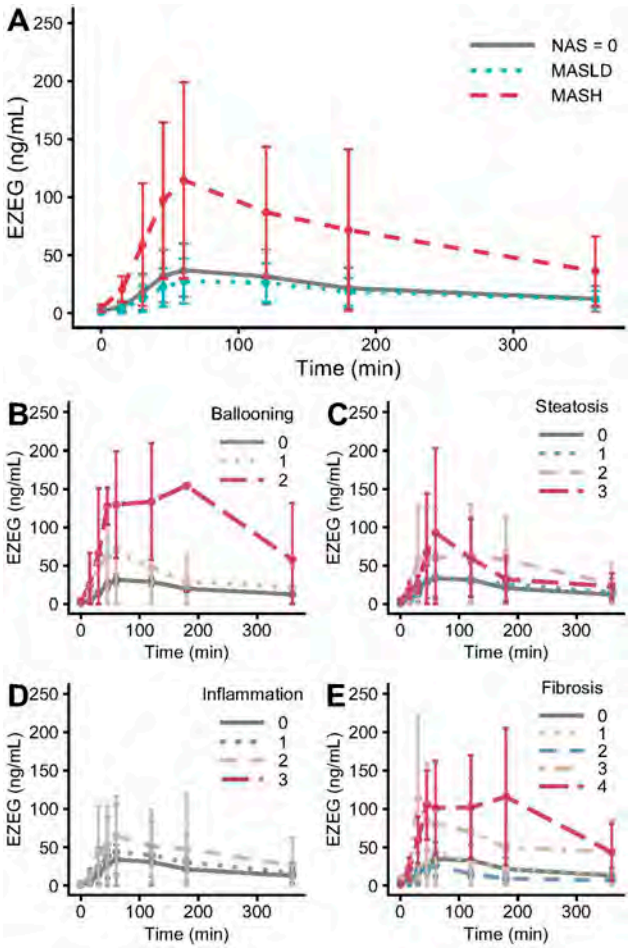
2406 | DISPOSITION OF THE EXOGENOUS BIOMARKER EZETIMIBE-GLUCURONIDE EFFECTIVELY IDENTIFIES MASH



Geoffrey Block[1] Dominique Farrera[2] Kayla Frost[2] Joseph Jilek[2] Raxton Sample[2] Jailyn Isu[2] Mina Alaaldin[2] Paige Linberg[2] Max Maloney[2] David Rodrigues[3] Emi Yamaguchi[3] Ryu Sangwoo[3] Yi-An Bi[3] Mark West[3] Sumathy Mathialagan[3] Sarah Lazzaro[3] Brooke Rabe[4] Aiden-Hung Nguyen[5] Katherine Ho[6] Susie Messenger[6] Ahmad Omid Rahimi[6] Ryan Kian Aknbari[6] Carolina Säll[7] Walter Klimecki[2] Mary Paine[5] Stephen Wright[8] Dean Billheimer[6] Iman Ghaderi[6] Nathan Cherrington[2], [1]Boyer Liver Institute, College of Medicine, University of Arizona-Tucson, [2]College of Pharmacy, University of Arizona, Tucson, AZ, [3]Pfizer Inc., Groton, CT 06340, USA, [4]BIO5 Insitute, University of Arizona, Tucson, AZ, [5]College of Pharmacy and Pharmaceutical Sciences, Washington State University, Spokane, WA 99202, [6]College of Medicine, University of Arizona, Tucson, AZ, [7]Novo Nordisk A/S, 2760 Måløv, Denmark, [8]Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease with an urgent need for reliable, noninvasive biomarkers that can serve as reasonably likely surrogate endpoints, as diagnosis remains limited by the invasiveness of liver biopsy and the limited accuracy of existing noninvasive tests. MASH disrupts hepatic and renal transporter expression and function (OATP1B1, MRP2, MRP3), leading to increased systemic retention of drug substrates. Because ezetimibe-glucuronide (EZEG) is a substrate of transporters altered in MASH, we evaluated whether EZEG could serve as a noninvasive, mechanism-based exogenous diagnostic function test. **Methods:** Subjects at risk for MASLD, with normal renal function, underwent liver biopsy to confirm SLD (N = 52) and enrolled in this hIRB-approved study. Following p.o. administration of a 1 mg subtherapeutic dose of ezetimibe (EZE), plasma and urine EZEG concentrations were quantified by LC-MS/MS. The pathology reader was blinded to EZEG results. Patients were classified as MASLD (NAFLD Activity Score [NAS] ≤3 or NAS = 4 without ballooning) or MASH (NAS ≥5 or NAS = 4 with ballooning, N = 10). **Results:** At 60 minutes post-dose, patients with MASH exhibited significantly elevated plasma EZEG concentrations relative to MASLD individuals and biopsied subjects with NAS = 0, with a geometric mean ratio of 3.44 (95% CI: 1.63–7.25, p = 0.004) (Figure, Panel A). Excluding patients with cirrhosis

(fibrosis score = 4) did not materially alter these findings. Plasma EZEG demonstrated strong diagnostic discrimination for MASH, with an area under the receiver operating characteristic curve (AUROC) of 0.82 (95% CI: 0.64–1.00). Renal clearance of EZEG did not vary significantly across NAS scores. EZEG levels by NAS component scores and fibrosis scores are shown (Figure, Panel B-E), consistent with altered EZEG levels driven by hepatocyte cytosolic dysfunction/disruption. **Conclusion:** These findings support the concept that MASH-associated transporter dysfunction leads to systemic EZEG accumulation and suggest that plasma EZEG may serve as a promising mechanism-based, noninvasive diagnostic function test for disease detection and stratification.

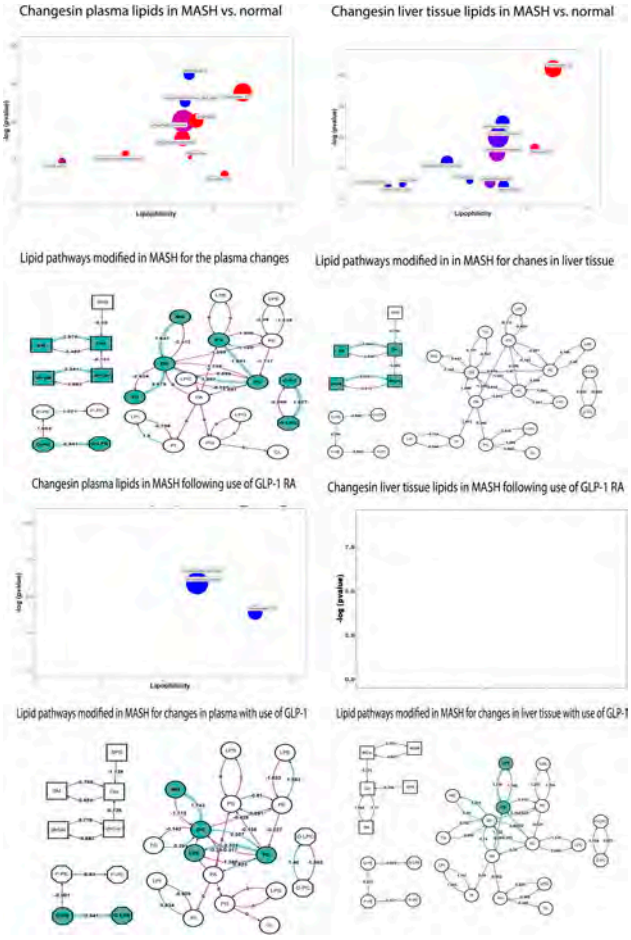
2407 | EFFECTS OF GLP-1 ON LIVER TISSUE AND PLASMA LIPIDS AMONG PATIENTS WITH MASLD



Achuthan Sourianarayanane[1] Christopher Brydges[2], [1]Medical College of Wisconsin, [2]Duke's University

Background: Glucagon-like peptide 1 (GLP-1) receptor agonists (RA) are increasingly used to manage diabetes, obesity, and metabolic dysfunction-associated steatotic liver disease (MASLD). Studies have shown that GLP-1 RA use improves plasma lipid profiles, metabolic dysfunction, and histological features of MASLD. The changes in liver tissue lipids following GLP-1 RA use in patients with MASLD are unknown. This study assesses relative changes in liver tissue lipids using GLP-1 RA. It also correlates) plasma markers in these patients. **Methods:** We collected liver tissue and plasma/serum at the time of liver biopsy for histological diagnosis and stored them at -80°C in our biobank. We performed untargeted multiomics on samples from both liver tissue and plasma, including lipid analysis. Serum from these patients was analyzed for a panel of adipokines, cardiovascular disease markers, metabolic hormones, and inflammatory markers. We had three study groups: MASLD without metabolic dysfunction-associated steatohepatitis (MASH) [n = 10], MASH (n = 17), and controls (n = 18). Nearly 50% of patients with MASLD had been on a GLP-1 RA for more than six months. **Results:** Patients with MASH, compared with controls, had increased levels of unsaturated and saturated triglycerides (TG) and reduced levels of plasmalogens in both plasma and liver tissue. Different phosphoethanolamine and phosphatidylcholine species showed increases and decreases in both compartments. Patients who used GLP-1 RA showed reductions in unsaturated TG, phosphoethanolamine, and phosphatidylcholine in plasma, but no differences were observed in liver tissue for any lipid group (as shown in the Figure). Similar differences were observed between plasma and liver tissue in lipid group changes with GLP-1 RA use among patients with MASLD without MASH (data not shown). The

lipid pathways modified in these conditions also differed. Among the three study groups, MASLD without MASH and MASH showed statistically significant reductions in serum adiponectin and sVCAM and increases in PAI-1, IL8, MCP-1, GIP, and leptin levels compared with controls. Following GLP-1 RA use in patients with MASLD, reductions in PAI-1 and increases in GIP and PP were observed, with no change in serum GLP-1 levels. (data not shown). **Conclusion:** Compared with controls, patients with MASLD and MASH have altered lipid profiles in both plasma and liver tissue. They also had changes in adipokines, cardiovascular disease markers, and metabolic hormones. GLP-1 RA alters plasma lipid profiles; however, its effects on liver tissue in MASH were not observed. The changes observed following GLP-1 RA do not appear to reverse the lipid profile seen in MASH towards the control. There were also changes in adipokines and metabolic hormones in GLP-1 RA. The beneficial histological effects observed in MASH following GLP-1 RA may result from mechanisms other than lipid improvements.

2408 | IMPROVING RECOGNITION OF LIVER DISEASE IN PRIMARY CARE RESIDENT CLINICS USING FIB-4 EDUCATION: A PRE/POST COMPARISON ACROSS TRAINING LEVELS

Husam Mikati[1] Mirjana Grocic[1] Matthew Ambrosio[2] Richard Sterling[1], [1]Virginia Commonwealth University Health System, [2]Virginia Commonwealth Univertisy

Background: Hepatitis C virus (HCV) and metabolic-dysfunction associated steatohepatitis (MASLD) are frequently under-recognized and under-managed by primary care providers (PCP). FIB-4, is a simple validated tool used to evaluate MASLD. Within our Veterans Affairs (VA) Hospital, FIB-4 is automatically calculated with routine labs, while at VCU calculation is done through a dot phrase in the electronic health record (EHR) that, however, is not included in most notes. We hypothesized that, irrespective of site of care, a brief educational intervention on FIB-4 will improve diagnostic workup and hepatology referrals. **Methods:** Resident PCP clinics were identified at VCU and the VA. Demographic, clinical and laboratory data from each EHR were extracted over a 4-week period on all eligible patients (pts) along with post-graduate year (PGY) of the trainee (1-3). Then, a single, 30-minute standardized educational session was embedded in routine resident teaching that highlighted knowledge of FIB-4, how to calculate it, how to interpret it, its limitations, and suggested follow up actions based on that. Data were collected again 4 weeks after the education session across each hospital system. Univariate and multivariate mixed-effects model analyses was used to determine the effects of the training while adjusting for covariates. **Results:** Between both sites, 1104 pts were included: 522 VA and 582 VCU. Mean age was 60, 34% female, 36% White, no HCV testing in 19%, 27% had type 2 diabetes (T2DM), 67% had hypertension (HTN), 28% had increased triglycerides (TG), and 52% were obese with differences between the clinic sites (Table). There were marked differences in documented FIB-4: 88% at the VA and 26% at VCU ($p < .001$) and highest among PGY3 (41%) and lowest PGY1 (29%). Among those with FIB-4, scores > 1.3 were observed more at the VA compared to VCU (32% vs 17%; $p < .001$). Among those with FIB-4 > 1.3, hepatology referrals were low (7.1% at the VA and 11% at VCU). After the educational session, FIB-4 documentation increased at the VA clinic while decreased at VCU with no difference by PGY level or presence of metabolic features (Figure). Overall, training did not significantly increase or decrease

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

the likelihood of FIB-4 use in those without or without metabolic features. Multivariate regression identified VA site ($p < .001$), PGY level ($p = .038$), and HCV positive test ($p = .001$) as predictors of documenting FIB-4 while age, sex, race, T2DM, HTN, and obesity were not. Among those with FIB-4 > 1.3 or HCV positive, 30% were referred to hepatology. **Conclusion:** Despite an EMR that automatically calculates FIB-4 when relevant variables are available (VA), referral to hepatology is low in those with FIB-4 > 1.3. Additionally, with the use of a dot phase (VCU), documenting FIB-4 remained low even after education on its use and importance. Therefore, additional strategies to educate PCPs on recognizing liver disease are needed.

Table 1. Composite Data Evaluating Differences Between Resident Clinic Site and Training Level.

Characteristic	Overall (N = 1,104)	VA N=522	VCU N=582	P-value
No FIB-4 done	489 (44%)	60 (12%)	429 (74%)	
FIB-4 Included	612 (56%)	461 (88%)	151 (26%)	0.081
No Hepatology Referral (FIB-4 >1.3)	359 (35%)	140 (30%)	219 (39%)	0.019
Referral not indicated (FIB-4 < 1.3, no HCV, normal ALT)	578 (56%)	291(63%)	287(51%)	0.331
Referral indicated and Ordered (FIB-4 > 1.3	95 (9.2%)	33 (7.1%)	62(11%)	<0.001
Characteristic	**Overall N=1,102**	**FIB-4 Not Included N=490**	**FIB-4 Included N=612**	**P-value**
PGY-1	307 (28%)	132 (27%)	175 (29%)	<0.001
PGY-2	400 (36%)	212 (43%)	188 (31%)	<0.001
PGY 3/4	394 (36%)	146 (30%)	248 (41%)	<0.001

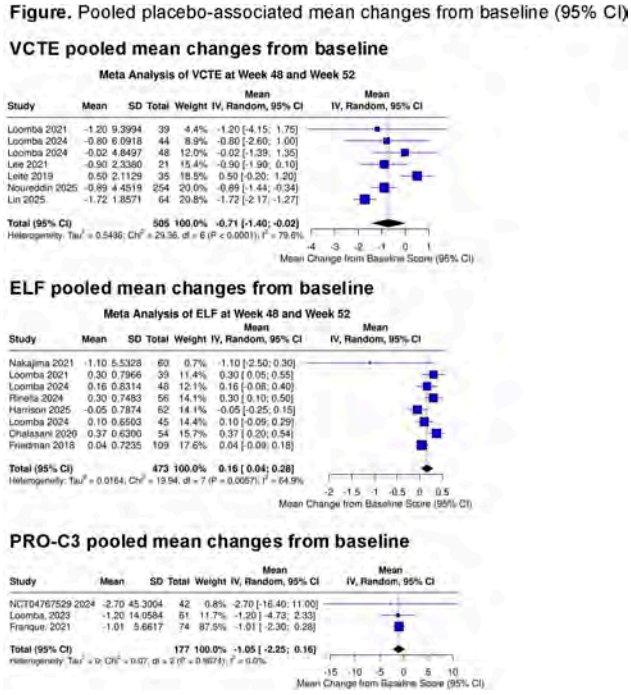
2409 | DIFFERENTIAL PLACEBO-ASSOCIATED LONGITUDINAL CHANGES IN NONINVASIVE FIBROSIS BIOMARKERS IN F2-F4 MASH: A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS

Mazen Noureddin[1] Alma Laura Ladrón de Guevara[2] Sarah Williams[3] Valentina D'Arienzo[3] Steven Levitte[4] Jorge Alfonso Ross Terres[4] KT Park[4], [1]Houston Research Institute and Houston Methodist Hospital, [2]Roma Gastroenterology Research Center, [3]F. Hoffmann-La Roche Ltd, [4]Genentech, Inc.



Background: Noninvasive biomarkers are increasingly used to assess disease activity and fibrosis progression in metabolic dysfunction–associated steatohepatitis (MASH). However, longitudinal placebo-associated changes in these biomarkers remain poorly characterized despite increasing use in endpoint assessment and treatment-effect interpretation in clinical trials. We conducted a systematic literature review and meta-analysis to evaluate placebo-associated changes in noninvasive tests, including enhanced liver fibrosis (ELF), vibration-controlled transient elastography (VCTE), N-terminal pro-peptide of type III collagen (PRO-C3) and MRI iron-corrected T1 (MRI-cT1) in randomized controlled trials in patients with F2-F4 MASH. **Methods:** A systematic search of MEDLINE, Embase, CENTRAL and ClinicalTrials.gov and AI-assisted supplementary full-text searches were conducted to identify relevant trials published within the last 10 years. Placebo-arm data for ELF, VCTE liver stiffness, PRO-C3 and MRI-cT1 were extracted from eligible studies. Random-effects meta-analyses were performed using studies reporting approximately 1-year follow-up data for changes from baseline in ELF and VCTE (48-52 weeks) and PRO-C3 (24 weeks); MRI-cT1 data were insufficient for meta-analysis. Heterogeneity was assessed by visually inspecting the forest plots, χ^2 values and I^2 statistics. **Results:** A total of 3459 records were screened; 84 records from 75 unique studies were included. Biomarker data were reported in 40 records for ELF, 37 for VCTE, 26 for PRO-C3 and 12 for MRI-cT1. A total of 15 studies were included in the meta-analyses; the majority evaluated predominantly F2-F3 populations. Meta-analysis demonstrated modest placebo-associated longitudinal changes across biomarkers. Placebo-treated patients demonstrated a pooled mean increase in ELF of 0.16 (95% CI, 0.04 to 0.28; I^2 = 64.9%; n = 473). In contrast, pooled mean changes demonstrated slight reductions in VCTE liver stiffness (−0.71; 95% CI, −1.40 to −0.02; I^2 = 79.6%; n = 505) and PRO-C3 (−1.05; 95% CI, −2.25 to 0.16; I^2 = 0; n = 177). Biomarker-specific differences in directionality and heterogeneity were observed across modalities. **Conclusion:** Placebo-

associated longitudinal changes in noninvasive fibrosis biomarkers in F2-F4 MASH trials were generally modest over approximately 1 year. ELF demonstrated a small but consistent increase over time, whereas VCTE and PRO-C3 showed reduced placebo-associated biomarker values. These findings consider the specific characteristics of this patient cohort and help contextualize the limited scope of the changes recorded. These findings also provide important context for interpretation of biomarker endpoints in MASH clinical trials. Understanding biomarker variability and placebo dynamics may help inform endpoint interpretation and future MASH trial design.

Figure. Pooled placebo-associated mean changes from baseline (95% CI)

2410 | OPTIMIZING ELASTOGRAPHY REFERRAL IN MASLD SCREENING USING ROUTINELY AVAILABLE HEALTH CHECK-UP DATA

Jung Pyo Hong[1] Jaehong Jeong[2] Dong Yun Kim[2] Jae Seung Lee[2] Mi Na Kim[2] Beom Kyung Kim[2] Jeong Eun Song[3] Hyun Chin Cho[1] Jun Yong Park[2] Do Young Kim[2] Sang Hoon Ahn[2] Hye Won Lee[2] Seung Up Kim[2], [1]Gyeongsang National University College of Medicine, [2]Yonsei University College of Medicine, [3]Daegu Catholic University School of Medicine

Background: Liver fibrosis stage determines the risk of liver-related mortality in metabolic dysfunction-associated steatotic liver disease (MASLD). We developed and validated a machine learning-based triage algorithm using health check-up data to identify patients with MASLD warranting specialized vibration-controlled transient elastography (VCTE) referral. **Methods:** We retrospectively analyzed 4,212 patients with MASLD from a health check-up cohort (2012–2020). The prevalence of significant (liver stiffness [LS] > 7.0 kPa) and advanced fibrosis (LS ≥ 8.0 kPa) was 2.6% and 1.4%, respectively. We trained a Balanced Random Forest model using 24 anthropometric and laboratory variables. The cohort was partitioned into training (70%, n = 2,948), internal testing (20%, n = 842), and independent validation (10%, n = 422) sets. **Results:** In the independent validation cohort, the Balanced Random Forest model achieved an area under the receiver operating characteristic curve (AUROC) of 0.658 (95% confidence interval [CI], 0.599–0.717, P = 0.037) for predicting significant fibrosis (sensitivity 63.6%, specificity 85.9%, and negative predictive value [NPV] of 98.9%) and 0.709 (95% CI, 0.650–0.768, P = 0.040) for predicting advanced fibrosis (sensitivity 66.7%, specificity 82.5%, and NPV 99.4%), respectively. SHAP analysis further identified body mass index, gamma-glutamyl transferase, platelet count, and waist circumference as the primary predictive features. Decision curve analysis demonstrated a higher clinical net benefit than the FIB-4 index across clinically relevant threshold probabilities. **Conclusion:** A machine learning model trained on health check-up data provides an effective zero-cost triage step for identifying patients with MASLD at high risk for significant and advanced fibrosis, optimizing referral decisions in low-prevalence screening settings.

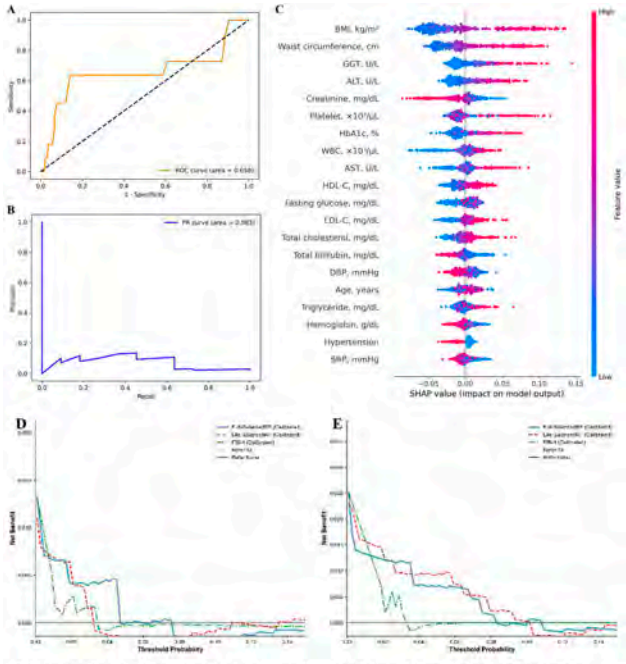

Figure 1. Predictive performance, feature interpretability, and clinical utility of the Balanced Random Forest m odel in the validation cohort (n=422). **(A)** ROC curve and **(B)** precision-recall curve for significant fibrosis (liv er stiffness >7.0 kPa). **(C)** SHAP summary plot showing the magnitude and direction of each feature's contribut ion to the model output; red indicates high feature values and blue indicates low values. **(D, E)** Decision curve analysis comparing the full (24-feature) and parsimonious (8-feature) Balanced Random Forest models with the FIB-4 index for predicting **(D)** significant and **(E)** advanced fibrosis (liver stiffness ≥8.0 kPa). ★ 2411 | SERUM AND HEPATIC LIPIDOMICS ANALYSES IN PATIENTS WITH MASLD IDENTIFY GLYCEROL TRIPALMITATE AS A BIOMARKER ELEVATED IN MASH

Misa Norita[1] Mako Eguchi[1] Takuya Kuwashiro[1] Hirokazu Takahashi[1], [1]Saga university hospital

Background: The prevalence of metabolic dysfunction–associated steatotic liver disease (MASLD) has been rising in parallel with obesity. Approximately 10–20% of patients with MASLD progress to metabolic dysfunction–associated steatohepatitis (MASH), which has a higher risk of fibrosis. The primary pathophysiology of MASLD involves the accumulation of triglycerides (TGs) in the liver due to excessive lipid intake. Although noninvasive biomarkers have increasingly been explored for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

predicting MASH without liver biopsy, reliable diagnostic approaches remain insufficiently established. Moreover, the lipid species that accumulate in the liver or are detectable in the circulation in MASH have not been fully characterized. This study aimed to identify serum lipid biomarkers capable of differentiating MASL from MASH. **Methods:** We performed liver and serum LC-MS-based lipidomics analyses in patients with biopsy-confirmed MASL (n = 39) and MASH (n = 38), with the latter defined by the presence of ballooning and inflammation. Healthy controls without liver disease (n = 50) underwent serum analysis only. Correlation of glycerol tripalmitate, TG (16: 0/16: 0/16: 0) with clinical parameters were tested. ROC analysis was performed for assessing the accuracy of predicting MASL and MASH. **Results:** A total of 101 and 90 lipid species were detected in liver tissue and serum, respectively, with 89 TGs identified in both. TGs exhibiting positive correlations between liver and serum levels were enriched with those containing C16: 0 (palmitic acid). Notably, TG (16: 0/16: 0/16: 0), glycerol tripalmitate, showed a strong positive correlation between liver and serum concentrations ($\rho = 0.70$). TG (16: 0/16: 0/16: 0) was significantly elevated in MASH compared with MASL in both liver (1.148 vs. 0.6011, $p < 0.001$) and serum (4.577 vs. 2.374, $p = 0.009$). Serum TG (16: 0/16: 0/16: 0) levels significantly correlated with AST, ALT, body weight, triglyceride, HbA1c, HDL cholesterol, HOMA-IR, and FIB-4 index. A predictive model combining serum TG (16: 0/16: 0/16: 0) and AST yielded an AUC of 0.8441 in ROC analysis. **Conclusion:** Serum TG (16: 0/16: 0/16: 0) correlated with its liver levels, significantly increased in MASH, and was associated with metabolic parameters of insulin resistance. This lipid species may serve as a promising non-invasive biomarker for distinguishing MASH from MASL, reflecting key pathological features of MASLD.

Background: The aim of this study was to evaluate the clinical utility and predictive capacity of a panel of soluble, tissue and genetic biomarkers in relation to histological severity in a cohort of MASLD patients. **Methods:** A total of 229 patients with biopsy-proven MASLD were included as part of the UNMASK Project (EPPERMED2024-496). Serum levels of ICAM1, vWF, CK-18, FGF21 and NRF2 were quantified by ELISA. Activation and nuclear translocation of phosphorylated NRF2 (pNRF2) in liver tissue were analyzed by immunohistochemistry (IHC). Genotyping of SNPs located in the *PNPLA3* (rs738409), *IL28B* (rs8099917), *FGF21* (rs838133), CPS1 (rs1047891) and *TLR9* (rs5743836) genes was performed by PCR. **Results:** Regarding serum biomarkers, ICAM1 levels showed a significant positive correlation with NAS Score ($r = 0.429$; $p < 0.0001$) and fibrosis stage ($r = 0.376$; $p < 0.0001$), with significantly higher concentrations in patients with MASH compared to those with simple steatosis (468.8 ± 230.3 *vs.* 362 ± 107.4 ng/mL; $p < 0.0001$) and significant fibrosis patients (515.9 ± 263.2 vs. 384.2 ± 132.6 ng/mL; $p < 0.0001$). Likewise, FGF21 was found to be increased in MASH vs. steatosis (552.1 ± 442,9 vs. 374.9 ± 341.9 pg/mL; $p = 0.008$). Finally, both vWF and FGF21 levels were further found to be increased in significant fibrosis ($\geq$ F2) (vWF: 1905.6 ± 937.8 *vs.* 2317.1 ± 788.5 mIU/mL; $p = 0.004$ and FGF21 420.1 ± 370.3 *vs.* 562.7 ± 457.3 pg/mL; $p = 0.040$). CK-18 and NRF2 levels did not reach statistical significance. Quantification of hepatic pNRF2 revealed a

significant increase in patients with advanced fibrosis compared with those with mild fibrosis (F3–F4: 90.1 ± 9.03 vs. F0–F2: 65.7 ± 15.9 positive cells; p = 0.025). As previously reported, GG genotype of *PNPLA3* was associated with a more aggressive phenotype characterized by higher rates of steatosis (p = 0.001), inflammation (p = 0.011), hepatocellular ballooning (p = 0.021), MASH (p = 0.001), and liver fibrosis (p = 0.008). Furthermore, the T allele of *IL28B* was significantly associated with a higher prevalence of MASH (p = 0.015), while the AA genotype of *FGF21* was associated with a higher proportion of hepatocellular ballooning (p = 0.005). After multivariate analyses, ICAM1 remained as an independent predictor of both MASH (OR = 1.005 [CI 95% 1.001-1.009]; p = 0.007) and significant fibrosis (OR = 1.007 [CI 95% 1.004-1.010]; p < 0.0001). Finally, the combined model based on ICAM1 levels and age demonstrated the best non-invasive diagnostic performance for predicting significant liver fibrosis, achieving an AUROC of 0.78 (CI95% 0.69-0.86; p < 0.0001). **Conclusion:** The integration of soluble biomarkers such as FGF21 enables the effective prediction of histological severity in MASLD. In particular, a combined model based on age and circulating ICAM1 levels appears to be a promising non-invasive strategy for assessing the risk of significant liver fibrosis. Acknowledgments: UNMASK EPPERMED CÓDIGO AND ISCIII PI24/02008.

2413 | AUTOMATED AI-BASED QUANTITATIVE FIBROSIS STAGING TO SUPPORT IDENTIFICATION OF MASH PATIENTS ELIGIBLE FOR APPROVED THERAPIES

Yukti Choudhury[1] Daniel Tan[1] Serene Lek[1] Desiree Abdurrachim[2] Asad Abu Bakar Ali[2] Naim Alkhouri[3], [1]HistoIndex Pte Ltd, [2]MSD, Singapore, [3]Summit Clinical Research

Background: Approved pharmacotherapies are available for the treatment of adults with metabolic dysfunction-associated steatohepatitis (MASH) and F2–F3 fibrosis. However, selection algorithms based on non-invasive tests (NITs) often fail to accurately identify the treatment-eligible population defined by histological criteria, and these NIT-based criteria identify a large target population, placing a financial burden on the healthcare system. This may be alleviated by direct liver biopsy evaluation in select cases. This study aimed to evaluate FibroSIGHT™ Plus, a fully automated artificial intelligence (AI)-based fibrosis scoring tool for MASH liver biopsies, and compared its performance to fibrosis staging using standard methods by community pathologists. **Methods:** A total of 75 MASH liver biopsies from a retrospective cohort from Mount Sinai were selected across a range of fibrosis stages (F0-F4) and their Masson's trichrome stained images were reviewed by three expert hepatopathologists. The median score for each biopsy was used to assign a reference NASH-CRN fibrosis stage as ground truth. Three community pathologists also reviewed the same images and assigned fibrosis stages to each case. An adjacent unstained section from each of the biopsies underwent second harmonic generation (SHG) imaging and analysis with FibroSIGHT™ Plus to generate continuous qFibrosis® scores and qFibrosis® stage assignments. Concordance of community pathologists' staging and qFibrosis® staging with the reference stages was assessed. **Results:** Among pathologists, inter-reader agreement differed by experience – exact stage agreement by all three experts across 75 cases was observed in 65.33% of cases vs. only 26.67% for three community pathologists. qFibrosis® continuous scores correlated well with reference stage (Spearman's r = 0.84, p < 0.001). Overall, qFibrosis® stage was concordant with reference stage in 58.67% of cases, whereas the average concordance of community pathologists staging compared to reference stage was 53.33% ± 3.52. In F2/F3 (treatment-eligible) cases (n = 38), qFibrosis® stage concordance exceeded community pathologists (60.53% vs. 51.75% ± 3.04%). **Conclusion:** The automated fibrosis assessment tool, FibroSIGHT™ Plus, had higher concordance with expert-assigned reference fibrosis staging than community pathologists, particularly in the treatment-eligible population. FibroSIGHT™ Plus may serve as a decision-support tool to provide more consistent fibrosis staging for treatment selection, particularly in resource-constrained settings with large MASH populations.

2414 | DEVELOPMENT AND VALIDATION OF A NON-INVASIVE SCORE FOR SEVERE MASH BASED ON ROUTINE SEROLOGICAL MAKERS: THE SEVERE METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS SCORE (SMASH)

Miaoyang Chen[1] Shasha Li[2] Jialuo Wang[1] Hongli Liu[1] Yongfeng Yang[1], [1]The Second Hospital of Nanjing, [2]Nanjing University

Background: Early diagnosis of severe metabolic dysfunction-associated steatohepatitis (MASH) patients deserves high priority, given their increased disease progression risk. We developed and validated a non-invasive score to identify severe MASH. **Methods:** Liver biopsy-proven metabolic dysfunction-associated steatotic liver disease (MASLD) patients were randomly allocated to the training and validation set at a 7: 3 ratio. We utilized the least absolute shrinkage and selection operator and multivariate logistic regression to selected variables and construct a model, termed the SMASH (severe metabolic dysfunction-associated steatohepatitis) score. SHapley Additive exPlanations was employed to measure feature importance. Finally, a nomogram was adopted to visualize the model. The performance of the SMASH score was assessed by area under curve (AUC), calibration curve, and decision curve analysis. Also, we further compared the SMASH score with fibrosis-4 (FIB-4), FibroScan-aspartate aminotransferase (FAST) and aspartate aminotransferase-alanine aminotransferase ratio (AAR). **Results:** The age, overweight, hyperuricemia, platelet, aspartate aminotransferase, gamma-glutamyl transferase, and phosphorus were independent predictors of severe MASH. The diagnostic performance of the SMASH score demonstrated an AUC, sensitivity, specificity, and positive and negative predictive values of 0.840, 0.812, 0.709, 0.876, and 0.598 in the training set, and 0.781, 0.714, 0.750, 0.879, and 0.508 in the validation set. Compared to FIB-4 and AAR, the SMASH score exhibited a superior performance. Compared to FAST, the SMASH score showed comparable diagnostic efficacy but fewer patients with indeterminate scores. **Conclusion:** This non-invasive SMASH score has an excellent performance in severe MASH identification and enables risk stratification and timely intervention among MASLD patients.

2415 | EVALUATING THE IMPACT OF NIS2+® ON REFERRALS OF PATIENTS WITH AT-RISK MASH

Amreen Dinani[1] Chukwuemeka Oko[2] Mark Miller[3] Victor Llanes[3] Margery Connelly[4] Kendrick Basso[4] Kristi Cohn[5] Andrea Econome[5] Kristen Shea[5] Meena Bansal[6], [1]Duke University School of Medicine, [2]Duke University Hospital, [3]Icahn School of Medicine at Mount Sinai, [4]Labcorp, [5]MASHNET, [6]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) poses a global threat, with at least 38% of the global adult population impacted. Diabetes has been identified as an at-risk population for MASLD, fibrotic metabolic dysfunction-associated steatohepatitis (MASH) and progressive disease. The performance of noninvasive liver disease assessments (NILDAs), such as FIB-4, is sub-optimal in patients with diabetes and ages 65 years and older. NIS2+® is a serum-based non-invasive diagnostic to detect patients with at-risk MASH, or patients with a MASLD Activity Score (MAS) ≥ 4 and at least stage 2 fibrosis ($\geq$ F2 fibrosis). The aim of this study is to assess the accuracy of NIS2+® as a first-line test to risk stratify individuals with metabolic risk factors (e.g., diabetes) for fibrotic MASH. **Methods:** A prospective study is underway to evaluate the impact of NIS2+® on referrals for at-risk MASH patients to hepatology at two tertiary care clinics. Patients meeting enrollment criteria, defined as patients ≥ 18 years with metabolic risk factors (e.g., diabetes), are randomly assigned to two cohorts:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Cohort 1 receives standard of care only (NIS2+® results blinded), and Cohort 2 receives standard of care with NIS2+® results communicated to the endocrinologists overseeing patients' care. **Results:** To date, 268 patients with metabolic risk factors have been enrolled in the study; 46.3% (124) were assigned to cohort 1 (blinded), and 53.7% (144) were assigned to cohort 2 (non-blinded). 61.9% (166) were female, 37.3% (100) were male, 0.7% (2) were MtF; 44.0% (118) patients self-reported as White, 41.0% (110) Black, 6.7% (18) Asian, and 8.2% (22) did not disclose their race. 10.1% (27) were Hispanic or Latino. 74.3% (199) of enrolled patients were living with diabetes, and 31.0% (83) of enrolled patients were <35 years or ≥ 65 years. 55.6% (149) of enrolled patients had FIB-4s that were low risk (<1.3), 23.5% (63) were intermediate risk (1.3 – 2.66 if <65, 2.0 – 2.66 if ≥ 65), 3.7% (10) were high risk (≥ 2.67 if <65, ≥ 2.0 if ≥ 65), and 17.2% (46) had no data. 45.1% (121) of patients with NIS2+® scores were low risk (<0.46), 12.7% (34) were intermediate risk (0.46 – 0.67), and 8.6% (23) were high risk (≥ 0.68). Of those with available referral data (166), patients in cohort 2 (non-blinded) were 3.5 times more likely to be referred to hepatology than those in cohort 1 (blinded), and 5 patients with a low FIB-4 score and high-risk NIS2+ score were referred (80% of which were from cohort 2). **Conclusion:** While early data suggests NIS2+® is effective at improving referrals for patients with at-risk MASH, additional data is needed to demonstrate trends across a larger study population.

Referrals by Cohort

Cohort 1 (Blinded)	Referred = Yes (6)		Referred = No (82)	
	n	% Total with Referral Data (166)	n	% Total with Referral Data (166)
Low Risk (NIS2+ < 0.46)	2	1.2%	48	28.9%

2416 | METABOLIC ASSOCIATION BETWEEN TRIGLYCERIDE-TO-HIGH-DENSITY LIPOPROTEIN CHOLESTEROL RATIO AND FATTY LIVER DISEASE AND LIVER FIBROSIS IN PARTICIPANTS FROM AN OBSERVATIONAL STUDY

Amin Yarahmadi[1] Ulrike Lorch[1] Jorg Taubel[1] Edward Jackson[1] James Rickard[2], [1]Richmond Pharmacology, [2]Richmond Research Institute

Background: The triglyceride-to-high-density lipoprotein cholesterol (TG/HDL-C) ratio has emerged as a potential marker of metabolic dysfunction and cardiovascular risk. This study investigated the association between TG/HDL-C ratio, metabolic dysfunction-associated steatotic liver disease (MASLD), and liver fibrosis in participants enrolled in study (NCT04873258). **Methods:** This cross-sectional study included 1,544 participants from the observational study. Demographic, laboratory, and transient elastography data were analysed to evaluate the triglyceride-to-high-density lipoprotein cholesterol (TG/HDL-C) ratio as a potential risk factor for metabolic dysfunction-associated steatotic liver disease (MASLD). TG/HDL-C ratio was calculated from serum triglyceride and HDL cholesterol levels. MASLD was defined as controlled attenuation parameter (CAP) ≥ 274 dB/m, and significant liver fibrosis as liver stiffness measurement (LSM) ≥ 8.2 kPa. Participants were stratified by TG/HDL-C quartiles. Associations with MASLD and liver fibrosis were assessed using multivariable logistic regression adjusted for age, sex, and ethnicity. Nonlinear relationships were evaluated using restricted cubic spline models. **Results:** Higher TG/HDL-C ratios were positively associated with increased prevalence of MASLD. After adjustment for potential confounding clinical variables, participants in the highest TG/HDL-C quartile had significantly greater odds of MASLD compared with those in the lowest quartile (OR 13.1, 95% CI 7.59–22.4; $p < 0.001$). A nonlinear relationship between TG/HDL-C ratio and MASLD was identified using smoothed curve fitting models. In contrast, although an initial association between TG/HDL-C ratio and liver fibrosis was observed, this relationship was not statistically significant after adjustment for confounders ($p = 0.025$), and no nonlinear association was identified. These findings are consistent with the existing literature and support the homogeneity and external validity of participant recruitment within this observational cohort. **Conclusion:** Elevated TG/HDL-C ratio was strongly associated with MASLD prevalence in this cohort and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

may represent a useful non-invasive biomarker for identifying individuals at increased risk of MASLD. These findings are consistent with the existing literature and support the homogeneity and external validity of participant recruitment within this observational cohort. Future analyses will incorporate additional established risk factors, including smoking status and educational attainment, to further refine risk prediction models.

2417 | METABOLOMIC AND LIPIDOMIC SIGNATURES OF STEATOTIC LIVER DISEASE IN PREGNANCY FROM THE PROSPECTIVE FATTY LIVER IN PREGNANCY COHORT

Himel Mallick[1] Cecilia Katzenstein[2] Amy Deik[3] Nina Rodriguez[2] Jeanette Rios[2] Rhoda Sperling[2] Norah Terrault[4] Lauren Alpert[2] Baran Ersoy[5] Keith Sigel[2] Tatyana Kushner[5], [1]Cornell University, [2]Icahn School of Medicine at Mount Sinai, [3]Broad Institute, [4]University of Southern California, [5]Weill Cornell Medicine

Background: The prevalence of steatotic liver disease (SLD) in pregnancy has tripled over the past decade and is associated with adverse pregnancy outcomes. In non-pregnant populations, SLD is characterized by circulating lipid signatures including elevated triacylglycerols, diacylglycerols, sphingolipids, and sterols as well as phosphatidylethanolamine remodeling. We aimed to characterize circulating metabolomic and lipidomic signatures associated with SLD and identify pregnancy-specific SLD signatures. **Methods:** The Fatty Liver in Pregnancy (FLIP) cohort is a prospective cohort in which pregnant patients were evaluated for SLD using ultrasound and transient elastography. Hybrid nontargeted metabolomic profiling was performed in a subcohort using four LC-MS platforms that combined complementary chromatography modalities with either positive or negative ion mode MS: C8-pos, C18-neg, HILIC-pos, and HILIC-neg. The combined analyses yielded profiles of 1,136 identified plasma metabolites and lipids. Associations between SLD and metabolites were assessed using multivariable linear models with BMI adjustment. Log fold changes (LFCs) were evaluated and P-values were FDR-adjusted. **Results:** Among 154 participants, 35 (22.7%) had SLD. Participants were predominantly Hispanic/Latina (56%) and Medicaid-insured (86%), with median age 29 years (IQR, 25-33) and pre-pregnancy BMI 29.3 kg/m² (IQR, 26.5-33.2); 90% had BMI $\geq$25 kg/m². Across 1,136 measured metabolite features, 165 (14.5%) differed between SLD and non-SLD participants (n = 119) after BMI adjustment at FDR-adjusted P < 0.05, with 149 elevated and 18 reduced metabolites, establishing a largely BMI-independent signature. Differences were dominated by elevations in triacylglycerols (n = 74; e.g., TG 38: 2 LFC = 1.76; TG 40: 3 LFC = 1.74) and diacylglycerols (n = 20; e.g., DG 32: 2 LFC = 1.29). Phosphatidylethanolamines (n = 20), phosphatidylcholines (n = 14), ceramides (n = 6), and lysophosphatidylethanolamines (n = 4) were also elevated. In contrast, medium- and long-chain acylcarnitines (n = 13; e.g., CAR 14: 3 LFC = -1.02; CAR 16: 4 LFC = -0.76) and polyunsaturated cholesterol esters (n = 3; e.g., CE 22: 4 LFC = -0.73; CE 19: 4 LFC = -0.66) were reduced, differing from non-pregnancy MASLD, where cholesterol esters are typically elevated (**Fig. 1**). **Conclusion:** SLD in pregnancy exhibits a robust, BMI-independent plasma lipidomic signature characterized by elevated triacylglycerols, diacylglycerols, phosphatidylethanolamines, and ceramides, largely concordant with non-pregnancy MASLD, but with pregnancy-specific reductions in acylcarnitines and polyunsaturated cholesterol esters that may reflect altered β-oxidation and PUFA flux during gestation. These findings support circulating metabolite profiling as a tractable approach for identifying and characterizing SLD in pregnancy and suggest potential mechanisms linking SLD to adverse pregnancy outcomes.

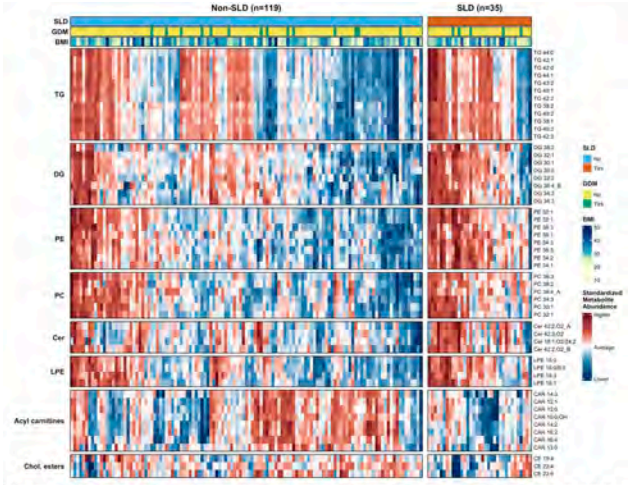

Figure 1. Heatmap of 53 plasma lipid species differentially abundant between pregnant individuals with (n=35) and without (n=119) SLD, selected from 165 features significant after BMI adjustment (MaAsLin2, FDR-adjusted P <0.05; 149 elevated, 18 reduced). Rows are clustered within lipid subclass; columns within SLD group. Cell color reflects standardized metabolite abundance (red, higher; blue, lower). Triacylglycerols, diacylglycerols, phosphatidylethanolamines, phosphatidylcholines, ceramides, and lysophosphatidylethanolamines were uniformly elevated in SLD; acylcarnitines and polyunsaturated cholesterol esters were reduced.

2418 | GAPS IN LABORATORY TESTING FOR FIB-4 SCREENING AMONG HIGH-RISK PATIENTS IN RESIDENCY-AFFILIATED PRIMARY CARE CLINIC

Alex Chang[1] Kimberly Ho[1] Julio Blasco Jimenez[1] Alex Friefeld[1] Timothy Greenfield[1] Paige McLean Diaz[2] Rebekah Gardner[1], [1]Brown University, [2]Brown Medicine/Brown University Health

Background: The primary care setting is an important site for screening for metabolic dysfunction-associated steatotic liver disease (MASLD). The most recent American Diabetes Association (ADA) guidelines now recommend FIB-4 screening every 1-2 years for patients with risk factors for MASLD, including prediabetes, diabetes, and obesity. However, uptake of the FIB-4 score for MASLD screening in primary care practice remains unclear. We undertook a quality-improvement initiative at an internal medicine residency-affiliated primary care clinic to improve FIB-4 screening rates. This study characterizes the eligible patient population and identifiespatient characteristics associated with the absence of laboratory testing needed for FIB-4-based screening. **Methods:** Among the 8,453 patients seen in the past year at the primary care clinic, 5,469 had a diagnosis of prediabetes, diabetes, or obesity and thus were identified as eligible for FIB-4 screening. Among those eligible patients, we looked to see if they had an AST, ALT, and platelet count, which are needed to calculate a FIB-4, drawn during their time in the clinic. We also collected data on patient characteristics including age, sex, BMI, race, insurance type, most recent A1c, and presence of diabetes or obesity. We compared categorical variables using Chi-square and continuous variables using t-tests (GraphPad Software). **Results:** Among the clinic patients eligible for FIB-4 screening, the mean age was 52.8, more than half were male (53.1%), the mean BMI was 33, and most had some form of insurance (87.8%). Most eligible patients had an AST, ALT, and platelet count completed (88.3%). Patients who had completed screening labs had an older mean age than those did not have labs completed (54.2 years old vs

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

42.6 years old, p < 0.01) and had a higher mean A1C (6.59 vs 5.96, p < 0.01) (Table 1). Higher proportions of patients who had completed screening labs had a diagnosis of diabetes compared with those who did not have labs completed(27.7% vs 8.9%, p < 0.01). **Conclusion:** The first step to screening high-risk patients for MASLD is to draw the labs needed to calculate a FIB-4. In our clinic, more than one in ten high-risk patients did not have an AST, ALT, and platelet count on file. The current study suggests that primary care patients who appear healthier (i.e., younger, well-controlled diabetes) may be a population at risk of being overlooked for MASLD screening despite meeting recommendations. We plan to use these findings to implement quality improvement initiatives aimed at clinician education on MASLD risk factors and at increasing uptake of screening guidelines.

Table 1 Patient Characteristics Associated with FIB-4 Screening Completion

	Screening Completed (n = 4830)	Screening Incomplete (n = 639)	P-value
Age	54.2 (16.1)	42.6 (14.8)	**<0.01**

2419 | URIC ACID-TO-HIGH-DENSITY LIPOPROTEIN CHOLESTEROL RATIO IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF ASSOCIATION AND DIAGNOSTIC ACCURACY

Yazan Alnairah[1] EzzElDien A. Ibrahim[2] Abdallfatah Abdallfatah[3] Mostafa Adel T. Mahmoud[4] Ahmed Kertam[5] Yasmin Aly[6] Abdelrahman A. Hashem[7] Nourhan Hatem[8] Mohamed R. Murad[9] Oshaz Fatima[10] Omar Medhat Abdelaziz Farag[11] Mustafa Gandhi[12] Islam Mohamed[12] Ashraf Almomani[12], [1]Jordanian Royal Medical Services, Amman, Jordan, [2]University of Missouri-Columbia, [3]October 6 University, [4]Beni Suef university, Beni Suef, Egypt, [5]Ain Shams University, [6]University of Arkansas for Medical Sciences, [7]Assiut University, Egypt, [8]Suez Canal University,Ismailiia , Egypt, [9]Al-Azhar University, Cairo, Egypt, [10]King Edward Medical University, Pakistan, [11]Cairo University, [12]University of Missouri, Columbia, Missouri, USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease worldwide. The uric acid-to-high-density lipoprotein cholesterol ratio (UHR) is an inexpensive metabolic-inflammatory biomarker that may reflect both hyperuricemia and impaired lipid metabolism. We evaluated the association between UHR and prevalent MASLD and assessed its diagnostic accuracy. **Methods:** We performed a systematic review and meta-analysis of observational studies assessing UHR in adults with prevalent NAFLD, MASLD, or MAFLD. For association analysis, adjusted odds ratios (ORs) comparing the highest versus lowest UHR categories were pooled using a random-effects model. Diagnostic accuracy was assessed using a bivariate model, with pooled sensitivity, specificity, likelihood ratios, diagnostic odds ratio (DOR), and hierarchical summary receiver operating characteristic (HSROC) area under the curve (AUC). **Results:** Fourteen studies involving 79,805 patients were included in the systematic review; nine studies (20,936 patients) were eligible for the association meta-analysis and eight studies contributed to the diagnostic accuracy analysis. In the categorical association analysis, individuals in the highest UHR category had significantly higher odds of prevalent MASLD compared with those in the lowest category (OR 2.33, 95% CI 1.70–3.21; $I^2 = 57.5\%$). The prediction interval included the null (0.88–6.17). In diagnostic accuracy analysis, pooled sensitivity was 0.68 (95% CI 0.63–0.74), pooled specificity was 0.61 (95% CI 0.56–0.66), and DOR was 3.40 (95% CI 3.06–3.78). The HSROC AUC was 0.69 (95% CI 0.68–0.71), indicating modest discriminative performance. Deeks' test did not suggest significant publication bias. **Conclusion:** Higher UHR is significantly associated with prevalent MASLD and may serve as a simple, low-cost marker for metabolic risk stratification. However, its standalone diagnostic accuracy is modest (AUC 0.69), suggesting that UHR should complement rather than replace established diagnostic approaches. Prospective studies using standardized UHR cutoffs are needed before routine clinical application.

2420 | CIRCULATING MICRORNAS AS DIAGNOSTIC BIOMARKERS ACROSS THE MASLD DISEASE SPECTRUM: A SYSTEMATIC REVIEW AND META-ANALYSIS

Aryan Gupta[1] Era Gupta[2] Omar Oudit[3] Priyanshi Mehulkumar Gandhi[4] Rewanth Katamreddy[5] Pius Ojemolon[6] Dushyant Singh Dahiya[7] Aakash Desai[8], [1]Bangalore Medical College and Research Institute, India, [2]Guthrie/ Robert Packer Hospital, PA, USA, [3]Brookdale University Hospital Medical Centre, NY, USA, [4]Government Medical Colege, Surat, India, [5]Guthrie/Robert Packer Hospital, PA, USA, [6]Emory University School Of Medicine, GA, USA, [7]The University Of Kansas School Of Medicine, Kansas, USA, [8]Allegheny Health Network, PA, USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) encompasses a spectrum from hepatic steatosis to metabolic dysfunction-associated steatohepatitis (MASH) and hepatocellular carcinoma (HCC). As MASLD is a leading etiology of non-viral HCC, circulating miRNAs were evaluated across the full disease spectrum. Circulating microRNAs (miRNAs), extracted from serum or plasma via liquid biopsy, have emerged as promising minimally invasive biomarkers given their role in hepatic inflammation, lipid metabolism, and fibrogenesis. We performed a systematic review and meta-analysis evaluating their diagnostic utility in MASLD, MASH, and MASLD-associated HCC. **Methods:** This review followed PRISMA guidelines. PubMed, Google Scholar, and ScienceDirect were searched for studies evaluating circulating miRNAs extracted from serum or plasma as liquid biopsy-derived biomarkers in MASLD, MASH, and HCC. Studies reporting AUC were included. Subgroup analyses were performed by disease stage (MASLD, MASH, and HCC) and by individual miRNA profile. Data were analyzed using Meta, Metadata, and Metafor packages in R Studio using a common effects model. **Results:** Twenty-two studies were included. For MASLD, miR-298 (AUC 0.98 [0.94-1.02, 95% CI]), miR-200 (AUC 0.96 [0.88-1.04, 95% CI]), and miR-342 (AUC 0.94 [0.83-1.05, 95% CI]) demonstrated the highest individual diagnostic accuracy. The best-performing panel combined changes in hepatic fat content, total cholesterol, triglycerides, miR-15b-3p, and BMI (AUC 0.89 [0.85-0.93, 95% CI]). For MASH, miR-200, miR-298, and miR-342 achieved near-perfect AUCs of 0.99 [0.97-1.01, 95% CI], while the panel of miR-21-5p, miR-151a-3p, miR-192-5p, and miR-4449 achieved AUC 0.99 [0.98-1.00, 95% CI]. For MASLD-associated HCC, miR-214 showed the highest individual AUC at 0.88 [0.66-1.100, 95% CI], while a panel of miR-34a, miR-221, miR-16, miR-23-3p, miR-122-5p, miR-198, and miR-199a-3p achieved AUC 0.99 [0.98-1.00, 95% CI]. Overall pooled AUCs were 0.86 [0.81-0.91, 95% CI] for MASLD, 0.99[0.98-1.00, 95% CI] for MASH, and 0.760 [0.64-0.88, 95% CI] for HCC. **Conclusion:** Circulating microRNAs show promising diagnostic utility in MASLD, MASH and HCC and may serve as minimally invasive biomarkers for disease detection. However, variability in profiling techniques and validation approaches limits current clinical translation. Standardized large-scale prospective studies are needed to confirm their role in routine hepatology evaluation.

2421 | PREVALENCE OF STEATOTIC LIVER DISEASE AMONG COMMUNITY-DWELLING ADULTS ASSESSED BY MAGNETIC RESONANCE IMAGING–PROTON DENSITY FAT FRACTION

Ruyu Liu[1] Kaiyue Zhao[2], [1]Xuzhou Infectious Disease Hospital, [2]Xuzhou Infectious Diseases Hospital

Background: Steatotic liver disease (SLD) is a common chronic liver condition in China. However, there is limited epidemiological data based on MRI-PDFF, the non-invasive gold standard. This study aims to assess the prevalence of SLD using MRI-PDFF and to analyze the distribution of its subtypes and associated metabolic risk factors. **Methods:** This cross-sectional study enrolled patients who underwent abdominal MRI at a tertiary hospital between March and November 2025. After applying inclusion and exclusion criteria, 1,414 patients were ultimately included. SLD was diagnosed based on MRI-PDFF $\geq$5%. According to the 2023 AASLD-EASL-ALEH consensus, SLD was subclassified into metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction and alcohol-related steatotic liver disease (MetALD), alcohol-related liver disease (ALD), and cryptogenic SLD. Demographic and metabolic data were collected. Prevalence by sex, age, and metabolic comorbidities was analyzed, and logistic regression was performed. **Results:** Among the 1,414 participants (mean age 48.9 ± 13.6 years; mean BMI 25.6 ± 3.7 kg/m²), 817 (57.8%) had SLD. Of these 817 SLD cases, MASLD accounted for 83.0%, MetALD 8.2%, ALD 7.1%, and cryptogenic SLD 1.7%. SLD prevalence was higher in men than in women (71.9% vs. 45.4%). Prevalence among individuals with metabolic syndrome, obesity, and diabetes was 86.5%, 85.8%, and 72.9%, respectively. Multivariable logistic regression showed that age (OR = 1.015, 95%CI 1.004–1.026), BMI (OR = 1.236, 95%CI 1.177–1.302), triglycerides (OR = 2.365, 95%CI 1.898–2.984), HOMA-IR (OR = 1.169, 95%CI 1.068–1.285), and GGT (OR = 1.013, 95%CI 1.006–1.022) were independent risk factors for SLD (all $P < 0.05$). **Conclusion:** Among community-dwelling

adults in this study, the MRI-PDFF-based prevalence of SLD was 57.8%, with MASLD being the predominant subtype. SLD was closely associated with metabolic abnormalities. Age, BMI, TG, HOMA-IR, and GGT were identified as independent risk factors, supporting early screening and intervention.

2422 | MULTIPARAMETRIC MRI BASED RISK MODEL HAS STRONG DIAGNOSTIC ACCURACY AT DETECTING LIVER CIRRHOSIS

Charlie Diamond[1] Michele Pansini[1] Yi-Chun Wang[1] Masato Yoneda[2] Atsushi Nakajima[2] Kento Imajo[3] Mark Muthiah[4] Dan Yock Young[4] ELEGANCE Consortium[5] Pierce Chow[6] Andrea Dennis[1], [1]Perspectum, [2]Yokohama City University School of Medicine Graduate School of Medicine, [3]Shin Yurigaoka General Hospital, [4]Yong Loo Lin School of Medicine, [5]NA, [6]Singapore General Hospital and National Cancer Centre Singapore

Background: Non-invasive assessment of liver fibrosis and cirrhosis is crucial in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). MRI-derived iron-corrected T1 (cT1) correlates with fibrosis, whilst liver fat content (LFC) correlates with steatosis and declines in advanced fibrosis. Increasing spleen volume can occur in cirrhosis, reflecting portal hypertension. Combining these metrics may improve identification of patients with cirrhosis compared to individual metrics alone. **Methods:** We combined data from 368 individuals with biopsy-confirmed MASLD, collected from 2 observational studies in Japan and Singapore (histology training cohort) and 261 individuals with clinically diagnosed MASLD from a separate study in Singapore (clinical validation cohort).In the training cohort (mean age 54 years, 55% male, mean BMI 30 kg/m²) 56 individuals (15%) had histological cirrhosis (F4). In the validation cohort (mean age 62 years, 56% male, mean BMI 26 kg/m²) 98 individuals (38%) had a clinical diagnosis of cirrhosis. All underwent standardised cT1, LFC and spleen volume (body surface area adjusted) measurements by MRI. A multivariate logistic regression model was developed in the training cohort to identify cirrhosis. The model was then applied to the validation cohort, where diagnostic accuracy for cirrhosis was assessed by area under the receiver operating characteristic curve (AUC). **Results:** In the training data, mean cT1 and spleen volume (BSA) were significantly higher in individuals with cirrhosis (889 vs. 842ms and 147 vs. 91 ml/m², both $p < 0.01$), while LFC was significantly lower (9% vs. 13%; $p < 0.001$). Used independently, cT1, LFC and spleen volume identified F4 with AUCs of 0.64, 0.69 and 0.72, respectively. The combination risk score substantially improved diagnostic accuracy for identifying F4 in the training data (AUC 0.86 [0.81-0.91]). When applied to the independent clinical validation cohort, the performance was maintained (0.83 [0.78-0.89]). **Conclusion:** Non-invasive multiparametric MRI combining of liver disease activity, liver fat and spleen volume can detect cirrhosis with excellent accuracy in MASLD and may have potential applications in enrichment or stratification of clinical trial populations.

Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [3]Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [4]King Saud University, Riyadh, Saudi Arabia, [5]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia

Background: Polysomnography is resource-intensive and rarely accessible during routine hepatology consultations. A simple anthropometric rule to identify which patients with metabolic dysfunction-associated steatotic liver disease (MASLD) merit further obstructive sleep apnea (OSA) evaluation has not been established. We aimed to evaluate body mass index (BMI) and waist circumference (WC) thresholds for identifying Berlin Questionnaire-defined high risk for OSA among adults with MASLD. **Methods:** Within the GENESIS prospective cohort, adults with MASLD (hepatic steatosis on VCTE defined by controlled attenuation parameter [CAP] $\geq$268 dB/m plus $\geq$1 of the 5 cardiometabolic risk factors per the 2023 multisociety Delphi consensus) and complete Berlin Questionnaire data were analyzed. High-risk OSA was defined per the standard Berlin Questionnaire scoring (positive in $\geq$2 of the 3 categories: (Snoring/witnessed apneas, daytime sleepiness, and hypertension/obesity risk factors). Analyses were restricted to complete cases with available BMI and WC measurements. Receiver operating characteristic (ROC) analysis assessed the discrimination of BMI and WC for high-risk OSA. The Youden index identified optimal cutoffs; area under the curve (AUC), sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were computed. Because BMI contributes to Berlin Questionnaire classification, BMI-based discrimination was interpreted as a pragmatic triage assessment rather than independent diagnostic validation. **Results:** Among 1,107 participants with MASLD (mean age 46.1 ± 13.0 years; 58.2% male), 410 (37.0%) screened as high risk for OSA. BMI discriminated high-risk OSA better than WC overall (BMI AUC, 0.675; 95% CI, 0.644–0.707 vs WC AUC, 0.646; 95% CI, 0.613–0.679). At the Youden-optimal cutoff of 30 kg/m², BMI achieved a sensitivity of 83.7%, specificity of 49.4%, PPV of 49.2%, NPV of 83.8%, and a Youden index of 0.332. The Youden-optimal WC cutoff (102.5 cm) traded sensitivity for specificity (sensitivity, 64.9%; specificity, 58.7%; PPV, 48.0%; NPV, 74.0%; Youden index, 0.236). **Conclusion:** A BMI threshold of 30 kg/m², already routinely measured in hepatology practice, identifies the majority of patients with MASLD at high risk for OSA while reliably excluding low-risk individuals. Embedding this single-variable rule into MASLD clinical workflows may enable evidence-based, scalable OSA case-finding without additional equipment or cost. Because BMI is already part of Berlin Questionnaire scoring, BMI $\geq$30 kg/m² should not be interpreted as a new diagnostic rule. Rather, it may provide a simple clinic-based trigger to prioritize MASLD patients for formal sleep evaluation, pending prospective validation with formal sleep testing.

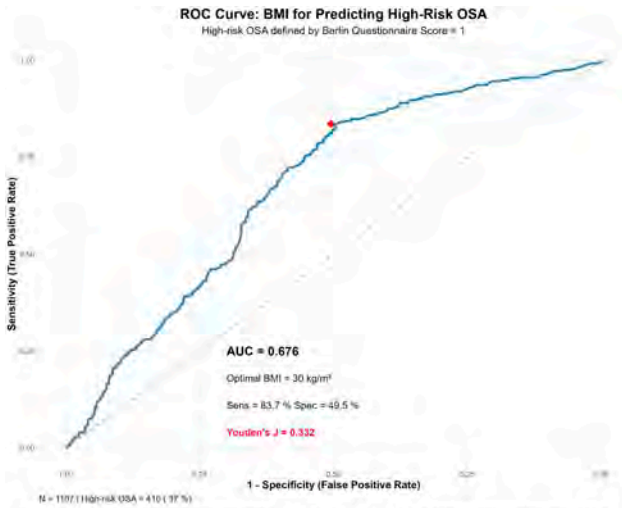

Figure 1. Receiver operating characteristic curve for body mass index predicting high-risk obstructive sleep apnea, defined per the standard Berlin Questionnaire scoring (positive in ≥2 of the 3 categories).

AUC 0.675 (95% CI 0.644–0.707). Optimal cutoff 30 kg/m²: sensitivity 83.7%, specificity 49.4%, Youden index 0.332. AUC, area under the curve; CI, confidence interval.

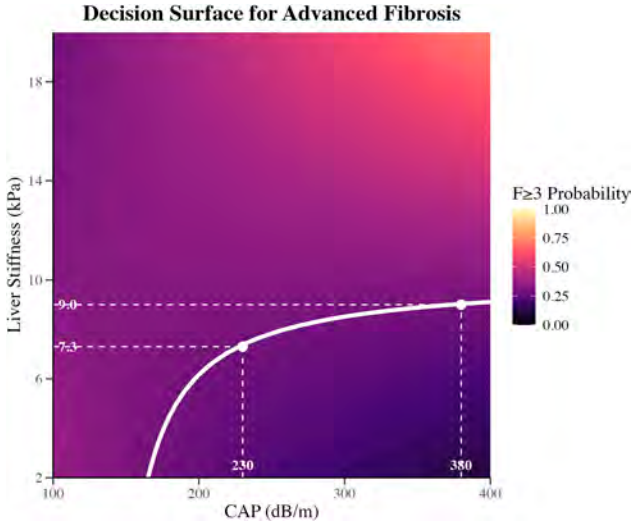
2424 | BEYOND ADDITIVE SCORES: A MULTIPLICATIVE LSM × CAP INTERACTION DEFINES AN ETIOLOGY-SPECIFIC PIVOT POINT THAT REFRAMES DIAGNOSTIC THRESHOLDS FOR ADVANCED FIBROSIS (F$\geq$3) IN THE ERA OF RESMETIROM



Lucia Parlati[1] Clemence Moreau[2] Jerome Boursier[2] Marc De Saint Loup[2] Vincent Mallet[1], [1]AP-HP.Centre Université Paris Centre, Groupe Hospitalier Cochin Port Royal, [2]Angers University Hospital

Background: The advent of targeted antifibrotic therapies (e.g., resmetirom) demands precise non-invasive identification of MASLD patients with advanced fibrosis (F$\geq$3). FibroScan-based scores currently combine liver stiffness (LSM) and controlled attenuation parameter (CAP) additively, assuming independent effects. We tested whether a multiplicative LSM×CAP interaction captures a MASLD-specific signal justifying dynamic, CAP-dependent thresholds. **Methods:** We analyzed 502

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

biopsy-referenced MASLD patients (median age 61 years, 62% male, 57% diabetic; 177 [35%] $F \geq 3$) and 151 controls (alcohol-associated, HCV, HBV). Firth-penalized logistic regression with a mean-centered LSM×CAP interaction was fitted per etiology to ensure robust estimation. The composite score was compared to FAST and AGILE4 (DeLong test) with 5-fold cross-validated AUC. **Results:** LSM was strongly elevated in $F \geq 3$ (mean 15.1 vs 8.6 kPa), whereas CAP barely differed (322 vs 317 dB/m). Centered on cohort means, LSM independently predicted $F \geq 3$ ($\beta = +1.11$, $p < 10^{-15}$); CAP alone did not ($\beta = +0.04$, $p = 0.83$). Their multiplicative interaction was highly significant ($\beta\_int = +0.57$ [95% CI: 0.27–0.94], $p = 0.0008$) and reversed in ALD ($\beta\_int = -1.39$, $p = 0.064$), establishing MASLD specificity. This interaction generates a unique pivot at LSM = 10.2 kPa, defining two phenotypes. Below this pivot, steatosis masks true fibrosis risk. Clinically, a raw 9.0 kPa reading at a CAP of 380 dB/m carries the identical biological $F \geq 3$ risk (30%) as a 7.3 kPa reading at a CAP of 230 dB/m (**Figure**). Additive scores ignore this interference, driving the massive over-staging of steatotic patients. Conversely, above the 10.2 kPa pivot, steatosis synergistically amplifies the diagnostic signal, locking in active MASH fibrogenesis. Applying this dynamic threshold achieved 76% sensitivity and 84% NPV. Cross-validated AUC was 0.80, significantly exceeding FAST (0.76; $p = 0.005$) and comparable to AGILE3+ (0.83; $p = 0.18$) AGILE4 (0.83; $p = 0.19$), without any blood test. **Conclusion:** The LSM×CAP interaction enables a blood-test-free, point-of-care diagnostic tool for MASLD. It defines two phenotypes pivoting around LSM ≍ 10.2 kPa: below, steatosis acts as a signal moderator; above, it accelerates MASH-driven fibrosis. CAP-dependent upward adjustment of LSM cut-offs prevents over-staging highly steatotic patients—directly relevant for resmetirom candidate selection. The interaction's reversal in ALD underscores a distinct biomechanical reality.

2425 | POINT-OF-CARE MR-PDFF™ DEVICE ACCURATELY STAGES HEPATIC STEATOSIS IN SLD

Muhammad Sheikh[1] Jerry Mabary[2], [1]Fresno Clinical Research Center, [2]Livivos

Background: MRI-PDFF is the reference standard for noninvasive quantification of hepatic steatosis in MASLD and MASH, but use is constrained by cost and limited access. With the approval of multiple at-risk MASH therapeutics, point-of-care PDFF-based steatosis quantification may improve disease management. The LiverScope® device (Livivos, Inc.) is a point-of-care steatosis assessment system that employs magnetic resonance proton density fat fraction (MR-PDFF™) technology. In this study, we evaluated the accuracy of LiverScope-derived MR-PDFF™ for steatosis staging, using MRI-PDFF as the reference standard. LiverScope MR-PDFF™ sensitivity and specificity for MASLD and MASH prediction were determined using published MRI-PDFF thresholds. **Methods:** Hepatic steatosis was evaluated in 36 subjects who underwent paired same-day MRI-PDFF and LiverScope-based MR-PDFF™ assessments in the fasted state. LiverScope MR-PDFF™ data were acquired by trained operators at Fresno Clinical Research Center who were blinded to MRI-PDFF results. MRI-PDFF was performed at California Imaging Center using a GE 1.5T scanner and analyzed centrally with Perspectum MultiScan to quantify hepatic PDFF. LiverScope-derived MR-PDFF™ sensitivity and specificity for MASLD and MASH were calculated using published MRI-PDFF thresholds[1] from Panagiotopoulos et al of 4.4% and 6.9%, respectively, with MRI-PDFF determined PDFF as the reference standard. **Results:** Using MRI-PDFF as the reference standard and Panagiotopoulos et al MRI-PDFF thresholds of 4.4% for MASLD and 6.9% for MASH,1 LiverScope-derived MR-PDFF™ achieved a sensitivity of 1.0 for both MASLD and MASH, and a specificity of 0.62 and 0.93, respectively (Figure 1). In this cohort, LiverScope MR-PDFF™ did not miss any MRI-PDFF–defined cases of MASLD or MASH. (Figure 1). Figure 1. MASLD-MASH Staging Prediction Accuracy using same-day MRI-PDFF reference standard and published Panagiotopoulos et al thresholds. **Conclusion:**

The LiverScope device predicted MRI-PDFF-defined MASLD, and MASH with high sensitivity using point-of-care MR-PDFF™ technology. These findings support a potential future role for point-of-care MR-PDFF™ in MASLD and MASH disease management, pending validation in larger, multisite studies. 1. Proton Density Fat Fraction for Diagnosis of MASLD; Panagiotopoulos et al; Hepatology. 2026;83: 127–141. Caution: LiverScope is an investigational device limited by federal law to investigational use.

		MR-PDFF™ Staging Performance	
Steatosis Stage	MRI-PDFF Cut-Off[1]	Sensitivity	Specificity
MASLD	≥ 4.4%	1.0	0.62
MASH	≥ 6.9%	1.0	0.93

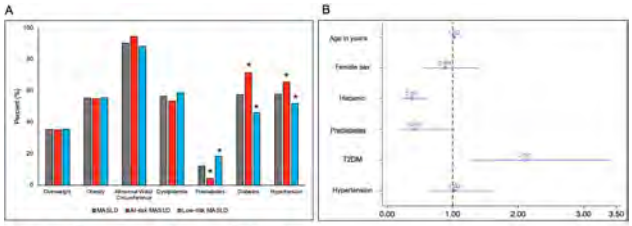
2426 | CARDIOMETABOLIC RISK FACTORS ASSOCIATED WITH AT-RISK MASLD: A MULTI-CENTER PROSPECTIVE COHORT STUDY



Kaleb Tesfai[1] Nikhil Kalita[1] Francisco Idalsoaga[2] Mario Pessoa[3] Claudia Oliveira[4] Patricia Ziteli[3] Scherezada loza[5] Ezequiel Ridruejo[6] Mirta Peralta[7] César Castro[8] Jorge Garavito[8] Rommel Huailla[8] Gustavo Ayares Campos[9] Nancy Solis[9] Maria Orellana[9] Francisco Barrera[9] Sebastian Marciano[10] Adrián Gadano[10] Jorge Martínez[10] Maria Jose Acosta[10] Martin Tagle[11] Hugo Cedron[11] Ismael Yepes[12] Dalis Pérez[12] MaríaFernanda SaavedraChacón[13] Samuel Perez[14] Ignacio García-Juárez[15] Orfanel Sebastian Pineda-Arzat[15] Liz Toapanta-Yanchapaxi[16] Aline Sorribas[17] Manuel Mendizabal[18] Lorena Castro Solari[19] Loreto Aguilar Barría[20] Samantha Wu[21] Catalina Roa[21] Fabiana Nina[22] Estefanía Liza Baca[23] Javier Diaz Ferrer[23] Roberto Pérez Ravier[24] Maria Martinez[24] Natalie Vilcinskas[24] Daniza Alexandra Contreras[25] Daniela Simian[26] Juan Roblero[27] Pamela Gil[24] Arun Sanyal[28] Juan Pablo Arab[28] Luis Díaz[29] Marco Arrese[29], [1]University of California San Diego, [2]Pontificia Universidad, [3]Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, [4]University of Sao Paulo School of Medicine, [5]Hospital Juárez de México, [6]Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno "CEMIC, [7]Hospital Francisco J Muñiz, Ciudad Autónoma de Buenos Aires, [8]Hospital Nacional Arzobispo Loayza, [9]Pontificia Universidad Católica de Chile, [10]Hospital Italiano de Buenos Aires, [11]Clínica Anglo Americana, San Isidro, [12]Universidad de Cartagena, [13]Servicio de Hepatología Clínica y Medicina Interna, Clínica CES, Medellín, Colombia., [14]Servicio de Hepatología Clínica y Medicina Interna, Clínica CES, Medellín, Colombia, [15]Department of GastroenterologyNational Institute of Medical Sciences and Nutrition Salvador Zubirán, [16]Department of Gastroenterology,National Institute of Medical Sciences and Nutrition Salvador Zubirán, [17]Unidad de Hígado y Trasplante Hepático, Hospital Universitario Austral, Pilar, Provincia de Buenos, [18]Hospital Universitario Austral, [19]Centro de Enfermedades Digestivas, Clínica Universidad de los Andes, Santiago, Chile., [20]Centro de Investigación e Innovación Biomédica, Universidad de los Andes, Santiago, Chile., [21]Escuela de Medicina, Universidad de los Andes, Santiago, Chile., [22]Escuela de Medicina, Universidad del Alba, Santiago, Chile., [23]Hospital Nacional Edgardo Rebagliati Martins, Jesús María, Lima, Perú., [24]Liver Unit, Hospital Central de Mendoza, Mendoza, Argentina., [25]National Institute of Diabetes, Nutrition, and Endocrinology (INDEN), Santo Domingo, Dominican Repub, [26]Sección de Gastroenterología, Departamento de Medicina Interna,Hospital Clínico Universidad de Chile, [27]University of Chile, [28]Virginia Commonwealth University, [29]Pontificia Universidad Católica de Chile, Santiago, Chile

Background: Although MASLD diagnosis is based on the presence of at least one cardiometabolic risk factor (CMRF), the role of individual CMRFs in the diagnosis and severity of MASLD has been poorly characterized. Thus, we aimed to identify the most relevant CMRFs for diagnosing MASLD and predicting at-risk MASLD in a well-characterized multinational cohort. **Methods:** We conducted a cross-sectional analysis of prospectively enrolled adults with MASLD at 16 tertiary centers in seven countries (Argentina, Brazil, Chile, Colombia, the Dominican Republic, Mexico, and Peru). At-risk MASLD was defined as the presence of MASLD and ≥ F2 on biopsy or a FAST score ≥ 0.67, if liver biopsy was not available. Analyses included a logistic regression model adjusted for age, sex, Hispanic ethnicity, and CMRFs. **Results:** The cohort comprised of 408 participants; 67.8% were female and 30.2% were Hispanic. The prevalence of at-risk MASLD was 44.9%. The median [IQR] age and body mass index (BMI) were 65 [55–72] years and 30.4 [27.4–34.0] kg/m², respectively. Compared with low-risk MASLD, participants with at-risk MASLD had a significantly greater prevalence of type 2 diabetes (T2D) (71.4% vs. 45.9%, $p < 0.001$) and hypertension (65.4% vs. 51.8%, $p = 0.006$), while a significantly lower prevalence of prediabetes, 4.4% vs. 18.6%, $p < 0.001$. There were no differences in the prevalence of other CMRFs between

those with at-risk MASLD and low-risk MASLD: overweight, 34.9% vs. 35.5%, p = 0.902; obesity, 54.9% vs. 55.5%, p = 0.906; abnormal waist circumference, 94.6% vs. 88.3%, p = 0.176; dyslipidemia, 53.4% vs. 58.8% p = 0.275 (**Figure A**). In multivariable logistic regression, only T2D (OR 2.10; 95% CI 1.29–3.41; p = 0.003) remained a significant CMRF predictor of at-risk MASLD (**Figure B**). **Conclusion:** In a multicenter Latin American prospective cohort study, abnormal waist circumference was present in 9 of 10 patients, while type 2 diabetes was the only CMRF that predicted increased odds of at-risk MASLD. While patients with MASLD may present with multiple cardiometabolic risk factors, the presence of increased adiposity and dysglycemia should be considered major diagnostic criteria for MASLD (FONDECYT 1241450).

A) Prevalence of different cardiometabolic risk factors across MASLD risk subtype
B) Multivariable adjusted odds ratio of cardiometabolic risk factors, significant on univariate analysis, predicting odds of at-risk MASLD

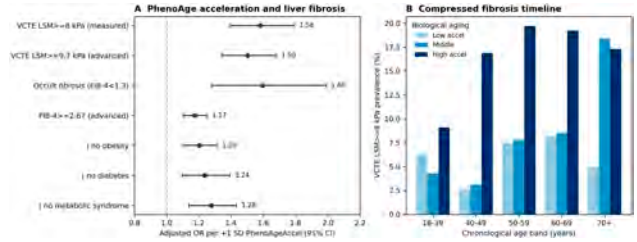
2427 | BIOLOGICAL AGE ACCELERATION FROM ROUTINE LABS CLASSIFIES ELASTOGRAPHY-MEASURED LIVER FIBROSIS AND DETECTS DISEASE MISSED BY FIB-4: A SURVEY-WEIGHTED NHANES ANALYSIS



Harika Dadigiri Srinivas Venkatanarayanan[1] Jeril Lasington[2] Anas Al Mardini[3] Venkatesh Gondhi[2] Vinod Nookala[2], [1]UCF, [2]NYMC Saint Clare's and Saint Marys's Hospital, [3]NYMC, St Clare St Mary hospital

Background: Fibrosis stage drives mortality in chronic liver disease, yet routine risk tools (FIB-4) are age-centric and miss early disease. DNA-methylation aging clocks predict liver outcomes but need costly methylation absent from population data. Whether lab-derived phenotypic age acceleration (PhenoAgeAccel), computable from routine bloodwork, classifies liver fibrosis and adds to FIB-4 is unknown. **Methods:** ross-sectional NHANES 2005-2018 (5 cycles with C-reactive protein). Levine PhenoAge was computed from 9 routine labs; PhenoAgeAccel = residual of PhenoAge on chronological age. Primary outcome: vibration-controlled transient elastography (VCTE/FibroScan, 2017-2018) liver stiffness (LSM) > = 8 and > = 9.7 kPa (reliable scans only). Secondary: FIB-4 > = 2.67. Survey-weighted logistic regression with Taylor-linearised SE adjusted for age, sex, race/ethnicity, income, smoking, and alcohol; a metabolic model added BMI, diabetes, and hypertension. Sensitivity analyses used a non-hepatic PhenoAge (excluding hepatic markers), multiple imputation, and serology-based viral hepatitis exclusion. AI (ChatGPT/Claude) aided language only; all analysis and conclusions are the authors'. De-identified public data; IRB-exempt (45 CFR 46). **Results:** 26,771 adults had computable FIB-4 (representing ~216 million US adults); 4,461 had reliable VCTE. Per +1 SD PhenoAgeAccel, adjusted odds of measured fibrosis rose: LSM > = 8 kPa OR 1.58 (95% CI 1.39-1.79); LSM > = 9.7 OR 1.50 (1.34-1.68); FIB-4 > = 2.67 OR 1.17 (1.10-1.25); all p < 0.001 (p-trend < 0.001). Among low-risk adults (FIB-4 < 1.3), 7.5% had occult VCTE fibrosis; PhenoAgeAccel flagged it (OR 1.60, 1.28-1.99) and improved discrimination over FIB-4 (AUROC 0.60 to 0.68; delta-AUROC 0.081, 0.040-0.132; IDI 0.029). The FIB-4 > = 2.67 association was strongest in metabolically low-risk strata (no metabolic syndrome OR 1.28; no diabetes 1.24). Biologically older adults aged 40-49 had

higher fibrosis prevalence (16.9%) than biologically younger adults aged > = 60 (5-8%). Inflammation (CRP) and glucose dominated component drivers; PhenoAgeAccel stayed associated beyond RDW and CRP (OR 1.41). Findings were unchanged with non-hepatic PhenoAge (OR 1.55) and multiple imputation. PhenoAgeAccel independently predicted all-cause mortality (HR 1.44 per SD; 2,731 deaths). Adjusting for BMI and diabetes attenuated the VCTE association, indicating partial metabolic mediation. **Conclusion:** Routine-laboratory biological age acceleration classifies gold-standard, elastography-measured liver fibrosis, detects fibrosis missed by FIB-4, and is strongest in metabolically low-risk adults, identifying aging as a fibrosis risk axis beyond traditional metabolic factors. PhenoAgeAccel is a free, scalable adjunct to FIB-4 for fibrosis risk stratification.

2428 | THE PERSONAL CARE CHEMICAL EXPOSOME AND MASLD IN U.S. ADULTS: A MULTI-POLLUTANT NHANES 2017–2018 ANALYSIS USING VCTE-DEFINED LIVER PHENOTYPES

Jagadish Koyi[1] Mounika Kotte[2] Digantkumar Patel[3] Pragathi Munnangi[4] Sri Ram Charan Gundapaneni[5] Serene Sara John[6] Hardik Dineshbhai Desai[7], [1]Integris Health, Oklahoma City, Oklahoma. USA. 73112, [2]Prime south consortium, Weslaco, Texas, USA,78596, [3]Springfield Clinic, Springfield, IL, USA, [4]BronxCare Health System , Bronx , New York - 10457, [5]UCF/HCA Florida Ocala Hospital, Ocala, Florida, United States, 34471, [6]Detroit medical center, Detroit, Michigan, 48201, [7]AB Plus Multispecialty Hospital, Ahmedabad, Gujarat, India

Background: Personal care and consumer-product chemicals (phenols, parabens, bisphenols, antimicrobials) are widely detected in the general population and may contribute to metabolic liver injury. However, their single-pollutant and combined mixture-level associations with metabolic dysfunction-associated steatotic liver disease (MASLD) particularly elevated-stiffness and lean MASLD phenotypes—remain insufficiently characterized. **Methods:** We analyzed adults aged ≥18 years from the National Health and Nutrition Examination Survey (NHANES) 2017–2018 with valid vibration-controlled transient elastography (VCTE), urinary phenol/paraben measurements, urinary creatinine, and eligible survey weights. Participants with viral hepatitis, significant alcohol intake, pregnancy, invalid VCTE examinations, or missing covariates were excluded. MASLD was defined as controlled attenuation parameter (CAP) ≥248 dB/m with ≥1 cardiometabolic risk factor. Elevated-stiffness MASLD was defined as MASLD with liver stiffness measurement (LSM) ≥8.0 kPa, and lean MASLD as MASLD with body mass index (BMI) <25 kg/m². Survey-weighted logistic regression estimated adjusted odds ratios (aORs) per doubling of creatinine-standardized urinary chemical concentration. **Results:** Among 1,132 adults, the weighted prevalence of MASLD was 56.1%, elevated-stiffness MASLD was 7.4%, and lean MASLD was 5.0%. In single-pollutant models, benzophenone-3 was inversely associated with MASLD (aOR 0.88 per doubling; 95% confidence interval [CI] 0.83–0.95; p < 0.001), as was triclosan (aOR 0.87; 95% CI 0.80–0.95; p = 0.001). Butyl paraben showed a positive but nonsignificant association with overall MASLD (aOR 1.10; 95% CI 0.98–1.24; p = 0.108), but was significantly associated with lean MASLD (aOR 1.31; 95% CI 1.07–1.62; p = 0.009). For elevated-stiffness MASLD, methyl paraben (aOR 1.22; 95% CI 1.06–1.40; p = 0.005) and propyl paraben (aOR 1.13; 95% CI 1.01–1.25; p = 0.025) were significantly associated with higher odds. Approximate mixture models demonstrated significant positive cumulative associations with MASLD (mixture odds ratio [OR] 2.03; 95% CI 1.26–3.27; p = 0.004), elevated-stiffness MASLD (mixture OR 3.99; 95% CI 1.57–10.14; p = 0.004), and lean MASLD (mixture OR 9.54; 95% CI 2.09–43.48; p = 0.004). The leading positive contributors to the MASLD mixture index were butyl paraben, triclocarban, ethyl paraben, bisphenol F, and bisphenol S. **Conclusion:** In this nationally representative NHANES analysis, creatinine-standardized consumer-product chemical mixtures were significantly associated with MASLD phenotypes, with particularly strong signals for elevated-stiffness and lean MASLD. Individual chemicals showed heterogeneous associations, including inverse associations for benzophenone-3 and triclosan with overall MASLD and positive paraben-related associations with elevated-stiffness or lean MASLD.

2429 | THE TRIGLYCERIDE-GLUCOSE (TYG) INDEX AS A NON-INVASIVE BIOMARKER OF MASLD AND HEPATIC STEATOSIS SEVERITY IN A SOUTH ASIAN COHORT

Mihika Aggarwal[1] Akash Rawat[2] Drishtdeum Malik[3],
[1]Himalayan Instituite Of Medical Sciences, Dehradun,
[2]Himalayan Institue of Medical Sciences, Dehradun,
[3]Himalayan Institute of Medical Sciences, Dehradun

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) spans a spectrum from simple steatosis to fibrosis. Existing diagnostic tools, including FibroScan and biopsy, are resource-intensive, limiting screening in low-resource settings. The triglyceride-glucose (TyG) index, a validated surrogate of insulin resistance, has emerged as a potential non-invasive biomarker of metabolic liver disease. We aimed to evaluate the diagnostic utility of the TyG index for MASLD and its relationship with the degree of hepatic steatosis severity. **Methods:** This cross-sectional study enrolled 106 adults at a tertiary care centre in northern India. The TyG index was calculated as ln(TG [mg/dL] × FBG [mg/dL] / 2). Hepatic steatosis was graded on ultrasound as S0 (none) to S3 (severe), and patients were classified into MASLD (n = 52) and non-MASLD (n = 54) groups per the 2023 multi-society Delphi consensus criteria. TyG across steatosis grades was compared using ANOVA, Kruskal-Wallis, and trend tests. Ordinal logistic regression evaluated the relationship between TyG and steatosis severity. ROC analysis, multivariable logistic regression, and Pearson/Spearman correlation were performed to identify the independent predictors and discriminative performance of TyG for MASLD. **Results:** TyG increased progressively across steatosis grades: S0 8.95 ± 0.53, S1 9.07 ± 0.48, S2 9.39 ± 0.35, S3 9.39 ± 0.54 (ANOVA $p = 0.003$; Kruskal-Wallis $p = 0.001$; P for trend < 0.001; Spearman $\rho = 0.354$, $p < 0.001$). On ordinal logistic regression, each 1-unit rise in TyG was associated with a 4-fold higher odds of a higher steatosis grade (OR = 3.93, 95% CI 1.83–8.42, $p < 0.001$), unchanged after age/sex adjustment. On multivariable logistic regression adjusting for hypertension, BMI, and HbA1c, TyG was the strongest independent predictor of MASLD (adjusted OR = 13.28, 95% CI 3.24–54.46, $p = 0.0003$); hypertension was the only other significant predictor (aOR = 5.77, $p = 0.0004$). Model fit was good (Nagelkerke $R^2 = 0.418$; Hosmer-Lemeshow $p = 0.494$). ROC analysis demonstrated good discriminative performance of TyG for MASLD (AUC 0.769, 95% CI 0.674–0.855, $p < 0.001$), with an optimal cut-off of 9.063 yielding sensitivity 86.5%, specificity 59.3%, NPV 82.1%, and accuracy 72.6%. **Conclusion:** TyG is significantly and independently associated with hepatic steatosis severity and is the strongest independent predictor of MASLD on multivariable analysis. TyG demonstrated good discriminative performance for MASLD (AUC 0.769) and, at a cut-off of 9.063, showed high sensitivity and NPV. These findings support its potential utility as a simple, non-invasive biomarker for MASLD screening and risk stratification in South Asian populations. External validation in larger, ethnically diverse cohorts is warranted.

2430 | CORRELATION OF FIB-4 INDEX WITH LIVER STIFFNESS MEASUREMENT ON VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY IN PATIENTS WITH MASLD IN A SAFETY-NET HOSPITAL

Kathryn Thompson[1] Dominique Mosley[1] Lesley Miller[1], [1]Emory University School of Medicine

Background: The Fibrosis-4 (FIB-4) index is a validated non-invasive liver fibrosis assessment with high negative predictive value to rule out advanced fibrosis. The AASLD recommends using the FIB-4 index to stratify patients with MASLD to determine the need for further work-up and treatment. However, data suggests that the FIB-4 index may not be as reliable among subgroups of age and race. The aim of this study was to compare FIB-4 scores with liver stiffness measurement (LSM) on vibration-controlled transient elastography (VCTE) in patients with MASLD to determine if the FIB-4 index reliably predicts advanced fibrosis in this diverse, underserved patient population. **Methods:** A retrospective cohort analysis was conducted in 305 patients with MASLD who underwent VCTE from 01/01/2018-03/31/2024 at Grady Memorial Hospital in Atlanta, Georgia. Demographic, laboratory, and VCTE data were reviewed. Mean FIB-4 indices were calculated for all patients who had VCTE exams. We compared FIB-4 indices to LSM on VCTE to evaluate differences in FIB-4 indices based on sex, race/ethnicity (Other/Hispanic/Latino, Black/African American (AA), White/Caucasian), and age (< 40 y/o, 40-49 y/o, 50-59 y/o, 60-69 y/o, ≥ 70 y/o). **Results:** For all patients, the mean FIB-4 index increased with LSM on VCTE: 1.17 for F0-F1, 1.34 for F2, 1.66 for F3, and 2.82 for F4. Females had higher mean FIB-4 indices for F2 and F3 fibrosis compared to males (1.38 and 1.83 vs. 1.26 and 1.28) but males had a higher mean FIB-4 index for F4 fibrosis (3.26 vs. 2.50). Hispanic and White patients had similar rises in mean FIB-4 indices by LSM while AA patients had overall lower mean FIB-4 indices, especially for F3 and F4 fibrosis (1.32 and 2.57). Younger patients < 40 y/o had lower mean FIB-4 indices with highest mean FIB-4 index of 1.21 correlating with F3 fibrosis. On the contrary, older patients ≥ 70 y/o had higher mean FIB-4 indices, including for F0-F1 and F2 fibrosis (1.61 and 2.44). **Conclusion:** Overall, FIB-4 indices correlated with LSM but there were key differences in FIB-4 by gender, race, and age. Males had less FIB-4 elevation by LSM compared to females and even with F3 fibrosis, their mean FIB-4 index < 1.3 would have precluded secondary risk assessment for advanced fibrosis. Further, lower mean FIB-4 indices across all LSM in AA patients suggests that the severity of liver fibrosis is underpredicted with the FIB-4 index among AA patients in our study. Lastly, lower mean FIB-4 indices for younger patients and higher mean FIB-4 indices for older patients do not correlate with LSM. This aligns with current data that suggests the FIB-4 index is not as accurate in younger and older populations as alternative non-invasive fibrosis assessments to the FIB-4 index are recommended in younger patients and higher FIB-4 index thresholds are recommended in older patients.

2431 | DEVELOPMENT OF PREDICTIVE MODELS FOR HEPATOCELLULAR CARCINOMA IN CIRRHOTIC AND NON-CIRRHOTIC METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Daniel Sanmuganathan[1] Prerana Vatsavayi[1] Michael Yee[1] Fernando Iorra[1] Shahid Khan[1] Mark Thursz[1] Pinelopi Manousou[1], [1]Imperial College London

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is an increasingly important cause of hepatocellular carcinoma (HCC). Current HCC surveillance is largely cirrhosis-based. However, approximately 39% of MASLD-HCC cases occur in non-cirrhotic patients. We aimed to identify factors associated with HCC in a North-West London MASLD population, and to derive HCC risk

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

prediction models for overall and non-cirrhotic MASLD. **Methods:** We included consecutive MASLD patients with HCC, seen between 1st January 2014 and 31st December 2025 at Imperial College NHS Trust, London. Collected data included demographic, clinical, and biochemical factors 12-18 months before HCC diagnosis. A cohort of MASLD patients without HCC was age-matched. Univariate and multivariate binary logistic regression analyses were used to identify factors associated with HCC. Four prediction models were derived from age-matched and unmatched MASLD cohorts, including non-cirrhotic subcohorts, using 70: 30 derivation-validation splits. Model discrimination was assessed using area under the receiver operating characteristic curve (AUROC). **Results:** There were 219 HCC cases and 219 age-matched controls. Residual age imbalance persisted between these two cohorts. Sensitivity analyses used the full, unmatched control cohort of 656. HCC patients were more frequently male, older, and were more likely to have higher FIB-4 and cirrhosis, and MetALD. MASLD models incorporated combinations of male sex, age, cirrhosis, MetALD, statin use, and type 2 diabetes mellitus, while non-cirrhotic MASLD models incorporated male sex, age, MetALD, statin use, and platelet count. In sensitivity analysis of the age-matched non-cirrhotic MASLD cohort, higher FIB-4 was associated with HCC. The age-matched MASLD and non-cirrhotic MASLD models demonstrated AUROCs of 0.809 and 0.755, respectively, for predicting HCC in 12 months. The corresponding sensitivity analysis models demonstrated higher AUROCs of 0.901 and 0.884, respectively. **Conclusion:** We derived MASLD-HCC risk models using routinely available clinical variables, with acceptable-to-excellent discrimination in both overall and non-cirrhotic MASLD. These findings could support risk-based stratification studies beyond cirrhosis for identifying MASLD patients who may benefit from HCC surveillance.

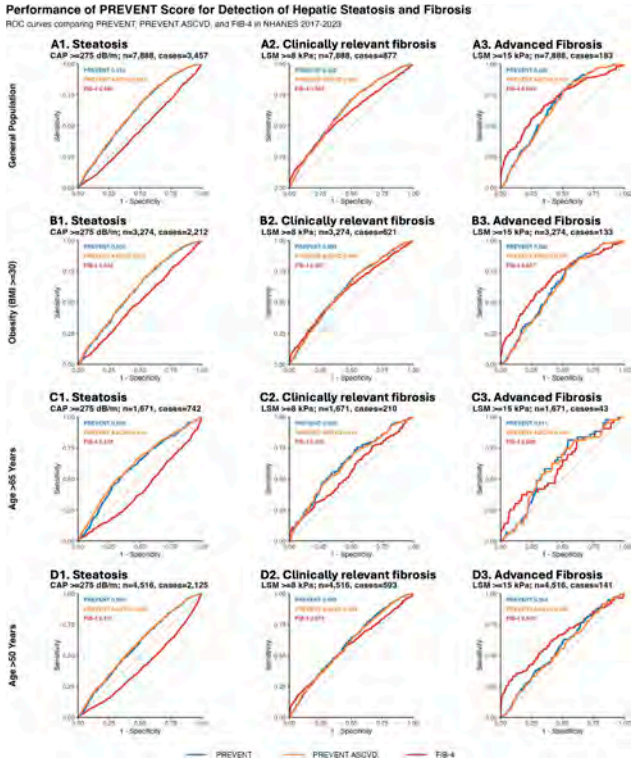
2432 | DISCRIMINATIVE PERFORMANCE OF THE PREVENT CVD AND ASCVD RISK SCORE FOR HEPATIC STEATOSIS AND FIBROSIS COMPARED WITH FIB-4 SCORE



Anna Strauss[1] Timothy Davie[1] Jesse Fletcher[1] Kartik Dapke[2] Serena Brosten[1] Giovanni Roldan[3] Prowpanga Udompap[4], [1]Department of Medicine, University of Minnesota, [2]Department of Medicine, Saint Vincent Hospital, Worcester, MA, [3]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, [4]Division of Gastroenterology, Minneapolis VA Medical Center

Background: PREVENT CVD and ASCVD equations are designed to predict cardiovascular risk. Their component variables closely mirror the cardiometabolic drivers of metabolic dysfunction-associated steatotic liver disease (MASLD). Given its widespread use in primary care, PREVENT CVD and/or ASCVD could serve as an opportunistic tool to increase MASLD awareness and enhance risk stratification alongside the recommended FIB-4 index. We evaluated the discriminative performance of PREVENT for hepatic steatosis (HS) and fibrosis in a nationally representative cohort. **Methods:** Using the data from National Health and Nutrition Examination Survey (NHANES) 2017–2023, adults aged 30 to 79 were included. PREVENT CVD, PREVENT ASCVD, and FIB-4 scores were calculated. HS was defined as controlled attenuation parameter $\geq$275 dB/m, clinically relevant fibrosis (CRF) as liver stiffness measurement (LSM) $\geq$8 kPa, and advanced fibrosis (AF) as LSM $\geq$15 kPa. Diagnostic performance was assessed using AUROC analyses, sensitivity, and specificity. Subgroup analyses included BMI $\geq$30 and age $\geq$50 and $\geq$65 years. Multivariable logistic regression estimated odds ratios per 5% PREVENT increment within cardiometabolic subgroups. **Results:** Among 8,969 adults representing 148.6 million (M) U.S. adults (mean age 52.2 years; 50.4% women; mean BMI 29.8 kg/m^2), 7,888 had complete data: 3,457 with HS, 877 with CRF, and 183 with AF. For detection of HS, PREVENT CVD and ASCVD outperformed FIB-4 in the overall cohort (AUROC: 0.616 and 0.622 vs. 0.468), especially among adults aged $\geq$65 years (0.599 and 0.616 vs. 0.418). For CRF, PREVENT CVD demonstrated moderate discrimination superior to FIB-4 in the overall cohort (0.632 vs. 0.592), obesity subgroup (0.609 vs. 0.557), and adults aged $\geq$65 years (0.626 vs. 0.555). For AF, FIB-4 had the highest discrimination in the overall cohort (0.699), compared to PREVENT CVD and ASCVD (0.663, 0.654). At PREVENT CVD thresholds of $\geq$10% and $\geq$20%, specificity for CRF was 80.6% and 95.3%, respectively. Also, each 5-percentage-point PREVENT CVD increase was associated with higher odds of AF in obesity (OR 1.29; $p<0.001$), hypertension (OR 1.18; $p=0.006$), and ALT >40 U/L (OR 1.62; $p=0.003$), but not diabetes (OR 1.07; $p=0.48$). **Conclusion:** The PREVENT CVD and ASCVD risk scores outperform the FIB-4 index in predicting HS and demonstrates comparable or modestly superior discrimination for CRF, particularly in older adults and those with obesity. FIB-4 retained an advantage for AF. Because PREVENT CVD and ASCVD risk scores are already established in primary care cardiovascular workflows, an elevated score may serve as an opportunistic signal

2433 | TREATED HYPOTHYROIDISM AS A DISEASE MODIFIER IN MASLD: HEPATIC PROGRESSION, DECOMPENSATION, AND MORTALITY IN A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Archana Salek[1] Jashanveer Johal[1] Bianca Patel[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Abdallah Hussein[1] Jason Hyman[2] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Hypothyroidism impairs hepatic fatty acid oxidation and promotes lipogenesis through reduced thyroid hormone receptor-β (THRβ) signaling, the same pathway targeted by resmetirom in MASLD. However, the independent effect of hypothyroidism on MASLD progression remains poorly defined, confounded by coexisting metabolic disease. We evaluated whether treated hypothyroidism is associated with accelerated hepatic progression in MASLD. **Methods:** We performed a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 included adults with MASLD (K76.0/K75.81) and hypothyroidism (E03.8, E03.9, or E06.3) treated with levothyroxine after MASLD diagnosis. Cohort 2 included MASLD patients without thyroid disease. Patients with prior cirrhosis, hepatocellular carcinoma (HCC), chronic viral hepatitis, alcoholic liver disease, or thyroid malignancy were excluded. After 1: 1 propensity matching, 14,039 patients remained in each cohort with 6–60 months follow-up. Outcomes included incident cirrhosis, ascites, hepatic encephalopathy (HE), HCC, AST/ALT normalization, inpatient utilization, and all-cause mortality. **Results:** Treated hypothyroidism was associated with increased risk of incident cirrhosis (HR 1.62, 95% CI 1.30–2.04; $p < 0.001$), with cirrhosis-free survival of 93.4% in the hypothyroid cohort versus 97.1% in control cohort at study end, ascites (HR 1.31, 95% CI 1.09–1.59; $p = 0.005$), and HE (HR 1.50, 95% CI 1.01–2.23; $p = 0.045$). HCC incidence trended higher but was not significant (HR 1.44, 95% CI 0.66–3.11; $p = 0.35$). AST/ALT normalization was delayed in the hypothyroid cohort (HR 1.22, 95% CI 1.07–1.40; $p = 0.004$), with median time to normalization of 1,627 versus 1,219 days. All-cause mortality was higher in the hypothyroid cohort (5.5% vs. 4.4%; HR 1.53, 95% CI 1.37–1.70; $p < 0.001$). Despite worse hepatic outcomes, inpatient encounter burden was lower in the hypothyroid cohort. **Conclusion:** In this large propensity-matched real-world study, treated hypothyroidism was independently associated with accelerated hepatic progression in MASLD, including higher rates of cirrhosis, hepatic decompensation, delayed biochemical recovery, and increased mortality despite levothyroxine therapy. Persistent hepatic risk despite levothyroxine therapy suggests thyroid hormone replacement alone may not fully reverse THRβ-mediated hepatic dysregulation in MASLD. These findings support hypothyroidism as an independent modifier of MASLD progression and reinforce the clinical relevance of THRβ signaling in MASLD pathogenesis and emerging targeted therapies.

2434 | IDENTIFICATION OF BIOMARKERS IN HUMAN PLASMA EXOSOMES WITH RELEVANCE TO METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Raja Gopoju[1] Majd Aboona[2] Pooja Rangan[3] Mrinalini Kala[1] Karn Wijarnpreecha[3] Yanqiao Zhang[4], [1]University of Arizona, [2]Banner University Medical Centre, [3]Banner University Medical Center, [4]University of Arizona College of Medicine - Phoenix

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH) are common chronic liver diseases characterized by liver steatosis, inflammation, and fibrosis. There are limited non-invasive biomarkers available for early diagnosis or tracking the disease progression towards fibrosis and hepatocellular carcinoma. In this study, we have characterized biomarkers from plasma samples in MASLD/MASH patients. **Methods:** The individuals were segregated into 5 groups based on disease prognosis assessed by Vibration-Controlled Transient Elastography (VCTE) or Fibroscan: Healthy control (N), fibrosis stage 0-1 (F1), fibrosis stage 2 (F2), fibrosis stage 3 (F3), and fibrosis stage 4 (F4). Each group had 5 samples, with mean ages of 35, 59.8, 52.8, 51.8, and 67.6 years. The plasma was separated from whole blood, and exosomes were isolated by ultracentrifugation. Exosomal miRNAs were isolated and sequenced, and exosomal proteins were analyzed by non-targeted proteomics. Highly significant miRNAs and proteins were identified. The data were analyzed statistically by one-way ANOVA. **Results:** miRNA studies revealed that miR-126-5p, miR-99b-5p, and miR-361-5p were reduced in the F1–F4 groups compared with the N group. miR-1307-3p, miR-3138, and miR-30C-1-3p levels were induced in the F3 group compared to normal, early, and late stages of fibrosis. miR-339-3p levels were increased in the F3 group compared to F1 or F2 groups. In the proteomics studies, ficolin-3 (FCN3) and inter-alpha-trypsin inhibitor heavy chain H4 (ITIH4) were elevated in the F2 group compared with the normal, early, and late fibrosis stages. Smooth muscle alpha actin (ACTG2) and beta actin (ACTB) were prominently increased in the F1 group compared to the normal group and declined gradually towards later stages of fibrosis (F3, F4 groups). **Conclusion:** Our studies have identified a few miRNAs that are changed in MASLD/MASH. In particular, plasma miR-1307-3p, miR-3138, and miR-30C-1-3p are increased in the F3 group. Also, plasma exosomal proteins FCN3 and ITIH4 are increased in the F2 group. These miRNA and protein markers may have potential for non-invasive diagnosis of MASH and tracking fibrotic stages in MASLD. Further studies will help determine the significance of the changes in these biomarkers.

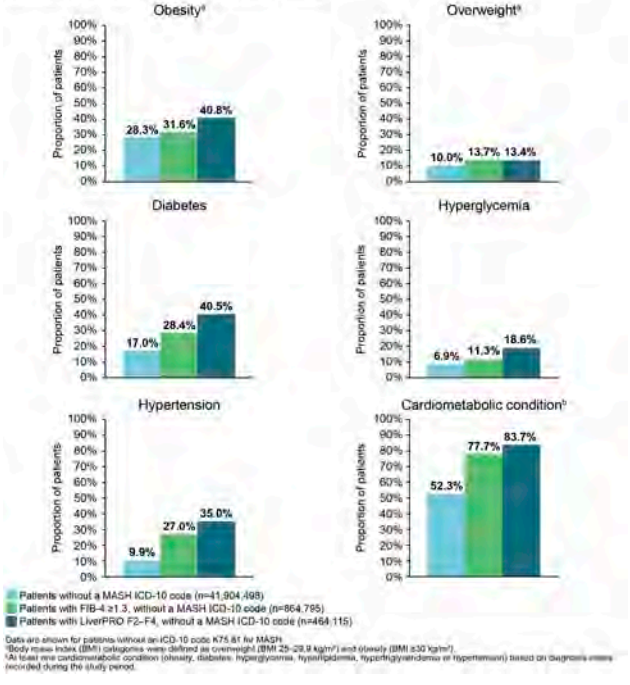
2435 | BRIDGING THE DIAGNOSTIC GAP IN MASH: REAL-WORLD EVIDENCE OF UNDERDIAGNOSIS IN THE US

Jörn Schattenberg[1] Zuleika Aponte Torres[2] Lu Zhang[2] Katrine Prier Lindvig[3] Mireia Raluy[4] Mark Yates[4] Faizan Mazhar[4] Claudio Sartini[2] Zobair Younossi[5], [1]Saarland University Medical Center Homburg, [2]Boehringer Ingelheim, [3]Evido Health, [4]Thermo Fisher Scientific, [5]The Global NASH/MASH Council



Background: Low prevalence of metabolic dysfunction–associated steatohepatitis (MASH) International Classification of Diseases (ICD-10) codes in real-world administrative claims databases indicate its burden may be inadequately captured, particularly with respect to fibrosis stage. Non-invasive test (NIT) screening tools such as Fibrosis-4 Index (FIB-4) and LiverPRO use routinely collected lab and patient data to assess fibrosis risk and may enable risk stratification in people at risk for developing MASH. **Methods:** This retrospective observational study used electronic health record and claims data from the Optum® Market Clarity (OMC) US database (January 1, 2021–December 31, 2023). Adults aged $\geq$18 years, with $\geq$1 healthcare encounter during the study period were included; those with non-MASH liver disease etiologies were excluded. Patients were classified as diagnosed with MASH (ICD-10 code K75.81) or at risk for MASH using combinations of the ICD-10 code for metabolic dysfunction–associated steatotic liver diseases (MASLD [K76.0]); FIB-4 scores $\geq$1.3 estimating moderate-to-advanced liver fibrosis risk; and/or LiverPRO-defined F2–4 fibrosis risk. NITs, age and same-day lab

measurements were required for calculations. Suspected metabolic syndrome (MetS) was defined as presence of ≥3 cardiometabolic conditions (obesity, diabetes, hyperglycemia, hyperlipidemia, hypertriglyceridemia, hypertension), based on ICD-10 codes during the study period. **Results:** Of 42,596,381 patients in the study population, 3,409,957 (8%) and 4,734,642 (11%) had sufficient data to calculate FIB-4 and LiverPRO, respectively. Among these, 814,276 (24%) had FIB-4 ≥1.3 and no MASLD/MASH codes, and 422,608 (9%) had LiverPRO-defined F2–4 fibrosis without MASLD/MASH codes, indicating a substantial population with elevated fibrosis risk but no recorded diagnosis. Among patients with a MASLD or MASH code, 3% and 46% respectively, had FIB-4 ≥1.3; rates of suspected MetS were 72% and 86%. Among patients without MASLD/MASH codes, 43% and 55% of those with FIB-4 ≥1.3 and LiverPRO F2–4, respectively, had suspected MetS. In patients without a MASH code, conditions associated with MASH risk were more prevalent in those with signs of fibrosis by FIB-4 or LiverPRO (Figure). Advanced evaluation procedures were infrequently used among patients at risk for MASH, despite a high burden of cardiometabolic conditions. **Conclusion:** Real-world data indicate a substantial gap between MASH diagnoses and fibrosis risk identified using NITs, suggesting underdiagnosis in routine clinical practice. A sizeable proportion of patients without MASLD/MASH codes showed elevated fibrosis risk by NITs, many of whom had cardiometabolic conditions consistent with MASH risk. Targeted use of NIT screening in patients with metabolic risk factors or MASLD may improve identification of patients at risk for MASH, though broader application is limited by data availability.

Prevalence of cardiometabolic conditions indicative of MASH risk among patients without a MASH ICD-10 code

Data are shown for patients without an ICD-10 code K75.81 for MASH.
[a]Body mass index (BMI) categories were defined as overweight (BMI 25–29.9 kg/m²) and obesity (BMI ≥30 kg/m²).
[b]At least one cardiometabolic condition (obesity, diabetes, hyperglycemia, hyperlipidemia, hypertriglyceridemia or hypertension) based on diagnosis codes recorded during the study period.

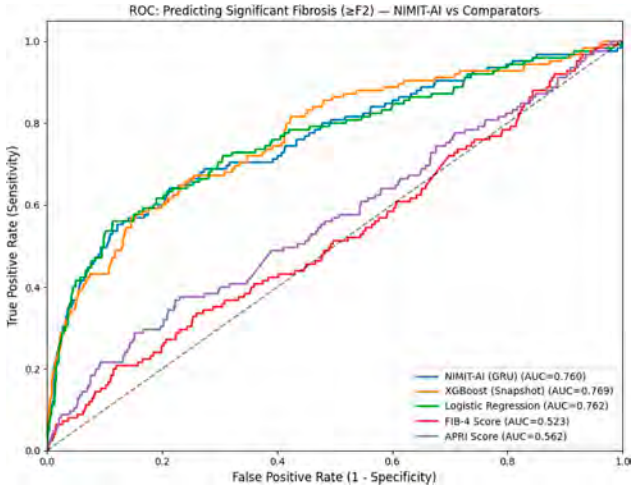
2436 | NIMIT-AI: A LONGITUDINAL DEEP LEARNING FRAMEWORK FOR NON-INVASIVE MASLD FIBROSIS TRIAGE USING ROUTINE ELECTRONIC HEALTH RECORD TRAJECTORIES



Teerachod Suwanwilaikul[1] Tawesak Tanwandee[2] Supot Nimanong[2], [1]Faculty of Medicine Siriraj Hospital, Mahidol University, [2]Siriraj Hospital/Mahidol University

Background: Every year, thousands of patients with MASLD leave outpatient clinics without a clear fibrosis verdict because the triage tools we use cannot read it properly. Current triage relies on FIB-4, static serum indices with positive predictive values of 20 to 60% that regularly fail to justify definitive management without confirmatory elastography. More fundamentally, FIB-4 requires a full laboratory set at every visit; a single missing platelet count or transaminase renders the score uncomputable. This is a failure that recurs routinely in clinical practice. We developed NIMIT-AI (Neural Inference for Metabolic-liver Integrated Trajectories), a GRU-based deep learning model that learns fibrosis risk from serial routine laboratory results from years of follow-up, enabling reliable one-step triage without elastography dependence. **Methods:** NIMIT-AI was trained on three consecutive CDC NHANES cycles (2013 to 2018; n = 5,651 elastography-labelled adults). Fibrosis was staged per 2024 EASL and Baveno VII thresholds: F0–F1 (<7.0 kPa), F2 (8.0 to 10.0 kPa), and F3–F4 cACLD (≥10.0 kPa), with a 1.0 kPa

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

censoring buffer applied during training to sharpen inter-class separation. Inputs comprised 18 features across four clinical domains: hepatology laboratories (AST, ALT, GGT, platelets, albumin, total bilirubin), metabolic markers (HbA1c, BMI, lipid panel), comorbidities (T2DM, CKD, OSA), and medication exposures (SGLT2i, GLP-1RA, statins). Binary input masking distinguished true missing values from observed zeros, preserving model integrity under real-world data sparsity and irregular follow-up intervals, allowing our model to operate natively on incomplete visit records without imputation. Performance was benchmarked against FIB-4, APRI, XGBoost, and logistic regression for identification of significant fibrosis ($F \geq 2$). **Results:** NIMIT-AI achieved AUROC 0.76 for significant fibrosis ($F \geq 2$), outperforming FIB-4 (0.52) and APRI (0.56), with a sensitivity of 81% compared to 69% for FIB-4. Discrimination for cACLD (F3–F4) from earlier fibrosis stages reached AUROC 0.78. SHAP analysis identified longitudinal AST-to-platelet dynamics and declining albumin trajectory as the strongest predictors of stage transition, findings consistent with established portal hypertension physiology. **Conclusion:** NIMIT-AI offers a practical and scalable one-step triage alternative for MASLD that outperforms conventional non-invasive indices, with particular relevance in resource-constrained settings where elastography access remains limited. Critically, unlike FIB-4, which yields no output whenever a required value is absent, NIMIT-AI processes incomplete records by design, ensuring every clinical encounter contributes to risk estimation rather than being discarded. This native tolerance for missing data makes it directly compatible with real-world EHR practice.

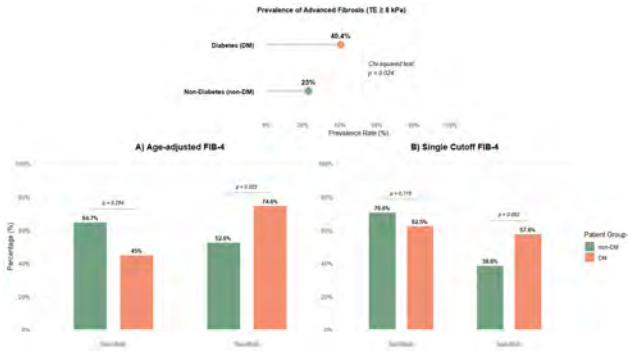
★ 2437 | HIGH PREVALENCE AND SUBOPTIMAL FIB-4 SENSITIVITY SUPPORT DIRECT VCTE REFERRAL FOR DIABETIC PATIENTS WITH MASLD



Pimsiri Sripongpun[1] Chitchai Rattananukrom[2] Huttakan Navadurong[3] Kessarin Thanapirom[4] Kanokwan Pinyopornpanish[5] Supot Nimanong[6] Apichat Kaewdech[1] Sakkarin Chirapongsathorn[7] Chalermrat Bunchorntavakul[8] Chanunta Hongthanakorn[9] Sith Siramolpiwat[10] Abhasnee Sobhonslidsuk[11] Sarita Ratana-Amornpin[11] Watcharasak Chotiyaputta[6] Sombat Treeprasertsuk[4] Teerha Piratvisuth[1], [1]Prince of Songkla University, [2]Khon Kaen University, [3]Navamindradhiraj University, [4]Chulalongkorn University, [5]Chiang Mai University, [6]Siriraj Hospital, [7]Phramongkutklao Hospital and College of Medicine, [8]Rajavithi Hospital, [9]Bhumibol Adulyadej Hospital, [10]Thammasart University, [11]Ramathibodi Hospital

Background: Current guidelines recommend screening for advanced fibrosis (AF) in patients at risk of metabolic dysfunction-associated steatotic liver disease (MASLD) using an age-adjusted FIB-4, followed by vibration-controlled transient elastography (VCTE) for those above the threshold. Conversely, the recent AGA clinical care pathway suggests direct VCTE referral for patients with diabetes (DM) due to a higher baseline risk. The applicability of this direct-referral strategy remains to be validated. This study evaluated advanced fibrosis prevalence and compared age-adjusted versus single-cutoff FIB-4 strategies among Thai MASLD patients with and without DM. **Methods:** This study is a preliminary analysis of the ongoing, multicenter Gastroenterological Association of Thailand (GAT) Fibroscan registry, focusing on patients who underwent VCTE for MASLD across six tertiary academic centers between 2016 and 2026. Those with unreliable VCTE results or aminotransferase levels >200 IU/mL were excluded. Advanced fibrosis (AF) was defined as a liver stiffness measurement ≥ 8 kPa. Two FIB-4 triage strategies were evaluated: a single-cutoff approach (FIB-4 >1.3 across all ages) and an age-adjusted strategy (FIB-4 >1.3 for patients <65 years and >2.0 for those ≥ 65 years). **Results:** Of 359 patients evaluated, 302 were eligible. The prevalence of AF was significantly higher in the DM than the non-DM group (35.7% vs. 19.8%, $p = 0.006$). In a subset of 173 patients (99 DM, 74 non-DM) with concurrent laboratory data to calculate FIB-4, the AF prevalence was 40.4% vs. 23.0% ($p = 0.024$). In this subset, the age-adjusted FIB-4 strategy demonstrated

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

lower sensitivity (45.0% vs. 64.7%, p = 0.284) but significantly higher specificity (74.6% vs. 52.6%, p = 0.023) in patients with DM compared to non-DM. Conversely, the single-cutoff approach yielded comparable sensitivity between groups (62.5% vs. 70.6%, p = 0.778), with a trend toward higher specificity in the DM cohort as shown in Figure. Notably, both strategies, particularly the age-adjusted approach, missed a substantial proportion of AF cases in patients with DM due to compromised sensitivity. **Conclusion:** Thai MASLD patients with DM exhibit a notably high prevalence of AF. Both FIB-4 strategies demonstrate suboptimal sensitivity in the diabetic cohort, potentially underestimating the true disease burden. These findings corroborate the AGA pathway suggesting that direct VCTE assessment may optimize case-finding in DM. However, caution is warranted as this registry-based cohort inherits potential selection bias by including only patients referred for VCTE. Further validation in primary care cohorts is required. Notably, recruitment for this multi-center registry remains active, with a larger sample size anticipated for future definitive validation.

2438 | LOW-RISK ADVANCED FIBROSIS BY TRANSIENT VIBRATION ELASTOGRAPHY (TVE FIBROSCAN 502 ≤ 8 KPAS) SCORE COMPARED TO FIB-4 SCORE, 2D-SHEARWAVE ELASTOGRAPHY SUPERSONIC (2D-SWE) AND LIVER BIOPSY: REAL WORD DATA WITH SOBERING RESULTS

Allan Weston[1] Kimberly Wood[2] Jennifer Rickman[1],
[1]Digestive Health Center of the Four States, LLC,
[2]Joplin Internal Medicine

Background: AASLD Guidelines have been published 2024 (1) concerning the estimate of fibrosis severity based on the combination of blood based fibrosis using FIB-4 or NFS scores along with LSM with TVE. Blood bases fibrosis scores generate three groups of pts; low, intermediate, and high risk, and along with TVE LSM score, predict actual liver fibrosis. LSM TVE ≤ 8 are predictive of non-advanced fibrosis, and when used in conjunction with FIB-4 score predicts either F0-F1 fibrosis or requires follow up versus liver biopsy (1). Fibroscan LSM measurements do not allow real time US and concurrent TVE imaging. 2D-SWE allows for real time, concurrent US imaging and a 2D-SWE image that the operator can readily accept or reject using Q-Box tool to ensure all data is at least 90% reliable. Due to the ability of SSI to generate SWE with reliable data, we speculated that this would lead to improved concurrence of FIB-4 risk stratrification to LSM and liver biopsy. **Methods:** Retropsective review of consecutive pts that underwent outpt in office FIBROSCAN 502 TVE followed immediately by SSI 2D-SWE from 10/10/2023 to 05/17/2026. Pts were excluded if TVE was unattainable or unreliable (IQR/M > 30%). Pts who underwent multiple studies during the review are included only once (their first US imaging exam). Demographic data (age, gender, BMI), PMH (HTN, DM, ETOH intake, Smoking Hx, Hepatitis C/B status), Lab data (ast/alt, albumin, Plt Ct) within 90 days of US exam and prior CT/MRI/US imaging was recorded. Only pts with low risk TVE LSM ≤ 8 are included in this analysis to determine the accuracy TVE LSM at truly predicting F01-F1 fibrosis. Low risk TVE LSM measurements were compared to FIB-4 risk groups (low ≤ 1.3, intermediate > 1.3 to 2.67, and high > 2.67), SSI 2D-SWE LSM [with ≤ 7.1 kPas used for F0-F1 fibrosis cutoff (3)], and liver biopsy. **Results:** A total of 602 pts were seen over the study period. 250 had TVE ≤ 8 kPas, their mean age 58.4+/-9.5 yrs, 92 male: 158 females, BMI mean 30.7+/-5.3, DM Type 2 73, Type 1 2, HTN 107. FIB-4 low risk group was 55 pts, intermediate 27, high risk 14 and not obtained 154. 2D-SWE was not done in 5 pts. Recent Liver Bx were obtained in 30 pts. Of the 55 patients in the low risk TVE

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

group and with low risk FIB-4 scores, SWE agreed with F0-F1 fibrosis in 83.6%. In the FIB-4 intermediate group, SWE concurrence noted in 77.8%, in the high-risk FIB-4 group, SWE concurrence in only 35.7%, and for the not done FIB-4 patients 70.8%. In only 14/30 (46.7%) pts, the liver bx F0-F1 severity concured with a TVE ≤ 8 kPas score. 16 pts overall in the low risk TVE group had a liver bx showing ≥ F2 fibrosis: 10 F2, 2 F3, and 4 F4 fibrosis. 6/6 (100%) of the pts with F3 or F4 fibrosis were properly predicted as having advanced fibrosis by 2D-SWE and 70% (7/10) for F2. **Conclusion:** Fibroscan 502 TVE scores ≤ 8 that are not in concurrence a low risk FIB-4 score warrants further investigation with a more accurate fibrosis severity overall generated from SSI 2D-SWE evaluation which was confirmed by liver bx data.

2439 | UNSUPERVISED CLINICAL CLUSTERING IDENTIFIES A GUT–LIVER IGA IMMUNE CLUSTER WITH HIGH RISK OF LIVER-RELATED EVENTS IN MASLD

Takefumi Kimura[1] Shun-Ichi Wakabayashi[1] Takuro Uchida[2] Naoki Tanaka[1], [1]Shinshu University School of Medicine, [2]Oita University

Background: MASLD is clinically heterogeneous, and fibrosis stage alone does not fully explain liver-related event (LRE) risk. We aimed to use unsupervised clinical clustering to identify prognostically relevant MASLD clusters and characterize IgA-associated immune mechanisms linked to disease progression. **Methods:** We performed unsupervised clustering using 51 baseline clinical and biochemical variables in a biopsy-proven MASLD discovery cohort (n = 349). Histological variables and outcome data were excluded from clustering. Cluster reproducibility was assessed by applying the same clustering framework to an independent multicenter validation cohort (n = 272), and phenotypic validation was performed in an internal VCTE cohort (n = 287). LREs were defined as hepatocellular carcinoma, grade ≥ II hepatic encephalopathy, ascites requiring hospitalization, or varices requiring intervention. IgA-related mechanisms were investigated using hepatic qPCR, spatial transcriptomics, single-cell RNA sequencing, liver and colonic immunohistochemistry, serum IgA subclass analyses, and serum EndoCAb IgG. **Results:** Variational Bayesian Gaussian mixture modeling identified four clinically distinct MASLD clusters. Among them, Cluster 2 showed the highest 5-year cumulative incidence of LREs (24.0%; 95% CI, 14.8%–37.4%; P < 0.001) and was characterized by elevated serum IgA and hyaluronic acid levels, reduced platelet count, and a high fibrosis burden. Cluster 2 was strongly associated with LRE risk (HR 15.96, 95% CI 4.20–60.68; P < 0.001). Serum IgA increased stepwise with fibrosis stage (P = 0.0001), correlated with liver stiffness in the VCTE cohort (r = 0.444; P < 0.0001), and a cutoff of 318 mg/dL independently predicted LREs after adjustment for advanced fibrosis (HR 3.17, 95% CI 1.27–7.91; P = 0.013). The IgA-enriched cluster and the prognostic relevance of IgA were reproduced in the external multicenter validation cohort (P = 0.039). Patients with both elevated IgA and advanced fibrosis had the highest 10-year cumulative LRE incidence (48%; P < 0.0001). Mechanistically, colonic immunohistochemistry demonstrated increased IgA-positive cells in the mucosa and submucosa of MASLD patients with advanced fibrosis, and serum IgA correlated with EndoCAb IgG, supporting a link between gut barrier dysfunction and systemic IgA activation. Hepatic IGHA1 expression correlated with EndoCAb IgG and increased with fibrosis stage, suggesting coordinated intestinal and intrahepatic IgA-associated immune activation. Spatial transcriptomics and immunohistochemistry demonstrated portal enrichment of IGHA1/IgA-positive B-lineage cells, with spatial concordance between IGHA1-enriched spots and IgA-positive cell–rich portal regions. Single-cell RNA sequencing localized IGHA1 expression predominantly to B-lineage/plasma cells. IGHA1-high spatial niches were enriched for pathways related to B-cell receptor signaling, Fc receptor-associated signaling molecules, extracellular matrix organization, hepatic stellate cell activation, fibrogenesis, and vascular remodeling. **Conclusion:** Unsupervised clinical clustering identified a reproducible IgA-enriched MASLD cluster with high LRE risk. Serum IgA may support cluster-based risk stratification, while gut–liver IgA activation may link barrier dysfunction, immune–fibrotic remodeling, vascular remodeling, and LRE development.

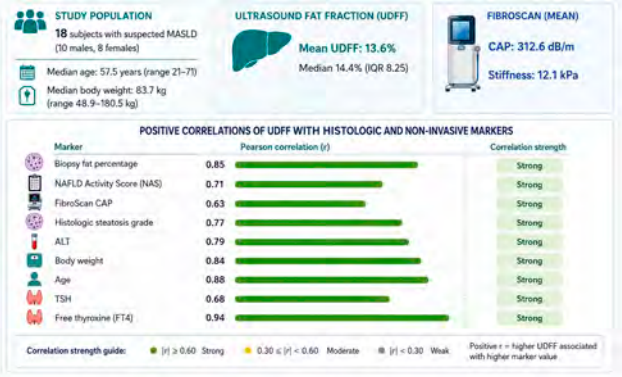
2440 | CORRELATION OF ULTRASOUND-DERIVED FAT FRACTION WITH HISTOLOGIC AND NON-INVASIVE BIOMARKERS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE



Ipshita Gupta[1] Dan Young[2] Arati Gurung[1] Yassin Labyed[1], [1]Siemens Healthineers, [2]National University Hospital Singapore

Background: Accurate non-invasive quantification of hepatic steatosis remains an unmet need in metabolic dysfunction-associated steatotic liver disease (MASLD). Ultrasound-derived fat fraction (UDFF) is an emerging quantitative ultrasound biomarker with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

potential utility for steatosis assessment and disease monitoring. This study evaluated the relationship between UDFF and histologic, elastographic, and biochemical markers of liver disease severity. **Methods:** Adults with suspected MASLD underwent multimodal clinical evaluation including quantitative ultrasound, FibroScan, laboratory assessment, and liver histology where available. Quantitative ultrasound parameters included UDFF (%). Correlation analysis was performed between UDFF, stiffness parameters, histologic findings, and biochemical markers using Pearson correlation coefficients. Strong correlations were defined as $|r| \geq 0.60$. **Results:** Eighteen subjects with suspected MASLD (10 males, 8 females) were recruited. Median age at enrolment was 57.5 years (range 21–71 years) and median body weight was 83.7 kg (range 48.9–180.5 kg). Mean UDFF was 13.6% (median 14.4%, IQR 8.25), while mean FibroScan CAP was 312.6 dB/m and mean FibroScan stiffness was 12.1 kPa. UDFF demonstrated strong positive correlations with histologic and non-invasive steatosis markers, including biopsy fat percentage ($r = 0.85$), NAFLD Activity Score (NAS) ($r = 0.71$), FibroScan CAP ($r = 0.63$), and histologic steatosis grade ($r = 0.77$). UDFF also correlated positively with ALT ($r = 0.79$), body weight ($r = 0.84$), age ($r = 0.88$), TSH ($r = 0.68$), and free thyroxine/FT4 ($r = 0.94$). **Conclusion:** UDFF demonstrated strong concordance with biopsy-derived fat quantification, FibroScan CAP, NAS, and histologic steatosis grade, supporting its role as a promising non-invasive biomarker for hepatic steatosis assessment in MASLD. Quantitative ultrasound biomarkers may provide clinically useful information for disease stratification and longitudinal monitoring while reducing dependence on invasive liver biopsy.

2441 | HETEROGENEITY OF DIFFUSE LIVER STEATOSIS IN PATIENTS WITH METABOLIC ASSOCIATED STEATOHEPATITIS (MASH) OR ALCOHOL LIVER DISEASE (ALD)

Renaud Winzenrieth[1] Juliette Foucher[2] Nora Fruilo[3] Adèle Delamarre[2] Benoit Recur[1] Paul Hermabessière[2], [1]SoQut-Imaging, Begles, France, [2]Hepatology, Hôpital Haut-Lévêque, Pessac, France, [3]Digestive Imaging, Hôpital Haut-Lévêque, Pessac, France

Background: Magnetic resonance imaging (MRI) is a simple, noninvasive and accurate modality for detecting and quantifying liver fat. Among MRI existing methods, chemical shift-encoded MRI (CSE-MRI) is a method of choice and allows simultaneous liver fat and iron content estimations through PDFF and R2* measurements. Steatosis in the liver is generally diffuse, but it can also be focal. However, even when diffuse, this fat accumulation may also be distributed heterogeneously within the liver. This study aims to assess fat heterogeneity distribution in patient suffering from MASH or ALD with diffuse steatosis. **Methods:** We retrospectively analyzed 53 patients suffering from MASH ($n = 43$) and ALD ($n = 10$). These patients underwent a 1.5T MRI with CSE-MRI acquisition between April 2024 and June 2025 and had a retrospective delay of 6-month between MRI and blood tests and Fibroscan®. PDFF values and distributions of each entire patient's liver were automatically computed using EliBio® software (SoQut-imaging, France). PDFF value of each patient's liver voxel were categorized as normal ($< 5.75\%$), stage1 (5.75-15%), stage 2(15-30%) or stage 3 ($\geq 30\%$). Related liver volume (expressed in % of the total liver volume) per category was also assessed. Patient's steatosis was also evaluated using Fibroscan's Controlled Attenuation Parameter (CAP) considering the following thresholds: normal (150-238 dB/m), stage 1(238-260 dB/m), stage 2 (260-290 dB/m) and stage 3(≥ 290 dB/m). **Results:** In overall, 45% of the patients had normal PDFF-steatosis while 30% had stage 1, 23% had stage 2 and 2% had stage 3. In comparison, 10% of the patients had normal CAP-steatosis while 35% had stage 1, 19% had stage 2 and 37% had stage 3. A poor agreement exists between CAP and PDFF staging (Kappa = 0.19). Of the 53 patient livers, the majority showed at least three grades of steatosis (58%) within the entire liver volume, while 40% showed two grades. Only one patient showed a single grade of steatosis. In 14 of the 43 MASH patients, more than 30% of the liver volume (32 to 58%) showed a one-grade worsening compared to their average based staging. Only 2 out of 10 ALD patients exhibited this one-grade worsening. Variability of PDFF Standard deviation in ALD patients was more

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

homogeneous (0.17-2.02) than the one from MASH patients (0.18-6.2). **Conclusion:** Almost all patients with diffuse hepatic steatosis exhibit a heterogeneous accumulation of fat within the liver. This heterogeneity can lead to misclassification of the severity of steatosis in the patient, resulting in an underestimation of the stage of steatosis in 16 out of 53 patients in whom more than 30% of the liver volume showed a one-grade worsening compared to their average based staging of the entire liver. Patients with MASH had a more heterogeneous fat accumulation than those with ALD, suggesting a different mechanism of hepatic fat accumulation.

2442 | LONGITUDINAL EVOLUTION OF STEATOTIC LIVER DISEASE SUBTYPES IN YOUNG BRAZILIANADULTS: A PROSPECTIVE COHORT STUDY USING TRANSIENT ELASTOGRAPHY

Fabiana Silva[1] Ana Cardoso[2] Katia Bloch[1] Nathalie Leite[3] Cristiane Villela-Nogueira[2], [1]School of Medicine, Universidade Federal do Rio de Janeiro, [2]School of Medicine, Hepatology Division , Universidade Federal do Rio de Janeiro, [3]Hepatology Division, Universidade Federal do Rio de Janiero

Background: Steatotic liver disease (SLD) has been recently redefined according to subcategories such as metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction-associated alcohol-related liver disease (MetALD), and alcohol-related liver disease (ALD). Longitudinal data in young adults remain limited. Our aim was to evaluate the prevalence and longitudinal evolution of steatotic liver disease (SLD) subtypes in young adults, as well as their association with cardiometabolic risk factors. **Methods:** This longitudinal study included a subcohort of young adults evaluated in 2018 (BL) and reassessed in 2024-2025 (FU) regarding anthropometric data, cardiometabolic factors, FINDRISC score and elastography with CAP (Fibroscan®, Echosens,Fr). SLD was defined by controlled attenuation parameter (CAP) $\geq$ 248 dB/m. Additionally, in both periods, steatosis subtypes were defined. **Results:** At BL, 123 individuals were evaluated (age 19.5 ± 1.5 years; 68.3% female), with SLD prevalence of 21.9%. Among these, 52% were MASLD, 33% MetALD, and 15% ALD. Individuals with steatosis had higher BMI. and waist circumference (all $p < 0.001$). After 64.5 (62-66), months 50 individuals were re assessed. SLD increased to 26% (MASLD 77%, MetALD 23% and ALD 0%), with significant increases in BMI, waist circumference, and systolic blood pressure (all $p < 0.001$). During follow-up, 4% developed type-2 diabetes and 44% worsened FINDRISC score by ≥ 1 category. **Conclusion:** SLD and cardiometabolic factors are highly prevalent in young adults, specially MASLD subtype. SLD presents a dynamic profile over time and needs constant reassessment in this population. Increasing awareness of MASLD in this population is essential to promote lifestyle interventions aimed at reducing long-term cardiometabolic and liver-related outcomes.

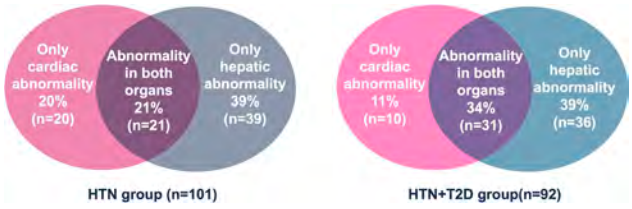
2443 | MULTI-ORGAN MRI REVEALS HIGH BURDEN OF HEPATIC AND CARDIAC ABNORMALITIES IN HYPERTENSIVE ADULTS WITH AND WITHOUT TYPE 2 DIABETES



Yameng Deng[1] Edward Jackson[1] Jennifer Bryant[2] Yiying Han[2] Aisyah Binte Latib[2] Thu-Thao Le[2] Andrea Dennis[3] Helena Thomaides Brears[1] Masliza Mahmod[1] Calvin Chin[2], [1]Perspectum Ltd, [2]National Heart Centre Singapore, [3]Perspectum

Background: Cardiac and hepatic abnormalities independently predict adverse cardiovascular outcomes, yet their relationship in hypertension (HTN) remains poorly characterised. We used quantitative multi-organ magnetic resonance imaging (MRI) to characterise cardiac and hepatic phenotypes in adults with HTN, with and without type 2 diabetes (T2D). **Methods:** The REMODEL study (NCT 02670031) evaluates cardiometabolic disease in adults with HTN recruited from outpatient and primary care settings in Singapore. 193 participants underwent blood biomarker assessment and multi-organ MRI to measure cardiac structure and function, including left ventricular ejection fraction (LVEF), global longitudinal strain (GLS), LV mass index (LVMi), maximal wall thickness (LVWT), and late gadolinium enhancement (LGE), extracellular volume (ECV), alongside liver fat content (LFC) and disease activity assessed by iron-corrected T1 (cT1). Baseline comparisons were performed between HTN alone ($n = 101$) and HTN+T2D ($n = 92$). A subgroup of 51 participants underwent repeat MRI after 5 ± 2 years

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and correlations between relative weight change and MRI biomarkers changes were evaluated. MRI phenotypes were hepatic (MASLD (LFC ≥ 5 %) and MASH (MASLD and cT1 ≥ 800 ms)) and cardiac (any of: reduced LVEF, elevated LVMi, elevated LV mass-to-volume ratio, left atrial enlargement or presence of LGE). **Results:** At baseline, groups were well matched for BMI and sex (obesity prevalence 33% vs 46%, p = 0.14; female sex 63% vs 52%, p = 0.14), although participants with HTN+T2D were older (62 vs 56 years, p < 0.001). Both groups showed a high burden of MRI-defined MASLD (73% with T2D vs 59% without, p = 0.05) and MASH (29% vs 27%, p = 0.7). NT-proBNP ≥400 pg/mL in only 6% with HTN+T2D and 3% without T2D (p = 0.5). Median LVEF of 59% in both groups (p = 0.5). However, HTN+T2D group demonstrated lower LV stroke volume (69 vs 81 mL, p < 0.001), impaired GLS (-16% vs -17%, p = 0.034), higher ECV (26.3% vs 25.1%, p = 0.049), and greater non-ischaemic fibrosis burden on LGE imaging (34% vs 26%), despite limited differences in LVMi, LVWT, and left atrial size. The prevalence of MRI phenotypes in both organs was higher with T2D (34% vs 21%, p = 0.04). Despite this, hepatic and cardiac phenotypes showed limited association. In the follow-up subgroup, relative weight change correlated with changes in LFC (r = 0.62, p < 0.001) and cT1 (r = 0.47, p < 0.001), whereas changes in cardiac MRI measures showed limited association with weight change. **Conclusion:** In adults with hypertension and T2D there was a high burden of adverse hepatic and cardiac MRI phenotypes that were not tightly coupled. This suggests shared metabolic drivers for disease in the liver and heart but heterogeneous organ expression, supporting the value of multi-organ imaging in characterisation of such organ-specific manifestations.

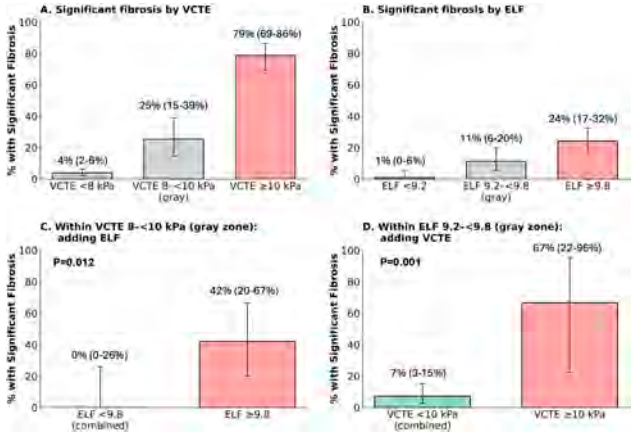
2444 | SEQUENTIAL TESTING REFINES THE DIAGNOSIS OF SIGNIFICANT FIBROSIS IN GRAY-ZONE VCTE AND ELF BUT IS UNNECESSARY FOR HIGH-RISK SINGLE CUT-POINTS IN MASLD



Veeral Ajmera[1] Luis Antonio Diaz[2] Egbert Madamba[1] Kaleb Tesfai[1] Rohit Loomba[1], [1]University of California, San Diego, [2]Pontificia Universidad Católica de Chile

Background: Non-invasive tests (NITs), including vibration-controlled transient elastography (VCTE) and the Enhanced Liver Fibrosis (ELF) score, are widely used to identify significant fibrosis in metabolic dysfunction–associated steatotic liver disease (MASLD), but whether single high cut-points suffice and whether gray-zone results benefit from a concordant second test is unclear. Using magnetic resonance elastography (MRE) as the reference standard for significant fibrosis, we evaluated diagnostic performance of VCTE and ELF and the incremental value of concordance. **Methods:** Adults at-risk for or with MASLD enrolled in a prospective cohort underwent same-visit VCTE, MRE, ELF, and labs. Significant fibrosis was defined as MRE ≥3.3 kPa. We computed prevalence of significant fibrosis within each NIT stratum at **low** (VCTE < 8kPa, ELF < 9.2), **gray** (VCTE 8–<10 kPa, ELF 9.2–<9.8) and **high** (VCTE ≥10 kPa, ELF ≥9.8) cut-points. Within each gray zone we further stratified by sequential use of the other NIT. **Results:** Among 858 adults with MRE (68% MASLD; median age 59 years, 61% female, 38% Hispanic, 59% T2DM), 156 (18%) had significant fibrosis (MRE ≥3.3 kPa). Among 555 with both VCTE and MRE, the prevalence of significant fibrosis by VCTE category was: **low** (VCTE < 8kPa): 4.0% (95% CI: 2.3–6.4%); **gray** (VCTE 8–<10kPa): 25.5% (95% CI: 14.7–39.0%); and **high** (VCTE ≥10kPa): 78.8% (95% CI: 69.4–86.4%). The prevalence of significant fibrosis by ELF category (n = 315) was: **low** (ELF <9.2): 1.1% (95% CI: 0–5.7%); **gray** (ELF 9.2–<9.8): 11.4% (95% CI: 5.6–19.9%); and **high** (ELF ≥9.8): 24.2% (95% CI: 17.2–32.5%). High single cut-points performed well alone: VCTE ≥10 kPa: sensitivity 72%, specificity 95%, PPV 79%, NPV 93% and ELF ≥9.8: sensitivity 74%, specificity 63%, PPV 24%, NPV 94%. Concordance added little to VCTE ≥10 (PPV 79% alone vs 81% concordant with ELF ≥9.8). Concordance substantially refined diagnosis within gray zones. Within gray zone VCTE adding ELF ≥9.8 increased the prevalence of significant fibrosis to 42.1% (20.3–66.5%) vs 0% (0–26%) for ELF <9.8, P = 0.012. Within gray zone ELF adding VCTE ≥10 kPa increased the prevalence of significant fibrosis to 66.7% (22.3–95.7%) vs 7.3% (2.7–15.2%) for VCTE <10 kPa, P = 0.001. **Conclusion:** In adults with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

MASLD, single high-risk cut-points, particularly VCTE ≥ 10 kPa, have high PPV for significant fibrosis and do not require a concordant second NIT. In contrast, gray-zone VCTE (8–< 10 kPa) and gray-zone ELF (9.2–< 9.8) benefit from a concordant second test, supporting a strategy of acting on high single-NIT cut-points alone, and reserving sequential testing for gray-zone results.

2445 | INVESTIGATING PRIMARY CARE MANAGEMENT OF PATIENTS WITH LIVER STEATOSIS ON ABDOMINAL IMAGING, STRATIFIED BY RISK FOR ADVANCED FIBROSIS

Rahul Sandella[1] Hee Yeon Kim[2] Christopher Kasia[1] Andrew Davis[1] Mary Rinella[1], [1]The University of Chicago, [2]The Catholic University of Korea

Background: Liver steatosis identified on imaging is often an incidental finding but can be an early clue to suspect a patient has metabolic dysfunction-associated steatotic liver disease (MASLD). Primary care doctors are regularly tasked with the initial evaluation of these patients. International guidelines suggest utilizing non-invasive tests like FIB-4 to stratify these patients by their advanced fibrosis risk and guide referral, evaluation, and management. The purpose of this study was to evaluate if the presence of hepatic steatosis on abdominal imaging led to augmented evaluation for advanced liver fibrosis in the primary care setting. **Methods:** We conducted a retrospective cohort study of 43,661 patients aged 35-70 years with a calculable FIB-4 score. Patients were seen between January 2018 and April 2026 at one of 28 primary care clinics within a large urban academic health system. Natural language processing on MDCLONE kiosk analytic software was used to analyze abdominal CT and ultrasound reports for mention of “steatosis”, “fatty”, or “echogenic”. In total, 2,470 patients with these liver imaging findings were included in the study. MDCLONE software also identified demographics, medication use, hepatology visits, fibrosis testing, and metabolic risk factors. We examined these variables across 3 tiers of FIB-4 using ANOVA and chi-squared testing. **Results:** Of 2,470 patients with evidence of hepatic steatosis on imaging, 70% were low risk, 21% moderate risk, and 9% high risk for advanced fibrosis based on FIB-4.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Demographics, laboratory values, and clinical management varied significantly across fibrosis categories (Table 1). The prevalence of diabetes was highest among patients in the highest risk fibrosis group ($p < 0.001$, 38%). Vibration controlled elastography score correlated with increasing FIB-4 culminating in mean 11.99 kPa in the high risk group. There was no difference in hepatology visits nor completed liver stiffness testing between fibrosis risk groups ($p = 0.37$, $p = 0.67$, respectively). The percentage of patients prescribed GLP-1 medications paradoxically decreased with higher FIB-4 ($p < 0.001$). Among high risk patients, the presence of steatosis on imaging did not increase the frequency of hepatology visits ($p = 0.75$). **Conclusion:** The majority of primary care patients with high risk for liver fibrosis and evidence of steatosis on imaging are not undergoing AASLD guideline-suggested management. Despite evidence of liver steatosis on imaging, overall 75% of high-risk FIB-4 patients have not had liver stiffness assessed nor been seen in hepatology. Targeted system-wide intervention is clearly needed to improve MASLD evaluation, referral, and management in the populations most at risk.

Table 1: Characteristics and management of primary care patients noted to have steatosis on imaging stratified by fibrosis risk categories

Parameters (Results are n (%) or mean (SD))	FIB-4 Category			P-value
	Low-risk FIB-4 < 1.3 if < 65 y FIB-4 < 2.0 if ≥ 65 y N=1,720	Intermediate-risk FIB-4: 1.3 - 2.66 if < 65 y FIB-4: 2.0 - 2.66 if ≥ 65 y N=534	High-risk FIB-4 ≥ 2.67 N=216

2446 | COMBINING BODY ROUNDNESS INDEX WITH FIB-4 IMPROVES FIBROSIS TRIAGE IN MASLD: A VCTE-CONFIRMED CROSS-SECTIONAL STUDY

Dogan Can Gavcar[1] Nilay Danis[2], [1]Izmir Atatürk Education and Research Hospital, [2]Dokuz Eylül University

Background: The Body Roundness Index (BRI) is a simple anthropometric measure that has shown value in detecting hepatic steatosis. However, its value in predicting clinically significant fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD) is unknown. This study evaluated: (I) BRI performance for liver stiffness measurement (LSM) ≥ 8 kPa in a vibration-controlled transient elastography (VCTE)-confirmed MASLD cohort; (II) whether BRI+FIB-4 improves fibrosis prediction over individual non-invasive scores; and (III) the correlation between BRI and the FAST score. **Methods:** This single-centre, cross-sectional study included 58 adults with VCTE-confirmed MASLD. Patients were classified according to the following kPa thresholds: < 8 ($n = 17$), 8–12 ($n = 24$), and > 12 kPa ($n = 17$). BRI was calculated from waist circumference and height. Kruskal–Wallis, Mann–Whitney U, Spearman correlation, logistic regression, and ROC analyses were performed. **Results:** BRI was numerically higher in the kPa ≥ 8 group (5.60 vs. 4.63, $p = 0.063$). BRI did not correlate with LSM ($r = 0.116$, $p = 0.384$) or FAST score ($r = 0.155$, $p = 0.245$). Neither BRI (AUC = 0.656, $p = 0.063$) nor FIB-4 (AUC = 0.664, $p = 0.051$) achieved significant individual ROC performance. The BRI+FIB-4 combined model achieved AUC =

0.726 (95% CI 0.579–0.873, p = 0.007), outperforming all individual blood-based scores. **Conclusion:** BRI alone was not a significant predictor of fibrosis severity and FAST-defined Metabolic Dysfunction-Associated Steatohepatitis (MASH) activity in this cohort. However, Its combination with FIB-4 improved the discrimination of significant fibrosis. and may be useful as a simple triage approach, especially in patients with intermediate LSM values.

Figure 2. Receiver Operating Characteristic (ROC) Curve Analysis of Blood-Based Fibrosis Scores and BRI + FIB-4 Combined Score for Prediction of Liver Stiffness ≥ 8 kPa

Area under the curve (AUC) comparison across individual and combined indices

AUC = area under the curve; CI = confidence interval; BRI = Body Roundness Index; FIB-4 = Fibrosis-4 Index; APRI = AST-to-Platelet Ratio Index; NFS = NAFLD Fibrosis Score; BARD = BMI, AST/ALT ratio, Diabetes score. ROC curves are estimated from reported AUC values using a parametric approximation. While BRI and FIB-4 individually did not reach statistical significance (p > 0.05), their combined score achieved significant discriminative performance (AUC = 0.726, p = 0.007). * Statistically significant at p < 0.05.

2447 | COMPARATIVE PERFORMANCE OF NONINVASIVE TESTS FOR HISTOLOGIC SEVERITY IN A NORTH TEXAS TERTIARY COHORT WITH MASH

Jeevin Sandhu[1] Zixin Zeng[1] Simran Joshi[2] Kinnari Modi[1] Ashwini Mehta[1] Mangesh Pagadala[1] Parvez Mantry[1], [1]Methodist Dallas Medical Center, [2]Yale New Haven Health

Background: Liver biopsy remains the standard for assessment of disease severity in metabolic dysfunction-associated steatohepatitis (MASH), but non-invasive tests (NITs) are increasingly used in routine care. Real world comparative data evaluating how commonly used NITs relate to histologic severity remain limited. We evaluated the performance of serum and elastography based NITs against biopsy severity in a tertiary MASH cohort. **Methods:** We performed a retrospective analysis of 450 adults with MASH from a North Texas tertiary care cohort. Histologic severity was assessed using Brunt severity and NAFLD activity score (NAS). Available NITs included Fibrosis-4 (Fib-4), FibroScan liver stiffness measurement (kPa), controlled attenuation parameter (CAP), FibroScan fibrosis stage, FibroSure fibrosis stage, FibroSure NASH grade, enhanced liver fibrosis (ELF), and initial LIVERFASt fibrosis, steatosis, and activity scores. Continuous variables underwent variable specific outlier trimming using a 3×IQR Tukey approach. Associations between NITs and histologic severity were assessed using Spearman rank correlation. Receiver operating characteristic (ROC) analysis was performed for advanced Brunt severity. **Results:** Liver biopsy was available in 272/450 patients (61.1%). Among biopsy linked analyses, Brunt severity correlated with NAS (rho = 0.313, p < 0.001), baseline FibroScan kPa (rho = 0.312, n = 111, p = 0.0013), Fib-4 (rho = 0.210, n = 224, p = 0.0015), FibroSure NASH grade (rho = 0.351, n = 67, p = 0.003), and FibroScan fibrosis stage (rho = 0.255, n = 104, p = 0.008). CAP did not significantly correlate with Brunt severity. For advanced Brunt severity, FibroSure fibrosis stage showed the highest discriminatory performance among available NITs (AUC 0.709), followed by baseline FibroScan kPa (AUC 0.693) and Fib-4 (AUC 0.620), while CAP showed no meaningful discrimination (AUC 0.494). Correlations involving ELF and LIVERFASt were limited by smaller sample sizes and did not demonstrate robust histologic association in the available subsets. **Conclusion:** In this North Texas tertiary MASH cohort, FibroSure fibrosis stage and FibroScan liver stiffness showed the strongest overall performance for histologic severity, while Fib-4 demonstrated a more modest but still significant association with biopsy-based disease severity. CAP showed limited histologic discrimination in this cohort. These findings suggest that fibrosis-oriented NITs more closely reflect biopsy severity than steatosis focused measures in real-world MASH practice.

Noninvasive test	Biopsy linked n	Spearman rho vs Brunt severity	p-value	AUC for advanced Brunt severity
FibroSure fibrosis stage	73	0.285	0.0147	0.709
Baseline FibroScan kPa	103	0.312	0.0013	0.693
Fib-4	224	0.210	0.0015	0.620
FibroSure NASH grade	68	0.351	0.0033	0.647
FibroScan fibrosis stage	108	0.255	0.0077	0.685
CAP	98	-0.070	0.492	0.494

Table 1. Comparative performance of noninvasive tests for histologic severity in a North Texas tertiary MASH cohort.

2448 | ASSOCIATION OF NONINVASIVE PARAMETERS WITH HISTOLOGICAL SCORES AND A DIAGNOSTIC MODEL FOR MASH IN BIOPSY-CONFIRMED MASLD

Sidan Fu[1] Ke Yang[1] Li Liu[1] Yu Lei[1], [1]The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent, yet noninvasive identification of metabolic dysfunction-associated steatohepatitis (MASH) and advanced fibrosis remains challenging. We aimed to evaluate the association of clinical and noninvasive parameters with liver histology and develop a practical MASH prediction model in a biopsy-confirmed MASLD cohort. **Methods:** This retrospective study included 106 patients with biopsy-confirmed MASLD from 2018 to 2026. Clinical data were collected, including demographic and medical history, blood routine, serum biochemical indicators, urine routine, abdominal imaging, liver controlled attenuation parameter (CAP), liver stiffness value (LSM), FIB-4, MASLD fibrosis score (NFS). Histological steatosis, ballooning, lobular inflammation, NAFLD activity score (NAS), and fibrosis stage were scored. Ordinal logistic regression was used to identify independent factors for each histological component. Binary logistic regression was used to construct a diagnostic model for definite MASH (histologically defined by steatosis, lobular inflammation, and ballooning, with NAS $\geq$ 5) and high-risk MASH (definite MASH + significant fibrosis F $\geq$ 2). Model performance was assessed by AUROC. **Results:** On multivariate ordinal analysis, ALT (OR 1.013, P = 0.024) and CAP (OR 1.018, P = 0.013) were independent risk factors for steatosis grade. Age (OR 1.095, P = 0.005) and negative urine glucose (OR 0.095, P = 0.041) were independently associated with ballooning grade. Fasting glucose, ALT, CAP, and LSM were independently associated with NAS total score (all P < 0.05). For fibrosis stage, platelet count (OR 0.995, P = 0.023) was a protective factor and LSM (OR 1.134, P < 0.001) a risk factor. Male sex was independently protective against severe MASLD (OR 0.324, P = 0.026), while LSM remained a risk factor (OR 1.120, P = 0.005). FIB-4 correlated better with fibrosis stage than NFS (r_s = 0.338 vs 0.241). For MASH diagnosis, the model combining CAP and LSM achieved an AUROC of 0.742 (sensitivity 93.1%, specificity 51.1%). For high-risk MASH, LSM alone yielded an AUROC of 0.814 (optimal cutoff 9.45 kPa, sensitivity 82.4%, specificity 69.2%). Both models demonstrated good calibration and clinical net benefit. **Conclusion:** LSM and CAP are core noninvasive indicators reflecting histological injury in MASLD. Abnormal liver function effectively indicates disease activity. FIB-4 is superior to NFS for fibrosis assessment. The proposed MASH and high-risk MASH models show good discrimination and clinical utility, supporting their use for early screening and risk stratification in clinical practice.

2449 | CAP SCORE VARIATION ACROSS CARDIOMETABOLIC AND RACIAL SUBGROUPS IN A U.S. MASLD COHORT: DOES RACE MODIFY THE METABOLIC LIVER DISEASE BURDEN?

Alfred Barritt IV[1] Melissa Estevez[2] Nate Nussbaum[2] Sriram Krishnan[2] Laney Bowden[2] Elizabeth Verna[3] Coleman Smith[4] TARGET-LD investigators[2] Michael Fried[2], [1]The University of North Carolina at Chapel Hill, [2]Pedestal Health, [3]Columbia University Vagelos College of Physicians and Surgeons, [4]MedStar Georgetown Transplant Institute

Background: FibroScan Vibration Controlled Transient Elastography (VCTE) has emerged as a noninvasive, cost-effective alternative to liver biopsy for quantifying hepatic fibrosis and steatosis in metabolic dysfunction associated steatotic liver disease (MASLD)/metabolic dysfunction-associated steatohepatitis (MASH), simultaneously measuring liver stiffness (LSM) and the Controlled Attenuation Parameter (CAP). Existing studies of CAP in relation to cardiometabolic comorbidity have been conducted predominantly in non-U.S. cohorts with limited racial and ethnic diversity, leaving unanswered whether insulin-resistance-defining conditions (IR-defining) differentially affect steatosis severity across race and ethnicity groups. **Methods:** Patients with a diagnosis of MASLD/MASH were selected from the Pedestal Health multi-center EHR-derived database, and VCTE test results between first ICD diagnosis code up to July 31, 2025 were extracted using artificial intelligence/ large language models (LLMs). LLM accuracy was benchmarked against human abstraction performance, both measured against a reference standard. Adults with at least one VCTE test following the first MASLD/MASH diagnosis code were included. Annual VCTE testing volume was tracked over time. Hepatic steatosis severity

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

by CAP score was stratified by LSM-defined fibrosis stage (F0–F1 <8 kPa, F2 8–10 kPa, F3–F4 ≥10 kPa), race/ethnicity, and cardiometabolic condition type (IR-defining [obesity and/or T2DM] vs. non-IR-defining [hypertension and/or dyslipidemia only]). To evaluate whether race/ethnicity modifies the association between IR-defining cardiometabolic conditions and CAP score, we fit an unadjusted linear regression model with a multiplicative interaction term. **Results:** In a test set of 357 patients, the LLM had slightly lower completeness for VCTE test date relative to human abstraction (84% vs. 94%). LLM accuracy for extracting the correct VCTE test date (+/- 15 days), LSM result and CAP score was on par with human performance (within 4% of human accuracy). In a cohort of 3383 MASH/MASLD patients, testing volume increased from 454 tests in 2021 to 1278 tests in 2024. Stratified analyses found lower CAP scores among patients with minimal fibrosis (F0-F1), Non-Hispanic Black (vs. White), and patients without IR-defining comorbidities (Table 1). The interaction between race and insulin-resistance-defining cardiometabolic conditions was non-significant. **Conclusion:** FibroScan use is increasing in clinical practice. AI is a viable tool for extracting LSM and CAP values from unstructured text in the EHR for real world research. CAP score distributions across subgroups were broadly consistent with clinical expectations. The relationship between IR-defining condition and hepatic steatosis severity persisted across race/ethnicity groups in the study population.

Table 1. CAP Distribution by Subgroup

Subgroup	CAP Score median, (IQR)
F0-F1 (No/Minimal)	285 (244, 323)
F2 (Intermediate)	303 (267, 340)
F3-F4 (Advanced)	306 (266, 343)
IR-defining (Obesity and/or T2DM)	298 (259, 334)
Not IR-defining	272 (233, 309)
NH White	294 (254, 332)
NH Black	288 (244, 321)
Hispanic	289 (251, 322)
Other	296 (258, 334)

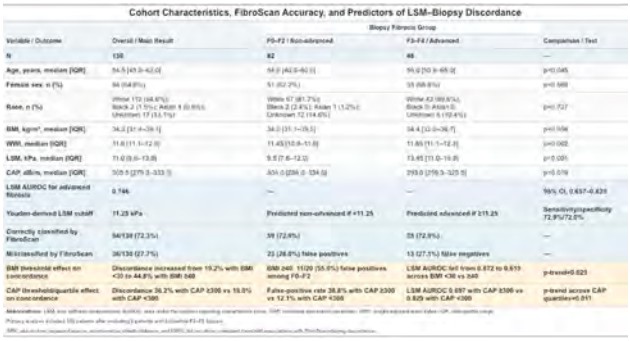
2450 | STEATOSIS BURDEN AND SEVERE OBESITY ARE ASSOCIATED WITH FIBROSCAN–BIOPSY DISCORDANCE IN MASLD



Krishna Venkata[1] Hussein Harb[1] Fabian Rodas[1] Eric Lawitz[1], [1]Texas Liver Institute

Background: Liver stiffness measurement (LSM) by FibroScan may over-stage fibrosis in some patients with metabolic dysfunction–associated steatotic liver disease (MASLD), but factors contributing to FibroScan–biopsy discordance are not well defined. We evaluated the performance of LSM for biopsy-confirmed advanced fibrosis in MASLD and examined whether adiposity, steatosis burden, ultrasound body-habitus measures, or measurement reliability were associated with discordance. **Methods:** We prospectively analyzed patients with MASLD who underwent paired FibroScan and liver biopsy. Advanced fibrosis was defined as METAVIR F3–F4 and non-advanced fibrosis as F0–F2; borderline F2–F3 cases were excluded. LSM discrimination for advanced fibrosis was assessed using AUROC and a Youden-derived cutoff. Discordance was defined as disagreement between LSM-predicted and biopsy-confirmed advanced fibrosis. Candidate predictors included controlled attenuation parameter (CAP), body mass index (BMI), weight-adjusted waist circumference index (WWI), skin-to-liver capsule distance, skin-to-rectus sheath distance, and LSM IQR%. **Results:** The MASLD cohort included 130 patients: 82 with non-advanced fibrosis and 48 with advanced fibrosis. LSM demonstrated moderate discrimination for advanced fibrosis (AUROC 0.746; 95% CI, 0.657–0.835), with an optimal cutoff of 11.25 kPa. Overall, 94 patients were correctly classified and 36 (27.7%) were discordant. Discordance was driven predominantly by false-positive LSM overestimation. Compared with concordant patients, discordant patients had higher CAP values and BMI ≥40 kg/m², whereas WWI and ultrasound-depth measures were not significantly different. Discordance increased across BMI categories, reaching 44.8% among patients with BMI ≥40 kg/m², where LSM discrimination was lowest. Discordance was also higher among patients with CAP ≥300 dB/m. Across ordered strata, discordance increased with both BMI category and CAP quartile, but not with WWI, skin-to-liver distance, skin-to-rectus distance, or IQR%. In parsimonious multivariable models, CAP remained independently associated with discordance after adjustment for WWI and ultrasound-depth measures, whereas the association between BMI and discordance attenuated after CAP adjustment. **Conclusion:** In this biopsy-paired MASLD cohort, FibroScan LSM showed moderate accuracy for advanced fibrosis, but more than one-quarter of patients were discordantly

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

classified. Discordance was driven mainly by false-positive LSM overestimation and was most consistently associated with higher CAP and severe obesity. WWI and ultrasound body-habitus measures provided limited additional explanatory value. Elevated LSM values in patients with MASLD, particularly those with marked steatosis or class III obesity, may warrant confirmatory testing before upstaging fibrosis severity.

Cohort Characteristics, FibroScan Accuracy, and Predictors of LSM–Biopsy Discordance

		Biopsy Fibrosis Group		
Variable / Outcome	Overall / Main Result	F0–F2 / Non-advanced	F3–F4 / Advanced	Comparison / Test
N	130	82	48	—
Age, years, median [IQR]	54.5 [45.0–62.0]	54.0 [42.0–60.0]	55.0 [50.0–65.0]	p=0.045

2451 | AST-ASSOCIATED INFLAMMATORY ACTIVITY CONTRIBUTES TO DISCORDANT FIBROSIS ESTIMATION IN SUSPECTED MASH POPULATION

Joseph Scaravalle[1] Nicholas Kruzdlo[1] Stephanie Oliveros-Diaz[1] Elisabeth Verwest[1] Lily Lu[1] Kirsten Hobson[1] Cameron Rolph[1] Isabelle Crotsley[1] Raymond Bell[1] Yovanni Rosario[1] Guy Neff[1], [1]Covenant Metabolic Specialists, LLC

Background: Transient elastography–derived liver stiffness measurement (LSM) is widely used to noninvasively stage fibrosis in metabolic dysfunction–associated steatohepatitis (MASH), though hepatocellular injury and inflammation may elevate LSM independent of fibrosis. While this effect is recognized in other liver diseases, its significance and relevant transaminase thresholds in MASH remain unclear. We aimed to determine whether transaminase elevation independently increases FibroScan LSM in suspected MASH and identify AST and ALT thresholds at which inflammation significantly confounds interpretation. **Methods:** 162 patients with suspected MASH (elevated transaminases and/or imaging steatosis/fibrosis) who underwent FibroScan prior to liver biopsy were analyzed. Multivariable linear regression assessed associations between continuous transaminase elevations and liver stiffness measurement (LSM), adjusting for age, sex, BMI, fibrosis stage, and steatosis grade. Sensitivity analyses evaluated AST thresholds of 50/60/70/80/85/90 IU/L and ALT thresholds of 80/90/100 IU/L. Analyses were repeated excluding F4 patients to isolate inflammation-related effects in F0 to F3 disease (n = 126). Fibrosis overestimation was defined as LSM-predicted stage exceeding histology, with cutoffs of 7/8.5/10.5/14 kPa for F1/F2/F3/F4. Multivariable logistic regression evaluated associations between AST elevation and fibrosis overestimation while controlling demographic and histologic factors. **Results:** In the full F0 to F4 cohort, neither continuous nor threshold transaminase values were independently associated with liver stiffness after adjustment. After excluding cirrhosis (F4), higher AST thresholds (AST $\geq$ 60, 70, 80, 85) showed a stepwise association with increased LSM, whereas AST $\geq$50 and $\geq$90 were not significant. Continuous AST was also significantly associated with LSM in this subgroup; however, ALT thresholds and continuous ALT were not significant. Higher AST thresholds were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

associated with increased odds of fibrosis overestimation, with significant effects at AST ≥80 and ≥85. Lower AST thresholds and continuous AST values were not significant predictors of overestimation. **Conclusion:** AST elevation independently increases liver stiffness measurements in noncirrhotic MASH, with AST ≥80 IU/L associated with approximately 3.0 kPa higher LSM and increased risk of fibrosis overestimation. The non-significant result at AST ≥90 likely reflects limited power (n = 7) rather than a true threshold ceiling. This effect was greatest in F0 to F3 disease, suggesting inflammation contributes more to LSM at lower fibrosis stages. ALT was not associated with increased LSM. In patients with AST ≥80, FibroScan results should be interpreted with caution and may warrant repeat measurement after transaminase normalization.

Multivariable Linear Regression (F0-F4 pop.) (Table 1)

Total n	AST Threshold	n(≥Threshold)	p-value	Coefficient (β)	95% Confidence Interval

2452 | LIVERSCAN VS. MRI: A PILOT STUDY OF A NOVEL PORTABLE VCTE DEVICE

Zhuoru Jiang[1] Zihao Huang[2] Yongping Zheng[2] Jie Li[1], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, [2]The Hong Kong Polytechnic University

Background: Vibration-controlled transient elastography (VCTE) is widely used for liver fibrosis assessment. While the diagnostic accuracy of standard VCTE, particularly Fibroscan, has been extensively compared to magnetic resonance elastography (MRE), Liverscan is a novel, portable, phased array transducer-based VCTE system whose diagnostic performance remains to be rigorously validated. This study aimed to perform a head-to-head comparison between this novel portable VCTE device vs. the MRE for liver stiffness measurement and Liverscan-derived multi-domain attenuation parameter (MAP) vs. MRI-proton density fat fraction (PDFF) for fat measurement, specifically investigating physiological factors driving measurement discordance. **Methods:** We performed a cross-sectional analysis of 81 participants, including 49 metabolic dysfunction-associated steatotic liver disease (MASLD) patients and 32 healthy controls (HC), who underwent concurrent liver stiffness measurement (LSM) using the portable Liverscan (Eieling Technology Limited, Hong Kong, China) and MRE (uPMR 790, United Image, Shanghai, China). Liver fat quantification was also compared between the Liverscan-derived MAP and MRI-PDFF. Agreement was assessed using Spearman's correlation. **Results:** The correlation between LSM by Liverscan and MRE was significant (r_s = 0.62, $p < 0.001$). Similarly, liver fat quantification demonstrated strong concordance with MRI-PDFF (r_s = 0.84, $p < 0.001$). Importantly, this diagnostic performance was sustained in the MASLD subgroup, where LiverScan maintained significant correlations with MRE for stiffness (r_s = 0.69, $p < 0.001$) and with MRI-PDFF for fat quantification (r_s = 0.66, $p < 0.001$). **Conclusion:** Liverscan demonstrates robust diagnostic concordance with MRE and MRI-PDFF, providing a reliable point-of-care solution for the simultaneous assessment of liver fibrosis and steatosis. However, due to the limited sample size and heterogeneous etiologies of participants, the results are preliminary and inconclusive. Future research should compare the diagnostic accuracy of MRI-based techniques against Liverscan for the diagnosis of liver fibrosis and steatosis using histology as the reference standard.

2453 | ARTIFICIAL INTELLIGENCE-BASED PREDICTION OF HEPATOCELLULAR CARCINOMA IN INDIVIDUALS WITHOUT HBV OR HCV INFECTION IN THE MASLD ERA

Young Seok Kim[1], [1]Soon Chun Hyang University

Background: Current surveillance guidelines for hepatocellular carcinoma (HCC) focus on individuals with liver cirrhosis or viral hepatitis. This study aimed to develop an artificial intelligence (AI)-based model to predict HCC risk in individuals without viral hepatitis. **Methods:** Using the South Korean National Health Insurance Service (NHIS) database, we retrospectively analyzed 7,961,075 individuals aged 20 to 79 years who underwent health screening in 2017 and were followed through 2023. Twelve AI models, including deep learning and machine learning algorithms, were trained and validated using a 7: 3 split. **Results:** The Multi-Head Attention with Deep Neural Network (MHA_DNN) model demonstrated the highest predictive performance (AUC 0.9385, 95% confidence interval [CI]: 0.9312–0.9455) and was selected as the final model. Risk stratification based on predicted probabilities showed a significantly higher incidence of HCC in the High and Extremely High-Risk groups compared to the Low-Risk group (hazard ratio [HR] 11.08 and 91.09, respectively; both $P < 0.001$). SHAP analysis identified the fatty liver index (FLI) and triglyceride (TG) as key factors for predicting HCC. In individuals with FLI < 60, TG ≥ 150 mg/dL was a significant risk factor for HCC (HR 1.14, 95% CI 1.04–1.25), whereas in those with FLI ≥ 60, higher TG levels were associated with a markedly reduced HCC risk (HR 0.27, 95% CI 0.25–0.29). **Conclusion:** We developed a robust AI model for predicting HCC risk in an HBV/HCV-negative general population. FLI and TG emerged as major predictors, supporting the use of metabolic indicators for personalized surveillance in the era of MASLD.

Background: Chronic liver disease (CLD) is rapidly increasing worldwide, largely driven by the growing epidemics of obesity, diabetes, and alcohol consumption. China, which has the world's largest population affected by these conditions, lacks prospective, community-based data to estimate the true burden of CLD. We aimed to determine the prevalence of liver fibrosis and steatotic liver disease (SLD) and identify their associated factors among community-dwelling adults in China. **Methods:** This prospective, community-based, investigator-initiated cohort study (the LiverHealth project) was conducted at 18 sites across 13 provincial-level administrative regions in China between September 2024 and January 2026. Participants were recruited from the general community rather than through clinical referrals or health check-ups, guided by local age- and sex-specific population distributions to enhance representativeness. Adults aged 18 years or older underwent vibration-controlled transient elastography. The primary outcome was the prevalence of significant fibrosis (liver stiffness measurement [LSM] $\geq$ 8 kPa). Secondary outcomes included the prevalence of advanced fibrosis (LSM $\geq$ 12 kPa), SLD (controlled attenuation parameter $\geq$ 248 dB/m), and SLD spectrum —metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic and alcohol related/associated liver disease (MetALD), and alcohol-associated/related liver disease (ALD). Factors associated with fibrosis and SLD were assessed using mixed-effects logistic regression. **Results:** Of 25805 community-dwelling adults enrolled (median age 51.0 years; 44.9% men), 4.4% had significant fibrosis and 0.8% had advanced fibrosis. SLD was present in 43.7% of participants, with MASLD in 39.4%, MetALD in 2.0%, and ALD in 1.6%. The highest prevalences of significant fibrosis were observed in individuals with obesity (10.6%) and diabetes (10.4%). In multivariable analyses, male sex, older age, overweight or obesity, central obesity, prediabetes or diabetes, hypertension, dyslipidaemia, and an increasing number of cardiometabolic risk factors were independently associated with both steatosis and fibrosis. Heavy alcohol consumption was independently associated with significant fibrosis and was consistently linked to higher fibrosis prevalence across all cardiometabolic and chronic viral hepatitis subgroups, with no significant interaction between alcohol and any individual risk factor (all $p > 0.05$; Figure 1). **Conclusion:** Liver fibrosis and SLD are highly prevalent in community-dwelling Chinese adults, driven by metabolic factors and alcohol consumption. The 4.4% prevalence of significant fibrosis corresponds to nearly 49 million adults in China. Identifying these individuals at an early stage offers a critical opportunity to deliver targeted interventions and curb the progression to cirrhosis and hepatocellular carcinoma.

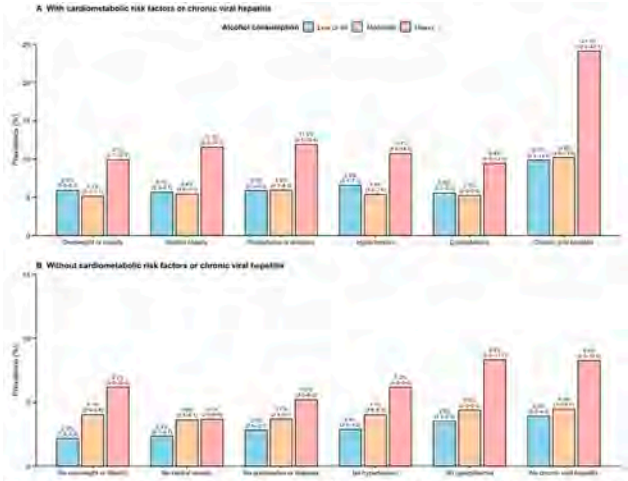

Figure 1. Prevalence of significant fibrosis (LSM ≥8 kPa) by alcohol consumption across cardiometabolic and chronic viral hepatitis subgroups

(A) Prevalence of significant fibrosis by alcohol consumption category among individuals with each cardiometabolic risk factor or chronic viral hepatitis. (B) Prevalence of significant fibrosis by alcohol consumption category among individuals without each cardiometabolic risk factor or chronic viral hepatitis. Data are presented as % (95% CI). Alcohol consumption was categorized as low or no (≤30 g/day for men and ≤20 g/day for women), moderate (>30-60 g/day for men and >20-50 g/day for women), and heavy (>60 g/day for men and >50 g/day for women), corresponding to MASLD, MetALD, and ALD criteria in the multi-society nomenclature, respectively. LSM=liver stiffness measurement. CI=confidence interval. MASLD=metabolic dysfunction-associated steatotic liver disease. MetALD=metabolic and alcohol related/associated liver disease. ALD=alcohol-associated/related liver disease.

2455 | ◆ TRANSITION FROM CHRONIC VIRAL HEPATITIS TO METABOLIC PREDOMINANCE IN LIVER FIBROSIS IN CHINA: A PROSPECTIVE COMMUNITY-BASED STUDY

Shanghao Liu[1] Yilin Zhang[1] Xibin Liu[2] Lan Ma[3] Yuxia Qi[4] Yang Bo[5] Ruyu Liu[6] Yijun Tang[7] Yan Yang[8] Guo Zhang[9] Huizhen Fan[10] Tingting Bian[11] Xiao Liang[12] Hui Yang[13] Kunyu Ke[14] Haiying Feng[2] Yiwei Shen[1] Diya Lu[3] Kun Xu[4] Jing Wang[5] Chuanchun Mao[6] Zhongji Meng[7] Junhong Yang[8] Wenjuan Wang[9] Jianwen Sheng[10] Zhaowei Tong[11] Yongfen Zhu[12] Yajuan Zhao[13] Junchao Zhang[14] Wenhong Zhang[14] Gao-Jun Teng[1] Aleksander Krag[15] Xiaolong Qi[1], [1]Zhongda Hospital, School of Medicine, Southeast University, [2]People's Hospital of Huanghua, [3]Bozhou People's Hospital, [4]Qingdao Public Health Clinical Center, [5]General Hospital of Ningxia Medical University, [6]Beijing Ditan Hospital, Xuzhou Hospital, Capital Medical University, [7]Taihe Hospital, Hubei University of Medicine, [8]Baiyin Central Hospital, [9]Guangxi Hospital Division of The First Affiliated Hospital, Sun Yat-sen University, [10]Yichun People's Hospital, [11]Huzhou Central Hospital, Affiliated Central Hospital, Huzhou University, [12]Sir Run-Run Shaw Hospital, Zhejiang University School of Medicine, [13]The Second Affiliated Hospital of Guangzhou Medical University, [14]Mengchao Hepatobiliary Hospital of Fujian Medical University, [15]Odense University Hospital

Background: Chronic viral hepatitis has historically been the dominant cause of chronic liver disease in China. However, rapid increases in metabolic dysfunction and alcohol consumption, alongside declining viral hepatitis prevalence, may be reshaping the aetiological landscape of liver fibrosis. Robust population-based evidence quantifying this transition remains limited. We aimed to characterise the contemporary aetiological distribution of liver fibrosis in China, with a focus on the relative contributions of metabolic dysfunction, chronic viral hepatitis, and harmful alcohol consumption. **Methods:** In this large, prospective, community-based cohort study (the LiverHealth project), adults aged ≥18 years were recruited across 13 sites in 12 provincial-level administrative regions in China between December 2024 and January 2026. All participants underwent standardised serological testing for hepatitis B virus and hepatitis C virus, structured assessment of alcohol consumption, comprehensive metabolic dysfunction evaluation, and vibration-controlled transient elastography for liver fibrosis assessment. Participants were classified into four mutually exclusive aetiological groups using a hierarchical framework: chronic viral hepatitis, harmful alcohol consumption, metabolic dysfunction, and no major aetiological factor identified. The primary outcome was the aetiological distribution of significant fibrosis (liver stiffness measurement ≥8 kPa). **Results:** We enrolled 17610 participants (median age 50.0 years; 43.2% male). Metabolic dysfunction accounted for the largest proportion of significant fibrosis cases (69.5%, 95% CI 65.9-72.8), substantially exceeding the contributions of chronic viral hepatitis (14.0%, 11.6-16.8) and harmful alcohol consumption (13.3%, 10.9-16.0). The relative contribution of metabolic dysfunction was greater in women and older adults, whereas harmful alcohol consumption contributed more in men and younger individuals (Figure 1). Across all aetiological groups, obesity (adjusted odds ratios 3.41-5.44), severe central obesity (3.58-6.54), and diabetes (2.26-4.67) were independently associated with significant fibrosis. Coexistence of metabolic dysfunction markedly increased fibrosis prevalence among individuals with chronic viral hepatitis or harmful alcohol consumption. **Conclusion:** Metabolic dysfunction has emerged as the predominant driver of liver fibrosis in China. Metabolic risk factors—particularly obesity and diabetes—consistently increase fibrosis risk across underlying aetiologies. These findings underscore the need for integrated

metabolic health strategies and support the incorporation of liver fibrosis screening into community-based chronic disease management programmes to prevent progression to cirrhosis and hepatocellular carcinoma.

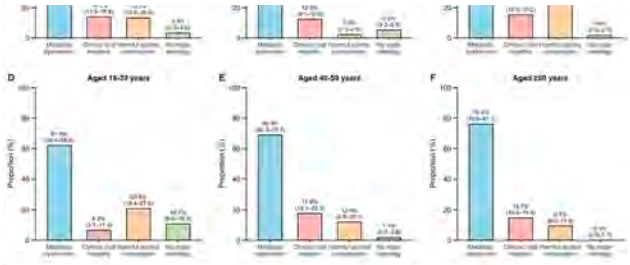

Figure 1. Aetiological distribution of significant fibrosis (LSM ≥8 kPa) overall and by sex and age

(A) Overall population; (B) female; (C) male; (D) participants aged 18-39 years; (E) participants aged 40-59 years; (F) participants aged ≥60 years. 2456 | ◆ HOW ARE PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH) MANAGED IN THE REAL WORLD? A DESCRIPTIVE ANALYSIS OF DIAGNOSTIC TESTING, TREATMENT, AND MONITORING IN US ADMINISTRATIVE CLAIMS

Christopher Bell[1] Guillaume Germain[2] Hannah Mei[3] Patricia Juliao[4] Patrick Gravelle[2] Sophie Ma[2] Jessica Abou Shaar[2] François Laliberté[2], [1]GSK, Durham, NC, USA, [2]Groupe d'analyse SRI, Montréal, QC, Canada, [3]GSK, Collegeville, PA, USA, [4]GSK, Philadephia, PA, USA

Background: Metabolic dysfunction-associated steatohepatitis (MASH) affects ~17 million US adults, yet <5% carry a coded diagnosis. Fibrosis stage predicts liver-related events and mortality, and fibrosis regression assessed by non-invasive tests (NITs) is a key predictor of clinical benefit. Guidelines recommend at-risk patient identification, diagnosis, NIT-based fibrosis staging, specialist referral, treatment, and ongoing fibrosis monitoring, yet real-world pathway completion is limited. We conducted a retrospective analysis to characterize patients with MASH and assess diagnostic, treatment, and monitoring patterns. **Methods:** This retrospective cohort study used claims from Komodo Health Research Database (>230 million US patients). Adults with MASH (K75.81; ≥1 inpatient or ≥2 outpatient claims) or a resmetirom claim without a MASH diagnosis were identified (Jan 2017 to July 2025). Index date was the earliest qualifying diagnosis/pharmacy claim. Cohorts included incident (no MASH claim 12 months pre-index) and prevalent (prior MASH claim) patients. At least 12 months of continuous enrollment pre- and post-index were required, and patients with non-MASH liver disease were excluded. Outcomes included demographics, comorbidities, medication history, diagnostic testing, specialist visits, treatment, and costs (2025 US$). **Results:** In total, 108,856 adults were included (incident: 78.5%; prevalent: 21.5%). Mean (SD) age was 55.8 (13.7) years, 55.2% of patients were female and 55.7% were commercially insured. Comorbidities included hypertension (61.8%), hyperlipidemia (54.6%), type 2 diabetes (43.2%), obesity (40.8%), and cirrhosis (12.4%) (Table). Fibrosis-specific testing was low in the observation period: VCTE (7.2%), MRE (0.5%), and liver biopsy (4.6%). While components of serum-based fibrosis scores were identifiable, full panel completion was limited: (FIB-4: 20.8%; APRI: 21.1%; Agile 3+/4: 25.1%; NFS: 17.8%; ELF: 0.1%). General metabolic testing was common (comprehensive metabolic panel: 82.8%), suggesting patients were metabolically monitored but rarely fibrosis assessed. Overall, 36.4% of patients saw a gastroenterologist and 3.7% saw a hepatologist post-index, an increase from pre-index levels. MASH-directed pharmacotherapy was rare (resmetirom: 0.1%; semaglutide: 6.9%; note: study period largely preceded MASH-specific approval). Mean (SD) total costs were $24,735 ($44,651), rising to $43,976 ($68,680) with cirrhosis — a 78% increase. **Conclusion:** In >100,000 US patients with MASH, there was limited fibrosis-specific testing, specialist visits, and use of MASH-specific therapy, indicating gaps in care. As therapies with direct antifibrotic mechanisms become available, closing these gaps will ensure patients are staged, treated, and managed according to fibrosis-direct goals.

2457 | ◆ THE MASLD ACCESS PENALTY: FRAILTY TOLERANCE AND 90-DAY WAITLIST OUTCOMES ACROSS STEATOTIC LIVER DISEASE PHENOTYPES IN 44,935 UNOS CANDIDATES

Islam Mohamed[1] Mohamed Nadeem[2] Basil Jalamneh[2] Mohamad Ali Ibrahim[3] Prasun Jalal[3], [1]The Cleveland Clinic Foundation-Fairview hospital, [2]Cleveland Clinic Foundation, [3]Baylor College of Medicine

Background: Karnofsky Performance Status (KPS) is the only frailty surrogate collected nationally in UNOS, yet whether the transplant system applies consistent functional thresholds across steatotic liver disease (SLD) phenotypes and whether the prognostic weight of functional impairment differs by etiology is unknown. We hypothesized that frailty tolerance at listing would vary across ALD, MetALD, and MASLD, with differential consequences for waitlist mortality and transplant access. **Methods:** We analyzed OPTN/UNOS STAR data (2017–2023), classifying 44,935 adults at 117 centers as ALD (n = 7,319), MetALD (n = 20,494), or MASLD (n = 17,122) using the validated SLD algorithm. Center-level KPS clustering was quantified by ICC from a multilevel mixed-effects model; Spiegelhalter over-dispersion-adjusted funnel plots identified outlier centers. 90-day waitlist death/too-sick removal and transplant were modeled as competing risks using Fine-Gray regression adjusted for MELD-Na, demographics, and insurance. Phenotype-stratified Fine-Gray models examined whether outcome associations differed by etiology; a multilevel cause-specific Cox model decomposed patient vs. centers contributions to observed disparities. **Results:** KPS at listing was lower in MetALD (55.5 ± 21.6) and ALD (55.3 ± 20.7) than MASLD (59.6 ± 19.5; $p < 0.001$), despite higher MELD in MetALD (23.4) and ALD (22.8) versus MASLD (19.1). Center membership explained 21.8% of KPS variance after case-mix adjustment (ICC = 0.218). Medicare and Medicaid patients listed with 2.6–2.7 fewer KPS points than privately insured patients, independent of disease severity ($p < 0.001$). Despite lower KPS and higher MELD at listing, MetALD achieved the highest 90-day transplant access (47.8%) and lowest mortality (5.5%), while MASLD with the best KPS at listing had the lowest access (34.7%) and highest mortality (6.4%; Gray's $p < 0.001$). In adjusted models, MetALD carried significantly lower mortality than MASLD (sHR 0.79, 95% CI 0.71–0.87); ALD did not differ significantly (sHR 0.94). Hispanic candidates had 23% lower transplant access (sHR 0.77) and Black candidates 25% higher mortality (sHR 1.25), independent of phenotype. Black and Medicare mortality disparities were fully robust to center clustering, reflecting patient-level inequities. Hispanic transplant and Medicaid access disparities were largely explained by where patients listed. **Conclusion:** MetALD and ALD candidates list with worse functional status yet achieve superior waitlist outcomes compared to MASLD, demonstrating that the transplant system is more tolerant of functional impairment in ALD. MASLD candidates face a systematic access penalty: a paradox of withheld urgency despite relatively preserved KPS. Center-level KPS variation is clinically meaningful and contributing independently to insurance-based listing disparities across the SLD spectrum.

2458 | ◆ ALCOHOL USE DISORDER AND STEATOTIC LIVER DISEASE ARE COMMON IN RURAL INDIA-A CROSS SECTIONAL POPULATION-BASED STUDY

Anand Kulkarni[1] Sridevi Prasanna[2] Keerthi Bandi[3] Murali Mohan Reddy Gopireddy[2] Shailaja Tetali[3] Rachana Domudala[2] Rohit Kumar[2] Sasikala Mitnala[4] Padaki Nagaraja Rao[2] K Rajender Reddy[5] Nageshwar Reddy[2], [1]Asian Institute of Gastroenterology, [2]AIG Hospitals, [3]Indian Institute of Public Health, [4]AHF, [5]University of Pennsylvania

Background: At a population level, few studies have assessed the prevalence of metabolic dysfunction-associated liver disease (MASLD), while the impact of alcohol use has not been well addressed worldwide. It is also common to consider that all patients with SLD in the community are related to MASLD, and the impact of alcohol use on SLD has not been evaluated with validated methods. We aimed to assess the prevalence of alcohol use disorder (AUD) and its impact on SLD, and hepatic fibrosis, in rural India. **Methods:** A cross-sectional community based study was conducted and adults were screened for AUD using AUD identification test (AUDIT) in 77 villages in rural Southern India. Demographic, clinical, and behavioural assessments, along with vibration-controlled transient elastography (FibroScan by Echosens, Paris), biochemical tests, and viral marker tests were performed. The objectives were to assess the prevalence of AUD, SLD and hepatic fibrosis, and to identify factors associated with AUD and fibrosis. **Results:** Among 4,281 participants (age: 54.42 ± 14.37 years; Women: 51.7%; BMI: 24.80 ± 4.72 kg/m^2 ; overweight/obese: 63.2%; diabetes mellitus: 18.3%; hypertension: 30.7%) with complete data, AUD was identified in 22.3% (95% CI, 21.0–23.5) with hazardous, harmful, and dependent alcohol use observed in 21.1%, 0.8%, and 0.3%, respectively. The median controlled attenuation parameter (CAP) was 228 (IQR 68 db/m) and median liver stiffness measurement (LSM) was 4.9 (IQR, 1.8 kPa). 35.4% (95%CI, 34-36.9) had hepatic steatosis (CAP > 248 dB/m) and 5.8% (95%CI, 5.2-6.6) had fibrosis (LSM > 8.2 kPa). HBsAg was positive in 1.1% (95% CI, 0.9-1.5) and anti HCV in 0.2% (95% CI, 0.1-0.4). Among individuals with steatosis (n = 1517), MASLD was the predominant subtype (70.1%), followed by MetALD (22.3%), cryptogenic (5.6%), and ALD (1.2%). Adjusted analysis showed significantly higher odds of AUD among individuals aged 31–45 years (aOR: 2.53; p = 0.021), men (aOR: 3.29; p < 0.001), and those with lower educational status. Diabetes mellitus (aOR: 1.77), AUD (aOR: 1.50), and hepatic steatosis (aOR: 2.87) were independently associated with Hepatic fibrosis (^{3}F2). **Conclusion:** AUD is highly prevalent in rural India and is associated with high rates of SLD. Its significant association, along with diabetes, with hepatic fibrosis highlights the need for integrated community-based screening and targeted interventions to reduce burden of ALD/MetALD.

2459 | ◆ INDEPENDENT AND JOINT ASSOCIATIONS OF HYPERTENSION SEVERITY AND GLYCEMIC DYSFUNCTION WITH ADVANCED LIVER FIBROSIS IN U.S. ADULTS WITH MASLD: NHANES 2017–2023

Ridwan Lawal[1] Sarpong Boateng[2] Guy Loic Nguefang Tchoukeu[3] Cherechi Nwabueze[4] Bright Nwatamole[5] Mayowa Adefuye[6] Chimezirim Ezeano[7] Ihunanya Kanu[8] Eunice Omeludike[9] Basile Njei[10], [1]University of Texas Rio Grande Valley, [2]Yale New Haven Health, Bridgeport Hospital, [3]Texas Tech University Health Science Center, Permian Basin, [4]John H. Stroger Jr. Hospital of Cook County, [5]Zucker School of Medicine at Hofstra/Northwell at Vassar Brothers Medical Center, [6]Bridgeport hospital, Bridgeport CT, [7]Advocate Aurora Healthcare, [8]Baptist Memorial Hospital- Golden Triangle, [9]Piedmont Athens Regional Medical Center, [10]Yale University

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is closely linked to cardiometabolic comorbidities, including hypertension and dysglycemia. However, the independent and combined contributions of hypertension severity and glycemic dysfunction to advanced liver fibrosis remain incompletely characterized in contemporary U.S. populations. We evaluated the associations of hypertension severity and glycemic status with advanced liver fibrosis among U.S. adults with MASLD. **Methods:** We analyzed adults with MASLD from NHANES 2017–2023 using survey-weighted analyses. Hypertension severity was categorized per ACC/AHA criteria (normal, elevated, stage 1, stage 2). Glycemic status was classified as normoglycemia, prediabetes, well-controlled diabetes (HbA1c $<7\%$), and uncontrolled diabetes (HbA1c $\geq 7\%$). Advanced liver fibrosis was primarily defined by vibration-controlled transient elastography liver stiffness measurement (LSM) ≥ 10 kPa. Secondary analyses evaluated continuous liver stiffness and alternative fibrosis thresholds. Multivariable survey-weighted logistic and linear regression models adjusted for demographic, socioeconomic, lifestyle, and metabolic factors. Trend analyses across hypertension and glycemic severity categories were performed. **Results:** Among 67.7 million weighted U.S. adults with MASLD, advanced fibrosis prevalence increased progressively across worsening cardiometabolic phenotypes, from 5.9% among normotensive normoglycemic individuals to 35.8% among those with stage 2 hypertension and uncontrolled diabetes. Compared with the reference phenotype (normal blood pressure plus normoglycemia), uncontrolled diabetes demonstrated the strongest associations: normal blood pressure plus uncontrolled diabetes (aOR 5.58, 95% CI 1.71–18.20), stage 1 hypertension plus uncontrolled diabetes (aOR 6.87, 95% CI 2.06–22.91), and stage 2 hypertension plus uncontrolled diabetes (aOR 9.93, 95% CI 2.49–39.59). Increasing hypertension severity (p-trend $= 0.026$) and glycemic severity (p-trend < 0.001) were independently associated with advanced fibrosis. Continuous liver stiffness analyses were consistent, with the highest burden among participants with stage 2 hypertension and uncontrolled diabetes ($\beta = 0.40$, $p < 0.001$). No significant multiplicative interaction was observed (p-interaction $= 0.15$), suggesting additive cardiometabolic effects. **Conclusion:** Among U.S. adults with MASLD, worsening hypertension severity and glycemic dysfunction were independently associated with progressively higher advanced liver fibrosis burden, with uncontrolled diabetes demonstrating the strongest associations. These findings highlight the cumulative impact of cardiometabolic dysfunction in MASLD and support integrated cardiometabolic risk stratification and aggressive metabolic optimization in high-risk populations.

2460 | ◆ FIBROSIS SCREENING DESERTS: A NATIONAL COUNTY-LEVEL ANALYSIS OF METABOLIC BURDEN, HEPATOLOGY ACCESS, AND CIRRHOSIS MORTALITY

Harika Dadigiri[1] Srinivas Venkatanarayanan[2] Jeril Lasington[3] Anas Mardini[3] Venaktesh Gondhi[3] Edward Barbarito[4], [1]New York Medical college Saint Clare's and Saint Mary's Hospital, [2]UCF, [3]NYMC Saint Clare's and Saint Mary's Hospital, [4]Saint Clare's Health

Background: Although MASLD affects approximately 38% of U.S. adults, advanced fibrosis remains largely undetected. Prior studies have linked upstream determinants to preventable MASLD mortality, but no national framework has defined counties where metabolic risk overlaps with limited hepatology screening capacity. We operationalised and mapped "Fibrosis Screening Deserts" and evaluated their association with cirrhosis mortality at the county level. **Methods:** We performed an ecological study of 3,134 U.S. counties using CDC PLACES, HRSA AHRF, SVI, USDA RUCC, HME GHDX, SAHIE, and OPTN data. A Metabolic Burden Index combined obesity, diabetes, and hypertension using Z-scores (Cronbach's a = 0,85), while an Access Index combined GI density, inverse HPSA status, and SVI Theme 4 using percentile ranks, given zero gastroenterologists in 69% of counties. Deserts were defined as top-tertile MBI plus bottom-tertile AI. Primary outcome was 2017-2019 IHME age-adjusted cirrhosis mortality. Multivariable OLS with HC SE adjusted for socioeconomic, demographic, rurality, insurance, transplant-distance, and state effects; multiple sensitivity analyses were performed. **Results:** Of 3,134 counties, 478 (15.3%) met Desert criteria, encompassing 10.3 million Americans. Desert counties were predominantly rural (82%) with mean non-Hispanic Black proportion of 22.5% vs. 6.4%. Among Desert counties, 97% had zero gastroenterologists (0.1 vs. 1.7 per 100,000). Obesity (42.1% vs. 36.5%), diabetes (17.2% vs. 13.0%), and unadjusted cirrhosis mortality (26.6 vs. 20.4 per 100,000) were higher in Deserts (all $p < 0.001$). In adjusted analyses, Desert status was associated with 2.53 excess cirrhosis deaths per 100,000/year (95% CI 1.53–3.52, $p < 0.001$), corresponding to ~260 preventable deaths annually (PAF 0.43%). A 66% dose-response gradient spanned MBI-by-AI tertiles (16.1 to 26.6 per 100,000; Spearman $\rho = 0.505$, $p < 0.001$). Desert status showed spatial concordance with cirrhosis mortality (bivariate Moran's $I = 0.163$, $p = 0.001$). Adjusted liver-specific excess (+12.4%) was three times non-liver excess (+4.1%); external-cause mortality was null in the 12-covariate model ($\beta = 0.01$, $p = 0.996$), confirming a liver-specific mechanism. The E-value was 1.93 (lower CI bound 1.36). Results were robust across eight specifications ($\beta = 0.84$–2.53, all $p < 0.05$). **Conclusion:** Fibrosis screening deserts affect 10.3 million Americans in the rural South and Appalachia, disproportionately burden minority populations, and are independently associated with 2.53 excess cirrhosis deaths/100,000/year. Based on the published cost-effectiveness of community FIB-4 to VCTE screening ($78,647/QALY; Park 2025), targeted community screening with telemedicine hepatology in desert counties is a cost-effective policy intervention.

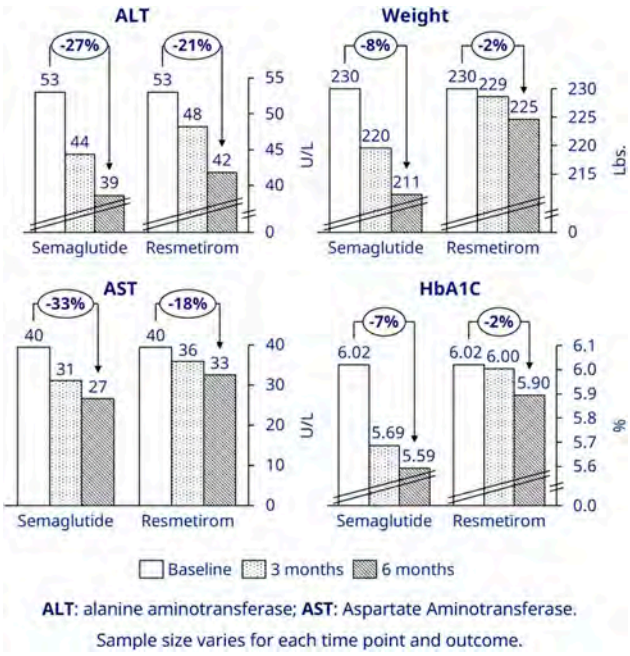
2461 | ◆ REAL-WORLD COMPARATIVE EFFECTIVENESS OF SEMAGLUTIDE VERSUS RESMETIROM ON LIVER ENZYMES AND CARDIOMETABOLIC MARKERS IN PATIENTS WITH MASH



Prachi Arora[1] David Shi[1] Abdalla Aly[1] Husam Albarmawi[1] Maximilian Kurt Jara[2] Eric Lawitz[3], [1]Novo Nordisk, [2]Novo Nordisk Inc., [3]Texas Liver Institute, University of Texas Health San Antonio

Background: Semaglutide and resmetirom received FDA conditional approval for the treatment of metabolic dysfunction associated steatohepatitis (MASH) with F2-F3 fibrosis. Real-world evidence comparing both agents is limited. This study compared the effectiveness of semaglutide versus resmetirom on liver enzymes and cardiometabolic markers in patients with MASH. **Methods:** This observational retrospective cohort study used EMR data from 30 health systems in the Truveta data (June 2021–March 2026). Adults with MASH diagnosis who initiated semaglutide injection or resmetirom were identified (index date was the first dispensation of either agent). Patients were followed until death, disenrollment, discontinuation/switching, or end of study. Patients with evidence of cirrhosis or other chronic liver diseases were excluded. Changes from baseline in ALT, AST, weight, and HbA1C were assessed at 1, 3, 6, and 12 months. To

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

reduce confounding, inverse probability of treatment weighted generalized estimating equations were used to estimate changes at 3 and 6 months. Models were adjusted for baseline outcome, age, sex, race, ethnicity, baseline BMI, comorbidities (hypertension, hyperlipidaemia, type 2 diabetes, heart failure and atherosclerotic cardiovascular disease), and prescription drug use. For all analysis, persistence to treatment (45-day gap allowed) was required for each time point. A subgroup with abnormal baseline ALT (>33 U/L for males and >25 U/L for females) was also analyzed. **Results:** The study included 2,873 and 2,285 patients treated with semaglutide and resmetirom, respectively. Semaglutide cohort was younger (48 vs 59 years), more frequently female (67% vs 58%), had higher BMI (39 vs 34 Kg/m^2), higher baseline weight (243 vs 218 lbs.), had more frequently hypertension (51% vs 45%), hyperlipidemia (60% vs 44%), lower baseline ALT (51 vs 58 U/L), AST (33 vs 43 U/L), and HbA1C (5.63 vs 6.63%); (all $P<0.05$). In unadjusted analyses, semaglutide cohort showed greater 1-month reductions in ALT (-6.0 vs +5.4 U/L) and AST (-4.5 vs +4.0 U/L) and greater 6- and 12-month reductions in weight (-20.2 vs -3.6 lbs., -31.6 vs -4.1 lbs.), and HbA1C (-0.36 vs -0.09%, -0.4 vs -0.2%); (all $P<0.05$). In adjusted analyses, semaglutide cohort had significantly greater reductions in ALT, AST, weight, and HbA1C at 3 and 6 months (Figure). Similar relative reductions were observed in the sub-group analysis. **Conclusion:** Patients treated with semaglutide achieved significantly greater reductions in ALT, AST, weight, and HbA1C compared to patients treated with resmetirom.

ALT: alanine aminotransferase; **AST**: Aspartate Aminotransferase.
Sample size varies for each time point and outcome.

2462 | ◆ LEAN MASLD IS NOT BENIGN: HIGHER CARDIOVASCULAR RISK COMPARED WITH OVERWEIGHT AND OBESITY

Sainan Li[1] Shannan Tujios[1] Maddie Kubiliun[2] Rita Lepe[3] Lafaine Grant[1] Sarah Lieber[1] Ludovic Saba[4] Michel Toutoungy[1] Janvi Patel[1] Lisa VanWagner[1], [1]University of Texas Southwestern Medical Center, [2]UT Southwestern, [3]UTSW Medical Center, [4]UT Southwestern Medical Center

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is strongly linked to cardiovascular disease (CVD), the leading cause of mortality in this population. While obesity is a known risk factor, individuals with MASLD and normal body mass index (BMI) may exhibit adverse cardiometabolic phenotypes. Comparative real-world data across BMI categories in non-cirrhotic MASLD are limited. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network (3/2006– 3/2026), a federated database of de-identified electronic health records from multiple healthcare systems. Adults (≥18 years) with MASLD, identified using ICD codes K75.81 and K76.0, and available BMI were included. BMI was categorized as normal (18.5–24.9 kg/m2), overweight (25.0–29.9 kg/m2), or obesity (≥30.0 kg/m2), with obesity further stratified as class I (30.0–34.9 kg/m2), class II (35.0–39.9 kg/m2), and class III (≥40.0 kg/m2). The index date was the first MASLD diagnosis with documented BMI. Persons with cirrhosis (baseline or incident), hepatocellular carcinoma, other chronic liver diseases, or prior cardiovascular events were excluded. The primary outcome was incident major adverse cardiovascular events (MACE: myocardial infarction, ischemic stroke, heart failure, or cardiovascular mortality). Propensity score matching balanced demographics, comorbidities, and cardiometabolic therapies. Kaplan–Meier and Cox models were used to assess MACE. **Results:** After matching, 14,051 persons with non-cirrhotic MASLD were included in the normal vs. overweight cohort and 12,926 in the normal vs. obese cohort. Over ~2.5 years (35,100 and 32,300 person-years), MACE occurred in 7.9% vs. 7.1% (normal vs. overweight) and 7.7% vs. 6.9% (normal vs. obesity). Overweight and obesity were associated with lower MACE risk compared with normal BMI (overweight: aHR 0.87, 95% CI 0.79–0.96; obese: aHR 0.82, 95% CI 0.75–0.91). This association persisted for class I–II obesity but not class III obesity (Figure 1A). Kaplan–Meier analyses showed higher cumulative MACE incidence in normal BMI versus overweight and class I–II obesity (all $p < 0.01$, Figure 1B), with no difference for class III obesity ($p = 0.57$, Figure 1C). **Conclusion:** In non-cirrhotic MASLD, overweight and class I–II obesity were associated with lower MACE compared with normal BMI, with no apparent benefit in class III obesity. These findings highlight substantial heterogeneity in cardiometabolic risk across BMI categories. Importantly, MASLD with normal BMI ("lean MASLD") appears to represent a distinct phenotype with disproportionate cardiovascular risk, underscoring the limitations of BMI-based risk assessment and the need for improved cardiometabolic risk stratification in this population.

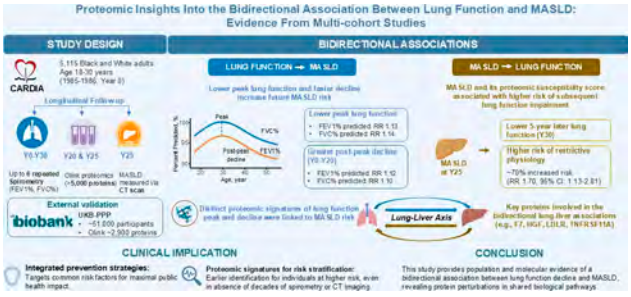
2463 | ◆ PROTEOMIC INSIGHTS INTO THE BIDIRECTIONAL ASSOCIATION BETWEEN LUNG FUNCTION AND MASLD: EVIDENCE FROM MULTI-COHORT STUDIES



Yun Chen[1] Longgang Zhao[2] Bharat Thyagarajan[3] Ravi Kalhan[4] George Washko[5] Jing Li[6] Raúl San José Estépar[5] Alexander Arynchyn[6] David Jacobs[7] Lifang Hou[8] Xuehong Zhang[2], [1]Yale School of Nursing, [2]Yale University, [3]University of Minnesota, [4]Feinberg School of Medicine, Northwestern University, [5]Brigham and Women's Hospital, [6]The University of Alabama at Birmingham, School of Medicine, [7]School of Public Health, University of Minnesota, [8]Northwestern University Feinberg School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent among individuals with impaired lung function, and the association may be bidirectional. However, prospective evidence is limited. We aimed to investigate these relationships at both population and molecular levels. **Methods:** In CARDIA cohort, 5115 participants aged

18 to 30 years were enrolled in 1985-1986 (Year 0, Y0). Forced expiratory volume in 1 second (FEV1) and forced vital capacity (FVC) were repeatedly measured via spirometry from young adulthood through middle age (Y0 to Y30). MASLD was measured using CT at Y25. Proteomic signatures for lung function and MASLD were constructed using elastic net regression based on profiling at Y20 and Y25. Bidirectional associations between lung function, protein signatures, and MASLD were estimated using Poisson and linear regression, with Mendelian randomization (MR) to evaluate potential causality. Proteomic results were validated in the UK Biobank Pharma Proteomics Project (UKB-PPP). **Results:** In CARDIA, lower peak FEV1% and FVC% predicted, and accelerated post-peak declines over 20 years (Y0 to Y20), were associated with higher MASLD risk (relative risks per SD: 1.10 to 1.14). Distinct proteomic signatures correlated with peak lung function and post-peak decline, showing strong independent associations with MASLD across both CARDIA and UKB-PPP. MR analyses supported a link between genetic predicted lung functions to MASLD. Conversely, MASLD at Y25 was associated with lower lung function 5-years later and a 70% higher risk of restrictive respiratory physiology. MASLD-related proteomic susceptibility score was also independently associated with lung function traits and restrictive physiology in both CARDIA and UKB-PPP. Key proteins (e.g., HGF, LDLR, F7, TNFRSF11A) were identified involving in the bidirectional associations. **Conclusion:** This study provides population and molecular evidence of a bidirectional association between lung function decline and MASLD, revealing protein perturbations in shared biological pathways. Proteomic signatures demonstrated potential clinical utility for risk stratification and early prevention in both conditions, even in the absence of decades of spirometry or CT.

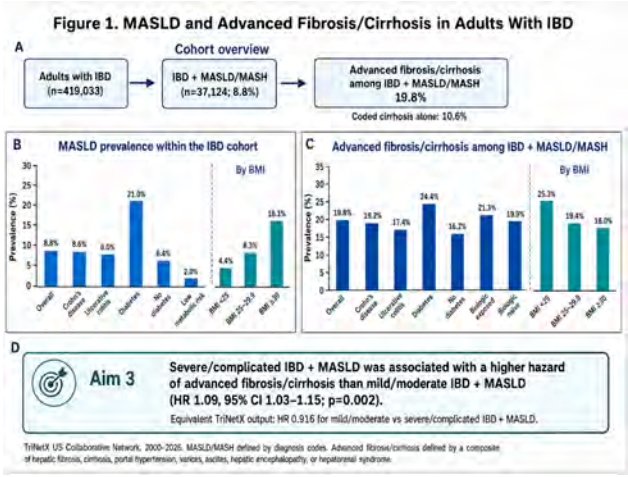
2464 | ◆ THE RISK OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AND ADVANCED HEPATIC FIBROSIS IN ADULTS WITH INFLAMMATORY BOWEL DISEASE: A MULTICENTER REAL-WORLD DATABASE STUDY



Stefanie Gallagher[1] Brandon Havranek[2] Leanna Rucker[1] Navya Pendyala[1] Ali Awadalla[2] Dina Halegoua-De Marzio[1], [1]Thomas Jefferson University Hospital, [2]Sidney Kimmel Medical College

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly recognized in patients with inflammatory bowel disease (IBD), yet its real-world prevalence and association with advanced hepatic fibrosis/cirrhosis remain incompletely defined. This study examined the burden of MASLD and advanced fibrosis/cirrhosis among adults with IBD in a large multicenter cohort. **Methods:** A retrospective cohort study was performed using the TriNetX US Collaborative Network. From January 1, 2000 to April 14, 2026, adults with IBD were identified using ICD-10-CM codes for Crohn's disease or ulcerative colitis. MASLD/MASH was defined using diagnosis codes for fatty liver or nonalcoholic steatohepatitis. Patients with competing chronic liver diseases or prior liver transplant were excluded. Advanced fibrosis/cirrhosis was defined using a composite of diagnosis codes for hepatic fibrosis, cirrhosis, and complications of portal hypertension. Prevalence estimates were calculated overall and across subgroups. Severe/complicated IBD was defined by complication codes including obstruction, fistula, abscess, or rectal bleeding. Cox proportional hazards modeling was used to evaluate the association between severe/complicated IBD and incident of advanced fibrosis/cirrhosis among patients with IBD and MASLD. **Results:** Among 419,033 adults with IBD, 37,124 had MASLD corresponding to an overall prevalence of 8.8%. MASLD prevalence increased with body mass index, from 4.4% in patients with BMI < 25 kg/m² to 8.3% with BMI 25–29.9 kg/m² and 16.1% with BMI ≥ 30 kg/m². In a low-metabolic-risk subgroup

defined by BMI < 25 kg/m² and absence of diabetes, hypertension, and dyslipidemia, MASLD prevalence decreased to 2%. Among patients with IBD and MASLD, 19.8% had advanced fibrosis/cirrhosis by composite definition, while coded cirrhosis alone was present in 10.6%. Advanced fibrosis/cirrhosis was similar in Crohn's disease and ulcerative colitis, occurring in 19.2% and 17.4% respectively. Notably, fibrosis/cirrhosis prevalence was highest among patients with BMI < 25 kg/m² (25.3%) compared with BMI 25–29.9 kg/m² (19.4%) and BMI ≥ 30 kg/m² (18.0%). Exposure to biologics resulted in an increased prevalence of fibrosis/cirrhosis. In a Cox analysis, mild/moderate IBD + MASLD was associated with lower hazard of advanced fibrosis/cirrhosis compared with severe/complicated IBD + MASLD, HR 0.916, 95% CI 0.866–0.968, p = 0.002. **Conclusion:** In this real-world IBD cohort, nearly 1 in 5 patients with IBD and MASLD had advanced fibrosis/cirrhosis. Severe/complicated IBD was independently associated with higher hazard of fibrosis/cirrhosis, suggesting that inflammatory disease burden contributes to liver disease progression in patients with MASLD. These findings support targeted MASLD screening and fibrosis risk assessment in patients with IBD and complicated intestinal disease, including those with normal BMI.

2465 | ◆ MASLD IS ASSOCIATED WITH MARKEDLY INCREASED RISK OF COLORECTAL POLYPS DESPITE HIGHER COLORECTAL CANCER SCREENING UTILIZATION

Lina AlQirem[1] Ragesh Thandassery[1], [1]The University of Arkansas for Medical Sciences

Background: The relationship between MASLD and colorectal neoplasia remains underrecognized, particularly in the context of standard colorectal cancer screening practices. **Methods:** We conducted retrospective propensity score-matched cohort analysis using TriNetX, a global federated health research network of de-identified electronic medical records. A total of 59,400 MASLD patients and 59,400 non-MASLD matched controls were identified between January 2010 and December 2012 and were followed longitudinally through December 2025. Those with prior extrahepatic malignancy and other causes of hepatic steatosis, including alcohol use disorder, chronic hepatitis C infection, celiac disease, hemochromatosis, and long-term use of steatosis-associated medications (systemic corticosteroids, methotrexate, tamoxifen, or amiodarone) were excluded. Propensity score 1: 1 matching was based on age and baseline characteristics with standardized mean differences < 0.1. Outcomes included colorectal polyp incidence and CRC screening utilization, Risk Ratios (RR), and hazard ratios (HR), with Kaplan-Meier analysis for time-to-event outcomes. **Results:** MASLD was associated with significantly higher risk of colorectal polyps (20.6% vs 6.1%; RR 3.37, 95% CI 3.26-3.50; OR 3.99; p < 0.001). Time-to-event analysis demonstrated increased hazard (HR 3.36, p < 0.001) and reduced polyp-free survival (65.2% vs 85.0%). MASLD patients also had more frequent polyp events (mean 3.74 vs 2.43; p < 0.001). CRC screening was more common in MASLD patients (29.2% vs 12.3%; RR 2.38; p < 0.001), with higher screening rates over time (HR 2.49, p < 0.001), however this did not offset the increased polyp burden. **Conclusion:** MASLD is associated with a three fold increased risk of colorectal polyps despite higher screening rates. While increased screening may contribute to higher polyp detection, the magnitude of association and increased polyp burden support MASLD as an independent risk factor for colorectal neoplasia. This supports consideration of earlier or intensified CRC screening in this population.

2466 | ◆ SEX-SPECIFIC AND ADIPOSITY-DEPENDENT ASSOCIATIONS BETWEEN SOCIAL JETLAG AND MASLD: A NATIONWIDE CROSS-SECTIONAL STUDY

Xiaosheng Tao[1] Xinyuan He[1] Zhiluo Yang[1] Xindi Huang[1] Yuzhen Zhao[1] Qiaoman Fei[1] Dou Qu[1] Yue Zhang[1] Enrui Xie[1] Fanpu Ji[1], [1]the Second Affiliated Hospital of Xi'an Jiaotong University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects approximately 30% of adults around the world, frequently progressing to cirrhosis, hepatocellular carcinoma, and broader cardiometabolic diseases. Social jetlag (SJL), defined as the discrepancy in mid-sleep time between workdays and free days, reflects chronic circadian disruption and has been associated with insulin resistance and hepatic steatosis. However, its specific impact on MASLD risk and phenotypic susceptibilities remains unclear. Our study aimed to evaluate the independent association between SJL and MASLD, exploring susceptibility patterns by sex and body mass index (BMI). We hypothesise that elevated SJL independently increases MASLD risk, particularly in females and individuals with higher adiposity. **Methods:** From 15,560 NHANES participants, 7,049 were included after excluding those aged < 12 or > 70, heavy alcohol use, and missing data. SJL was quantified as the absolute difference in mid-sleep times between free days and workdays. MASLD was defined as Controlled Attenuation Parameter (CAP) ≥ 288 dB/m with ≥ 1 cardiometabolic risk factor, stratified as lean or obese by BMI status. Weighted multivariable logistic regression, progressively adjusting for demographic, lifestyle, and biochemical covariates, was utilised to evaluate the SJL-MASLD association, and tested effect modification by sex and BMI. **Results:** Among 7,049 participants (33.0% MASLD prevalence), the overall mean SJL was 1.56 ± 2.63 hours, with significantly higher levels observed in the MASLD group ($p < 0.05$). Compared to the lowest quartile (Q1), individuals in Q4 independently exhibited a 43% increased risk of MASLD (OR = 1.43, p = 0.031) in the fully adjusted model. Subgroup analyses revealed pronounced risks in overweight/obese individuals (BMI interaction p = 0.026) and non-diabetic cohorts. Crucially, sex-stratified analyses uncovered a profound sex-specific susceptibility; females in the highest SJL quartile exhibited a two-fold increased MASLD risk (OR = 2.07, p = 0.002) following comprehensive adjustment, whereas no significant association occurred in males. High SJL thus emerges as a potent, female-specific independent driver of MASLD. **Conclusion:** SJL is an independent MASLD risk factor, with particularly heightened vulnerability in females and those with excess adiposity, highlighting circadian–endocrine–metabolic interplay. Consequently, targeted sleep-wake interventions should be prioritised as fundamental preventive and therapeutic strategies for these highly vulnerable populations.

2467 | ◆ REDUCTION IN VISCERAL FAT PREDICTS IMPROVEMENT IN HEPATIC STEATOSIS INDEPENDENT OF WEIGHT LOSS IN MASLD

Ani Bernardi[1] Sophie Silbert[1] Adam Buckholz[1] Sonal Kumar[1] Melina Manolas[2], [1]Weill Cornell Medicine, [2]Weill Cornell

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

Background: Visceral adiposity is strongly linked to hepatic steatosis in metabolic dysfunction-associated steatotic liver disease (MASLD), but it remains less clearly defined whether reductions in visceral fat improve steatosis independent of overall weight loss. We evaluated whether change in visceral fat area (VFA) predicts change in controlled attenuation parameter (CAP) independent of body weight change. **Methods:** We performed a retrospective longitudinal study of adults with MASLD who underwent paired FibroScan and InBody assessments. Change in CAP (ΔCAP) was the primary outcome and change in VFA (ΔVFA) was the primary exposure. Multivariable linear regression models evaluated associations between ΔVFA and ΔCAP adjusting for baseline BMI, change in BMI, baseline CAP, age, sex, type 2 diabetes (T2D), GLP-1RA exposure, and follow-up time. Secondary analyses evaluated additional body composition markers and odds of steatosis improvement. Predictive margins across quartiles of ΔVFA were also assessed. **Results:** A total of 352 patients with paired FibroScan and InBody measurements were included; 59.4% were women, 31.0% had T2D, and 51.9% had GLP-1RA exposure. Mean age was 51.0 ± 13.0 years and baseline CAP was 307.1 ± 40.6 dB/m. Over a mean follow-up period of 723 days, mean BMI decreased from 33.3 to 31.6 kg/m², CAP from 307.8 to 278.9 dB/m, and VFA from 181.1 to 169.5 cm². Reduction in VFA was independently associated with improvement in hepatic steatosis based on CAP after adjustment for baseline BMI, change in BMI, age, sex, T2D, and GLP-1RA exposure ($\beta = 0.49$, $p = 0.001$) and remained significant after adjusting for follow-up time. Similar associations were observed for change in % body fat and truncal fat mass, whereas changes in skeletal muscle indices were not associated with CAP improvement. The association between ΔVFA and ΔCAP did not differ by sex, menopausal-age subgroup among women, or T2D status. While there was no statistically significant interaction,T2D appeared to attenuate the BMI response. GLP-1RA exposure significantly attenuated the relationship between VFA reduction and CAP improvement (interaction $p = 0.027$), suggesting that steatosis improvement among GLP-1RA users may occur through mechanisms beyond visceral fat reduction alone. Adjusted for BMI change, resolution of elevated VFA was associated with higher dCAP (+27.1 dB/m, $p = 0.008$). **Conclusion:** Reduction in visceral adiposity predicted improvement in hepatic steatosis independent of overall weight loss in MASLD. This association was consistent across sex and diabetes subgroups, while GLP-1RA exposure attenuated the relationship between visceral fat reduction and CAP improvement. Visceral adiposity may represent a clinically meaningful therapeutic target beyond BMI reduction alone in MASLD.

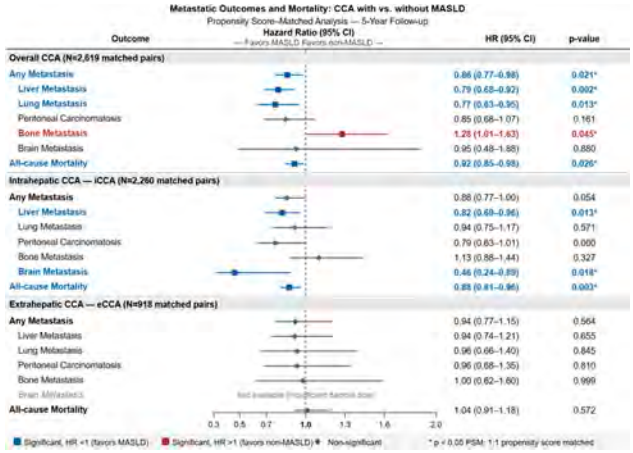
2468 | CHOLANGIOCARCINOMA: INCIDENCE, METASTATIC PATTERNS, AND SURVIVAL OUTCOMES IN PATIENTS WITH AND WITHOUT MASLD: A PROPENSITY SCORE–MATCHED ANALYSIS



Guy Loic Nguefang[1] Sarpong Boateng[2] Ridwan Lawal[3] Yussif Issaka[2] Joel Gabin Konlack Mekontso[4] Armand Ngassam[5] Chimezirim Ezeano[6] Basile Njei[7], [1]Texas Tech University Health Sciences Center, [2]Yale New Haven Health, Bridgeport Hospital, [3]University of Texas Rio Grande Valley, [4]New York City Health Hospitals, South Brooklyn Health, [5]Sovah Health, [6]Advocate Aurora Healthcare, [7]Yale University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) has been implicated in hepatobiliary carcinogenesis; however, its

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

association with cholangiocarcinoma (CCA) incidence and metastatic patterns remains poorly characterized. We aimed to investigate the relationship between MASLD and CCA incidence, site-specific metastatic patterns, and overall mortality. **Methods:** We conducted a retrospective cohort study using the TriNetX database from January 2009 to May 2026. Adults older than 18 years with at least one metabolic risk factor were included and subsequently divided into two cohorts: MASLD and non-MASLD. Individuals with alcoholic liver disease, autoimmune hepatitis, primary biliary cholangitis, primary sclerosing cholangitis, and malignancy were excluded. The incidence of CCA was then analyzed in both cohorts. Additionally, a 1: 1 propensity score–matched (PSM) analysis was performed, with covariates including age, sex, BMI, comorbidities, alcohol use, and tobacco use, to compare site-specific metastatic patterns among CCA patients with and without MASLD. Sensitivity analyses were conducted separately for patients with intrahepatic (iCCA) and extrahepatic (eCCA). The index date was defined as the date of CCA diagnosis, with a follow-up period of 5 years. Time-to-event analysis was performed using Cox proportional hazards regression to generate hazard ratios (HR) with 95% confidence intervals (CI). **Results:** A total of 12,677 patients with MASLD and 24,805 without MASLD were included. Patients with MASLD demonstrated a higher crude CCA incidence compared to non-MASLD patients (241 vs. 85 per 100,000 persons). When stratified by subtype, iCCA incidence was higher in the MASLD cohort (241 vs. 69 per 100,000 persons), as was eCCA incidence (80 vs. 40 per 100,000 persons). We matched 2,619 patients in both the MASLD and non-MASLD CCA cohorts. MASLD was associated with a significantly lower risk of overall metastasis (HR 0.87, 95% CI 0.77–0.98), but a significantly higher risk of bone metastasis (HR 1.28, 95% CI 1.01–1.63). All-cause mortality was also significantly lower in the MASLD group compared to non-MASLD (HR 0.92, 95% CI 0.85–0.98). In the iCCA subgroup, MASLD was associated with significantly reduced risks of liver metastasis (HR 0.82, $p = 0.013$), brain metastasis (HR 0.46, 95% CI 0.24–0.89, $p = 0.018$), and mortality (HR 0.88, $p = 0.003$). In contrast, among eCCA patients, no statistically significant differences in metastatic outcomes or mortality were observed. **Conclusion:** The incidence of CCA is higher in MASLD. Paradoxically, MASLD confers a more favorable metastatic profile and survival. The unexpected increase in bone metastasis risk warrants further investigation. These findings underscore the biological heterogeneity between CCA subtypes and have implications for risk stratification, surveillance, and prognostication in patients with MASLD.

2469 | ESTIMATION OF CARDIOVASCULAR EVENT PREVENTION WITH SEMAGLUTIDE THERAPY IN PATIENTS WITH HIGH-RISK TYPE 2 DIABETES AND MASLD

Alex Chang[1] JF Monteiro[1] Kimberly Ho[1] Sahas Chandragiri[1] Paige Mclean DIaz[1] Kittichai Promrat[2], [1]Brown University, [2]Brown University School of Medicine

Background: The SOUL trial is a large randomized controlled trial demonstrating lower risk of major adverse cardiovascular events (MACE) for patients with high-risk type 2 diabetes treated with oral semaglutide. The current study identifies the proportion of the US population with co-morbid MASLD and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

high-risk type 2 diabetes and uses data from the SOUL trial to project MACE that can be prevented through prescribing semaglutide to patients with dual indications. **Methods:** The current study utilizes the 2017 – 2020 US NHANES survey. Patients eligible for semaglutide therapy for MASLD were identified by including those with FIB-4 > 1.3 and a transient elastography with liver stiffness of kPa > 8 and < 15. Patients with other etiologies of liver disease were excluded. We then identified those with co-morbid high-risk Type 2 diabetes patients defined by the inclusion criteria for the SOUL trial: 50 years of age or older, an A1C of 6.5 to 10.0%, and diagnosis of coronary artery disease, cerebrovascular disease, or chronic kidney disease. We set the incidence rate of MACE in these patients to be equal to the incidence observed in the placebo arm of the SOUL trial (668 events out of 4825 patients, or 13.8%). With this incidence rate, we estimated the number of MACE events and used the hazard ratio in the treatment arm of the SOUL trial to calculate the number of MACE that could be prevented over 54 months. **Results:** Applying sampling weights, approximately 3,091,327 individuals with MASLD in the US are estimated to be eligible for semaglutide (**Table 1**). Of the patients eligible for semaglutide, 10% or 307,701 patients are further characterized as having high-risk Type 2 diabetes and thus may benefit from risk reduction in MACE. The number of patients increases to 360,666 if utilizing a higher stiffness cutoff for semaglutide eligibility. The characteristics of the patients who may benefit from MACE reduction are described in **Table 2**.The projected number of MACE prevented in the United States if 100% of patients eligible for semaglutide therapy for MASLD were placed on the therapy is 5,945 (95% CI: 1,699 - 9,766) events. This would increase to 6,968 (95% CI: 1,991 - 11,448) events if semaglutide were prescribed up to stiffness threshold of kPA < 20. Reduction in secondary outcomes such as fatal or nonfatal MI or coronary revascularization as well as variation in adverse events prevented according to percentage of population prescribed is summarized in **Figure 1** . **Conclusion:** In patients with MASLD and high-risk type 2 diabetes, treatment with semaglutide may have favorable effects not only on liver fibrosis but also cardiovascular event reduction. The current guidelines indicate that treatment of MASLD for patients with liver stiffness between 15 to 20 should be an individualized decision. In these patients, consideration of comorbid conditions may be useful for individualized decision making when discussing treatment options for MASLD.

Boursier[6] Faisal Abaalkhail[7] Ahmed Al-jedai[1] Hussain Abdulrahman Al-Omar[1] Maria Stepanova[1] Fatema Nader[1] Markos Kalligeros[1] Laurent Castera[8] Saleh Alqahtani[1] James Paik[9], [1]The Global NASH/MASH Council, [2]Universidade Federal do Rio de Janeiro, [3]University of São Paulo, [4]University of Sao Paulo School of Medicine, [5]Kurume University School of Medicine, [6]Angers University, [7]KING FAISAL SPECIALIST HOSPITAL, [8]Hopital Beaujon, [9]Global NASH/MASH Council

Background: T2D is the dominant metabolic driver of progression in MASH. The long-term clinical and economic consequences of MASH with T2D and the population-level impact of pharmacotherapy under real-world conditions remain poorly characterized across diverse health systems. **Methods:** An age-stratified Markov model projected clinical and economic outcomes of MASH with T2D from 2025 to 2045 across nine countries (US, Germany, Spain, France, Italy, UK, Japan, Brazil and Saudi Arabia), incorporating fibrosis progression, decompensated cirrhosis (DCC), hepatocellular carcinoma, liver transplantation, cause-specific mortality, and QALYs. Base-case pharmacotherapy included semaglutide or resmetirom for MASH with F2 to F3 using country-specific effective treatment exposure, defined as the sequential product of coverage, diagnosis and eligibility, adherence, and persistence. An optimized scenario introduced a next-generation MASH drugs starting in 2031. **Results:** By 2045, By 2045, MASH with T2D prevalence is projected to reach 6.75 million in the US (63% increase), 3.91 million in Brazil, and 1.07 million in Saudi Arabia (Figure). US annual costs are estimated to rise from $43.45 billion to $115.00 billion (165% increase), with indirect costs representing 75% of the total economic burden. Despite nominal treatment coverage of 65% for semaglutide and 43% for resmetirom, effective exposure remains approximately 30% and 20%, respectively, due to attrition across diagnosis, eligibility, adherence, and persistence phases. Base pharmacotherapy averts 12,696 liver-related deaths, 63,879 cardiovascular deaths, and 243,760 disability-adjusted life-years. An optimized treatment scenario amplifies these outcomes 3.5–4.0-fold: advanced fibrosis avoided increases from 3.4% to 13.8%, liver-related deaths averted from 12,696 to 44,897, and quality-adjusted life-years gained from 72,407 to 251,585. These findings underscore both the urgent need to address MASH-T2D and the substantial value of interventions that improve treatment engagement and persistence. **Conclusion:** MASH with T2D will impose a rapidly escalating global burden through 2045. Population-level impact is constrained primarily by implementation efficiency rather than therapeutic efficacy. Systematic risk stratification, earlier diagnosis, and integrated metabolic-hepatic care pathways can amplify disease burden reduction 4-fold, delivering substantially greater benefits than incremental pharmaceutical innovation alone.

Figure. Projected Clinical and Economic Burden of MASH With Type 2 Diabetes, 2025-2045.

2471 | A HISTORY OF EARLY ADULTHOOD OBESITY IS ASSOCIATED WITH LIVER FIBROSIS BEYOND CURRENT OBESITY STATUS: A NATIONAL CROSS-SECTIONAL STUDY

Yinan Su[1] Jennifer Dodge[1] Brian Lee[1], [1]University of Southern California Keck School of Medicine

Background: Obesity has doubled in young adults in the US over the past 30 years. Fibrosis risk is typically assessed from current obesity, but whether a history of early adulthood obesity adds risk information beyond current obesity status is understudied. **Methods:** We performed a cross-sectional study using the National Health and Nutrition Examination Survey 2017-2020, including adults aged ≥27 with weight history and valid vibration-controlled transient elastography (VCTE) data. Significant liver fibrosis was liver-stiffness ≥8 kPa by VCTE. Obesity (BMI ≥30 or ≥27.5 kg/m^2 for Asians) at age 25 and at baseline (survey time) defined four obesity history groups: never obese (neither timepoint), remitted (age 25 only), incident (baseline only), and persistent (both age 25 and baseline). Survey-weighted multivariable logistic regression (adjusted for age, sex, education, increased alcohol) estimated significant liver fibrosis prevalence and its association with obesity history group overall and across risk-factor strata (glucose intolerance, ≥2 cardiometabolic risk factors [CMRFs], increased alcohol). **Results:** Among 5,608 (mean age 51.6, 51.3% female), 2,945 (52.5% [95%CI 51.2-53.8%]) were never obese, 156 (2.8% [2.4-3.2%]) remitted, 1,843 (32.9% [31.6-34.1%]) incident, and 664 (11.8% [11.0-12.7%]) persistent. Adjusted weighted prevalence of significant liver fibrosis was highest in the persistent group (26.6% [20.4-32.8%]), followed by incident (13.4% [9.8-17.0%]), remitted (5.4% [1.0-9.8%]), and never obese (3.5% [2.5-4.4%]). Among adults with current obesity, prevalence was nearly 2-fold higher in the persistent vs incident group, whereas the remitted group approximated never-obese individuals. Persistent obesity was associated with significant liver fibrosis vs never obese, overall (aOR 10.69 [6.42-17.80]) and within every stratification. Persistent obesity carried the highest fibrosis prevalence among those with glucose intolerance (32.2% [23.4-41.0%]) or ≥2 CMRFs (29.7% [23.3-36.1%]); the remitted group carried the lowest among those without glucose intolerance (3.3% [0.0-6.9%]) or ≥2 CMRFs (2.9% [0.0-6.9%]). **Conclusion:** Liver fibrosis prevalence varied by obesity history, not current obesity status alone. Among currently obese adults, prevalence was 2-fold higher in those obese since early adulthood, while the remitted group had a prevalence similar to never-obese individuals. Obesity history may identify high-risk adults not captured by current BMI; longitudinal studies are needed to determine whether preventing or reversing early adulthood obesity reduces liver fibrosis.

Figure. Adjusted weighted prevalence of significant liver fibrosis (LSM ≥8kPa) by obesity history group and stratified by risk factors.

Adjusted weighted prevalence of significant liver fibrosis (LSM ≥8 kPa) % (95% CI)

2472 | GENETIC RISK STRATIFICATION AND MODIFIABLE LIFESTYLE FACTORS IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE

Mei-Hsuan Lee[1] Yan-Lin You[2] Xia-Rong Liu[2] Szu-Ching Yin[2] Yen-Feng Lin[3] Ming-Lung Yu[4] Chien-Jen Chen[5], [1]National Yang Ming Chiao Tung University (NYCU), [2]National Yang Ming Chiao Tung University, [3]NHRI, [4]KMU, [5]Academia Sinica, Taiwan

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease worldwide and results from complex interactions between inherited susceptibility and modifiable lifestyle factors. While polygenic risk scores (PRS) capture cumulative inherited risk, how inherited susceptibility and lifestyle behaviors jointly influence MASLD remains incompletely understood, particularly in Asian populations. **Methods:** We conducted a population-based study using Taiwan Biobank data. A multi-trait PRS was derived in a PRS derivation population (n = 81,452) using genome-wide association summary statistics for eight cardiometabolic traits and constructed using PRS-CS. The PRS was subsequently applied to an analytical population (n = 15,951) with imaging-defined MASLD. Lifestyle behaviors, including physical activity, smoking, and dietary behaviors, were assessed using structured questionnaires. Logistic regression models were used to evaluate independent and joint associations between PRS, lifestyle factors, and MASLD. **Results:** Higher multi-trait PRS was significantly associated with increased MASLD risk, with adjusted odds ratios (ORs) of 1.19 (95% CI 1.09–1.31) and 1.55 (95% CI 1.39–1.73) for intermediate and high PRS categories, respectively, compared with the lowest category. Higher physical activity was independently associated with lower MASLD risk (adjusted OR 0.80, 95% CI 0.74–0.86), and healthier dietary patterns were also inversely associated with MASLD, whereas cigarette smoking was associated with increased risk. Favorable lifestyle behaviors were consistently associated with lower odds of MASLD across all levels of inherited susceptibility, including among individuals with elevated PRS. No significant gene–lifestyle interactions were observed. **Conclusion:** Inherited susceptibility and modifiable lifestyle factors independently contribute to MASLD risk. Favorable lifestyle behaviors were associated with lower MASLD risk even among individuals with elevated inherited susceptibility, supporting lifestyle intervention as a key strategy for MASLD prevention and precision prevention approaches.

2473 | SEMAGLUTIDE 2.4 MG AND THE CHANGES IN LIVER ENZYMES AND CARDIOMETABOLIC MARKERS IN PATIENTS WITH MASH: A DESCRIPTIVE REAL-WORLD DATA STUDY

Husam Albarmawi[1] David Shi[1] Abdalla Aly[2] Katie Brown[3] Katherine Gilbert[3] Sunny Guin[3] Benjamin Hong[3] Maximilian Kurt Jara[4] Amy Wu[3] Eric Lawitz[5], [1]Novo Nordisk Inc., USA, [2]Novo Nordisk, [3]Truveta, USA, [4]Novo Nordisk Inc., [5]The Texas Liver Institute, USA

Background: Semaglutide 2.4 mg received an accelerated US Food and Drug Administration approval in 2025 for the treatment of noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH) with moderate to advanced liver fibrosis in adults. Real-world evidence on the impact of semaglutide on MASH remains limited. **Methods:** This retrospective cohort analysis utilized de-identified electronic health records from Truveta Data. Patients with a MASH diagnosis were identified between June 2021 and March 2026. We compared patients who initiated semaglutide and those who did not. The index date was semaglutide first dispensing date for the semaglutide group. For the no-semaglutide group, it was randomly assigned to match the distribution of semaglutide index dates. Patients with cirrhosis or other liver disease etiologies were excluded, as were those treated with other glucagon-like peptide-1 agonists or resmetirom. Within each group, we reported mean absolute and percent changes in liver enzymes (alanine aminotransferase [ALT]; aspartate aminotransferase [AST]) and cardiometabolic markers at 3, 6, and 12 months post-index. Liver enzyme changes were also reported in a subgroup with elevated baseline ALT (> 25 U/L in women; > 35 U/L in men). **Results:** We identified 2,479 patients in the semaglutide group and 70,702 in the no-semaglutide group. Patients receiving semaglutide were younger (mean age: 48 vs 54 years), more often female (67% vs 59%), and had higher body mass index (mean: 39 vs 34 kg/m^2). Cardiometabolic conditions

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

were similar between groups, except for type 2 diabetes, which was less common in the semaglutide group (8% vs 28%). Among patients with paired baseline and 1-year laboratory measurements in the semaglutide group, ALT decreased by 16 U/L (33%; mean at baseline = 48 U/L; N = 99; $P < 0.01$) and AST decreased by 10 U/L (29%; baseline = 33 U/L; N = 99; $P < 0.01$). HbA1c decreased by 0.46 percentage points (8%; baseline = 5.7%; N = 56; $P < 0.01$). Body weight decreased by 30 lb. (12%; baseline = 247 lb.; N = 267; $P < 0.01$). In the no-semaglutide group, ALT decreased by 4 U/L (9%; baseline = 46 U/L; N = 10653; $P < 0.01$), AST decreased by 2 U/L (6%; baseline = 34 U/L; N = 10620; $P < 0.01$), HbA1c decreased by 0.09 percentage points (1%; baseline = 6.7%; N = 7063; $P < 0.01$), and body weight decreased by 2 lb. (1%; baseline = 214 lb.; N = 23689; $P < 0.01$). In the subgroup with elevated baseline ALT, mean ALT reduction was 26 U/L (42%; baseline = 62 U/L; N = 66; $P < 0.01$) in the semaglutide group and 10 U/L (17%; baseline = 62 U/L; N = 6524; $P < 0.01$) in the no-semaglutide group. Changes at 3, 6, and 12 months among patients with available data are shown in the table. **Conclusion:** These real-world findings are directionally consistent with those observed in the ESSENCE trial and support the use of semaglutide as a disease modifying option in routine MASH care. Improvements in liver enzymes were more pronounced in those with elevated baseline ALT.

Changes in liver enzymes and cardiometabolic markers among patients with available data at 3, 6 and 12 months post-index

	Mean change at 3 months		Mean change at 6 months		Mean change at 12 months	
Marker	Semaglutide	No semaglutide	Semaglutide	No semaglutide	Semaglutide	No semaglutide
ALT (U/L)	-7 (-13%)	-3 (-7%)	-11 (-20%)	-3 (-7%)	-16 (-33%)	-4 (-9%)
AST (U/L)	-5 (-14%)	-1 (-4%)	-7 (-21%)	-2 (-5%)	-10 (-29%)	-2 (-6%)
Weight (lb.)	-10 (-4%)	-1 (-1%)	-20 (-8%)	-2 (-1%)	-30 (-12%)	-2 (-1%)
HbA1c (percentage points)	-0.29 (-5%)	-0.14 (-2%)	-0.42 (-7%)	-0.06 (-1%)	-0.46 (-8%)	-0.09 (-1%)
	Subgroups with elevated ALT (>25 in women and >35 in men) at baseline					
ALT (U/L)	-11 (-16%)	-8 (-13%)	-16 (-25%)	-9 (-14%)	-26 (-42%)	-10 (-17%)

2474 | PEDIATRIC MALSD AND EARLY ONSET OBESITY: INVESTIGATING A GENETIC SIGNATURE

Anna Pitts[1] Sara Hassan[1], [1]University of Texas Southwestern Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease in children, yet pathogenic drivers of hepatic steatosis in very young children remain incompletely understood. Early onset obesity (onset prior to age 5) is increasingly recognized as a distinct entity often reflecting underlying monogenic or syndromic causes. We describe a single-center cohort of children and adolescents with MASLD or steatohepatitis (MASH) and early-onset obesity, evaluated with targeted genetic testing to determine the prevalence of monogenic and syndromic causes in this population. **Methods:** We performed a retrospective analysis of a prospectively maintained cohort from a single-center pediatric hepatology clinic over 12 months. Patients were eligible if they developed obesity onset prior to age 5 and imaging (ultrasound or MRI with hepatic steatosis, a controlled attenuation parameter (CAP) $\geq$ 248 dB/m on vibration-controlled transient elastography (FibroScan)) or biopsy-confirmed MASLD. Of the forty-seven patients initially

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

identified; 4 were excluded (3 with suspected autoimmune hepatitis, 1 without steatosis at our center), yielding 43 patients. All 43 patients underwent genetic testing using a next-generation sequencing panel covering genes associated with monogenic obesity, ciliopathies, and related metabolic disorders. For each identified variant, mode of inheritance (MOI) and in silico missense pathogenicity predictions were recorded clinical data extracted from the electronic medical record included demographics, anthropometrics, alanine aminotransferase (ALT), fasting lipid panel, hemoglobin A1c (HbA1c), vitamin D, FibroScan (CAP and LSM), comorbidities, and medications. Liver stiffness measurement (LSM), was assessed via FibroScan, with a threshold of ≥ 7 kPa used to indicate clinically significant fibrosis. Descriptive statistics were calculated. **Results: Demographics** : The cohort (n = 43) included 23 males (53%) with a median age of 12 years (range 4-18). The cohort was predominantly Hispanic (79%). Mean BMI was 145% of the 95th percentile; 60% had Class III obesity. Hypertension was present in 37% and obstructive sleep apnea in 23%. Median ALT was 63 U/L (range 10-554). Among those with available FibroScan data, (n = 19), mean CAP was 289 dB/m, consistent with moderate-to-severe hepatic steatosis. The median LSM was 7.1 kPa (n = 24), including those children with MR Elastography (n = 5). Four patients underwent liver biopsy, all demonstrating histologic steatohepatitis; two had fibrosis. **Genetic testing** : Of 43 patients, 40 had interpretable genetic results (2 pending, 1 quality control failure). Of these, 30 (75%) had at least one pathogenic or likely pathogenic variant: 14 patients (47%) had a single gene variant, 9 (30%) had two, and 7 (23%) had three or more. Ten patients (25%) were negative. Sixteen of the 30 (53%) carried variants in genes with established obesity or metabolic associations. The most enriched pathway was ciliopathy-associated (with a second prominent cluster involving semaphorin). Autosomal recessive inheritance predominated (20 patients); 8 had autosomal dominant or mixed variants. In silico predictions showed damaging/pathogenic results in 4 patients, conflicting in 22, and tolerated/uncertain in 4. These are represented in Table 2. **Conclusion:** In this descriptive cohort of children with very early onset obesity and MASLD, 75% of patients harbored at least one pathogenic or likely pathogenic variant, and more than half carried variants in two or more genes. The predominance of ciliopathy genes and genes with established obesity associations suggests that MASLD coupled with early onset obesity may represent a genetically distinct entity in which disrupted cilia function, hypothalamic satiety signaling, and metabolic regulation lead to hepatic steatosis at an unusually young age. These in conjunction with gestational exposures such as maternal pre-pregnancy obesity and environmental exposures likely impact weight in early life. While direct comparison to typical MASLD in youth was beyond the scope of this study, these findings are consistent with a genetic landscape that may differ from the one described in older cohorts. This study suggests that routine testing with rare obesity gene panels may be warranted in children with MASLD presenting with obesity before 5 years of age. Larger prospective studies are needed to validate these findings, better define associations between genetic subtypes, histologic severity, and disease progression, and explore potential implications for targeted therapeutic strategies.

Table 2. Genetic testing results (n = 40 with interpretable results)
Values are n (%) unless otherwise indicated. Three patients excluded from denominator: 2 results pending, 1 quality-control failure.

Variable	Value
Overall yield	
Pathogenic or likely pathogenic variant(s) identified	30 (75)
Negative	10 (25)
Variant burden among positive cases (n = 30)	
1 variant	14 (47)
2 variants	9 (30)
≥3 variants	7 (23)
Genes with established obesity or metabolic associations (n = 30)	
At least one such variant	16 (53)
Genes identified	MC4R, PCSK1, ALMS1, BBS1, BBS5, BBS10, MAGEL2, SIM1, SH2B1, MKKS, KSR2
Pathway enrichment	
Ciliopathy-associated genes	ALMS1, CEP290, RPGRIP1L, INPP5E, IFT172, MKKS, NPHP1, SDCCAG8, VPS13B
Semaphorin / axon guidance genes	SEMA3A, SEMA3C, SEMA3D, SEMA3G, PLXNA1, PLXNA2, PLXNA3, NRP1
Mode of inheritance (n = 40)	
Autosomal recessive	20 (50)
Autosomal dominant or mixed AR/AD	8 (20)
Indeterminate	2 (5)
Negative	10 (25)
In silico pathogenicity predictions (n = 30)	
Damaging / pathogenic (SIFT, PolyPhen-2, CADD concordant)	4 (13)
Conflicting	22 (73)
Tolerated / uncertain	4 (13)

AR = autosomal recessive; AD = autosomal dominant. In silico predictions recorded per variant using SIFT, PolyPhen-2, and CADD scores.

2475 | STATIN USE AND LIVER-RELATED OUTCOMES IN PATIENTS WITH DIABETES-ASSOCIATED MASLD: A NATIONWIDE COHORT STUDY WITH GENETIC RISK ANALYSIS

Hyein Han[1] Moon Haeng Hur[2] Hyunjae Shin[2] Sungho Won[1] Yun Bin Lee[2] Eun Ju Cho[3] Jeong-Hoon Lee[2] Su Jong Yu[2] Jung-Hwan Yoon[2] Yoon Jun Kim[2], [1]Seoul National University, [2]Seoul National University College of Medicine, [3]Seoul National University Hospital

Background: Patients with metabolic dysfunction-associated steatotic liver disease (MASLD) and diabetes mellitus (DM) are at high risk of liver-related outcomes (LROs), including hepatocellular carcinoma

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(HCC) and cirrhosis decompensation. Although statins may have hepatoprotective effects beyond lipid lowering, their role in DM-MASLD remains insufficiently defined. We aimed to evaluate the association between statin use and LROs in patients with DM-MASLD using the Korean National Health Insurance Service database, complemented by Mendelian randomization (MR) analysis. **Methods:** We conducted a nationwide retrospective cohort study of adults who underwent national health screening between 2009 and 2013 and met the criteria for DM-MASLD. A 3-year landmark design was used to classify statin users, defined as those with a cumulative defined daily dose ≥ 30 during the landmark period. Baseline characteristics were balanced using inverse probability of treatment weighting (IPTW) and 1:1 propensity score matching (PSM). The primary outcome was a composite LRO, comprising HCC, liver transplantation, decompensated cirrhosis, and liver-related death. Additional analyses included time-varying Cox models and target trial emulation (TTE). To support causal inference, 2-sample MR was performed using HMGCR cis-locus genetic variants as proxies for HMG-CoA reductase inhibition and cirrhosis-related outcomes from the FinnGen R12 cohort. **Results:** Among 171,580 patients with DM-MASLD, 63,553 were statin users and 108,027 were non-users. After IPTW, baseline characteristics were well balanced. Statin use was associated with significantly lower risks of the composite LRO (adjusted hazard ratio [aHR], 0.85; 95% confidence interval [CI], 0.78–0.92; $p < 0.001$), HCC (aHR, 0.79; 95% CI, 0.67–0.92; $p = 0.002$), and decompensated cirrhosis (aHR, 0.78; 95% CI, 0.71–0.87; $p < 0.001$). These associations were consistent in PSM and time-varying Cox analyses. In TTE, statin use was also associated with reduced risks of LRO (pooled odds ratio [OR], 0.85; 95% CI, 0.80–0.90) and HCC (pooled OR, 0.80; 95% CI, 0.71–0.90). Among statin subtypes, lipophilic statin use showed a more pronounced protective association across all outcomes compared to hydrophilic statin. In MR analysis, genetically proxied HMG-CoA reductase inhibition was associated with reduced risks of cirrhosis (OR, 0.60; 95% CI, 0.42–0.85; $p = 0.004$), and the fibrosis/cirrhosis composite outcome (OR, 0.56; 95% CI, 0.34–0.92; $p = 0.021$), with directionally consistent results across sensitivity analyses. **Conclusion:** In this study, statin use was associated with lower risks of LRO, and complementary MR findings supported a potential causal role of HMG-CoA reductase inhibition in reducing cirrhosis-related risk. These results suggest that statins may have a chemopreventive role in liver disease progression among patients with DM-MASLD, warranting prospective validation.

2476 | LEVERAGING REAL-WORLD DATA AND NLP TO IDENTIFY AT RISK METABOLIC DYSFUNCTION ASSOCIATED STEATOHEPATITIS IN THE GENERAL POPULATION

April Chan[1] Or Shaked[1] Talia Tron[1] Gadi Lalazar[2], [1]Briya, Tel Aviv, Israel, [2]Shaare Zedek Medical Center, Jerusalem, Israel

Background: Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) affects approximately 25% of the global population. Its progressive form, Metabolic Dysfunction-Associated Steatohepatitis (MASH), is associated with cirrhosis and hepatocellular carcinoma. Yet MASLD screening remains inconsistent, EHR documentation is incomplete, and emerging therapies have made identifying undiagnosed or under-documented cases increasingly important. This study aimed to leverage real-world data (RWD) and develop an advanced natural language processing (NLP) model to identify patients with at-risk MASH through radiology reports and laboratory test results. **Methods:** This retrospective study analyzed de-identified EHR, laboratory, and radiology data from a partnering hospital accessed and harmonized using Briya AIRE. The study cohort included patients who underwent abdominal ultrasound between 2020 and 2024. An NLP model was developed to identify signs of fatty liver in ultrasound reports using commonly documented clinical terminology. Patients were then stratified by MASH risk using Fibrosis-4 (FIB-4) scores. To enhance fibrosis risk detection, an additional NLP-derived "Fibrosis Score" was generated from ultrasound report features, including spleen size, liver morphology and dimensions, ascites, varices, and other radiological indicators, and integrated with FIB-4 results to classify patients into high- and low-risk groups. **Results:** The analysis included 28,795 radiology reports from 20,422 unique patients. NLP-based analysis identified 4,036 additional patients with confirmed fatty liver disease, increasing the relevant study population by 360%, from 1,122 to 5,158 patients. Only 22% of MASLD patients had a documented diagnosis in structured EHR fields, while 85% had evidence of fatty liver in ultrasound reports; 78% were identified exclusively through unstructured ultrasound data, and 7% were identified by both ICD-10 codes and ultrasound analysis. Among 20,422 patients, 13,368 available FIB-4 scores were identified, including 9,279 within three months of the reference ultrasound date. Of these, 4,368 patients had

scores above the at-risk threshold. External validation demonstrated high NLP performance, achieving precision of 0.94 and recall of 0.97 for fatty liver detection, and precision of 0.77 and recall of 0.94 for fibrosis signs among patients with fatty liver. **Conclusion:** This RWD-driven NLP approach significantly improved identification of under-documented fatty liver disease and enabled risk stratification for at-risk MASH using existing clinical data, facilitating earlier detection, monitoring, and intervention for patients at risk of progressive liver disease.

2477 | REAL-WORLD LIVER STIFFNESS TRAJECTORIES IDENTIFY GLYCEMIC CONTROL AS AN IMPORTANT PREDICTOR OF RAPID FIBROSIS PROGRESSION IN A DIVERSE URBAN MASLD POPULATION

Adeeba Tak[1] Yulu He[1] Maryfe Coronel Novoa[1] Mark Miller[1] Victor Llanes[1] Asher Leviton[1] Francecs Lee[1] Ryan Walker[1] Dania Valvi[1] Scott Friedman[1] Meena Bansal[2] Xiaotao Zhang[1], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: MASLD is the most common chronic liver disease worldwide and is increasing in parallel with obesity and type 2 diabetes. However, real-world longitudinal data on liver stiffness trajectories, a noninvasive surrogate of fibrosis dynamics, remain limited in diverse MASLD populations. We used serial VCTE measurements to characterize liver stiffness regression and progression and identify baseline factors associated with rapid progression. **Methods:** Adults with MASLD and paired baseline/follow-up VCTE ≥6 months apart were included (n=505). Annualized LSM percent change was calculated as the percent change in LSM between baseline and follow-up, divided by the interval between measurements in years. This was classified into six predefined trajectories ranging from marked regression (≥30% decrease) to rapid progression (≥30% increase). Rapid-progression rates were compared across demographic, cardiometabolic, and medication-use strata, and baseline predictors of rapid progression were evaluated using logistic regression. **Results:** The cohort was 55.6% female, mean age was 55.5 years (SD 13.8), 50.7% Hispanic, 37.0% diabetic, 58.2% had obesity, and 39.2% had documented GLP-1 RA or dual GLP-1/GIP agonist exposure (active at baseline and/or initiated during follow-up). Median baseline LSM was 7.5 kPa (IQR 4.7-9.6). Over a median follow-up of 23.7 months (IQR 14.6-31.7), 54.2% regressed (rapid 8.3%, moderate 26.5%, slight 19.4%), while 45.7% progressed (slight 18.4%, moderate 16.8%, rapid 10.5%). Rapid progression (n=53) was similar by age, sex, and ethnicity. Progressors were mainly characterized by cardiometabolic burden. In univariate logistic regression, rapid progression was associated with diabetes (OR 1.87, 95% CI 1.05-3.33), higher HbA1c (OR 1.23 per 1 percentage-point increase 95% CI 1.04-1.43), metformin (OR 2.12, 95% CI 1.18-3.80), statin (OR 1.86, 95% CI 1.04-3.39), and aspirin use (OR 2.48, 95% CI 1.29-4.60). In multivariable analysis, only HbA1c remained independently associated with rapid progression (aOR 1.21 per 1 percentage-point increase, 95% CI 1.01-1.46). Rapid regressors had significantly lower baseline HbA1c than rapid progressors in a symmetric head-to-head contrast (mean 6.1% vs 6.9%, p=0.018), confirming a bidirectional HbA1c-trajectory association. **Conclusion:** About 1 out of 10 patients experienced rapid progression. Rapid progression was more prevalent among patients with diabetes and higher HbA1c, while the lowest HbA1c concentrated among rapid regressors, identifying dysregulated glycemic control as a bidirectional signal of liver stiffness trajectory. Findings motivate routine longitudinal VCTE monitoring and suggest glycemic optimization as a modifiable target. Future work should incorporate physical activity, dietary quality, and fasting plasma glucose to refine the cardiometabolic signal.

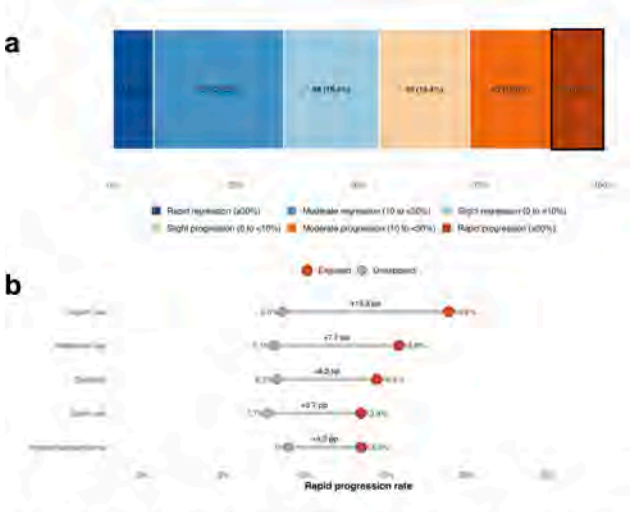

Figure 1. Liver stiffness trajectories and cardiometabolic predictors of rapid progression in a diverse urban MASLD cohort. Mount Sinai MASLD Registry; adults with paired baseline and follow-up VCTE ≥6 months apart (n=505; median follow-up 23.7 months). Rapid progression defined as ≥30% annualized LSM increase. **(a)** Distribution of annualized LSM percent change across six categories from rapid regression (≥30% decrease) to rapid progression (≥30% increase); 54.2% regressed and 45.7% progressed, with rapid progression in 10.5%. **(b)** Rapid progression rates stratified by cardiometabolic burden and medication exposure (exposed vs unexposed). On univariable analysis, progression was associated with diabetes, HbA1c, and metformin, statin, and aspirin use; only HbA1c remained independent on multivariable analysis (aOR 1.21 per 1-percentage-point, p=0.039).

2478 | LLM-ASSISTED PHENOTYPING REVEALS MULTILEVEL PREDICTORS OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) PROGRESSION IN A LARGE PRIMARY CARE COHORT

Janet Chu[1] Aryana Far[1] Mindy DeRouen[2] Alyssa Cortella[1] Alison Canchola[1] Pushkar Inamdar[1] Salma Shariff-Marco[1] Jin Ge[1], [1]University of California, San Francisco, [2]New Mexico State University

Background: Identifying multilevel predictors (individual, healthcare system, and neighborhood) of MASLD progression is critical for risk stratification and sub-specialty referral for high-risk patients. Structured electronic health record (EHR) data underdiagnoses MASLD, misclassifies disease severity, and omits progression events, which are found in unstructured data such as clinical, radiology, and pathology notes. Large language model (LLM)-assisted natural language processing (NLP) extracts and analyzes unstructured text, thereby improving accurate ascertainment of MASLD and multilevel predictors of progression. **Methods:** We included adults 18+ years old with 1+ primary care visit and diagnosis of steatosis between 2019-2024 at UCSF; those with other etiologies of liver disease were excluded. We extracted structured data (sociodemographic characteristics; vital signs; diagnostic codes; medications; labs) and used a PHI-protected implementation of GPT-5.2 to apply NLP on unstructured data (clinical, Vibration-Controlled Transient Elastography, radiology, and pathology notes) for evidence of steatosis, fibrosis, cirrhosis, or hepatocellular carcinoma (HCC). Area Deprivation Indices (ADI) were defined using patient ZIP codes. First MASLD progression event (outcome) was defined as incident F2 fibrosis, cirrhosis, or HCC based on ICD code or unstructured data. Patients were censored at first progression event, death, or study end date. We used multivariable LASSO-Cox proportional hazards regression adjusted for clustering by area code to determine multilevel factors associated with first MASLD progression. **Results:** Of 5,585 primary care patients found to have steatosis, 62% (N = 3,456) were only identified through LLM-assisted NLP (i.e. without an ICD code (K76.0 or K78.51)). A progression event was identified for 16% (N = 881; median time to event = 885 days (IQR 360-1289)); the majority (62%) were identified through NLP. Among patients with progression events, 557 had F2 fibrosis or more, 392 cirrhosis, and 35 HCC. In multivariable analyses adjusted for number of inpatient days and outpatient visits, age (HR 1.01; 95%CI 1.00-1.01), hypertension (HR 1.20; 95%CI 1.02-1.42), and higher ADI (HR 1.04; 95%CI 1.00-1.08) were associated with progression. BMI was inversely associated with progression (HR 0.99; 95%CI 0.98-1.00). **Conclusion:** LLM-assisted NLP captured 62% of MASLD cases and 62% of progression events lacking ICD codes, highlighting critical EHR data gaps. Older age, hypertension, greater healthcare utilization, and socioeconomic disadvantage were associated with disease progression; the inverse BMI association warrants further investigation. Future studies should incorporate additional neighborhood-level variables, including measures of healthcare access, environmental exposures, and food environment, to better characterize contextual drivers of MASLD progression.

2479 | COMPARABLE FIBROSIS BURDEN IN MASLD AND METALD DESPITE DIFFERENCES IN CARDIOMETABOLIC RISK: A NATIONALLY REPRESENTATIVE NHANES ANALYSIS 2021-2023

Saad Nadeem[1] David Victor[2] Sudha Kodali[2] Tamneet Basra[2] Michelle Jones-Pauley[2] Mohammad Siddiqui[3] R. Mark Ghobrial[4] Mazen Noureddin[2] Kavish Patidar[2], [1]Texas A&M College of Medicine, [2]Houston Methodist Hospital, [3]Virginia Commonwealth University, [4]Houston Methodist JC Walter Transplant Center

Background: The 2023 multi-society nomenclature introduced metabolic dysfunction and alcohol associated liver disease (MetALD). Although MetALD is often conceptualized as an overlap phenotype between metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol associated liver disease, its fibrosis burden and relationship to cardiometabolic risk factor (CMRF) burden remain unclear in nationally representative data. We compared fibrosis prevalence in MASLD versus MetALD and tested whether the association between CMRF burden and fibrosis differs by steatotic liver disease (SLD) subtype. **Methods:** We analyzed adults aged ≥20 years in the NHANES 2021–2023 with a transient elastography (n = 5,327; weighted N = 217.7 million U.S. adults). SLD was defined as a controlled attenuation parameter ≥285 dB/m. Applying 2023 AASLD-EASL-ALEH criteria, participants with ≥1 CMRF were classified as MASLD if alcohol intake was ≤210 g/wk in men, ≤140 g/wk in women and MetALD if alcohol intake was 211–420 g/wk in men and 141–350 g/wk in women. Fibrosis defined as ≥8.0 (≥F2) and ≥11.7 kPa (≥F3). Multivariable logistic regression with primary sampling unit-clustered standard errors tested SLD subtype × CMRF interaction, adjusting for age, sex, and race/ethnicity. **Results:** Prevalence was 30.9% (95% CI 29.0–32.8) for MASLD and 2.2% (1.8–2.6) for MetALD. Fibrosis prevalence was similar between groups (≥F2: 24.2% vs. 24.8%; ≥F3: 10.8% vs. 9.4%) despite comparable CMRF burden (median 3 [IQR 2–4]) and higher alcohol intake in MetALD. In MASLD, ≥F2 fibrosis increased stepwise across 1–2, 3, and 4–5 CMRFs (16.7% → 26.7% → 28.9%), whereas in MetALD it was highest at 1–2 CMRFs (33.1%) and lower at higher CMRF counts (19.3% and 19.6%). Each additional CMRF increased odds of ≥F2 (OR 1.28; 95% CI 1.15–1.41; p < 0.001) and ≥F3 fibrosis (OR 1.36; 95% CI 1.20–1.54; p < 0.001). The subtype × CMRF interaction suggested a weaker association in MetALD but was not statistically significant (OR 0.70; 95% CI 0.45–1.07; p = 0.098) (Figure 1). **Conclusion:** In this U.S. sample, MetALD affected 2% and had a similar fibrosis burden to that of MASLD, despite lower CMRF burden. Unlike MASLD, fibrosis in MetALD did not track with higher CMRF burden, suggesting that moderate alcohol intake may identify a distinct fibrosis-risk phenotype not captured by MALD-centric risk stratification. These findings support fibrosis assessment in moderate drinkers with SLD, even with modest CMRF burden.

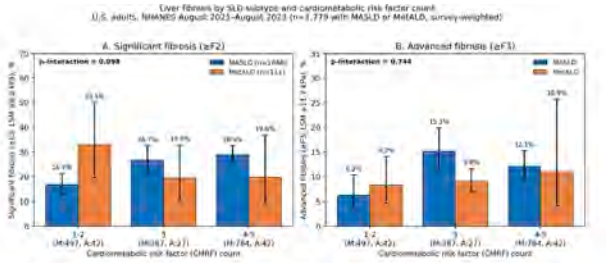

Figure 1. Weighted prevalence of significant (≥F2, panel A) and advanced (≥F3, panel B) fibrosis by cardiometabolic risk factor (CMRF) count, stratified by SLD subtype (MASLD vs. MetALD). Error bars: 95% confidence intervals. p-interaction values from multivariable logistic regression adjusting for age, sex, and race/ethnicity, with PSU-clustered robust SEs. Bracketed labels show unweighted sub-sample sizes (M = MASLD, A = MetALD).

2480 | IMPLEMENTATION OF A PATIENT-CENTERED MOBILE FIB-4 APPLICATION FOR FIBROSIS RISK STRATIFICATION AND HEPATOLOGY REFERRAL IN TYPE 2 DIABETES

Tung-Hung Su[1] Chih-Yuan Wang[2] Tien-Jyun Chang[2] Chia-Hung Lin[2] Hung-Yuan Li[2] Jin-Ying Lu[2] Yi-Cheng Chang[2] Wan-Chen Wu[2] Feng-Jung Nien[3] Shyang-Rong Shih[2] Chia-Wen Lu[4] I-Weng Yen[2] Chyi-Feng Jan[4] Jia-Horng Kao[2], [1]National Taiwan University Hospital, [2]Department of Internal Medicine, National Taiwan University Hospital, [3]Department of General Medicine, National Taiwan University Cancer Center, [4]Department of Family Medicine, National Taiwan University Hospital

Background: Patients with type 2 diabetes mellitus (T2DM) are at increased risk of liver fibrosis. Current guidelines recommend hepatology referral for patients with FIB-4 > 2.67, but such referrals remain suboptimal. We evaluated whether a patient-centered mobile FIB-4 application could facilitate fibrosis risk stratification and hepatology referral. **Methods:** We developed a mobile phone-based FIB-4 application that automatically calculates the FIB-4 score from electronic medical records and provides management recommendations based on risk categories (< 1.3, 1.3–2.67, and > 2.67). In this prospective cluster-randomized trial (NCT06694974), endocrinologists and family medicine physicians were randomized to either the FIB-4 App group or standard care group, and their enrolled patients were assigned accordingly. Adults with T2DM aged 35–65 years were included. Patients in the FIB-4 App group received education on accessing their FIB-4 results through the App after 3-month follow-up laboratory testing and were encouraged to remind their physicians of recommended management based on the FIB-4 guidance. The primary endpoint was hepatology referral among patients with FIB-4 > 2.67. Secondary endpoints included vibration-controlled transient elastography (VCTE) utilization and prevalence of metabolic dysfunction-associated steatotic liver disease. **Results:** A total of 561 patients were enrolled (FIB-4 App group, n = 281; standard care group, n = 280). Median age was 58 years, 53% were male, median BMI was 26.3 kg/m², and median HbA1c was 6.9%. Overall, 77.4%, 21.4%, and 1.2% had FIB-4 < 1.3, 1.3-2.67, and > 2.67, respectively. Among patients with FIB-4 > 2.67,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hepatology referral occurred in neither the standard care group (0/4) nor the FIB-4 App group (0/3). Referral rates were 2.5% (3/120) in the intermediate-risk group and 0% (0/434) in the low-risk group. Nineteen patients underwent VCTE with a median liver stiffness of 4.7 kPa (IQR 4.3–5.6). Two patients had liver stiffness >8 kPa, with corresponding FIB-4 values of 1.05 and 2.12. Correlation between FIB-4 and liver stiffness was weak (Spearman's rho = 0.20, $p = 0.419$). Among patients undergoing abdominal ultrasound, 71% (29/41) had steatotic liver disease, and 24% fulfilled criteria for metabolic dysfunction-associated steatohepatitis. In the FIB-4 App group, 83% completed the satisfaction survey, with a median satisfaction score of 10 (IQR 8–10). Patients appreciated the convenience of self-monitoring, although elderly users reported technical difficulties and frequently forgot to review their FIB-4 results. **Conclusion:** Only 1.2% of patients with T2DM younger than 65 years had FIB-4 >2.67. Although this patient-initiated FIB-4 referral reminder system was feasible and well accepted, hepatology referral rates remained extremely low. Greater awareness and implementation efforts are needed among both physicians and patients.

2481 | ASSOCIATION BETWEEN VITAMIN E AND METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) PREVALENCE, STEATOSIS SEVERITY, AND FIBROSIS SEVERITY: A CROSS-SECTIONAL ANALYSIS OF NHANES 2017–2018

Nishat Anjum Shaik[1] Mohammed Rifat Shaik[2] Kamran Qureshi[3], [1]SSM Health/Saint Louis University, [2]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, [3]Saint Louis University

Background: Vitamin E has antioxidant and anti-inflammatory properties relevant to pathogenesis of metabolic dysfunction–associated steatotic liver disease (MASLD), and supplementation is recommended for select patients with biopsy-proven metabolic dysfunction–associated steatohepatitis (MASH). However, population-level data evaluating serum vitamin E and MASLD outcomes remain limited. Prior studies largely relied on dietary intake and older NAFLD definitions without separately assessing steatosis and fibrosis severity. Because α-tocopherol circulates bound to lipoproteins, lipid adjustment is important for accurate assessment. We evaluated the association between lipid-adjusted serum vitamin E and MASLD prevalence, severe steatosis, and clinically significant fibrosis in U.S. adults. **Methods:** Adults aged ≥ 18 years from NHANES 2017–2018 with serum α-tocopherol, lipid panel, and transient elastography (TE) data were included. Lipid-adjusted vitamin E was calculated as α-tocopherol/(total cholesterol + triglycerides), and participants were categorized into weighted quartiles (Q4 highest = reference). MASLD was defined as CAP ≥ 274 dB/m with ≥ 1 cardiometabolic risk factor and no significant alcohol use or viral hepatitis. Severe steatosis was defined as CAP ≥ 302 dB/m and significant fibrosis as TE ≥ 8 kPa among participants with MASLD. Multivariable logistic regression models adjusted for demographics, socioeconomic factors, smoking, and physical activity. Exploratory models additionally adjusted for BMI, diabetes, hypertension, and dyslipidemia. **Results:** Among 5,036 participants (mean age 47.3 years; 51.8% female), those in the lowest vitamin E quartile (Q1) versus highest (Q4) were younger (42.8 vs. 53.6 years), more likely male (59.9% vs. 36.1%), and had higher BMI (32.3 vs. 27.3 kg/m²; all $p < 0.001$). A stepwise increase ALT (19.7 to 28.2 U/L) was observed from Q4 to Q1 ($p < 0.001$). After adjustment for sociodemographic and lifestyle factors, Q1 was associated with higher odds of MASLD (adjusted OR [aOR] 5.17, 95% CI 4.07–6.57), severe steatosis (aOR 5.29, 95% CI 3.66–7.63), and significant fibrosis (aOR 1.65, 95% CI 1.12–2.41) versus Q4, with a dose-response relationship across quartiles for MASLD and steatosis. After additional metabolic adjustment, associations remained significant for MASLD (aOR 2.40, 95% CI 1.74–3.32) and severe steatosis (aOR 2.38, 95% CI 1.48–3.84), while the fibrosis association was attenuated. **Conclusion:** Lower lipid-adjusted serum vitamin E levels were independently associated with MASLD prevalence and steatosis severity, but not fibrosis after metabolic adjustment. These findings support a potential role for vitamin E in early MASLD

2482 | ASSOCIATION BETWEEN GLP-1 RECEPTOR AGONIST USE AND MORTALITY IN TYPE 2 DIABETES AND DECOMPENSATED CIRRHOSIS

Kai-Lou Yue[1] Charanpreet Sasan[1] Taylor Seacor[1] Anita Krishnarao[2], [1]UMass Chan Medical School, Worcester, MA, [2]UMass Memorial Medical Center, Worcester, MA

Background: Glucagon-like peptide-1 receptor agonist (GLP-1) use is associated with reduced decompensation risk in compensated cirrhosis. This study examined if patients with type 2 diabetes (T2DM) and decompensated cirrhosis (DC) may also benefit from GLP-1 use. **Methods:** We conducted a retrospective cohort study using TriNetX Global Network data (2015-2023), including adults with T2DM, subsequent cirrhosis, and ≥ 1 decompensation event (DE). Patients with prior liver transplant (LT) or hepatocellular carcinoma were excluded. The primary exposure was continuous GLP-1 use (study group) or oral antidiabetic/insulin use without GLP-1 (control group) maintained through first DE, defined as ≥ 1 exposure instance in each interval: 6-12 months before, 0-6 months before, 0-6 months after, and 6-12 months after first DE. Propensity score matching (PSM) balanced cohorts by age, sex, race, ethnicity, LT waitlist status, HbA1c, creatinine, albumin, total bilirubin, sodium, and INR. Logistic regression and survival analyses assessed 3-year outcomes. Secondary analyses compared 3-year outcomes in patients initiating GLP-1 therapy after first DE vs. controls, and 5-year outcomes in those using GLP-1s both before and after first DE vs. initiation after first DE. **Results:** A total of 1,906 patients were identified: 157 with GLP-1 use and 1,749 without. PSM yielded 154 matched pairs (MP) with a mean age of 61 years (±11). Among patients with GLP-1 use before first DE, 14.8% died within 3 years compared to 32.5% of controls, representing a 50% lower hazard of mortality (HR 0.50, 95% CI 0.30-0.84). Groups were comparable in inpatient encounters (GLP-1: 4.2±9.0 vs. controls: 9.4±36.9, p=0.09) and HbA1c (6.9±1.5 vs 7.2±1.6, p=0.08). In secondary analyses, patients initiated on a GLP-1 after first DE (75 MP) also demonstrated lower mortality compared to controls (HR 0.43, 95% CI 0.21-0.86). There were no significant differences in inpatient utilization (7.2±12.9 vs. 6.5±10.7, p=0.72) or HbA1c (7.0±1.8 vs. 7.2±1.8, p=0.45). Mortality did not differ significantly in those who initiated GLP-1 use before vs. after first DE (HR 0.78, 95% CI 0.36-1.66). **Conclusion:** In patients with T2DM and cirrhosis, GLP-1 use at time of first DE was associated with significantly lower 3-year mortality compared to controls. This benefit appeared independent of glycemic control and inpatient healthcare utilization, suggesting that the observed survival advantage was not attributable to baseline differences in disease severity between groups.

Table 1: GLP-1 associated outcomes in patients with type 2 diabetes and decompensated cirrhosis

	GLP-1 before + after DE vs control HR (95% CI)			GLP-1 only after DE vs control HR (95% CI)			GLP-1 before + after DE vs only after DE HR (95% CI)

2483 | RACIAL AND ETHNIC DISPARITIES IN STEATOTIC LIVER DISEASE (SLD) SUBTYPES USING A NOVEL ALCOHOL-CORRECTED CLASSIFICATION

Zobair Younossi[1] Markos Kalligeros[1] Annette Paik[1] Khalid AlNaamani[1] Waleed Alhazzani[1] Shadan AlMuhaidib[1] Basmah Khoja[1] Saleh Alqahtani[1] James Paik[2], [1]The Global NASH/MASH Council, [2]Global NASH/MASH Council

Background: Prior estimates of SLD subtypes relied on uncorrected self-reported alcohol intake, underestimating ALD and MetALD prevalence and risking misclassification, a paradox given that ALD is the most common cause of cirrhosis. A recently validated, sex- and frequency-specific alcohol correction algorithm, calibrated to national per-capita consumption, now enables accurate SLD subtype classification. We characterized SLD burden across racial, ethnic, and sex groups and identified drivers of racial and ethnic disparities. **Methods:** NHANES 2017–2020 adults aged ≥18 years with vibration-controlled transient elastography (n = 8,226) were analyzed. Steatosis was defined by controlled attenuation parameter (CAP ≥280 dB/m). MASLD, MetALD, and ALD were classified per multi-society nomenclature using alcohol-corrected intake. Prevalence of each subtype was estimated according to gender and race/ethnicity. Survey-weighted Oaxaca-Blinder decomposition partitioned racial/ethnic SLD subtype prevalence gaps into metabolic, corrected alcohol, demographic, and unexplained components. **Results:** Of 8,226 participants (mean age 47.5 years; 48.6% male; 63.5% Non-Hispanic (NH) White; 15.6% T2D; 42.6% obesity), alcohol-corrected prevalence of MALD, MetALD, and ALD was 29.2%, 3.5%, and 4.7%. Mexican Americans showed the highest prevalence in MASLD (38.5%), MetALD (6.2%) and ALD (6.7%), while Asian Americans had the lowest in MetALD (1.6%) and ALD (1.0%) **(Figure)** . NH Black adults had the lowest MASLD prevalence (23.2%) despite the highest rates for obesity/T2D/hypertension (49.9%/17.7%/58.7%), representing metabolic dissociation. Males had higher ALD than females across all racial groups (7.7% vs 1.9%; 4.1-fold), most pronounced in Mexican American males (11.5% vs females 1.5%; 7.7-fold). NH Black males showed a reverse pattern for MASLD (prevalence in males 20.5% vs females 25.3%). Oaxaca-Blinder decomposition revealed that 13.2 percentage-point Mexican American-White MASLD gap was not explained by metabolic risk factors, suggesting biological or genetic susceptibility beyond conventional cardiometabolic pathways. MetALD and ALD disparities were similarly unexplained. For ALD, alcohol-corrected intake was the single largest explaining factor (14.7% of the gap), a contribution undetectable without correction for underreporting. **Conclusion:** A validated alcohol correction reveals substantial racial and sex disparities in SLD subtypes. The disproportionate MASLD burden in Mexican Americans persists despite metabolic risk adjustment, suggesting genetic or other unmeasured factors as potential drivers. Corrected alcohol intake resolves the ALD paradox, highlighting the critical importance of accurate alcohol ascertainment in liver disease equity research.

Figure. Alcohol-corrected MASLD prevalence by race/ethnicity and sex

2484 | US DIETARY HEALTH CARE POLICIES 2025–30 MAY BE DETRIMENTAL TO LIVER HEALTH

Nicholas Dunn[1] Sheel Patel[2] Luis Antonio Diaz[3] Robert Wong[4] Juan Pablo Arab[5] Shira Zelber-Sagi[6] Aleksander Krag[7] Zobair Younossi[8] Naim Alkhouri[9] Mazen Noureddin[10] Ashwani Singal[11], [1]University of Missouri-Kansas City School of Medicine, [2]Department of Medicine, University of Louisville School of Medicine, KY, USA, [3]Pontificia Universidad Católica de Chile, [4]Stanford/VA Palo Alto Healthcare System, [5]Virginia Commonwealth University, [6]The University of Haifa, [7]University of Southern Denmark, [8]The Global NASH/MASH Council, [9]Summit Clinical Research, [10]Houston Methodist Hospital, [11]University of Louisville

Background: The 2025–2030 Dietary Guidelines for Americans (DGA-2025) introduced major changes in dietary recommendations, including greater emphasis on total protein intake, de-emphasis of seafood and plant-based proteins, and removal of explicit alcohol guidance. We evaluated associations between individual dietary components and steatotic liver disease (SLD), fibrosis, and cirrhosis in U.S. adults using NHANES 2017–2023. **Methods:** We analyzed 10,944 adults from NHANES 2017–2023 with dietary recall and vibration-controlled transient elastography (VCTE). Dietary exposures included Healthy Eating Index-2020 (HEI-2020) component scores and energy-adjusted nutrient-density z-scores reflecting DGA-2025-aligned food groups. Outcomes included SLD (CAP $\geq$274 dB/m with cardiometabolic risk factor), significant fibrosis (LSM $\geq$8 kPa), advanced fibrosis ($\geq$10 kPa), and cirrhosis ($\geq$15 kPa). Survey-weighted multivariable logistic regression and stepwise models adjusted for demographic, metabolic, and lifestyle factors. **Results:** The weighted prevalence of SLD, significant fibrosis, advanced fibrosis, and cirrhosis was 40.0%, 10.1%, 5.8%, and 2.2%, respectively. Higher intake of total and whole fruit, vegetables, greens and beans, whole grains, and seafood/plant protein was associated with lower odds of SLD and fibrosis. In contrast, higher intake of red/processed meat, sodium, saturated fat, added sugars, and total protein was associated with greater liver disease burden. Whole grains were independently protective for significant and advanced fibrosis, whereas higher total protein intake was independently associated with advanced fibrosis. Greater adherence to prior DGA-2020 alcohol recommendations was associated with lower prevalence of significant fibrosis, advanced fibrosis, and cirrhosis. Protective dietary components, including greens and beans, seafood/plant protein, and alcohol restriction, were absent or de-emphasized in DGA-2025. **Conclusion:** In a nationally representative U.S. cohort, multiple dietary components promoted or omitted in DGA-2025 were significantly associated with SLD and fibrosis outcomes. Emphasis on total protein intake without consideration of protein source, alongside reduced emphasis on plant-based proteins and omission of alcohol guidance, may conflict with liver health–associated dietary patterns. These findings support a more liver-focused, source-specific nutritional framework for future dietary recommendations.

Wangensteen[1] Alina Allen[3] Konstantinos Lazaridis[1] Eric Klee[1], [1]Mayo Clinic, [2]University of Michigan, [3]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide. While fibrosis progression is typically slow, a substantial subset of patients advances rapidly to severe liver disease (SLD). For which the major drivers remain poorly understood. Current non-invasive tests such as FIB-4 were developed primarily to detect advanced fibrosis; yet nearly half of patients who later develop liver-related events do not have elevated FIB-4, and about one-third to half of hepatocellular carcinoma cases in MASLD occur in the absence of cirrhosis. The multifactorial nature and long asymptomatic phase in MASLD represent major challenges for accurate risk prediction. **Methods:** We identified subtypes using latent class analysis (LCA) and 9 clinical variables (Fig. 1) in a MASLD cohort (n = 4,623) from Mayo Clinic Biobank. Genetic and metabolic profiles were used to define subtype-specific signatures. To enable accurate time-to-event analyses, we developed a composite algorithm to define the earliest MASLD index date by integrating ICD-coded diagnoses, elevated ALT, and metabolic comorbidities. We developed subtype-aware, interpretable machine learning (ML) models to predict 5-year risk of SLD. SHAP analysis was applied to identify key features of progression. **Results:** LCA identified 5 subtypes that broadly segregated into cardiometabolic-dominant and liver-centric phenotypes (Fig. 2). The former was marked by high prevalence of obesity and type 2 diabetes while the latter were enriched for hepatic genetic variants and showed higher prevalence of SLD. Notably, patients in liver-centric subgroup had 25% higher proportion of patients progressing to SLD and nearly twice as many fast progressors (within 0.5–3 years) vs. cardiometabolic-dominant subgroup (Fig. 3) . Subtype-specific ML models substantially outperformed model trained on the full cohort, achieving AUCs of 0.95 in the liver-centric and 0.87 in the cardiometabolic-dominant subgroup, vs. 0.76 overall (Fig. 4). SHAP analysis revealed that the liver-centric subgroup was dominated by AST, whereas the cardiometabolic-dominant subgroup was more strongly influenced by metabolic and renal markers, including average BMI, HDL cholesterol, and creatinine. Notably, sex ranked among the top predictors in the cardiometabolic-dominant subgroup but had minimal importance in the liver-centric subgroup and the full cohort model (Fig. 4). **Conclusion:** Our subtype-aware ML modeling framework demonstrates that phenotypic subgroups in MASLD are driven by distinct sets of clinical predictors. By explicitly accounting for this heterogeneity in subtype-specific modeling, we achieved substantially better predictive performance compared with conventional population-level approaches. These findings support the incorporation of mechanistically defined subtypes to enhance risk prediction in MASLD.

Supplemental Figures:

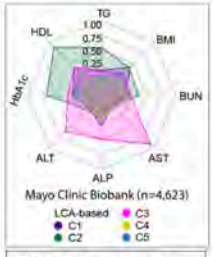

Figure 1: Proportion of patients in the highest category across 8 variables. TG, triglyceride.

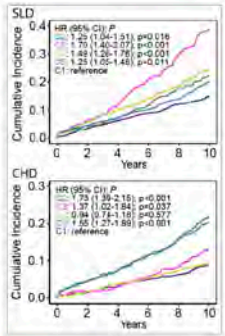

Figure 2: Cumulative incidence of SLD and CHD across subtypes in the Mayo Biobank cohort (n=4,623). Hazard Ratio (95% Confidence Interval) and p value were calculated using Cox proportional hazards regression model, adjusted by age. SLD, severe liver disease; CHD, coronary heart disease.

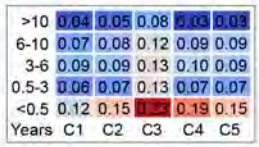

Figure 3: Proportion of patients progressing to SLD at discrete time frames, separated by subtype, in the Mayo Biobank cohort (n=4,623). Time-to-event was estimated from the index date to the first incidence of an SLD event.

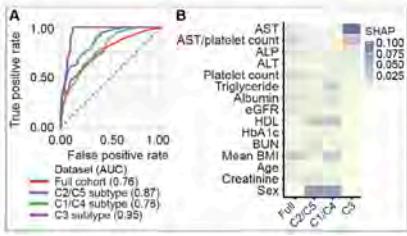

Figure4: Performance of ML models in predicting SLD **(A)** and top features **(B)**. The dashed gray diagonal line in (**A**) represents random chance. Important features are based on SHAP values, with a higher value indicating more importance. SHAP, SHapley Additive exPlanations.

2486 | LAP-BASED METABOLIC STEATOSIS-RISK PHENOTYPES AND CARDIOMETABOLIC MULTIMORBIDITY TRAJECTORIES AMONG MIDDLE-AGED AND OLDER CHINESE ADULTS

Bowen Qin[1] Xinyuan He[1] Sikai Qiu[2] Qian Wang[1] Qiaoman Fei[1] Zhiluo Yang[1] Ruiyuan Zhang[1] Yajing Bo[1] Mingzhu Liu[1] Qi Shang[1] Yi Liu[1] Haidan Shi[1] Fanpu Ji[1], [1]The Second Affiliated Hospital of Xi'an Jiaotong University, [2]The First Affiliated Hospital of Xi'an Jiaotong University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a manifestation of systemic metabolic impairment and is closely linked to cardiometabolic complications. In community-based cohorts where liver imaging is often unavailable, simple and reliable markers are needed to identify steatosis-related metabolic risk. The lipid accumulation product (LAP), derived from waist circumference and triglycerides, may reflect central lipid accumulation, but whether elevated LAP, alone or in combination with additional non-LAP metabolic abnormalities, predicts cardiometabolic disease onset and subsequent progression to cardiometabolic multimorbidity (CMM) remains unclear. **Methods:** We used China Health and Retirement Longitudinal Study data from 2011, 2013, 2015, and 2018. The primary analysis included 6,559 adults aged $\geq$45 years free of diabetes, heart disease, and stroke at baseline. Additional non-LAP metabolic abnormalities were defined as $\geq$1 of the following: prediabetes, elevated blood pressure, or low HDL-C. Participants were classified into four phenotypes: low LAP without additional abnormalities, high LAP only, additional abnormalities only, and high LAP with additional abnormalities. Incident CMM was defined as at least two conditions among diabetes, heart disease, and stroke. Cox models estimated hazard ratios (HRs). Multi-state models evaluated transitions from no disease to single disease, direct transition to CMM, and progression from single disease to CMM. First-event and sensitivity analyses were performed. **Results:** During follow-up, 246 participants developed CMM. In phenotype-based Cox analysis, high LAP with additional abnormalities had the highest CMM risk versus low LAP without additional abnormalities (HR 3.74, 95% CI 2.14–6.52), whereas no statistically significant associations were observed for high LAP only or additional abnormalities only. In multi-state models, all abnormal phenotypes were associated with transition to a first cardiometabolic disease. However, only high LAP with additional abnormalities was consistently associated with direct transition to CMM (HR 2.49, 95% CI 1.23–5.03) and progression from single disease to CMM (HR 3.97, 95% CI 1.44–10.94). First-event analysis further showed that this phenotype was associated with higher risks of first-onset diabetes, heart disease, stroke, and direct CMM, suggesting that its link to multimorbidity was not driven by a single disease pathway. Findings were robust in sensitivity analyses and remained consistent when chronic kidney disease was included. **Conclusion:** Elevated LAP may capture early cardiometabolic disease onset, whereas high LAP with additional abnormalities identifies individuals prone to progression from single disease to multimorbidity. This LAP-based phenotype offers a simple tool for cardiometabolic risk stratification when liver imaging is unavailable.

2487 | POOR SLEEP HEALTH IDENTIFIES A HIGH-BURDEN FIBROTIC MASLD PHENOTYPE IN U.S. ADULTS: A NATIONAL NHANES VCTE ANALYSIS

Mounika Kotte[1] Digantkumar Patel[2] Jagadish Koyi[3] Serene Sara John[4] Sri Ram Charan Gundapaneni[5] Pragathi Munnangi[6] Hardik Dineshbhai Desai[7], [1]Prime south consortium, [2]Springfield Clinic, Springfield, IL, USA, [3]Integris Health, Oklahoma City, Oklahoma. USA. 73112, [4]Detroit medical center, Detroit, Michigan, 48201, [5]UCF/HCA Florida Ocala Hospital, Ocala, Florida, United States, 34471, [6]BronxCare Health System , Bronx , New York - 10457, [7]AB Plus Multispecialty Hospital

Background: Poor sleep health is linked to cardiometabolic dysfunction, but its association with fibrotic metabolic dysfunction–associated steatotic liver disease remains unclear. We examined sleep health phenotypes and vibration-controlled transient elastography (VCTE)-defined fibrotic MASLD among U.S. adults. **Methods:** We analyzed National Health and Nutrition Examination Survey 2017–March 2020 adults aged ≥20 years with valid VCTE and sleep data, excluding heavy alcohol use and hepatitis C. Poor sleep health was defined using a composite of abnormal sleep duration, frequent snoring, sleep apnea symptoms, physician-reported trouble sleeping, and frequent daytime sleepiness. MASLD was defined as controlled attenuation parameter ≥285 dB/m plus ≥1 cardiometabolic risk factor. Fibrotic MASLD was defined as MASLD with liver stiffness measurement (LSM) ≥8.0 kPa, and advanced fibrotic MASLD as MASLD with LSM ≥9.7 kPa. Survey-weighted prevalence and logistic regression models were used. **Results:** The analytic sample included 4,330 adults, representing 125.6 million U.S. adults. MASLD prevalence increased from 27.3% in adults with healthy sleep health to 38.9% with intermediate sleep health and 45.0% with poor sleep health. Fibrotic MASLD prevalence increased from 5.0% to 6.0% and 10.5%, while advanced fibrotic MASLD increased from 2.9% to 4.8% and 7.0%, respectively. Compared with healthy sleep health, poor sleep health was associated with higher mean body mass index, 32.0 vs 28.0 kg/m², and higher moderate depressive symptoms, 18.7% vs 2.1%. In demographic, socioeconomic, and behavioral adjusted models, poor sleep health was associated with higher odds of MASLD, OR 2.07, 95% CI 1.71–2.50, p < 0.001, fibrotic MASLD, OR 2.35, 95% CI 1.71–3.25, p < 0.001, and advanced fibrotic MASLD, OR 2.62, 95% CI 1.73–3.95, p < 0.001. After additional adjustment for body mass index, diabetes/prediabetes, hypertension, and dyslipidemia, associations were attenuated, suggesting partial mediation through metabolic dysfunction. **Conclusion:** Poor sleep health identifies a high-burden phenotype with substantially higher MASLD, fibrotic MASLD, and advanced fibrotic MASLD prevalence. These findings support sleep health as a modifiable risk marker that may improve population-level liver disease risk stratification beyond traditional metabolic factors alone.

2488 | PROGNOSTIC VALUE OF ALKALINE PHOSPHATASE IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AND TYPE 2 DIABETES

Cristiane Villela-Nogueira[1] Nathalie Leite[2] Mariana de Almeida[1] Ana Carolina Cardoso[3] Natalia Balassiano Wajsbrot[1] Claudia MAria Equi[1] Claudia Regina Cardoso[1] Gil Salles[1], [1]Universidade Federal do Rio de Janeiro, [2]Universidade do Rio de Janeiro, [3]Universidaed Federal do Rio de Janeiro

Background: The role of elevated alkaline phosphatase levels in liver fibrosis staging and in the prognosis of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) in patients with type 2 diabetes mellitus (T2DM) has not yet been well established. The aim was to evaluate the association between elevated alkaline phosphatase levels and the presence of moderate/advanced fibrosis assessed by histology

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and/or transient liver elastography (TE), and to determine its impact on liver-related outcomes in a cohort of patients with MASLD and T2DM. **Methods:** Individuals aged ≥18 years with MASLD and T2DM followed at a tertiary hospital were included. Anthropometric measurements, clinical variables, laboratory tests, PNPLA3 and TM6SF2 genotyping, as well as fibrosis staging by liver biopsy or TE, were evaluated. Moderate/advanced fibrosis was defined as F2–F4 on histology and/or liver stiffness ≥8 kPa measured by VCTE (FibroScan®). During follow-up, liver-related outcomes (ascites, encephalopathy, variceal bleeding, and hepatocellular carcinoma [HCC]) were recorded. Follow-up duration was defined as the interval between baseline alkaline phosphatase (ALP) levels and the last clinical visit or the occurrence of outcomes. **Results:** A total of 456 patients were included, of whom 66% were women, with a mean age of 62 ± 10 years and BMI of 31 ± 5 kg/m². At baseline, 63 (14%) had elevated ALP levels, and 174 (38%) had moderate/advanced fibrosis. Compared with patients with normal ALP levels, those with elevated ALP levels more frequently had moderate/advanced fibrosis (57% vs. 35%, $p = 0.001$). In multivariate logistic regression analysis, moderate/advanced fibrosis was independently associated with elevated ALP levels in a model including age, sex, BMI, smoking status, alcohol intake, type of diabetes treatment and glycemic control, and the presence of PNPLA3 and/or TM6SF2 risk alleles (OR 2.71; 95% CI 1.42–5.17; $p = 0.003$).During follow-up over a median period of 69 (52–85) months, 21 patients developed liver-related outcomes. Kaplan–Meier curves showed a significantly higher cumulative incidence of outcomes among patients with elevated versus normal ALP levels (log-rank $p < 0.001$). In Cox regression analysis, elevated baseline ALP levels were independently associated with the occurrence of liver-related outcomes in a model including age, sex, BMI, smoking status, alcohol intake, type of diabetes treatment and glycemic control, and the presence of PNPLA3 and/or TM6SF2 risk alleles (HR 7.31; 95% CI 2.74–19.53; $p < 0.001$). **Conclusion:** Elevated ALP levels are associated with moderate/advanced fibrosis and may predict the risk of clinically significant liver-related outcomes in our cohort of patients with T2DM and MASLD. Further studies are needed to identify the underlying mechanisms and the impact of this presentation pattern on the diagnostic and prognostic approach in this specific subgroup of patients.

2489 | COMPARATIVE EFFECTIVENESS OF GLP-1 RECEPTOR AGONISTS VERSUS OTHER ANTIDIABETIC THERAPIES ON LIVER OUTCOMES IN PATIENTS WITH MASLD AND TYPE 2 DIABETES: A PROPENSITY-MATCHED REAL-WORLD STUDY

Arunkumar Krishnan[1] Diptasree Mukherjee[1] Naim Alkhouri[2] Tatyana Kushner[3] Doan Dao[4] Nicola Pugliese[5] Jörn Schattenberg[6] Christina Lindenmeyer[7] Saleh Alqahtani[8], [1]Atrium Health, [2]Summit Clinical Research, [3]Weill Cornell Medical College, [4]Massachusetts General Hospital, [5]Humanitas Research Hospital, [6]Rheinland-Pfalz, [7]Cleveland Clinic, [8]King Faisal Specialist Hospital & Research Centre

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) in individuals with type 2 diabetes (T2D) is associated with an elevated risk of advanced chronic liver disease, hepatocellular carcinoma (HCC), and all-cause mortality. Although GLP-1 receptor agonists (GLP-1RAs) can improve metabolic parameters and promote weight loss, their comparative effectiveness for liver-related outcomes versus other glucose-lowering classes remains poorly defined. We compared liver outcomes following GLP-1RA initiation with those of other antidiabetic therapies in patients with MASLD and T2D. **Methods:** We conducted a new-user, active-comparator cohort study within a global federated electronic health record network. Adults ≥18 years with MASLD and T2D and ≥12 months of prior observation were identified. GLP-1RA initiators (≥2 prescriptions within 6 months) were each compared with initiators of each comparator class in four separate 1: 1 propensity-matched trials, with the index date set at the first prescription. Patients with prior HCC, other primary liver cancer, or liver transplantation were excluded. Propensity scores balanced demographics, BMI, HbA1c, comorbidity burden, causes of liver disease, and medications. The primary outcome was incident HCC; secondary outcomes were hepatic decompensation (composite of ascites, variceal bleeding, or hepatic encephalopathy) and all-cause mortality. Time-to-event analyses used Cox proportional hazards models. **Results:** Prior to matching, GLP-1RA initiators

(n = 198764) were younger, had higher BMI, and had a greater comorbidity burden than comparator initiators (several standardized mean differences [SMDs] > 0.1); all SMDs were < 0.1 after matching. GLP-1RA initiation was associated with lower hazards of incident HCC versus insulin (HR 0.25, 95% CI 0.18–0.34) and sulfonylureas (0.45, 0.28–0.72), a nonsignificant reduction versus metformin (HR 0.70, 095% CI .42–1.15), and no significant difference versus DPP-4 inhibitors (0.98, 0.75–1.27). For hepatic decompensation, GLP-1RA initiation was associated with lower HRs than all comparators: insulin (0.60, 0.52–0.70), sulfonylureas (0.72, 0.59–0.89), metformin (0.82, 0.68–0.99), and DPP-4 inhibitors (0.86, 0.74–0.99). All-cause mortality findings followed a similar gradient (HR 0.32, 95% CI 0.21–0.43). Effect directions were consistent across subgroups defined by cirrhosis status, with attenuation but persistence of benefit in patients with established cirrhosis. **Conclusion:** GLP-1RA initiation was associated with lower hazards of incident HCC and hepatic decompensation compared with insulin or sulfonylureas, a smaller reduction than with metformin, and no difference in HCC versus DPP-4 inhibitors. The gradient of effect across comparator classes suggests that the apparent benefit is partly dependent on the reference group, raising the possibility of residual confounding by indication.

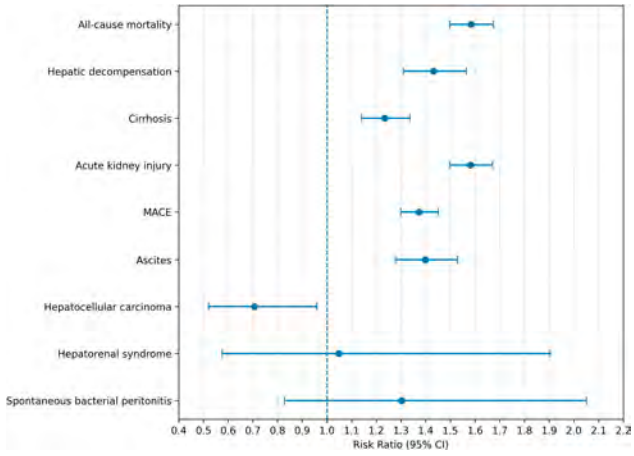
2490 | ASSOCIATION BETWEEN CANNABIS USE AND CLINICAL OUTCOMES IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE: INSIGHTS FROM A LARGE TRINETX ANALYSIS



Muhamad Oum[1] Ahmed Ibrahim[2] Sammy Saab[3], [1]Saint Agnes Medical Center, [2]San Joaquin General Hospital, [3]University of California, Los Angeles

Background: Cannabis use has been associated with increased risks of major adverse cardiovascular events, including myocardial infarction, stroke, arrhythmias, and cardiovascular mortality; however, its impact on liver disease remains poorly understood. We aimed to evaluate the association between cannabis use and liver-related and systemic outcomes among patients with metabolic dysfunction–associated steatotic liver disease (MASLD). **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network. Adult patients with MASLD identified using ICD-10 code were included. Patients with alcoholic liver disease, viral hepatitis, autoimmune hepatitis, primary biliary cholangitis, and primary sclerosing cholangitis were excluded. Cannabis users were identified using ICD-10 codes for cannabis abuse, dependence, or unspecified cannabis use and compared with nonusers. Propensity score matching was performed 1: 1 adjusting for demographics and major comorbidities including diabetes mellitus, hypertension, hyperlipidemia, nicotine dependence, albumin, and international normalized ratio (INR). Outcomes included all-cause mortality, hepatic decompensation, cirrhosis, hepatocellular carcinoma (HCC), acute kidney injury (AKI), major adverse cardiovascular events (MACE), ascites, hepatorenal syndrome (HRS), and spontaneous bacterial peritonitis (SBP). MACE was defined as myocardial infarction, cerebrovascular accident, and heart failure. **Results:** A total of 31,120 cannabis users and 1,730,942 nonusers with MASLD were identified. Before propensity score matching, cannabis users were younger (mean age 44.4 vs 52.0 years), more likely to be male (55.2% vs 45.3%), and less likely to be Hispanic (11.7% vs 13.9%) compared with nonusers. After propensity score matching, 31,115 patients remained in each cohort, with all

standardized mean differences below 0.1. Cannabis users demonstrated significantly increased risks of all-cause mortality (RR 1.58, 95% CI 1.50–1.68), hepatic decompensation (RR 1.43, 95% CI 1.31–1.56), cirrhosis (RR 1.23, 95% CI 1.14–1.34), AKI (RR 1.58, 95% CI 1.50–1.67), MACE (RR 1.37, 95% CI 1.30–1.45), and ascites (RR 1.40, 95% CI 1.28–1.53) compared with nonusers. Cannabis users had a lower risk of HCC (RR 0.71, 95% CI 0.52–0.96). No significant differences were observed in HRS or SBP. **Conclusion:** Among patients with MASLD, cannabis use was associated with significantly increased risks of hepatic decompensation, cirrhosis, AKI, cardiovascular events, ascites, and all-cause mortality. These findings suggest cannabis use may adversely affect disease progression and outcomes in MASLD. More comprehensive prospective studies are needed to further evaluate the relationship between cannabis use and chronic liver disease progression.

2491 | PROJECTIONS OF MASLD BURDEN AND IMPACT OF GLP-1/GIP RECEPTOR AGONIST UTILIZATION AMONG U.S. ADULTS WITH TYPE 2 DIABETES: A MICROSIMULATION ANALYSIS

Ha Tran[1] Phuc Le[2] Olajide Adekunle[2] Naim Alkhouri[3] William Herman[4] Michael Rothberg[2] Srinivasan Dasarathy[2], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic, [3]Summit Clinical Research, [4]University of Michigan

Background: Type 2 diabetes (T2D) accelerates the progression of metabolic dysfunction-associated steatotic liver disease (MASLD) to advanced liver-related complications. We projected the future burden of MASLD among U.S. adults with T2D through 2050 and quantified the potential impact of glucagon-like peptide-1 (GLP-1) and dual GLP-1/glucose-dependent insulinotropic polypeptide (GIP) receptor agonists (RAs) on hepatic outcomes. **Methods:** We developed an agent-based state transition microsimulation model of MASLD progression among U.S. adults with T2D. The model comprised 14 health states with annual cycles over a lifetime horizon and incorporated use of pioglitazone, semaglutide, liraglutide, and tirzepatide—medications with beneficial impacts on liver outcomes. Treatment effects on MASLD progression were derived from randomized clinical trials, while treatment uptake trends were informed by population-based surveys and Epic Cosmos data. In the base-case analysis, GLP-1/GIP RA use was assumed to increase at the rate observed before 2025 until reaching a 50% overall uptake, after which it remained stable. We also explored two scenarios: accelerated uptake, in which use after 2025 increased at twice the base-case rate until reaching 100% overall uptake (best-case), and stagnant uptake, in which future use remained at the 2025 level of 22% (worst-case). **Results:** Model prediction between 2000 and 2024 aligned well with observed epidemiologic data. In the base-case analysis, MASLD cases in patients with T2D rose from 27.3 million (65.5%) in 2025 to 39.7 million (71.8%) in 2050. Over the same period, metabolic dysfunction-associated steatohepatitis cases increased from 12.4 to 16.4 million. Although the prevalence of advanced fibrosis ($F \geq F2$) decreased from 42.8% to 37.8%, the number of decompensated cirrhosis cases increased by 48.7%, from 362,100 to 538,400. Annual hepatocellular carcinoma (HCC) cases, liver transplants (LTs), and liver-related deaths also increased by 17.3%, 59.7%, and 64.6%, respectively. Compared with the base-case analysis, accelerate uptake of GLP-1/GIP RAs reduced HCC cases by 13.7%, LTs by 15.3%, and death by 11.9%, although these reductions did not occur until 2030. Conversely, stagnant uptake increased cumulative HCC cases, LTs, and liver-related deaths by 9.1%, 12.8%, and 7.3%, respectively, relative to the base-case analysis. **Conclusion:** MASLD burden among U.S. adults with T2D is projected to increase substantially over the next 25 years, even under an assumption of 50% uptake of GLP-1/GIP receptor agonists. Expanded GLP-1 and GLP-1/GIP access may reduce future liver-related complications, but the delayed benefit highlights the importance of early adoption.

Figure. Cumulative MASLD-Related Clinical Events from 2025 to 2050 Under Three Drug Utilization Scenarios. Cumulative cases of (A) hepatocellular carcinoma, (B) liver transplantation, and (C) liver-related death attributable to MASLD among U.S. adults with T2D are shown for the base-case (utilization increasing linearly to 50% by 2050), doubled GLP-1/GIP utilization (twice the base-case rate), and constant GLP-1/GIP utilization scenarios (held at 2025 levels). The three scenarios showed meaningful divergence over time, with differences driven by the effect of treatment on fibrosis progression and MASH resolution rather than MASLD prevalence. Abbreviations: HCC = hepatocellular carcinoma; MASLD = metabolic dysfunction–associated steatotic liver disease; T2D = type 2 diabetes.

2492 | LIVER FIBROSIS QUANTIFIED BY FIB-4 IMPROVES CARDIOVASCULAR RISK CLASSIFICATION BEYOND THE AHA PREVENT SCORE IN ADULTS WITH MASLD: NHANES 2017–2023

Rahul Falodia[1] *Sushil Kumar Falodia*[2], [1]*All India Institute of Medical Sciences, Jodhpur,* [2]*Sardar Patel Medical College*

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), the 2023 multi-society renamed successor to NAFLD, affects over half of U.S. adults and is increasingly recognized as a cardiometabolic condition. The FIB-4 index calculable from routine biochemistry (age, AST, platelets, ALT) stratifies MASLD severity by hepatic fibrosis stage. Whether FIB-4 improves CVD risk classification beyond the AHA PREVENT score in a contemporary nationally representative MASLD population has not been evaluated. **Methods:** We analyzed NHANES 2017–2023 (n = 9,962 adults ≥18 years). MASLD was defined per 2023 multi-society consensus using Hepatic Steatosis Index proxy plus ≥1 cardiometabolic risk factor. FIB-4 was categorized as Low (<1.30), Intermediate (1.30–2.67), or High (>2.67). Prevalent CVD (self-reported MI, stroke, or heart failure) was the primary outcome. Survey-weighted logistic regression and restricted cubic splines (4 knots) modeled FIB-4–CVD associations. Net reclassification improvement (NRI) and integrated discrimination improvement (IDI) tested incremental value of FIB-4 beyond PREVENT. **Results:** MASLD prevalence was 52.5%. Among 5,167 MASLD patients, CVD prevalence increased markedly across FIB-4 categories: Low 5.5%, Intermediate 18.9%, High 28.1%. In adjusted models, High FIB-4 was associated with 65% higher odds of CVD vs. Low FIB-4 (OR 1.65, 95% CI 0.89–3.08), with a significant nonlinear dose-response (p for nonlinearity <0.0001). FIB-4 significantly improved CVD risk classification beyond PREVENT alone: categorical NRI 0.081 (95% CI 0.032–0.131, p = 0.001), continuous NRI 0.509 (p<0.001), IDI 0.027 (p<0.001). Diabetes (OR 2.62), smoking (OR 2.54), and BP treatment (OR 1.45) were the strongest independent CVD predictors. **Conclusion:** In the first nationally representative analysis applying updated MASLD nomenclature, FIB-4 liver fibrosis staging significantly improves 10-year CVD risk classification beyond the AHA PREVENT score. These findings support FIB-4 as a low-cost hepato-cardiac risk enhancer warranting consideration in the cardiovascular evaluation of the 52% of U.S. adults meeting MASLD criteria.

2493 | GLP-1RA USE IS ASSOCIATED WITH GREATER APPENDICULAR LEAN MASS DECLINE IN PATIENTS WITH MASLD ACHIEVING SIGNIFICANT WEIGHT LOSS

Sophie Silbert[1] Melina Manolas[1] Ani Bernardi[1] Adam Buckholz[2] Sonal Kumar[1], [1]Weill Cornell Medicine, [2]New York Presbyterian Hospital Program

Background: Glucagon-like-peptide-1 receptor agonists (GLP-1RAs) produce weight loss through reductions in both fat and muscle mass. While they are increasingly prescribed in patients with metabolic dysfunction-associated steatotic liver disease (MASLD) to treat its metabolic comorbidities, given the elevated risk of sarcopenia in MASLD and its advanced form steatohepatitis (MASH), GLP-1 agonism effects on body composition warrants investigation. We examined longitudinal changes in body composition among patients with MASLD, with particular attention to factors that may modify lean mass change during weight loss. **Methods:** We conducted a retrospective longitudinal study of patients with MASLD who had paired Fibroscan and InBody assessments. Change in Appendicular Lean Mass Index (ΔALMI) was the primary outcome and any GLP-1RA use was the primary exposure. Multivariable linear regression analysis evaluated the relationships between baseline ALMI, change in BMI, age, diabetes status, fibrosis stage, and sex. A sensitivity analysis was performed restricted to those who had a minimum of 5% total body weight loss (TBWL). **Results:** A total of 352 patients with paired Fibroscan and InBody scans for body impedancea analysis were included; 59.4% were women, 31.0% had T2D, and 51.9% had any GLP-1 exposure. The mean age was 51 years, the mean baseline ALMI was 8.06 (8.91 M, 7.48 F), and the mean follow up time was 23.7 months. Mean BMI decreased from 33.3 to 31.6 kg/m², mean TBWL was 4.53%, and mean ΔALMI was – 0.19. Among individuals achieving ≥ 5% TBWL, GLP-1RA use was independently associated with greater ALMI decline after adjustment for baseline ALMI, BMI reduction, age, T2D status, and fibrosis stage (β = +0.11, p = 0.023), with no evidence of sex interaction. GLP-1RA users also experienced greater ALMI loss per unit BMI reduction than those who lost weight without GLP-1RA therapy (0.57 vs 0.27 per BMI point, p < 0.01). Male sex was independently associated with less ALMI decline than female sex (β = −0.24, p < 0.001). In exploratory sex-stratified analyses, GLP-1 use remained significantly associated with greater ALMI decline among women (β = +0.088, p = 0.025), with a similar but non-significant directional trend observed in men (β = +0.17, p = 0.076). **Conclusion:** In patients with MASLD achieving at least 5% TBWL, GLP-1RA exposure was independently associated with greater ALMI decline, including greater ALMI loss per unit of BMI reduction. Although women exposed to GLP-1RAs demonstrated a greater ALMI loss than men, there was no significant sex interaction. These findings suggest that muscle preservation strategies may be important during GLP-1R-associated weight loss in MASLD. Incorporating body impedance analysis into MASLD care may help contextualize guideline-recommended 5–7% TBWL by distinguishing favorable fat loss from potentially clinically relevant lean mass loss during treatment.

A: Change in ALMI by sex and GLP-1RA use status. Violin plots show the distribution of ΔALMI, where higher values indicate greater ALMI loss. GLP-RA exposure was associated with greater ALMI loss, while males showed less loss overall, regardless of GLP1-RA use. **B**. GLP-1RA use was associated with more ALMI loss per point of BMI reduction than weight loss achieved without GLP1-RA use.

2494 | COMMON VARIANTS ASSOCIATED WITH LIPODYSTROPHY INFLUENCE MASLD SUSCEPTIBILITY BUT NOT ITS HISTOLOGICAL SEVERITY

Jingyi Tan[1] Tae-Hwi Schwantes-An[2] Xiuqing Guo[1] Callie Zaborenko[2] Cristian Sanchez-Torres[3] Marco Abreu[2] Jie Yao[1] Samer Gawrieh[2] Jerome Rotter[1] Naga Chalasani[4] Kashyap Patel[5] Rebecca Brown[6] Miriam Vos[7], [1]Lundquist Institute, [2]Indiana University, [3]Emory University, [4]Indiana University Medical Center, [5]University of Exeter Medical School, [6]National Institute of Diabetes and Digestive and Kidney Diseases, [7]Michigan State University, Helen DeVos Children's Hospital

Background: Lipodystrophy is characterized by altered adipose tissue distribution and severe metabolic dysfunction, features that overlap with MASLD and MASH. However, the relationship between genetic risks for lipodystrophy and MASLD and MASH is not well understood. We therefore examined the relationship between a lipodystrophy polygenic risk score (PRS) and MASLD and its histological severity in adults using several well-characterized datasets. **Methods:** We interrogated the weighted lipodystrophy PRS, which consisted of 53 SNPs without *PNPLA3*. First, we examined the relationship between lipodystrophy PRS and MASLD by comparing the NASH CRN adult participants (1,791 European and 358 Hispanic MASLD) and steatosis-free adult controls from MESA (2,002 European and 1,044 Hispanic). Second, within the NASH CRN adult cohort (N = 2149), we evaluated the association between PRS and histologic severity measures, including advanced fibrosis (AF) and NAS $\geq$ 4. We replicated our finding in the Indiana Biobank Liver cohort, including adults with MASLD (N = 342) and without liver disease (N = 3,245). **Results:** In individuals of European ancestry from the NASH CRN and MESA, lipodystrophy PRS was significantly associated with MASLD risk. Individuals in the 4th PRS quartile had an odds ratio (OR) of 1.69 (95% CI 1.37-2.08; p = 6.69e^{-07}) compared with those in the 1st quartile. The 2nd and 3rd quartiles showed significant but smaller ORs (Table 1). Among Hispanic participants, higher quartiles showed a statistically significant association with MASLD, although the OR point estimates were increased risk for MASLD (Table 1). The association in European-ancestry individuals was replicated in the Indiana Biobank Liver cohort, where each SD increase in the PRS was associated with an OR of 1.12 (95% CI 1.01-1.26; p = 0.04). In comparison between NASH CRN and MESA European participants, the OR for MASLD was 1.23 (1.14-1.32, p = 4.66e^{-08}) for each SD increase. However, there was no significant association between PRS and histologic severity within the NASH CRN. **Conclusion:** Lipodystrophy PRS is associated with MASLD risk in two large, independent cohorts, supporting a shared genetic basis between lipodystrophy and MASLD involving common variants, independent of PNPLA3. The lack of association between the PRS and the histologic severity suggests that common variants associated with lipodystrophy influence disease susceptibility rather than progression.

Table 1. Relationship between lipodystrophy PRS by quartiles and the risk for MASLD: Comparison between adults with MASLD in the NASH CRN vs adults without steatosis in the MESA

Phenotype-Group	Quartile	OR (95% C.I.)	P-value
NASH CRN MASLD vs MESA Controls Without Steatosis: European	1	Ref	
	2	1.27 (1.03-1.56)	2.35E-02
	3	1.45 (1.18-1.78)	3.86E-04
	4	1.69 (1.37-2.08)	6.69E-07
NASH CRN MASLD vs MESA Controls Without Steatosis: Hispanic	1	Ref	
	2	1.37 (0.90-2.09)	1.41E-01

Wajahat Mehal[1] Bubu Banini[1], [1]Yale School of Medicine, [2]Yale School of Public Health

Background: Weight loss is a cornerstone of metabolic dysfunction-associated steatotic liver disease (MASLD) management; ≥5% total body weight loss typically reduces hepatic steatosis, ≥7% may improve steatohepatitis, and ≥10% may improve fibrosis. Although multiple weight loss strategies are available for patients with MASLD, real-world data on their use and effectiveness remain limited. In this study, we characterize patients seen in a multidisciplinary, MASLD clinic over a 7-year period and describe weight loss strategy uptake and longitudinal outcomes. **Methods:** This is a single-center, retrospective cohort study of adult patients evaluated at a multidisciplinary, MASLD clinic between May 2018 and November 2025. Demographic, clinical, laboratory, imaging, prescription, and clinic visit data were extracted from the electronic medical record. Time to achieve ≥5%, ≥7%, and ≥10% weight loss was estimated using Kaplan–Meier (KM) methods, and percent of cohort achieving these weight loss thresholds at 24 months was assessed. Within-patient longitudinal changes in ALT, as well as fibrosis (liver stiffness measurement, LSM) and steatosis (controlled attenuation parameter, CAP) measured by vibration-controlled transient elastography (VCTE), were evaluated using the Wilcoxon signed-rank test. **Results:** A total of 3,026 adult patients were evaluated with mean baseline age 53 years, mean BMI 36 kg/m², median ALT 41 IU/L, median LSM 6.4 kPa, and median CAP 304 dB/m. Over an average follow-up period of 3 years, 762 patients (25%) utilized no strategies aside from lifestyle counseling received during clinic appointment; 1,369 (45%) utilized 1 strategy; and 791 (26%) and 104 (4%) utilized 2 and ≥3 strategies, respectively. Anti-obesity pharmacotherapy was the most used strategy (65% of cohort), followed by nutrition consultation (38%), bariatric surgery (3%), and meal replacement program (2%). KM estimates of time to achieve weight loss thresholds are shown in the figure. Achievement of ≥5%, ≥7%, and ≥10% weight loss by 24 months was 63.1% (95% CI 61.1-64.9%), 49.8% (95% CI 47.8-51.8%), and 36.8% (95% CI 34.8-38.7%), respectively. Median ALT improved within 24 months in 828 patients with elevated ALT at baseline (49 versus 35 IU/L; $p < 0.001$). Within 24 months, significant improvements were noted also for median LSM (6.7 versus 5.8 kPa; $p < 0.001$; $n = 262$) and median CAP (310 versus 279 dB/m; $p < 0.001$; $n = 222$) compared to baseline. **Conclusion:** In a large cohort of patients with MASLD undergoing multidisciplinary management, most patients utilized one or more weight loss interventions and achieved clinically meaningful weight loss thresholds. Importantly, improvement in liver status as demonstrated by a decrease in ALT, steatosis, and fibrosis were noted. These findings underscore the utility and effectiveness of multidisciplinary MASLD care in the real-world setting.

2496 | LONGITUDINAL MUSCLE LOSS CONFERS AN INCREASED RISK OF CARDIOVASCULAR OUTCOMES AND ALL-CAUSE

Siru Wu[1] Xiao Han[1] Chenglin Sun[1] Hanshu Liu[1] Yankun Gao[1] Shuyan Chen[1] Yameng Sun[1] Hong You[2], [1]Liver Research Center, Beijing Friendship Hospital, Capital Medical University, [2]Capital Medical University

Background: Low baseline muscle mass is associated with increased cardiovascular risk in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). However, the prognostic significance of dynamic muscle mass changes over time remains poorly defined. We aimed to investigate whether longitudinal changes in muscle mass and the rate of depletion are associated with incident cardiovascular disease (CVD) and all-cause mortality in MASLD. **Methods:** We analyzed prospective data from 5,761 MASLD individuals free of CVD at baseline from the China Health and Retirement Longitudinal Study (CHARLS). MASLD was defined using TyG-WC criteria. Muscle mass was assessed using appendicular skeletal muscle mass / body weight (ASM/BW). Dynamic muscle change was quantified as the percentage change in ASM/BW (ΔASM/BW%), with categorical muscle loss defined as the lowest tertile (<33.3%) of this distribution. Primary endpoints included incident CVD (physician-diagnosed heart disease or stroke) and all-cause mortality. Risk

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

associations were quantified using Bayesian joint modeling (JMbayes2) and time-dependent Cox regression. **Results:** Over a median follow-up of 84 months among 4,848 included individuals who completed at least two muscle mass assessments, 944 (19.5%) incident CVD cases and 378 (7.8%) all-cause deaths occurred. An accelerated annualized rate of ASM/BW depletion (slope) was significantly associated with incident CVD in the age- and sex-adjusted model (HR = 9.17, 95% CI: 1.90–58.84, $P = 0.004$) and with all-cause mortality upon further adjustment for metabolic comorbidities (HR = 7.85, 95% CI: 1.13–43.00, $P = 0.027$), as evaluated via Bayesian joint modeling. Conversely, higher longitudinal ASM/BW values over time were inversely associated with risks of CVD (HR = 0.81, 95% CI: 0.71–0.93, $P < 0.001$) and mortality (HR = 0.70, 95% CI: 0.54–0.93, $P = 0.007$) in the corresponding models. For clinical risk stratification, categorical muscle loss independently elevated overall CVD risk (aHR = 1.55, 95% CI: 1.11–2.18, $P = 0.011$) in time-dependent Cox regression. This association was primarily driven by heart disease rather than stroke, with the heart disease risk being particularly pronounced among male patients (aHR = 3.53, 95% CI: 1.63–7.61, $P = 0.001$) and overweight/obese individuals (aHR = 3.10, 95% CI: 1.66–5.80, $P < 0.001$). **Conclusion:** Dynamic ASM/BW status is significantly associated with the risk of cardiovascular progression and mortality in MASLD. Specifically, the annualized rate of muscle depletion (slope) provides incremental prognostic value over static measurements, particularly exhibiting a robust independent association with all-cause mortality. These findings support that integrating long-term monitoring of individualized muscle trajectories into the management of MASLD is essential for optimizing cardiovascular risk stratification and improving patient survival.

2497 | WAIST-TO-HIP RATIO IMPROVES IDENTIFICATION OF LIVER FIBROSIS BEYOND BMI IN A NATIONAL NHANES ELASTOGRAPHY COHORT

Navin Prasad[1], [1]*Presbyterian Hospital*

Background: Body mass index (BMI) is widely used for metabolic dysfunction–associated steatotic liver disease (MASLD) risk stratification but incompletely reflects visceral adiposity, a major driver of hepatic fibrogenesis. We evaluated whether waist-to-hip ratio (WHR), a marker of central adiposity, improves identification of liver fibrosis beyond BMI in a nationally representative U.S. cohort. **Methods:** We performed a cross-sectional analysis of adults aged ≥ 18 years with transient elastography data from the National Health and Nutrition Examination Survey (NHANES) 2017–March 2020 and 2021–2023 cycles. Significant liver fibrosis risk was defined as liver stiffness measurement ≥ 8 kPa. WHR was calculated using measured waist and hip circumferences and categorized into quartiles. Survey-weighted logistic regression evaluated associations between WHR and fibrosis after adjustment for BMI, age, and sex. Predictive discrimination was assessed using survey-weighted receiver operating characteristic (ROC) analysis. **Results:** Among 13,190 adults, the weighted prevalence of significant liver fibrosis risk was 10.4%. Fibrosis prevalence increased progressively across WHR quartiles from 3.7% in the lowest quartile to 19.7% in the highest quartile (p-trend < 0.001). In multivariable analysis adjusting for BMI, age, and sex, individuals in the highest WHR quartile had significantly increased odds of fibrosis compared with the lowest quartile (OR 2.02, p = 0.001). BMI also remained independently associated with fibrosis risk (OR 1.13 per unit increase, p < 0.001). WHR provided incremental improvement in fibrosis discrimination beyond BMI alone (AUC 0.758 vs 0.750, $p = 6.1\times10^{-6}$). Stratified analyses demonstrated substantial heterogeneity in fibrosis prevalence across WHR quartiles within BMI categories, with the highest prevalence observed among individuals with BMI ≥ 35 and WHR Q4 (37.8%). **Conclusion:** WHR independently identifies increased liver fibrosis risk beyond BMI and provides incremental improvement in fibrosis risk discrimination in a nationally representative U.S. population. Central adiposity measures may help identify high-risk individuals with MASLD who could be underrecognized using BMI-based screening approaches alone.

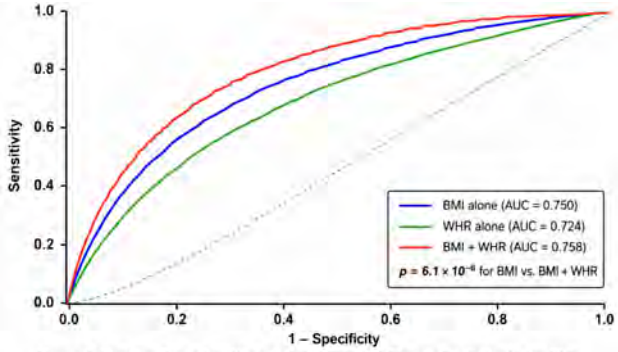

Figure 4. Receiver Operating Characteristic Curves for Fibrosis Prediction Using BMI, WHR, and Combined Models.
ROC curves comparing BMI alone, WHR alone, and combined BMI + WHR models for prediction of liver stiffness ≥8 kPa. Addition of WHR to BMI improved discrimination compared with BMI alone (AUC 0.758 vs 0.750; p = 6.1 × 10⁻⁶).

2498 | RISK OF EXTRAHEPATIC MALIGNANCIES IN PATIENTS WITH MASLD WITH AND WITHOUT CIRRHOSIS: A PROPENSITY-MATCHED COHORT STUDY

Lina AlQirem[1] Ragesh Thandassery[1], [1]The University of Arkansas for Medical Sciences

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is considered to have increased risk of extrahepatic malignancies; however, the impact of cirrhosis on this risk remains poorly understood. We aimed to evaluate the incidence of extrahepatic malignancies among patients with MASLD with and without cirrhosis compared to matched non-MASLD controls. **Methods:** We conducted a retrospective cohort study using the TriNetX global research network of de-identified electronic health records. Patients with MASLD (with and without cirrhosis) were compared to non-MASLD controls and stratified by cirrhosis status. Those with prior diagnosis of extrahepatic malignancy and other causes of hepatic steatosis, including alcohol use disorder, chronic hepatitis C infection, celiac disease, hemochromatosis, and steatosis-associated medications (systemic corticosteroids, methotrexate, tamoxifen, or amiodarone) were excluded. Before propensity score matching, 19,444,137 non-MASLD patients and 5,716 MASLD patients with cirrhosis were identified between the years 2010 and 2012; after 1: 1 matching, 5,716 pairs remained. For MASLD without cirrhosis, 55,270 matched pairs were included. Matching was based on age and baseline characteristics with standardized mean differences <0.1. Risk ratios (RR) and hazard ratios (HR) were calculated, with Kaplan-Meier analysis for time-to-event outcomes. **Results:** Among 5,716 matched pairs (mean age 57.9 ± 12.5 years), MASLD with cirrhosis was associated with increased risk of colorectal cancer (1.1% vs 0.8%; RR 1.50, $p=0.032$; HR 1.79, $p=0.002$), pancreatic cancer (0.9% vs 0.4%; RR 2.25, $p<0.01$; HR ~1.78, $p<0.05$), and renal cancer (0.7% vs 0.4%; HR 1.78, $p=0.023$). Breast, lung, and thyroid cancers were not significantly different. Prostate cancer showed lower cumulative incidence (1.1% vs 1.9%; RR 0.57, $p<0.001$) but higher hazard over time (HR 1.44, $p=0.021$), suggesting likely delayed diagnosis. In a larger cohort of 55,270 matched pairs, MASLD without cirrhosis was associated with increased risk of breast (2.4% vs 1.9%), lung (1.8% vs 1.4%), colorectal (1.0% vs 0.6%), renal (0.9% vs 0.4%), and pancreatic cancer (0.7% vs 0.3%) (all $p<0.001$), with consistently higher hazards over time. **Conclusion:** MASLD is associated with increased risk of extrahepatic malignancies even without cirrhosis, with further increased risk in colorectal and pancreatic cancers with cirrhosis. These findings support heightened cancer awareness and tailored surveillance strategies in MASLD.

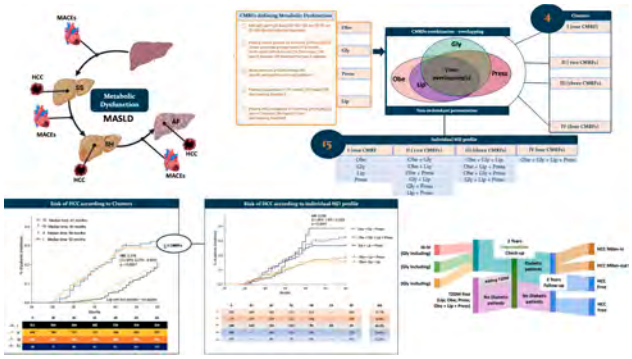
2499 | METABOLIC SIGNATURES SHAPE HEPATOCELLULAR CARCINOMA RISK AND TRAJECTORIES IN MASLD PATIENTS WITH ADVANCED FIBROSIS



Mario Romeo[1] Marcello Dallio[1] Carmine Napolitano[1] Fiammetta Di Nardo[1] Paolo Vaia[1] Claudio Basile[1] Luigi Di Puorto[1] Mattia Indipendente[1] Marco Niosi[1] Luigi Maria Vitale[1] Alessandro Federico[1], [1]Hepatogastroenterology Division, University of Campania Luigi Vanvitelli, 80138, Naples

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is an increasingly prevalent cause of hepatocellular carcinoma (HCC) (**Figure**). While individual cardiometabolic risk factors (CMRFs) such as obesity, type 2 diabetes mellitus (T2DM), hypertension, and dyslipidemia have been linked to HCC, the impact of their cumulative burden and specific combinations on HCC trajectories in patients with advanced fibrosis (AF) remains poorly defined. We aimed to assess HCC risk according to distinct metabolic dysfunction (MD) profiles in a large Italian cohort of MASLD-AF patients. **Methods:** We retrospectively analyzed 1,921 consecutive patients with MASLD and advanced fibrosis (F3-F4) undergoing semiannual ultrasound-based surveillance at a tertiary referral center network. MD was defined by the presence of four CMRFs: obesity, T2DM, hypertension, and dyslipidemia. Patients were stratified into four clusters according to the number of CMRFs (I, II, III, or IV) and into specific nonredundant metabolic profiles (n.15) based on all possible combinations (**Figure**). The primary endpoint was incident HCC. Secondary endpoints included HCC beyond Milan criteria at first diagnosis and the impact of incident T2DM during follow-up. **Results:** Patients were distributed across

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

metabolic burden clusters as follows: Cluster I (1 CMRF), n = 311; Cluster II (2 CMRFs), n = 840; Cluster III (3 CMRFs), n = 680; and Cluster IV (4 CMRFs), n = 90. HCC risk significantly increased across clusters, with the highest incidence observed in patients with ≥ 3 CMRFs. Patients with ≥ 3 CMRFs were more likely to present with HCC and with HCC beyond Milan criteria at first diagnosis (OR 2.46; p = 0.016; OR: 1.54, p = 0.035). Within Cluster III, the obesity-diabetes-hypertension profile showed the highest risk of both overall HCC and Milan-out HCC (**Figure**). In multivariable competing-risk analysis, the presence of ≥ 3 CMRFs (Clusters III-IV) was independently associated with HCC development (HR 2.05, 95% CI 1.42-2.96; p < 0.0001), together with age (HR 1.03 per year, 95% CI 1.01-1.05; p = 0.004) and baseline T2DM (HR 1.82, 95% CI 1.30-2.54; p < 0.0001). In dynamic analyses, restricted to patients free of diabetes at baseline, incident diabetes during follow-up markedly modified HCC trajectories, accounting for most of the association between cumulative metabolic burden and cancer risk (risk attenuation 82% after mediation modelling). **Conclusion:** In MASLD patients with AF, HCC risk is driven by distinct cardiometabolic signatures rather than by the mere presence of MD. The coexistence of obesity, T2DM, and hypertension identifies a particularly high-risk phenotype, while incident T2DM acts as a disease-modifying event that largely mediates the relationship between metabolic burden and HCC. These findings support precision surveillance strategies based on individualized metabolic profiling.

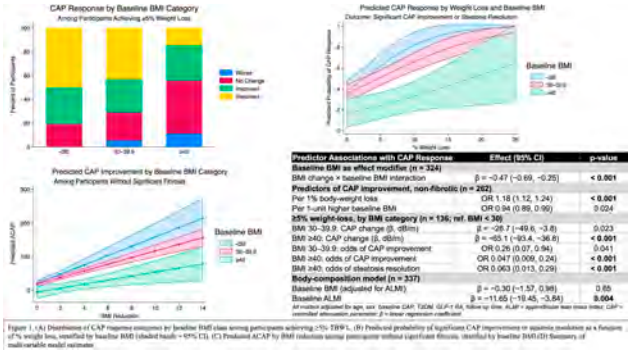
2500 | ONE SIZE DOES NOT FIT ALL: HIGHER STARTING BMI AND LOWER APPENDICULAR LEAN MASS ATTENUATE STEATOSIS IMPROVEMENT BY TRANSIENT ELASTOGRAPHY AFTER WEIGHT LOSS



Alec Chang[1] Sophie Silbert[1] Ani Bernardi[1] Carolyn Newberry[1] Reem Sharaiha[1] Sonal Kumar[1] Melina Manolas[1] Adam Buckholz[1], [1]NewYork-Presbyterian/ Weill Cornell Medical Center

Background: MASLD is the leading chronic liver disease worldwide, and weight loss remains the cornerstone treatment for hepatic steatosis. Guidelines recommend ≥ 5% total body weight loss (TBWL) for steatosis improvement in non-fibrotic disease, yet whether this threshold produces comparable controlled attenuation parameter (CAP) reductions across BMI classes is unclear. We hypothesized that higher baseline BMI attenuates CAP response to weight loss. **Methods:** We retrospectively studied adults with MASLD (CAP > 238 dB/m) who underwent paired FibroScan and Body Impedance Analysis, excluding patients with liver stiffness ≥ 15 kPa, suggestive of F4-range fibrosis. Multivariable linear regression assessed the association between ΔBMI and ΔCAP, adjusted for baseline BMI and CAP, age, sex, type 2 diabetes (T2D), and GLP-1 receptor agonist (GLP1-RA) use. Logistic regression evaluated CAP improvement (> 30-point reduction) and steatosis resolution (CAP < 238 dB/m). Among patients achieving ≥ 5% TBWL, CAP outcomes were compared across BMI categories (< 30, 30–39.9, ≥ 40 kg/m²). Sensitivity analyses incorporated baseline appendicular lean mass index (ALMI) to evaluate whether body composition explained the BMI effect. **Results:** Of 337 subjects with mean age 51.0 years and follow-up 24 months, 59.4% were female, 30.0% had T2D, and 51.2% GLP-1RA use, 42.4% achieved ≥ 5% TBWL. Mean baseline CAP was 305.9 dB/m, median kPa 6.1, and 281 lacked clinically meaningful fibrosis (kPa < 8). Greater BMI reduction was associated with greater CAP improvement (p < 0.001), but this effect diminished with higher baseline BMI (interaction β = −0.47, p < 0.001; nonfibrotic sensitivity analysis β = −0.49, p = 0.003). Among nonfibrotic participants, each 1% TBWL increased the odds of CAP improvement by 18% (OR 1.18, 95% CI 1.12–1.24, p < 0.001), while each 1-unit higher baseline BMI reduced the odds by 6% (OR 0.94, p = 0.024). Among those achieving ≥ 5% TBWL, BMI 30–39.9 and ≥ 40 had 27- and 65-dB/m smaller ΔCAP, respectively, versus BMI < 30. Class III obesity (BMI ≥ 40) had significantly lower odds of CAP improvement (OR 0.047, p < 0.001) and steatosis resolution (OR 0.063, p < 0.001). A mediation analysis identified baseline ALMI as a significant mediator of BMI to ΔCAP association, with the direct effect of BMI attenuated to non-significance (β = −0.30, p = 0.65), while

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

ALMI independently predicted CAP response (β = −11.65, p = 0.004). **Conclusion:** In this real-world MASLD cohort, CAP improvement with BMI reduction was progressively blunted at higher baseline BMI, independent of clinical predictors. Class III obesity was associated with markedly reduced odds of steatosis improvement even after ≥5% TBWL, and attenuation of the BMI effect by ALMI suggests that body composition phenotype may underlie differences in steatosis responsiveness. These findings support establishing BMI- and body composition–informed weight loss targets in MASLD management and future studies.

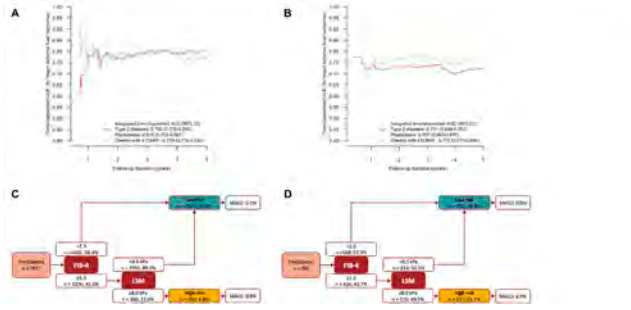
2501 | PREDICTION OF MAJOR ADVERSE LIVER OUTCOMES (MALOS) BY THE TWO-STEP ALGORITHM FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) BASED ON AMERICAN DIABETES ASSOCIATION (ADA)-PROPOSED AT-RISK POPULATION: A MULTINATIONAL COHORT STUDY

Jimmy Che-To Lai[1] Grace Wong[1] Huapeng Lin[2] Emmanuel Tsochatzis[3] Mirko Zoncapè[3] Salvatore Petta[4] Elisabetta Bugianesi[5] Masato Yoneda[6] Ming-Hua Zheng[7] Javier Crespo[8] Paula Iruzubieta[8] Jerome Boursier[9] Jose Luis Calleja[10] Boon Bee George Goh[11] Eugene Wong[12] Wah-Kheong Chan[13] Rocio Gallego-Durán[14] Arun J Sanyal[15] Victor de Ledinghen[16] Philip Newsome[17] Jian-Gao Fan[18] Laurent Castera[19] Grazia Pennisi[4] Angelo Armandi[5] Kamela Gijni[5] Atsushi Nakajima[6] Wen-Yue Liu[7] Ming-Hua Zheng[7] Ying Shang[20] Marc De Saint Loup[9] Elba Llop[10] Kevin Kim Jun Teh[11] Carmen Lara Romero[14] Racio Macias[10] Amon Asgharpour[15] Sara Mahgoub[21] Adrien Lannes[9] Manuel Romero-Gómez[22] Seung Up Kim[23] Vincent Wong[1] Terry Cheuk-Fung Yip[1] Hye Won Lee[23], [1]The Chinese University of Hong Kong, [2]Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, [3]Royal Free Hospital and UCL, [4]University of Palermo, [5]University of Torino, [6]Yokohama City University Graduate School of Medicine,, [7]The First Affiliated Hospital of Wenzhou Medical University, [8]Marqués de Valdecilla University Hospital, [9]Angers University, [10]Universidad Autonoma de Madrid, [11]Singapore General Hospital, [12]Changi General Hospital, [13]University of Malaya, [14]University of Seville, [15]Virginia Commonwealth University School of Medicine, [16]Echosens, [17]King's College London, [18]Xinhua Hospital Affiailted to Shanghai Jiaotong University School of Medicine, [19]Université Paris Cité, [20]Karolinska Institutet, [21]University Hospitals Birmingham NHS Foundation Trust and University of Birmingham, [22]Virgen del Rocio University Hospital, [23]Yonsei University College of Medicine



Background: Building on the two-step algorithms for MASLD introduced by liver societies, ADA endorsed a simplified pathway using FIB-4 at a single cutoff of 1.3, followed by vibration-controlled transient elastography (VCTE) at a liver stiffness measurement (LSM) cutoff of 8.0 kPa for fibrosis risk stratification. The ADA-defined at-risk population also extends to prediabetes, which is broader than type 2 diabetes (T2D) and obesity with ≥1 cardiometabolic risk factor (CMRF) as in other guidelines. However, the prognostic performance of this algorithm across these metabolic risk groups, particularly among individuals with prediabetes, remains uncertain. We validated this algorithm across ADA-defined at-risk populations. **Methods:** We analyzed two VCTE-based multicenter cohorts in different clinical settings: the V-LINK cohort comprising tertiary-care patients with chronic liver disease and health screening subjects in Korea, and the international VCTE-Prognosis cohort of patients with MASLD from 16 tertiary centers in the US, Europe, and Asia. The primary outcome was MALOs, defined as hepatic decompensation, hepatocellular carcinoma, liver transplantation, and/or liver-related death. **Results:** Of 26,362 adults in V-LINK, 8,365 (31.7%) had T2D, 7,877 (29.9%) had prediabetes, and 6,980 (26.5%) had obesity with ≥1 CMRF. Corresponding numbers among 4,680 adults in VCTE-Prognosis were 1,644 (35.1%), 992 (21.2%), and 1,987 (42.5%), respectively. During median follow-up of 5.0 and 4.2 years, MALOs occurred in 85 (1.0%), 35 (0.4%), and 66 (0.9%) patients with T2D, prediabetes, and obesity with ≥1 CMRF in V-LINK, and in 76 (4.6%), 16 (1.6%), and 62 (3.1%) patients in VCTE-Prognosis, respectively. Integrated time-dependent AUCs for MALO prediction demonstrated good discrimination across cohorts and metabolic risk groups, ranging from 0.78 to 0.82 in V-LINK and 0.73 to 0.79 in VCTE-Prognosis (Fig 1A,B). In V-LINK, the two-step

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

algorithm classified 11.5%, 10.6%, and 4.6% of patients with T2D, obesity with ≥1 CMRF, and prediabetes as high risk, respectively; in VCTE-Prognosis, these proportions were 44.5%, 34.0%, and 21.1%, respectively. Across T2D, prediabetes, and obesity with ≥1 CMRF, high-risk patients had consistently higher 5-year cumulative MALO incidence than low-risk patients in both V-LINK (7.1%-8.0% vs 0.2%-0.5%) and VCTE-Prognosis (8.9%-11.8% vs 0.6%-1.6%). Prediabetes had the lowest high-risk yield in both cohorts. Among patients with prediabetes and FIB-4 ≥1.3, second-step LSM reclassified a large proportion as low risk, with LSM <8.0 kPa in 89.0% of V-LINK and 50.5% of VCTE-Prognosis patients (Fig 1C,D). **Conclusion:** The ADA two-step algorithm effectively stratified MALO risk stratification across T2D, prediabetes, and obesity with ≥1 CMRF in distinct clinical settings. False-positive referrals are common in prediabetes, limiting the utility of two-step algorithm.

Figure 1. Performance of the ADA two-step algorithm for MALO across metabolic risk groups. (A) Time-dependent AUROC for MALO by the two-step algorithm among patients with T2D, prediabetes and obesity with ≥1 CMRF in V-LINK cohort, (B) Time-dependent AUROC for MALO by the two-step algorithm among patients with T2D, prediabetes and obesity with ≥1 CMRF in VCTE-Prognosis cohort, (C) Categorisation of patients with prediabetes by two-step algorithm in V-LINK cohort, (D) Categorisation of patients with prediabetes by two-step algorithm in VCTE-Prognosis cohort.

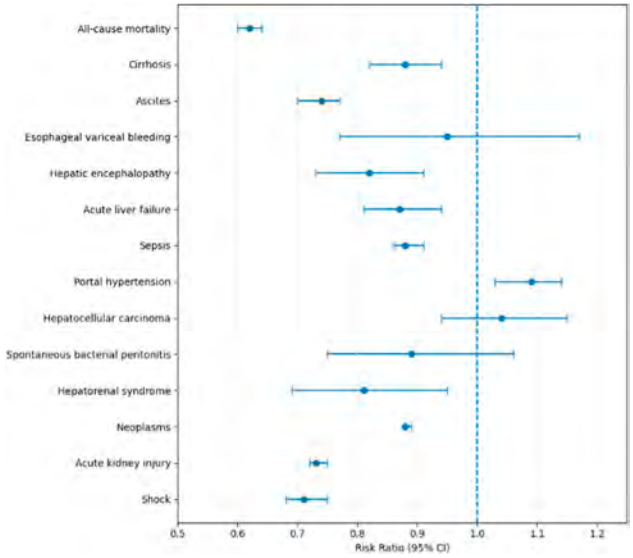
2502 | DO HISPANIC PATIENTS WITH METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE HAVE WORSE OUTCOMES? A LARGE PROPENSITY SCORE–MATCHED STUDY



Muhamad Oum[1] Osama Alshakhatreh[2] Gokul Karthikeyan[3] Sammy Saab[4], [1]Saint Agnes Medical Center, [2]Eastern Virginia Medical School at Old Dominion University, [3]Drexel University College of Medicine, [4]David Geffen School of Medicine at UCLA

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) disproportionately affects Hispanic populations and has been associated with worse liver-related outcomes and mortality. However,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

it remains unclear whether Hispanic ethnicity independently contributes to adverse outcomes after controlling for associated metabolic and systemic comorbidities. We aimed to compare liver-related and systemic outcomes between Hispanic and non-Hispanic patients with MASLD using a large multicenter propensity score–matched analysis. **Methods:** We conducted a retrospective cohort study using the TriNetX US multicenter electronic health records network. Adult patients with MASLD were identified using ICD-10 code K76.0. Patients with preexisting advanced liver disease, including cirrhosis, ascites, esophageal varices with bleeding, hepatic encephalopathy, and acute liver failure, were excluded. Hispanic patients with MASLD were compared with non-Hispanic patients with MASLD. Propensity score matching was performed 1: 1 adjusting for demographics and major comorbidities. Outcomes assessed within 1 year included all-cause mortality, cirrhosis, ascites, hepatic encephalopathy, acute liver failure, portal hypertension, hepatocellular carcinoma, spontaneous bacterial peritonitis, hepatorenal syndrome, acute kidney injury, sepsis, shock, and neoplasms. **Results:** A total of 254,107 Hispanic patients and 1,278,495 non-Hispanic patients with MASLD were identified. After matching, 226,088 patients remained in each cohort, with all standardized mean differences below 0.1. Hispanic patients demonstrated significantly lower risks of all-cause mortality (RR 0.62, 95% CI 0.60–0.64), cirrhosis (RR 0.88, 95% CI 0.82–0.94), ascites (RR 0.74, 95% CI 0.70–0.77), hepatic encephalopathy (RR 0.82, 95% CI 0.73–0.91), acute liver failure (RR 0.87, 95% CI 0.81–0.94), sepsis (RR 0.88, 95% CI 0.86–0.91), acute kidney injury (RR 0.73, 95% CI 0.72–0.75), shock (RR 0.71, 95% CI 0.68–0.75), hepatorenal syndrome (RR 0.81, 95% CI 0.69–0.95), and neoplasms (RR 0.88, 95% CI 0.88–0.89). Portal hypertension was more common among Hispanic patients (RR 1.09, 95% CI 1.03–1.14). No significant differences were observed in hepatocellular carcinoma, spontaneous bacterial peritonitis, or esophageal variceal bleeding. **Conclusion:** After rigorous propensity score matching, Hispanic patients with MASLD demonstrated lower risks of all-cause mortality and multiple liver-related complications compared with non-Hispanic patients. These findings suggest that previously reported disparities in MASLD outcomes among Hispanic populations may be driven predominantly by associated cardiometabolic and socioeconomic factors rather than ethnicity alone. Importantly, MASLD remained associated with substantial morbidity across all populations once established, regardless of ethnicity.

2503 | CRYPTOGENIC STEATOTIC LIVER DISEASE IS RARE BUT NOT FULLY BENIGN: A VCTE-BASED CLINICAL AND BODY COMPOSITION STUDY

Vasily Isakov[1] Alexei Goncharov[2] Igor Maev[3], [1]Federal Research Center of Nutrition and Biotechnology, [2]Federal Research Center of Nutrition, Biotechnology & Food Safety, [3]Russian University of Medicine

Background: The 2023 steatotic liver disease nomenclature introduced cryptogenic steatotic liver disease (CSLD), defined by hepatic steatosis without cardiometabolic criteria, alcohol-related liver disease, or other identifiable causes. Its prevalence and phenotype remain poorly characterized. **Methods:** We retrospectively analyzed 4,673 adults who underwent vibration-controlled transient elastography with controlled attenuation parameter (CAP) assessment at a tertiary nutrition clinic. Steatosis was defined as CAP $\geq$ 248 dB/m; liver stiffness measurement was used for fibrosis staging. Patients with viral, autoimmune, cholestatic,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

genetic, drug-related, alcohol-related, postsurgical, or other secondary causes of steatosis were excluded. CSLD was diagnosed when steatosis was present but no cardiometabolic criterion was met. MASLD patients and healthy controls without steatosis, fibrosis, or cardiometabolic criteria were comparator groups. Body composition was assessed by bioimpedance analysis. **Results:** Among 2,643 patients with hepatic steatosis, CSLD was identified in 22 patients (0.8%), whereas MASLD accounted for 2,389 cases (90.4%). Compared with MASLD, CSLD showed a milder hepatic phenotype: severe steatosis (S3) was less frequent (27.3% vs 67.6%; $p < 0.001$), and significant-to-advanced fibrosis (F2–F4) was uncommon (9.1% vs 29.3%; $p = 0.02$), with no CSLD patient classified as F3–F4. Compared with healthy controls ($n = 266$), CSLD patients had higher BMI despite normal-range values (24.1 [22.1–24.5] vs 22.4 [20.7–23.7] kg/m²; $p = 0.008$), driven mainly by greater fat mass (19.0 [16.6–26.7] vs 16.4 [12.2–20.5] kg; $p = 0.03$) and higher visceral fat area. In contrast, sex distribution, age, triglycerides, LDL cholesterol, total cholesterol, fasting glucose, HbA1c, HOMA-IR, ALT, and AST did not differ significantly between CSLD and controls. **Conclusion:** In this VCTE-based cohort, CSLD was rare, representing < 1% of patients with hepatic steatosis. CSLD was hepatically and metabolically milder than MASLD but was not fully identical to health, showing increased adiposity despite normal BMI and preserved routine metabolic markers. These findings suggest that "benign" steatosis is uncommon and that incidentally detected steatosis should prompt structured cardiometabolic and fibrosis assessment.

2504 | RECREATIONAL PHYSICAL ACTIVITY AND METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) PREVALENCE, STEATOSIS SEVERITY, AND FIBROSIS SEVERITY: A CROSS-SECTIONAL ANALYSIS OF NHANES 2017–2018

Nishat Anjum Shaik[1] Mohammed Rifat Shaik[2] Kamran Qureshi[3], [1]SSM Health/Saint Louis University, [2]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, [3]Saint Louis University

Background: Physical activity is a cornerstone of lifestyle management for metabolic dysfunction-associated steatotic liver disease (MASLD). However, population-level data evaluating the association between recreational physical activity and MASLD-related outcomes remain limited. We examined the association between recreational physical activity and MASLD prevalence, steatosis severity, and fibrosis severity in a nationally representative cohort of U.S. adults. **Methods:** This cross-sectional study used NHANES 2017–2018 data from adults aged ≥ 18 years with complete recreational physical activity and transient elastography (TE) data. Recreational activity was quantified as weekly metabolic equivalent (MET)-minutes from self-reported moderate- and vigorous-intensity recreational activities and categorized into weighted quartiles (Q1 = reference). MASLD was defined as controlled attenuation parameter (CAP) ≥ 274 dB/m with ≥ 1 cardiometabolic risk factor in the absence of significant alcohol use or viral hepatitis. Severe steatosis was defined as CAP ≥ 302 dB/m, and clinically significant fibrosis as TE ≥ 8 kPa among participants with MASLD. Survey-weighted logistic regression models included unadjusted, primary adjusted (age, sex, race/ethnicity, education, poverty-income ratio, smoking), and exploratory metabolic models (additionally adjusted for BMI, diabetes, hypertension, and dyslipidemia). **Results:** A total of 5,848 participants were included (mean age 49.9 years; 51.5% female). Compared with participants in the lowest recreational activity quartile (Q1), those in the highest quartile (Q4) were younger (41.7 vs 53.6 years), more likely male (57.9% vs 46.4%), had lower BMI (28.5 vs 30.4 kg/m²), and had lower prevalence of diabetes (9.8% vs 23.6%), hypertension (23.6% vs 42.3%), and dyslipidemia (39.3% vs 56.2%) (all $p < 0.001$). In the primary adjusted model, Q4 recreational activity was independently associated with lower odds of MASLD (OR 0.44, 95% CI 0.36–0.54) and severe steatosis (OR 0.45, 95% CI 0.32–0.63) using Q1 as reference. In exploratory metabolic models, associations were attenuated but remained significant for MASLD (OR 0.69, 95% CI 0.56–0.84) and severe steatosis (OR 0.75, 95% CI 0.58–0.97). There was no significant difference in clinically significant fibrosis in Q2, Q3, or Q4 compared to Q1 across all models. **Conclusion:** Higher recreational physical activity was independently associated with lower MASLD prevalence and lower steatosis severity, but not with significant fibrosis. The concentration of benefit within the highest activity quartile suggests a potential threshold effect, whereby substantial recreational activity may be required for hepatoprotection. These findings reinforce current lifestyle recommendations and support targeted interventions to promote higher-intensity recreational physical activity among adults with MASLD.

2505 | GLYCEMIC TRAJECTORIES MODIFY LONG-TERM OUTCOMES IN METABOLIC STEATOTIC LIVER DISEASE

Won Kim[1] Gi-Ae Kim[2] Bo Kyung Koo[1] Yeonjin Kim[3] Woojoo Lee[3], [1]Seoul National University College of Medicine, [2]Kyung Hee University School of Medicine, [3]Seoul National University

Background: Background and Aims: The impact of evolving glycemic status over time in metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction and alcohol-related liver disease (MetALD) remains uncertain. We aimed to investigate the influence of 2-year fasting plasma glucose (FPG) trajectories on major cardiovascular events (MACE), all-cause mortality, and liver-related events (LREs) in MASLD and MetALD. **Methods:** This cohort study recruited 269,128 adults with MASLD or MetALD who underwent biennial health examinations in 2012 and 2014 from the Korean National Health Insurance Service database. The patients were classified into normal fasting glucose (NFG), impaired fasting glucose (IFG), and diabetic fasting glucose (DFG). The category transitions in 2 years labeled them as improvers, sustainers, or worseners. Competing-risk Fine–Gray models yielded adjusted subdistribution hazard ratios (aSHRs). **Results:** Over 7.3 years, 10,695 MACE, 6,310 deaths, and 6,529 LREs occurred. Relative to IFG-sustainers, IFG-worseners showed a higher risk of MACE (aSHR 1.22; 95% confidence interval [CI], 1.11–1.34). DFG-improvers experienced a lower risk of MACE than DFG-sustainers (aSHR 0.85; 95% CI, 0.77–0.94). NFG worseners and IFG worseners exhibited increased risk of all-cause mortality (aSHR 1.16; 95% CI, 1.07–1.26 and aSHR 1.30; 95% CI, 1.16–1.46, respectively). Glycemic change did not significantly influence LREs. Findings persisted in sensitivity analyses using ≥6 mg/dL and ≥10 mg/dL for thresholds. **Conclusion:** In metabolic steatotic liver disease (SLD), worsening glycemia augments cardiovascular and mortality risks, whereas improvement from FPG levels mitigates MACE risk. Vigilant and proactive glycemic management should be integral to the care of metabolic SLD.

2506 | SARCOPENIC OBESITY AND LONG-TERM RISKS OF LIVER-RELATED OUTCOMES AND ALL-CAUSE MORTALITY: A PROSPECTIVE COHORT STUDY

Jiayue Li[1] Ruoqi Zhou[2] Yuhua Hao[3] Rongtao Lai[4] Yuankai Wu[3] Yifei Tao[3] Vincent Wong[5] Yu Shi[2] Xinrong Zhang[6], [1]Northwestern University, [2]The First Affiliated Hospital, Zhejiang University School of Medicine, [3]School of Public Health, Sun Yat-sen University, [4]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [5]The Chinese University of Hong Kong, [6]Stanford University Medical Center

Background: Sarcopenic obesity (SO), defined as the coexistence of sarcopenia and obesity, is a high-risk phenotype associated with adverse metabolic and hepatic outcomes. Although cross-sectional studies have suggested an association between SO and metabolic dysfunction-associated steatotic liver disease (MASLD), the impact of SO on the long-term outcomes of patients with MASLD remains poorly characterized. Therefore, we investigated the associations of sarcopenia-obesity phenotypes with all-cause mortality, cirrhosis, and hepatocellular carcinoma (HCC) in a prospective cohort study. **Methods:** Participants were categorized into non-obesity, obesity

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

alone, and SO using data from UK Biobank. Sarcopenia was defined according to the European Working Group on Sarcopenia in Older People criteria: low handgrip strength (< 27 kg for men, < 16 kg for women) and/or low skeletal muscle index (< 7.0 kg/m² for men, < 5.5 kg/m² for women). Obesity was defined as body mass index ≥ 30 kg/m² for non-Asian participants, and ≥ 25 kg/m² for non-Hispanic Asian individuals. Cox proportional hazards models were used to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs) for all-cause mortality, cirrhosis, and HCC. **Results:** A total of 457,708 eligible participants were included. Median age was 58 years, and 45.7% were male. Participants were categorized into non-obesity (n = 346,744), obesity alone (n = 103,904), and SO (n = 7,060). Compared with the non-obese group, those with SO were older, more likely to be female, and had a higher burden of cardiometabolic risk factors, including type 2 diabetes, hypertension, and dyslipidemia (all p < 0.001). During follow-up, 48,943 deaths, 2,768 cases of cirrhosis, and 488 cases of HCC were recorded. In fully adjusted models, SO was associated with significantly higher risks of all-cause mortality (aHR 1.66, 95% CI: 1.57-1.74, p < 0.001), cirrhosis (aHR 2.69, 95% CI: 2.25-3.23, p < 0.001), and HCC (aHR 2.37, 95% CI: 1.52-3.68, p < 0.001). These associations were consistently stronger for SO than obesity alone. Subgroup analyses showed that the increased risks of all-cause mortality and liver outcomes associated with SO were broadly consistent across age, sex, and racial subgroups. **Conclusion:** In this prospective cohort study, SO was independently associated with higher risks of all-cause mortality, cirrhosis, and HCC, with stronger effects than obesity alone. These findings identify SO as a high-risk phenotype warranting targeted monitoring and intervention.

Table. Associations between obesity and sarcopenia status and all-cause mortality, liver cirrhosis and hepatocellular carcinoma in UK Biobank.

All-cause mortality		HR (95% CI)	P value	HR (95% CI)	P value	HR (95% CI)	P value

2507 | HIGH RISK OF UNDIAGNOSED ADVANCED LIVER DISEASE LEADING TO HEPATIC DECOMPENSATION IN PATIENTS WITH DIABETES MELLITUS DESPITE ENGAGEMENT IN AMBULATORY CARE

Emily Leven[1] Anna Mageras[1] Xiaotao Zhang[1] Meena Bansal[2], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Patients with diabetes mellitus (DM) are at high risk for the development of metabolic-associated steatotic liver disease (MASLD) which may be asymptomatic and without significant laboratory abnormalities even in the presence of advanced fibrosis. The purpose of this study was to identify and describe patients whose first diagnosis of advanced liver disease was at the time of liver decompensation ("late diagnosis") despite participation in outpatient care. **Methods:** A retrospective review of a large, single, urban health system's validated Diabetes Registry (Nathani et al., 2026) was performed from 2000-2025. Inclusion criteria were registry patients with an ambulatory visit to primary care or endocrinology from 2023-2024. Hepatic decompensation was defined as: diagnosis code for hepatic encephalopathy (HE), variceal bleeding (EVB), ascites, liver failure, hepatorenal syndrome, or hepatocellular carcinoma; prescription for lactulose or rifaximin (HE); prescription for furosemide with spironolactone (ascites); procedure code for paracentesis (ascites), variceal band ligation (EVB), or transjugular intrahepatic portosystemic shunt (TIPS)/surgical shunt (shunt). Known diagnosis of advanced liver disease was defined as a diagnosis of cirrhosis, referral to hepatology, or visit in hepatology clinic predating first decompensating event (hepatology and gastroenterology are separate in our health system). **Results:** 3768 patients (50% female, 25.6% White) had liver decompensation. Most common decompensating events were HE, ascites, and HCC. 3015 patients had late diagnosis (Table 1). 1923 (64%) had lab data within 1 year of decompensation allowing for Fibrosis-4 liver index for fibrosis (FIB-4) risk stratification. Patients with late diagnosis had fewer mean number of outpatient encounters across specialties prior to decompensation compared to those with known liver disease (7.5 vs. 12.2, p < 0.01). Of patients with available FIB-4 scores (the majority of patients), most were high or indeterminate, and most were female (52.4% vs 47.6% chi-squared p < 0.01). There were no other significant differences in demographics between patients who had available FIB-4 data compared to those who did not. **Conclusion:** These findings suggest a missed opportunity for linkage to hepatology despite engagement in ambulatory care, often with multiple specialists. Simple FIB-4 calculation

could highlight those requiring further secondary risk assessment such as vibration-controlled transient elastography, Enhanced Liver Fibrosis testing, or magnetic resonance elastography. It is critical to identify patients during the compensated cirrhosis phase when targeted preventive measures may be employed to avoid decompensation and the associated high costs that come with urgent hospitalization. Careful attention to hepatic end-organ damage is needed as part of regular DM healthcare maintenance and screening.

Table. Decompensated patients: demographics and pre-decompensation care

	LATE DIAGNOSIS (n=3015)		KNOWN ADVANCED LIVER DISEASE (n=753)		
	n	Percent	n	Percent	Chi-squared P

2508 | WAITLIST OUTCOMES FOR CANDIDATES WITH MASH AND LOW MELD SCORES COMPARED WITH VIRAL HEPATITIS

Eman Chaudhry[1] Catherine Kelty[2] Ralph Quillin[2] Christine Haugen[2] Khurram Bari[2], [1]Northeast Ohio Medical University, [2]University of Cincinnati

Background: MELD-based allocation prioritizes liver transplant candidates using laboratory markers but does not capture metabolic burden, frailty, or portal hypertensive complications. We evaluated whether candidates with metabolic dysfunction-associated steatohepatitis (MASH) have worse waitlist outcomes than candidates with viral hepatitis, focusing on low MELD, where non-liver factors may be underrecognized. **Methods:** We performed a retrospective cohort study using Scientific Registry of Transplant Recipients data of adult liver-only waitlist candidates listed between Feb 1, 2016 and Jan 31, 2023 (MELD 1.0 to ensure adequate follow up and cohort size). Etiology was defined using candidate diagnosis codes for MASH and viral hepatitis. Candidates with prior liver transplant or hepatocellular carcinoma exception were excluded and stratified by MELD at listing: < 15, 15-20, and 21-30. The primary outcome was waitlist removal due to deterioration/death. Secondary outcomes included 90-day and 1-year removal, time to transplant, and MELD change from listing to transplant/removal. Time to deterioration/death was assessed by Kaplan-Meier analysis. MELD > 30 was excluded from this analysis because severe hepatic dysfunction and short wait times may obscure non-liver contributors to waitlist risk. **Results:** The cohort included 24,280 candidates with MELD < 30: 11,850 with MELD < 15, 7,496 with MELD 15-20, and 4,934 with MELD 21-30. In MELD < 15, candidates with MASH had higher BMI (31 vs 28, $p < 0.001$), higher initial MELD (12 vs 10, $p < 0.001$), lower albumin (3 vs 4, $p < 0.001$), and more moderate ascites (25.1% vs 11.5%, $p < 0.001$) compared with candidates with viral hepatitis (Table 1). In MELD 15-20 and 21-30, MASH was associated with higher BMI and more moderate ascites (37.3% MASH vs. viral hepatitis: 31.2%; 49.0% vs 41.7%, both $p < 0.001$). For MELD < 15, overall removal due to deterioration/death was higher with MASH (20.6% vs 18.5%, $p = 0.003$), while 90-day (2.1% vs 2.0%, $p = 0.658$) and 1-year removal (9.4% vs 10.5%, $p = 0.058$) were not different. Candidates with MASH had shorter time to transplant (226 vs 255 days, $p < 0.001$) and greater MELD increase (2 vs 1, $p < 0.001$), while time to deterioration/death did not differ (306 vs 292 days, $p = 0.747$). MASH was associated with significantly shorter time to waitlist deterioration or death across MELD 15–20 (152 vs 169 days, $p = 0.016$) and 21–30 (36 vs 51 days, $p < 0.001$) compared to viral hepatitis. Kaplan-Meier curves showed increased removal with MASH in MELD 15-20 at 1 year, 3 years, and anytime, and in MELD 21-30 at all assessed time points. **Conclusion:** Among candidates with MELD < 15, MASH was associated with greater metabolic/portal hypertensive burden, higher removal due to deterioration/death, and greater MELD progression. When combined with findings in MELD 15-20 and 21-30 cohorts, these data suggest MELD may incompletely capture MASH risk before

2509 | DOES INFLAMMATION IN LIVER BIOPSY REALLY MATTER IN CLINICAL OUTCOMES OF PEOPLE WITH METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)?

Khadija Qazi[1] Pinelopi Manousou[1] Michael Yee[1] Maria Kalafateli[1] Mark Thursz[1] Rob Goldin[1] Fernando Iorra[1], [1]Imperial College London

Background: Fibrosis stage has been established as the strongest predictor of liver-related and all-cause mortality in MASLD. Yet the independent prognostic contributions of metabolic dysfunction-associated steatohepatitis (MASH), lobular inflammation, and hepatocyte ballooning, particularly for clinical outcomes, remain controversial. **Methods:** We conducted a retrospective longitudinal cohort study of 396 adults with biopsy-proven MASLD across Imperial College Healthcare NHS Trust (2003–2026). Histological features were scored using the NASH CRN system. Outcomes comprised composite liver-related events (incident cirrhosis, hepatic decompensation, hepatocellular carcinoma), major adverse cardiovascular events (MACE), all-cause mortality, extrahepatic malignancy, and a major composite endpoint aggregating the first three. Multivariable Cox proportional hazards regression, adjusted for baseline age and type 2 diabetes mellitus (T2DM), were performed. **Results:** Over a median (IQR) follow-up of 60.0 (40.5–84.0) months, the cohort (mean age 50.7 years; 55.1% T2DM; 57.3% stage F3/F4 at baseline) experienced 21 liver-related events, 14 cardiovascular events, 19 extrahepatic malignancies, and 15 deaths. Advanced fibrosis (F3–F4) independently predicted liver-related events (adjusted hazard ratio [aHR] 1.96 [95% confidence interval (CI): 1.13–3.40], p = 0.016) and the major composite outcome (aHR 2.84 [95% CI: 1.22–6.64], p = 0.016). MASH independently predicted liver-related events when adjusted for age and T2DM alone (aHR 3.08 [95% CI: 1.22–7.73], p = 0.017); however, when fibrosis was entered simultaneously, MASH was attenuated to non-significance (HR 2.41 [95% CI: 0.96–6.09], p = 0.062), with fibrosis dominating (HR 6.60 [95% CI: 1.53–28.60], p = 0.012). Neither lobular inflammation (grades 2–3 vs 0–1) nor hepatocyte ballooning (grades 1–2 vs 0) independently predicted any outcome. No histological feature predicted cardiovascular events, extrahepatic malignancy, or all-cause mortality after multivariable adjustment. **Conclusion:** Fibrosis stage is the only histological feature to independently predict both liver-specific and global composite outcomes in this MASLD cohort. MASH provides no additional prognostic information once fibrosis is accounted for. These findings challenge the use of MASH resolution as a standalone surrogate endpoint in clinical trials and support fibrosis regression as the primary therapeutic target in MASLD.

Table 1. Univariable and multivariable histological predictors of liver-related and systemic outcomes. Standard multivariable Cox proportional hazards models were adjusted for baseline age and type 2 diabetes mellitus. To assess independent prognostic utility, an additional simultaneous model evaluated advanced fibrosis and definitive MASH as competing covariates. Significant p-values (<0.05) are bolded. *Liver-related events*: composite of incident cirrhosis, hepatocellular carcinoma, or hepatic decompensation. *Major composite outcome*: composite of liver-related events, cardiovascular events, and all-cause mortality.

Outcome category	Histological predictor	Univariable HR (95% CI)	p-value	Adjusted HR (95% CI)	p-value

2510 | PRIMARY CARE UPTAKE OF MASH SCREENING AND PREDICTORS OF REFERRAL FOR SECONDARY FIBROSIS TESTING AFTER ELEVATED FIB-4

Nghiem Ha[1] Janet Chu[1] Max Goldman[2] Maria Tolentino[1] Mohsen Merati[1] Mandana Khalili[1] Bilal Hameed[1] Rena Fox[1], [1]University of California, San Francisco, [2]Kaiser Permanente

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) screening pathways rely on a stepwise approach using the fibrosis-4 index (FIB-4) followed by vibration-controlled transient elastography (VCTE) or blood-based risk scores. However, little is known about how primary care providers (PCPs) respond to elevated FIB-4 results, particularly among patients with obesity and/or type 2 diabetes mellitus (DM). We aimed to evaluate VCTE referral patterns by PCPs and identify factors associated with referral behavior across metabolic risk phenotypes. **Methods:** We conducted a prospective pragmatic implementation trial of screening for MASLD with significant fibrosis among primary care patients with obesity and/or DM during 2024-2026. We calculated FIB-4s with existing laboratory inputs. Using the most recent FIB-4 and age-based cutoffs, for patients with indeterminate- or high FIB-4s, we prompted their PCP to refer for VCTE as a second-step fibrosis assessment. PCPs opted whether to refer each patient. Descriptive statistics were used to compare characteristics of referred versus non-referred patients. Univariable and multivariable logistic regression analyses were performed to identify factors associated with referral patterns. **Results:** Among 453 patients, the majority were male (58%) with mean age 64 ± 8 years and mean BMI of 31.0 ± 6.3 kg/m^2 . They were diverse with 40% White, 27% Asian, 15% Black, and 11% Hispanic. Metabolic risk factors included 54% DM, 69% hypertension, 75% hyperlipidemia, and 34% obstructive sleep apnea. The overall referral rate was 53%; by FIB-4 category, the rate was 56% among indeterminate-risk and 44% among high-risk. Referral rates were similar for those with obesity without DM (53%) and DM without obesity (52%), and somewhat higher for DM with obesity (59%). There were no significant differences at baseline among those referred vs non-referred including age, sex, ethnicity/race, insurance status, BMI, mean HbA1c, mean ALT, frequency of primary care visits, or FIB-4 category. On univariable and multivariable logistic regression, adjusted for age, sex, BMI, and metabolic risk factors, neither elevated ALT, HbA1c, nor FIB-4 category was significantly associated with referral, though DM with or without obesity, compared to obesity alone, approached significance (OR 1.51, 95% CI 0.99-2.32). **Conclusion:** In this prospective implementation trial of MASLD- fibrosis screening, PCPs referred just over half of patients to VCTE. Importantly, we found PCP referrals were not associated with FIB-4, suggesting that the decision to refer may be driven by other patient and/or provider-related factors rather than objective liver-related measurements. These data point to important gaps between screening recommendations and real-world practices and support the need for greater PCP education and PCP-focused guidelines for the use of standardized MASLD referral pathways in primary care.

2511 | THE PREVENT CARDIOVASCULAR RISK SCORE AS AN OPPORTUNISTIC TOOL TO IDENTIFY UNDERRECOGNIZED MASLD AND FIBROSIS IN PRIMARY CARE: AN ANALYSIS FROM NHANES 2017-2023

Jesse Fletcher[1] Timothy Davie[1] Serena Brosten[1] Kartik Dapke[2] Anna Strauss[1] Giovanni Roldan[3] Prowpanga Udompap[4], [1]Department of Medicine, University of Minnesota, [2]Department of Medicine, Saint Vincent Hospital, Worcester, MA, [3]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, [4]Division of Gastroenterology, Minneapolis VA Medical Center

Background: The PREVENT equations are widely utilized in primary care to predict cardiovascular risk. Because their component variables closely mirror the cardiometabolic drivers of metabolic dysfunction-associated steatotic liver disease (MASLD), these equations could serve as a pragmatic tool to simultaneously increase disease awareness and enhance risk stratification. We hypothesized that the prevalence of hepatic steatosis and significant fibrosis increases step-wise with rising PREVENT cardiovascular risk scores. **Methods:** Using National Health and Nutrition Examination Survey (NHANES) data from 2017–March 2020 and August 2021–August 2023, we included adults aged 30–79 years with valid vibration-controlled transient elastography and complete data required for the PREVENT total cardiovascular disease (CVD) equation. Ten-year cardiovascular risk was categorized as $<5\%$, 5% to $<10\%$, 10% to $<20\%$, and $\geq 20\%$. Outcomes evaluated across strata included hepatic steatosis (HS; defined by controlled attenuation parameter or CAP ≥ 275 dB/m), clinically relevant fibrosis (≥ 8 kPa), advanced fibrosis (≥ 15 kPa), self-reported CVD, and liver disease awareness. Survey-weighted prevalences and Rao-Scott p-values were estimated. **Results:** Among 8,969 participants (representing approximately 148 million U.S. adults), increasing 10-year PREVENT CVD risk scores ($<5\%$, 5 to $<10\%$, 10 to $<20\%$, and $\geq 20\%$) correlated step-wise with higher rates of hepatic steatosis (37.2% to 59.3%) and clinically relevant fibrosis (LSM ≥ 8 kPa; 7.2% to 21.3%; $p<0.001$). Despite this rising disease burden, liver disease awareness was profoundly deficient and decoupled from clinical risk. Among individuals with objective hepatic steatosis, awareness never exceeded 10.2% in any stratum (ranging from 4.4% to 9.1%; $p<0.001$). Crucially, even among those with clinically relevant fibrosis (LSM ≥ 8 kPa), awareness remained alarmingly low, peaking at just 21.4% in the 10 to $<20\%$ risk group and dropping to 14.3% in the highest-risk stratum ($p=0.006$). Conversely, self-reported CVD awareness scaled appropriately across the same strata (2.8% to 34.7%, $p<0.001$) (Table 1). **Conclusion:** Elevated PREVENT CVD risk scores are strongly associated with a high prevalence of hepatic steatosis and clinically relevant fibrosis in the U.S. population. Despite this substantial disease burden, patient awareness of liver disease remains dismal across all risk strata. Because the PREVENT equation is already an established staple in primary care clinics, leveraging it to identify patients at risk for MASLD and those at risk of disease progression represents a highly feasible opportunity to improve early detection, increase clinical awareness, and optimize metabolic care.

Table 1: Characteristics and disease awarness of NHANES participants in each PREVENT CVD risk group

Characteristic	PREVENT CVD RISK				P value
	<5%	5–<10%	10–<20%	≥20%	
Unweighted n	4,262	1,816	1,947	924	
Weighted N (in millions; M)	83.7	28.3	25.8	10.9	
Age, years	43.3 (42.9–43.6)	56.5 (57.6–59.2)	66.1 (65.6–66.6)	71.5 (70.9–72.0)	<0.001
BMI, kg/m^2	29.5 (29.2–29.8)	30.3 (29.8–30.9)	30.3 (29.9–30.8)	30.5 (30.0–31.0)	<0.001
Female sex	54.5% (52.6–56.4)	48.7% (45.6–51.8)	43.5% (40.7–46.4)	38.8% (34.5–43.3)	<0.001
Liver Disease Severity					
Steatosis (CAP ≥275 dB/m)	37.2% (35.5–38.9)	54.8% (51.0–58.5)	54.5% (51.1–57.7)	59.3% (55.5–63.0)	<0.001
FIB-4 high risk (>2.67)	0.6% (0.4–0.9)	3.0% (2.2–4.1)	3.7% (2.8–4.8)	7.5% (6.0–9.3)	<0.001
SAFE high risk (≥100)	2.6% (2.0–3.2)	13.9% (11.7–16.5)	26.2% (25.7–30.9)	53.7% (49.3–58.1)	<0.001
Fibrosis (LSM ≥8 kPa)	7.2% (6.2–8.3)	14.3% (11.7–17.2)	18.2% (12.6–18.2)	21.3% (17.5–25.7)	<0.001
Advanced fibrosis (LSM ≥15 kPa)	1.3% (0.8–1.8)	3.6% (2.5–5.2)	3.4% (2.5–4.5)	8.2% (4.5–8.0)	<0.001
Disease Awareness — Overall Participants Included					
CVD awareness	2.8% (2.3–3.4)	9.5% (7.6–11.9)	16.5% (16.0–21.2)	34.7% (29.9–39.9)	<0.001
Liver disease awareness	3.6% (2.8–4.6)	7.8% (6.0–10.1)	8.4% (6.9–10.2)	9.7% (6.3–11.8)	<0.001
Disease Awareness — Among Those with Steatosis					
CVD awareness	3.4% (2.1–5.3)	10.2% (7.1–14.5)	20.6% (17.4–24.3)	34.8% (29.1–40.9)	<0.001
Liver disease awareness	4.4% (3.3–5.9)	9.4% (6.8–12.9)	10.2% (8.1–12.7)	9.1% (6.3–13.0)	<0.001
Disease Awareness — Among Those with Fibrosis ≥8 kPa					
CVD awareness	4.4% (2.2–8.8)	9.0% (6.1–13.1)	20.2% (14.5–27.4)	41.1% (32.4–50.4)	<0.001
Liver disease awareness	7.5% (5.1–10.9)	19.0% (11.7–29.3)	21.4% (14.6–30.1)	14.3% (9.3–21.3)	0.006

2512 | ULCERATIVE COLITIS IS ASSOCIATED WITH WORSE LIVER-RELATED OUTCOMES IN PATIENTS WITH MASLD: A PROPENSITY-MATCHED REAL-WORLD COHORT STUDY

Basil Jalamneh[1] Rashid Abdel-Razeq[1] Wahid Aloweiwi[2] Walid Hazem[3] Omar Sims[1] Dian Chiang[1], [1]Cleveland Clinic Foundation, [2]University of Jordan, [3]University Hospitals, Case Western Reseve University

Background: Extraintestinal hepatic manifestations occur in up to 30–50% of patients with inflammatory bowel disease (IBD), driven by gut dysbiosis, intestinal permeability, portal endotoxemia, and chronic systemic inflammation. Among these, MASLD has emerged as a significant hepatic comorbidity. The clinical hepatic behavior of MASLD in the setting of concurrent UC remains poorly understood. We therefore conducted a large real-world cohort study to determine whether concomitant UC independently worsens liver-related outcomes in patients with established MASLD, excluding those with PSC. **Methods:** We performed a retrospective propensity score–matched (1: 1) cohort study using the TriNetX Research Network, a large multicenter federated EHR database. Adult patients with MASLD and concomitant UC were matched to MASLD patients without IBD. Patients with Crohn's disease, pre-existing cirrhosis or hepatic decompensation, hepatocellular carcinoma, liver transplantation, viral hepatitis, autoimmune or alcoholic liver disease, or other chronic liver conditions were excluded. Follow-up = 5 years. The primary outcome was progression to cirrhosis; secondary outcomes included ascites, esophageal varices, hepatic encephalopathy, hepatocellular carcinoma (HCC), cholangiocarcinoma, composite hepatic decompensation, and all-cause mortality. Propensity score matching balanced baseline demographic, metabolic, cardiovascular, medication, and laboratory variables. Kaplan-Meier survival analyses with log-rank testing were used to estimate time-to-event outcomes, and hazard ratios (HRs) with 95% confidence intervals (CIs) were reported. **Results:** After propensity score matching, 23,771 patients were retained in each cohort. MASLD +UC was associated with significantly higher risks of cirrhosis progression (HR 2.40, 95% CI 2.06–2.80; $p < 0.001$), esophageal varices, ascites, hepatic encephalopathy, HCC (HR 1.97, 95% CI 1.22–3.20; $p = 0.005$), and composite hepatic decompensation (HR 1.80, 95% CI 1.58–2.06; $p < 0.001$). Cholangiocarcinoma risk did not differ between groups. All-cause mortality was numerically higher in the UC cohort but did not reach statistical significance. Figure-1. **Conclusion:** In this large propensity-matched real-world study, concomitant UC independently conferred substantially elevated risks of cirrhosis, hepatic decompensation, esophageal varices, ascites, hepatic encephalopathy, and HCC among patients with MASLD, even in the absence of PSC. The MASLD-UC overlap represents a distinct high-risk hepatic phenotype that warrants systematic fibrosis screening, heightened hepatic surveillance, and proactive multidisciplinary care. The nearly twofold increased risk of HCC in MASLD-UC patients without PSC represents a clinically significant signal. Whether this excess risk arises independently of cirrhosis remains an unanswered question that warrants prospective validation.

2513 | EPIDEMIOLOGIC TRENDS IN CIRRHOSIS AND METABOLIC SYNDROME MORTALITY AMONG ADULTS AGED ≥65 YEARS: A NATIONWIDE ANALYSIS, 1999–2024

Bland Ahmed[1] Mahrukh Mahrukh[2] Zainab Attiq[2] Shehryar Rasheed Sohail[3] Arishman Yasin Chaudhary[2] Palwasha Farooqi[1] Ehsanullah Alokozay[4], [1]Desert Regional Medical Center, Palm Springs, Ca, USA, [2]University Medical and Dental College, University of Faisalabad, Faisalabad, Pakistan, [3]Jinnah Sindh Medical University, [4]Faculty of Medicine, Kandahar University, Kandahar, Afghanistan

Background: Metabolic Syndrome (MetS) has become a significant contributor to chronic liver disease, with cirrhosis being its most severe outcome. In individuals aged 65 and older, metabolic syndrome hastens the progression of hepatic fibrosis due to insulin resistance, altered lipid levels, and the accumulation of visceral fat, ultimately increasing

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

cirrhosis related mortality. This study aims to analyze long-term mortality trends due to cirrhosis and MetS among older adults. **Methods:** This retrospective study utilized data from the CDC WONDER Multiple Cause of Mortality database from 1999 to 2024 among older adults (>65 years) using ICD-10 codes K74.0-K74.6 for cirrhosis and I10, E10–E14, E66, E78, E88 for MetS. Age-adjusted mortality rates (AAMR) per 100,000 population were calculated. Joinpoint regression analysis was used to calculate annual percent changes (APC) and average annual percent changes (AAPC), with $p < 0.05$ considered significant. **Results:** From 1999-2024, a total of 115,056 deaths were recorded due to cirrhosis and MetS among older adults. The AAMR rose from 6.53 in 1999 to 16.9 in 2024 (AAPC: 3.75; 95% CI: 3.54 to 4.09). Throughout the study period, Men (AAPC: 4.10; 95% CI: 3.81 to 4.46) consistently had higher mortality trend than Women (AAPC: 3.47; 95% CI: 3.21 to 3.85). All age groups showed notable long-term changes, but the most pronounced increase was shown by 85+ age cohort (AAPC: 5.20; 95% CI: 4.88 to 5.59). Regionally, highest mortality rate was shown by the South region (AAPC: 4.48; 95% CI: 4.21 to 4.77), followed by the West region (AAPC: 3.58; 95% CI: 3.18 to 3.99). Racial analysis showed that the White individuals had the greatest mortality burden (AAPC: 4.02; 95% CI: 3.82 to 4.33). Although both urban and rural areas showed rising trends, rural areas (AAPC: 4.21; 95% CI: 3.79 to 4.72) had greater mortality burden than urban areas (AAPC: 3.13; 95% CI: 2.81 to 3.56). **Conclusion:** Deaths due to cirrhosis and metabolic syndrome rose among older adults throughout the study span. Notably, significant demographic and geographical differences persist. Fluctuations in mortality rates highlight the need for targeted prevention approach and equitable access to healthcare for the most at-risk populations.

2514 | NATURAL HISTORY OF MASLD IN LATIN AMERICA: CIRRHOSIS INCIDENCE AND PREDICTORS OF PROGRESSION IN A MULTINATIONAL COHORT

Ximena Parraga[1] Denisse Rubio Cruz[2] Leandro Sierra[3] Paula Huerta[4] Kriti Soni[1] Stephen Hoang[1] S. Fisher Rhoads[1] Ezequiel Ridruejo[5] Sebastian Marciano[6] Jorge Martínez[6] Maria Jose Acosta[6] Adrian Gadano[6] Cristiane Villela-Nogueira[7] Ana Carolina Cardoso[7] Natalia Balassiano Wajsbrot[7] Nathalie Leite[7] Gil Salles[7] Claudia Cardoso[7] Claudia Couto[8] Guilherme Grossi Cancado[9] Rafael Theodoro[10] Mísia Joyner de Sousa Dias Mo[11] Igor Lima Ferraz[12] Roberta Araújo[12] Claudia Oliveira[13] Mario Pessoa[12] Natalia Baeza[14] Francisco Idalsoaga[14] Gustavo Ayares[14] Marco Arrese[14] MaríaFernanda SaavedraChacón[15] Katherine Marrugo[16] Alonso Vera Torres[16] Juan Diego Torres[16] Valentina Mejía Valdés[16] Daniza Alexandra Contreras[17] José Antonio Velarde-Ruiz Velasco[18] Graciela Castro-Narro[19] Eira Cerda Reyes[20] Stefanny Cornejo Henández[20] Luis Díaz[14] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Lahey hospital, Virginia Commonwealth University, [3]Cleveland Clinic, [4]Los Angeles Hospital, Chile, [5]Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno "CEMIC, [6]Hospital Italiano de Buenos Aires, [7]Universidade Federal do Rio de Janeiro, [8]Federal University of Minas Gerais, [9]Universidade Federal de Minas Gerais, [10]rafaeltheodoro.f@gmail.com, [11]misiajoyner@hotmail.com, [12]Universidade de São Paulo, [13]University of Sao Paulo School of Medicine, [14]Pontificia Universidad Católica de Chile, [15]Clínica CES, [16]Fundación Santa Fe de Bogotá, [17]Instituto Nacional de Diabetes, Endocrinología y Nutrición (INDEN), [18]Hospital Civil de Guadalajara, [19]Hospital Médica Sur, Ciudad de México. Instituto Nacional de Ciencias Médicas y Nutrición, [20]Central Military Hospital

Background: Latin America carries a substantial burden of MASLD; however, data describing its natural history remain scarce. Most existing cohort studies derive from North America, Europe, and Asia, limiting the applicability of risk stratification models to Latin American populations. We characterized cirrhosis incidence and its predictors in a large multinational Latin American MASLD cohort. **Methods:** We conducted a retrospective cohort study of adults with MASLD across six Latin American countries (n = 1,529), (Brazil, Argentina, Chile, Colombia, Dominican Republic, and Mexico). Patients with baseline cirrhosis were excluded from incidence analyses yielding a remaining analytic cohort of n = 1,341. Baseline fibrosis was staged by liver biopsy, VCTE, or FIB-4. Cirrhosis incidence rates were estimated per 100 person-years, and Cox proportional hazards models identified independent predictors of progression. **Results:** We included 1,529 participants (mean age 56.2 ± 12.9 years and 62% female), with a mean follow-up of 3.7 years. The mean body mass index was 32.2 ± 6.0 kg/m2, 61% had type 2 diabetes, 59% hypertension, and 61% hyperlipidemia. Cohort characteristics differed significantly across countries (all $p < 0.001$); type 2

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

diabetes prevalence ranged from 23% (Colombia) to 87% (Brazil), hypertension from 29% (Chile) to 80% (Brazil), and mean follow-up from 0.2 years (Dominican Republic) to 5.5 years (Brazil and Chile). At baseline, 76% had non-advanced fibrosis (F0–F2) and 12% advanced fibrosis (F3). Overall, cirrhosis incidence showed marked variation by country (Brazil 1.1, Argentina 2.2, Chile 1.3, Colombia 3.8, Mexico 0.9 per 100 PY). Advanced baseline fibrosis (F3) carried a 3-fold higher incidence rate versus non-advanced disease (4.4 vs. 1.0 per 100 PY). On multivariable Cox analysis, older age (HR 1.06/year, 95% CI 1.04–1.08; $p < 0.001$) was independently associated with cirrhosis development, while hyperlipidemia (HR 0.37, 95% CI 0.21–0.66; $p < 0.001$) was associated with a lower risk. **Conclusion:** In this first large multinational Latin American MASLD cohort, cirrhosis incidence varied markedly across countries, and advanced baseline fibrosis identified a high-risk subgroup with significantly greater progression rates. The protective association of hyperlipidemia warrants further investigation, as it may reflect statin use or metabolic phenotype differences. These findings support the need for region-specific fibrosis-based risk stratification in Latin American MASLD populations.

2515 | FROM PRESCRIPTION TO DISPENSE: PRIMARY ADHERENCE TO RESMETIROM IN REAL-WORLD CLINICAL PRACTICE

Phuc Le[1] Naim Alkhouri[2] Ha Tran[1] Hamlet Gasoyan[1] Michael Rothberg[1], [1]Cleveland Clinic, [2]Summit Clinical Research

Background: Resmetirom is the first approved pharmacotherapy for adults with noncirrhotic metabolic dysfunction-associated steatohepatitis and moderate-to-advanced liver fibrosis. However, little is known about whether patients who are prescribed resmetirom successfully obtain the medication in routine clinical practice or which factors are associated with primary adherence. **Methods:** We conducted a retrospective cohort study using Epic Cosmos data. Adults aged ≥ 18 years with a new resmetirom prescription between April 1, 2024 and March 1, 2026 and ≥ 30 days of follow-up were included. The index date was the first observed prescription after a 183-day washout period without prior resmetirom prescription or dispense. Primary adherence was defined as ≥ 1 resmetirom dispense within 30 days after the index date. We estimated prevalence of adherence and median time from prescription to first dispense. Multivariable logistic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

regression was used to identify factors associated with adherence. **Results:** Of the 10,591 patients with a new resmetirom prescription (mean age, 57.9 years, 59.4% female, 58.3% White), 6,453 (60.9%) filled it during the study period. Of them, 64.7% (n = 4,172), 78.5% (n = 5,066), and 84.6% (n = 5,457) did so within 30, 60, and 90 days respectively. Median time from prescription to first dispense was 18 days (IQR, 7-49). More than 10% of patients had a liver biopsy at baseline. Primary adherence was highest in Asian patients (47.5%) and Medicare beneficiaries (43.2%). In adjusted analysis, Asian race (vs White; adjusted odds ratio [aOR], 1.39; 95% CI, 1.11-1.74), Medicare insurance (vs private; aOR, 1.16; 95% CI, 1.04-1.29), and having liver biopsy (aOR, 1.18; 95% CI, 1.04-1.34) were positively associated with adherence. Patients who used GLP-1, SGLT-2i, statin, and hypertensive medications also had increased odds of adherence. In contrast, Hispanic ethnicity (aOR, 0.86; 95% CI, 0.75-0.98), Medicaid insurance (aOR, 0.73; 95% CI, 0.54-0.97), type 2 diabetes (aOR, 0.86; 95% CI,0.79-0.95), and clopidogrel use (aOR, 0.76; 95% CI, 0.58-0.98) were negatively associated with adherence. **Conclusion:** In this large real-world study, fewer than 4 in 10 patients prescribed resmetirom filled the prescription within 30 days, with notable differences by race, ethnicity and insurance. These findings provide early evidence on access to resmetirom in clinical practice and identify patient and prescribing factors associated with successful medication initiation.

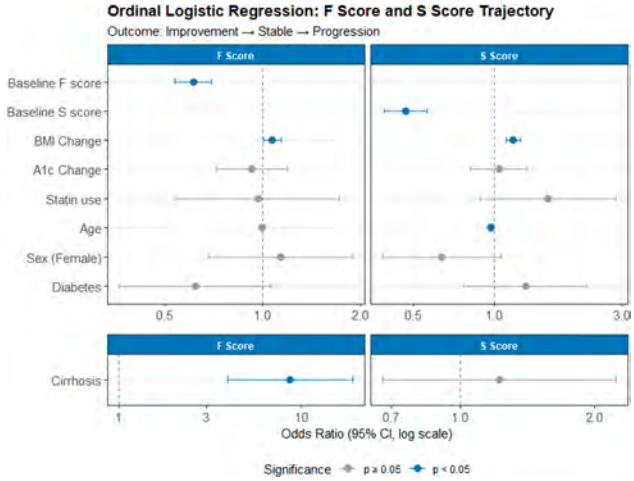
2516 | WEIGHT CHANGE, NOT STATIN USE OR GLYCEMIC CONTROL, DRIVES FIBROSIS TRAJECTORY IN MASLD: A REAL-WORLD COHORT STUDY



Anju Pradeep[1] Fnu Rashi[2] James Mo[1] Allen Chehimi[3] Sadie Knill[1] Aastha Bahl[3] Xuan Ma[1] Syed-Mohammed Jafri[4], [1]Henry Ford Health, [2]Henry Ford Macomb, [3]Michigan State University, [4]Henry Ford Health System

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is one of the most common causes of chronic liver disease globally. More data is needed to determine if weight change outweighs pharmacologic metabolic interventions in determining fibrosis trajectory in real world practice. We evaluated whether statin use, glycemic control, and BMI change independently predicted fibrosis outcomes in a real-world MASLD cohort. **Methods:** We conducted a retrospective cohort study of adults with MASLD evaluated at Henry Ford Health from January 2019 to December 2024. Patients with ≥ 2 FibroScan assessments ≥ 12 months apart comprised Cohort A (n = 317); those with ≥ 2 FIB-4 measurements comprised Cohort B (n = 288). Fibrosis trajectory was classified as improvement, stable, or progression. Multivariable linear regression modeled continuous changes in kPa, CAP, and FIB-4. Ordinal and binary logistic regression and linear mixed-effects models (LMM) assessed predictors of fibrosis trajectory, adjusting for age, sex, diabetes, cirrhosis, and time-matched metabolic variables. **Results:** Mean age was 58 years (51% female, mean BMI of 35.7 kg/m^2); 53% had diabetes, 23% had cirrhosis at baseline. By FibroScan, mean kPa declined from 10.5 to 8.3 (Δ −2.3 kPa). On F score trajectory, 52.8% improved, 30.7% were stable, and 16.5% progressed. On multivariable analysis, BMI change was independently associated with fibrosis trajectory on ordinal F score analysis (OR 1.07, 95% CI 1.01-1.14, $p = 0.034$) and was the dominant predictor of steatosis progression by ordinal S score (OR 1.18, 95% CI 1.11-1.26, $p < 0.001$). Baseline cirrhosis markedly amplified fibrosis progression risk on both binary (OR 4.64, 95% CI 1.79-12.6, $p = 0.002$) and ordinal F score models (OR 8.65, 95% CI 4.01-19.6, $p < 0.001$) but was not associated with steatosis trajectory. Statin use and HbA1c change were not independently associated with any outcome (all $p > 0.1$). LMM confirmed BMI as the dominant time-varying predictor of kPa (β 0.18, $p = 0.009$) and CAP (β 2.2, $p < 0.001$), but not FIB-4 (β 0.00, $p = 0.6$). Despite 92% of patients meeting GLP-1 receptor agonist

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

therapy eligibility criteria, only 48% were initiated during follow-up. **Conclusion:** In this real-world MASLD cohort, BMI change was the dominant modifiable predictor of both fibrosis and steatosis trajectory, while statin use and glycemic control did not independently predict outcomes. Baseline cirrhosis markedly amplified progression risk irrespective of BMI change or pharmacologic therapy but did not influence steatosis trajectory. Critically, BMI predicted FibroScan-derived fibrosis and steatosis measures, but not FIB-4 change, underscoring FIB-4's limitations as a dynamic monitoring tool in MASLD. Weight management remains the critical therapeutic target, with an urgent need to close the substantial GLP-1 treatment gap in this population.

2517 | UPDATED OBESITY DEFINITION RECLASSIFIES INDIVIDUALS WITH MASLD AT RISK OF MORTALITY AND ADVERSE NONLIVER OUTCOMES

Xiaohan Qian[1] Ruoqi Zhou[2] Haotian Zhang[2] Mindie Nguyen[1] Yu Shi[2], [1]Stanford University Medical Center, [2]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) occurs across body mass index (BMI) categories, yet BMI inadequately captures visceral adiposity, limiting precise subtyping. An updated obesity definition incorporating waist circumference (WC), waist-to-hip ratio (WHR), and waist-to-height ratio (WHtR) beyond BMI has been proposed, but its prognostic significance in MASLD remains under-evaluated. **Methods:** This prospective cohort study included 122,202 participants with MASLD identified from the UK Biobank (2006–2010), classified as nonobese or obese by updated criteria (BMI $\geq$ 30 kg/m² with $\geq$ 1 elevated body size measure; $\geq$ 2 elevated body size measures regardless of BMI; or BMI $\geq$ 40 kg/m²; with elevated body size defined as WC > 102/88 cm [men/women], WHR > 0.90/0.85 [men/women], or WHtR $\geq$ 0.50. We stratified the obese group further by BMI cutoff of 30 kg/m²). We evaluated all-cause mortality, adverse liver (hepatocellular carcinoma, decompensated cirrhosis, liver transplantation, liver-related death) and nonliver (CVD, CKD and nonliver cancers) events. Subgroup analyses explored effect modification by age, sex, race, diabetes, cardiometabolic risks (CMRF), and FIB-4. Sensitivity analyses included Fine-Gray models and additional adjustments for FIB-4 and alcohol consumption, and exclusions for baseline adverse liver events, prior bariatric surgery, or anti-obesity medication use. **Results:** Updated obesity criteria reclassified 39,699 individuals (32.5%: 31.2% with BMI 25–29.9 kg/m²; 1.2% with BMI < 25 kg/m²) as obese. All-cause mortality per 1,000 person-years (PY) was lowest in nonobese but similar between the obese BMI < 30 kg/m² and $\geq$ 30 kg/m² groups (5.9, 9.6, 9.7). Similar patterns were observed for CVD (9.2, 14.2, 14.4), CKD (3.0, 5.1, 6.7), and nonliver cancers (9.8, 13.7, 12.1), but not for adverse liver events (0.8, 1.0, 1.2, respectively, all $P < 0.001$; Figure 1). In multivariable Cox models, compared to nonobese participants, both obese groups had higher risks of all-cause mortality (BMI < 30 kg/m²: aHR 1.13 [1.04–1.23]; BMI $\geq$ 30 kg/m²: aHR 1.25 [1.16–1.36]) and nonliver events (aHR 1.12 [1.05–1.20]; 1.24 [1.16–1.32] for CVD; 1.14 [1.01–1.28]; 1.39 [1.24–1.56] for CKD and 1.15 [1.07–1.23]; 1.14 [1.07–1.22] for nonliver cancers, respectively), though not adverse liver events (aHR 0.97 [0.77–1.22]; 1.10 [0.88–1.37]). Findings were largely consistent across subgroup and sensitivity analyses. **Conclusion:** Updated obesity criteria reclassified a substantial proportion (32.5%) of individuals with MASLD with BMI < 30 kg/m² as obese. The findings of higher rates of CVD, CKD, nonliver cancers and all-cause mortality in the newly classified obese individuals with MASLD as compared to the nonobese group lend support to the validity of the updated criteria. Its clinical application can help identify higher risk phenotype for monitoring and treatment.

2518 | ACCELERATED LATE MORTALITY AFTER LIVER TRANSPLANTATION FOR MASLD: TIME-VARYING HAZARD DRIVEN BY PROGRESSIVE DIABETIC BURDEN

Aadarsh Barot[1] Karn Wijarnpreecha[2] Pojsakorn Danpanichkul[3] Andrew Keaveny[1] Omar Mousa[1], [1]Mayo Clinic Florida, [2]University of Arizona College of Medicine-Phoenix, [3]Texas Tech University Health Sciences Center

Background: Short-term post liver transplantation (LT) survival in metabolic dysfunction-associated steatotic liver disease (MASLD) recipients is comparable to other etiologies, but late mortality may increase as metabolic comorbidities, particularly diabetes, accumulate over time. We hypothesized that MASLD recipients exhibit accelerated late mortality due to progressive metabolic risk. **Methods:** We retrospectively studied adult first-time, single-organ LT recipients at a single academic transplant center from 2002–2016. The primary outcome was all-cause post-LT mortality. Piecewise Cox proportional hazards models were constructed at prespecified 5-, 10-, and 15-year cutpoints with covariate–time interaction terms to detect non-proportional hazards, and were fit for 0–10 year and >10-year intervals to identify temporal predictor transitions. Kaplan-Meier survival analysis with log-rank testing was performed. Claude (Anthropic) was used to assist with Python code development for data analysis; data analyses, result interpretation and conclusions were performed and verified by the investigators. **Results:** Among 1,972 LT recipients (184 MASLD, 1,788 non-MASLD) with a median follow-up of 11.1 years (maximum 23 years), MASLD recipients were significantly older, had higher BMI, and had more diabetes ($p < 0.001$). Overall Kaplan-Meier survival did not significantly differ (log-rank $p = 0.06$), masking an important late divergence (15-year survival: 44.1% vs. 50.9%). Piecewise analysis revealed a dynamic, non-linear hazard trajectory: mortality risk decreased after 5 years (HR 0.80, 95% CI 0.69–0.94, $p = 0.006$), then significantly increased after 10 years (HR 1.30, 95% CI 1.13–1.50, $p < 0.001$) and 15 years (HR 1.41, 95% CI 1.14–1.75, $p = 0.002$). Diabetes was the only covariate demonstrating significant time-interaction at all cutpoints, with a progressively strengthening deleterious effect (interaction HR: 1.31, $p = 0.029$ at 5 years; 1.34, $p = 0.028$ at 10 years; 1.75, $p = 0.006$ at 15 years). Period-specific models revealed a predictor transition: creatinine (HR 1.18, $p = 0.002$) and MELD (HR 0.98, $p = 0.002$) dominated 0–10 year mortality, whereas recipient age (HR 1.06, $p < 0.001$), BMI (HR 1.03, $p = 0.005$), and donor age (HR 1.01, $p = 0.019$) emerged as significant predictors beyond 10 years. **Conclusion:** This study demonstrates that post-LT mortality follows a non-linear, time-varying trajectory in which MASLD recipients experience accelerated late mortality linked to the progressive impact of diabetes. Standard analyses may miss this temporal shift. These findings support long-term metabolic surveillance extending beyond the first post-transplant decade and incorporation of time-varying risk into post-LT care models to improve late outcomes.

2519 | AT-RISK FIBROSIS IS ASSOCIATED WITH ELEVATED CARDIOVASCULAR RISK IN MASLD: DEVELOPMENT AND INTERNAL VALIDATION OF A 5-YEAR RISK PREDICTION MODEL

Robert Wilechansky[1] Prasanna Challa[2] Marc Sherman[2] Tracey Simon[2], [1]Oregon Health & Science University, [2]Massachusetts General Hospital

Background: Cardiovascular disease (CVD) is a leading cause of mortality in metabolic dysfunction–associated steatotic liver disease (MASLD). However, the relative contribution of MASLD disease characteristics to CVD risk remains uncertain, and existing CVD prediction models have suboptimal performance in MASLD. In patients with biopsy-proven MASLD in a hospital network-based cohort, we evaluated the associations of steatohepatitis and at-risk fibrosis (≥F2) with incident CVD and developed a 5-year CVD risk prediction model in patients with MASLD and at-risk fibrosis. **Methods:** We identified all adults with biopsy-confirmed MASLD and without baseline CVD in the Mass General Brigham health network, between 1999 and 2021, using a validated natural language processing algorithm. Cox proportional hazards models were used to evaluate the association between histologic steatohepatitis and at-risk fibrosis (≥F2) with incident CVD events (composite of hospitalization for myocardial infarction, heart failure, cerebrovascular disease, and peripheral vascular disease) as defined by ICD codes. Covariates included age, sex, diabetes, hypertension, aspirin use, statin use, insulin use, and smoking status. A 5-year CVD risk prediction model was then developed among patients with at-risk fibrosis using multivariable logistic regression and internally validated with bootstrap resampling. Model performance was assessed using area under the receiver operating characteristic curve (AUC) and calibration analyses. **Results:** A total of 1624 patients with biopsy-proven MASLD were identified, including 861 with steatohepatitis and 320 with at-risk fibrosis. There were 359 CVD events and a median follow-up of 3.3 years. In age-adjusted models, both steatohepatitis (aHR 1.22; 95% CI, 0.99-1.51; P = 0.06) and at-risk fibrosis (aHR 1.55; 95% CI, 1.23-1.96; P < .001) were associated with incident CVD. After multivariable adjustment, steatohepatitis was no longer associated with CVD risk, whereas at-risk fibrosis remained associated with incident CVD (aHR 1.43; 95% CI, 1.12-1.81; P = 0.003). The association of at-risk fibrosis and CVD strengthened after further adjustment for steatohepatitis (aHR, 1.51; 95% CI, 1.17-1.95; P = 0.001). A 5-year CVD risk prediction model containing the aforementioned covariates plus AST and ALT was tested in MASLD patients with at-risk fibrosis; the model demonstrated good discrimination (AUC 0.75) with bootstrap internal validation AUC of 0.72 and optimism-corrected calibration slope of 0.927. **Conclusion:** Among patients with biopsy-proven MASLD, at-risk fibrosis, but not steatohepatitis, was associated with future CVD events. A 5-year CVD risk prediction model in patients with MASLD and at-risk fibrosis demonstrated acceptable discrimination and calibration, supporting its potential utility for CVD risk stratification in this population. External validation is needed to confirm these findings.

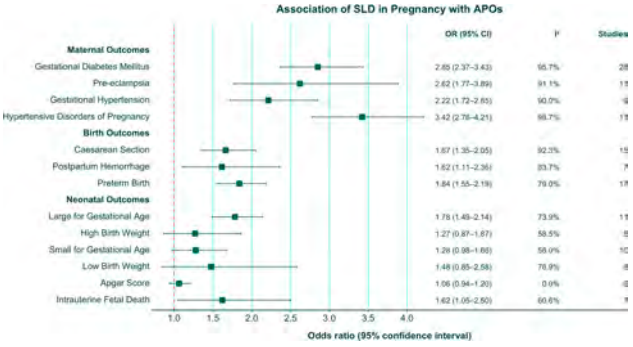
2520 | ASSOCIATION OF STEATOTIC LIVER DISEASE WITH PERINATAL OUTCOMES: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 75 MILLION PREGNANT INDIVIDUALS



Jacqueline Slobin[1] Nina Rodriguez[1] Cecilia Katzenstein[1] Nadejda Capatina[2] Caroline Ovadia[3] Tatyana Kushner[4], [1]Icahn School of Medicine at Mount Sinai, [2]Guy's and St Thomas' NHS Foundation Trust, London, UK, [3]University of Edinburgh, Edinburgh, Scotland, UK, [4]Weill Cornell Medicine

Background: The prevalence of steatotic liver disease (SLD) in pregnancy has tripled over the past decade, affecting up to 18% of pregnant individuals. Prior studies report varied associations between SLD and adverse pregnancy outcomes (APOs). **Methods:** We conducted a systematic review and meta-analysis querying PubMed, Embase, and Web of Science for studies reporting APOs in individuals with SLD. Two independent reviewers screened titles and abstracts, full texts, and extracted data. Pooled prevalence and odds ratios

(ORs) with 95% confidence intervals (CI) were calculated using random-effects models in R 4.6.0. **Results:** Thirty-one studies with 75 million pregnant individuals and 105,185 SLD cases were included. In 18 studies reporting prevalence, the pooled prevalence of SLD was 14.6% (95% CI: 11.0% – 19.0%). SLD was diagnosed by ultrasound (17), ICD codes (5), Hepatic Steatosis Index (5), Fibroscan (3), biopsy (1), and Fatty Liver Index (2). Studies were conducted in Asia (19), North America (5), Europe (4), Australia (2), and Africa (1). SLD was significantly associated with hypertensive disorders of pregnancy (OR 3.42, 95% CI 2.77–4.22), gestational diabetes (OR 2.85, 95% CI 2.38–3.41), preeclampsia (OR 2.62, 95% CI 1.81–3.80), and gestational hypertension (OR 2.22, 95% CI 1.78 – 2.75). Additionally, SLD was associated with cesarean delivery, postpartum hemorrhage, and preterm birth <37 weeks. Among neonatal outcomes, SLD was associated with large for gestational age, small for gestational age, and intrauterine fetal demise, but not low birth weight, high birth weight, or Apgar <7 at 5 minutes (Figure). In subgroup analyses of studies that diagnosed SLD with ultrasound or Fibroscan, associations with intrauterine fetal demise, small for gestational age, and postpartum hemorrhage were no longer significant, and the association with preeclampsia was attenuated. Associations with gestational diabetes (OR 2.92), preeclampsia (OR 3.01), and gestational hypertension (OR 2.79) were strongest in Asian cohorts. **Conclusion:** SLD in pregnancy was associated with increased risk of several APOs, with strongest associations for maternal outcomes and more variable findings for neonatal outcomes. These findings highlight the importance of screening for early gestational diabetes, potential aspirin use to decrease risk of associated preeclampsia, and counseling patients on elevated risk of APOs. Future directions are focused on completing an individual participant data meta-analysis to identify subgroups of patients with SLD at highest risk of APOs.

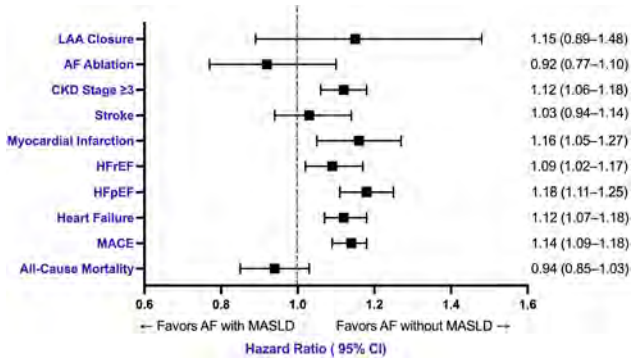
2521 | METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AND INCREASED CARDIOVASCULAR MORBIDITY IN ATRIAL FIBRILLATION



Pojsakorn Danpanichkul[1] Yanfang Pang[2] Nithila Sivakumar[1] Primrose Tothanarungroj[3] Ahmad Anouti[4] Matheus Henrique Gonçalves de Souza[5] Kwanjit Duangsonk[3] Omar Mousa[6] Thomas Cotter[7] Donghee Kim[8] Suthat Liangpunsakul[9] Chayakrit Krittanawong[10] Mazen Noureddin[11], [1]Texas Tech University Health Sciences Center, [2]Affiliated Hosp of Youjiang Medical University, Chiang Mai University, [3]Chiang Mai University, [4]University of Texas Southwestern, [5]Federal University of Rio de Janeiro, [6]Mayo Clinic, [7]Evidentis Clinical Research, [8]Stanford University School of Medicine, [9]Indiana University School of Medicine, Roudebush Veterans Administration Medical Center, [10]HumanX, [11]Houston Methodist Hospital, Houston Research Institute

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is associated with incident atrial fibrillation (AF), but its prognostic impact in patients with established AF is unclear. We evaluated whether concomitant MASLD is linked to adverse clinical outcomes in this population. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network. Adult patients with AF were classified as AF with or without MASLD. Cohorts were 1: 1 propensity score-matched for demographic, clinical, and laboratory variables. Outcomes were assessed over 3 years using Kaplan–Meier methods and Cox proportional hazards models to estimate hazard ratios (HRs) with 95% confidence intervals (CIs). **Results:** After matching, 19,154 patients were included (9,577 per group) with balanced baseline characteristics. All-cause mortality was similar between groups (HR 0.94, 95% CI 0.85–1.03). MASLD was associated with higher risk of major adverse cardiovascular events (MACE; HR 1.14, 95% CI 1.09–1.18), heart failure (HR 1.12, 95% CI 1.07–1.18), including HFpEF (HR 1.18, 95% CI 1.11–1.25) and HFrEF (HR 1.09, 95% CI 1.02–1.17), and myocardial infarction (HR 1.16, 95% CI 1.05–1.27). Stroke risk was similar (HR 1.03, 95% CI 0.94–1.14). MASLD was also associated with increased incidence of CKD stage ≥3 (HR 1.12, 95% CI 1.06–1.18). **Conclusion:** Among patients with established AF, concomitant MASLD is associated with higher risks of MACE, heart failure, myocardial

2522 | TRENDS IN MORTALITY FROM METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE, HEART FAILURE, AND ATRIAL FIBRILLATION IN THE UNITED STATES FROM 1999-2020

Ahamed Lazim Vattoth[1] Adnan Said[2], [1]University of Wisconsin - Madison, [2]University of Wisconsin School of Medicine and Public Health

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), heart failure (HF), and atrial fibrillation (AFib) are major contributors to morbidity and mortality in the United States, with growing evidence of shared cardiometabolic pathways linking these conditions. Despite this, population-level mortality trends and demographic disparities across all three diagnoses remain incompletely characterized. This study examined temporal patterns in MASLD, HF, and AFib mortality in the US from 1999 to 2020, with a focus on variation by sex, age, race, and Hispanic ethnicity. **Methods:** Death certificate data were obtained from the CDC Wide-Ranging Online Data for Epidemiological Research (CDC WONDER) database, which compiles underlying cause of death records for the US population from 1999 to 2020. MASLD-related deaths were captured using ICD-10 code K76.0 (fatty change of liver, not elsewhere classified). HF-related deaths were identified using ICD-10 code I50 (heart failure), and AFib-related deaths using code I48 (atrial fibrillation and flutter). Age-adjusted mortality rates (AAMRs) per 100,000 population, standardized to the year 2000 US population, were calculated stratified by race and sex. Crude mortality rates were used for age-group comparisons, and linear regression assessed temporal trends. **Results:** MASLD and AFib mortality rose consistently over the study period. HF mortality declined from 1999 through ~2012 before rebounding through 2020. Men had higher AAMRs for HF (36.9 vs. 28.0) and AFib (10.2 vs. 9.5) in 2020, while women had a higher MASLD AAMR (1.7 vs. 1.1). The 85+ age group recorded the highest crude rates for HF (663.9) and AFib (222.0); MASLD mortality peaked in the 75–84 group (5.8). Hispanic patients had modestly higher MASLD mortality (AAMR 1.6 vs. 1.4) but substantially lower HF (18.8 vs. 33.2) and AFib (4.7 vs. 10.3) rates compared to non-Hispanic patients. Black or African American patients had the highest AAMRs for HF (40.1) and AFib (6.7), while White patients had the highest MASLD AAMR (1.6). Asian or Pacific Islander patients had the lowest AAMRs across all three conditions. **Conclusion:** MASLD and AFib mortality rose substantially from 1999 to 2020, while HF exhibited a distinctive biphasic pattern. Pronounced disparities by sex, age, race, and Hispanic ethnicity were observed across all three conditions, underscoring the uneven distribution of cardiometabolic disease burden in the US population. The concurrent rise in MASLD mortality alongside persistent cardiovascular mortality from HF and AFib points to shared upstream risk factors and suggests that condition-specific management approaches may be insufficient. Coordinated strategies targeting the cardiometabolic continuum, with deliberate focus on groups bearing the greatest burden, are needed to address these converging trends.

2523 | BEYOND FIB-4: A NON-FASTING MACHINE-LEARNING STRATEGY FOR FIRST-LINE TRIAGE OF SIGNIFICANT LIVER FIBROSIS

David Guardamino Ojeda[1] Marco Guardamino Ojeda[2] Marco Montoya Flores[3] Renato Luque[4] Samuel Lagos[2], [1]University of Miami / Jackson Memorial Hospital, [2]Universidad Nacional Mayor de San Marcos, [3]Universidad Peruana Cayetano Heredia, [4]Universidad Cientifica del Sur

Background: Scalable fibrosis risk stratification requires tools that are accurate, broadly applicable, and feasible without specialized testing conditions. Conventional first-line noninvasive fibrosis scores such as FIB-4 and APRI are easy to calculate but may have limited discrimination for fibrosis triage. We aimed to determine whether machine learning applied to routine clinical data could improve identification of significant liver fibrosis and support a practical non-fasting triage strategy. **Methods:** We analyzed adults from NHANES 2017–2023 with valid vibration-controlled transient elastography (VCTE). Significant fibrosis was defined as liver stiffness measurement (LSM) $\geq$7.0 kPa. Two predictive frameworks were developed: a universal non-fasting model using routine clinical variables and an extended fasting model including fasting glucose, insulin, HOMA-IR, LDL cholesterol, and triglycerides. XGBoost, Random Forest, and LASSO were trained using stratified 70/30 train-test splits and compared against FIB-4 and APRI in held-out test sets. We further assessed variable importance, decision-curve performance, calibration, and threshold-based triage characteristics. **Results:** The universal and extended cohorts included 10,900 and 6,363 participants, respectively,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

with significant fibrosis prevalence of 17.5% in both. Across both cohorts, machine-learning models consistently outperformed conventional fibrosis scores. In the universal cohort, XGBoost achieved the highest discrimination (AUC 0.784, 95% CI 0.763–0.806), followed by Random Forest (0.774) and LASSO (0.772), versus 0.599 for FIB-4 and 0.608 for APRI. In the fasting cohort, XGBoost again performed best (AUC 0.786, 95% CI 0.757–0.814), with near-identical performance relative to the universal model (ΔAUC = 0.002), indicating minimal incremental value from fasting biomarkers. Waist circumference and BMI were the dominant predictors, accounting for 46.4% of total XGBoost gain in the universal model. Decision-curve analysis showed that XGBoost provided the highest and most consistent net benefit across clinically relevant threshold probabilities. Threshold analysis identified a rule-out cutoff of 0.26 (sensitivity 91.2%, NPV 95.3%) and a rule-in cutoff of 0.66 (specificity 90.1%, PPV 49.2%), stratifying the test set into low-risk (32.9%; fibrosis rate 4.7%), indeterminate (51.0%; 15.7%), and high-risk (16.1%; 49.2%) groups. **Conclusion:** Machine learning applied to routine non-fasting clinical variables enables a pragmatic, population-level triage strategy for significant fibrosis that substantially outperforms conventional serum scores. The negligible performance gain from fasting biomarkers suggests that scalable first-line fibrosis triage may be achievable without fasting requirements, supporting staged downstream evaluation with elastography or adjunctive biomarker testing.

2525 | ASSOCIATION BETWEEN HEPATIC FIBROSIS AND CARDIOVASCULAR RISK BASED ON PREVENT RISK SCORE IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Mohsen Merati[1] Janet Chu[2] Rena Fox[2] Max Goldman[3] Bilal Hameed[4] Mandana Khalili[2] Maria Tolentino[4] Nghiem Ha[2], [1]Sutter Health / University of California San Francisco, [2]University of California, San Francisco, [3]Kaiser Permanente, [4]University of California San Francisco (UCSF)

Background: Cardiovascular disease (CVD) remains the leading cause of mortality in metabolic dysfunction-associated steatotic liver disease (MASLD), underscoring the need for integrated cardiometabolic risk assessment. The American Heart Association recently introduced the PREVENT score as a tool for estimating CVD risk; however, its relationship with hepatic fibrosis and/or steatosis has not been well characterized. We aimed to evaluate the association between PREVENT risk categories and hepatic fibrosis and steatosis among patients with MASLD. **Methods:** We conducted a retrospective study of adult primary care patients with MASLD who had indeterminate or high-risk FIB-4 scores on initial screening and subsequently underwent vibration-controlled transient elastography (VCTE), with available PREVENT risk scores, between 2021 and 2026. PREVENT risk scores were calculated using clinical and laboratory values within 6 months of VCTE. PREVENT risk was categorized as low/intermediate (< 10%), high (10-20%), and very high (> 20%). Clinical and metabolic characteristics were compared across PREVENT risk groups (Table). Associations between PREVENT risk categories and liver fibrosis or steatosis were separately evaluated using univariable and multivariable logistic regression. **Results:** Among 96 patients, 52% were male with median age 66 years (59-73). Compared with patients with low/intermediate PREVENT risk, those with high/very high PREVENT risk were older ($p < 0.001$) and demonstrated greater MASLD severity, including greater FIB-4 scores (1.87 vs 1.50, $p = 0.03$), more severe CAP scores (274 vs 238, $p = 0.003$), and higher liver stiffness (6.3 vs 4.6 kPa, $p = 0.007$). Patients with high/very high PREVENT risk scores also had less favorable metabolic profiles, with significantly greater prevalence of hypertension (87% vs. 31%, $p < 0.001$), diabetes mellitus (69% vs. 35%, $p = 0.003$), and hyperlipidemia (89% vs. 58%, $p = 0.006$). In multivariable logistic regression adjusted for age, sex, body mass index, diabetes, and hyperlipidemia, higher PREVENT categories remained independently associated with advanced fibrosis (aOR 6.12, 95% CI 1.25-41.47) and severe steatosis (aOR 3.93, 95%CI 1.36-13.00) (Table). **Conclusion:** In patients with MASLD, higher PREVENT cardiovascular risk categories were independently associated with more advanced fibrosis stage and severe steatosis. These findings support the close interplay between hepatic and cardiovascular risk and highlight the potential value of integrating PREVENT and liver fibrosis assessment into MASLD screening and management strategies to identify high-risk patients who may benefit from earlier intervention and multidisciplinary care.

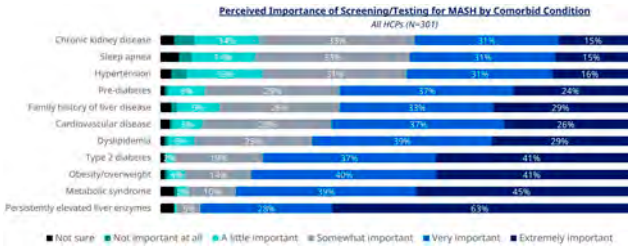
2526 | ACT ON MASH – US DATA: A SURVEY OF AWARENESS, UNDERSTANDING, AND PERCEPTIONS OF MASLD AND MASH AMONG HEALTHCARE PROFESSIONALS



Husam Albarmawi[1] Nathalie Marcela Eklöf[2] Maximilian Kurt Jara[3] Jeff McIntyre[4] Marco Petti[1] Lauren Nephew[5], [1]Novo Nordisk Inc., USA, [2]Novo Nordisk, Denmark, [3]Novo Nordisk Inc., [4]Patient Advocate, Washington DC, USA, [5]Indiana University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent in the United States (US); however, research remains limited regarding healthcare professionals' (HCPs) awareness, knowledge, and perceptions of MASLD and metabolic dysfunction-associated steatohepatitis (MASH), and the associations between these conditions and cardiometabolic comorbidities. **Methods:** In 2025, an online cross-sectional survey was conducted with healthcare professionals (HCPs) in multiple countries. This analysis includes data from respondents in the US only. HCPs were recruited through online panels and comprised gastroenterologists, hepatologists, endocrinologists, cardiologists, obesity specialists, primary care physicians, radiologists, and nurse practitioners/physician assistants (NPs/PAs). **Results:** In the US sample, 301 HCPs completed the survey. Respondents reported a mean of 19 years in clinical practice, and most worked in outpatient (72%) or hospital settings (24%). Most HCPs reported being "very" or "extremely" knowledgeable about MASLD (68%) and MASH (69%), with the highest ratings among gastroenterologists and hepatologists and the lowest among cardiologists. 56% of HCPs were "very" or "extremely" confident in identifying people at risk of MASH, ranging from 32% for radiologists to 95% for hepatologists. Agreement was high that MASH and MASLD increase the risk of cardiovascular events (88%) and that early diagnosis and management improve health outcomes (90%). Only 35% of HCPs reported changing MASH screening approach in the past year

due to guidelines. Hepatologists, endocrinologists, and gastroenterologists were the most likely to include Fibrosis-4 (FIB-4) as part of their testing for MASH (65-74%) while cardiologists, NPs/PAs, and PCPs were the least likely (30-45%). HCPs estimated that nearly half of MASLD (49%) and MASH (46%) diagnoses followed incidental findings that first raised suspicion of steatotic liver disease. Following incidental detection of MASH or MASLD, the most common actions taken by HCPs were initiating lifestyle counseling related to diet or exercise (70%) and initiating non-invasive laboratory testing (70%). Radiologists reported incidental findings of MASLD and MASH in 25% and 17% of scans evaluated in a typical month, respectively. Perceived importance of screening patients with cardiometabolic conditions for MASH varied by condition; results are shown in the Figure. Finally, 30% reported that fear of stigmatizing patients with obesity was a barrier to screening. **Conclusion:** US HCPs reported strong knowledge of MASLD and MASH. However, variability in identifying people at risk of MASH, gaps in guideline-informed screening, and the high rate of incidental detection of MASLD and MASH highlight opportunities to strengthen health-professional education.

2527 | METABOLIC-ASSOCIATED STEATOTIC LIVER DISEASE IN POLYCYSTIC OVARY SYNDROME AND LONG-TERM ADVERSE OUTCOMES: A PROPENSITY SCORE-MATCHED RETROSPECTIVE COHORT STUDY

Mythily Rao Ponaganti[1] Moksha Prasoona Avvaru[2] Ronald Blanco Montecino[1] Dharani Kunireddi[3] Suresh Kumar Nayudu[1] Naga Praneeth Vakkalagadda[4], [1]SBH Health System, [2]Harnett Health, [3]Clemson University, [4]University of Alabama at Birmingham

Background: Polycystic ovary syndrome (PCOS) and metabolic-associated steatotic liver disease (MASLD) frequently coexist in young women and share common pathophysiologic mechanisms. While both conditions independently have an elevated cardiometabolic risk, the long-term outcomes in PCOS women with MASLD are scarcely reported. We aimed to evaluate cardio-metabolic outcomes of MASLD and PCOS compared to PCOS alone. **Methods:** A retrospective cohort study was conducted using the TriNetX Global Collaborative Network. Women aged 18–50 years with a diagnosis of PCOS were identified and divided into two cohorts based on presence or absence of MASLD. Patients with pre-existing cardiovascular disease were excluded from both cohorts. Propensity score matching (1: 1) was performed to balance baseline characteristic and comorbidities. Outcomes of interest included Diabetes Mellitus [DM], Chronic Kidney Disease [CKD], Myocardial Infarction [MI], Cardiovascular revascularization procedures, ischemic stroke and all-cause mortality, assessed at 3-year, 5-year, and anytime follow-up intervals. Hazard ratios (HR) with 95% confidence intervals (CI) were calculated using Kaplan-Meier survival analysis. **Results:** After propensity score matching, 43,049 PCOS females with and without MASLD in each cohort were included for analyses. The PCOS + MASLD cohort had a mean age of 30.8 ± 8.0 years compared to 28.0 ± 7.2 years in the PCOS-only cohort with predominantly non hispanic [65% vs 60%] and white population [69% vs 58%] in both cohorts respectively. In PCOS females with MASLD the risk of incident DM was approximately doubled at all the follow up time points (HR 1.95-2.02) as shown in table1. Similarly, CKD risk was consistently elevated (HR 1.79-1.82) across all follow-up intervals whereas risk of ischemic stroke was significant starting at 5 years and over the entire follow-up period with a non-significant trend observed at 3 years. Notably, no cases of myocardial infarction or cardiac revascularization were observed in either cohort at any time point during follow-up but all-cause mortality was nearly twofold higher at 3 years and remained significantly elevated at 5 years and over the entire follow-up period. **Conclusion:** The presence of MASLD with PCOS significantly increased risks of DM, CKD, stroke and all-cause mortality compared to PCOS alone. On the other hand the absence of MI and cardiac revascularization events in this young, premenopausal female population suggests that the cardiovascular burden of MASLD in PCOS may initially manifest through cerebrovascular and metabolic pathways rather than acute coronary events. These findings highlight the importance of early identification and management of MASLD in women with PCOS to mitigate long-term risk and mortality.

2528 | SEX- AND BMI-MODIFIED NONLINEAR ASSOCIATION BETWEEN SLEEP DURATION AND LIVER FIBROSIS

Nazli Begum Ozturk[1] Matthew Solway[2] Ahmet Gurakar[3], [1]St. Louis University, [2]Henry Ford Hospital, [3]Johns Hopkins University

Background: Sleep duration is increasingly recognized as a modifiable determinant of metabolic dysfunction and systemic inflammation, both closely linked to chronic liver disease. However, population-level data evaluating its relationship with liver fibrosis and potential effect modification by demographic and metabolic factors remain limited. We examined the association between sleep duration and liver fibrosis in a nationally representative U.S. cohort. **Methods:** We analyzed 4653 adults from the National Health and Nutrition Examination Survey (NHANES). Survey-weighted generalized linear models accounting for complex sampling were used to evaluate associations with liver fibrosis. Sleep duration was modeled using restricted cubic splines (df = 3) to capture nonlinear effects. Multivariable models adjusted for age, sex, race/ethnicity, body mass index (BMI), diabetes, hypertension, alcohol use, smoking status, education, and poverty-income ratio (PIR). Effect modification by sex and BMI was assessed using interaction terms with Wald F-tests. A secondary analysis evaluated fibrosis severity as a continuous outcome. **Results:** In multivariable-adjusted models, metabolic risk factors were strongly associated with fibrosis. BMI was significantly associated with fibrosis (OR 1.13 per kg/m², 95% CI 1.10–1.16, $p < 0.001$), as was diabetes (OR 2.46, 95% CI 1.71–3.54, $p < 0.001$). Female sex was associated with lower odds of fibrosis compared with males (OR 0.48, 95% CI 0.32–0.72, $p = 0.001$). Higher socioeconomic status was inversely associated with fibrosis (PIR OR 0.88, 95% CI 0.78–0.99, $p = 0.038$). Sleep duration was not linearly associated with fibrosis (OR 0.98 per hour, 95% CI 0.95–1.02, $p = 0.29$). However, spline modeling demonstrated a nonlinear (U-shaped) association, with increased predicted fibrosis risk at both short and long sleep durations. There was significant effect modification by sex (Wald F = 7.07, p = 0.026) and BMI (Wald F = 8.01, p = 0.020), indicating that the association between sleep duration and fibrosis varies across demographic and metabolic subgroups. In secondary analysis, fibrosis severity was not significantly associated with sleep duration (β = -0.0004, $p = 0.74$), but remained strongly associated with BMI ($p < 0.001$) and diabetes ($p < 0.001$). Alcohol use, smoking status, hypertension, and education level were not independently associated with fibrosis after adjustment. **Conclusion:** In a nationally representative cohort of U.S. adults, sleep duration demonstrates a nonlinear association with liver fibrosis, with significant modification by both sex and BMI. While metabolic risk factors remain the dominant drivers of fibrosis, these findings highlight sleep as a potential behavioral correlate of liver disease risk, particularly in metabolically high-risk populations.

2529 | CLINICAL OUTCOMES IN MASH WITH COMPENSATED CIRRHOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF REAL-WORLD DATA

Ratree Sawangjit[1] Alexandre Watanabe[2] Saranrat Sadoyu[3] Jirawan Viengthoun[4] Muhammed Rashid[5] Prakash Navaratnam[6] Gail Fernandes[2] Yuzhi Xi[2] Zobair Younossi[7] Nathorn Chaiyakunapruk[5], [1]CTEBs RU, Faculty of Pharmacy, Mahasarakham University, Thailand, [2]Merck & Co., Inc., [3]Pakchongnana Hospital, Nakhon Ratchasima, Thailand, [4]Faculty of Pharmacy, Siam University, Thailand, [5]College of Pharmacy, University of Utah, Salt Lake City, Utah, USA, [6]DataMed solution, USA, [7]The Global NASH/MASH Council

Background: Metabolic dysfunction-associated steatohepatitis (MASH) with advanced fibrosis and compensated cirrhosis is a critical disease stage with substantial complications. However, real-world evidence on outcomes remain fragmented. This study aimed to synthesize evidence on clinical outcomes among adults with MASH and advanced fibrosis in real-world settings. **Methods:** A systematic literature review following PRISMA guidelines was conducted in PubMed, Embase, and Web of Science from inception to September 2025 (PROSPERO CRD420251168041). Observational studies evaluating risk of liver events and mortality among adults with MASH and advanced fibrosis (F3-F4) were included. Outcomes included all-cause mortality, hepatic decompensation events, and severe liver-related complications. Two reviewers independently reviewed studies and extracted the data. Random-effects meta-analyses generated odds ratios (ORs) with 95% confidence intervals (CIs). Heterogeneity was assessed using I^2 statistics and Cochran's chi-squared tests. **Results:** Thirteen cohort studies (733,561 participants) were included in the meta-analysis of compensated cirrhosis (F4/CC). All results are presented in Figure 1. Compared with non-cirrhotic (F0–F3), adults with F4/CC had significantly increased risks of all-cause mortality (OR 8.2; 95%CI: 5.9-11.3), with stronger association in US cohorts (OR 9.8; 95%CI: 7.9-12.1;). MASH with F4/CC was associated with a substantially higher risk of hepatic decompensation, including ascites (OR 30.7; 95%CI: 8.82-106.72), variceal bleeding (OR 38.5; 95%CI: 4.82-307.31), and hepatic encephalopathy (OR 92.9; 95%CI: 17.75-486.49). Consistent findings were observed in studies using composite measures of decompensation, including liver-related events (OR 23.3; 95%CI 11.7–46.1) and progression to decompensated cirrhosis (OR 33.4; 95%CI 17.0–65.6). Additionally, MASH F4/CC was associated with increased risks of severe liver-related complications, including liver transplantation (OR 70.3; 95%CI: 43.9-112.5) and hepatocellular carcinoma (OR 18.5; 95%CI: 5.1-67.5). However, these findings should be interpreted with caution because the number of studies directly comparing non-cirrhotic MASH with F4/CC was limited. **Conclusion:** In real-world practice, adults with F4/compensated MASH cirrhosis experience markedly increased risks of mortality, hepatic decompensation, and severe liver-related complications compared with non-cirrhotic populations. These patients have 8 times higher risk of mortality,23 times higher risk of liver events and 18 times higher risk of HCC. These findings highlight the importance of disease screening, the need for effective approved therapies for adults with compensated cirrhosis, and the need for further research into clinical outcomes and healthcare burden in this population.

2530 | REAL-WORLD MEDICATION ADHERENCE AND PERSISTENCE TO RESMETIROM IN PATIENTS WITH MASH

Joaquim Fernandes[1] Raman Kumar[1] Sheila Thomas[1] Nipun Atreja[2] Blake Thomas[2] Francis Lobo[2], [1]CVS Healthspire Life Sciences Solutions, [2]Madrigal Pharmaceuticals

Background: Metabolic dysfunction–associated steatohepatitis (MASH), previously referred to as NASH/NAFLD, is a progressive liver disease with limited approved

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

therapies and a growing clinical burden. In March 2024, resmetirom, a selective thyroid hormone receptor beta (THR-β) agonist, became the first FDA-approved liver-directed treatment for MASH. Given its recent introduction into clinical practice, evaluating real-world treatment patterns—particularly adherence and persistence—is critical to understanding its effectiveness and optimizing patient outcomes. **Methods:** This retrospective cohort study utilized large specialty and retail pharmacy fill data for resmetirom between March 14, 2024 and April 30, 2026. Inclusion criteria were patients (aged ≥18 years) with at least 2 prescription fills for resmetirom consistent with standard medication measures used to assess treatment compliance. Patients were considered persistent if they were actively filling resmetirom scripts at 6- and 12-months post initiation with a permissible 60/90-day fill grace period. Adherence was measured using a proportion of days covered (PDC), calculated from the first dispensation for 6 and 12 months. **Results:** At 6 months, 11,469 patients were assessed (mean age, 57.5 years; 56.1% female). Persistence was 89.4% and 94.5% using 60- and 90-day grace periods, respectively, with a mean PDC of 85.6% (75.9% meeting PDC ≥80%). At 12 months, 6,898 patients were assessed (mean age, 57.1 years; 56.4% female). Persistence was 72.4% and 75.8%, with a mean PDC of 76.4% (61.7% meeting PDC ≥80%). **Conclusion:** In this large real-world cohort of patients with MASH, adherence and persistence to resmetirom were high at 6 months and 12 months as indicated by both persistence and PDCs. Findings indicate the need for continued monitoring and the need for targeted strategies to sustain long-term treatment use and optimize clinical outcomes. Further research is warranted to identify factors influencing long-term persistence and to evaluate the clinical outcomes associated with high adherence to resmetirom.Sponsorships: Madrigal Pharmaceuticals.

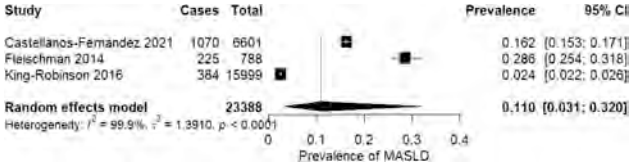
2531 | HIDDEN BURDEN OF METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE IN CARIBBEAN POPULATIONS: A SYSTEMATIC REVIEW AND META-ANALYSIS



Francesca Farina[1] Aurgho Datta[1] Adam Hassan[1] Thierry Fotsing Tadjo[1] Genevieve Gore[2] Jihoon Lim[3] Felice Cinque[4] Sherrydene Barrett[5] Harold Munnings[6] Trevor Murphy[7] Giada Sebastiani[2], [1]McGill University Health Centre, [2]McGill University, [3]Research Institute of the McGill University Health Centre, [4]University of Milan, [5]University Hospital of the West Indies (UHWI), [6]The Centre for Digestive Health, Bahamas, [7]University of the West Indies

Background: Caribbean populations face a disproportionately high burden of obesity, diabetes, and other cardiometabolic risk factors, along with potential genetic susceptibility, all strongly associated with metabolic dysfunction-associated steatotic liver disease (MASLD). However, the epidemiology of MASLD in this region remains poorly defined, with fragmented data across island nations and limited access to contemporary diagnostic tools. We conducted a systematic review and meta-analysis to estimate the prevalence of MASLD in Caribbean populations and characterize associated metabolic comorbidities. **Methods:** We systematically searched studies reporting MASLD prevalence and metabolic risk factors in Caribbean populations. Among 4,425 records screened, 11 studies met inclusion criteria and were included in the final meta-analysis. Pooled prevalence estimates with 95% confidence intervals (CI) were calculated using random-effects models. MASLD prevalence was derived from studies reporting hepatic steatosis prevalence, while metabolic comorbidities were pooled from all eligible studies reporting risk factor data among individuals with MASLD. Between-study heterogeneity was assessed using the I^2 statistic. **Results:** MASLD prevalence was estimated from three studies including 2,088 individuals, yielding a pooled prevalence of 11.0% (95% CI 3.1%–32.0%) with marked heterogeneity ($I^2 = 99.9\%$). Diagnostic approaches varied substantially and included abdominal ultrasound, computed tomography, and liver biopsy in selected cohorts. Among 23,388 individuals with MASLD, metabolic comorbidities were highly prevalent: obesity 48.0% (95% CI 33.9%–62.3%; $I^2 = 85.9\%$), hypertriglyceridemia 55.9% (95% CI 31.1%–78.0%; $I^2 = 93.2\%$), dyslipidemia 43.1% (95% CI 21.2%–68.2%; $I^2 = 95.0\%$), hypertension 32.5% (95% CI 18.1%–51.2%; $I^2 = 91.0\%$), and type 2 diabetes 25.6% (95% CI 15.3%–39.6%; $I^2 = 92.4\%$). Liver biochemistry was sparsely reported, with only three studies (n = 180) contributing data on aminotransferases. Pooled mean ALT was 50.4 U/L (95% CI 14.6–173.9; $I^2 = 99.0\%$) and AST 44.4 U/L (95% CI 11.9–165.4; $I^2 = 99.4\%$). **Conclusion:** Despite a high burden of obesity, diabetes, and other cardiometabolic risk factors, reported MASLD prevalence in Caribbean populations remains substantially lower than global estimates, strongly suggesting under-recognition and underdiagnosis. This discrepancy likely reflects reliance on older studies, heterogeneous and insensitive diagnostic methods, and limited

access to contemporary non-invasive liver assessment. These findings highlight a major unmet public health need and underscore the urgency of standardized MASLD definitions, contemporary population-based epidemiological studies, and integrated liver-metabolic care pathways tailored to Caribbean populations.

2532 | RECLASSIFYING OBESITY USING THE LANCET COMMISSION FRAMEWORK RESOLVES THE OBESITY-CARDIOVASCULAR MORTALITY PARADOX IN MASLD

Guy Loic Nguefang[1] Sarpong Boateng[2] Christian Akem Dimala[3] Solomon Gyabaah[4] Yazan Al Ajlouni[5] chimezirim ezeano[6] Khaled Halwani Halwani[7] Ulrick Sidney Kanmounye[8] Nso Nso[9] Basile Njei[10], [1]Texas Tech University Health Sciences Center, [2]Yale New Haven Health, Bridgeport Hospital, [3]University of Texas Southwestern Medical Center, [4]Komfo Anokye Teaching Hospital, [5]Montefiore Medical Center/Albert Einstein College of Medicine, [6]Advocate Aurora Healthcare, [7]Yale University School of Medicine, [8]Research Department, Association of Future African Neurosurgeons, [9]Division of Cardiology, University of Chicago, [10]Yale University

Background: In MASLD, lower BMI has been paradoxically associated with higher cardiovascular (CVD) mortality (obesity paradox). This reflects BMI's inability to distinguish sarcopenia and visceral adiposity from metabolically healthy obesity. We evaluated whether the 2025 Lancet Commission obesity framework resolves this paradox in a nationally representative U.S. MASLD cohort. **Methods:** Adults with MASLD were identified from NHANES III (1988–1994), linked to National Death Index mortality data through December 2019. MASLD required hepatic steatosis on ultrasound plus ≥1 cardiometabolic criterion. Participants were classified by traditional BMI categories and the Lancet framework: Non-Obese (BMI < 30), Preclinical Obesity (BMI ≥ 30, no obesity-related complications), and Clinical Obesity (BMI ≥ 30 plus ≥ 1 complication: hypertension, type 2 diabetes, renal dysfunction, ECG abnormality, or functional limitation). Complex-survey-weighted Cox proportional hazards models estimated adjusted HRs for CVD mortality. Subgroup analyses by sex and age (<65 vs. ≥65 years) and Fine-Gray competing risks regression were performed. **Results:** A total of 1721 participants (weighted 13 million US adults) met MASLD criteria. Using the Lancet framework, we identified 60.3% non-obese, 11.3% preclinical obesity, and 28.4% clinical obesity. Clinical obesity carried the highest burden of comorbidity: hypertension (22.8%), diabetes (27.7%), and functional limitations (47.1%). Over 30.5 years, 1,720 deaths and 1,089 CVD deaths occurred. Traditional BMI categories were not associated with cardiovascular mortality, and overweight showed a non-significant trend toward lower risk (HR 0.82; 95% CI 0.66-1.01; p = 0.062). With the Lancet framework, clinical obesity independently predicted 27% higher CVD mortality vs. non-obese (HR 1.27; 95% CI 1.00–1.60; p = 0.048), while preclinical obesity had neutral risk (HR 1.01; 95% CI 0.80-1.27; p = 0.95). Among adults <65 years, clinical obesity conferred a 38% higher CVD mortality risk (HR 1.38; 95% CI 1.10–1.74; p = 0.006). After competing risks analysis, the association between clinical obesity and CVD mortality was attenuated (HR 1.06; 95% CI 0.92–1.23; p = 0.399). Fine-Gray competing risks regression accounting for non-CVD deaths attenuated the clinical obesity-CVD mortality association (HR 1.06; 95% CI 0.92–1.23; p = 0.399). **Conclusion:** Staging obesity using the Lancet Commission framework attenuates the obesity-CVD mortality paradox in MASLD and identifies clinical obesity as a high-risk phenotype. Cardiovascular risk appears to be driven by obesity-related complications and metabolic dysfunction rather than BMI categories. These findings underscore the importance of transitioning from anthropometry-focused paradigms to complication-focused obesity staging to improve CVD risk stratification in MASLD.

Table Head-to-head comparison: traditional BMI vs. Lancet obesity framework on CVD mortality
Fully adjusted Cox proportional hazards models†

Predictor	Adjusted HR (95% CI)	P-value
Model A — Traditional BMI categories		
Normal weight (reference)	1.00	—
Overweight	0.82 (0.66–1.01)	0.062
Class I obesity	0.94 (0.72–1.22)	0.616
Class II obesity	1.36 (0.97–1.91)	0.071
Class III obesity	1.37 (0.92–2.05)	0.119
Model B — Lancet obesity framework		
Non-obese (reference)	1.00	—
Preclinical obesity	1.01 (0.80–1.27)	0.950
Clinical obesity	1.27 (1.00–1.60)*	0.048*

2533 | LIMITED ADOPTION OF MET-ALD AS A DIAGNOSIS FOR LIVER TRANSPLANTATION

Previn Ganesan[1] Scott Biggins[2] Kymberly Watt[3] Neil Shah[4] Allison Kwong[5], [1]Stanford University, [2]University of PIttsburgh, [3]Mayo Clinic, [4]University of North Carolina at Chapel Hill, [5]Stanford University Medical Center

Background: Metabolic and alcohol-related liver disease (Met-ALD) was formally introduced in 2023 with the intention of highlighting a clinically distinct subgroup of individuals with steatotic liver disease (SLD), at the intersection of metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-related liver disease (ALD). In 2024, the diagnosis of Met-ALD was incorporated into the UNOS registry to better understand outcomes in this subpopulation. In addition, NASH was re-categorized to MASH. In this study, we seek to examine the use of Met-ALD as a primary diagnosis code since its implementation. **Methods:** We analyzed the UNOS transplant registry to review adult liver registrations and transplants 1 year before (pre-diagnosis update) and after (post-diagnosis update) the inclusion of Met-ALD as a diagnosis code on 10/10/2024. Demographic data, primary and secondary diagnosis at time of listing and transplant, and cardiometabolic risk factors including body mass index (BMI) and presence of diabetes were collected. We compared two scenarios: (1) the actual use of the Met-ALD diagnosis with (2) a previously validated estimate of Met-ALD (henceforth called Met-ALD*, *Hepatology* 2025). Met-ALD* was defined by (1) a primary diagnosis of MASH and secondary diagnosis of ALD (or vice versa), or (2) a diagnosis of ALD with diabetes or obesity, adjusted for the severity of ascites. **Results:** During the study period, there were a total of 29,927 new registrations (14,569 before, 15,358 after the diagnosis update) and 22,313 transplants (10,780 before, 11,533 after the diagnosis update). Met-ALD was the primary diagnosis for 4.5% (N = 687) of registrations and 3.9% (N = 419) of transplants. However, using the surrogate definitions (Met-ALD*), 18.5% (N = 2,844) of registrations and 18.4% (N = 2,117) of transplants during the same period were estimated to have Met-ALD* (*Figure 1*). Median MELD of registrations and transplants was higher in the Met-ALD* population (23 and 27, respectively) than the observed Met-ALD population (21 and 26, respectively). The Met-ALD* group included a higher proportion of men and individuals with diabetes than the Met-ALD group. **Conclusion:** In the year following its incorporation into the UNOS registry, Met-ALD has been underutilized as a primary diagnosis for registration or transplantation. The estimated prevalence of Met-ALD among transplant candidates and recipients is significantly higher than the observed use of Met-ALD as a diagnosis. Met-ALD may be underrecognized in men and patients with diabetes. The lower-than-expected usage of the Met-ALD diagnosis may be due to (1) limited awareness of the updated diagnosis codes and (2) the challenge of accurately distinguishing among MASLD, Met-ALD, and ALD in the context of cirrhosis. The transplant community would benefit from increased education and awareness regarding the diagnosis of Met-ALD.

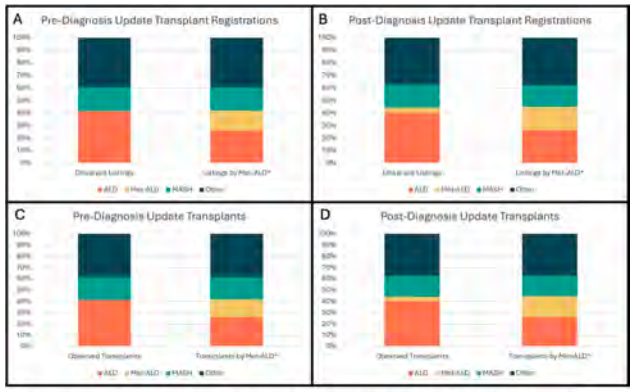

Figure 1: Comparison of percentages of transplant registrations and transplants in the pre- and post-diagnosis update (addition of Met-ALD as a diagnosis code) periods. Met-ALD* represents the use of a previously validated estimate of the Met-ALD diagnosis.

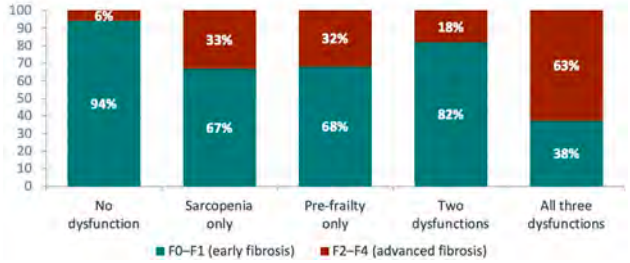
2534 | THE MULTI-DOMAIN FRAMEWORK OF METABOLIC SYNDROME MYOPATHY IDENTIFIES WORSE HEALTH-RELATED QUALITY OF LIFE (HRQOL) AMONG PATIENTS WITH MASLD

Melinda Wang[1] Dorothea Kent[1] Fawzy Barry[1] Lisa Catalli[2] Jennifer Lai[1], [1]UCSF, [2]University of California, San Francisco



Background: Metabolic syndrome myopathy, dysfunction in three domains: muscle mass, quality, and function, is common among MASLD patients. Risk factors associated with metabolic syndrome myopathy may

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

identify vulnerable patients who may benefit from targeted intervention. We aimed to characterize phenotypes of metabolic syndrome myopathy and evaluate its relationship with HrQoL. **Methods:** Adults with MASLD by ICD-10 code were enrolled in the single-center prospective cohort between October 2025 and May 2026. All participants underwent fibroscan (stiffness and CAP), bioelectrical impedance analysis (BIA; Quantum VII, RJL Systems), Liver Frailty Index (LFI), and patient-reported outcomes including PROMIS-29 and Duke Activity Status Index (DASI). Dietary quality was assessed by ASA24 or DietID® and scored using the Healthy Eating Index (HEI-2020). Metabolic syndrome myopathy domains were defined as: sarcopenia (skeletal muscle index $<9.2 kg/m^2$ in men, <7.4 kg/m^2 in women), myosteatosis (phase angle <5.6 for men, <5.4 for women), and/or physical pre-frailty (LFI ≥ 3.2). Binary covariates were defined as advanced fibrosis (F0-F1 vs F2-F4 by fibroscan), adequate exercise capacity (DASI ≥ 34 vs <34) and good dietary quality (HEI2020 ≥ 80 vs <80). Mann-Whitney U tests assessed number of domain dysfunctions across binary exposures. Multivariable logistic regression analyzed odds of worse general health by phenotype. **Results:** Among 100 adults, median age was 54 (IQR 46-62), 48% were women, 36% were non-White, 70 (75%) had adequate exercise capacity, 28 (38%) had good dietary quality, and 76% had F0-F1 fibrosis; 45% had sarcopenia, 49% were pre-frail, and 16% had myosteatosis. Overall, 40% met criteria for dysfunction in one domain, 22% in two, and 9% in all three domains. Phenotype distribution differed significantly by fibrosis group ($p=0.005$, Figure A). Each additional domain dysfunction was associated with 2.20 times greater odds of poor general health (OR 2.20, 95%CI 1.11-4.35, $p=0.02$). **Conclusion:** Dysfunction in domains of metabolic syndrome myopathy demonstrate variability across fibrosis stages and are associated with worse HrQoL. The multidomain metabolic syndrome myopathy framework identifies MASLD patients with worse HrQoL and should be used when assessing muscle health among adults with MASLD.

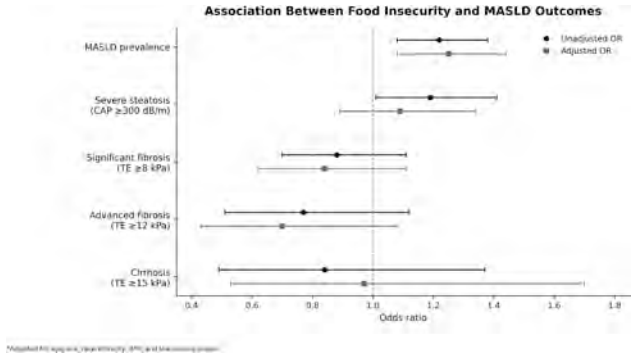
2535 | ASSOCIATION BETWEEN FOOD INSECURITY AND METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)



Nishat Anjum Shaik[1] Mohammed Rifat Shaik[2] Vincenzo Cardinale[3] Lewis Frey[3] Wing-Kin Syn[4], [1]SSM Health/Saint Louis University, [2]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, [3]Division of Gastroenterology, Department of Internal Medicine, SSM Health/Saint Louis University, [4]Saint Louis University School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects over one-third of U.S. adults and is projected to become the leading indication for liver transplantation. Food insecurity affects ~12.8% of U.S. households and promotes reliance on energy-dense, nutrient-poor diets that contribute to visceral adiposity and insulin resistance. Prior studies linking food insecurity to MASLD have largely relied on serological fibrosis indices but its independent contribution across the full disease spectrum from steatosis to fibrosis remains unclear. We aimed to determine whether food insecurity is independently associated with MASLD prevalence, severe steatosis, and liver fibrosis severity among U.S. adults. **Methods:** We conducted a cross-sectional analysis of adults aged ≥ 18 years from NHANES 2017–2020 with complete transient elastography (TE) and food security data. MASLD was defined as controlled attenuation parameter (CAP) ≥ 263 dB/m with at least one cardiometabolic risk factor and no other chronic liver disease etiology. Food insecurity was assessed using the USDA Household Food Security Survey Module. Primary outcomes were MASLD prevalence, severe steatosis (CAP ≥ 300 dB/m), and elevated liver stiffness at multiple thresholds (LSM ≥ 8, ≥ 12, and ≥ 15 kPa). Multivariable logistic regression models adjusted for age, sex, race/ethnicity, BMI, and low-income status. **Results:** Among 3,459 eligible adults, 804 (23.2%) were food insecure. Food-insecure adults were younger (48.8 vs. 53.4 years, $p<0.001$), more likely female (53.1% vs. 46.5%, $p=0.001$), had higher BMI (34.9 vs. 33.2 kg/m², $p<0.001$), and were more likely to have low income (60.9% vs. 22.4%, $p<0.001$). Food insecurity was independently associated with MASLD prevalence after adjustment for age, sex, race/ethnicity, and low-income status (OR 1.25, 95% CI 1.08–1.44, $p=0.003$). Among adults with MASLD, food insecurity was associated with severe steatosis in unadjusted analysis (OR 1.19, 95% CI

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

1.01–1.41, p = 0.040), but this was attenuated after adjustment (OR 1.09, 95% CI 0.89–1.34, p = 0.415). Food insecurity was not associated with elevated liver stiffness at any threshold: TE ≥ 8 kPa (adjusted OR 0.84, 95% CI 0.62–1.11), TE ≥ 12 kPa (adjusted OR 0.70, 95% CI 0.43–1.08), or TE ≥ 15 kPa (adjusted OR 0.97, 95% CI 0.53–1.70). Sensitivity analyses using an alternative MASLD definition (CAP ≥ 248 dB/m) yielded consistent results. **Conclusion:** Food insecurity is independently associated with MASLD prevalence and demonstrates a signal toward increased steatosis severity but is not independently associated with liver fibrosis. These findings suggest that food insecurity primarily drives MASLD burden through adiposity and dietary quality rather than directly promoting fibrosis progression. Food insecurity may represent a modifiable upstream determinant of MASLD, supporting integration of food security screening into hepatology practice.

2536 | THE MASH CIRRHOSIS EVIDENCE GAP: A DECADE-LONG CLINICALTRIALS.GOV ANALYSIS

Saad Nadeem[1] David Victor[2] Sudha Kodali[2] Tamneet Basra[2] Michelle Jones-Pauley[2] Mohammad Siddiqui[3] R. Mark Ghobrial[4] Mazen Noureddin[2] Kavish Patidar[2], [1]Texas A&M College of Medicine, [2]Houston Methodist Hospital, [3]Virginia Commonwealth University, [4]Houston Methodist JC Walter Transplant Center

Background: Despite FDA approvals of resmetirom and semaglutide, both medications are available only to adults with noncirrhotic MASH and significant fibrosis (F2-F3). MASH cirrhosis patients, who carry the highest liver-related morbidity and mortality, lack approved treatments due to this evidence gap. It is unclear whether this gap reflects systematic underrepresentation in the MASH trial pipeline. We evaluated the inclusion of patients with cirrhosis across a decade of MASH drug trials. **Methods:** We queried ClinicalTrials.gov for trials initiated from 2015 to 2025 that referenced MASH, MASLD, NASH, or NAFLD. Eligibility criteria and title were programmatically classified as cirrhosis-targeted, cirrhosis-allowed, F2–F3 only, cirrhosis-excluded (explicit exclusion of cirrhosis, Child-Pugh B/C, decompensation, or portal hypertension), or unspecified. Compared with 2015–2023, trends in 2024–2025 were analyzed by start year, phase, mechanism, and sponsor type. **Results:** Among 470 MASH trials enrolling 75,677 participants, only 28 (6.0%) targeted cirrhosis, while 236 (50.2%) explicitly excluded cirrhosis, and 15 (3.2%) restricted enrollments to F2-F3. In the post-resmetirom era, cirrhosis-targeted trials remained low (annual range: 1.7-16.1%), while the proportion of patients explicitly excluded for cirrhosis increased (69.9% vs. 49.9%) (Figures A and B). Despite 47 Phase 3 trials, only 5 (10.6%) targeted cirrhosis and 27 (57.4%) excluded it. Trials targeting cirrhosis accounted for 10.6% of total planned enrollment (8,021/75,677). Exclusion was most pronounced among PPAR agonists (0% cirrhosis-targeted), GLP-1 RAs (4%), SGLT2 inhibitors (7%), and GLP-1/glucagon dual agonists (10%); antifibrotic biologics (50%), FGF21 analogs (42%), and ACC inhibitors (36%) had higher cirrhosis expression (Figure C). Industry sponsored 61.1% of trials; 12.6% were terminated/withdrawn. **Conclusion:** Despite rapid therapeutic progress in noncirrhotic MASH, patients with MASH cirrhosis remain largely excluded from drug development. Across 470 interventional trials, cirrhosis-targeted studies represented only 6% of trials and 11% of planned enrollment, with exclusion increasing after the first MASH approval. These findings identify a widening therapeutic evidence gap and support urgent regulatory, sponsor, and protocol-design strategies to responsibly extend MASH therapeutics to compensated cirrhosis, with carefully designed pathways for decompensated populations.

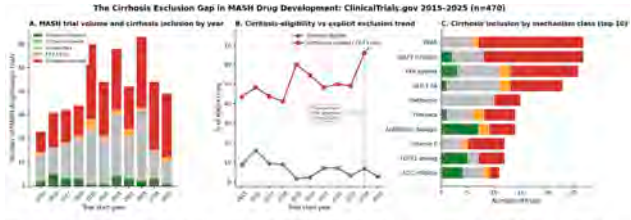

Figure 1. The cirrhosis exclusion gap in MASH drug development (ClinicalTrials.gov, 2015–2025; n=470). (A) Stacked trial volume by start year. (B) Annual % of trials that are cirrhosis-eligible (green) versus explicitly cirrhosis-excluded or F2–F3 only (red); dashed line marks resmetirom FDA approval (Mar 2024). (C) Cirrhosis-inclusion bucket within the top 10 mechanism classes. Classification performed via programmatic parsing of eligibility-criteria text, condition tags, and study titles.

2537 | IMPACT OF MACE EXPOSURE AND GLP-1 USE ON NON-CIRRHOTIC HCC DEVELOPMENT IN MASLD

Kai-Lou Yue[1] Charanpreet Sasan[1] Taylor Seacor[1] Anita Krishnarao[2], [1]UMass Chan Medical School, Worcester, MA, [2]UMass Memorial Medical Center, Worcester, MA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a risk factor for hepatocellular carcinoma (HCC) in non-cirrhotic individuals. This study examined major adverse cardiovascular events (MACE) as a risk factor for HCC, along with the differential impact of glucagon-like peptide-1 receptor agonists (GLP-1) on HCC risk by MACE status in this population. **Methods:** Data from the TriNetX Global Network from 1/1/2005 to 12/31/2025 were used. We included adults with hepatic steatosis and ≥ 1 MASLD-associated cardiometabolic risk factor (e.g. hypertension, type 2 diabetes, hyperlipidemia, or obesity) as a surrogate definition for MASLD. Study group inclusion required patients to also have ≥ 1 MACE, defined as acute myocardial infarction, heart failure, cerebral infarction, or unstable angina. Patients with viral hepatitis, cirrhosis, alcohol use disorder, or prior HCC were excluded. Cox regression identified risk factors for HCC, adjusting for age, sex, race, ethnicity, body mass index (BMI), hemoglobin A1c (HbA1c), low-density lipoprotein (LDL), aspartate aminotransferase (AST), and nicotine dependence. Secondary analyses assessed the association between ≥ 1 instance of GLP-1 use and HCC risk stratified by MACE status. **Results:** A total of 1,481,092 patients with non-cirrhotic MASLD were identified: 276,469 with MACE and 1,204,623 without MACE. The presence of MACE was associated with two-fold higher hazard of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

developing HCC (HR 2.20, 95% CI 1.92-2.52) compared to those without MACE. Male sex (HR 1.70, 95% CI 1.51-1.91) and increasing age per year (HR 1.05, 95% CI 1.05-1.06) were independently associated with higher HCC risk. White race (HR 0.38, 95% CI 0.34-0.43) was associated with lower HCC risk. In secondary analyses of non-cirrhotic MASLD patients without MACE, GLP-1 users (n = 79,254) had a lower hazard of HCC than non-users (n = 946,957; HR 0.44, 95% CI 0.26-0.75). In patients with MACE, GLP-1 use (n = 7,038) was associated with a lower but non-significant hazard of HCC compared to controls (n = 173,885; HR 0.15, 95% CI 0.02-1.11). **Conclusion:** In patients with non-cirrhotic MASLD, MACE was an independent predictor of HCC development. While GLP-1 exposure was associated with lower HCC risk in patients without MACE, this association attenuated among patients with MACE. These findings suggest a potential HCC-related benefit to GLP-1 initiation in MASLD at earlier stages of cardiometabolic disease.

Table 1: Cox regression analysis of HCC risk factors and the differential impact of GLP-1s by MACE status in non-cirrhotic MASLD

	Non-Cirrhotic MASLD *MACE vs. No MACE*			Non-Cirrhotic MASLD without MACE *GLP-1 vs no GLP-1*			Non-cirrhotic MASLD with MACE *GLP-1 vs no GLP-1*

2538 | RECURRENT MASLD AFTER ORTHOTOPIC LIVER TRANSPLANTATION: IDENTIFYING CARE GAPS TO GUIDE STRUCTURED FOLLOW-UP

Hamsika Moparty[1] Rohan Karkra[1] Lucie Pham[1] Nishanth Moparty[2] Annie Xu[1] Anika Makol[1] Shivani Patel[1] Zaid Tafesh[1] Paul Gaglio[3], [1]Rutgers New Jersey Medical School, [2]Bhaskar Medical College, NTR University, [3]Rutgers NJ Medical School

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) has become one of the leading indications for liver transplantation. However, recurrence or new onset of MASLD after transplant is increasingly recognized but poorly studied. There is a growing need for a standardized post-transplant approach to monitor metabolic risk factors, incorporate regular non-invasive fibrosis assessment, and coordinate multidisciplinary care. This quality improvement project aims to better define recurrence patterns, identify care gaps, and use these data to design a structured follow-up pathway. **Methods:** A single-center retrospective chart review was conducted on all orthotopic adult liver transplant recipients over the past 10 years who had MASLD as an indication for transplant. Demographic, metabolic, serologic, histological, and imaging data were extracted at pre-transplant baseline, at 6- and 12-month, and 1-, 3- and 5- years post-OLT time points. Key outcomes included MASLD recurrence, Fib-4 risk stratification, non-invasive fibrosis testing rates, metabolic markers, weight management referral practices, and use of novel pharmacotherapies. **Results:** We searched hospital records to identify patients who received an orthotopic liver transplant between 2015 and 2025 for the primary indication of MASLD cirrhosis. We describe a cohort of 26 patients. Mean age was 60.3 ± 9.2 years and 61.5% were male. Patients had a high pre-transplant metabolic burden, including hypertension (65.4%), diabetes (53.8%), hyperlipidemia (46.2%), and obesity (36% with BMI > 30 kg/m²). Mean MELD score was 26.9 ± 9.1. Explant pathology showed cirrhosis in 60% and hepatocellular carcinoma in 20%.Post-transplant liver enzymes and bilirubin normalized by 6 months, but metabolic parameters increased over time. Mean triglycerides rose from 114.7 to 172.9 mg/dL, total cholesterol from 129.3 to 165.7 mg/dL, and HbA1c from 5.4% to 6.3% by 12 months. The proportion of patients with BMI > 30 kg/m² increased from 36% pre-transplant to 56.2% at 12 months. Recurrent MASLD was identified in 3 patients (11.5%) at a mean follow-up of 4.1 years. FibroScan or FibroSure was performed in only 1 patient (3.8%) at each time point, and among patients with BMI > 30 kg/m², 55.6%, only 7.7% of patients received GLP-1 receptor agonists. **Conclusion:** Orthotopic Liver transplant recipients with MASLD demonstrated worsening metabolic risk factors over time despite stable graft function, indicating that the risks for metabolic syndrome continued post-transplant. These findings highlight the importance of developing a structured post-transplant MASLD surveillance protocol with routine metabolic monitoring, Fib-4 assessment, non-invasive fibrosis testing, and multidisciplinary management to support early identification and treatment of recurrent disease.

Structured Post-OLT MASLD Surveillance Protocol

Timepoint	Recommended Evaluation
6 months	Weight/BMI, blood pressure, HbA1c, lipid panel, liver enzymes, FIB-4 calculation ± FibroSure; consider TTE in high cardiovascular-risk patients
12 months	FibroScan or ultrasound elastography ± ELF/FibroSure, repeat metabolic profile, cardiology follow-up/TTE if indicated
Annually thereafter	Repeat above fibrosis and metabolic assessment; nutrition, endocrinology, and bariatric referral if criteria met
As indicated	GLP-1 receptor agonists, obesity pharmacotherapy, or bariatric intervention

2539 | STEATOTIC LIVER DISEASE (SLD) SUBTYPES AMONG ADOLESCENTS IN THE UNITED STATES: A NATIONALLY REPRESENTATIVE STUDY

Zobair Younossi[1] Annette Paik[1] Fatema Nader[2] Andrei Racila[1] James Paik[3], [1]The Global NASH/MASH Council, [2]Center for Outcomes Research in Liver Diseases, CORLD, [3]Global NASH/MASH Council

Background: SLD is common cause of liver disease in the U.S., yet its burden among adolescents is poorly characterized due to limited alcohol exposure data. This study used the National Health and Nutrition Examination Survey (NHANES) to estimate the prevalence of SLD and its subtypes among U.S. adolescents **Methods:** NHANES 2017–2023 participants aged 12–17 years with controlled attenuation parameter (CAP) and liver stiffness measurement (LSM) data and no other liver diseases were analyzed. SLD was defined as CAP $\geq$280 dB/m. Significant fibrosis (SF) and advanced fibrosis (AF) were defined as LSM $\geq$8.0 and $\geq$12.0 kPa. Obesity was defined using CDC 2000 BMI-for-age percentiles. Cardiometabolic risk (CMR) factors were adapted for pediatric populations. Participants were classified by past-30-day alcohol use as: no exposure (never drank), low (experimental or 1–2 days per month, no binge episodes), moderate (2-5 days per month and no binge episodes), or high-risk (>5 days or 1-5 binge episode per month) and severe (>5 days and >5 episodes of binge per month). Metabolic-associated fatty liver disease (MASLD) was defined as SLD with no/low alcohol exposure plus $\geq$1 CMRs; metabolic dysfunction-associated alcoholic liver disease (MetALD) as SLD with moderate/high-risk plus $\geq$1 CMRs and alcohol associated liver disease (ALD) was SLD with severe alcohol use. **Results:** Among 1,775 adolescents (mean age 14.5 years; 52.1% male; 46.7% White; 24.7% with obesity; 2.4% with hypertension; 0.6% with type 2 diabetes(T2D), weighted prevalence of SLD in this group was 13.5% [11.8% for (MASLD), 1.1% for MetALD, 0% for ALD, 3.8% for SF, and 1.1% for AF]. Prevalence of MASLD and MetALD differed by age group (12–15 vs. 15–17 years): 10.7% vs 12.9% and 0.07% vs. 2.05% [Figure A]. Boys had higher prevalence of all SLDs than girls [Figure B]. Mexican American adolescents had the highest prevalence of SLD and MASLD (p = 0.0001), while Non-Hispanic Black adolescents had the highest prevalence of SF (p = 0.0008; Figure C). In socioeconomic-adjusted models, low household income was independently associated with MASLD (OR 1.85, 95% CI 1.03–3.30). In fully adjusted model, obesity (OR 15.90, 95% CI 6.54–38.64), T2D (OR 4.69, 95% CI 1.28–17.16), and hypertension (OR 3.43, 95% CI 1.04–11.34) were independently associated with MASLD. Across all adolescents, obesity (β = 0.095, p = 0.002) and hypertension (β = 0.130, p = 0.023) were independently associated with higher LSM. Among adolescents with SLD, hypertension was the only independent clinical correlate of higher LSM (β = 0.193, p = 0.018). **Conclusion:** Steatotic liver disease affects approximately 1 in 8 U.S. adolescents, with substantial racial/ethnic disparities. MASLD is the predominant subtype of SLD, while MetALD represents a small but important subset. Among adolescents with SLD, hypertension was the strongest independent clinical correlate of liver stiffness, warranting longitudinal investigation.

★2540 | CARDIOVASCULAR AND MORTALITY RISKS IN YOUNG-ONSET VERSUS LATE-ONSET TYPE 2 DIABETES AMONG PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Xinrong Zhang[1] Ruoqi Zhou[2] Yuankai Wu[1] Zilong Lu[1] Haotian Zhang[2] Yuhua Hao[1] Fanpu Ji[3] Rongtao Lai[4] Vincent Wai-Sun Wong[5] Yu Shi[2], [1]Sun Yat-sen University, [2]The First Affiliated Hospital, Zhejiang University School of Medicine, [3]Xi'an Jiaotong University, [4]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [5]The Chinese University of Hong Kong

Background: The concurrent rise in type 2 diabetes mellitus (T2DM) and metabolic dysfunction-associated steatotic liver disease (MASLD) represents a major public health challenge. Young-onset T2DM (YO-T2DM) is associated with a more aggressive disease phenotype and higher complication risks than late-onset T2DM (LO-T2DM). However, whether this excess risk persists among T2DM patients with coexisting MASLD, who are already at elevated risk for adverse outcomes, remains unclear. In addition, data directly comparing major adverse cardiovascular events (MACE) and mortality between YO- and LO-T2DM in patients with MASLD are limited. **Methods:** Participants with MASLD (defined by Fatty Liver Index >60 plus at least one cardiometabolic risk factor, excluding excessive alcohol use and other liver diseases) and coexisting T2DM were identified from the UK Biobank. YO-T2DM was defined as T2DM diagnosed before 40 years of age, whereas all other cases were classified as LO-T2DM. The primary outcomes were all-cause mortality, cardiovascular mortality, and MACE. We estimated these associations by age-scaling Cox proportional hazards models with stepwise adjustment for demographics, T2DM duration, comorbidities, laboratory indicators and medication use. Propensity score matching (PSM) and restricted cubic splines (RCS) were conducted to validate the findings. **Results:** A total of 8,691 MASLD patients were included, comprising 7,898 with LO-T2DM and 793 with YO-T2DM. Compared to the LO-T2DM group, MASLD patients with YO-T2DM exhibited higher risks of adverse outcomes after full adjustment for covariates, including a 1.74-fold increased risk for all-cause mortality, a 3.13-fold increased risk for cardiovascular mortality, and a 1.17-fold increased risk for MACE (**Table**). These significant elevated risks in the YO-T2DM population were consistently observed after PSM analyses. Furthermore, the RCS analysis supported an inverse association between age at T2DM diagnosis and adverse outcomes among patients with MASLD. **Conclusion:** In this large prospective cohort of MASLD patients, YO-T2DM was associated with higher risks of all-cause mortality, cardiovascular mortality, and MACE than LO-T2DM. These results support YO-T2DM as a high-risk phenotype in MASLD, emphasizing the need for early and intensive cardiovascular risk management.

2541 | RISK OF HEPATOCELLULAR CARCINOMA IN ELDERLY PATIENTS WITH METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE AND PROPOSAL OF AN EFFECTIVE NATIONWIDE SURVEILLANCE STRATEGY

Young Eun Chon[1] Kyung-Do Han[2] Ju-Yeong Park[3] Beom Kyung Kim[4], [1]CHA University, [2]Department of Statistics and Actuarial Science, Soongsil University, [3]Department of Statistics and Actuarial Science, Soongsil University, Seoul, Republic of Korea, [4]Yonsei University College of Medicine, Seoul, Republic of Korea

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is increasingly prevalent among aging populations. We evaluated hepatocellular carcinoma (HCC) risk across MASLD spectrum in this population and developed a nomogram to guide optimized surveillance. **Methods:** Using a nationwide South Korean database, we identified participants aged ≥75 years undergoing health screening between 2012 and 2015. Steatotic liver disease (SLD) was classified as MASLD, MetALD (MASLD with increased alcohol intake), or alcohol-associated liver disease (ALD). Competing-risk regression for HCC risk was used to estimate adjusted subdistribution hazard ratios (a-sHRs) by SLD subtype, using Fine–Gray models. **Results:** Among 1,088,314 participants, 34.3% had SLD (351,583 MASLD; 11,586 MetALD; 9,619 ALD). The overall 5-year HCC incidence in SLD group (0.769%) was higher, compared to non-SLD group (0.334%). It increased stepwise from MASLD (0.687%) to MetALD (1.856%) and ALD (2.443%): a-sHRs of 1.93, 2.99, and 4.35, respectively. Stratified analyses consistently demonstrated the same pattern. A nomogram incorporating age, sex, smoking, diabetes, statin use, SLD subtype, gamma-glutamyl transferase, body mass index, liver cirrhosis, and aspartate transaminase/alanine transaminase ratio was developed, with good discriminative ability. Scores < 103 (87.7% of participants) corresponded to annual HCC risk < 0.2%, suggesting exemption from HCC screening, whereas scores > 171 (0.14%) corresponded to annual risk > 1%, indicating the need for continuous screening. **Conclusion:** Elderly individuals with MASLD spectrum exhibit a significant HCC risk, with higher risk in MetALD and ALD groups. Given the very small proportion who require HCC screening, our nomogram serves as a practical tool for community-based risk stratification and optimized surveillance.

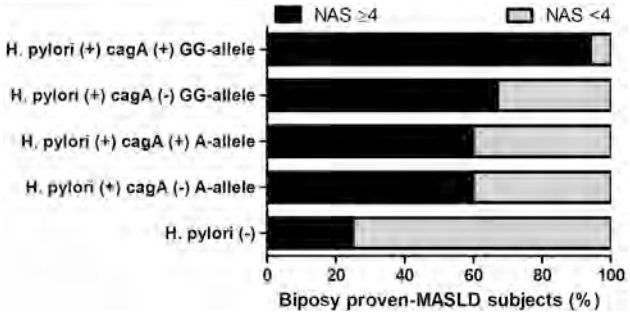
2542 | A VIRULENCE–HOST GENE INTERACTION BETWEEN HELICOBACTER PYLORI CAGA AND NOD1 IS ASSOCIATED WITH MASLD SEVERITY



Fernando Barreyro[1] Facundo Maiorana[1] Maria Virginia Caronia[2] Soraya Acardi[3] Georgina Veron[4] Pedro Zapata[1], [1]Instituto de Biotecnología de Misiones (InBioMis). Universidad Nacional de Misiones, [2]Instituto de Biotecnología de Misiones (InBioMis). Universidad Nacional de Misiones, [3]Fundación HA Barceló, Instituto Universitario en Ciencias de la Salud., [4]Fundación HA Barceló, Instituto Universitario en Ciencias de la Salud

Background: Helicobacter pylori (Hp) is increasingly recognized as a gut exposome factor that may amplify metabolic inflammation and liver injury in metabolic dysfunction-associated steatotic liver disease (MASLD). We assessed whether the Hp virulence gene *cagA* and the host innate-immunity sensor NOD1 rs2075820 were associated with MASLD severity. **Methods:** In this prospective study conducted in northeast Argentina (2021–2024), 494 adults with Rome-IV functional dyspepsia underwent upper endoscopy. Clinical, biochemical, ultrasound, FIB-4, liver stiffness measurement (LSM) by vibration-controlled transient elastography, gastric biopsies, Hp *cagA* status, and NOD1 rs2075820 genotype were evaluated. A second retrospective cohort included 127 patients with biopsy-proven MASLD who underwent gastroscopy with gastric biopsies. Comparisons used chi-square testing, ANOVA with Tukey post hoc analysis, and logistic regression. *$p < 0.05$. **Results:** The cohort included 60% women, with mean age 49 ± 13 years and BMI 27.9 ± 13.1 kg/m². MASLD was present in 209 subjects (42%) and active Hp infection in 51%. Hp positivity was associated with higher BMI and MASLD prevalence (52% vs 32%,*), whereas T2D, dyslipidemia, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hypertension did not differ by Hp status. In MASLD subgroup, Hp+ with cagA+ strain was associated with higher AST (Hp- 25 ± 11, Hp+/cagA- 28 ± 13, Hp +/cagA+ 33 ± 14*), FIB-4 (Hp- 1 ± 0.5, Hp+/cagA- 1.4 ± 0.9, Hp+/cagA+ 1.5 ± 0.8*), and LSM (Hp- 5.7 ± 2.8, Hp+/cagA- 6.9 ± 5.8, Hp+/cagA+ 7.8 ± 5.2*), but not with ALT and GGT. Notably, carriers of cagA+/NOD1GG allelic combination were associated with higher FIB-4 (Hp- 1 ± 0.5, cagA-/A-allele 1.1 ± 0.7, cagA+/A-allele1.3 ± 0.6, cagA+/GG-allele 1.5 ± 0.6*), and LSM (Hp- 5.7 ± 2.9, cagA-/A-allele 5.6 ± 3.1, cagA+/A-allele 6.2 ± 2.16, cagA+/GG-allele 8.5 ± 3.6*). Indeed, more proportion of patients with cagA+/GG-allele combination (Hp- 15%, cagA-/A-allele 11%, cagA+/A-allele 29%, cagA+/GG-allele 41%*) were observed with the LSM cut-off for high-risk of significant/advanced- fibrosis (≥8kPa). Hp *cagA*+/NOD1 GG carriers had increased odds of LSM ≥8 kPa (OR 3.99; 95% CI, 1.6–10.0), remaining significant after adjustment for age, T2D, BMI, dyslipidemia, and hypertension (adjusted OR 4.98; 95% CI, 1.9–13.5). In biopsy-proven MASLD, Hp *cagA*+/NOD1 GG was associated with higher NAS, fibrosis stage, and MASH prevalence. The odds of MASH were increased in Hp *cagA*+/NOD1 GG carriers (OR 48.0; 95% CI, 8.7–393.0), remaining significant after multivariable adjustment (adjusted OR 36.4; 95% CI, 6.2–400.3). **Conclusion:** Hp infection, particularly *cagA*+ strains, was associated with greater MASLD severity. The Hp *cagA*+/NOD1 GG combination independently identified patients at higher risk of significant/advanced fibrosis by LSM and biopsy-confirmed MASH, supporting a potential virulence–host gene interaction that may exacerbate liver injury in MASLD.

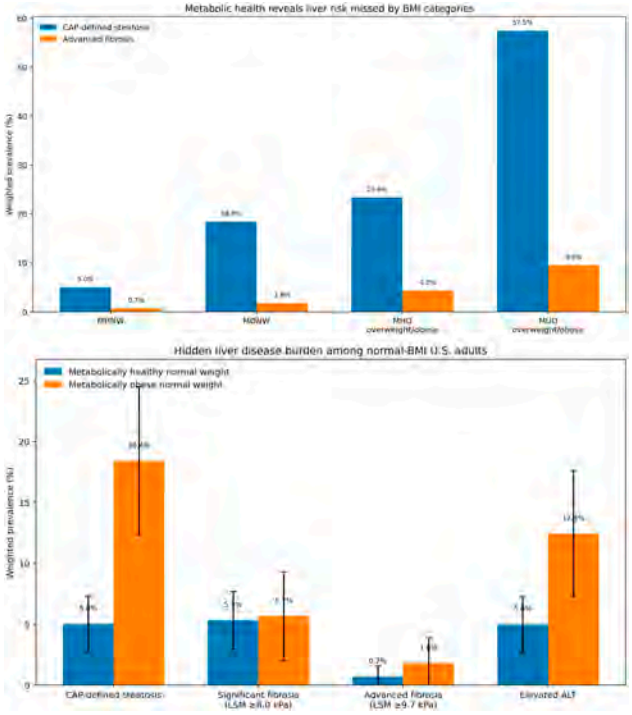
2543 | NORMAL BMI, HIDDEN LIVER RISK: METABOLICALLY OBESE NORMAL-WEIGHT PHENOTYPE AND FIBROTIC LIVER DISEASE IN U.S. ADULTS



Madhu babu Adusumilli[1] Serene Sara John[2] Sri Ram Charan Gundapaneni[3] Pragathi Munnangi[4] Mounika Kotte[5] Jagadish Koyi[6] Hardik Dineshbhai Desai[7], [1]HCA Ocala hospital/ UCF, [2]detroit medical center, [3]University of Central Florida, HCA Healthcare GME, [4]BronxCare Health System, [5]Prime South Consoritum, Texas, [6]Integris Health, Oklahama, [7]AB Plus speciality hospital, Ahmedabad, India

Background: Normal body mass index (BMI) may obscure clinically important metabolic dysfunction and liver disease risk. We examined whether the metabolically obese normal-weight (MONW) phenotype is associated with vibration-controlled transient elastography (VCTE)-defined steatosis and fibrosis among U.S. adults. **Methods:** We analyzed National Health and Nutrition Examination Survey (NHANES) 2017–March 2020 adults aged ≥20 years with valid VCTE and BMI data, excluding underweight adults, heavy alcohol use, and hepatitis C. Normal BMI was defined as 18.5–24.9 kg/m². MONW was defined as normal BMI plus ≥2 metabolic abnormalities, including central adiposity, dysglycemia, hypertension, hypertriglyceridemia, or low high-density lipoprotein cholesterol. Outcomes included controlled attenuation parameter (CAP)-defined steatosis, liver stiffness measurement (LSM)-defined significant fibrosis, advanced fibrosis, and elevated alanine aminotransferase (ALT). Survey-weighted prevalence estimates and logistic regression models were used. **Results:** The analytic sample included 5,045 adults, representing 135.0 million U.S. adults. Among normal-BMI adults, 26.8% had MONW, representing 9.2 million adults. Compared with metabolically healthy normal-weight adults, MONW adults were older, 61.2 vs 43.8 years, had higher waist circumference, 85.1 vs 79.1 cm, and higher mean metabolic abnormality count, 2.42 vs 0.45. CAP-defined steatosis was 18.4% in MONW versus 5.0% in metabolically healthy normal-weight adults. Elevated ALT was 12.4% vs 5.0%, significant fibrosis was 5.7% vs 5.3%, and advanced fibrosis was 1.8% vs 0.7%. In age/sex-adjusted models, MONW was associated with higher odds of steatosis, odds ratio (OR) 3.09, 95% confidence interval (CI) 1.96–4.86, $p < 0.001$, and elevated ALT, OR 2.86, 95% CI 1.64–5.01, $p < 0.001$. In extended models adjusting for socioeconomic, behavioral, sleep, depression, and insurance factors, MONW remained associated with steatosis, OR 4.34, 95% CI 2.01–9.37, $p < 0.001$, significant fibrosis, OR 3.20, 95% CI

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

1.39–7.36, p = 0.006, and showed a strong trend toward advanced fibrosis, OR 5.67, 95% CI 0.82–39.07, p = 0.078. **Conclusion:** More than 1 in 4 normal-BMI U.S. adults had a metabolically obese phenotype. MONW identified a hidden high-risk group with substantially higher steatosis, elevated ALT, and fibrosis signal despite normal BMI. These findings support metabolic-risk-based liver screening beyond BMI alone.

2544 | IMPACT OF DIETARY PROFILE AND BODY COMPOSITION ON RISK OF FIBROSIS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Ozge Ozgur[1] Renwei Wang[1] Jian-Min Yuan[1] Jaideep Behari[1], [1]University of Pittsburgh Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects more than 30% of adults worldwide and is associated with significant liver-related morbidity and mortality. Although MASLD is closely linked to metabolic dysfunction, the independent effects of anthropometric, demographic, and dietary factors on fibrosis severity remain incompletely understood. We aimed to determine the impact of body composition and nutritional variables associated with risk of liver fibrosis in patients with MASLD. **Methods:** Patients with MASLD were prospectively enrolled from a tertiary care clinic in the United States. Clinical history was obtained from electronic health records, body composition determined by bioimpedance analyzer, liver stiffness measurement by Transient Elastography, and dietary history by the validated ASA24 and DHQ3 questionnaire. We performed univariate and multivariate analyses evaluating associations between clinical, demographic, anthropometric, and dietary variables with fibrosis stage, treated as an ordinal outcome (stages 1-3). Fibrosis stage was analyzed as an ordinal outcome variable (stages 1-3), with corresponding mean liver stiffness measurements of 5.5 kPa for stage 1, 9.2 kPa for stage 2, and 22.4 kPa for stage 3. Variables significant in univariate analysis were entered into a stepwise generalized linear model selection procedure to identify independent predictors of fibrosis. Model performance was assessed using adjusted R-square and analysis of variance metrics. **Results:** Among 583 participants included in the analysis, six variables were independently associated with increasing fibrosis stage in the final multivariate model. Type 2 diabetes mellitus (T2DM) demonstrated a significant positive association with higher stage severity. Increased waist circumference and older age were also independently associated with advanced stage. Male sex was associated with higher fibrosis stage compared with female sex. Dietary composition was significantly associated with fibrosis stage. Lower protein-to-carbohydrate ratio intake and lower total dietary protein intake were independently associated with increasing stage severity. The final model demonstrated moderate explanatory capacity (R^2 = 0.18, adjusted R^2 = 0.17; F = 15.81, p < 0.001). **Conclusion:** Higher fibrosis stage in MASLD was independently associated with metabolic risk factors, central adiposity, demographic characteristics, and dietary composition. Our findings highlight the potential contribution of nutritional composition in fibrosis progression and may help guide future dietary and risk stratification strategies in MASLD.

2545 | DEPRESSION, ANXIETY, AND PTSD BURDEN AMONG ADULTS WITH EHR-DOCUMENTED MASLD IN THE ALL OF US RESEARCH PROGRAM

Ihunanya Kanu[1] Sarpong Boateng[2] Chimezirim Ezeano[3] Bolaji Ayinde[4] Olamide Asifat[5] Joshua Kalu[6] Richard Heard[1], [1]Baptist Memorial Hospital- Golden Triangle, [2]Yale New Haven Health, Bridgeport Hospital, [3]Advocate Aurora Healthcare, [4]Northeast Georgia Medical Center, [5]Jiann-Ping Hsu College of Public Health, [6]SUNY Downstate Medical Center

Background: The gut-brain-liver axis suggests bidirectional links between psychiatric health and metabolic dysfunction-associated steatotic liver disease (MASLD). However, the burden of psychiatric comorbidity among adults with MASLD remains incompletely characterized in diverse U.S. populations. We examined the prevalence and adjusted odds of depression, anxiety, and post-traumatic stress disorder (PTSD) among adults with EHR-documented MASLD/MASH in the All of Us Research Program. **Methods:** We conducted a cross-sectional analysis of adults aged ≥18 years with EHR data in the All of Us Controlled Tier Dataset v8. EHR-documented MASLD/MASH was identified using diagnosis concepts for nonalcoholic fatty liver disease, nonalcoholic steatohepatitis, and NASH-related cirrhosis, excluding alcoholic fatty liver and acute fatty liver of pregnancy. Psychiatric comorbidities were identified using EHR diagnosis concepts for depression, anxiety, and PTSD. Psychiatric multimorbidity was defined as ≥2 psychiatric diagnoses. Multivariable logistic regression estimated adjusted odds of psychiatric outcomes among adults with MASLD/MASH compared with those without MASLD/MASH, adjusting for age, BMI, sex at birth, race/ethnicity, and type 2 diabetes. Sex-stratified models evaluated associations with any psychiatric comorbidity. Analyses were performed using Python in Jupyter Notebook. **Results:** Among 388,424 adults with EHR data, 3,700 had EHR-documented MASLD/MASH. Depression was present in 53.92% of adults with MASLD/MASH versus 27.12% without MASLD/MASH, anxiety in 49.51% versus 25.61%, PTSD in 12.97% versus 5.39%, and any psychiatric comorbidity in 64.41% versus 36.04%. Psychiatric multimorbidity was also higher in MASLD/MASH, with 41.84% having ≥2 psychiatric diagnoses compared with 18.62% without MASLD/MASH. After adjustment for age, BMI, sex at birth, race/ethnicity, and type 2 diabetes, MASLD/MASH remained associated with higher odds of depression (aOR 2.02, 95% CI 1.88–2.16), anxiety (aOR 2.01, 95% CI 1.88–2.15), PTSD (aOR 1.81, 95% CI 1.64–2.00), any psychiatric comorbidity (aOR 2.13, 95% CI 1.99–2.29), and ≥2 psychiatric diagnoses (aOR 2.07, 95% CI 1.93–2.21). Sex-stratified models showed persistent associations in females (aOR 2.18, 95% CI 1.99–2.40) and males (aOR 2.08, 95% CI 1.86–2.32). **Conclusion:** Adults with EHR-documented MASLD/MASH had a substantially higher burden of depression, anxiety, PTSD, and psychiatric multimorbidity, with associations persisting after adjustment for metabolic and demographic factors. These findings highlight the need to integrate mental health screening and support into MASLD care, supporting a more integrated, multidisciplinary MASLD care model.

2546 | CLINICOPATHOLOGICAL CHARACTERISTICS AND RISK FACTORS FOR ADVANCED LIVER FIBROSIS IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE

Suwen Jiang[1] Airong Hu[1] Jialan Wang[2] Menghan Jin[3] Shiqi Yang[4] Shiyang Fan[5], [1]Ningbo No. 2 Hospital, [2]Huangshan City People's Hospital, [3]Ningbo University, [4]Wenzhou Medical University, [5]Shaoxing University

Background: To investigate the clinical pathological features and the possible influencing factors of advanced liver fibrosis in patients with metabolic dysfunction-associated fatty liver disease (MAFLD), in order to provide guidance for clinical diagnosis and treatment. **Methods:** A total of 222 patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

diagnosed with MAFLD based on pathological and clinical characteristics from January 2019 to December 2024 were enrolled as study subjects. MASH and liver fibrosis (F) were assessed using the SAF scoring system within the FLIP algorithm (SAF/FLIP). Patients were stratified into groups without or with advanced fibrosis (less than F3 vs. F3 or more), as well as into F3 and F4 subgroups. Propensity score matching (PSM) was performed at a 1: 1 ratio to balance baseline characteristics between the two groups. **Results:** Based on the SAF/FLIP scoring, MASH was diagnosed in 204 patients (91.89%). The numbers of patients with less than F3 and F3 or more were 159 and 63, respectively. A total of 162 patients had 2 or more MetS components. After PSM, 126 patients (63 pairs) were included in the final analysis. Compared with the F3 or more group, the less than F3 group had lower age, SAF/FLIP score, levels of GLB, AST, AST/ALT ratio, ADA, INR, APRI, and FIB-4. The less than F3 group had lower proportions of hypertension, hyperglycemia, 2 MetS components or more, and MASH, as well as lower mean Ridit values for hepatocellular ballooning and inflammation activity. All these indicators showed a positive correlation with advanced fibrosis. Conversely, levels of ALB, ALB-to-GLB ratio, and PLT were significantly higher in the less than F3 group than in the F3 or higher group, and showed a negative correlation with advanced fibrosis. A interaction was observed between the hepatic steatosis score and the hepatocellular ballooning score. Compared with the F3 subgroup, the F4 subgroup had significantly higher age, AST/ALT, INR, and FIB-4, but significantly lower ALT, total cholesterol, low-density lipoprotein cholesterol, and PLT (all P less than 0.05). Pathological factors independently associated with advanced fibrosis were hepatocellular ballooning and inflammation activity. Clinical factors independently associated with advanced fibrosis were hypertension components, ADA, PLT , and 2 MetS components or more. During follow-up, patients with advanced fibrosis had an increased risk of developing cirrhosis. **Conclusion:** Among hospitalized patients with MAFLD, 28.38% present with advanced liver fibrosis. Patients with cirrhosis exhibit lower levels of ALT, total cholesterol, and low-density lipoprotein cholesterol. A negative interaction exists between hepatic steatosis and hepatocellular ballooning, partially counteracting the pro-fibrotic effect of the latter. Multidimensional parameters integrating ADA, PLT, metabolic components, and pathological characteristics may inform stratified intervention strategies for advanced fibrosis.

Table 1 Logistic regression analysis of risk factors for advanced fibrosis

Risk factor	univariate		multivariate			
			Model 1/model 2		Model 3/model 4	
	OR (95% CI)	*P*-value	*OR (95% CI)*	*P*-value	*OR (95% CI)*	*P*-value
Age	1.061(1.030 ~ 1.093)	<0.001

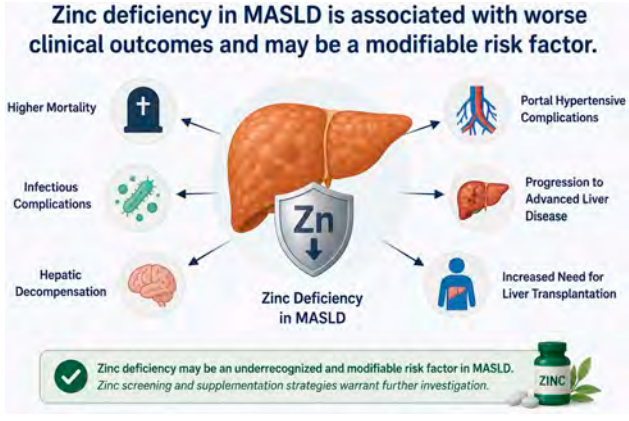
2547 | IMPACT OF CLINICAL AND GENETIC FACTORS ON CARDIOVASCULAR RISK IN MASLD

Tomomi Kogiso[1] Yuri Ogasawara[1] Makiko Taniai[1] Yousuke Nakai[1], [1]Tokyo Women's Medical University

Background: Cardiovascular disease (CVD) is an important extrahepatic complication in patients with metabolic dysfunction–associated steatotic liver disease (MASLD). However, the contribution of genetic background to CVD risk in MASLD remains unclear. We investigated clinical and genetic predictors of CVD events in patients with MASLD. **Methods:** We retrospectively analyzed 345 patients (178 men; median age, 54 years) clinicopathologically diagnosed with MASLD at our institution between 1990 and 2018. Twenty-six patients (7.5%) had CVD events, including 17 incident cases during follow-up. Clinical characteristics, laboratory findings, liver histology, and single nucleotide polymorphisms associated with MASLD progression, including patatin-like phospholipase domain-containing protein 3 (PNPLA3), hydroxysteroid 17-beta dehydrogenase 13 (HSD17B13), glucagon-like peptide-1 receptor (GLP1R), and glucokinase regulatory protein (GCKR), were evaluated. A joint genetic risk score (GRS) was calculated from the cumulative number of risk alleles of these variants to assess their

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



combined impact on CVD risk. **Results:** Patients with CVD events were significantly older than those without events (median age: 67 vs. 53 years). Obesity (BMI $\geq$ 23 kg/m²) was less frequent in patients with CVD events (73.1% vs. 88.1%), whereas hypertension (88.5% vs. 51.7%) was significantly more prevalent, and dyslipidemia tended to be more common (84.6% vs. 66.5%). There were no significant differences in sex or fibrosis stage between the groups. Serum total bilirubin (0.6 vs. 0.7 mg/dL, p = 0.03), albumin (4.1 vs. 4.4 g/dL, p < 0.01), and platelet count (18.0 vs. 20.3 $\times 10^4$/μL, p = 0.01) were significantly lower in patients with CVD events. Multivariate analysis identified older age (odds ratio [OR] 1.04, p = 0.009) and hypertension (OR 4.06, p = 0.040) as independent clinical predictors of CVD events. In genetic analyses, PNPLA3 was positively associated with CVD risk (OR 1.97, p = 0.007), whereas HSD17B13 showed a protective association (OR 0.39, p = 0.023). Furthermore, age, hypertension, and GRS remained independently associated with CVD events. **Conclusion:** Older age and hypertension are major determinants of CVD events in MASLD. Genetic susceptibility, particularly PNPLA3 and HSD17B13 variants, may further influence cardiovascular risk. Combined clinical and genetic risk assessment may help identify high-risk patients requiring intensive cardiovascular surveillance and management.

2548 | ZINC DEFICIENCY AND ADVERSE CLINICAL OUTCOMES IN MASLD: A LARGE MULTICENTER PROPENSITY-MATCHED ANALYSIS

Adham Obeidat[1] Nour Mansour[2] Ahmad Alqam[2] Christopher Chang[2], [1]Presbyterian Medical Group, [2]University of New Mexico

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is commonly associated with micronutrient deficiencies that may contribute to hepatic decompensation and systemic complications. Zinc plays an important role in ammonia metabolism, oxidative stress regulation, immune function, and hepatocellular repair. However, large-scale data evaluating the clinical impact of zinc deficiency in MASLD are limited. We aimed to assess the association between zinc deficiency and adverse clinical outcomes among patients with MASLD using a large multicenter database. **Methods:** We performed a retrospective cohort study using the TriNetX Research Network. Adult patients with MASLD were identified and stratified by the presence or absence of zinc deficiency. Propensity score matching was conducted for demographics and baseline comorbidities. Primary outcomes included all-cause mortality and liver-related complications. Secondary outcomes included sepsis, spontaneous bacterial peritonitis (SBP), portal hypertension, esophageal varices, hepatic encephalopathy, variceal bleeding, acute liver failure, cirrhosis, and liver transplantation. Outcomes were reported as odds ratios (ORs) with 95% confidence intervals (CIs). **Results:** Following propensity score matching, 6,263 patients with MASLD and zinc deficiency were matched to 6,263 MASLD patients without zinc deficiency. Zinc deficiency was independently associated with increased odds of mortality (OR 1.41, 95% CI 1.19–1.67; P < 0.001), sepsis (OR 2.07, 95% CI 1.87–2.29; P < 0.001), spontaneous bacterial peritonitis (OR 1.83, 95% CI 1.38–2.43; P < 0.001), cirrhosis (OR 1.62, 95% CI 1.47–1.79; P < 0.001), portal hypertension (OR 1.57, 95% CI 1.39–1.77; P < 0.001), esophageal varices (OR 1.51, 95% CI 1.35–1.69; P < 0.001), hepatic encephalopathy (OR 1.69, 95% CI 1.46–1.95; P < 0.001), variceal bleeding (OR 1.61, 95% CI 1.23–2.11; P < 0.001), and acute liver failure (OR 1.74, 95% CI 1.41–2.15; P < 0.001). In addition, patients with zinc deficiency had higher odds of liver transplantation (OR 1.56, 95% CI 1.11–2.18; P = 0.009). **Conclusion:** In this large multicenter propensity-matched analysis, zinc deficiency was associated with increased mortality, infectious complications, portal hypertensive complications, hepatic decompensation, and liver transplantation among patients with MASLD. To our knowledge, this is among the first large-scale real-world studies demonstrating the adverse clinical impact of zinc deficiency in MASLD. These findings suggest that zinc deficiency may represent an underrecognized and potentially modifiable risk factor in this population, warranting further investigation into zinc screening and supplementation strategies.

2549 | ARTIFICIAL INTELLIGENCE–BASED IDENTIFICATION OF MASLD IN CLINICAL PRACTICE: DIFFERENTIAL HEPATIC AND CARDIOVASCULAR RISK ACROSS INCREASING METABOLIC FACTOR LOAD

Manuel Mendizabal[1] Magdalena Princz[1] Federico Piñero[1] Amparo Gabrielli[1] Luciano Olguin[1] Pablo Bizzotto[1] Matias Cortiñas[1] Jimena Flores[1] Josefina Pages[1] Marcello Silva[1] Juan Pablo Arab[2], [1]Hospital Universitario Austral, [2]Virginia Commonwealth University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) remains underrecognized in clinical practice. We aimed to use artificial intelligence (AI) applied to electronic health records (EHRs) to identify adults with MASLD and assess the effect of metabolic factors (MFs) on major hepatic (MAHE) and cardiovascular events (MACE). **Methods:** We performed a cross-sectional study using EHR data from 2015–2025 applying non-probability sampling using an AI strategy integrating natural language processing and structured variables to identify adults with hepatic steatosis. Metabolic factors included obesity, diabetes, hypertension, and dyslipidemia. MAHE comprised cirrhosis, ascites, hepatic encephalopathy, variceal bleeding, hepatocellular carcinoma, and liver transplantation. MACE included myocardial infarction, heart failure, peripheral arterial disease, and stroke. Multivariable logistic regression models were used to estimate the effect of MFs on MAHE and MACE adjusted for age quintiles and sex. Model performance was evaluated by calibration and discrimination. **Results:** Among 627,274 EHRs screened, 486,774 (77.6%) corresponded to adults, and 42,594 (8.8%) had steatosis. After excluding 1,694 (4.0%) patients with alcohol use disorder, 40,900 (8.4%) had steatotic liver disease and 36,993 (7.6%) fulfilled MASLD criteria. In the the MASLD cohort, dyslipidemia, diabetes, hypertension, and obesity were present in 61.4%, 60.5%, 56.2%, and 52.1%, respectively. Overall, MAHE and MACE occurred in 1,291 (3.2%) and 3,895 patients (9.5%); respectively. In the hepatic model, MAHE were associated with the presence of 2 MFs (OR 1.43, 95% CI 1.13–1.82) and 3 MFs (OR 1.35, 95% CI 1.07–1.70), adjusted for age quintiles (OR 6.55, 95% CI 5.25–8.18. MACE showed a stronger stepwise association with metabolic burden (Table), with sex acting as an effect modifier. For 4 MFs, the was OR 24.76 (95% CI 16.31–37.58) for men and OR 13.25 (95% CI 8.23–21.32) for women. Among individual factors, diabetes was associated with markedly higher odds of MAHE (OR 2.31, 95% CI 2.02–2.63), whereas dyslipidemia was associated with substantially higher odds of MACE in both men (OR 7.70, 95% CI 6.69–8.86) and women (OR 4.18, 95% CI 3.56–4.92). **Conclusion:** AI-enabled EHR screening identified a large MASLD population. Increasing MF burden was modestly associated with MAHE but showed a stronger sex-specific association with MACE. Prospective longitudinal studies are needed to confirm these findings.

steatohepatitis (MASH), over 50% of at-risk adults remain unscreened. Delayed diagnosis increases patient and health system burden, particularly in advanced stages, while knowledge gaps among providers limit opportunities for early intervention. Community-based provider educational resources are needed to improve MASLD care delivery. **Methods:** Two live, in-person MASLD community education workshops were conducted in Los Angeles (February 2026) and Atlanta (March 2026). Invitees included physicians, advanced practice providers, and extended care team members specializing in primary care, gastroenterology, hepatology, endocrinology, nutrition, and social work. Outreach targeted providers affiliated with federally qualified health centers, health systems, and independent practices within a 25-mile radius of each workshop venue. The curriculum combined a didactic lecture on MASLD prevalence, risk factors, screening, test interpretation, and management approaches with interactive case discussions. **Results:** Of the 20 attendees, 16 completed pre- and post-session surveys. Most were in practice for $\geq$11 years (62.5%), and 50% held MD or DO licensure. Primary care (25%) and hepatology (25%) were the most represented specialties. Baseline care pathway utilization was limited, with 69.2% reporting unfamiliarity with or an institutional absence of systemized protocols. However, 93.75% indicated the session influenced their clinical practice. Open-response data highlighted intended actions within 30 days, including increased MASLD screening for high-risk patients using Fibrosis-4 (FIB-4) and prioritization of continued MASLD education and best practice sharing. Additional planned changes included greater focus on preventative care, such as patient education and nutrition counseling. Participants demonstrated improved confidence across multiple areas, including a 60% increase in ability to identify risk factors, 75% in recognizing early-stage MASLD, and 100% in counseling patients on risk factors, diagnostics, and treatment options. All participants reported the workshop achieved its learning objectives. Beyond providing education, these sessions also helped inform future programming, with attendees emphasizing the need for broader community-based interventions for both patients and providers. **Conclusion:** Expanded community-based education is needed to improve awareness and adoption of MASLD screening and management best practices. Educational initiatives should prioritize interactive, case-based learning to enhance engagement and facilitate practical application. Future programs may amplify their impact through earlier outreach and proactive scheduling to reduce conflicts with local competing events and maximize attendance.

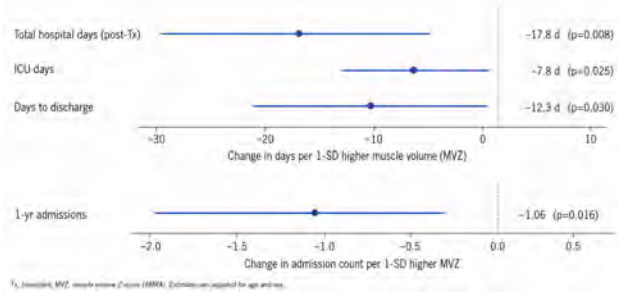
2551 | FIBRO-INFLAMMATORY LIVER INJURY, NOT STEATOSIS, PREDICTS INCIDENT COMPOSITE NEUROPSYCHIATRIC EVENTS AND MORTALITY IN THE UK BIOBANK

Tsubasa Tsutsumi[1] Wen Hui Lim[2] Darren Jun Hao Tan[2] Jing Kai Tioh[3] Damien Chua[4] Hun Jee Choe[5] Ryan YanZhe Lim[3] Mirudhula Gnanavelou[3] Jordan Jun Yi Low[3] Benjamin YQ Tan[3] Hirokazu Takahashi[6] Huang Wei Ting[7] Mamas A. Mamas[8] Anurug Methra[9] Mei Chin Lim[2] Cheng Han Ng[2] Mark Muthiah[3],
[1]Kurume University Scool of Medicine, [2]National University Hospital, [3]National University of Singapore, [4]Nanyang Technological University, [5]Hallym University Dongtan Sacred Heart Hospital, [6]Saga University, [7]National Heart Centre Singapore, [8]Keele University, [9]Emory University School of Medicine

Background: Steatotic liver disease may be linked to neuropsychiatric outcomes, but the relevant liver MRI signal remains uncertain. Iron-corrected T1 (cT1) reflects fibro-inflammatory liver injury, whereas proton density fat fraction (PDFF) quantifies hepatic fat. We examined associations of cT1 and PDFF with incident neuropsychiatric events and mortality and assessed whether combined liver-brain MRI phenotyping identifies a higher-risk subgroup. **Methods:** This prospective UK Biobank study included 29,344 participants with liver MRI measures of cT1 and PDFF and brain MRI quantification of white matter hyperintensity (WMH) volume. Participants were classified into four imaging phenotypes according to liver imaging impairment (cT1 $\geq$800 ms) and high WMH burden, defined as age-adjusted WMH volume >80th percentile. Cause-specific Cox models estimated risks of composite neuropsychiatric events, defined as stroke, dementia, or late-life depression, liver events, and all-cause mortality. Models were adjusted for age, sex, diabetes, hypertension, dyslipidemia, smoking, alcohol intake, education, and deprivation index. **Results:** Over a median follow-up of 5.7 years, 530 neuropsychiatric events, 231 liver events, and 631 deaths occurred. Higher cT1 per 100 ms was associated with neuropsychiatric events (HR 1.31, 95% CI 1.04–1.65), liver events (HR 2.36, 1.77–3.15), and mortality (HR 1.29, 1.04–1.60). PDFF was not associated with neuropsychiatric events (HR 1.00, 0.98–1.03) or mortality (HR 1.00, 0.97–1.03),

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



but was associated with liver events (HR 1.09, 1.07–1.12). Log-transformed WMH volume was associated with neuropsychiatric events (HR 1.26, 1.08–1.48) and mortality (HR 1.17, 1.01–1.35). Participants with both liver and brain imaging impairment had the highest risk estimates for neuropsychiatric events (HR 2.30, 1.00–5.29) and liver events (HR 7.13, 3.32–15.33) compared with participants without either imaging impairment. In the prespecified MASLD subgroup, markedly elevated cT1 ($\geq$875 ms) was associated with neuropsychiatric events (HR 4.48, 1.55–12.98) and liver events (HR 6.11, 2.03–18.36). **Conclusion:** Higher cT1 was associated with incident neuropsychiatric events, liver events, and mortality, while PDFF was associated only with liver events. The combined cT1-WMH phenotype identified the highest-risk imaging group. In this cohort, cT1 was more closely associated with extrahepatic outcomes than PDFF.

2552 | LOWER MRI-DERIVED MUSCLE VOLUME Z-SCORE IS ASSOCIATED WITH GREATER POST-TRANSPLANT HOSPITAL BURDEN IN PATIENTS WITH CIRRHOSIS EVALUATED FOR LIVER TRANSPLANTATION

Tsubasa Tsutsumi[1] Mary Rinella[2] Omar Jamil[2], [1]Kurume University Scool of Medicine, [2]The University of Chicago

Background: Few markers anticipate post-transplant hospital burden in patients with cirrhosis undergoing liver transplantation. Body-composition assessment in cirrhosis remains inconsistent, but may provide markers relevant to post-transplant recovery. The AMRA(R) Profiler 4 MAsS Scan provides automated fat-water-separated whole-body MRI measures of muscle volume, muscle fat infiltration, adipose tissue, and liver fat. We examined whether AMRA-derived muscle volume Z-score (MVZ) provides MELD-independent information associated with post-transplant hospital burden. **Methods:** We studied a single-center retrospective cohort of 55 patients with cirrhosis evaluated for liver transplantation (LT), including 18 LT recipients and 37 non-LT patients. AMRA-derived metrics were MVZ (sex and BMI adjusted), muscle fat infiltration (MFI; sex adjusted), and liver fat. Associations between AMRA metrics and MELD 3.0 were assessed by Spearman correlation and across transplant status. In LT recipients, post-transplant hospital days, ICU days, days to discharge, and 1-year admissions were analyzed using age- and sex-adjusted linear models. **Results:** Median age was 64 years, 36% were female, and median MELD was 10. MELD was higher in LT recipients than non-LT patients (median 13 vs 9; $p = 0.024$). MVZ and MFI were essentially uncorrelated with MELD (rho −0.04 and −0.02) and did not differ by transplant status (MVZ $p = 0.49$; MFI $p = 0.99$). In contrast, liver fat was inversely correlated with MELD (rho −0.57; $p < 0.001$). Among LT recipients, each 1-SD higher MVZ was associated with fewer post-transplant hospital days (−17.8; $p = 0.008$), ICU days (−7.8; $p = 0.025$), days to discharge (−12.3; $p = 0.030$), and 1-year re-admissions (−1.06; $p = 0.016$) in age- and sex-adjusted models. In parallel age/sex-adjusted models, MELD was not associated with these outcomes (all $p \geq 0.36$). MFI and general-population adverse-muscle-composition thresholds did not separate these post-transplant outcomes. **Conclusion:** Among LT recipients, pre-transplant AMRA (R) Profiler 4 MAsS Scan-derived MVZ was associated with post-transplant hospitalization and ICU burden not captured by MELD. These findings support MRI-derived muscle volume as a potential prognosticator of post-transplant course. These exploratory findings warrant validation in larger multicenter cohorts.

2553 | LIVER FAT IN RELATION TO PROGNOSTIC OUTCOMES OF COLORECTAL CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

Deborah Ophoff[1] Nienke Zwart[1] Moniek van Zutphen[1] Daniel Bos[2] N. Tjarda van Heek[1] Johannes de Wilt[3] Harm Westdorp[4] Edward Giovannucci[5] Ellen Kampman[1] Dieuwertje Kok[1], [1]Division of Human Nutrition and Health, Wageningen University and Research, The Netherlands, [2]Department of Radiology and Nuclear Medicine, Erasmus MC University Medical Center, The Netherlands, [3]Department of Surgery, Radboud University Medical Center, The Netherlands, [4]Department of Medical Oncology, Radboud University Medical Center, The Netherlands, [5]Department of Epidemiology, Harvard T.H. Chan School of Public Health, The United States of America

Background: Liver steatosis is a prevalent liver condition which shares risk factors with colorectal cancer (CRC), such as body fatness and having a Western lifestyle. Several studies have investigated the role of liver steatosis in CRC recurrence, metastasis, and mortality, but study results are inconsistent and large between-study heterogeneity exists. Here, we summarized and analysed all available literature on liver steatosis in relation to prognostic outcomes of CRC to explain between-study heterogeneity. **Methods:** We systematically searched PubMed, Scopus and Web of Science databases using Medical Subject Headings and free-text words. The search was conducted on 11 February 2026 and relevant prognostic outcomes included cancer recurrence, cancer metastasis, synchronous liver metastases, metachronous liver metastases, disease-free survival (DFS), overall survival (OS), and cancer-specific survival (CSS). If sufficient ($n \geq 3$) studies reported risk estimates on the respective prognostic outcome, we conducted meta-analyses with random-effects models, Quality of the included studies was assessed with the Newcastle-Ottawa Scale. **Results:** In total, 33 studies were identified for the systematic review, of which 17 studies were included in the meta-analyses. Liver steatosis at time of cancer diagnosis was associated with a higher risk of metachronous metastases ($n = 4$ studies, pooled hazard ratio [HR] 1.65, 95% confidence interval [CI] 1.14-2.37, I^2 = 64%) and worse DFS ($n = 7$, HR 1.22, 95%CI 1.02-1.47, I^2 = 65%). Liver steatosis was not associated with OS ($n = 8$, HR 0.86, 95%CI 0.66-1.12, I^2 = 82%), nor CSS ($n = 5$, HR 1.02, 95%CI 0.79-1.32, I^2 = 84%). Results remained consistent when restricting meta-analyses to studies that solely investigated metastatic cancer ($n = 4$ and 5 studies for DFS and OS, respectively). Further subgroup analyses based on cancer stage or tumour location were not possible ($n < 3$ studies per subgroup). **Conclusion:** Liver steatosis at time of diagnosis was associated with higher risk of liver metastases during follow-up and poorer DFS in patients with all stages of CRC. Future studies should consider exploring relevant subgroups based on primary tumour location and cancer stage.

2554 | THE INTERPLAY OF ALCOHOL USE PATTERNS AND CARDIOMETABOLIC RISK FACTORS ON FIBROSIS IN STEATOTIC LIVER DISEASE

Baila Elkin[1] Sindhuja Battula[1] Adnan Said[2], [1]University of Wisconsin Hospitals and Clinics, [2]University of Wisconsin School of Medicine and Public Health

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Alcohol use and metabolic syndrome are the two leading causes of steatotic liver disease (SLD). Recently, there has been increasing recognition of the complexity of interplay of these risk factors. However, further research is needed to tease out the interactions of these risk factors, with recent studies pointing to insulin resistance as particularly significant cardiometabolic risk factor CMRF, and alcohol use as contributing to fibrosis risk even among patients with MASLD. These findings raise questions pertaining to the optimal threshold for alcohol use in defining the subtype of SLD as well as the impact of alcohol use patterns. Similarly, the relative impact of CMRF on SLD requires exploration, in terms of the impact of increasing number of cardiometabolic risk factors, control of these risk factors, and whether specific risk factors, particularly type 2 diabetes, have a greater impact on fibrosis. **Methods:** We preformed a population-based study using the NHANES database, using data from transient elastography (FibroScan) and survey questions to examine fibrosis, alcohol use patterns, and CMRF. We included patients >18 years of age with the presence of valid elastography and steatotic liver disease, and excluded patients with HBSag+, HCV RNA+, Ferritin>300 and Tsat>45%. We used descriptive statistics with mean and standard deviation (SD) for normally distributed continuous variables, medians and interquartile range (IQR) for non-normally distributed continuous variables, and frequency (percentage) for categorical variables. We used ANOVA test to compare the degree of fibrosis between groups if normally distributed and the Kruskal-Wallis test if non-normally distributed. A p-value of 0.05 defined significance. **Results:** Of 4073 patients, 915 had no drinking, 2066 moderate, 609 heavy, and 208 high-intensity. Fibrosis score was significantly impacted by the number of CMRF and by presence of diabetes, at all levels of alcohol use. However, the impact of additional CMRF in patients with diabetes was not significant. Of 3721 patients with MASLD by AASLD criteria, 591 had heavy drinking by NIAAA criteria, and 205 had high-intensity drinking by NIAAA criteria. Drinking patterns had a statistically significant effect on fibrosis within the MASLD group, but there was no clear dose-dependent effect. **Conclusion:** Alcohol use patterns and CMRF coexist and contribute to fibrosis risk in SLD. The presence and control of diabetes was the most significant CMRF across alcohol use levels. A significant number of patients with classified as MASLD display high-risk alcohol use by NIAAA criteria. While drinking patterns had a statistically significant impact on fibrosis in patients with MASLD, the clinical impact is less clear.

Impact of DM2 on fibrosis, stratified by alcohol use

	No drinking	Moderate drinking	Heavy drinking	High-intensity drinking
Poorly controlled DM2 (A1c>7)	6.4 (4.9–8.9), n=154	6.2 (5–8.3), n=218	6.1 (4.8–9.1), n=58	7.6 (6.2–10.7), n=20
Well-controlled DM2 (A1c<7)	6 (4.9–7.4), n=176	6 (4.8–8.4), n=251	5.7 (4.3–7.7), n=62	6.4 (4.5–8.1), n=20
No DM2	5.4 (4.3–6.5), n=585	5.1 (4.2–5.3), n=1597	5 (4.1–6.2), n=643	5.4 (4.4–6.5), n=289
P value	<0.05	<0.05	<0.05	<0.05

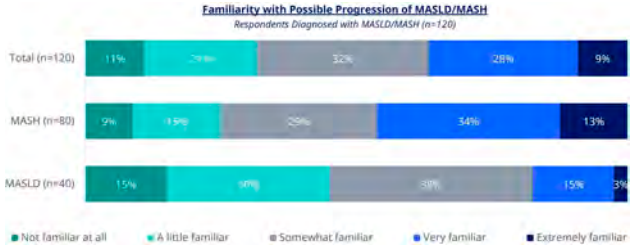
2555 | PREVALENCE, DEMOGRAPHIC PROFILE AND ETIOLOGY OF LIVER DISEASE IN WOMEN WITH NEWLY DIAGNOSED BREAST CANCER: A RETROSPECTIVE COHORT STUDY

Sujatha Lakshminarayanan[1] Thirumoorthi Natarajan[1], [1]Cancer Institute (WIA)

Background: Breast cancer is the most frequent cancer among women globally and is increasingly linked to metabolic and hepatic comorbidities that can negatively impact therapeutic outcomes. Baseline hepatic dysfunction in newly diagnosed breast cancer patients can be due to viral hepatitis, alcohol-related liver injury, metabolic dysfunction-associated steatotic liver disease (MASLD), or hepatic metastases. Systemic breast cancer therapies possess significant hepatotoxic potential. Pre-existing hepatic abnormalities may increase toxicity from treatment, result in dose modifications and impair therapeutic efficacy . Thus, at the critical clinical intersection of oncology and hepatology, comprehensive baseline hepatic and metabolic phenotyping of treatment-naïve breast cancer patients. **Methods:** This was a retrospective cohort study of treatment-naive women with breast cancer who were registered at a tertiary oncology referral center between January 2020 and December 2024. Clinical, biochemical and radiological data were obtained from the electronic medical records. Available baseline assessments included liver function tests (LFTs), abdominal ultrasound, viral serology and metabolic comorbidities. Statistical analysis was done by SPSS version 16. **Results:** A total of 4394 women with a new breast cancer diagnosis were included. The median age was 53 years (range 21-89 years). Baseline viral screening (HBsAg, Anti-HCV and HIV) was negative in 99.7% of patients tested. MASLD was defined as imaging-proven hepatic steatosis with one or more

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient



© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

cardiometabolic risk factors. Hepatic steatosis was found in 41.2% (n = 1,488) of the 3,612 patients who underwent baseline abdominal ultrasonography. 40.2% (n = 1,452) met criteria for MASLD. Among patients with hepatic steatosis, 97.6% met criteria for MASLD, while 2.4% (n = 36) had isolated steatosis without identifiable metabolic risk factors. Out of (4,046) tested patients, 20.37% (n = 824) had abnormal baseline LFTs, consisting of 16.26% (n = 658) with isolated transaminitis, 2.20% (n = 89) with isolated increased ALP, and 1.90% (n = 77) with both abnormalities. Other hepatobiliary abnormalities were cholelithiasis in 5.8% (n = 211), hepatic cysts in 2.1% (n = 76), radiologically evident liver metastases in 1.2% (n = 45) and 16 patients had cirrhosis (0.44%) prior to initiation of oncological therapy. **Conclusion:** Women with newly diagnosed breast cancer have a high prevalence of baseline hepatic abnormalities, with MASLD as the leading cause. These findings underscore the need for complete baseline hepatic evaluation before initiating potentially hepatotoxic systemic or radiation therapy. Early detection of MASLD and other liver abnormalities may help with risk stratification, treatment plan optimization, proactive hepatology referral, and optimization of oncologic outcomes.

2556 | ACT ON MASH – US DATA: A SURVEY OF AWARENESS, UNDERSTANDING, AND PERCEPTIONS OF MASLD AND MASH AMONG PEOPLE LIVING WITH MASLD/MASH OR AT RISK FOR MASH

Husam Albarmawi[1] Nathalie Marcela Eklöf[2] Maximilian Kurt Jara[3] Jeff McIntyre[4] Marco Petti[1] Lauren Nephew[5], [1]Novo Nordisk Inc., USA, [2]Novo Nordisk, Denmark, [3]Novo Nordisk Inc., [4]Patient Advocate, Washington DC, USA, [5]Indiana University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects about 1 in 3 people in the US; yet, the experiences and views of those living with, or at risk for, MASLD have been insufficiently described. This study evaluated the awareness, knowledge, and perceptions of MASLD and metabolic dysfunction–associated steatohepatitis (MASH) among people diagnosed with, or at risk for, MASLD/MASH. **Methods:** In 2025, we conducted an online cross-sectional survey of people diagnosed with, or at risk for, MASLD/MASH in multiple countries. This analysis includes data from respondents in the US. The survey was developed by a multidisciplinary team, including a patient advocacy representative. "At risk" was defined as having ≥1 cardiometabolic risk factor or elevated liver enzymes but no MASLD/MASH diagnosis. Recruitment was conducted via online panels, targeted outreach, and social media. **Results:** 160 respondents completed the survey: 40 with MASLD, 80 with MASH, and 40 at risk for MASLD/MASH. The mean age of the respondents was 50 years. 19% were of Hispanic ethnicity and 58% were females. The most common cardiometabolic comorbidities among respondents with MASLD were: obesity/overweight (78%), hypertension (60%), and sleep apnea (48%); among those with MASH: obesity/overweight (61%), hypertension (46%), type 2 diabetes (39%), and dyslipidemia (39%); and among those at risk for MASH: obesity/overweight (63%), hypertension (60%), and type 2 diabetes (43%). The reported time between initial testing and diagnosis of liver disease averaged 22 months for respondents with MASH and 24 months for those with MASLD. Perceived timeliness of MASLD/MASH diagnosis was common (69%). Few respondents reported being "very" or "extremely" familiar with disease progression (MASLD, 18%; MASH, 47%; Figure). 53% of all respondents have not had their healthcare provider (HCP) discuss MASLD/MASH risk factors prior to diagnosis. Among at-risk respondents, 60% were aware of being at risk for MASLD/MASH, and only 33% reported having received screening. Among at-risk respondents who had not received screening, 67% reported that an HCP had not recommended screening. Overall, 30% of at-risk respondents reported no intention of asking an HCP for liver disease screening. 47% of all respondents with MASLD/MASH and those at-risk for MASH who received screening reported that primary care physicians were the first to recommend screening for liver disease. 55% of respondents agreed or strongly agreed that liver disease is associated with stigma. **Conclusion:** US respondents reported gaps in familiarity with MASLD/MASH progression and low screening uptake among those at risk for MASH. The low screening uptake and the presence of perceived stigma underscore the need for patient-focused education and strengthened patient-HCP communication to support earlier screening and improve patients' awareness of MASLD/MASH.

2557 | AUDIT-C SCORE IN PATIENTS WITH MASLD AND ADVANCED LIVER FIBROSIS-ANALYSIS OF A LARGE REGIONAL VETERANS AFFAIRS COHORT

Ragesh Thandassery[1] Shambhavi Anshumali[2] Suria Devarapalli[2] Drew Castleberry[2] Tamar Taddei[3], [1]University of Arkansas for Medical Sciences, Little Rock, [2]University of Arkansas for Medical Sciences, [3]Yale University

Background: Alcohol use is frequently observed in patients with metabolic dysfunction-associated steatotic liver disease (MASLD), even when criteria for MetALD are not met. We sought to determine whether alcohol use, as identified by Alcohol Use Disorders Identification Test-Consumption (AUDIT-C) scores, was associated with liver fibrosis burden, cardiovascular risk, and preventive care utilization in a regional (South-Central) Veterans Affairs MASLD cohort. **Methods:** In this retrospective primary care cohort, we identified 315,578 veterans with MASLD for fiscal year 2024, excluding those with significant alcohol use (< 30g/day for men and < 20g/day for women). Veterans with BMI above 30 (37.1%) and advanced liver fibrosis (3.3%) were included; decompensated cirrhosis was excluded. Advanced fibrosis was defined by Fibrosis-4 (FIB-4) > 2.67, with age capped at 65. AUDIT-C scores ≥ 4 for men and ≥ 3 for women were classified as positive screens. Scores < 8 were classified as low and ≥ 8 as high. **Results:** Of the 4,107 veterans meeting inclusion criteria, 97.3% had AUDIT-C scores recorded. Median age was 67 years (IQR 61–72), 94.6% male, 72.4% Caucasian (17.9% African American). AUDIT-C screens were positive in 1.6% of men and 8.1% of women; 140 (3.5%) had high and 3,855 (96.5%) had low scores (58.3% scored 0). Veterans with positive AUDIT-C scores were younger and less often above 65 years (73.2% vs 91.0%, p < 0.001). Positive AUDIT-C screening was associated with significantly greater liver fibrosis burden, including higher median FIB-4 scores [3.7 (IQR 3.1– 4.9) vs 3.2 (2.8 – 4.1), p = 0.004] and NAFLD Fibrosis Scores [1.89 (1.14–2.71) vs 1.39 (0.84–2.05), p = 0.008]. Incremental rise in ALT compared with the previous year (2023) was more common among positive screens (54.9% vs 32.2%, p = 0.001). Despite greater liver disease severity, positive AUDIT-C patients demonstrated lower use of preventive cardiometabolic therapies and services. They were less likely to attend weight loss clinics (12.7% vs 24.6%, p = 0.028) and receive statin therapy (43.7% vs 62.4%, p = 0.004). Among patients with high ASCVD risk (> 20%), positive screens remained less likely to receive statins (54.2% vs 78.0%, p = 0.014). AUD pharmacotherapy use was higher among positive screens (5.6% vs 0.7%, p = 0.011), though overall utilization remained low. In secondary analyses, high (≥ 8) versus low (< 8), high AUDIT-C scores were associated with higher median FIB-4 (3.5 vs 3.3, p = 0.013) and NAFLD Fibrosis Scores (1.76 vs 1.42, p = 0.021). **Conclusion:** Positive AUDIT-C screening among veterans with MASLD was associated with increased liver fibrosis and biochemical liver injury, yet reduced utilization of cardiovascular preventive therapies and weight management services. These findings highlight a significant care gap and support the integration of alcohol-focused interventions and cardiometabolic risk reduction strategies in veterans with MASLD.

Table 1. Clinical, liver fibrosis, and cardiometabolic characteristics by AUDIT-C screening status in veterans with MASLD

Variable	Negative AUDIT-C Screen	Positive AUDIT-C Screen	p value
Age >65 years	87.3%	12.7%	<0.001
Median FIB-4 score (IQR)	3.2 (2.8–4.1)	3.7 (3.1–4.9)	0.004
Median NAFLD Fibrosis Score (IQR)	1.39 (0.84–2.05)	1.89 (1.14–2.71)	0.008
Elevated AST in prior 1 year	30.2%	52.1%	0.001
Elevated ALT in prior 1 year	32.2%	54.9%	<0.001
NSBB use	18.2%	9.9%	0.08
GI/liver follow-up	54.2%	43.7	0.11
High ASCVD risk (>20%)	54.7%	33.8%	0.002
Type 2 diabetes among high ASCVD risk patients	72.9%	45.8%	0.009
Elevated HbA1c among high ASCVD risk patients	45.8%	25.0%	0.048
Statin use, overall	62.4%	43.7%	0.004
Weight loss clinic attendance[1]	24.6%	12.7%	0.028
Weight loss medication use	10.5%	4.2%	0.11
Nutrition follow-up	35.4%	25.4%	0.12
Use of medications associated with weight gain	38.1%	25.4%	0.047
AUD diagnosis	29.3%	5.6%	0.011

2558 | COFFEE BUT NOT SUGAR-SWEETENED BEVERAGES IS ASSOCIATED WITH LOWER FIBROSIS RISK IN METABOLIC LIVER DISEASE: SYNERGY WITH ALCOHOL CONSUMPTION

Sebastian Niezen[1] Markos Kalligeros[1] Manaav Mehta[2] Elliot Tapper[3], [1]Beth Israel Deaconess Medical Center, [2]University of Massachusetts Medical School, [3]University of Michigan Medical Center

Background: Coffee consumption has been associated with reduced liver fibrosis, though data in metabolic dysfunction–associated steatotic liver disease (MASLD) and metabolic dysfunction–associated alcohol-related liver

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

disease (MetALD) remain limited. We evaluated the association of coffee and sugar-sweetened beverage (SSB) intake with advanced fibrosis in a nationally representative cohort. **Methods:** We performed a cross-sectional analysis of adults from NHANES 2021–2023. Advanced fibrosis was defined as liver stiffness measurement (LSM) ≥10 kPa. Coffee and SSB intake were categorized as 0, >0–1, >1–3, and >3 cups/day. Survey-weighted logistic regression models were adjusted for demographic, metabolic, and behavioral covariates. Trend analyses assessed dose-response relationships using ordinal exposure modeling. Interaction models evaluated effect modification by continuous alcohol consumption. Exploratory stratified analyses by alcohol use category and a sensitivity analysis restricted to MASLD only (excluding MetALD) were performed. **Results:** The study included 245,061,169 weighted participants (median age 48 years; 52% female). Steatosis was present in 36% (88.2 million) and advanced fibrosis in 8.0% (19.6 million) of US adults. MASLD and MetALD accounted for 24% (58.8 million) and 1.9% (4.7 million) of the population, respectively. In adjusted analyses, moderate coffee intake (>1–3 cups/day) was associated with lower odds of advanced fibrosis (OR 0.62, 95% CI 0.41–0.95, p = 0.043). Trend analysis demonstrated a significant inverse dose-response relationship for coffee intake (OR 0.84 per category increase, 95% CI 0.75–0.95, p = 0.012). SSB intake was not significantly associated with advanced fibrosis across any category, and no significant dose-response trend was identified (OR 0.93, 95% CI 0.77–1.11, p = 0.406). Formal coffee with alcohol interaction testing did not identify significant effect modification (all p > 0.48). In exploratory stratified analyses by alcohol use, the protective association of moderate coffee intake appeared most pronounced among moderate drinkers (OR 0.20, 95% CI 0.05–0.76, p = 0.032), though this should be interpreted cautiously given limited subgroup power and a non-significant formal interaction test. Sensitivity analyses restricted to MASLD only yielded directionally consistent results. **Conclusion:** Moderate coffee intake was associated with significantly lower odds of advanced fibrosis among adults with MASLD and MetALD, with evidence of a graded dose-response relationship. SSBintake was not independently associated with fibrosis risk, and the coffee-fibrosis association appeared independent of alcohol consumption.

2559 | LONG-TERM SURVIVAL OUTCOMES IN LEAN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A COHORT ANALYSIS

Yajing Bo[1] Enrui Xie[1] Xiao Yuan[1] Xinyuan He[1] Zhiluo Yang[1] Xin Liu[1] Qi Shang[1] Xinrong Zhang[2] Yee Hui Yeo[3] Fanpu Ji[1], [1]The Second Affiliated Hospital of Xi'an Jiaotong University, [2]Sun Yat-sen University, [3]Cedars-Sinai Medical Center

Background: The long-term prognosis of lean metabolic dysfunction-associated steatotic liver disease (MASLD) remains controversial, and its specific associations with all-cause and cardiovascular mortality have not been fully elucidated. **Methods:** Data from 3568 participants with MASLD in the Third National Health and Nutrition Examination Survey ((NHANES III) were analyzed. Cox proportional hazard models and Fine-Gray competing-risk models were used to assess all-cause and cardiovascular mortality, respectively. A 10-year landmark analysis was performed to evaluate stage-specific mortality risks. Restricted cubic spline analyses examined dose-response associations between body mass index (BMI) and early all-cause mortality. Subgroup analyses were conducted to identify high-risk populations. **Results:** Over a median follow-up of 27.7 years, lean MASLD was independently associated with an increased risk of early all-cause mortality within 0-120 months (adjusted hazard ratio [HR], 1.68; 95% confidence interval [CI], 1.29-2.20), whereas this association was no longer significant after 120 months (adjusted HR 1.04, 95%CI 0.87-1.25). No significant association between lean MASLD and cardiovascular mortality was observed during either period. RCS analysis demonstrated a nonlinear U-shaped association between BMI and early all-cause mortality, with an inflection point at 29.5 kg/m². The increased early mortality risk was most pronounced among males aged ≥ 60 years and participants with a baseline FIB-4 index ≥ 1.30. **Conclusion:** Lean MASLD was associated with increased early all-cause mortality and demonstrated a U-shaped relationship with BMI and mortality risk. Males aged ≥ 60 years and patients with FIB-4 ≥ 1.30 may represent high-risk phenotypes requiring closer clinical monitoring.

2561 | METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE: HISTOLOGICAL SPECTRUM IN LEAN VERSUS OVERWEIGHT, AND PATIENTS WITH OBESITY

Helma Cotrim[1] Luiz Antonio de-Freitas[2] Antonio Ricardo Antonio Ricardo Andrade[2] Ana Cristina Ana Cristina Landin[2] Neilson Souza[2], [1]Medicine School-Universidade Federal Da Bahia - Brazil, [2]Federal University of Bahia -Brazil

Background and Aim: MASLD is a global health challenge. Although strongly linked to obesity, lean MASLD represents a distinct and underrecognized phenotype. Aim: to compare histological severity and non-invasive fibrosis assessment across lean, overweight, and patients with obesity. **Methods:** In this cross-sectional study, 133 patients with biopsy-proven MASLD/MASH were categorized as lean (n = 30), overweight (n = 59), and patients with obesity (n = 44) (Fig 1-A). Clinical variables, as well as non-invasive scores (e.g., FIB-4), were analyzed. Liver biopsies were assessed using the Kleiner classification and the NAFLD Activity Score (NAS). Multivariate logistic regression was performed to identify predictors of significant fibrosis ($\geq$F2) and steatohepatitis (NAS$\geq$3). Spearman correlation analysis was used to assess the relationship between histological, metabolic, and non-invasive markers. The diagnostic accuracy of FIB-4 for significant ($\geq$F2) and advanced fibrosis ($\geq$F3) was evaluated using receiver operating characteristic (ROC) curves. **Results:** Lean patients had a significantly lower prevalence of type 2 diabetes (DM2) (30.0% vs. 61.0% and 68.2%) and metabolic syndrome (13.3% vs. 42.4% and 54.5%) than overweight and patients with obesity ($p < 0.05$). Despite this more favorable metabolic profile, histological severity was comparable across BMI categories. Significant fibrosis ($\geq$ F2) was observed in 50.0% of lean, 49.1% of overweight, and 43.2% of patients with obesity ($p = 0.931$). Rates of steatohepatitis were also similar among groups ($p = 0.723$). In multivariate analysis, DM2 was the only independent predictor of significant fibrosis (OR: 4.01; 95% CI: 1.52–10.59; p = 0.005), whereas BMI categories were not associated with fibrosis ($p > 0.25$) or steatohepatitis ($p > 0.20$). Correlation analysis showed a negligible relationship between BMI and fibrosis stage (rho = -0.04). FIB-4 performed better in lean patients for significant ($\geq$F2; AUC: 0.822 vs. 0.743 and 0.695) and advanced fibrosis ($\geq$F3; AUC: 0.954 vs. 0.676 and 0.856) than in overweight and patients with obesity (Fig 1 B, C, D, E, F). **Conclusion:** Lean MASLD patients, in this sample, presented histological severity comparable to that observed in overweight and obesity patients, despite a lower burden of metabolic comorbidities. DM2, rather than BMI, appears to be the main driver of fibrosis progression. The high diagnostic accuracy of FIB-4 in lean patients demonstrated the need for vigilant fibrosis screening even in non-obese individuals with metabolic risk factors.

2562 | ALCOHOL-USE TRAJECTORIES AND MAJOR ADVERSE LIVER OUTCOMES IN METALD: A NATIONWIDE LONGITUDINAL COHORT STUDY

Eileen Yoon[1] Hyo Young Lee[2] Sang Bong Ahn[3] Mimi Kim[4] Bo-Kyeong Kang[5] Dae Won Jun[2], [1]Department of Internal Medicine, Hanyang University College of Medicine, [2]Department of Internal Medicine, Hanyang University, [3]Department of Internal Medicine, Nowon Eulji Medical Center, Eulji University, [4]Department of Radiology, Hanyang University College of Medicine, [5]Department of Radiology, Hanyang University College of Medicine

Background: Alcohol contributes to the progression of steatotic liver disease. However, in individuals with MetALD, the impact of changes in drinking behavior on disease progression remains unclear. We investigated whether longitudinal changes in alcohol consumption were associated with the risk of major adverse liver outcomes in people with MetALD. **Methods:** Data were obtained from the Korean National Health Screening Program. Adults with MetALD who completed three screening examinations (2009–2010, 2011–2012, and 2013–2014) were included (n = 58,434). Participants were categorized by alcohol consumption trajectories: Group 1 (sustained consumption), Group 2 (fluctuating consumption), and Group 3 (consistent reduction). The primary outcome was major adverse liver outcomes. Changes in cardiometabolic risk factors from baseline to the last examination were also evaluated. **Results:** Over a median follow-up of 8.1 years, 33.2% of participants were classified as Group 1, 34.8% as Group 2, and 32.0% as Group 3. After multivariable adjustment, Group 3 had a lower risk of major adverse liver outcomes than Group 1 (adjusted HR, 0.84; P = 0.032). For liver-related mortality, risk was lower in Group 2 (adjusted HR, 0.73; P = 0.023) and Group 3 (adjusted HR, 0.65; P = 0.004). Consistent alcohol reduction was accompanied by greater resolution of hypertriglyceridemia and hypertension compared with sustained consumption. **Conclusion:** Alcohol use in MetALD is highly dynamic, and hepatic risk is better captured using longitudinal drinking trajectories. Sustained alcohol reduction appears to confer cardiometabolic benefits, largely through improvements in hypertriglyceridemia and hypertension.

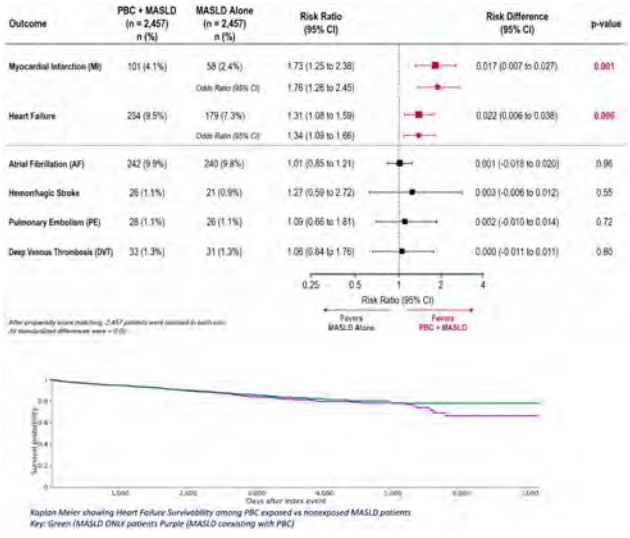
2563 | WHEN BILE MEETS FAT, THE HEART PAYS: COEXISTING PRIMARY BILIARY CHOLANGITIS AMPLIFIES MYOCARDIAL INFARCTION AND HEART FAILURE RISK IN MASLD



Emeka Stanley Obi[1] Adedeji Adenusi[2] Chimezirim Ezeano[3] Gedion Amdetsion[4] Olamide Asifat[5] Winifred Iklaki[6] Onyinye Ugonabo[7] Basile Njei[8], [1]Brookdale University Hospital and Medical Center, [2]Interfaith Medical Center, [3]Advocate Aurora Healthcare, [4]John H Stroger Hospital of Cook County, [5]Georgia Southern University, [6]University of Missouri Columbia Hospital, [7]Zucker School of Medicine Northwell, [8]Yale University

Background: MASLD is the leading chronic liver disease worldwide, and cardiovascular disease drives most mortality in this population. Primary biliary cholangitis (PBC) produces atherogenic dyslipidemia, autoimmune inflammation, and endothelial dysfunction. The two conditions increasingly coexist, yet the cardiovascular consequences remain poorly defined, and guidelines offer limited direction on cardiac risk in this overlap. Current AASLD and EASL guidance on PBC concentrates on hepatic progression and pruritus, with limited recommendations on extrahepatic cardiovascular risk stratification when MASLD is also present. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network (172 healthcare organizations). Adults aged 18 years and older with MASLD/MASH (ICD10CM K76.0 or K75.81) were identified. Adults with MASLD/MASH (ICD10CM K76.0, K75.81) were stratified by presence (exposure) or absence (control) of PBC (K74.3). Patients with competing liver diseases; alcoholic liver disease, viral hepatitis B or C, hepatic fibrosis, Wilson disease, toxic hepatitis, liver transplantation, or alcohol abuse were excluded. Outcomes included acute myocardial infarction (MI), atrial fibrillation (AF), heart failure (HF), hemorrhagic stroke, pulmonary embolism (PE), and deep venous thrombosis (DVT). Propensity score matching (1: 1) balanced age, sex, race, ethnicity, hypertensive disease, and other cardiometabolic cormobidities. Risk analyses excluded patients with the outcome prior to the time window. Kaplan Meier survival with log rank testing and hazard ratios were computed. **Results:** After matching, 2,457 patients were retained per cohort with all standardized differences below 0.02. Coexisting PBC conferred a significantly higher risk of MI (4.1% vs 2.4%; RR 1.73, 95% CI 1.25 to 2.38; p = 0.001) and heart failure (9.5% vs 7.3%; RR 1.31, 95% CI 1.08 to 1.59; p = 0.006). No significant differences emerged for AF (RR 1.01), hemorrhagic stroke (RR 1.27), PE (RR 1.09), or DVT

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(RR 1.06). Heart failure free survival at the end of the window was 66.4% in the PBC group versus 78.0% in controls. **Conclusion:** Coexisting PBC was associated with a 73% relative increase in MI, a 31% relative increase in heart failure an reduced heart failure survivability among adults with MASLD. The selective rise in cardiac events without a parallel rise in thromboembolic or cerebrovascular events suggests mechanisms rooted in cholestasis driven dyslipidemia, chronic autoimmune inflammation, and altered bile acid signaling rather than a generalized procoagulant state, and points towards coronary and myocardial vulnerability. The PBC and MASLD overlap should be recognized as a high cardiac risk phenotype warranting structured cardiovascular surveillance and lipid optimization in routine PBC care. Some limitations include reliance on administrative coding, absence of data on fibrosis stage, and UDCA use.

Kaplan Meier showing Heart Failure Survivability among PBC exposed vs nonexposed MASLD patients

2564 | LOW USE OF GLP-1 RECEPTOR AGONISTS AMONG U.S. ADULTS WITH OBESITY OR TYPE 2 DIABETES ACROSS LIVER DISEASE RISK MARKERS, NHANES 2005–MARCH 2020

Cheng Han[1] Maddie Kubilius[2] Wei Zhao[3], [1]UT Southwestern Medical Center, [2]UT Southwestern, [3]Central Hospital of Dalian University of Technology

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) provide glucose-lowering, cardiometabolic, anti-obesity and liver-protective benefits, with expanded indications for metabolic dysfunction-associated steatohepatitis (MASH). They are highly relevant for patients with obesity, type 2 diabetes (T2D), and metabolic dysfunction-associated steatotic liver disease (MASLD). Anti-obesity medication uptake was historically low before the modern GLP-1RA era, limited by patient access and clinician prescribing barriers. It remains unclear whether early GLP-1RA use aligned with cardiometabolic and liver risk or concentrated in populations with better economic and insurance access. This study evaluated GLP-1RA utilization trends in US adults using National Health and Nutrition Examination Survey (NHANES) data from 2005 to 2020. **Methods:** NHANES participants were divided into two eras: 2005–2014 and 2015–March 2020, corresponding to pre- and post-obesity indication expansion of GLP-1RAs.Three cohorts were analyzed: body mass index (BMI) $\geq$30 kg/m²; BMI $\geq$27 kg/m² with at least one weight-related comorbidity; and adults with T2D. MASLD was defined by the Fatty Liver Index, and liver fibrosis risk was stratified by FIB-4 using a cutoff of 1.3. Demographics, poverty-income ratio (PIR), insurance status, MASLD and FIB-4 levels were compared by GLP-1RA use. T-test, chi-square and Fisher's exact test were used for analysis. **Results:** GLP-1RA utilization nearly tripled across eras but remained low in all cohorts. From 2005–2014 to 2015–2020, use increased from 0.4% to 1.2% in adults with BMI $\geq$30 kg/m², 0.4% to 1.2% in those with BMI $\geq$27 kg/m² plus comorbidities, and 0.9% to 3.1% in adults with T2D. In 2015–2020, GLP-1RA users were older in obesity and overweight-comorbidity groups, while sex showed no association with medication uptake. Higher PIR and private insurance were consistently linked to greater GLP-1RA use. GLP-1RA uptake was numerically higher in participants with MASLD without statistical significance. Adults with elevated FIB-4 index had no preferential GLP-1RA prescription; T2D patients with FIB-4 $\geq$1.3 even showed lower utilization than those with lower fibrosis risk. **Conclusion:** GLP-1RAs were substantially underused among US adults with obesity, T2D and liver-risk markers during 2005–2020. Early GLP-1RA adoption was driven more by socioeconomic affordability and insurance coverage than by liver and fibrosis risk stratification. Limited historical indications, cost barriers and clinician prescribing reluctance contributed to low real-world uptake. Expanded GLP-1RA application should prioritize patients with the highest metabolic and hepatic burden to mitigate access disparities.

2565 | CLINICAL OUTCOMES BY DIABETES STATUS IN BIOPSY-PROVEN MASLD AND METALD: MULTICENTER PROSPECTIVE COHORT STUDY

Won Kim[1] Gi-Ae Kim[2] Bo Kyung; Koo[1], [1]Seoul National University College of Medicine, [2]Kyung Hee University School of Medicine

Background: Although type 2 diabetes (T2D) is associated with adverse clinical outcomes in metabolic dysfunction-associated steatotic liver disease (MASLD), this association has not been well established in biopsy-based studies. We aimed to investigate the risk of clinical outcomes according to T2D status in biopsy-proven MASLD and metabolic dysfunction and alcohol-related liver disease (MetALD). **Methods:** This multicenter prospective cohort study recruited patients with biopsy-proven MASLD and MetALD from eight tertiary hospitals in Korea between 2010 and 2023. The risks of all-cause mortality, cardiovascular disease (CVD), liver-related events (LREs), and extrahepatic malignancies were investigated. Adjusted subdistribution hazard ratios (aSHRs) were calculated using Fine–Gray models accounting for competing risks. **Results:** Among 1,871 patients, 910 (48.7%) had T2D. Patients with T2D exhibited a higher prevalence of significant fibrosis (54.1% vs 33.6%) and metabolic dysfunction-associated steatohepatitis (MASH) or metabolic dysfunction and alcohol-associated steatohepatitis (MetASH) (65.9% vs 52.5%; all $p < 0.001$). In inverse probability of treatment weighting analysis, T2D was associated with increased risks of all-cause mortality (aSHR, 2.06; 95% CI, 1.39−3.05; $p < 0.001$), CVD (aSHR, 1.91; 95% CI, 1.20−3.05; $p = 0.007$), and LREs (aSHR, 1.76; 95% CI, 1.14−2.70; $p = 0.010$) compared to those without T2D. In subgroup analysis of patients with T2D, those with MASH/MetASH or at-risk MASH/MetASH had higher risks of all-cause mortality and LREs, whereas no significant differences in CVD risk were observed. **Conclusion:** T2D is associated with substantially higher risks of all-cause mortality, CVD, and LREs in MASLD and MetALD. Tailored management strategies accounting for T2D status are warranted in MASLD and MetALD.

2566 | MORTALITY DISPARITIES FOLLOW THE PATIENT; ACCESS DISPARITIES FOLLOW THE CENTER: DECOMPOSING WAITLIST EQUITY ACROSS STEATOTIC LIVER DISEASE PHENOTYPES IN 44,935 CANDIDATES

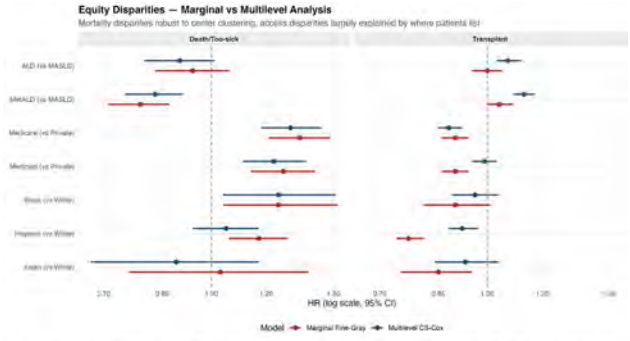
Islam Mohamed[1] Mohamed Nadeem[2] Basil Jalamneh[2] Shilpa Junna[2], [1]The Cleveland Clinic Foundation-Fairview hospital, [2]Cleveland Clinic Foundation

Background: The 2023 Delphi consensus defined MetALD as a distinct steatotic liver disease (SLD) phenotype, yet its waitlist prognosis relative to ALD and MASLD remains uncharacterized at scale. Karnofsky Performance Status (KPS), the sole frailty surrogate in UNOS, varies substantially by center but whether this variation contributes to inequitable waitlist outcomes across SLD phenotypes is unknown. **Methods:** We analyzed OPTN/UNOS STAR data (2017–2023), classifying 44,935 adults at 117 centers as ALD (n = 7,319), MetALD (n = 20,494), or MASLD (n = 17,122) using the validated SLD algorithm. Center-level KPS clustering was quantified by intraclass correlation coefficient (ICC) from a multilevel mixed-effects model; outlier centers were identified by Spiegelhalter overdispersion-adjusted funnel plots. Ninety-day waitlist death/too-sick removal and transplant were modeled as competing risks using Fine-Gray regression, adjusted for listing year, MELD-Na, age, sex, race/ethnicity, insurance, ascites, and encephalopathy. A multilevel cause-specific Cox model with random center intercepts then tested whether equity disparities were attenuated after accounting for center clustering. **Results:** Center membership explained 21.8% of KPS variance after case-mix adjustment (null ICC = 0.170; adjusted ICC = 0.218); Spiegelhalter correction identified 4/117 (3.4%) genuine outlier centers versus 74 by naive count. Medicare and Medicaid patients listed with 2.6–2.7 fewer KPS points than privately insured patients ($p < 0.001$), independent of MELD and disease severity. Ninety-day transplant access was lowest for MASLD (34.7%), intermediate for ALD (44.4%), and highest for MetALD (47.8%; Gray's $p < 0.001$). In adjusted competing risks models, MetALD had significantly lower 90-day mortality than MASLD (sHR 0.79, 95% CI 0.71–0.87). Black patients faced 25% higher mortality (sHR 1.25, 95% CI 1.04–1.52) and Hispanic patients 23% lower transplant access (sHR 0.77, 95% CI 0.74–0.81). Black mortality (sHR 1.25 to 1.25) and Medicare mortality disparities (sHR 1.34 to 1.30) were fully robust to center adjustment, reflecting patient-level inequities. Hispanic mortality (1.17 to 1.05, $p = 0.37$)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and Medicaid transplant disparities (0.90 to 0.99, p = 0.75) were substantially attenuated largely explained by where patients listed. Center random-effect SDs were twice as large for transplant access as for mortality (0.57 vs. 0.24). **Conclusion:** MASLD carries the greatest access disadvantage despite lower MELD severity at listing. Mortality disparities for Black and Medicare patients persist after center adjustment and represent patient-level inequities requiring systemic intervention. Access disparities for Hispanic and Medicaid patients are largely geographic, identifying high-disparity centers as tractable targets for equity-focused quality improvement.



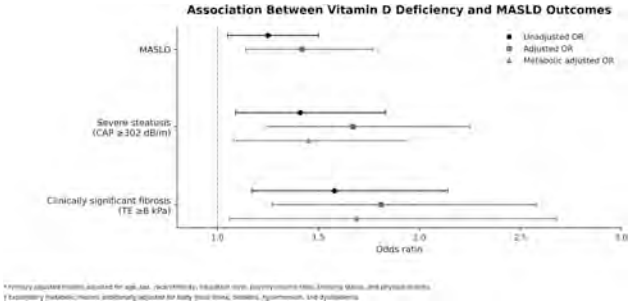


Figure 1. Equity disparities — marginal Fine-Gray vs. multilevel cause-specific Cox. Mortality disparities for Black and Medicare patients are robust to center adjustment; access disparities for Hispanic and Medicaid patients are largely attenuated, reflecting center-level geographic clustering.

2567 | VITAMIN D DEFICIENCY IS ASSOCIATED WITH METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) PREVALENCE, STEATOSIS SEVERITY, AND SIGNIFICANT FIBROSIS: A NATIONAL POPULATION-BASED STUDY

Nishat Anjum Shaik[1] Mohammed Rifat Shaik[2] Kamran Qureshi[3], [1]SSM Health/Saint Louis University, [2]National Institutes of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, [3]Saint Louis University

Background: Vitamin D deficiency has been implicated in pathogenesis of metabolic dysfunction–associated steatotic liver disease (MASLD) through effects on insulin resistance, lipid metabolism, and inflammatory pathways. Prior studies evaluating this relationship used older NAFLD/MAFLD definitions with inconsistent findings, and most assessed steatotic liver disease as a binary outcome without separately evaluating steatosis and fibrosis severity under the current MASLD nomenclature. We aimed to evaluate the association of vitamin D deficiency with MASLD prevalence, severe steatosis, and significant fibrosis in a nationally representative U.S. cohort. **Methods:** We conducted a cross-sectional analysis of adults aged ≥ 18 years from NHANES 2017–2018 with serum 25-hydroxyvitamin D and transient elastography (TE) data. Vitamin D deficiency was defined as serum 25-hydroxyvitamin D < 20 ng/mL. MASLD was defined as controlled attenuation parameter (CAP) ≥ 274 dB/m with ≥ 1 cardiometabolic risk factor, in the absence of excess alcohol use or viral hepatitis. Severe steatosis was defined as CAP ≥ 302 dB/m and significant fibrosis was defined as TE ≥ 8 kPa. Multivariable logistic regression models were used to evaluate associations between vitamin D deficiency and MASLD outcomes. Models were sequentially adjusted for demographics, socioeconomic factors, smoking, physical activity. An exploratory model additionally adjusted for body mass index (BMI), diabetes, hypertension, and dyslipidemia. **Results:** Among 5,225 participants, 1,542 (29.5%) had vitamin D deficiency. Compared with non-deficient participants, vitamin D deficient ones were younger (40.8 vs 49.4 years, p < 0.001), had higher BMI (31.0 vs 29.4 kg/m², p < 0.001), lower HDL (50.8 vs 54.3 mg/dL, p < 0.001), and were more likely to be Black (26.3% vs 6.4%) or Hispanic (26.2% vs 13.5%). Vitamin D deficiency was associated with higher MASLD prevalence on both unadjusted (OR 1.25, 95% CI: 1.05–1.50) and adjusted analyses (adjusted OR [aOR] 1.42, 95% CI: 1.14–1.77). Among those with MASLD, vitamin D deficiency was also associated with severe steatosis (unadjusted OR 1.41, 95% CI: 1.09–1.83; aOR 1.67, 95% CI: 1.24–2.25) and significant fibrosis (unadjusted OR 1.58, 95% CI: 1.17–2.14; aOR 1.81, 95% CI: 1.27–2.58). These associations were attenuated but persisted after additional adjustment for metabolic factors for both severe steatosis (aOR 1.45, 95% CI: 1.08–1.94) and significant fibrosis (aOR 1.69, 95% CI: 1.06–2.68) in exploratory analyses. **Conclusion:** Vitamin D deficiency is associated with MASLD prevalence, severe steatosis, and significant fibrosis. Partial attenuation after metabolic adjustment suggests that the associations may be mediated, in part, through metabolic pathways. These findings support vitamin D deficiency as a potential modifiable risk factor for MASLD and its severity, warranting further evaluation in prospective and interventional studies.

2568 | LEAN VERSUS NON-LEAN MASLD: FIBROSIS BURDEN, CARDIOMETABOLIC PROFILE, AND TEMPORAL TRENDS IN NHANES 2017–2023

Aleena Mujahid[1] Fatima Rajab[2] Mukarram Farooq[3] Ahmad Jalil[4] Haris Yaseen[5] Asim Elahi[1], [1]Harlingen Medical Center, [2]Baptist Hospitals of Southeast Texas, [3]South Texas Health System GME Consortium, [4]BAPTIST MEMORIAL HOSPITAL, [5]University at Buffalo

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) in lean individuals (BMI < 25 kg/m², or < 23 for Asians) is an emerging phenotype with unclear fibrosis risk and awareness. We compared liver fibrosis burden, undiagnosed rates, cardiometabolic profile, and temporal trends between Lean and Non-Lean MASLD using recent NHANES data. **Methods:** We conducted a cross-sectional analysis of NHANES 2017-2023 adults (≥ 18 years) with valid vibration-controlled transient elastography. MASLD defined as CAP ≥ 263 dB/m plus ≥ 1 cardiometabolic risk factor, excluding heavy alcohol and viral hepatitis. Lean defined as BMI < 25 (< 23 for Asians). Survey-weighted analysis compared mean liver stiffness (LSM), significant fibrosis (≥ 8.6 kPa), undiagnosed status, cardiometabolic risk factors, and temporal trends. Multivariable logistic regression with Lean MASLD as reference calculated adjusted odds ratios (aOR). Sensitivity analysis used CAP ≥ 285 dB/m. **Results:** Among 4,938 MASLD participants (weighted N ~159.5 million US adults), Lean MASLD patients (6.9%) had significantly lower mean LSM (5.06 vs 7.18 kPa, p < 0.001) and lower significant fibrosis prevalence (5.3% vs 16.4%, p < 0.001). Alarmingly, 98.3% of Lean MASLD and 99.1% of Non-Lean MASLD were undiagnosed. Cardiometabolically, Lean MASLD had lower dyslipidemia (27.3% vs 39.9%, p < 0.001), but similar rates of diabetes (22.5% vs 23.9%, p = 0.658), hypertension (37.7% vs 42.6%, p = 0.103), and prediabetes (49.0% vs 46.1%, p = 0.438). After multivariable adjustment, Lean MASLD was associated with significantly lower odds of significant fibrosis (aOR = 0.30, 95% CI: 0.18-0.49, p < 0.001). Female sex was protective (aOR = 0.74, 95% CI: 0.60-0.92, p = 0.008). Diabetes (aOR = 2.63) and hypertension (aOR = 1.63) were independent risk factors (both p < 0.001). Sensitivity analysis using CAP ≥ 285 dB/m confirmed findings. Temporal trend analysis showed no significant change in Lean MASLD proportion from pre-pandemic to post-pandemic (6.65% vs 7.22%, p = 0.637). **Conclusion:** Lean MASLD affects an estimated 11.1 million U.S. adults and is associated with substantially lower liver fibrosis burden compared with Non-Lean MASLD (70% lower adjusted odds). However, the very high proportion of undiagnosed disease across both phenotypes highlights an important gap in awareness and detection. These findings support consideration of fibrosis risk assessment in individuals with metabolic risk factors, including diabetes and hypertension, regardless of BMI status.

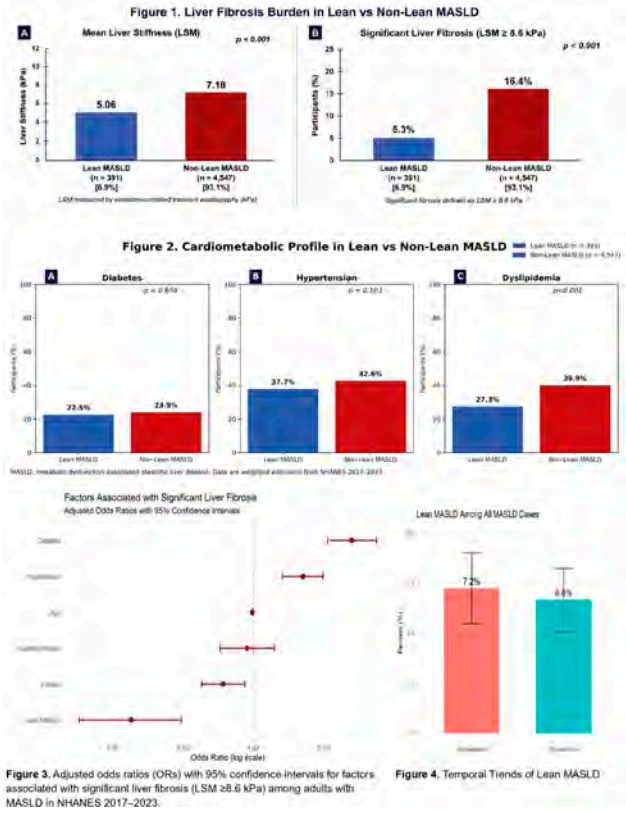

Figure 3. Adjusted odds ratios (ORs) with 95% confidence intervals for factors associated with significant liver fibrosis (LSM ≥8.6 kPa) among adults with MASLD in NHANES 2017–2023.

Figure 4. Temporal Trends of Lean MASLD

2569 | BRIDGING THE GAP BETWEEN MASLD TERMINOLOGY AND PATIENT PREFERENCES: A MULTINATIONAL SURVEY

Dana Ivancovsky Wajcman[1] Graciela Castro-Narro[2] Sara Fernández Hoffner[3] Marcela Villota[4] Melina Manolas[5] Vanessa Vilas-Riotorto[6] Anish Arora[7] Paul Brennan[8] Didac Mauricio[9] Damien Leith[8] Yumar Hidalgo[10] Veronika Vsetickova[11] José Willemse[12] Michael Betel[13] Faisal Alnase[14] Mohamed El-Kassas[15] Jeffrey Lazarus[4], [1]Barcelona Institute for Global Health (ISGlobal), [2]Hospital Médica Sur, Ciudad de México. Instituto Nacional de Ciencias Médicas y Nutrición, [3]Unidad de Hepatología y Trasplantes, Hospital Médica Sur, Mexico City, México, [4]Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, [5]Weill Cornell, [6]Faculty of Medicine and Health Sciences, University of Barcelona (UB), Barcelona, Spain, [7]Department of Health Sciences, Wilfrid Laurier University, Waterloo, Ontario, Canada, [8]University of Dundee, Division of Molecular and Clinical Medicine, School of Medicine, Dundee, Sc, [9]Department of Endocrinology & Nutrition, CIBERDEM, Hospital de la Santa Creu i Sant Pau, Barcelon, [10]Federación Nacional de Enfermos y Trasplantados Hepáticos (FNETH), Spain, [11]European Liver Patients' Association (ELPA), Brussels, Belgium, [12]Liver Patients International, Brussels, Belgium, [13]Fatty Liver Alliance, Toronto, Ontario, Canada, [14]Department of Primary Care & Public Health, Imperial College, London, UK, [15]Capital University

Background: The nomenclature for metabolic dysfunction-associated steatotic liver disease (MASLD) changed in 2023, yet little is known about patients' preferences for the new terminology and self-identification. This study evaluated terminology and self-description preferences among individuals with self-reported MASLD/ nonalcoholic fatty liver disease (NAFLD). **Methods:** A 15-question survey was disseminated in English (United States, United Kingdom, Canada), Spanish (Spain, Mexico), and Arabic (Egypt, Bahrain, Saudi Arabia) speaking countries through liver patient associations and hospitals. Only individuals who indicated a self-diagnosis of MASLD/NAFLD were eligible to participate. Individuals were asked to choose how they preferred to be identified (person/patient/no preference) and which term they preferred for their liver condition. Terms were classified as old (fatty liver/fatty liver disease/NAFLD), new (steatotic liver, steatotic liver disease/MASLD), or no preference. Demographic and anthropometric data were collected. Body mass index (BMI) was calculated and classified as normal (<25), overweight (25–29.99), or obesity (≥ 30). **Results:** From 420 individuals who started the survey, 58.8% (n = 247) had a self-reported MASLD/NAFLD diagnosis. Of those, 157 individuals were eligible and included in the analysis. Overall, 46.5% were women, the mean age was 48.8 years (SD = 13.4), and the mean BMI was 31.5 Kg/m² (9.1). Participants were from English (20.4%), Spanish (53.5%), and Arabic-speaking (26.1%) countries. Most individuals (51.6%) preferred to self-describe as a patient. Individuals preferring the term "patient" (compare to person) were significantly younger [47.2 (14.4) vs 51.2 (11.2), P = 0.034], had higher BMI [34.3 (10.8) vs 28.3 (4.4), P < 0.001], were more likely to be men (62.0% vs 37.7%, P = 0.004), and more likely to be from Arabic-speaking countries (46.9% vs 1.6%, P < 0.001). Most participants (36.9%) preferred the old terminology, while 31.6% preferred the new terminology, and 30.3% had no clear preference. Women and participants from English-speaking countries demonstrated a higher preference for the new terminology. A dose-response relationship was observed across BMI categories, with preferences for both the new terminology and self-identification as a patient increasing with higher BMI; these preferences were highest among individuals with obesity **(Figure 1). Conclusion:** A substantial gap exists between the recently adopted MASLD nomenclature and individuals' preferred terminology, with most participants favoring the former terminology. Preferences varied across demographic and cultural groups, suggesting that terminology is linked to individuals' identities and contexts. These findings highlight the need for patient-centered and culturally sensitive implementation strategies, incorporating patient perspectives to improve acceptance and engagement.

2570 | COMPARING AT-RISK POPULATION FOR MASLD SCREENING ACCORDING TO INTERNATIONAL GUIDELINE IN COMMUNITY-BASED COHORTS

Hanah Lee[1] Sang Gyune Kim[2] Soo Young Park[3] Young Youn Cho[1] Hyung Joon Kim[1] Yeon Seok Seo[4] Sung Hwan Yoo[5] Seung Up Kim[6] Dae Won Jun[7], [1]Chung-Ang University College of Medicine, Seoul, Korea, [2]Soonchunhyang University Bucheon Hospital, Seoul, Korea, [3]Kyungpook National University Hospital, School of Medicine, Kyungpook National University, Daegu, [4]Korea University, College of Medicine, Seoul, Korea, [5]Gangnam Severance Hospital, Yonsei University College of Medicine, Seoul, Korea, [6]Yonsei University College of Medicine, Seoul, Korea, [7]Hanyang University College of Medicine, Seoul, Korea

Background: Current guidelines provide heterogeneous definitions of the 'at-risk population' for metabolic dysfunction-associated steatotic liver disease (MASLD), resulting in substantial variability in screening eligibility. This study aimed to compare the "at-risk populations" requiring MASLD screening as defined by the five major guidelines, and to evaluate the burden of hepatic fibrosis and long-term outcomes according to key risk factors. **Methods:** We analyzed four community base cross-sectional cohorts (Korean MRE [N = 9,506], V-LINK health screening [N = 12,341], Japanese VCTE [N = 2,512], and US NHANES VCTE [N = 5,707]), and one hospital-based longitudinal cohort (V-LINK MASLD [N = 26,595]). We compared the fibrosis burden across different guideline-based 'at-risk population' for MASLD in the four community-based cohorts, and assessed their longitudinal prognostic performance for major adverse liver outcomes (MALO) in the hospital-based cohort. **Results:** Across the five guideline-based definitions, the proportion of individuals classified as the MASLD at-risk population varied substantially across the four community-based cohorts, ranging from 58.5% to 87.7%. In the US NHANES cohort, only 42.1% of individuals were consistently identified across all five guidelines. The overlap between the AASLD and EASL definitions was 68.7%, whereas the lowest concordance was observed between APASL and ADA, with only 59.8% of individuals overlapping. Despite this heterogeneity, four common risk factors were consistently associated with a high burden of significant hepatic fibrosis across the guidelines: imaging-defined steatosis, elevated ALT (> 40 U/L), type 2 diabetes, and obesity with additional cardiometabolic risk factors. Individuals with all four common risk factors also consistently showed a higher risk of MALOs in the longitudinal hospital-based cohort. **Conclusion:** The current five definitions of the 'at-risk population' for MASLD show substantial heterogeneity. Presence of four common risk factors across guidelines consistently identified individuals with a greater burden of hepatic fibrosis and a higher risk of MALOs.

2571 | LONGITUDINAL ALT MAINTANACE AND LIVER-RELATED EVENTS IN MASLD: A NATIONWIDE HEALTH-CHECKUP COHORT STUDY

Shun-Ichi Wakabayashi[1] Takefumi Kimura[1] Nobuharu Tamaki[2] Masayuki Kurosaki[2] Naoki Tanaka[1], [1]Shinshu University, [2]Musashino Red Cross Hospital

Background: ALT is routinely measured in checkups, but its value as a longitudinal surrogate of disease control in metabolic dysfunction-associated steatotic liver disease (MASLD) is uncertain. As biopsy and elastography are often unavailable outside specialist settings, a simple repeated biomarker linked to outcomes is needed. We aimed to determine whether the proportion of follow-up time with ALT < 30 U/L was associated with liver-related events (LREs) in a large Japanese MASLD cohort. **Methods:** Retrospective cohort study using Japanese claims database, linking claims with annual checkup data from Japanese employer-based insurance societies. Among 8,425,681 individuals, steatotic liver disease was defined by fatty liver index ≥ 60 or a fatty-liver diagnosis; after excluding other chronic liver diseases or prior LREs and restricting to MASLD, 1,362,475 were analyzed after multiple imputation (m = 20). The exposure was the proportion of follow-up time with ALT < 30 U/L; ALT ≥ 30 U/L was modeled as a time-varying covariate. The outcome was the first LRE (HCC, esophageal varices, hepatic ascites, hepatic encephalopathy). Cox models were adjusted for age, sex,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

smoking, diabetes, hypertension, and dyslipidemia, with estimates pooled by Rubin's rules. Three-year landmark Kaplan–Meier analyses across five categories (0%, 1–32%, 33–65%, 66–99%, 100%) used Holm-adjusted log-rank tests. **Results:** The MASLD cohort comprised 1,362,475 individuals (median follow-up 5.2 years, IQR 4.1–7.0), with 888 incident LREs. In the adjusted time-dependent Cox model, ALT ≥ 30 U/L was associated with markedly higher LRE risk (HR 2.27, 95% CI 1.96–2.62; $p < 0.001$), independent of age, sex, smoking, diabetes, hypertension, and dyslipidemia, with good discrimination (C-index 0.82). In the 3-year landmark analysis, 3-year LRE incidence decreased monotonically with greater proportion of time with ALT < 30 U/L, from 0.08% in the 0% group to 0.03% in the 100% group response between sustained ALT control and lower liver event risk. **Conclusion:** In a nationwide MASLD cohort, a higher proportion of follow-up time with ALT < 30 U/L was strongly and consistently associated with lower LRE incidence, with a clear dose–response across time-in-target. Longitudinal ALT control is a simple, routinely available metric to identify MASLD patients at higher risk of liver complications in non-specialist settings.

2572 | SEVERITY-GRADED CARDIOMETABOLIC AND HEPATIC BURDEN IN HEPATIC STEATOSIS: FINDINGS FROM THE PROSPECTIVE, POPULATION-BASED VCTE COHORT OF 2,979 SAUDI ADULTS (GENESIS STUDY)

Saleh Alqahtani[1] Shadan AlMuhaidib[2] Basmah Khoja[3] Mohammed Alghamdi[4] Haifa Otaibi[2] Mariam Seria[4] Layan Alsubki[5] Alwaleed Almojel[4] Nayef Alshabyli[6] Mohammed Aldrees[6] Alanood Aladel[7] Tatyana Kushner[8] Faisal Sanai[9] Waleed Alhazzani[2], [1]King Faisal Specialist Hospital & Research Center, [2]Research and Innovation Institute, Ministry of Defense Health Services, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [4]King Fahad Military Medical Complex, Dhahran, Saudi Arabia, [5]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [6]Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [7]King Saud University, Riyadh, Saudi Arabia, [8]Weill Cornell Medicine, New York, NY, USA, [9]King Abdulaziz Medical City, King Abdullah International Medical Research Center, Jeddah, KSA

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide, yet population-level data linking the severity of hepatic steatosis to metabolic and comorbid burden remain scarce in the Middle East. We aimed to characterize the gradient of cardiometabolic, hepatic, and comorbid markers across controlled attenuation parameter (CAP)–defined steatosis grades in a Saudi population-based cohort. **Methods:** We analyzed baseline data from the prospective, population-based GENESIS study conducted across seven Saudi primary care centers between March 2024 and June 2025. Adults underwent clinical assessment, laboratory testing, and vibration-controlled transient elastography using the SmartExam protocol on FibroScan Mini +430 (Echosens). Participants were classified by CAP into no steatosis (< 248 dB/m), mild (248–267), moderate (268–279), and severe (≥ 280 dB/m). Anthropometric, biochemical, and comorbidity measures were compared across groups using chi-square, one-way ANOVA, or Kruskal-Wallis tests. **Results:** Of 2,979 participants (mean age 41.9 ± 13.3 years; 49.7% men), 1,508 (50.6%) had no steatosis, 347 (11.6%) mild, 202 (6.8%) moderate, and 922 (30.9%) severe steatosis. Across the four CAP grades, group medians increased for body mass index (BMI) 26.4 to 31.9 kg/m², glycated hemoglobin (HbA1c) 5.5% to 5.9%, alanine aminotransferase (ALT) 15 to 24 U/L, gamma-glutamyl transferase (GGT) 16 to 28 U/L, and triglycerides 0.9 to 1.4 mmol/L, with mean waist circumference increasing from 87.4 ± 14.0 to 104.1 ± 14.0 cm (all $P < 0.001$). Comorbidity prevalence followed a similar gradient: diabetes 10.7% to 35.1%, hypertension 9.0% to 23.2%, and dyslipidemia 18.3% to 35.9% (all $P < 0.001$). Overall, 1,471 (49.4%) had hepatic steatosis on VCTE, and 1,111 met MASLD criteria, yielding a crude prevalence of 37.3% (95% confidence interval [CI] 35.6–39.0) and an age- and sex-adjusted prevalence of 34.2% (95% CI 32.5–35.9). Significant liver fibrosis (liver stiffness measurement ≥ 8 kPa) was identified in 57 participants (1.9%) overall, including 48 participants with MASLD (4.3% of the MASLD group). **Conclusion:** Hepatic

steatosis affects nearly half of Saudi adults, with CAP-defined severity tracking stepwise with cardiometabolic dysfunction and comorbidity. These findings provide the first prospective, population-level estimates of steatosis severity at a country level in Saudi Arabia and support scalable VCTE-based risk stratification in primary care.

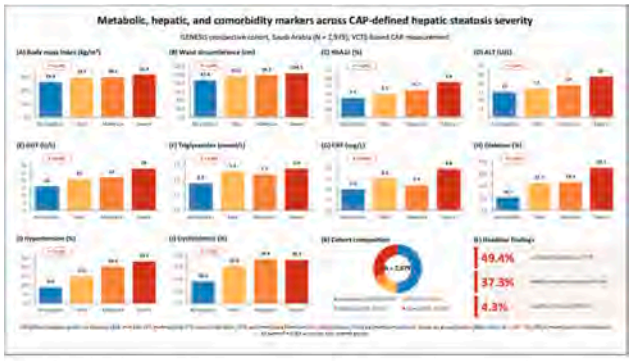

Figure 1. Metabolic, hepatic, and comorbidity markers across controlled attenuation parameter (CAP)–defined hepatic steatosis severity.
GENESIS prospective cohort, Saudi Arabia (N = 2,979). Panels (A)–(J) show stepwise increases in body mass index (BMI), waist circumference, glycated hemoglobin (HbA1c), alanine aminotransferase (ALT), gamma-glutamyl transferase (GGT), triglycerides, C-reactive protein (CRP), diabetes, hypertension, and dyslipidemia across the four CAP-defined steatosis grades (all $P < 0.001$). Panel (K) shows cohort composition; panel (L) summarises headline epidemiological findings, including metabolic dysfunction–associated steatotic liver disease (MASLD) prevalence. CAP-defined steatosis grades: no steatosis <248, mild 248–267, moderate 268–279, severe ≥280 dB/m. Vibration-controlled transient elastography (VCTE) performed using the SmartExam protocol on FibroScan Mini +430 (Echosens). Continuous values are group medians (BMI, HbA1c, ALT, GGT, triglycerides, CRP) or means (waist circumference).

2573 | SOCIAL VULNERABILITY AND SILENT FIBROSIS RISK IN MASLD: A NATIONAL NHANES VCTE ANALYSIS OF FOOD INSECURITY

Sri Ram Charan Gundapaneni[1] Serene Sara John[2] Mounika Kotte[3] Jagadish Koyi[4] Pragathi Munnangi[5] Hardik Dineshbhai Desai[6], [1]UCF/HCA Florida Ocala, [2]Detroit Medical Center, [3]Prime South Consortium, [4]Integris Health, Oklahoma City, [5]BronxCare Health System, [6]AB Plus Multispeciality Hospital, Ahmedabad

Background: Food insecurity is a major social determinant of cardiometabolic health, but its association with advanced hepatic fibrosis in metabolic dysfunction–associated steatotic liver disease remains unclear. We examined the national burden of food insecurity and its relationship with VCTE-defined advanced fibrosis among U.S. adults with MASLD. **Methods:** We analyzed NHANES 2017–March 2020 pre-pandemic adults aged ≥20 years with valid transient elastography. MASLD was defined as CAP ≥285 dB/m plus ≥1 cardiometabolic risk factor, excluding heavy alcohol use and hepatitis C. Food insecurity was assessed using the NHANES Food Security Questionnaire. Advanced fibrosis was defined as liver stiffness measurement ≥9.7 kPa. Survey-weighted prevalence estimates and logistic regression models were used. **Results:** Among 15,560 NHANES participants, 9,232 were adults, 7,395 had valid VCTE, 2,748 had CAP-defined steatosis, and 2,506 met MASLD criteria. The final analytic sample included 2,363 adults with MASLD and food security data, representing 66.3 million U.S. adults. Overall, 16.7% were food insecure, representing 11.1 million adults. Advanced fibrosis was present in 10.9%, corresponding to 7.2 million adults. Advanced fibrosis prevalence was 11.1% with full food security, 12.3% with marginal, 9.9% with low, and 8.5% with very low food security. When grouped, advanced fibrosis prevalence was 11.3% among food-secure/marginally secure adults versus 9.3% among food-insecure adults. Food-insecure adults with MASLD were younger than food-secure/marginally secure adults, with mean age 45.2 versus 52.0 years, had higher BMI, 35.7 versus 33.8 kg/m², and lower income-to-poverty ratio, 1.48 versus 3.45. Food insecurity was not associated with higher odds of advanced fibrosis in unadjusted analysis, OR 0.81, 95% CI 0.52–1.26, $p = 0.34$, or age/sex-adjusted analysis, OR 0.85, 95% CI 0.54–1.35, $p = 0.50$. In the fully adjusted model, food insecurity showed lower observed odds of advanced fibrosis, OR 0.56, 95% CI 0.32–1.00, $p = 0.049$, likely reflecting age and demographic structure rather than biological protection. **Conclusion:** Nearly 1 in 6 U.S. adults with MASLD experienced food insecurity. Food insecurity was not associated with higher advanced fibrosis prevalence; instead, affected adults represented a younger, higher-BMI, economically disadvantaged MASLD phenotype. These findings support fibrosis risk stratification that integrates social vulnerability with age, metabolic severity, and elastography-based assessment.

2574 | IBD IMPRINTS A PRO-TUMORIGENIC HEPATIC TRANSCRIPTOMIC SIGNATURE IN MASLD THAT PRECEDES AND IS AMPLIFIED BY FIBROSIS: A MULTICENTRE CLINICAL AND MOLECULAR STUDY

Maria Teresa Arias-Loste[1] Coral Rivas-Rivas[2] Sandra García-Mateo[3] Alfonso Bolado-Carrancio[4] Samuel Martinez-Dominguez[3] Enrique García-Nieto[5] sergio García-Mateo[3] Juan Carlos Rodriguez-Duque[5] Monserrat Rivero[5] Maria Escuin[3] María José García-García[5] Beatriz Gallego[3] Beatriz Castro[5] Marta Pascual[5] Carla Gargallo[3] Antonio Cuadrado[2] Fernando Gomollon[3] Jose Pedro Vaque[6], [1]Marqués de Valdecilla University Hospital. IDIVAL, [2]Clinical and Translational Research Group in Digestive Diseases, IDIVAL, [3]Hospital Clínico Universitario Lozano Blesa. Instituto Investigación Sanitaria de Aragon. CIBERehd, [4]Departamento de Biologia Molecular. Universidad de Cantabria, [5]Clinical and Translational Research Group in Digestive Diseases, IDIVAL. Santander. Spain, [6]Departamento de Biología Molecular. Universidad de Cantabria

Background: IBD confers excess cancer risk through disease-intrinsic and treatment-related mechanisms. MASLD is independently more prevalent in IBD and associated with extrahepatic malignancy. Whether IBD imprints a distinct oncogenic hepatic transcriptomic programme in MASLD and whether this translates into measurable clinical cancer risk remains undefined. **Methods:** Hepatic transcriptomics (limma-voom; GSEA; GEO: GSE268273) were analysed across three complementary pairwise models: IBD-MASLD vs. classical MASLD (Model A; n = 42 vs. 40, adj. BMI/sex/fibrosis); IBD-MASLD F ≥ 2 vs. F0-F1 (Model B; n = 7 vs. 35, adj. BMI/sex); and IBD-MASLD F ≥ 2 vs. classical MASLD F ≥ 2 (Model C; n = 7 vs. 16, adj. BMI/sex). For clinical validation, 1,508 IBD patients (712 CD, 796 UC) underwent prospective hepatic assessment by transient elastography at two Spanish tertiary centres. At-risk MASLD was defined as CAP ≥ 248 dB/m and LSM > 8 kPa. Cancer history was ascertained retrospectively and associations examined by logistic and Firth penalised regression adjusted for age and sex. **Results:** Transcriptomics identified a convergent pro-tumorigenic signature across all three models: coordinate suppression of the metallothionein tumour-suppressor cluster (MT1H, MT1M, MT1F, MT1G; $\log_2$FC up to −3.56 in Model C), upregulation of oncogenic drivers (IGFBP2, GDF15, MYC, SOX4, RRM2, SPP1), and collapse of the cytotoxic immune programme (PRF1, GNLY, EOMES, IL2RB). GSEA confirmed enrichment of cell cycle, Wnt/DVL degradation, and DNA replication pathways alongside depletion of metallothionein and cytokine-immune gene sets in all three models. This signature was detectable in non-fibrotic IBD-MASLD and progressively amplified with fibrosis advancement, with PTEN regulation uniquely enriched in Model C (NES +2.46). In the clinical cohort, only at-risk SLD and at-risk MASLD were significantly associated with digestive cancer prevalence (3.6% and 4.1% vs. 0.6% in the respective reference groups; p < 0.001). At-risk MASLD independently predicted digestive cancer (Firth OR 4.93, 95%CI 1.24–19.71; p = 0.024), and WHtR independently predicted digestive cancer risk as a continuous variable (Firth OR 3,761; p = 0.013) and overall cancer when dichotomised (OR 2.09; p = 0.006). **Conclusion:** IBD imprints a fibrosis-potentiated but fibrosis-independent pro-tumorigenic hepatic programme in MASLD, clinically translated into an independent digestive cancer risk emerging at the threshold of significant fibrosis and further amplified by visceral adiposity. These findings support systematic hepatic and anthropometric assessment in IBD as a cancer risk stratification strategy.

2575 | NEUROBEHAVIORAL BURDEN IN MASLD: PAIN-RELATED CONDITIONS, PSYCHIATRIC DISEASE, AND OPIOID USE DISORDER

Ihunanya Kanu[1] Omar Ebrahim Ibrahim[2] Sarpong Boateng[3] Chimezirim Ezeano[4] Ridwan Lawal[5] Oladoyin Ogunbayo-Jolaoye[6] Ifelunwa Osanakpo[7], [1]Baptist Memorial Hospital- Golden Triangle, [2]Baptist Memorial Hospital, [3]Yale New Haven Health, Bridgeport Hospital, [4]Advocate Aurora Healthcare, [5]University of Texas Rio Grande Valley, [6]university of illinois College of Medicine, [7]Carle Foundation Hospital

Background: MASLD is increasingly recognized as a multisystem disease extending beyond hepatic and metabolic complications. Pain-related conditions, psychiatric disease, and opioid use disorder may share behavioral, inflammatory, and neurobiological pathways that worsen quality of life and care complexity, yet their combined burden in MASLD remains poorly characterized. We examined pain-related conditions, psychiatric comorbidity, opioid use disorder, and overlapping neurobehavioral phenotypes among adults with EHR-documented MASLD/MASH in the All of Us Research Program. **Methods:** We conducted a cross-sectional analysis of adults $\geq$18 years with EHR data in the All of Us Controlled Tier Dataset v8. EHR-documented MASLD/MASH was identified using diagnosis concepts for nonalcoholic fatty liver disease, nonalcoholic steatohepatitis, and NASH-related cirrhosis, excluding alcoholic fatty liver and acute fatty liver of pregnancy. Pain-related conditions included chronic pain, back pain, fibromyalgia, neuropathic pain, arthritis, and osteoarthritis. Psychiatric comorbidity included depression, anxiety, and PTSD; opioid use disorder was identified using EHR diagnosis concepts. Composite phenotypes included pain-psychiatric and pain-psychiatric-OUD overlap. Multivariable logistic regression estimated adjusted odds of each outcome among adults with versus without MASLD/MASH, adjusting for age, BMI, sex at birth, race/ethnicity, and type 2 diabetes. Multinomial logistic regression assessed graded neurobehavioral burden across pain-related conditions, psychiatric comorbidity, and OUD. Analyses were performed using Python in Jupyter Notebook. **Results:** Among 388,424 adults with EHR data, 3,700 had EHR-documented MASLD/MASH. Pain-related conditions were present in 78.78% of adults with MASLD/MASH versus 45.59% without MASLD/MASH, opioid use disorder in 6.65% versus 3.62%, pain-psychiatric overlap in 55.11% versus 24.37%, and pain-psychiatric-OUD overlap in 5.89% versus 2.22%. After adjustment for age, BMI, sex at birth, race/ethnicity, and type 2 diabetes, MASLD/MASH was associated with higher odds of pain-related conditions (aOR 2.70, 95% CI 2.48–2.94), opioid use disorder (aOR 1.59, 95% CI 1.39–1.81), pain-psychiatric overlap (aOR 2.32, 95% CI 2.16–2.48), and pain-psychiatric-OUD overlap (aOR 1.82, 95% CI 1.58–2.11). A graded burden pattern was observed: compared with no neurobehavioral conditions, MASLD/MASH was associated with progressively higher adjusted odds of 1 condition (aOR 2.45, 95% CI 2.19–2.75), 2 conditions (aOR 4.09, 95% CI 3.67–4.57), and 3 conditions (aOR 4.86, 95% CI 4.10–5.77). **Conclusion:** Adults with EHR-documented MASLD/MASH had higher burdens of pain-related conditions, opioid use disorder, and overlapping pain-psychiatric phenotypes. These findings support integrating pain, mental health, and opioid-risk assessment into MASLD care.

2576 | IMPROVING EARLY DETECTION: A QUALITY IMPROVEMENT INITIATIVE FOR METABOLICALLY-DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)SCREENING IN AT-RISK POPULATIONS IN A RURAL ACADEMIC MEDICAL CENTER

Solomon Anighoro[1] Tsujung Yang[1] Ismaila Yusuf[1] John Pamula[1] Michelle Bernshteyn[1] Rajachandra Chakinalachakinala[1] Rewanth Katamreddy[1], [1]guthrie robert packer hospital

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: MASLD affects up to 38% of adults globally and approximately 70% of patients with type 2 diabetes mellitus, with a substantial proportion progressing to MASH and advanced fibrosis. Despite guideline recommendations for fibrosis screening using the FIB-4 index, implementation gaps remain significant - particularly in rural academic centers where access to hepatology is limited and competing clinical priorities are high. Guthrie Robert Packer Hospital (GRPH), a rural academic medical center in Sayre, Pennsylvania, identified a critical gap in MASLD screening among its internal medicine resident patient panel. **Methods:** A prospective QI study with retrospective chart review was conducted using Epic EHR data from GPRH's Internal Medicine Clinic. A 755-patient at-risk cohort was identified - adults aged 35-85 meeting ≥ 1 inclusion criterion: Type II DM, BMI ≥ 30 kg/m², ≥ 2 metabolic risk factors, incidental hepatic steatosis on imaging, first-degree relative with MASH cirrhosis, or known MASLD without prior NIT in the prior 2 years. Patients with known advanced fibrosis under active hepatology care, decompensated cirrhosis, HCC, pregnancy, or solid organ transplant were excluded. The multi-component intervention included resident education on current MASLD screening guidelines, instruction on FIB-4 calculation on EHR using a developed 'dot-phrase', a four-step MASLD screening flowsheet, and monthly individualized performance feedback to residents. The study interval was from October 1, 2025, to December 30, 2025. The primary aim was to increase the screening rate among eligible at-risk patients from baseline by $\geq 5.0\%$. Outcomes were assessed descriptively; no inferential statistical testing was performed, given the QI design. **Results:** The cohort was 55% (n = 416) male and 97% (n = 736) White, with a mean age of 64 years. Clinically, 75% had hypertension, 92% had ≥ 2 metabolic risk factors, 25% had a known MASLD diagnosis, and 14% were on GLP-1 therapy. At baseline, 0% (n = 0) of these 755 patients had screening or risk stratification in the prior 2 years. During the study period, 36% (n = 273) had a clinical encounter. Of these, 21% (n = 57) had risk stratification with documented FIB-4 scores - 7.55% of the total cohort, exceeding the primary $\geq 5.0\%$ target. Risk stratification: 67% low risk, 25% intermediate, 9% high risk. Of 14 intermediate-risk patients, 57% (n = 8) underwent ultrasound elastography, markedly exceeding the secondary $\geq 5.0\%$ target. Of 5 high-risk patients, 40% (n = 2) completed a MASLD-related GI visit. **Conclusion:** The structured QI initiative exceeded both MASLD screening targets within the first quarter at a rural academic center, demonstrating that education, clinical decision support tools, and performance feedback can rapidly improve FIB-4 implementation. Workflow automation via Epic OurPractice Advisory integration and expansion of this model to non-resident panels are the next steps.

2577 | PANCREATECTOMY AND RISK OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A PROPENSITY SCORE-MATCHED MULTICENTER COHORT STUDY

Omar Alkasabrah[1] Bayan Khasawneh[2] Mohamed Eldesouki[3] Tanuj Sharma[4] Banreet Dhindsa[5], [1]New York Medical College/Landmark Medical Center, Woonsocket, RI, USA, [2]Houston Methodist, Houston, TX, United States, [3]New York Medical College at Saint Michael Medical Center, [4]New York Medical College/Landmark medical center, Woonsocket, RI, United States, [5]Department of Gastroenterology and Hepatology, Warren Alpert School of Medicine at Brown University

Background: Patients with chronic pancreatitis or pancreatic cancer may ultimately require pancreatectomy, but its long-term impact on liver health is underexplored. Resection-induced exocrine/endocrine insufficiency, diabetes, and altered lipid metabolism may predispose patients to metabolic dysfunction-associated steatotic liver disease (MASLD). We evaluated the risk of MASLD and liver-related complications after pancreatectomy using a large multicenter database. **Methods:** We queried the TriNetX US Collaborative Network to identify adults (≥ 18 years) with chronic pancreatitis or pancreatic cancer who underwent pancreatectomy (study cohort) or did not (control cohort). MASLD was defined by ICD-10-CM codes for hepatic steatosis with ≥ 1 cardiometabolic risk factor (obesity, type 2 diabetes, hypertension, or hyperlipidemia), aligning with the Delphi consensus. Patients with pre-existing or competing chronic liver diseases (alcoholic, viral, autoimmune, or baseline cirrhosis) were excluded. Propensity score matching (PSM, 1: 1) was applied to balance baseline covariates (demographics, metabolic factors, comorbidities). Outcomes included new-onset MASLD, metabolic dysfunction-associated steatohepatitis (MASH), liver cirrhosis, and a composite liver outcome (cirrhosis, portal hypertension, varices, ascites, encephalopathy, hepatorenal syndrome) over a 5-year follow-up. Results were reported as adjusted odds ratios (aORs) with 95% confidence intervals (CIs). **Results:** Before matching, 11,802 pancreatectomy and 413,201 control patients were identified. After 1: 1 PSM, 10,577 patients remained in each cohort with well-balanced characteristics. Over 5-year follow-up,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

pancreatectomy was associated with significantly higher odds of MASLD (9.1% vs. 5.8%; aOR 1.62, 95% CI 1.45–1.79, p < 0.001) and composite liver outcomes (9.5% vs. 6.3%; aOR 1.57, 95% CI 1.42–1.74, p < 0.001). The incidence of MASH (0.4% vs. 0.4%; aOR 1.02, 95% CI 0.68–1.54, p = 0.92) and liver cirrhosis (0.5% vs. 0.3%; aOR 1.50, 95% CI 0.97–2.32, p = 0.07) did not differ significantly between cohorts. **Conclusion:** In this multicenter cohort study, pancreatectomy was associated with higher odds of MASLD and composite liver complications, without a clear increase in MASH or cirrhosis. These findings identify pancreatic resection as a high-risk setting for metabolic liver disease, supporting longitudinal hepatic surveillance and metabolic management post-resection.

Table 1. Baseline characteristics of patients with chronic pancreatitis or pancreatic cancer with and without pancreatectomy before and after propensity score matching.

Variables	Before PSM			After PSM		
	Pancreatectomy	No pancreatectomy	P-value	Pancreatectomy	No pancreatectomy	P-value
Number of patients	11,802	371,655	–	10,577	10,577	–
Age (yrs, mean ± SD)	64.0 ± 12.1	60.4 ± 14.9	<0.001	63.9 ± 12.1	64.4 ± 13.0	0.003

2578 | FIRST PROSPECTIVE COUNTRY-LEVEL PREVALENCE OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AND SIGNIFICANT FIBROSIS IN THE MIDDLE EAST: FINDINGS FROM SAUDI ARABIA&RSQUO;S GENESIS POPULATION-BASED COHOR

Saleh Alqahtani[1] Shadan AlMuhaidib[2] Faisal Sanai[3] Habeeb Razack[4] Abdulrahman Alnifayei[5] Salwa AlAwadh[6] Razan AlShammari[6] Layan Alsubki[7] Samar Alqussayer[2] Albandari Almotairi[8] Sara Khalil[9] Abdulmajeed AlMutairi[8] Shakir Alharthi[6] Hani Tamim[10] Basmah Khoja[7] Waleed Alhazzani[11], [1]King Faisal Specialist Hospital & Research Center, [2]Research and Innovation Institute, Ministry of Defense Health Services, Riyadh, Saudi Arabia, [3]King Abdulaziz Medical City, King Abdullah International Medical Research Center, Jeddah, KSA, [4]King Saud University, Riyadh, Saudi Arabia, [5]Family Medicine Department, Naval Base, Jeddah, Saudi Arabia, [6]Armed Forces Hospital, Dhahran, Saudi Arabia, [7]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [8]Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [9]King Fahad Armed Forces Hospital, Jeddah, Saudi Arabia, [10]Alfaisal University, Riyadh, Saudi Arabia, [11]Research and Innovation Institute, Ministryof Defense Health Services, Riyadh, SaudiArabia

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide, yet most population-level estimates are derived from Western or East Asian cohorts. Country-level, prospectively collected, vibration-controlled transient elastography (VCTE)-based estimates from the Middle East are largely absent and are needed to inform global burden modeling and screening policy. We aimed to estimate the national prevalence of MASLD and significant fibrosis and identify independent cardiometabolic and sleep-related predictors in Saudi adults. **Methods:** GENESIS is a prospective, national population-based cohort recruiting adults through community-based sampling across Saudi Arabia. All participants underwent VCTE (FibroScan) for controlled attenuation parameter (CAP) and liver stiffness measurement (LSM). MASLD was defined as hepatic steatosis on VCTE (CAP ≥ 268 dB/m) plus ≥ 1 of the 5 cardiometabolic risk factors per the 2023 multisociety Delphi consensus. Significant fibrosis was defined by LSM ≥ 8.0 kPa. High-risk

obstructive sleep apnea (OSA) was assessed using the Berlin Questionnaire. Prevalence estimates were age- and sex-standardized to the 2022 national census. Independent associations were assessed by multivariable logistic regression. **Results:** Among 2,979 adults with valid VCTE measurements, MASLD was identified in 1,111 (crude prevalence 37.3%; age- and sex-adjusted 34.2%, 95% confidence interval [CI] 32.5–35.9). Significant fibrosis was present in 48 participants with MASLD (4.3%). Diabetes (adjusted odds ratio [OR] 1.80), waist circumference (adjusted OR 1.35 per 5 cm), and high-risk OSA (adjusted OR 1.47) were independently associated with MASLD. Among participants with MASLD, diabetes (adjusted OR 4.41), male sex (adjusted OR 2.83), and waist circumference (adjusted OR 1.24 per 5 cm) were independently associated with significant fibrosis. **Conclusion:** In this first prospective country-level Middle Eastern cohort, MASLD was identified in 1 in 3 adults and significant fibrosis in 1 in 23 adults with MASLD. Diabetes and central adiposity were independently associated with both MASLD presence and significant fibrosis, while high-risk OSA was independently associated with MASLD presence. These findings support urgent integration of MASLD and fibrosis screening into high-yield clinical settings, particularly diabetes and obesity care, and provide a model for generating standardized VCTE-based burden estimates across the Middle East.

★ 2579 | DYNAMIC CHANGES IN STEATOTIC LIVER DISEASE SUBTYPE CLASSIFICATION AND PREDICTORS OF ADVANCED FIBROSIS IN LATIN AMERICA

Luis Antonio Diaz[1] Francisco Idalsoaga[1] Mario Pessoa[2] Claudia Oliveira[2] Patricia Ziteli[2] Scherezada Mejia[3] Ezequiel Ridruejo[4] mirta peralta[5] César Castro[6] Jorge Garavito[6] Rommel Zambrano-Huailla[6] Gustavo Ayares Campos[1] Nancy Solis[1] María Paz Orellana[1] Sebastian Marciano[7] Adrián Gadano[7] Jorge Martínez[7] Maria Jose Acosta[7] Martin Tagle[8] Hugo Cedron[8] Ismael Yepes[9] Dalis Perez[9] MaríaFernanda SaavedraChacón[10] Samuel Perez[10] Ignacio Garcia Juarez[11] Orfanel Sebastian Pineda-Arzate[12] Liz Toapanta-Yanchapaxi[12] Aline Sorribas[13] Manuel Mendizabal[13] Lorena Castro Solari[14] Loreto Aguilar Barría[15] Samantha Wu[15] Catalina Roa[15] Fabiana Nina[16] Estefanía Liza Baca[17] JAVIER DIAZ FERRER[17] Roberto Pérez Ravier[18] María Belen Martinez[18] Natalie Vilcinskas[18] Daniza Alexandra Contreras[19] Daniela Simian[20] Juan Roblero[21] Pamela Gil Galleguillos[20] Arun Sanyal[22] Juan Pablo Arab[22] Marco Arrese[1],
[1]Pontificia Universidad Católica de Chile, [2]University of São Paulo, [3]Hospital Juárez de México, [4]Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno "CEMIC, [5]Hospital Francisco J Muñiz, [6]Hospital Nacional Arzobispo Loayza, Lima, Perú, [7]Hospital Italiano de Buenos Aires, [8]Clínica Anglo Americana, [9]Centro Médico Gastropack, [10]Clínica CES, [11]The National Institute of Medical Science and Nutrition, [12]The National Institute of Medical Sciences and Nutrition, [13]Hospital Universitario Austral, [14]Clínica Universidad de los Andes, [15]Universidad de los Andes, [16]Universidad del Alba, [17]Hospital Nacional Edgardo Rebagliati Martins, [18]Hospital Central de Mendoza, [19]National Institute of Diabetes, Nutrition, and Endocrinology (INDEN), [20]Hospital Clínico Universidad de Chile, [21]University of Chile, [22]Virginia Commonwealth University

Background: Latin America is underrepresented in prospective steatotic liver disease (SLD) studies despite a high metabolic burden. This multinational study aims to identify the risk of advanced fibrosis across the SLD subtypes in Latin America. **Methods:** Cross-sectional analysis of prospectively enrolled adults with SLD (2023 criteria) at 16 tertiary centers in seven countries (Argentina, Brazil, Chile, Colombia, Dominican Republic, Mexico, and Peru) between 2024 and 2026. We performed standardized interviews and assessed fibrosis using liver biopsy or vibration-controlled transient elastography (VCTE) when biopsy was unavailable (advanced fibrosis: biopsy $\geq$F3 or VCTE $\geq$12 kPa). Predictors of advanced fibrosis were examined using binary logistic regression, including age, sex, ethnicity, body mass index (BMI), type 2 diabetes mellitus (T2DM), physical activity, and SLD subtype. **Results:** We included 914 participants (median age 62 [52–69] years; 56.6% women; 57.0% self-reported Hispanic ethnicity). The median BMI was 30.3 [27.3–34.0] kg/m^2, and 46.4% had T2DM. Based on registry diagnoses, 86.2% had MASLD, 5.4% MetALD, and 8.4% ALD. At enrollment, 87.8% with prior MetALD reported alcohol intake within the MASLD alcohol range, while 50.7% and 46.5% with prior ALD were within the MASLD and MetALD alcohol ranges, respectively (**Figure A**). Only 1.3% presumed MASLD cases were recategorized as MetALD or ALD, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

6.0% MetALD cases as ALD. Prevalence of advanced fibrosis was 35.5%. In the adjusted model, age (aOR 1.05, 95% CI 1.03–1.07; p < 0.0001), T2DM (aOR 3.65, 95% CI 2.32–5.74; p < 0.0001), MetALD (reference MASLD; aOR 2.72, 95% CI 1.32–5.58; p = 0.007) and ALD (reference MASLD; aOR 21.33, 95% CI 9.02–50.44; p < 0.0001) were independently associated with higher odds of advanced fibrosis, whereas those who walked >10,000 daily steps had lower odds (reference 1,000–5,000 daily steps; aOR 0.06, 95% CI 0.01–0.35; p = 0.002) (**Figure B**). **Conclusion:** In this multicenter Latin American SLD cohort, advanced fibrosis was common and mainly associated with alcohol intake (MetALD and ALD), T2DM, and older age, while physical activity was protective. The frequent discrepancy between self-reported alcohol intake at enrollment and registry-based historical diagnoses highlights the need for longitudinal ascertainment of prior alcohol exposure to improve SLD subtype classification and clinical decision-making (FONDECYT 1241450).

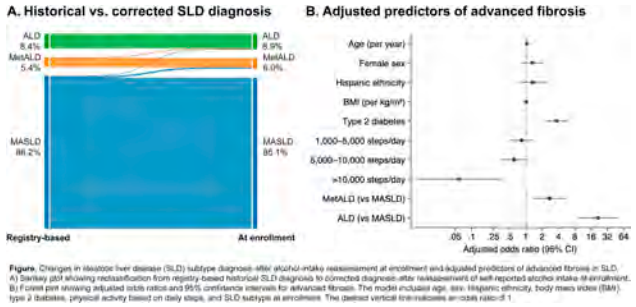

Figure. Changes in steatotic liver disease (SLD) subtype diagnosis after alcohol-intake reassessment at enrollment and adjusted predictors of advanced fibrosis in SLD. A) Sankey plot showing reclassification from registry-based historical SLD diagnosis to corrected diagnosis after reassessment of self-reported alcohol intake at enrollment. B) Forest plot showing adjusted odds ratios and 95% confidence intervals for advanced fibrosis. The model included age, sex, Hispanic ethnicity, body mass index (BMI), type 2 diabetes, physical activity based on daily steps, and SLD subtype at enrollment. The dashed vertical line indicates an odds ratio of 1.

2580 | PREVALENCE AND PREDICTORS OF LEAN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE AMONG ADULTS: A CROSS-SECTIONAL STUDY USING VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY AND METABOLIC PHENOTYPING

Noor Albusta[1] Ahmed Ali[2] Mohamed Hasan[2], [1]Lahey Hospital and Medical Center, [2]Bahrain Government Hospitals

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading global cause of chronic liver disease and is increasingly recognized among individuals without obesity. Lean MASLD may be particularly relevant in Middle East and North Africa (MENA) populations, where cardiometabolic risk and ethnicity-specific body composition may modify liver fat and fibrosis risk at lower BMI thresholds. However, regional data on lean MASLD remain limited. We aimed to characterize the prevalence, metabolic phenotype, fibrosis burden, and independent predictors of lean MASLD among adults undergoing vibration-controlled transient elastography (VCTE) in Bahrain. **Methods:** We conducted a cross-sectional study of consecutive adults (≥18 y) referred for VCTE (FibroScan) at Bahrain Government Hospitals from Jan 2024–Feb 2026. Exclusions included viral hepatitis, excess alcohol use, autoimmune/metabolic liver disease, decompensated cirrhosis, pregnancy, or prior LT. Steatosis was defined as CAP ≥275 dB/m; MASLD per 2023 Delphi criteria. Lean BMI was defined using ethnicity-specific cutoffs: <25 kg/m² for Arab/Caucasian and <23 kg/m² for South Asian adults. Fibrosis was assessed by LSM: <8, 8–12, and >12 kPa for no

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

significant, significant, and advanced fibrosis, respectively. Multivariable logistic regression identified predictors of lean MASLD. **Results:** Among 412 adults, mean age was 46.2 ± 12.8 years, 54.7% were male, 61.3% Bahraini, and 26.2% South Asian. Overall MASLD prevalence was 68.4% (282/412). By BMI category, MASLD was present in 19.2% of lean, 63.9% of overweight, and 87.6% of obese participants ($p < 0.001$); lean MASLD accounted for 3.4% of the total cohort. Lean MASLD patients had higher waist circumference than lean non-MASLD participants (86.4 ± 7.2 vs. 78.1 cm, $p < 0.001$), while CAP was lower than in non-lean MASLD (298 ± 24 vs. 326 ± 38 dB/m, $p = 0.001$). Despite lower steatosis burden, fibrosis estimates were comparable between lean and non-lean MASLD: LSM ≥ 8 kPa (21.4% vs. 28.1%, $p = 0.60$), LSM > 12 kPa (7.1% vs. 11.6%, $p = 0.61$), and FIB-4 (1.18 ± 0.62 vs. 1.24 ± 0.74, $p = 0.68$). ALT was normal in 71.4% of lean MASLD patients. South Asians had higher lean MASLD prevalence than Bahrainis (5.6% vs. 2.4%, $p = 0.04$), despite lower BMI. Independent predictors of lean MASLD were waist circumference ≥ 85 cm (aOR 3.42, $p = 0.004$), South Asian ethnicity (aOR 2.68, $p = 0.02$), and triglycerides ≥ 150 mg/dL (aOR 2.24, $p = 0.04$). **Conclusion:** Lean MASLD affected nearly one in five lean adults in this study and was often associated with normal ALT. Despite lower steatosis burden, fibrosis estimates were comparable to non-lean MASLD. South Asian ethnicity, increased waist circumference, and hypertriglyceridemia independently predicted lean MASLD, supporting ethnicity-sensitive screening strategies that incorporate central adiposity rather than BMI alone.

2581 | DECOMPENSATED LIVER DISEASE IN MASLD: WHO IS AT RISK IN A LARGE MULTI-ETHNIC US COHORT, AND DEVELOPMENT OF A 3-YEAR RISK SCORE

Sreepriya Balasubramanian[1] Maher Yassin[2] Varun Saxena[3] Nizar Mukhtar[4] Luis Rodriguez[5], [1]The Permanente Medical Group, [2]Department of Research, Kaiser Permanente, [3]University of California, San Francisco, [4]Kaiser Permanente San Francisco Medical Center, [5]Division of Research, Kaiser Permanente

Background: Despite increasing incidence of metabolic dysfunction–associated steatotic liver disease (MASLD), data on incidence and risk factors for liver decompensation are limited, particularly in multi-ethnic populations. The development of a risk score in a large, multi-ethnic US population would allow identification of patients at highest risk for decompensation early and inform targeted interventions to reduce disease progression. **Methods:** Within a cohort of 884950 adult Kaiser Permanente patients identified with MASLD from 1/2009 to 1/2019 using a validated MASLD prediction algorithm (diagnosis codes, radiology reports and the Dallas Steatosis Index (DSI)), we identified compensated advanced chronic liver disease (cACLD) between 1/2014 to 12/2021 based on at least one of: ICD 9/10 diagnosis of cirrhosis or F3 MASLD FIB4 score > 2.67 Transient elastography score > 10Kpa Hepatic decompensation was identified by ICD 9 codes for complications of cirrhosis, radiographic ascites, CPT codes for liver transplantation, endoscopy with variceal banding and paracentesis. Patients with < 1 year of membership prior and < 3 years of membership after cohort entry were excluded. Incidence of decompensation was calculated. We will develop a predictive score for decompensation using multivariable logistic regression using demographic and clinical data. Model performance will be evaluated using receiver operating characteristic (ROC) curves (C-statistic), sensitivity, specificity, positive predictive values, and number needed to evaluate across risk thresholds. **Results:** Among 884950 adults with MASLD, 93466 patients (11%) were identified with cACLD based on one or more of the following: ICD 9/10 diagnosis of cirrhosis (N = 4599) and F3 fibrosis MASLD (N = 152); FIB4 > 2.67 (N = 91727); Transient elastography score > 10Kpa (N = 1387). Mean (SD) age of the cohort was 66(12), with 51% women. Decompensation within one year of cohort entry was identified in 11114 patients (1.3%), with ICD 9/10 diagnosis of decompensation (N = 3241), Bilirubin > 2 mg/dl (N = 7102), CPT codes for paracentesis or variceal banding (N = 762), and liver transplantation (N = 9), and excluded from further analysis . A total of 54459 patients with cACLD and no prior decompensation were included for analysis of incidence of decompensation and development of the 3-year risk score, results of which will be presented. **Conclusion:** cACLD is found in approximately 11% of patients with MASLD in this large multi-ethnic US cohort, and is underdiagnosed, with only 4.8% identified by ICD 9/10 codes. Prevalent decompensation occurred in 1.3% of patients, with bilirubin > 2mg/dL as the most common marker. These findings highlight a large, high-risk population with unmet diagnostic need and support the development of a 3-year risk prediction tool to enable proactive risk-stratified care in MASLD. Additional results on incident decompensation and model performance will be presented.

2582 | DIETARY PATTERNS, ADEQUACY AND MODERATION COMPONENTS, AND RISK OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: FINDINGS FROM THE SHANGHAI SUBURBAN ADULT COHORT AND BIOBANK

Jiayi Xu[1] Xing Liu[1] Yiling Wu[2] Chunze Xu[2] Bo Chen[1] Jing Li[2] Wei Wang[3] Qin Wang[4] Xiedong Xu[5] Na He[1] Yonggen Jiang[2] Genming Zhao[1], [1]Department of Epidemiology, School of Public Health, Fudan University, Shanghai, China, [2]Songjiang District Center for Disease Control and Prevention, Shanghai, China, [3]Xinqiao Community Health Service Center, Songjiang District, Shanghai, China, [4]Sheshan Community Health Service Center, Songjiang District, Shanghai, China, [5]Maogang Community Health Service Center, Songjiang District, Shanghai, China

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a growing health burden closely related to dietary behaviors. This study aims to compare how different dietary patterns are related to the risk of MASLD in a Chinese population and to further examine whether adequacy and moderation components of diet-quality indices were differentially associated with MASLD risk. **Methods:** Participants free of MASLD at baseline were included from the Shanghai Suburban Adult Cohort and Biobank (SSACB) established since 2016 and followed-up until 2024. MASLD was diagnosed via ultrasonography with evaluation of cardiometabolic risk factors. Dietary intake was assessed using a validated food frequency questionnaire (FFQ). Adherence scores were calculated for the energy-standardized alternative Mediterranean Diet (aMED-e), the Chinese Healthy Diet Index (CHDI), and the Chinese Healthy Eating Index (CHEI). CHDI and CHEI were further separated into adequacy component scores, reflecting intake of recommended foods, and moderation component scores, reflecting limited intake of unfavorable dietary components. The aMED-e score was categorized into three groups: 0–3, 4–5, and 6–9 points, whereas CHDI and CHEI scores were categorized into quartiles. Multivariable Cox proportional hazards models were used to estimate hazard ratios and 95% confidence intervals. **Results:** A total of 11,358 participants were included, of whom 5,049 developed MASLD during a median follow-up of 4.28 years. Each 10-point increase in CHEI score was associated with a 3% lower risk of MASLD (HR = 0.97, 95% CI: 0.94–1.00, P = 0.033), while no significant association was observed for aMED-e (6–9 vs 0–3: HR = 1.02, 95% CI: 0.94–1.11) or CHDI (Q4 vs Q1: HR = 0.98, 95% CI: 0.90–1.07). Adequacy component scores of CHDI showed no association with MASLD risk (Q4 vs Q1: HR = 1.03, 95% CI: 0.95–1.12), while higher moderation component scores of CHDI were associated with lower MASLD risk (Q4 vs Q1: HR = 0.83, 95% CI: 0.76–0.90). For the adequacy component score of CHEI, modestly higher risks were observed in the intermediate quartiles, but the association was not statistically significant in the highest quartile (Q2 vs Q1: HR = 1.10, 95% CI: 1.02–1.19, Q3 vs Q1: HR = 1.10, 95% CI: 1.01–1.19, Q4 vs Q1: HR = 1.04, 95% CI: 0.96–1.14). Higher moderation component scores of CHEI were associated with lower MASLD risk (Q4 vs Q1: HR = 0.84, 95% CI: 0.77–0.91). Stratified analyses revealed that some heterogeneity was observed by sex, age, smoking, and alcohol consumption ($P_{heterogeneity}$ < 0.05). **Conclusion:** The moderation component scores of both CHDI and CHEI were inversely associated with the risk of MASLD in Chinese adults. These findings suggest that greater emphasis needed to be placed on limiting unfavorable dietary components rather than simply increasing recommended foods for MASLD prevention in Chinese population.

2583 | PREVALENCE AND METABOLIC PREDICTORS OF ADVANCED LIVER FIBROSIS USING AGE-ADJUSTED FIB-4 IN A REAL-WORLD COHORT OF MORE THAN 51,000 PRIMARY CARE PATIENTS

Adnan Baraka A Al Zanbagi[1] Faisal Sanai[2] Abdulaziz Tashkhandi[1] Ahmed Al-Ghamdi[3] Saleh Alqahtani[4] Khalid Alswat[5] Mohammed Shariff[1], [1]King Abdullah Medical City, [2]King Abdulziz Medical City, [3]Makkah Health Cluster, [4]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [5]King Saud University/KKUH

Background: Chronic liver disease remains underdiagnosed in primary care despite liver fibrosis being the strongest predictor of liver-related morbidity and mortality. Metabolic dysfunction-associated steatotic liver disease (MASLD) is strongly associated with obesity, diabetes mellitus, hypertension, and dyslipidemia and represents a growing public health burden worldwide. The Fibrosis-4 (FIB-4) index is a simple non-invasive tool derived from routinely available laboratory parameters that enables large-scale fibrosis risk stratification in primary care populations. **Methods:** This retrospective cross-sectional study evaluated primary care patients in the western region of Saudi Arabia with complete laboratory data enabling FIB-4 calculation. Patients with marked transaminitis (AST or ALT >400 U/L) or severe thrombocytopenia (platelet count $<100\times10^9$/L) were excluded to minimize overestimation of fibrosis risk unrelated to chronic liver disease. Age-adjusted FIB-4 thresholds were applied according to AASLD guidance. Metabolic risk was defined as the presence of one or more of the following: overweight/obesity, diabetes mellitus, hypertension, or dyslipidemia. Associations between fibrosis risk and metabolic factors were analyzed using subgroup and comparative statistical analyses. **Results:** A total of 51,445 patients met inclusion criteria. Using age-adjusted FIB-4 thresholds, 45,913 (89.2%) patients were classified as low risk, 4,892 (9.5%) as intermediate risk, and 640 (1.2%) as high risk for advanced fibrosis (Figure below). Patients with one or more metabolic risk factors demonstrated a higher prevalence of high-risk FIB-4 compared with metabolically healthy individuals (1.62% vs 0.80%, OR 2.31, 95% CI 1.73–3.08; $p<0.001$). Age-stratified analysis demonstrated increasing prevalence of high-risk FIB-4 with advancing age (<35 years: 0.1%, 35–64 years: 1.0%, ≥65 years: 5.3%; $p<0.001$) (Figure below). Intermediate-risk FIB-4 prevalence was also highest among patients aged ≥65 years (42.0%). High-risk FIB-4 prevalence by BMI category was 1.67% in overweight patients, 1.62% in normal BMI, 1.39% in obesity class I, 1.31% in obesity class II, and 1.19% in obesity class III patients. **Conclusion:** In this large real-world primary care cohort, approximately 10% of patients demonstrated intermediate or high-risk age-adjusted FIB-4 scores suggestive of clinically significant fibrosis risk. Metabolic dysfunction was strongly associated with advanced fibrosis risk, while severe obesity alone was not independently associated with higher fibrosis prevalence after age adjustment. These findings support implementation of non-invasive fibrosis screening strategies in primary care populations with metabolic disease and highlight the importance of age-adjusted FIB-4 interpretation in fibrosis risk assessment.

Mendler[1], [1]California Liver Research Institute, [2]California Liver Reasearch Instituite

Background: Racial and ethnic disparities in MASLD severity reflect differences in socioeconomics, lifestyle, and metabolic syndrome (MS). This study examined these in a large, diverse cohort in a non-academic hepatology clinic in Los Angeles County (LAC). **Methods:** A retrospective cross-sectional study of MASLD patients diagnosed by AASLD criteria, capturing a data within the first 6 months of initial presentation. MASLD was diagnosed with steatosis on CAP or other imaging, at least one metabolic syndrome (MS) component, with no other liver comorbidities. Fibrosis assessed by VCTE (kPa) and cirrhosis by usual imaging criteria. Continuous variables expressed as mean ± SD compared by t-test/ANOVA; categorical variables by chi-square; multivariate analyses by nominal logistic stepwise modeling. Significance: $p < 0.05$. **Results:** 2,488 patients seen between 2008-2023; mean age 53.1 ± 14.0y, 61.5% female, 64.2% married. Of the 1,811 who self-identified race, 38.7% were Caucasian, 1.9% Black, 19.1% Asian, and 40.3% other-Non-Caucasian. Of 1,981 who self-identified ethnicity, 55.7% were Hispanic/Latino (HL) and 44.3% were Non-Hispanic/Latino (NHL). Mean Area Deprivation Index (ADI; 1-10, least to most disadvantaged) was 4.6 ± 1.9: 30.0% ADI 1-3, 53.1% ADI 4-6, 16.9% ADI 7-10. 14.3% reported minimal/occasional alcohol use. Mean BMI was 32.1 ± 6.3 *kg*/m^2 : 9.4% lean, 31.9% overweight, 58.7% obese. 41.2% had DM2, 44.3% dyslipidemia, 46.3% HTN. Those with MS data: 29.7% had 1, 29.6% had 2, 26.5% had 3, and 14.2% had 4 components. 11.9% had cirrhosis; 85.3% had an ultrasound/imaging confirmation of MASLD. VCTE and CAP (n = 1,376): mean kPa 9.0 ± 6.6, CAP 318 ± 44 dB/m; IQR 13.5 ± 6.0. Mean HbA1c 6.6 ± 1.5%, platelets 251.8 ± 77.3x10^3 /µL, AST 46.1 ± 37.0 U/L, ALT 65.0 ± 53.1 U/L, ALP 89.6 ± 40.2 U/L, and AST/ALT ratio 0.83 ± 0.39. 73.7% had follow-up visits with a mean follow-up of 2.6 ± 3.2 years. As compared to NHL, HL had significantly higher BMI ($p < 0.0001$), rates of DM2 ($p = 0.0012$), greater numbers of MS components ($p = 0.0010$), greater socioeconomic deprivation ($p < 0.0001$), higher significant fibrosis [kPa ≥ 8 (≥ F2), $p = 0.0006$], and cirrhosis (15.0% vs 10.2%, $p = 0.0014$). On multivariate analysis: BMI, ALP, and HbA1c were independently associated with significant steatosis grade (S2+, AUC = 0.68); BMI, diabetes, age, CAP steatosis grade, and HL ethnicity were independently associated with significant fibrosis (kPa ≥ 8, AUC = 0.73); and low platelets, older age, elevated ALP, elevated HbA1c, and higher BMI with cirrhosis (AUC = 0.80). **Conclusion:** In this diverse Southern California MASLD cross-sectional group at initial diagnosis, as compared to NHL, HL patients presented with higher BMI, greater number of MS components, increased socioeconomic disparities, and higher degree of fatty liver, fibrosis and cirrhosis.

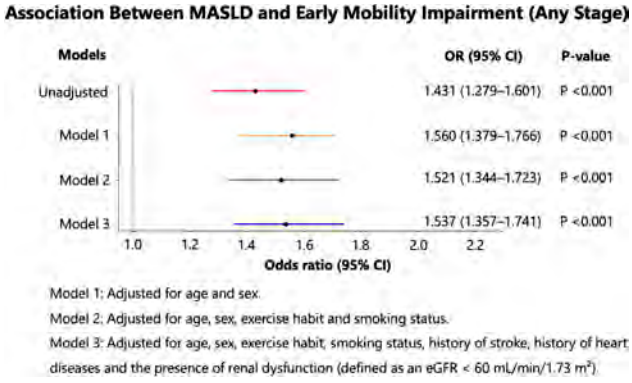
2585 | EARLY MOBILITY IMPAIRMENT AS A FUNCTIONAL PHENOTYPE OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE



Shinya Yokoyama[1] Takashi Honda[1] yoji ishizu[1] Norihiro Imai[2] Takanori Ito[1] Kenta Yamamoto[1] Tetsuhito Kojima[3] Naoyoshi Kariya[3] Hiroki Kawashima[1], [1]Nagoya University, [2]Nagoya University Graduate School of Medicine, [3]Aichi Health Promotion Foundation

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is increasingly recognized as a systemic cardiometabolic disorder with clinically relevant extrahepatic manifestations. However, its association with early functional decline remains unclear. Early mobility impairment may represent an early musculoskeletal phenotype of metabolic dysfunction before overt frailty, sarcopenia, or disability. We examined the association between MASLD and early mobility impairment in a large health examination cohort. **Methods:** This retrospective cross-sectional study included 7,776 adults who underwent health examinations between April 2018 and March 2025. MASLD was defined as ultrasonographic liver steatosis with cardiometabolic risk factors and alcohol intake below prespecified thresholds. Early mobility impairment was assessed using an established, standardized, equipment-free mobility-assessment battery consisting of the stand-up test, two-step test, and 25-question Geriatric Locomotive Function Scale. Participants were classified into stages 0–3 according to mobility impairment severity. Multivariable logistic regression was performed with adjustment for demographic, lifestyle, and comorbidity factors. **Results:** MASLD was present in 27.5% of participants. Early mobility impairment was more prevalent in individuals with MASLD than in those without (29.4% vs. 22.5%, $P < 0.001$). Early mobility impairment was independently associated with MASLD (adjusted odds ratio [OR] 1.537, 95% confidence interval [CI] 1.357–1.741, $P < 0.001$). A graded association was observed, with each one-stage increase in early mobility impairment being associated with higher odds of MASLD (adjusted OR 1.336, 95% CI 1.216–1.468, $P < 0.001$). This association was significant in participants aged <

65 years (OR 1.712, 95% CI 1.488–1.969) but not in those aged ≥ 65 years (OR 1.217, 95% CI 0.922–1.606; P for interaction = 0.0097). Among the three components of early mobility impairment, the two-step test showed the largest effect size (OR 1.759, 95% CI 1.437–2.152, P < 0.001). Obesity was consistently associated with early mobility impairment regardless of MASLD status, whereas hypertension showed an additional association with early mobility impairment only in the MASLD group. **Conclusion:** MASLD was independently associated with early mobility impairment, particularly in adults younger than 65 years. These findings suggest that simple mobility assessment may capture a clinically relevant extrahepatic phenotype at the metabolic–musculoskeletal interface and help identify individuals with MASLD who are vulnerable to early functional decline before overt frailty or disability. Incorporating mobility assessment into routine metabolic health screening may support earlier risk stratification and preventive intervention.

2586 | ROLE OF LATINO ETHNICITY IN POST-LIVER TRANSPLANT AND CARDIOMETABOLIC OUTCOMES FOR MASH

John Elsanadi[1] Jason Pan[1] Katherine Meneses[1] Mark Ebaid[1] Angshuman Saha[1] Sammy Saab[1], [1]David Geffen School of Medicine at UCLA

Background: Metabolic dysfunction-associated steatohepatitis (MASH) has become a leading indication for liver transplantation (LT). Emerging data suggests metabolic syndrome in LT recipients for MASH is substantial (Chan et al., 2025). Latino populations bear a disproportionate burden of MASH (Cumpian et al., 2025). However, granular data regarding post-LT outcomes is limited. We examined whether Latino ethnicity is associated with differences in cardiometabolic outcomes post-LT for MASH. **Methods:** This single-center retrospective study evaluated medical records of patients with MASH over 18 years of age who underwent LT between 2014 to 2024, noting pre-, post-LT outcomes and diagnoses including coronary artery disease (CAD), obesity, diabetes mellitus (DM), hypertension (HTN), hyperlipidemia (HLD). **Results:** Between 2014 to 2024, 332 patients at our center underwent LT for MASH, including 211 Latino recipients (63.6%) and 121 non-Latino recipients (36.4%). Latino recipients had lower median household income ($86,195 vs $103,803, p < 0.001) and greater possession of public insurance (69.2% vs 55.4%, p = 0.043) compared to non-Latinos. Pre-LT, Latino and non-Latino patients had significant differences in obesity (51.2% vs 38%, p = 0.028) and CAD (24.6% vs 36.4%, p = 0.032). Post-LT, the prevalence of obesity decreased in Latino patients and increased in non-Latino patients, while CAD increased in Latino patients. Subsequently, Latino and non-Latino patients had no significant post-LT differences in obesity (45.5% vs 43.0%, p = 0.741), DM (66.7% vs 57.0%, p = 0.102), HLD (58.1% vs 53.7%, p = 0.51), HTN (71.0% vs 77.7%, p = 0.228), CAD (33.2% vs 35.5%, p = 0.751). Post-LT, Latino and non-Latino patients had similar 1-year post-LT survival (92.9% vs 90%, p = 0.489), retransplant rates (2.4% vs 0.8%, p = 0.557), liver rejection (19.9% vs 17.4%, p = 0.656), median time to death (1.27 vs 2.23 years, p = 0.773). Kidney transplantation was more common among non-Latino recipients (14.2% vs 23.1%, p = 0.056). Only 19% of the post-LT population has had transient elastography with reassuring results: mean liver stiffness of 8.0 kPa (StD: 9.6) and CAP 270.7 db/m (StD: 53.3). **Conclusion:** Latino recipients represented nearly two-thirds of patients undergoing liver transplantation for MASH and achieved post-transplant cardiometabolic outcomes and survival rates comparable to those of non-Latino recipients despite greater socioeconomic disadvantage and a higher occurrence of pretransplant obesity. Persistent cardiometabolic dysfunction remained highly prevalent in both groups, and cardiovascular and cerebrovascular events were the leading documented case of death. Development of targeted surveillance and interventions pre-LT (prevention of obesity in Latino and early identification of CAD in non-Latino patients) may improve care consistency and long-term outcomes as MASH-related transplantation grows.

2587 | LEAN PHENOTYPE IN METALD AND ALD WAS ASSOCIATED WITH ADVERSE OUTCOMES ACROSS EAST ASIAN COHORTS: EAST ASIA LIVER ALLIANCE (EALA)

Norihiro Imai[1] Hanah Lee[2] Young-Sun Lee[3] Shang-Chin Huang[4] Kai-Chi Chang[5] Shih-Chieh Chien[6] Shun-Ichi Wakabayashi[7] Takefumi Kimura[8] Nobuharu Tamaki[9] Seung Up Kim[10] Sang Gyune Kim[11] Dae Won Jun[12] Soo Young Park[13] Tung-Hung Su[5] Jia-Horng Kao[5] W. Ray Kim[14] Takumi Kawaguchi[15] Jee-Fu Huang[16] Ming-Lung Yu[17] Young Suk Lim[18] Tetsuo Takehara[19], [1]Nagoya University Graduate School of Medicine, [2]Chung-Ang University College of Medicine, [3]Korea University College of Medicine, [4]National Taiwan University, [5]National Taiwan University Hospital, [6]National Cheng Kung University Hospital, [7]Shinshu University School of Medicine, [8]Shinshu University, [9]Musashino Red Cross Hospital, [10]Yonsei University College of Medicine, [11]Mayo Clinic Rochester, [12]Hanyang University College of Medicine, [13]Kyungpook National University, [14]Mayo Clinic Arizona, [15]Kurume University School of Medicine, [16]Kaohsiung Medical University Hospital, [17]Kaohsiung Medical University/ Kaohsiung Medical University Hospital, [18]University of Ulsan College of Medicine, [19]Kansai Rosai Hospital

Background: Body mass index (BMI), in particular lean, is a fundamental clinical parameter in steatotic liver disease (SLD). However, metabolic dysfunction–associated steatotic liver disease with increased alcohol intake (MetALD) and alcohol-associated liver disease (ALD) are currently subclassified primarily based on alcohol consumption. This study aimed to investigate the clinical characteristics of MetALD and ALD, focusing on the lean phenotype. **Methods:** We analyzed three independent cohorts: a Japanese health checkup-based MetALD cohort (N = 108,494), a Korean multicenter hospital-based MetALD cohort (V-LINK, N = 35,087), and a Taiwanese hospital-based ALD cohort (N = 1,352). Patients with MetALD and ALD were subclassified by BMI as lean (BMI < 23 kg/m²) or non-lean (BMI ≥ 23 kg/m²). **Results: :** (1) **In the Japanese health checkup-based cohort**, patients with lean MetALD were significantly older, consumed less alcohol, and had fewer cardiometabolic risk factors than those with non-lean MetALD (all $P < 0.01$). Despite this, the lean group exhibited significantly higher liver injury markers, including FIB-4 index (1.52 vs. 1.29, $P < 0.01$). Moreover, the cumulative incidence of liver-related events (LRE) was significantly higher in lean MetALD than in non-lean MetALD (5-year incidence: 0.18% vs. 0.09%, respectively, $P = 0.011$). Notably, no significant difference was observed in the cumulative incidence of 3-point major adverse cardiovascular events between the two groups (5-year incidence: 0.4% vs. 0.5%, respectively, $P = 0.39$). (2) **In the Korean multicenter hospital-based cohort,** BMI-based subclassification revealed distinct clinical phenotypes consistent with those observed in the Japanese health checkup cohort, including a significantly higher FIB-4 index in lean MetALD (3.46 vs. 1.69, $P < 0.01$). The cumulative incidence of LRE was also significantly higher in lean MetALD than in non-lean MetALD (5-year incidence: 21% vs. 7%, respectively, $P < 0.001$). Furthermore, multivariable analysis adjusting for age and sex showed that lean status was an independent risk factor for LRE (hazard ratio 2.75, $P < 0.001$). (3) **In the Taiwanese hospital-based ALD cohort**, with a median follow-up duration of 6.9 years and 501 deaths, lean patients with ALD had a worse prognosis after multivariable adjustment for age, sex, cirrhosis, alanine aminotransferase level, diabetes mellitus, and other metabolic comorbidities (hazard ratio 1.45, $P < 0.001$). **Conclusion:** This study provides robust evidence from three independent East Asian cohorts that the lean phenotype in MetALD and ALD was associated with adverse outcomes.

2588 | IMPACT OF ORTHOPEDIC CONDITIONS ON BMI TRAJECTORIES IN VETERANS WITH MASLD UNDERGOING LIFESTYLE-BASED WEIGHT MANAGEMENT

Rajat Chandra[1] David Kaplan[2] Nadim Mahmud[3], [1]Massachusetts General Hospital, [2]University of Pennsylvania, [3]Hospital of the University of Pennsylvania

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of liver disease globally. Lifestyle modification to achieve clinically significant weight loss remains first-line therapy, with >7-10% weight loss associated with histologic improvement. However, prior studies of MOVE!, a nationally implemented Veterans Health Administration (VHA) lifestyle-based weight management program, have shown limited efficacy. Patients with orthopedic injuries may benefit even less from lifestyle interventions due to impaired mobility and reduced activity. We therefore investigated body mass index (BMI) trajectories for VHA patients with MASLD enrolled in MOVE! according to the presence and type of orthopedic conditions. **Methods:** This was a retrospective cohort study of US VHA patients with MASLD and BMI $\geq$35kg/m^2 enrolled in MOVE! between 2008 and 2022 without prior bariatric surgery or glucagon-like peptide-1 receptor agonist (GLP-1RA) use. Baseline demographic, BMI, comorbidity, and laboratory data were obtained. Using a validated algorithm based on diagnosis codes, orthopedic conditions (primary exposure) were categorized as: (1) emergent or urgent (e.g. dislocations, fractures) and (2) nonurgent (e.g. sprains, osteoarthritis). Multivariable Cox regression was used to evaluate risk of both 10% BMI reduction and 10% BMI gain in patients with or without orthopedic injury. Patients were right-censored at GLP-1RA initiation, bariatric surgery, or maximum follow-up, up to 18 years. **Results:** Of the 115,550 patients meeting inclusion criteria, 345 had emergent or urgent orthopedic injury, 12,694 had nonurgent orthopedic injury, and 102,511 control patients had no orthopedic injury. The emergent or urgent patients had higher rates of cardiovascular and thromboembolic comorbidities compared to nonurgent and control patients, including coronary artery disease (20% vs 15% vs 15%, p = 0.009), deep vein thrombosis (4.9% vs 2.2% vs 1.7%, p < 0.001), and pulmonary embolism (2.0% vs 1.5% vs 1.3%, p = 0.020). Overall, 9.5% of patients had 10% BMI gain and 27.1% achieved 10% BMI loss. The adjusted hazard ratios for 10% BMI gain were 1.58 (95% confidence interval [CI]: 1.27 to 1.97, p < 0.001) for the emergent or urgent group and 1.16 (95% CI: 1.11 to 1.22, p < 0.001) for the nonurgent group, relative to the control group. Figure 1 shows BMI trajectories and adjusted Cox survival curves for 10% BMI gain. Adjusted hazard ratios for 10% BMI loss were similar for patients with and without orthopedic injury (p > 0.05). **Conclusion:** Orthopedic conditions, particularly emergent or urgent injuries, were associated with significantly increased risk of clinically meaningful BMI gain among VHA patients with MASLD participating in MOVE!. These findings suggest that patients with orthopedic conditions may benefit from earlier consideration of more intensive weight loss interventions, such as GLP-1RAs or bariatric surgery.

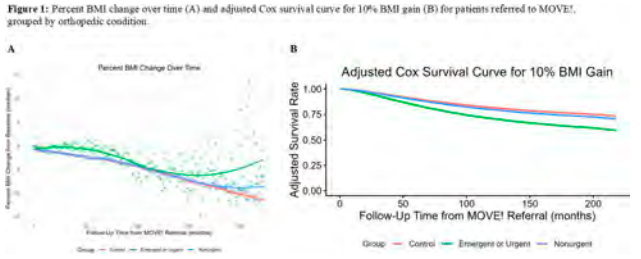

Figure 1: Percent BMI change over time (A) and adjusted Cox survival curve for 10% BMI gain (B) for patients referred to MOVE!, grouped by orthopedic condition.

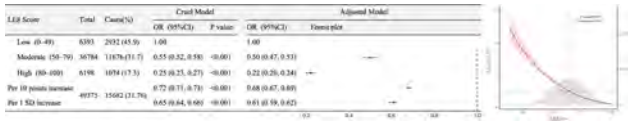
2589 | ASSOCIATION BETWEEN THE LIFE'S ESSENTIAL 8 SCORE AND MASLD: A CROSS-SECTIONAL STUDY AMONG COMMUNITY RESIDENTS IN SHANGHAI



Qi Zhang[1] Xing Liu[1], [1]Fudan University

Background: To investigate the association between the Life's Essential 8 (LE8) score and metabolic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

dysfunction-associated steatotic liver disease (MASLD) among community residents in Shanghai, and to provide evidence for MASLD prevention through lifestyle interventions. **Methods:** This study was based on baseline data collected from 2016 to 2019 in the Shanghai Suburban Adult Cohort and Biobank (SSACB) and included adults aged from 20 to 74. Demographic characteristics and lifestyle factors were collected by standardized questionnaires. MASLD was defined as the presence of hepatic steatosis identified by abdominal ultrasonography in individuals with at least one of five cardiometabolic risk factors, after exclusion of excessive alcohol consumption and other chronic liver diseases. The LE8 score was calculated based on the scoring algorithm proposed by the American Heart Association (AHA), with localized adaptations for Chinese population.The total LE8 score was calculated as the arithmetic mean of the eight component scores, ranging from 0 to 100, and was further categorized into low (0–49 points), moderate (50–79 points), and high cardiovascular health (80–100 points).Multivariable logistic regression models and restricted cubic spline (RCS) models were constructed after adjustment for confounders to assess the association between the LE8 score and the prevalence of MASLD. Stratified analyses were further performed according to demographic characteristics. **Results:** A total of 49,375 individuals were included in the study, and 15682 (30.8%) participants were determined to have MASLD. The mean LE8 score was significantly lower among participants with MASLD than among those without MASLD (60.8 ± 12.4 vs. 66.2 ± 12.8, P < 0.001). According to CVH categories, 6,393 (12.9%) ,36,784 (74.5%) and 6,198 (12.6%) participants were respectively classified into the low,moderate and high CVH group. Multivariable logistic regression models shows that compared with participants in the low CVH group, those in the moderate and high CVH groups had a 50% (OR = 0.50, 95% CI: 0.47–0.53; P < 0.001) and 78% (OR = 0.22, 95% CI: 0.20–0.24) lower odds of MASLD, respectively. Each 10-point increase in LE8 score was associated with a 32% lower odds of MASLD (OR = 0.68, 95% CI: 0.67–0.69). Stratified analyses showed that the inverse association between LE8 score and MASLD was more pronounced among women (OR = 0.62, 95% CI: 0.61–0.63), younger participants aged 20–39 years (OR = 0.62, 95% CI: 0.58–0.66) and participants with college education or above (OR = 0.66, 95% CI: 0.62–0.71). RCS analysis results suggested a significant nonlinear inverse association between LE8 score and MASLD risk (P for overall < 0.001, P for nonlinearity < 0.001). **Conclusion:** A higher LE8 score is significantly associated with a lower prevalence of MASLD. Maintaining a healthy lifestyle may help prevent MASLD.

Disclosures: Qi Zhang: Nothing to Disclose, Xing Liu: Nothing to Disclose.

2590 | COMPARATIVE EFFECTIVENESS OF FACTOR XA INHIBITORS AND WARFARIN ON HEPATIC OUTCOMES IN MASLD

Erik Almazan[1] Jonggi Choi[2] Tushar Kamath[2] Vy Nguyen[2] Eric Przybyszewski[2] Jiunn Song[3] Allison Carroll[2] Megan Michta[2] Tracey Simon[2] Raymond Chung[2], [1]Brigham and Women's Hospital, [2]Massachusetts General Hospital, [3]Massachussetts General Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease in the U.S. and frequently coexists with conditions requiring anticoagulation. Preclinical studies suggest that Factor Xa inhibitors (FXai) may confer hepatoprotective benefits through antifibrotic and anti-inflammatory mechanisms, yet clinical evidence is limited. We explored whether FXai use, compared with warfarin, is associated with differences in hepatic complications in pre-cirrhotic MASLD. **Methods:** Using the NIH's *All of Us* Research Program (Controlled Tier v8), we conducted a target trial emulation comparing adults with MASLD and type 2 diabetes (T2DM) who initiated FXai (apixaban and rivaroxaban) versus warfarin from 2013-2023. Participants with HBV, HCV, alcohol-associated liver disease, HIV, organ transplant, FIB-4 $\geq$2.67, or primary outcome components were excluded. The primary analysis used pooled inverse probability of treatment weighting (IPTW) at a 2-year MASLD ascertainment window, fitting a propensity score (PS) on 31 unique covariates with a weighted Cox model adjusting for calendar year. Sensitivity analyses included per-trial-year IPTW and 1: 1 PS matching. Analyses were replicated across 0-, 1-, and 3-year ascertainment windows. Cox models added imbalanced covariates (|SMD|$\geq$0.1) as adjustments. The primary outcome was a composite of incident cirrhosis, hepatic decompensation (esophageal varices, ascites, hepatic encephalopathy, spontaneous bacterial peritonitis, hepatorenal syndrome), hepatocellular carcinoma, or liver transplantation. Intention-to-treat (ITT) and per-protocol (PP) hazard ratios used multiple imputation (m = 20; Rubin's rules). Incident fracture was a negative control outcome. **Results:** In the primary pooled IPTW analysis at

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

the 2-year ascertainment window (median N = 738, 88 ITT/43 PP events across 20 imputations), FXai was associated with a lower but non-significant ITT hazard (HR 0.74, 95% CI 0.43-1.29, p = 0.29) and a significantly lower PP hazard (HR 0.39, 95% CI 0.19-0.81, p = 0.01). The PP signal was consistent across all windows, reaching significance at 1-year (p = 0.02) and 3-year (p = 0.03). Per-trial-year IPTW ITT was directionally consistent (HR 0.83, 95% CI 0.42-1.62, p = 0.58) and PP reached significance (HR 0.34, 95% CI 0.13-0.88, p = 0.03). Per-trial-year PS-matched ITT (HR 0.66, 95% CI 0.27-1.60, p = 0.36) and PP (HR 0.30, 95% CI 0.06-1.61, p = 0.16) were directionally consistent. Negative control analysis supported absence of residual confounding. **Conclusion:** In this target trial emulation, FXai use was associated with fewer hepatic complications than warfarin under per-protocol follow-up in pre-cirrhotic MASLD with T2DM. The protective signal was directionally consistent across multiple analyses, although limited by small event counts. These hypothesis-generating findings warrant validation in prospective cohorts.

2591 | ORAL CONTRACEPTIVE USE AND RISK OF STEATOTIC LIVER DISEASE IN WOMEN: A TRINETX GLOBAL COLLABORATIVE NETWORK STUDY

Omar Albhaisi[1] Vinay Jahagirdar[1] Hanna Blaney[1],
[1]Virginia Commonwealth University, Richmond, VA

Background: Steatotic liver disease (SLD) is a major contributor to the burden of chronic liver disease. Oral contraceptive pills (OCPs) comprise 22% of all contraceptive use in the United States. Despite widespread hormonal contraceptive exposure among reproductive-age women, data evaluating the relationship between contraceptive formulations and liver-related outcomes are limited. **Methods:** A retrospective cohort study was conducted using the TriNetX Global Collaborative Network, including females aged 10-40 years between January 2010 and January 2020. Exposure cohorts included combined OCP (COCP) users and progestin-only contraceptive users. Comparator cohorts consisted of females taking multivitamins without documented OCP exposure. Propensity score matching was performed for demographic factors, metabolic risk factors, liver disease risk factors, and medications. Outcomes assessed over 5 years included steatotic liver disease (SLD), MASLD, ALD, cirrhosis, and MALOs. Kaplan-Meier survival analyses were used to estimate hazard ratios (HRs). Similar analyses were performed to compare various contraceptives. **Results:** A total of 10,633 COCP users and 43,481 progestin-only contraceptive users were identified. Both COCP and progestin-only cohorts demonstrated lower observed hazards of SLD (HR 0.57, 95% CI 0.45-0.75, p < 0.001) and MASLD (HR 0.49, 95% CI 0.38-0.63, p < 0.001) compared with matched controls (Table 1). The progestin-only cohort also demonstrated lower hazard ratios for SLD and MASLD compared with the IUD cohort. No significant associations were identified when various contraceptives were compared (Table 2). **Conclusion:** Hormonal contraceptive use was associated with lower observed hazards of incident SLD and MASLD over 5 years, with no significant association with ALD, cirrhosis, or MALO. These findings suggest a potential protective metabolic or anti-inflammatory association, though residual confounding and detection bias remain important limitations. The absence of differences in cirrhosis or MALO may be attributable to the young study population, the limited duration of liver injury, and endogenous estrogen-mediated protection against MASLD in premenopausal women.

Outcome	Combined Oral Contraceptives vs multivitamin (HR (95% CI), p-value) N=10,633 in group	Progestin-Only vs multivitamin (HR (95% CI), p-value) N=43,481 in each group

2592 | ADVANCED FIBROSIS IS AN INDEPENDENT RISK FACTOR FOR DEPRESSIVE SYMPTOMS IN STEATOTIC LIVER DISEASE

Alexander Barton[1] Stella Thielmann[2] Leonard Kaps[1] Lisa Riescher[1] Saleh Alqahtani[3] Christian Labenz[2] Joern M. Schattenberg[1] Maurice Michel[1], [1]Department of Internal Medicine II, University Medical Center Saarland, Homburg, Germany, [2]Department of Internal Medicine I, University Medical Center Mainz, Mainz, Germany, [3]Liver Transplantation Center, King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabi

Background: Depressive symptoms contribute substantially to the global disease burden and are increasingly recognized in metabolic disorders. However, their association with steatotic liver disease (SLD) and fibrosis remains incompletely characterized. This study aimed to assess the prevalence and predictors of depressive symptoms in individuals with SLD. **Methods:** In this prospectively enrolling bicentric cohort study, adults with confirmed or suspected SLD based on cardiometabolic risk factors (CMRF) were recruited from hepatology outpatient clinics at the university medical centers of Mainz and Homburg, Germany. Demographics, CMRF (overweight/obesity, dysglycemia, hypertension, hypertriglyceridemia, low HDL cholesterol) and alcohol intake were recorded. Hepatic steatosis and advanced fibrosis were assessed by transient elastography using controlled attenuation parameter (CAP; ≥ 275 dB/m for SLD) and liver stiffness measurement (LSM; ≥ 10 kPa for advanced fibrosis). Depressive symptoms were evaluated using the Patient Health Questionnaire-9 (PHQ-9; cutoff ≥ 10). Univariable and multivariable logistic regression analyses were performed to identify predictors of depressive symptoms in patients with SLD. **Results:** Among 609 participants (47.8% female, mean age 55.4 ± 13.5 years), the prevalence of depressive symptoms was 18.6% with a mean PHQ-9 score of 5.7 ± 4.7. Female sex, BMI ≥ 35 kg/m^2, and SLD were significantly more prevalent in participants with depressive symptoms compared to those without. Mean BMI was 33.6 ± 7.8 kg/m^2, with 64.2% being obese. 72.7% and 52.7% of participants had ≥ 3 and ≥ 4 CMRF, respectively. SLD was present in 477 (78.3%) participants (mean CAP 305.0 ± 49.2 dB/m), comprising MASLD (n = 454, 74.5%), MetALD (n = 17, 2.8%) and ALD (n = 5, 0.8%). Advanced fibrosis was identified in 148 (24.3%) participants. The prevalence of depressive symptoms increased with disease severity, reaching 20.5% in SLD and 25.0% in advanced fibrosis (Fig. 1). In multivariable regression analysis, female sex (odds ratio [OR] 2.16, 95% confidence interval [CI] 1.34–3.47), advanced fibrosis (OR 1.90, 95% CI 1.15–3.14), and ≥ 4 CMRF (OR 1.88, 95% CI 1.15–3.06) were independently associated with depressive symptoms in participants with SLD after adjustment for age and sex. **Conclusion:** Depressive symptoms are common in individuals with SLD. Female sex, advanced fibrosis and a high burden of CMRF are independently associated with depressive symptoms, highlighting the need for mental health screening and management in SLD care.

Background: Obstructive sleep apnea (OSA) and metabolic dysfunction-associated steatotic liver disease (MASLD) share metabolic drivers, but population-level estimates of OSA risk within MASLD cohorts are scarce, with most prior data derived from sleep-clinic or biopsy-based samples. Identifying the independent predictors of high-risk OSA in MASLD is needed to guide targeted screening. We aimed to estimate the prevalence of high risk for OSA and identify independent predictors among adults with vibration-controlled transient elastography (VCTE)-defined MASLD. **Methods:** GENESIS is a prospective, national population-based cohort with VCTE phenotyping. MASLD was defined as hepatic steatosis on VCTE (controlled attenuation parameter [CAP] $\geq$ 268 dB/m) plus at least one of the 5 cardiometabolic risk factors per the 2023 multisociety Delphi consensus. The Berlin Questionnaire stratified participants into high-risk and low-risk OSA groups per its standard scoring (positive in $\geq$ 2 of the 3 categories: snoring, daytime sleepiness/fatigue, and hypertension or obesity). Multivariable logistic regression identified independent predictors of high-risk OSA, adjusting for age, sex, waist circumference, weekday sleep duration, and physical activity by the International Physical Activity Questionnaire (IPAQ). **Results:** Among 1,111 adults with MASLD (mean age 46.1 ± 13.0 years; 58.2% male), 411 (37.0%) screened high-risk for OSA. On multivariable logistic regression, three factors were independently associated with high-risk OSA: waist circumference (WC; odds ratio [OR] 1.21 per 5 cm; 95% confidence interval [CI] 1.15–1.27; $p < 0.001$), weekday sleep duration (OR 0.84 per additional hour; 95% CI 0.76–0.93; $p < 0.001$), and physical activity by the International Physical Activity Questionnaire (IPAQ; OR 0.71 per category increase; 95% CI 0.54–0.93; $p = 0.01$). Age (OR 1.03 per 10 years; 95% CI 0.93–1.14; $p = 0.55$) and male sex (OR 0.90; 95% CI 0.69–1.18; $p = 0.46$) were not independently associated. **Conclusion:** More than one in three adults with MASLD screened high risk for OSA, representing a substantial undiagnosed population-level burden. Central adiposity, shorter weekday sleep duration, and lower physical activity independently identify patients who may benefit from sleep evaluation. These findings support embedding a brief OSA screen, incorporating waist circumference, sleep duration, and physical activity, into routine MASLD hepatology workflows as part of an integrated cardiometabolic-hepatic-sleep care pathway.

Predictor	Adjusted OR (95% CI)	p value
Waist circumference (per 5 cm)	1.21 (1.15–1.27)	<0.001
Physical activity, IPAQ level	0.71 (0.54–0.93)	0.01
Weekday sleep duration (per hour)	0.84 (0.76–0.93)	<0.001
Age (per 10 years)	1.03 (0.93–1.14)	0.55
Male sex	0.90 (0.69–1.18)	0.46

Table 1. Independent predictors of high-risk obstructive sleep apnea in the metabolic dysfunction-associated steatotic liver disease subcohort (multivariable logistic regression, n=1,111). CI, confidence interval; IPAQ, International Physical Activity Questionnaire; OR, odds ratio.

2594 | HIGH-RISK OBSTRUCTIVE SLEEP APNEA IS ASSOCIATED WITH SUBSTANTIALLY LOWER HEALTH-RELATED QUALITY OF LIFE IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: 36-ITEM SHORT FORM HEALTH SURVEY FINDINGS FROM THE GENESIS COHORT

Waleed Alhazzani[1] Hani Tamim[2] Samar Alqussayer[1] Shadan AlMuhaidib[1] Haifa Alotaibi[1] Faisal Abaalkhail[3] Basmah Khoja[3] Ahmad Almalky[4] May Alzahrani[5] Bandar Al-Judaibi[3] Amr Arafat[1] Saleh Alqahtani[6], [1]Ministry of Defense Health Services, Riyadh, Saudi Arabia, [2]Alfaisal University, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [4]Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [5]King Faisal Specialist Hospital and Research Center, Jeddah, Saudi Arabia, [6]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia

Background: Patient-reported outcomes are now central endpoints in metabolic dysfunction-associated steatotic liver disease (MASLD) clinical care and drug development, yet the contribution of common comorbidities to quality-of-life impairment is underexplored. Obstructive sleep apnea (OSA) frequently coexists with MASLD, and the magnitude of any associated quality-of-life impact has not been quantified at the population level. We aimed to evaluate the association between high risk for OSA and health-related quality of life among adults with vibration-controlled transient elastography (VCTE)-defined MASLD in the GENESIS cohort. **Methods:** Within the GENESIS prospective population-based cohort, adults with VCTE-defined MASLD completed the 36-Item Short Form Health Survey (SF-36) and the Berlin Questionnaire. The SF-36 is a validated generic health-related quality-of-life instrument comprising 8 domains that aggregate into two summary measures, the Physical Component Summary (PCS) and the Mental Component Summary (MCS); scores range from 0 to 100, with higher scores indicating better health. PCS and MCS were compared between high-risk and low-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

risk OSA groups using Student's t-test or the Mann-Whitney U test as appropriate. **Results:** Of 1,111 adults with MASLD (mean age 46.1 ± 13.0 years; 58.2% male), 411 (37.0%) screened high-risk for OSA and 700 (63.0%) screened low-risk. Both SF-36 summary scores were lower in the high-risk group: PCS 75.5 ± 18.7 vs 82.1 ± 15.5 (mean difference 6.6 points; $p < 0.001$) and MCS 73.3 ± 18.8 vs 82.6 ± 14.5 (mean difference 9.3 points; $p < 0.001$). **Conclusion:** High-risk OSA in MASLD is associated with substantially lower health-related quality of life across both the physical and mental component summaries of the SF-36, with the mental component showing the larger absolute gap. These findings support routine quality-of-life screening as a low-burden way to identify patients with MASLD who may benefit from sleep evaluation.

SF-36 summary score	High-risk OSA (n=411)	Low-risk OSA (n=700)	Mean difference	p value
Physical Component Summary	75.5 ± 18.7	82.1 ± 15.5	6.6	<0.001
Mental Component Summary	73.3 ± 18.8	82.6 ± 14.5	9.3	<0.001

2595 | ADDRESSING UNDERDIAGNOSIS OF MASLD IN PRIMARY CARE: A QUALITY IMPROVEMENT EDUCATIONAL INTERVENTION USING AN AI-DRIVEN EMR ALGORITHM

Ashley Dotson[1] Ariana Stuart[2] Katya Swarts[2] Marion Granich[1] Jessica Yeung[1] Manish Dhyani[3] James Perkins[4] George Ioannou[3] Rotonya Carr[5], [1]University of Washington Department of Medicine, [2]University of Washington Division of Gastroenterology, [3]University of Washington, [4]University of Washington Division of Transplant Surgery, [5]University of Washington Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects nearly 30% of adults and is a rapidly growing indication for liver transplantation. Despite its prevalence, MASLD frequently remains underdiagnosed, with many cases identified incidentally on imaging. We developed an AI algorithm to identify patients meeting MASLD criteria within the EMR and found that only half carried a formal diagnosis, with even fewer undergoing fibrosis risk stratification. We subsequently conducted a QI educational intervention to improve primary care provider (PCP) recognition and management of MASLD. **Methods:** We performed a pre-post QI study evaluating the impact of a PCP educational intervention on paired MALSD patients identified by an AI algorithm. Eligible patients met MASLD criteria without a MASLD-related ICD diagnosis. Corresponding PCPs received an Epic-messaged educational "one-sheet" outlining guideline-based MASLD management recommendations. Outcomes assessed at baseline, 6 months, and 12 months included documented MASLD diagnosis, fibrosis risk stratification with FIB-4, referrals for elastography and Hepatology, screening for diabetes mellitus (DM), hyperlipidemia (HLD), and chronic kidney disease (CKD), and lifestyle counseling documentation. **Results:** The intervention was distributed to 259 PCPs, with a 24% response rate ($n = 61$). One patient died before follow up, leaving 60 paired patients for analysis. Formal MASLD diagnosis increased from 5% at baseline to 10% at 12 months ($p = 0.25$), while informal documentation remained unchanged at 11.7%. FIB-4 assessment rates remained low following intervention (6.7% at baseline, 5% at 6 months, and 3.3% at 12 months). Among intermediate risk patients (FIB-4 score ≥ 1.3; $n = 11$), only 1 was referred for elastography at 6-months, with no referrals at 12 months. The single high-risk patient had already been referred to Hepatology prior to intervention. Screening for MASLD-associated comorbidities improved following intervention. Approximately 50% of patients underwent DM and HLD screening at baseline, while only 8% underwent CKD screening. CKD screening increased to 35% at 6 months and 47% at 12 months. Lifestyle counseling documentation increased from 8% to 13% between 6 and 12 month follow up. However, only 28% and 40% of patients completed PCP follow up visits during the 6 and 12 month periods, limiting opportunities for longitudinal reassessment and intervention implementation. **Conclusion:** Our QI intervention highlights persistent underdiagnosis of MASLD and gaps in fibrosis risk stratification within primary care. Although modest improvements were observed in disease recognition, comorbidity screening, and lifestyle counseling, rates of FIB-4 documentation and referral for secondary fibrosis assessment remained low. These findings support the need for continued educational and EMR-based interventions to improve guideline-concordant MASLD management in primary care.

2596 | HIGHER TESTOSTERONE LEVELS ARE ASSOCIATED WITH ALT LEVELS AND STEATOSIS SEVERITY IN WOMEN WITH MASLD AND POLYENDOCRINE METABOLIC OVARIAN SYNDROME (PMOS)

Monika Sarkar[1] Norah Terrault[2] Heather Huddleston[3] Ala Koreitem[3] Jasmine Gamez[3] Lily Carbullido[3] Helen Oberweis-Manion[3] Carly Kelley[4] Amreen Dinani[5], [1]University of California, San Francisco, [2]University of Southern California, [3]UNIVERSITY OF CALIFORNIA SAN FRANCISCO, [4]Duke University Medical Center, [5]Duke University School of Medicine

Background: Polyendocrine metabolic ovarian syndrome (PMOS), formerly known as Polycystic Ovary Syndrome, is a risk factor for presence and severity of metabolic dysfunction-associated steatotic liver disease (MASLD). Whether higher androgens drive this risk, beyond established metabolic comorbidities, is not known. **Methods:** In this two-site prospective cohort study of reproductive-aged women with MASLD and PMOS, we evaluated the cross-sectional association of baseline androgen levels with severity of MASLD. Outcome measures included serum ALT, and steatosis and fibrosis assessment by transient elastography-controlled attenuation parameter (TE-CAP). Standardized protocols were employed to obtain socio-demographics, anthropomorphic measures, fasting metabolic labs, liver tests, and androgen levels. Linear and logistic regressions were used to evaluate the association of free testosterone (free T) with study outcomes, adjusting for potential confounding conditions, while ROC-analyses and Youden indices were used to identify optimal free T thresholds for predicting study outcomes. **Results:** Among 102 participants with MASLD and PMOS, median age was 31 years (IQR 28-35); 48.5% were White, 19.8% Asian, and 31.7% Hispanic. Median body mass index (BMI) was 35.0 kg/m^2 (31.5-40.2), median HOMA-IR was 3.5 (2.5-5.6), and median free T was 0.71 ng/dL (0.35-1.12). Dyslipidemia, hypertension, and type 2 diabetes mellitus were present in 30.4%, 20.6%, and 13.7%, respectively. Stable GLP-1 receptor agonist use ($\geq$ 3 months) occured in 18.6%. Median ALT was 37.0 U/L (20.0- 60.0) with 32.4% having ALT $\geq$ 50.0 U/L. Median CAP score was 313 dB/m (283-346) and 56.9% had severe steatosis (CAP $\geq$ 300 dB/m). Median fibrosis score was 5.6kPa (4.9-7.6), and 20.4% had fibrosis (kPa $\geq$ 8.0).On univariate analysis, free T was associated with higher ALT (back-transformed β coefficient = 1.6, 95% CI 1.2-2.0, p < 0.001), ALT levels $\geq$ 50.0 U/L (OR 2.6, 95% CI 1.3-5.5, p = 0.01), higher CAP scores (β = 14.7, 95% CI 2.2-,27.2, p = 0.02), and severe steatosis (OR 3.9, 95% CI 1.6,9.9, p = 0.004), while the association with fibrosis severity did not reach statistical significance (β = 1.1, 95% CI 1.0-1.3, p = 0.06). After adjustment for BMI and HOMA-IR, free T remained associated with higher ALT levels (β = 1.4, 95% CI 1.1-1.8, p = 0.004), ALT $\geq$ 50 (AOR 2.6, 95% CI 1.2-5.7, p = 0.02) and presence of severe steatosis (AOR 3.3, 95% CI 1.2-8.8, p = 0.02). On ROC-analyses, the optimal free T thresholds for predicting elevated ALT was 0.69 ng/dL (AUROC = 0.66) and for predicting severe steatosis was 0.85 ng/dL (AUROC = 0.70) (Figure). **Conclusion:** In this cohort of reproductive-aged women with MASLD and PMOS, free testosterone levels were associated with higher ALT levels and severe steatosis. These data support the role of testosterone in promoting worsening MASLD, and the need to consider hormonal modulation as a potential novel therapeutic mechanism for MASLD treatment in women with PMOS.

Figure: Free Testosterone Thresholds and Risk for MASLD-Related Outcomes in Women with PMOS (n=102)

Outcome	AUROC (95% CI)	Optimal Free T Threshold*	Sensitivity	Specificity	Youden Index
ALT ≥ 50 U/L	0.66 (0.54-0.78)	0.69	0.73	0.60	0.327
Severe Steatosis (CAP > 300 dB/m)	0.70 (0.59-0.80)	0.85	0.50	0.87	0.367

2598 | DISCORDANCE BETWEEN ILLNESS PERCEPTIONS AND REAL-WORLD DIETARY BEHAVIORS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A MIXED-METHODS EXPLORATORY ANALYSIS

Sangmin Lee[1] Mohammad Khan[1], [1]University of Western Ontario

Background: Dietary behavior is central to metabolic dysfunction-associated steatotic liver disease (MASLD) management, yet patients' illness perceptions and self-reported barriers may not align with real-world dietary practices. Examining this discordance at baseline using a mixed-methods approach may better capture the complexity underlying dietary adherence and change in MASLD. **Methods:** As part of a multidisciplinary MASH Clinic, 122 adult patients completed a baseline screening questionnaire and a 3-day food diary (2 weekdays, 1 weekend) prior to their first visit. The questionnaire assessed illness perception, dietary self-efficacy, and perceived barriers using a 7-point Likert scale (collapsed to Agree/Neutral/Disagree categories). Food diaries underwent direct content analysis in NVivo across 13 dietary domains, coded semi-quantitatively as Never, Occasional (1-2 instances), or Frequent (≥ 3 instances). Pilot analysis of the first 60 consecutive patients is presented. Limitations of social desirability and recall bias are acknowledged. **Results:** Participants had a mean age of 52 years, and 61.7% (n = 37)

were female. Frequent refined carbohydrate intake was observed in 72% of patients, while whole grain consumption was absent in 37%. Integrative analysis revealed substantial discordance across multiple domains. Among patients reporting a complete understanding of MASLD, frequent refined carbohydrate intake was universal (100%), suggesting disease knowledge alone does not translate into healthier dietary behaviors. Patients expressing low illness concern demonstrated lower lean protein (20% vs. 68%) and vegetable intake (60% vs. 77%) compared to those expressing concern. Among patients reporting no personal habits requiring change, 83% had frequent refined carbohydrate and/or high-sugar snack consumption. Patient reporting uncertainty about healthy eating (32%) did not demonstrate worse dietary patterns than confident peers, indicating knowledge gaps alone do not drive poor behavior. Symptoms of depression and anxiety were endorsed by 33% and 35% of patients, respectively, and were associated with greater meal irregularity compared to those not reporting symptoms (35% vs. 10%). **Conclusion:** Significant discordance exists between illness perceptions and real-world dietary behaviors in MASLD. Disease knowledge and perceived access to healthy living resources alone may be insufficient to drive behavioral change. Meanwhile illness perception and psychological factors appear to be more strongly associated with maladaptive dietary patterns. These findings underscore the need for integrating psychological and behavioral frameworks into multidisciplinary MASLD clinics alongside nutritional and exercise counselling.

2599 | THE IMPACT OF DIET AND ALCOHOL CONSUMPTION ON RISK OF STEATOTIC LIVER DISEAS

Kazuya Miyamoto[1] Zhengyi Wang[2] Luis Calzadilla Bertot[3] Oyekoya Ayonrinde[2] John Olynyk[4] Therese O'Sullivan[5] Trevor Mori[2] Lawrence Beilin[2] Leon Adams[2], [1]Okayama University, [2]University of Western Australia, [3]University of Sevilla, [4]Curtin University, [5]Edith Cowan University

Background: Diet and alcohol are both purported drivers of steatotic liver disease (SLD) however their relative impact and interaction is poorly understood. We assessed the impact and interacting effects of dietary components and alcohol consumption on the risk of SLD. **Methods:** Participants of the community based Raine Study cohort underwent assessment at age 27 years including anthropometrics, fasting serum biochemistry, *PNPLA3* genotyping and liver fat quantification by magnetic resonance imaging. SLD was defined using a biopsy validated volumetric fat fraction cut-off of $>3.55\%$. Habitual dietary intake and weekly alcohol consumption was assessed using a validated food frequency questionnaire. **Results:** Overall, 111/710 (15.6%) had SLD (55% male, average age 26.7 years). Those with SLD had higher body mass index, waist circumference, blood pressure, serum liver enzymes, fasting glucose and serum triglycerides when compared with those without SLD (all $p<0.01$). Dietary intake of total fat, saturated fat, carbohydrate, sugars, and starch did not differ by SLD status ($p>0.05$ for all). However, participants with SLD compared to those without reported lower long-chain omega-3 fatty acids (O-3FA) (median 238 vs 290 mg/day; $p<0.001$), lower dietary fibre (19.6 vs 22.7 gm/day; $p=0.002$) and lower caffeine intake (236 vs 501 gm/day; $p=0.057$). Following adjustment for sex, alcohol, caloric intake, physical activity, BMI and *PNPLA3* genotype, a protective association for SLD was observed with increasing O-3FA intake (OR 0.57, 95% CI 0.39-0.81) and caffeine (OR 0.73, 95% CI 0.55-0.96). Average weekly alcohol intake did not differ significantly between those with and without SLD (median 27 vs 52 g/week; $p=0.2$). The proportion exceeding sex-specific thresholds (≥ 20 g/day in females or ≥ 30 g/day in males) was also similar between groups (18.0% vs 15.2%; $p=0.4$). Significant interactions between alcohol and dietary O-3FA and fibre existed ($P<0.05$ for both). Among low alcohol users (<50 grams/wk), no significant associations between dietary components and SLD were seen. Among higher alcohol users (≥ 50 g/week), higher O-3FA and dietary fibre intake were independently associated with lower odds of SLD (O-3FA adjusted OR 0.45; 95% CI 0.22–0.93; fiber adjusted OR 0.36; 95% CI 0.17–0.75). **Conclusion:** Dietary intake of omega-3 fatty acids and caffeine may reduce the risk of SLD. Alcohol consumption modifies the protective association of omega-3 fatty acids and fibre on SLD.

2600 | MASLD IS ASSOCIATED WITH RENAL DYSFUNCTION INDEPENDENT OF DIABETES AND HYPERTENSION: A REAL-WORLD COHORT STUDY USING TRINETX

Ahmed Ibrahim[1] Moataz Aboeldahb[2] Fatima Israr[3] Muhamad Oum[4] Sajid Jalil[5], [1]San Joquin General Hospital, [2]Mayo Clinic, [3]Santa Clara Valley Medical Center, [4]Saint Agnes Medical Center, [5]Stanford University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly recognized as a systemic disease. While chronic kidney disease (CKD) is common in MASLD patients, most studies have focused on populations with coexisting diabetes and hypertension. We aimed to investigate whether MASLD is associated with an increased risk of new incident renal dysfunction in patients without diabetes or hypertension. **Methods:** We used the TriNetX database, which includes 120,102,956 patients from 67 US health care organizations. We examined adult patients ($\geq$18 years) diagnosed with MASLD (2010-2020), to allow for a minimum follow-up of 5 years. A 1:1 propensity score matching (PSM) was used to compare patients with MASLD to those without MASLD (control group). Patients with coexisting diabetes mellitus, hypertension, viral hepatitis, autoimmune liver disease, alcohol-related liver disease, liver/kidney transplant, or any of the outcomes of interest at baseline (acute kidney injury (AKI), chronic kidney disease (CKD), proteinuria) were excluded from both groups. Patients' demographics, clinical data, and outcomes were studied using ICD codes as follows: MASLD (K76.8), CKD (N18), AKI (N17), and proteinuria (R80). The primary outcome was incident AKI. Secondary outcomes included new-onset CKD, albuminuria/proteinuria, renal dialysis procedures, and/or major adverse cardiac outcomes (MACE; combined stroke, heart failure, and ischemic heart disease). Data were collected and analyzed using TriNetX Analytics Platform built-in functions (R, version 4.0, including HRs and their associated 95% CIs). **Results:** A total of 72,922 patients with MASLD, but without diabetes or hypertension, were identified and matched at a 1:1 ratio to non-MASLD controls. Before matching, patients with MASLD were generally younger (42 yrs vs 45 yrs), similar female percentages (60% vs 60%), and predominantly White individuals (73% vs 64%) compared to those without MASLD. After matching, each group had 72,922 patients (mean [SD] age, 42 [14] years; 61% women) and was evenly matched from a clinical standpoint. Among 72,922 MASLD patients, 14% developed incident AKI compared to 7% in the non-MASLD group (OR: 2.16, 95%CI: 2.08 -2.24; p < 0.001, **Table**). Rates of new incident albuminuria/proteinuria and CKD diagnoses were also higher in the MASLD group (OR: 1.79, 95% CI: 1.60-2.02, p < 0.001; OR: 2.18, 95% CI: 2.09-2.27, p < 0.001, **Table**). MACE was also observed more frequently in the MASLD group (OR: 2.42, 95% CI: 2.32-2.68, p < 0.001) compared to the non-MASLD group. However, there were no differences in the incidence of renal dialysis procedures between both groups (**Table**). **Conclusion:** MASLD is independently associated with an increased risk of renal dysfunction even in the absence of diabetes or hypertension. These findings highlight that routine renal monitoring in MASLD individuals might be beneficial.

Clinical outcomes

Outcome (%)	Non-MASLD group N= 72,922	MASLD group N= 72,922	OR (95% CI)	P value
New onset AKI*	7.0%	14.0%	2.16 (2.08 -2.24	<0.001
New onset albuminuria/proteinuria	0.6%	1.1%	1.79 (1.60 -2.02)	<0.001
New onset CKD**	5.7%	11.6%	2.18 (2.09 -2.27)	<0.001
New onset dialysis	0.2%	0.1%	0.88 (0.68-1.17)	0.4
MACE	3.6%	8.8%	2.42 (2.32-2.68)	<0.001

Abbreviations: CKD: chronic kidney disease; AKI: acute kidney injury; MACE: major adverse cardiac events.
*Defined by ICD-10 code diagnosis of AKI or creatinine >1.5mg/dL
**Defined by ICD-10 diagnosis of CKD or eGFR < 60 mL/min/1.73 m^2.
***Defined by a combination of heart failure, stroke, or ischemic heart disease.

2601 | COMPARING TRENDS OF ASSOCIATIONS OF SOCIODEMOGRAPHIC AND LIFESTYLE FACTORS WITH STEATOTIC LIVER DISEASE IN THE POST-PANDEMIC ERA, DOES THE RISK REMAIN THE SAME?

Iqra Arshad[1] Xinyuan Zhang[2], [1]SAINT LOUIS UNIVERSITY HOSPITAL, [2]Harvard Medical School and Brigham and Women's Hospital

Background: Sociodemographic and behavioral risk factors are reported to be closely linked to steatotic liver disease (SLD). However, data on changing trends of association with SLD since the pandemic remain limited. The current study aims to evaluate whether the association between certain sociodemographic and lifestyle factors with SLD has changed overtime in postpandemic era. **Methods:** We conducted a cross-sectional observational study using National Health and Nutrition Examination Survey (NHANES) data. Data on sociodemographic and behavioral factors were extracted from pre-pandemic (2017-2020) and post-pandemic (2021-2023)cycles. Primary outcome was SLD, defined as Controlled Attenuation Parameter (CAP) score $\geq$ 268 dB/m. Data missing at random were handled using Multiple Imputations Chain Equation method. Univariate regression models were used to assess prevalence, and multivariate models to evaluate associations with SLD in each cycle. The associations between cycles were compared as a ratio of adjusted odds ratios, and effect modification by time was used for statistical significance. A two-tailed p-value <0.05 was set as significant. **Results:** Among baseline characteristics in each cycle, majority of participants,(n = 6820 in pre- and n = 4607 in post-pandemic), were White males, employed, non-smokers, light to moderate drinkers, and obese. In each cycle, SLD group (52% in pre- and 55% in post-pandemic) were observed to have a higher risk profile, i.e., belonged to middle-income and lower education groups, were obese, having medical co-morbidities and no mental health follow-ups compared to controls. In the adjusted analysis, among sociodemographic factors, being unmarried was significantly associated with lower odds of SLD ($_a$OR; 0.69 [0.57-0.83]) in pre- and ($_a$OR; 0.75 [0.59-0.96]) in post-pandemic time and association remained significantly stronger (ratio;1.08 [p <0.001]) comparing time. People with no mental health follow-ups had a higher risk of SLD ($_a$OR; 1.05[0.82-1.33]) in post-pandemic era, but no significant evidence of effect modification by time (ratio; 1.31[p >0.99]) was observed. Among lifestyle factors, in both cycles, moderate and higher levels physical activity had significantly lowererd risk of SLD compared to reference groups and association remained stronger for both levels but was only significant for higher levels (ratio; 1.5 [p 0.006]) comparing time. Among dietary factors, a low fiber diet was associated with a higher risk of SLD in both eras but was significant in post-pandemic era. Comparing time, the association remained stronger but findings were not significant [Table 1]. **Conclusion:** Current study shows persistent positive associations of certain sociodemographic and lifestyle factors with SLD since pandemic and highlights importance of integrating these key drivers in decision making to provide comprehensive multidisciplinary care to SLD patients.

2602 | GLP-1 RECEPTOR AGONISTS REDUCE CARDIOVASCULAR AND RENAL EVENTS IN NON-OBESE, NON-DIABETIC MASLD: A PROPENSITY SCORE-MATCHED COHORT STUDY

Anh Thu Nguyen[1] Yahya Hamad[1] Riddhi Prateek[1] Daanish Imam[1] Harish Gopalakrishna[2] Gurinder Luthra[1], [1]University of Texas Medical Branch, [2]UTMB

Background: Non-obese individuals account for up to 30% of metabolic dysfunction-associated

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

steatotic liver disease (MASLD) cases but are often excluded from GLP-1 receptor agonist (GLP-1 RA) efficacy studies. While GLP-1 RAs demonstrate many benefits in general MASLD populations, their therapeutic role in non-obese, non-diabetic MASLD remains undefined. We evaluated the association between sustained GLP-1 RA use and clinical outcomes in this understudied population. **Methods:** We conducted a retrospective cohort study using the TriNetX federated electronic health records network. Non-obese MASLD patients (BMI ≤ 27 kg/m², ICD-10 K76.0 or K75.81, ≥ 1 cardiometabolic risk factor) in non-diabetics were identified. Exclusions were alternative liver disease, baseline cirrhosis, decompensation, bariatric surgery, or prior transplant. Exposed patients had sustained GLP-1 RA use (second prescription ≥ 3 months after first, initiated within 3 months of diagnosis). 1: 1 propensity score matching included demographics, comorbidities, medications, and labs. Outcomes included major adverse cardiovascular events (MACE), major adverse liver outcomes (MALO), acute kidney injury (AKI), and atrial fibrillation/flutter (afib). Cox models estimated hazard ratios over 5 years. Sensitivity analyses excluded baseline metformin, substance use disorders, and tirzepatide. **Results:** After 1: 1 PSM (n = 1,261/arm), GLP-1 RA use was associated with significant reductions in MACE (HR 0.54, p = 0.010), heart failure (HR 0.34, p < 0.001), AKI (HR 0.46, p = 0.005), and afib (HR 0.64, p = 0.033). (Table 1) MALO did not differ significantly. Benefits persisted after metformin exclusion and were directionally consistent after tirzepatide exclusion. In a broader non-diabetic MASLD cohort (n = 23,983/arm), significant reductions were seen across all endpoints. **Conclusion:** GLP-1 RA use was associated with reductions in MACE (46%), heart failure (66%), AKI (54%), and afib (36%) in non-obese nondiabetic MASLD patients, independent of metformin and consistent after tirzepatide exclusion, supporting a class effect. MALO showed no significant difference (HR 1.16, p = 0.67) versus 83% reduction in broader non-diabetics, likely due to 1) small sample size, 2) lower baseline severity in non-obese patients, and 3) distinct pathophysiology. Despite comprising 30% of MASLD cases, non-obese patients remain excluded from landmark trials [5]. These findings support prospective trials and guideline consideration of GLP-1 RAs for cardiorenal risk reduction in non-obese MASLD.

Characteristic/Outcome	Sustained GLP-1 RA	No GLP-1 RA	HR (95% CI) or Std Diff

2603 | DISTINCT CARDIOVASCULAR PHENOTYPES AND OUTCOMES IN HCV AND MASLD ACROSS FIBROSIS STAGES: A NHANES 2007–2016 ANALYSIS

Fatima Rajab[1] Aleena Mujahid[2] Barsha Baral[3] Ahmad Jalil[3] Umaiza Ihsan[4], [1]Baptist Hospitals of Southeast Texas, [2]Harlingen Medical Center, [3]BAPTIST MEMORIAL HOSPITAL, [4]King Edward Medical University

Background: Hepatitis C virus (HCV) infection and metabolic dysfunction-associated steatotic liver disease (MASLD) are both associated with increased cardiovascular disease (CVD) burden. However, differences in cardiovascular risk patterns between viral and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

metabolic liver disease across fibrosis stages remain incompletely understood. **Methods:** We performed a cross-sectional analysis of adults with HCV or MASLD from NHANES 2007–2016 linked to mortality data. MASLD was identified using the Hepatic Steatosis Index (HSI), and advanced fibrosis was defined using FIB-4 criteria (FIB-4 >2.67). Stage-matched analyses compared HCV and MASLD phenotypes among participants with and without advanced fibrosis. Survey-weighted multivariable logistic and Cox regression models adjusted for age, sex, BMI, diabetes, hypertension, and smoking were used to evaluate cardiovascular morbidity, all-cause mortality, and cardiovascular mortality. Exploratory analyses examined coronary artery disease (CAD), myocardial infarction (MI), stroke, and congestive heart failure (CHF). **Results:** The study included 4,431 participants, including 4,008 with MASLD and 423 with HCV. HCV-related advanced fibrosis demonstrated marked male predominance (77.1% male) with balanced distribution in MASLD group. Among participants without advanced fibrosis, HCV was associated with higher cardiovascular morbidity compared with MASLD (adjusted OR 2.41, 95% CI 1.51–3.84) and higher all-cause mortality (adjusted HR 3.36, 95% CI 2.12–5.31), while cardiovascular mortality was numerically higher but not statistically significant (adjusted HR 2.33, 95% CI 0.86–6.28). Among participants with advanced fibrosis, cardiovascular morbidity (adjusted OR 0.52, 95% CI 0.14–1.91) and cardiovascular mortality (adjusted HR 1.50, 95% CI 0.39–5.71) were comparable between HCV and MASLD, while all-cause mortality was numerically higher in HCV fibrosis (adjusted HR 1.96, 95% CI 0.90–4.31). Phenotype-specific analyses demonstrated differing cardiovascular patterns. Compared with MASLD without advanced fibrosis, HCV without advanced fibrosis was associated with higher stroke (adjusted OR 2.08, 95% CI 1.18–3.53) and CHF burden (adjusted OR 2.84, 95% CI 1.58–4.90), whereas CAD and MI burden were not increased. In advanced fibrosis, MASLD demonstrated a relatively stronger CAD phenotype, with lower CAD prevalence observed in HCV fibrosis (adjusted OR 0.24, 95% CI 0.07–0.79). **Conclusion:** HCV and MASLD may demonstrate distinct cardiovascular phenotypes across fibrosis stages. HCV was associated with increased cardiovascular morbidity and all-cause mortality even without advanced fibrosis, whereas MASLD-related fibrosis appeared more closely associated with atherosclerotic CAD burden. These findings suggest differing cardiovascular risk profiles between viral and metabolic liver disease.

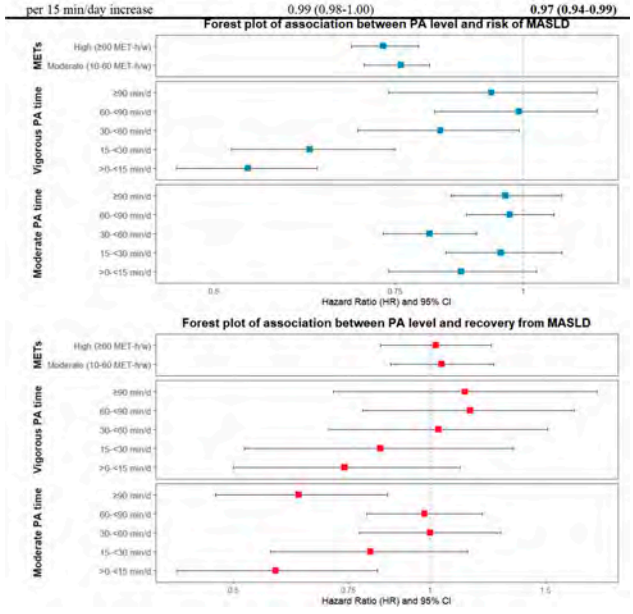
2604 | A COHORT STUDY ON THE ASSOCIATION OF PHYSICAL ACTIVITY LEVEL WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE BASED ON THE SHANGHAI SUBURBAN ADULT COHORT AND BIOBANK (SSACB)

Xinyu Hu[1], [1]Fudan University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent worldwide. Physical activity (PA) may protect



Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

against MASLD, but evidence from large Chinese cohorts is limited, and its role in disease recovery remains unclear. We prospectively evaluated the associations of PA with MASLD in a Chinese community-based cohort. **Methods:** This study was based on the Shanghai Suburban Adult Cohort and Biobank (SSACB). A total of 47,472 participants without MASLD at baseline and 10,799 participants with MASLD at baseline were included. Baseline PA information was collected using a physical activity questionnaire. Participants without MASLD at baseline were followed for new-onset MASLD, while those with MASLD at baseline were followed for recovery from MASLD. Multivariable Cox proportional hazards regression models were used to analyze the association between PA level and MASLD, and stratified analyses were performed across different subgroups. **Results:** In the incidence cohort, higher total PA was significantly associated with lower MASLD risk. Compared to the lowest tertile ($\leq$10 MET-h/w), the highest tertile ($\geq$60 MET-h/w) had a 27% lower risk (HR = 0.73, 95%CI: 0.68-0.79; P-trend < 0.001). Each 10 MET-h/w increment reduced risk by 2% (HR = 0.98, 95%CI: 0.97-0.98). Threshold effects were observed: 15-30 min/week of vigorous PA(VPA) gave the greatest benefit (HR = 0.62, 95%CI: 0.52-0.75), and 30-60 min/week of moderate PA(MPA) significantly reduced risk (HR = 0.81, 95%CI: 0.73-0.90), with no further benefit beyond 60 min/week. Stratified analyses showed no significant interactions (all P $\geq$ 0.05). In the recovery cohort, total PA was not significantly associated with MASLD recovery. Unexpectedly, MPA time was inversely associated with recovery: compared to no MPA, 0-15 min/day (HR = 0.58, 95%CI: 0.41-0.83) and $\geq$90 min/day (HR = 0.63, 95%CI: 0.47-0.86) showed lower likelihood of recovery (P-trend = 0.016). However, in patients with diabetes, higher PA levels tended to promote recovery (MPA: HR = 1.61, 95%CI: 1.00-2.60; VPA: HR = 1.66, 95%CI: 1.01-2.73; P-interaction = 0.149). **Conclusion:** PA level is an independent protective factor for the onset of MASLD, with a clear dose-response relationship and a threshold effect. The association between PA level and MASLD recovery was not confirmed in this study. It is recommended that the general population engage in at least 150 minutes of moderate-to-vigorous PA per week to prevent MASLD, while exercise interventions for patients with MASLD should be individually tailored.

2605 | RISK OF GERD IN PATIENTS WITH MASLD: A RETROSPECTIVE CASE-CONTROL STUDY BASED ON CLINICAL ENDOSCOPY DATA AND MULTI-OMICS ANALYSIS

Nan Li[1] CongCong Wang[1] Yulin Li[1] Zhiyu Ji[1] Changjiang Qin[1], [1]Huai He Hospital of Henan University

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Metabolic associated fatty liver disease (MASLD) and gastroesophageal reflux disease (GERD) share obesity and high-fat diet as common risk factors. However, high-quality large-sample evidence using gastroscopy to confirm their association remains limited, and shared pathogenic mechanisms are unclear. This study aims to analyze the association between MASLD and GERD using real-world clinical data. It also integrates multi-omics analysis to explore shared molecular pathways to guide gastrointestinal health monitoring in MASLD patients. **Methods:** This study integrates a retrospective case-control study with bioinformatic analysis. Adult patients who visited the Department of General Surgery at Huaihe Hospital Affiliated with Henan University from April 2025 to April 2026 were included. Patients were divided into the MASLD group and the non-MASLD group. All patients underwent gastroscopy and liver imaging examinations. After comparing the clinical characteristics of the two groups, univariate and multivariate logistic regression analyses were performed to identify the risk factors for GERD in MASLD patients. Expression profiles of MASLD (GSE89632) and GERD (GSE148381) were obtained from the GEO database. Common differentially expressed genes (DEGs) were selected to construct a PPI network. Finally, enrichment analyses were performed to explore the shared gene functions and pathways between MASLD and GERD. **Results:** This study ultimately included 156 patients with MASLD and 317 without MASLD patients for analysis. The prevalence of GERD in the MASLD group was 45.5%, significantly higher than the 31.2% in the non-MASLD group (p = 0.002). Additionally, the MASLD group was younger (median age 49 vs. 57, p < 0.001), had a higher proportion of males (52.6% vs. 42.3%, p = 0.035), and exhibited significantly higher levels of metabolic-related indicators, such as BMI, transaminase, and uric acid, compared to the non-MASLD group. The unadjusted regression model showed that MASLD was associated with an increased risk of GERD. After adjusting for age, gender, blood pressure, BMI, and uric acid, this association remained (OR = 1.62, 95% CI: 1.01-2.60, p = 0.047). This study identified 20 common differentially expressed genes (DEGs). Among these, MYH11, ACTG2, and VCAN emerged as the top three hub genes. The functional enrichment of the common DEGs was associated with muscle cell differentiation, myosin filament, and vascular smooth muscle contraction. **Conclusion:** MASLD increased the risk of GERD by 62%. Metabolic factors and vascular smooth muscle contraction may collectively mediate this association. The findings of this study underscore the importance of standardized gastroscopy in MASLD patients, offering evidence to refine clinical management strategies for comorbidities.

Table 1: Characteristics of participants enrolled in study.

Variables[a]	Overall N = 473	Non-MASLD N = 317	MASLD N = 156	P-value[b]

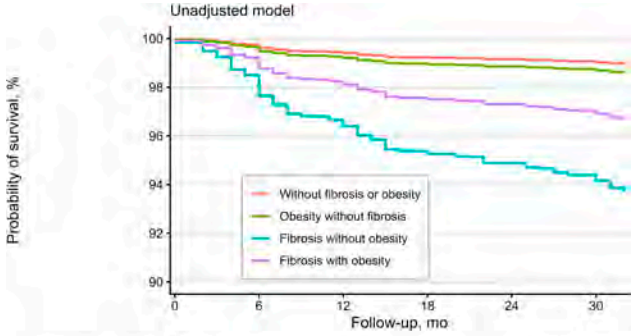
2606 | ASSOCIATION OF FIBROSIS-OBESITY PHENOTYPES WITH ALL-CAUSE MORTALITY AMONG U.S. ADULTS



Zilong Lu[1] Yuankai Wu[2] Yu Shi[3] Vincent Wai-Sun Wong[4] Xinrong Zhang[1], [1]School of Public Health, Sun Yat-sen University, [2]Department of Infectious Diseases, Third Affiliated Hospital of Sun Yat-sen University, [3]Zhejiang University School of Medicine,

[4]Department of Medicine and Therapeutics, The Chinese University of Hong Kong

Background: With epidemic of obesity, the burden of metabolic dysfunction-associated steatotic liver disease is increasing worldwide. Its more active histological phenotype, metabolic dysfunction-associated steatohepatitis, may progress to advanced liver fibrosis, cirrhosis and even mortality. However, whether coexisting fibrosis and obesity confer increased short-term mortality risk in the general population remains unclear. Therefore, we evaluated the associations between fibrosis–obesity phenotypes and all-cause mortality among U.S. adults. **Methods:** Adult participants with complete vibration-controlled transient elastography data were identified from the 2017-2018 National Health and Nutrition Examination Survey and linked to mortality data from the National Death Index through December 31, 2019. Advanced fibrosis was defined as liver stiffness measurement (LSM) $\geq$9.7 kPa. Obesity was defined as body mass index (BMI) $\geq$30 kg/m² for non-Asian participants and BMI $\geq$25 kg/m² for Asian participants. Cox proportional hazards models were used to estimate hazard ratios (HRs) and 95% confidence intervals (CIs) for all-cause mortality. **Results:** A total of 4,174 adults were included, with 62 deaths during follow-up. Individuals with both fibrosis and obesity exhibited a more adverse metabolic and cardiometabolic profiles than those without either fibrosis or obesity. Compared with participants without advanced fibrosis or obesity, advanced fibrosis without obesity was associated with markedly higher risk of all-cause mortality (HR, 6.15; 95% CI, 1.50-25.19), as was advanced fibrosis with obesity (HR, 3.20; 95% CI, 1.10-9.33), whereas obesity alone was not associated with mortality. After adjustment for age, sex, and race, the association for advanced fibrosis without obesity was attenuated (HR, 2.45; 95% CI, 0.61-9.77), while advanced fibrosis with obesity remained significantly associated with increased mortality risk (HR, 3.10; 95% CI, 1.03-9.31). Among participants with obesity, fibrosis stage was not significantly associated with mortality. Restricted cubic spline analyses showed no significant association between LSM and all-cause mortality. **Conclusion:** In this national study, the coexistence of fibrosis and obesity was associated with increased mortality risk, suggesting that fibrosis burden in individuals with obesity may help identify those at elevated short-term mortality risk.

2607 | MACHINE LEARNING–BASED PREDICTION OF SIGNIFICANT FIBROSIS IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE IN TAIWAN

Chia-Yen Dai[1] Tzu-Chun Lin[1] Yu- Wei Wei[2] Po-Cheng Liang[2] Tyng-yuan Jang[2] Chih-Wen Wang[2] Ming-Lun Yeh[2] Jee-Fu Huang[3] Chung-Feng Huang[2] Wan-Long Chuang[2] Ming-Lung Yu[4], [1]Kaohsiung Medical University Hospital, Kaohsiung Medical University, [2]Kaohsiung Medical University Hospital, Kaohsiung Medical University, [3]Kaohsiung Medical University Hospital, [4]Kaohsiung Medical University/ Kaohsiung Medical University Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a growing global health burden and a leading cause of chronic liver disease. Liver fibrosis is the strongest predictor of complications and liver-related mortality; however, early identification of significant fibrosis remains challenging. This study

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

aimed to develop and validate machine learning (ML) models for predicting significant fibrosis in MASLD using routinely available clinical variables and to improve model interpretability using explainable artificial intelligence. **Methods:** A total of 2,825 participants with FibroScan-confirmed MASLD were retrospectively enrolled. The cohort was randomly divided into training (80%, n = 2,260) and testing (20%, n = 565) datasets. Demographic, anthropometric, metabolic, and biochemical variables were analyzed, including age, sex, body mass index (BMI), waist circumference, liver enzymes, fasting plasma glucose, lipid profiles, and platelet count. Five supervised ML algorithms-Logistic Regression, Random Forest, CatBoost, Elastic Net, and XGBoost-were developed and evaluated using accuracy, precision, recall, F1-score, receiver operating characteristic area under the curve (AUROC), and precision-recall (PR) curve analysis. Model robustness was assessed using 1,000 bootstrap resampling iterations. SHapley Additive exPlanations (SHAP) analysis was applied to the best-performing model to identify key predictors and nonlinear threshold effects. **Results:** Among all models, CatBoost demonstrated the best predictive performance. In the training dataset, CatBoost achieved an AUROC of 0.93, compared with 0.91 for Random Forest and XGBoost and approximately 0.88 for Logistic Regression and Elastic Net. In the testing dataset, CatBoost maintained superior discrimination with an AUROC of 0.90, indicating strong generalizability and minimal overfitting. CatBoost also achieved the highest PR AUC values in both training (0.64) and testing (0.52) datasets, along with the highest testing accuracy (0.835), precision (0.355), and F1-score (0.486). Bootstrapping confirmed significantly superior model performance compared with other algorithms ($p < 0.001$). SHAP analysis identified aspartate aminotransferase (AST), gamma-glutamyl transferase (GGT), BMI, alanine aminotransferase (ALT), platelet count, and waist circumference as the most influential predictors of significant fibrosis. **Conclusion:** ML models, particularly CatBoost, demonstrated high accuracy and robustness for predicting significant fibrosis in MASLD using routinely available clinical data. Integration of SHAP analysis enhanced model interpretability and identified clinically meaningful predictors and threshold effects. These findings support the potential application of explainable ML models as scalable, non-invasive tools for fibrosis risk stratification and early clinical intervention in MASLD.

2608 | THE HASHIMOTO MIRAGE: WHY AUTOIMMUNE THYROIDITIS LOOKS PROTECTIVE AGAINST MASLD IN TYPE 2 DIABETES

Emeka Stanley Obi[1] Uwakmfonabasi Umoudoh[2] Adedeji Adenusi[3] Gedion Amdetsion[4] Abdulrahman Atasi[1] Chimezirim Ezeano[5] Somtochukwu Abazu[6] Abidemi Akinrinmade[7] Joshua Kalu[8], [1]Brookdale University Hospital and Medical Center, [2]NYCHHC/Lincoln Medical Center, [3]Interfaith Medical Center, [4]John H Stroger Hospital of Cook County, [5]Advocate Aurora Healthcare, [6]Howard University Hospital, [7]SUNY Upstate University, [8]Suny Downstate Medical Center

Background: Thyroid hormone signaling drives hepatic lipid metabolism, validated by resmetirom's MASH approval. Prior work links hypothyroidism to MASLD, but whether the autoimmune process of Hashimoto's thyroiditis (AT) confers independent hepatic or cardiometabolic risk, separate from hormone deficiency, is untested. We examined this in type 2 diabetes (T2DM), restricting both arms to patients not on levothyroxine to isolate the immune from the treated hypothyroid phenotype. **Methods:** Retrospective propensity matched cohort study using the TriNetX US Collaborative Network (65 HCOs). Adults ≥ 18 with T2DM in the prior 5 years were included; Cohort 1 had coexisting AT, Cohort 2 did not. Both excluded levothyroxine use, hyperthyroidism, T1DM, viral hepatitis, hemochromatosis, and Wilson's disease. 1: 1 propensity score matching balanced age, sex, race, BMI, hypertension, hyperlipidemia, obesity, tobacco or alcohol use, CKD, and OSA. Incident MASLD, MASH, cirrhosis, MI, and ischemic stroke were assessed ≥ 180 days after index via risk ratios (RR) and Cox hazard ratios (HR). **Results:** After matching, 9,192 patients per cohort (mean age 59.5; 81% female; post PSM Standardized Mean Difference < 0.10 except BMI 0.139). The AT cohort had lower incidence of MASLD (3.2% vs 4.3%; RR 0.74 [0.63–0.87], $p < 0.001$; HR 1.02, $p = 0.86$), MASH (0.58% vs 0.88%; RR 0.67 [0.47–0.94], $p = 0.021$; HR 0.94, $p = 0.72$), cirrhosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(0.97% vs 1.63%; RR 0.59 [0.46–0.77], p < 0.001; HR 0.65 [0.43–0.96], p = 0.029), acute MI (0.92% vs 2.06%; RR 0.45 [0.34–0.58], p < 0.001; HR 0.62 [0.48–0.81], p < 0.001), and ischemic stroke (1.24% vs 1.86%; RR 0.67 [0.53–0.85], p = 0.001; HR 0.98, p = 0.86). Prevalent MASLD before the window was more frequent in the AT cohort (1,451 vs 1,099), indicating depletion of susceptibles. **Conclusion:** Among diabetic adults not on levothyroxine, AT was associated with 26% lower MASLD, 33% lower MASH, 41% lower cirrhosis, 55% lower MI, and 33% lower ischemic stroke incidence, with the strongest signals, significant on both risk and survival analyses, for cirrhosis and acute MI. AT patients are surveilled more intensively, so steatotic and cardiometabolic disease is detected earlier and depleted from the at-risk pool. Excluding levothyroxine strips out the metabolically sickest AT patients, leaving an inherently healthier, euthyroid subgroup in the exposed arm. Intensified cardiometabolic care from chronic endocrine follow-up may accelerate diagnosis and treatment of dyslipidemia and hypertension, lowering downstream MI and cirrhosis risk independent of any thyroid mechanism. Possible immunometabolic crosstalk between thyroid, gut, and liver, together with the above explains AT without levothyroxine in T2DM as a lower risk cardiometabolic phenotype. Confirmatory analyses should incorporate anti-TPO titers, lab-confirmed euthyroid status, FIB-4 trajectories, and active-comparator designs against non-autoimmune euthyroid populations.

2609 | INTERMITTENT HYPOXIA AND CIRRHOSIS RISK IN MASLD-OSA OVERLAP: A PROPENSITY-MATCHED STUDY

Ihunanya Kanu[1] Chimezirim Ezeano[2] Cherechi Nwabueze[3] Nzubechukwu Okeke[4] Eunice Omeludike[5] Emeka Stanley Obi[6] Richard Heard[7], [1]Baptist Memorial Hospital- Golden Triangle, [2]Advocate Aurora Healthcare, [3]John H. Stroger Jr. Hospital of Cook County, [4]Zucker School of Medicine at Hofstra/Northwell at Vassar Brothers Medical Center, [5]Piedmont Athens Regional Medical Center, [6]Brookdale University Hospital and Medical Center, [7]Baptist Memorial Hospital - Golden Triangle

Background: Obstructive sleep apnea (OSA) and metabolic dysfunction-associated steatotic liver disease (MASLD) commonly coexist, with intermittent hypoxia implicated in hepatic inflammation and fibrogenesis. Although continuous positive airway pressure (CPAP) is the cornerstone of OSA management, its association with liver-related outcomes in MASLD-OSA overlap remains poorly characterized. We evaluated the association between documented CPAP exposure and incident cirrhosis in a large propensity-matched cohort derived from a federated electronic health record network. **Methods:** We conducted a retrospective propensity score-matched cohort study using the TriNetX Global Collaborative Network, including 16 U.S. healthcare systems. Adults aged ≥ 18 years with diagnostic codes for MASLD/MASH and OSA were identified. Patients with competing liver diseases, prior liver transplantation, or central sleep apnea were excluded. The exposed cohort included patients with ≥ 1 documented CPAP procedure or durable medical equipment code, while the comparator cohort had OSA without CPAP codes. Cohorts were propensity score matched 1: 1 on demographics and cardiometabolic comorbidities, yielding 844 patients per group. The primary outcome was incident cirrhosis, defined by de novo diagnostic codes. Risk differences, risk ratios, odds ratios, Kaplan-Meier curves with log-rank testing, and Cox proportional hazards models were used to compare outcomes. **Results:** Before matching, 845 CPAP-exposed and 88,382 unexposed patients were identified. After 1: 1 propensity score matching, 844 patients remained in each cohort. Mean follow-up was 1,415.9 ± 1,219.2 days in the CPAP cohort and 1,680.2 ± 1,346.6 days in the untreated cohort. Incident cirrhosis occurred more frequently in the CPAP cohort than in the untreated cohort, 56/780 (7.2%) vs 36/815 (4.4%), respectively, corresponding to a risk difference of 2.8% (95% CI, 0.5–5.1; p = 0.018), risk ratio of 1.63 (95% CI, 1.08–2.44), and odds ratio of 1.67 (95% CI, 1.09–2.58). Kaplan-Meier analysis similarly showed higher cumulative incidence of cirrhosis among CPAP-exposed patients, with a log-rank p = 0.005 and hazard ratio of 1.82 (95% CI, 1.19–2.78; p = 0.009). Cirrhosis-coded encounters were also higher in the CPAP cohort, 0.742 ± 4.727 vs 0.240 ± 2.146; p = 0.006. **Conclusion:** Documented CPAP exposure was associated with higher observed cirrhosis risk among adults with MASLD and OSA, likely reflecting unmeasured confounding by OSA severity, indication bias, and differential healthcare utilization. These findings underscore the need for prospective studies incorporating OSA severity metrics, CPAP adherence data, and longitudinal liver biomarkers and fibrosis measures before concluding that CPAP modifies MASLD progression.

2610 | ASSOCIATION BETWEEN NON-ALCOHOLIC FATTY LIVER DISEASE, METABOLIC SYNDROME, AND STROKE SUBTYPE: A HOSPITAL-BASED OBSERVATIONAL STUDY

Ajay Jain[1] Vishwa Gupta[2] Suchita Jain[3] Shohini Sircar[4] Sudhanshu Yadav[4], [1]Shalby Hospital, [2]All India Institute of Medical Sciences, [3]Sri Aurobindo Institute of Medical Sciences, [4]Shalby Institute of Gastroenterology

Background: NAFLD is often regarded as the hepatic manifestation of metabolic syndrome, with both conditions sharing pathophysiological links to cerebrovascular disease. However, whether NAFLD independently associates with stroke type and metabolic syndrome in Indian patients remains unexplored. We aimed to determine the prevalence of NAFLD in hospitalized stroke patients. **Methods:** This cross-sectional, observational study enrolled 110 acute stroke patients (age > 30 years) admitted to the Department of Neurology from April 2023 to August 2024. NAFLD was diagnosed by abdominal ultrasonography (USG) based on increased hepatic echogenicity after exclusion of secondary causes and significant alcohol use. The NAFLD fibrosis score (NFS) was computed to estimate fibrosis severity. Laboratory investigations included liver function tests (LFT), lipid profile, and fasting blood glucose. Metabolic syndrome was assessed using established criteria. Statistical analysis was performed using SPSS v25.0. **Results:** Of 110 patients (76.4% male; mean age 62.6 +/- 9.9 years), 89 (80.9%) had ischemic and 21 (19.1%) hemorrhagic stroke. On USG, 57 patients (51.8%) had fatty liver - grade I in 31.8%, grade II in 15.5%, and grade III in 4.5%. By NFS, 42.7% had no/mild fibrosis (F0-F2), 10% had significant fibrosis (F3-F4), and 47.3% were indeterminate. Hypertension (68.2%), overweight/obesity (61.8%), and diabetes mellitus (46.4%) were the most prevalent comorbidities. Metabolic syndrome was present in 50% of subjects. Serum albumin was significantly lower in NAFLD patients compared to those without NAFLD (p = 0.006). No statistically significant association was found between NAFLD and type of stroke, age, BMI, or metabolic syndrome. **Conclusion:** NAFLD was highly prevalent (51.8%) among stroke patients in this central Indian cohort. These findings underscore the need for routine screening of liver disease in stroke populations to guide comprehensive cardiometabolic management.

2611 | PREGNANCY OUTCOMES IN PATIENTS WITH MASLD FOLLOWING ROUX-EN-Y GASTRIC BYPASS: A PROPENSITY SCORE-MATCHED TRINETX ANALYSIS

Sherifatu Abu[1] Kailyn Brown[2] Shama Antala[2] Mitali Sarkar[3] Yedidya Saiman[4] Kimberly Forde[5], [1]Temple Univeristy Hospital, [2]Lewis Katz School of Medicine, Temple University, [3]Temple Univeristy, [4]Lewis Katz School of Medicine at Temple University, [5]Temple University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly prevalent among women of reproductive age and is associated with adverse maternal and pregnancy outcomes. Roux-en-Y gastric bypass (RYGB) improves obesity-related metabolic dysfunction and MASLD severity; however, pregnancy outcomes among patients with MASLD following bariatric surgery remain incompletely characterized. **Methods:** We performed a retrospective cohort study using the TriNetX Research Network database from 2005 to 2026. Pregnant patients with MASLD and prior RYGB were identified and compared to pregnant patients with MASLD without prior bariatric surgery. The index event was defined as a pregnancy diagnosis. MASLD diagnosis and RYGB were required to occur at least 6 months prior to the index event. Outcomes were assessed within 300 days following the index date and included hypertensive disorders of pregnancy, gestational metabolic complications, hemorrhagic complications, obstetric complications, severe maternal morbidity, and cesarean delivery. We performed 1: 1 propensity score matching using demographics and metabolic comorbidities including age, race, obesity, and type 2 diabetes mellitus. Multivariable Cox proportional

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hazards regression was subsequently performed to generate adjusted hazard ratios (aHRs) for maternal and obstetric outcomes. **Results:** A total of 23,360 pregnant patients with MASLD without bariatric surgery and 2,339 pregnant patients with MASLD and prior RYGB were identified. After propensity score matching, 2,334 patients remained in each cohort with balanced baseline characteristics and no significant differences in demographics or major metabolic comorbidities ($p > 0.05$). On multivariable regression analysis, prior RYGB remained independently associated with lower hazards of pre-eclampsia (aHR 0.55, 95% CI 0.47–0.65), gestational hypertension (aHR 0.75, 95% CI 0.66–0.86), gestational diabetes mellitus (aHR 0.53, 95% CI 0.47–0.58), postpartum hemorrhage (aHR 0.74, 95% CI 0.60–0.90), polyhydramnios (aHR 0.77, 95% CI 0.62–0.96), and cesarean delivery (aHR 0.85, 95% CI 0.77–0.95) (all $p < 0.05$). No significant adjusted differences were observed for premature rupture of membranes, preterm labor, antepartum hemorrhage, or severe obstetric complications. **Conclusion:** Among pregnant patients with MASLD, prior RYGB was associated with significantly lower risks of several adverse maternal and metabolic pregnancy outcomes, including hypertensive disorders of pregnancy, gestational diabetes, postpartum hemorrhage, and cesarean delivery. These findings suggest bariatric surgery may provide maternal benefits in this high-risk population. Prospective studies are needed to further evaluate maternal and fetal outcomes following bariatric surgery in patients with MASLD.

Table 1. Adjusted Maternal and Obstetric Outcomes Following Prior RYGB in Pregnant Patients with MASLD

Outcome	Adjusted Hazard Ratio	95% CI	P-value
Pre-eclampsia	0.55	0.47–0.65	<0.0001
Gestational HTN	0.75	0.66–0.86	<0.0001
Gestational DM	0.53	0.47–0.58	<0.0001
Preterm labor	1.10	0.93–1.31	0.2684
Postpartum hemorrhage	0.74	0.60–0.90	0.0032
Antepartum hemorrhage	1.16	0.99–1.36	0.0712
Polyhydramnios	0.77	0.62–0.96	0.0209
Severe maternal morbidity¥	0.78	0.46–1.33	0.3652
Cesarean delivery	0.85	0.77–0.95	0.0042
PROM	0.96	0.80–1.16	0.7031

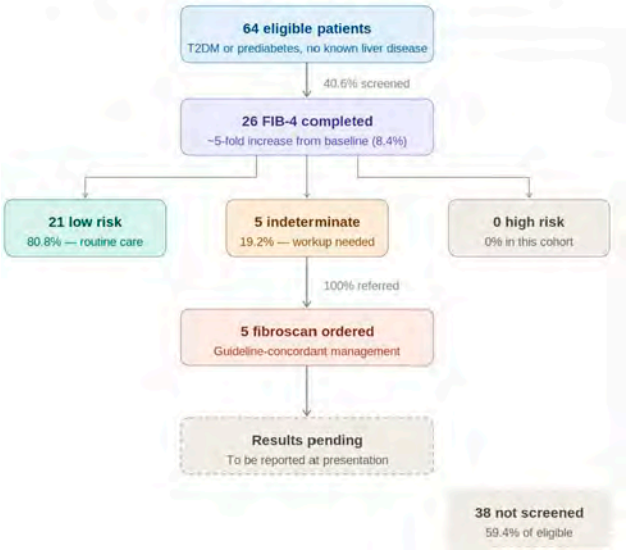
2612 | IMPROVING FIB-4-BASED MASLD FIBROSIS RISK ASSESSMENT AND DOWNSTREAM MANAGEMENT IN A RESIDENT PRIMARY CARE CLINIC

Tomas Correa-Gaviria[1] Maitri Patel[1] Jonathan Dranoff[1] Mario Ochoa Prieto[1], [1]Yale University



Background: MASLD affects up to 70% of patients with type 2 diabetes (T2DM) and disproportionately impacts underserved populations. The FIB-4 index is recommended as a first-line fibrosis tool but remains underutilized in primary care. We evaluated baseline FIB-4 use in a resident continuity clinic and assessed the impact of a multifaceted intervention on screening rates and downstream management. **Methods:** We conducted a single-center quality improvement initiative in a resident clinic embedded within a Federally Qualified Health Center. Eligible patients were adults with T2DM and without a prior diagnosis of liver disease. Baseline FIB-4 documentation was assessed retrospectively before January 2026. Resident surveys assessed barriers and knowledge gaps. Interventions included resident and preceptor education, an Epic SmartPhrase with automated FIB-4 calculation and interpretation guidance, and clinic-based visual reminders. The primary outcome was patient-level FIB-4 documentation; secondary outcomes included risk classification and guideline-concordant management. Outcomes were tracked prospectively from January through May 2026. **Results:** At baseline, FIB-4 was documented in 13/154 eligible patients (8.4%). Pre-intervention surveys identified uncertainty in FIB-4 interpretation and competing clinical priorities as major barriers. Post-intervention, 64 eligible patients were identified. FIB-4 was completed in 26 patients (40.6%), representing a ~5-fold increase from baseline. Risk stratification revealed 21 low-risk (80.8%) and 5 indeterminate (19.2%) results; no patients were classified as high-risk. All 5 patients with indeterminate FIB-4 had a guideline-concordant fibroscan ordered (100%). Fibroscan results are pending and will be reported at the time of presentation. **Conclusion:** A multifaceted EMR-integrated intervention significantly improved FIB-4-based fibrosis screening rates in a safety-net primary care clinic serving a high-risk, underserved population. The cascade of care identified patients with potentially unrecognized advanced fibrosis, underscoring the real-world clinical impact of systematic screening in this population. Persistent gaps between risk identification and completion of secondary evaluation highlight the ongoing need for continued workflow

2613 | TEMPORAL TRENDS IN MORTALITY DUE TO LIVER DISEASES AND COMORBID METABOLIC SYNDROME IN OLDER ADULTS IN THE UNITED STATES: CDC WONDER ANALYSIS (1999–2024)

Bland Ahmed[1] Mahrukh Mahrukh[2] Shehryar Rasheed Sohail[3] Hajra Umar Jaspal[4] Zainab Attiq[2] Arooj Ihsan Ullah[5] Palwasha Farooqi[6] Ehsanullah Alokozay[7], [1]Desert Regional Medical Center, [2]University Medical and Dental College, University of Faisalabad, Faisalabad, Pakistan, [3]Jinnah Sindh Medical University, [4]University College of Medicine and Dentistry (UCMD), The University of Lahore, Lahore, Pakistan, [5]FJMU lahore, [6]Desert Regional Medical Center, Palm Springs, Ca, USA, [7]Faculty of Medicine, Kandahar University, Kandahar, Afghanistan

Background: Liver diseases share pathophysiological mechanisms with metabolic syndrome, including chronic inflammation and insulin resistance. These conditions frequently co-occur in older adults (≥65 years) and may synergistically increase mortality risk. This study examined national mortality trends in concomitant liver diseases and metabolic syndrome among older U.S. adults from 1999 through 2024. **Methods:** A retrospective, population-based analysis was performed using the CDC WONDER Multiple Cause of Death database. Deaths with ICD-10 codes for liver diseases (K70–K76) and metabolic syndrome (Diabetes: E10–E14; Obesity: E66.0–66.2, E66.8–66.9; Hyperlipidemia and plasma protein metabolism disorders: E78, E88.0–88.3, E88.8–88.9; Essential hypertension: I10) were included. Age-adjusted mortality rates (AAMRs) were calculated per 100,000 population. Joinpoint regression was used to assess temporal trends. Analyses were stratified by sex, age group, race/ethnicity, census region, and urbanization. **Results:** Between 1999 and 2024, the overall AAMR for liver diseases with metabolic syndrome increased significantly from 11.92 to 29.27 per 100,000 (AAPC: +3.61%; 95% CI: 3.37–3.93). Sex-stratified analysis showed higher long-term increases in men (AAPC: +3.87%; 95% CI: 3.60–4.24) compared to women (AAPC: +3.20%; 95% CI: 2.95–3.58). Age-specific analysis revealed the sharpest increase among the 85 + years cohort (AAPC: +4.73%; 95% CI: 4.28–5.29), with notable acceleration after 2018 (APC: +16.23%). Regional analysis showed that the South recorded the largest long-term increase (AAPC: 4.17%; 95% CI: 3.96–4.40), while the Midwest showed the steepest rise between 2018 and 2021 (APC: 14.13%). Compared to urban areas, rural populations had a higher and more persistent rise in mortality (AAPC: +3.82%; 95% CI: 3.46–4.24). By race/ethnicity, White adults showed the highest long-term increase (AAPC: +3.97%; 95% CI: 3.75–4.23), followed by American Indian or Alaska Native adults (AAPC: +2.85%; 95% CI: 1.96–4.27). Black or African American adults showed a sharp short-term rise from 2016–2022 (APC: +10.76%). **Conclusion:** From 1999 to 2024, mortality among older adults with concurrent liver diseases and metabolic syndrome increased substantially, with pronounced acceleration after 2018. Older men (85+ years), rural residents, and White populations experienced the highest mortality burden. These data highlight the growing intersection of liver diseases and metabolic syndrome as a determinant of mortality in older adults, underscoring the need for integrated metabolic and hepatologic management in aging populations.

2614 | HEPATOLOGY REFERRAL TIMING IN MASLD-ASSOCIATED DECOMPENSATED CIRRHOSIS: A RETROSPECTIVE COHORT STUDY

Maitri Patel[1] Saumya Srivastava[1] Bubu Banini[1], [1]Yale University

Background: Decompensated cirrhosis is a leading cause of liver-related morbidity and mortality, with metabolic dysfunction-associated steatotic liver disease (MASLD) emerging as one of its fastest-growing etiologies. Patients who progress to decompensation face high short-term mortality and require timely, coordinated specialty care, yet access to hepatology services remains variable and infrequently studied. We aimed to evaluate referral patterns and the association between time-to-care and mortality amongst a sample of patients with decompensated MASLD cirrhosis to better characterize whether longer time-to-care contributes to worse outcomes. **Methods:** We performed a retrospective cohort study of patients with decompensated cirrhosis who were seen in a tertiary care fatty liver disease clinic between 2018-2022. Demographic, referral, and clinical outcomes data were abstracted from the electronic medical records. Time intervals were calculated between the diagnosis of cirrhosis, gastroenterology (GI)/hepatology referral, first outpatient GI visit, first hepatology visit, and mortality. Descriptive statistics were calculated and presented as medians and interquartile ranges (IQR). Kaplan-Meier curves were developed to evaluate this association between delays in hepatology care and time to mortality. **Results:** Of the 1,028 patients evaluated in the fatty liver disease clinic during this time period, 65 patients (6.3%) had decompensated cirrhosis. Mean age at the first hepatology visit was 57.1 years (median 58.8 years, IQR 48.1–65.8) and 35 (53.8%) were men. Primary care providers placed the largest proportion of referrals (38.5%), followed by GI/hepatology providers (33.8%), other specialists (15.4%), and hospitalists (10.8%). The median time from cirrhosis diagnosis to GI evaluation was 0 days (IQR -99–46), compared to 112 days (IQR 8–694) for hepatology evaluation. From referral time to initial clinic visit, wait times were also higher for hepatology visits (median 36 days; IQR 12-53) compared to gastroenterology (median 16 days; IQR 10-22). Notably, 24 of 65 patients (36.9%) experienced a decompensation event prior to hepatology referral placement. A total of 23 patients (35.4%) died during follow-up. Among deceased patients, median time from first hepatology visit to death was 907 days (IQR 328–2,034). **Conclusion:** Among patients with decompensated MASLD cirrhosis, over one-third experienced decompensation prior to referral placement. This pattern suggests that patients may be entering specialty care late in the disease course, potentially limiting opportunities for preventive interventions, surveillance, and transplant evaluation. Health-system strategies focused on earlier cirrhosis recognition and expedited hepatology referral pathways warrant further investigation, especially within primary care, where the majority of patients with MASLD are initially evaluated.

Disclosures: Maitri Patel: Nothing to Disclose, Saumya Srivastava: Nothing to Disclose, Bubu Banini: Nothing to Disclose.

2615 | NON-CIRRHOTIC METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE AND INPATIENT OUTCOMES AMONG ADULTS HOSPITALIZED FOR INFLAMMATORY BOWEL DISEASE FLARES: A NATIONWIDE ANALYSIS

Cherechi Nwabueze[1] Eunice Omeludike[2] Chimezirim Ezeano[3] Yetunde Akande[1] Ihunanya Kanu[4] Nzubechukwu Okeke[5] Ridwan Lawal[6] Ifelunwa Osanakpo[7], [1]John H. Stroger Jr. Hospital of Cook County, [2]Piedmont Athens Regional Medical Center, [3]Advocate Aurora Healthcare, [4]Baptist Memorial Hospital- Golden Triangle, [5]Zucker School of Medicine at Hofstra/Northwell at Vassar Brothers Medical Center, [6]University of Texas Rio Grande Valley, [7]Carle Foundation Hospital

Background: The gut–liver axis plays a central role in regulating immune responses and systemic inflammation. Metabolic dysfunction–associated steatotic liver disease (MASLD) and inflammatory bowel disease (IBD) frequently coexist and share overlapping inflammatory and metabolic pathways, however, the impact of pre-existing MASLD on outcomes during IBD flares remains unclear. We evaluated the association between non-cirrhotic MASLD and inpatient outcomes among adults hospitalized for IBD flares using a nationwide U.S. cohort. **Methods:** A retrospective cohort analysis of the National Inpatient Sample (2016–2022) was conducted. Adult hospitalizations with a primary diagnosis of IBD flare were identified using ICD-10-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

CM codes; those with pre-existing non-cirrhotic MASLD comprised the exposure group. Survey-weighted analyses generated national estimates. Multivariable logistic and linear regression models adjusted for demographics, hospital characteristics, IBD subtype, cardiometabolic comorbidities, and overall comorbidity burden were used to evaluate mortality, complications, healthcare utilization, and discharge outcomes. **Results:** Among 121,176 hospitalizations for primary IBD flares (weighted estimate: 605,880), 16,775 (2.8%) had documented non-cirrhotic MASLD. Compared with patients without MASLD, those with MASLD were older (49.5 vs 46.1 years) and had a greater comorbidity burden (mean Elixhauser score 4.01 vs. 2.23; both $p < 0.001$). After multivariable adjustment, MASLD was not associated with inpatient mortality (aOR 0.47, 95% CI 0.19-1.16; $p = 0.10$) but was associated with lower odds of major inpatient complications (aOR 0.72, 95% CI 0.65–0.80; $p < 0.001$), defined as a composite of sepsis, shock, acute kidney injury, respiratory failure, venous thromboembolism, colectomy, and bowel surgery. MASLD was also associated with lower odds of inpatient colectomy (aOR 0.57, 95% CI 0.46-0.70) and non-routine discharge (aOR 0.58, 95% CI 0.50–0.67), as well as shorter length of stay (β -1.08 days, 95% CI -1.35 to -0.82) and lower total hospital charges (β -$9,157, 95% CI -$13,414 to -$4,900) (all $p < 0.001$). Similar findings were observed in analyses stratified by Crohn's disease and ulcerative colitis. **Conclusion:** Despite a higher cardiometabolic burden, documented non-cirrhotic MASLD was not associated with increased short-term inpatient risk and was associated with lower healthcare utilization and complication rates during IBD flare hospitalizations. Further studies are needed to clarify the mechanisms underlying these unexpected findings and to better define the role of the gut–liver axis in acute inflammatory disease states.

2616 | PROGNOSTIC BURDEN OF 2023 STEATOTIC LIVER DISEASE SUBTYPES: DIFFERENTIAL IMPACTS ON MORTALITY, CANCER, AND CARDIOVASCULAR OUTCOMES

Parucha Paruchakul[1] Moongmun Anuntasainont[2] Mingkwan Ratanapipop[2] Sakkarin Chirapongsathorn[2], [1]Phramongkutklao Hospital, [2]Department of Medicine, Phramongkutklao Hospital and College of Medicine

Background: The 2023 steatotic liver disease (SLD) classification integrates metabolic dysfunction and alcohol exposure, but its prognostic implications remain uncertain, particularly in Asian populations. We evaluated long-term mortality, cancer, and cardiovascular disease (CVD) outcomes across 2023 SLD subtypes in an Asian cohort. **Methods:** Adults with ultrasonography-defined SLD in 2014 were retrospectively reclassified according to the 2023 SLD criteria and followed for up to 11 years. Outcomes included all-cause and cause-specific mortality, cancer incidence, and CVD incidence. Kaplan–Meier analysis and Cox regression analyses were used for mortality outcomes. Cancer and CVD analyses excluded patients with pre-existing disease and used incidence rate ratios (IRRs) and multivariable Cox models. Advanced fibrosis was defined using the FIB-4 (Fibrosis-4) index (≥ 2.67). **Results:** A total of 1,279 patients were included (median age 57 years; 57% male); advanced fibrosis was present in 11% of 705 evaluated patients. 88% had metabolic dysfunction–associated SLD (MASLD), 3% MASLD with increased alcohol intake (MetALD), 3% alcohol-associated liver disease (ALD), and 6% other SLDs. Over a median follow-up of 10.8 years (67 deaths), ALD had the highest mortality rate (58.6 per 1,000 person-years (PY)) and lowest 10-year survival (58.9%). ALD was independently associated with increased all-cause mortality compared with MASLD (adjusted hazard ratio [aHR] 4.02; 95% CI 1.14–14.15), after adjustment for FIB-4–defined fibrosis and metabolic comorbidities. Older age, diabetes, chronic kidney disease, inflammatory markers, and advanced fibrosis were independent mortality predictors. Mortality was primarily driven by liver- and cancer-related causes, while CVD mortality did not differ across subtypes.Among patients without baseline cancer, 102 cancers occurred over 10,220 PY (997 per 100,000 PY). ALD conferred a significantly increased cancer risk compared with MASLD (IRR 5.08; 95% CI 2.22–11.62; $p < 0.001$), with the highest rates of both hepatocellular and extrahepatic malignancies, particularly lung cancer. In contrast, among those without baseline CVD, 51 events occurred over 10,289 PY (495 per 100,000 PY), with no significant differences in cardiovascular outcomes across subtypes. **Conclusion:** In this long-term Asian cohort reclassified by the 2023 SLD criteria, ALD emerged as a high-risk subtype with markedly increased mortality and cancer burden, whereas cardiovascular risk did not differ significantly across subtypes. These findings suggest that prognostic differentiation in SLD is driven by mortality and malignancy rather than cardiovascular events.

2617 | NOVEL COMMUNITY-BASED LIVER HEALTH AWARENESS INITIATIVE USING NON-INVASIVE TESTING IDENTIFIES UNRECOGNIZED AT-RISK MASLD

Michael Betel[1] Sherri Brown[1] Michael McTighe[2] Lindsay Myles[3] Supriya Joshi[4] Magdy Elkhashab[5] Daniyal Khan[6] Mark Swain[6], [1]Fatty Liver Alliance, [2]Mindray, [3]Simcoe Liver Centre, Fatty Liver Alliance and Mountain Metabolic, [4]Trillium Health Partners (Credit Valley Hospital), [5]Toronto Liver Centre, [6]University of Calgary

Background: Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD) is highly prevalent and often remains undiagnosed until fibrosis has significantly progressed. There is a need for practical, individual-driven, community-based models to improve liver health awareness and support early identification and appropriate action. To address this gap, we developed and implemented a community-based, self-referral, non-invasive testing and education program at the Liver Health Awareness Centre (LHAC) in Toronto, Canada. **Methods:** Individuals ≥18 years of age who self-referred to LHAC were offered a no-cost liver stiffness measurement (LSM) using *Hepatus-5* transient elastography (TE), and provided with a concise NP-led structured liver health overview, including hepatic steatosis, fibrosis, and an interpretation of their LSM results. With consent, individual medical history and demographics were collected, including MASLD metabolic risk factors (dyslipidemia, hypertension, and type 2 diabetes). At-risk (LSM 8-12 kPa) or high-risk (LSM ≥12 kPa) individuals were offered a referral to a hepatologist for further assessment. Group characteristics were compared using chi-square tests for categorical variables, and t-tests and logistic regression for continuous variables. **Results:** A total of 210 individuals were sequentially assessed (128 females (60.9%); mean (SD) age 52.7 years (12.9)). Most individuals learned about LHAC online (65.7%). About half had a known history of liver disease (n = 104, 49.5%), but most had never had a LSM (n = 165, 78.6%, $p < 0.05$). Most individuals (63.8%) had at least one MASLD risk factor, with roughly half (47%) having multiple risk factors. Most common MASLD risk factors were elevated cholesterol (43.3%) and hypertension (24.3%). A total of 79 (37.6%) individuals had liver enzyme tests previously performed, with 43% reporting elevated levels. Individuals with known history of liver disease were more likely to have elevated liver enzymes ($p < 0.05$), higher BMI ($p < 0.05$), presence of a MASLD risk factor ($p < 0.05$), higher steatosis levels ($p < 0.05$), and higher stiffness scores compared to those without ($p < 0.05$). Mean (SD) steatosis scores on TE were 263.2 (42.8) dB/m, with 36.4% having S3 grade steatosis. Mean (SD) LSM measurement was 5.7 (3.1) kPa, with 11.4% assessed as being 'at-risk' or 'high risk' for advanced fibrosis (LSM > 8.0 kPa). Only prior history of hypertension (n = 51, OR: 1.83, $p < 0.05$) was associated with increased odds of at-risk liver stiffness. **Conclusion:** A community-based, no-cost, self-referral Liver Health Awareness Centre program may represent a feasible model for improving public awareness and identifying individuals with at risk MASLD who have been missed by gaps in the current health care processes. These pilot findings may support broader use of this approach as part of MASLD prevention, awareness, and referral pathways.

2618 | DIABETES AND LIVER FIBROSIS AS COMPOUNDING RISK FACTORS FOR CHRONIC KIDNEY DISEASE IN PATIENTS WITH

Seung Up Kim[1] Chan-Young Jung[2], [1]Yonsei University, [2]Asan Medical Center, Seoul, Korea

Background: Diabetes mellitus (DM) and liver fibrosis frequently coexist, yet whether they represent distinct or overlapping pathways for chronic kidney disease (CKD) remains unclear. We investigated whether liver fibrosis independently predicts CKD risk and confers additional risk when coexisting with DM in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** This retrospective cohort included 4,233 adults with MASLD without pre-existing CKD who underwent vibration-controlled transient elastography (VCTE) from 2006 to 2018. Participants were categorized into four groups based on DM and fibrosis status. Liver fibrosis was defined as fibrosis-4 index > 2.67 or liver stiffness ≥ 8 kPa. The primary outcome was incident CKD; secondary outcomes included ≥ 25% eGFR decline and 3- and 5-year CKD risk. **Results:** During a mean follow-up of 2.9 years, 181 (4.3%) participants developed incident CKD. Compared with those without DM or fibrosis, patients with both conditions had the highest adjusted risk of incident CKD (aHR 3.00, 95% CI 1.84–4.89) and 25% eGFR decline (aHR 2.55, 95% CI 1.85–3.51). Neither multiplicative nor additive interaction was significant (all $P > 0.05$), suggesting independent, compounding effects. Mediation analysis showed that liver fibrosis mediated a small but significant proportion of the DM-associated risk of incident CKD (4.8%, $P = 0.028$) and 25% eGFR decline (5.8%, $P = 0.013$). **Conclusion:** In patients with MASLD, DM and liver fibrosis are compounding risk factors for CKD, supporting integrated risk stratification based on both glycemic and hepatic fibrosis status.

2619 | IMPACT OF CARDIOMETABOLIC RISK FACTORS AND ALCOHOL CONSUMPTION IN DECOMPENSATED LIVER CIRRHOSIS

Keungmo Yang[1] Jaejun Lee[1] Ji Won Han[1] Pil Soo Sung[1] Chang Wook Kim[1] Heechul Nam[1] Ahlim Lee[1] U Im Chang[1] Do Seon Song[1] Haelim Lee[1] Hee Kim[1] Sung Won Lee[1] Jeong Won Jang[1], [1]College of Medicine, The Catholic University of Korea

Background: Cardiometabolic risk factors (CMRFs) and alcohol consumption are recognized determinants of disease progression in metabolic dysfunction–associated steatotic liver disease (MASLD). However, their relative prognostic impacts following the transition to decompensated cirrhosis remain unclear. This study aimed to clarify how CMRFs and alcohol exposure influence clinical outcomes in patients with decompensated cirrhosis. **Methods:** In this multicenter cohort study, 5,991 adults with MASLD-related cirrhosis who experienced their first hepatic decompensation between 2002 and 2024 were screened, and 2,670 were enrolled. Patients were classified into three categories: metabolic dysfunction–associated liver cirrhosis (MLC), metabolic dysfunction–associated alcohol-related liver cirrhosis (MALC), and alcohol–associated liver cirrhosis (ALC). Overall survival (OS) and transplant-free survival (TFS) were analyzed using multivariable Cox models, and discriminative performance was evaluated with the time-dependent area under the receiver operating characteristic curve. **Results:** Survival and liver-related outcomes decreased progressively from MLC to MALC to ALC ($P < 0.001$) **.** The incidences of hepatocellular carcinoma and cardio-cerebrovascular disease did not differ significantly across the subgroups. Daily alcohol consumption was independently associated with mortality in both OS ($P < 0.001$) and TFS ($P < 0.001$). Alcohol intake consistently emerged as a stronger prognostic determinant than CMRFs or related medications. Alcohol consumption showed superior short-term prognostic discrimination and, when incorporated into liver function–based models, significantly improved predictive performance and clinical net benefit, confirming its dominant role in survival. **Conclusion:** In decompensated cirrhosis, alcohol exposure—rather than CMRFs—emerges as the primary determinant of survival, in a dose-dependent manner. These findings underscore the necessity for refined risk stratification in decompensated cirrhosis, where the burden of alcohol consumption is a crucial factor influencing prognosis.

2620 | PERSISTENT CARE GAPS IN PATIENT-REPORTED STEATOTIC LIVER DISEASE EXPERIENCE ACROSS FIVE NATIONAL SURVEYS (2022-2026), DESPITE THE ARRIVAL OF MASH-SPECIFIC THERAPIES

Tiffany Mensah[1] Neeraj Mistry[1] Jenn Jones[2] Henry Chang[1] Wayne Eskridge[1], [1]Fatty Liver Foundation, [2]Sober Livers

Background: The State of Steatotic Liver Care in America survey serves as a yearly, patient-centered initiative designed to monitor the medical and social journeys of individuals with steatotic liver disease (SLD) across the United States. By examining data collected between 2022 and 2026, this analysis underscores the critical importance of documenting patient-reported experiences to pinpoint deficiencies in care and guide the development of focused policies and clinical interventions. **Methods:** Trends were identified using 2022–2026 data from US adults diagnosed with SLD. The mixed method survey consisted of 49 items across four domains: diagnosis and staging, medical management and physical impact, psycho-social and environmental impact, and current health. Core survey items were held consistent across all five waves to enable inter-year comparison. Items were developed in collaboration with the patient community, Fatty Liver Foundation Medical Advisory Group, and the Survey Analysis Group. Participants were recruited in person at a community clinic and online via email, social media, and patient fora. **Results:** Across all survey years, most respondents identified as living with MASLD or MASH, reflecting the survey's earlier focus on these populations prior to expanded outreach to individuals with ALD, MetALD, DILI, monogenetic or cryptogenic steatotic liver disease beginning in 2024. Diagnoses were most commonly initiated by a primary care provider during routine visits or identified incidentally during evaluation for unrelated issues. Blood-based testing and imaging remain the most common diagnosis methods. Although liver biopsy remains in use, its reported frequency has declined since 2023 relative to non-invasive methods (31.04% in 2023 to 19.09% in 2025). Diet and lifestyle counseling were the most common forms of support received, often paired with co-morbidity management. Few respondents were offered mental health resources, despite reports of anxiety, depression, and irritability; a modest increase in mental health support offered was observed in 2025 (5.83% in 2024 vs. 7.82% in 2025). Respondents identified peer support, condition-specific education, nutritional guidance, and greater physician empathy as their top unmet needs. **Conclusion:** These findings highlight persistent gaps in SLD care across diagnostic, clinical, and psychosocial domains. While non-invasive diagnostic approaches are increasingly favored, mental health support and patient-centered care remain underutilized. The consistency of unmet needs across five survey years underscores an urgent need for systemic improvements in SLD care delivery. Patient-reported data of this nature offer an actionable foundation for policy development, clinical guideline refinement, and the design of targeted support programs. Continued surveillance is essential to monitor progress and evaluate the impact of emerging interventions.

2621 | MYOSTEATOSIS, RATHER THAN SARCOPENIA, IDENTIFIES PHYSICAL FRAILTY IN COMPENSATED MASH CIRRHOSIS WITH OBESITY

Sobia Laique[1] Awwab Hammad[1] Sameer Gadani[1] Ricardo Rosero-Revelo[1] Nicole Welch[1] Annette Bellar[1] Yael Mauer[1] Paloma Rodriguez Alvarez[1] Shilpa Junna[1] Ali Aminian[1] Srinivasan Dasarathy[1], [1]Cleveland Clinic

Background: Sarcopenia predicts adverse outcomes in decompensated cirrhosis, but muscle quantity alone

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

may be an incomplete marker in compensated disease, particularly in patients with obesity. In compensated MASH cirrhosis, preserved skeletal muscle area may obscure impaired muscle quality from myosteatosis. This distinction is increasingly relevant as GLP-1 receptor agonists are widely used in this population and may reduce lean mass during weight loss. We characterized CT-defined body composition phenotypes in adults with compensated MASH cirrhosis and obesity and tested whether skeletal muscle radiodensity (SMD), a measure of muscle quality, was more closely associated with physical function than skeletal muscle index (SMI), a measure of muscle quantity. **Methods:** This cross-sectional study included 31 adults with compensated MASH cirrhosis and BMI ≥ 30 kg/m2 who underwent contrast-enhanced CT with L3-level body composition analysis using a dedicated semi-automated segmentation workstation. Measures included SMI, SMD corrected for portal venous phase contrast enhancement, and visceral and subcutaneous adipose tissue area. Sarcopenia was defined using cirrhosis-specific SMI cutoffs (<50 cm²/m² men, <39 cm²/m² women). Myosteatosis was defined as corrected SMD <33 HU. Liver Frailty Index (LFI) was available in 20 patients. **Results:** Median age was 58 years (IQR 50.7–63.5), 71% were female, median BMI was 39.4 kg/m², median MELD 3.0 was 8, and 58.1% had T2DM. Sarcopenia was present in 12.9% (4/31) vs myosteatosis in 87.1% (27/31; $p<0.001$). Median SMI was 51.1 cm2/m2 (IQR 42.8-56.7), generally above sarcopenia thresholds, while median corrected SMD was 14.4 HU (IQR 1.9-29.6), 18.6 HU below the myosteatosis cutoff. Among 20 patients with concurrent LFI and CT data, 16 (80%) were prefrail and 4 (20%) were robust; none met criteria for frailty. Functional impairment was reflected mainly by reduced grip strength and slower chair stands, while balance was preserved. The effect size for the association between myosteatosis and LFI was larger than that for sarcopenia and LFI (rank-biserial r = 0.89 vs. 0.28). Myosteatosis showed a strong trend toward association with prefrailty (U = 34, p = 0.051), whereas sarcopenia did not (U = 23, p = 0.571). Lower continuous SMI was also associated with prefrailty (U = 10, p = 0.039), but most prefrail patients did not meet binary sarcopenia thresholds. **Conclusion:** In compensated MASH cirrhosis with obesity, myosteatosis was more frequent than sarcopenia and showed strongest separation by frailty status. Conventional SMI-based sarcopenia screening may miss patients with impaired muscle quality and early functional vulnerability. CT-based body composition assessment should incorporate muscle quality metrics, and prospective studies are needed to determine whether myosteatosis predicts decompensation, functional decline, and body composition changes during GLP-1 RA therapy.

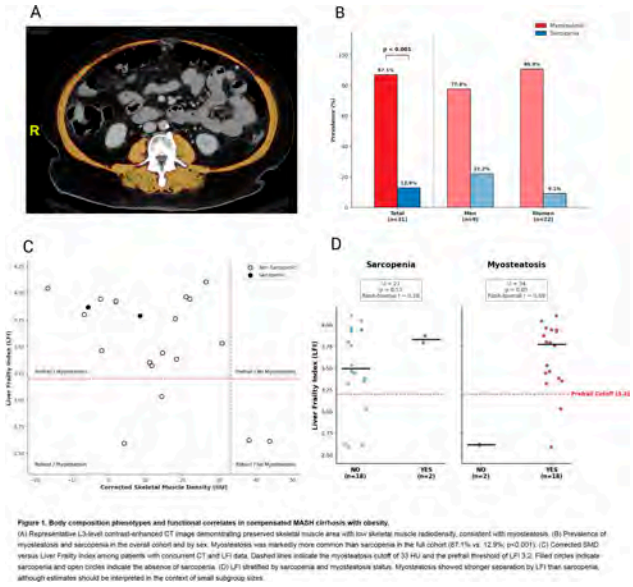

Figure 1. Body composition phenotypes and functional correlates in compensated MASH cirrhosis with obesity.
(A) Representative L3-level contrast-enhanced CT image demonstrating preserved skeletal muscle area with low skeletal muscle radiodensity, consistent with myosteatosis. (B) Prevalence of myosteatosis and sarcopenia in the overall cohort and by sex. Myosteatosis was markedly more common than sarcopenia in the full cohort (87.1% vs. 12.9%; p<0.001). (C) Corrected SMD versus Liver Frailty Index among patients with concurrent CT and LFI data. Dashed lines indicate the myosteatosis cutoff of 33 HU and the prefrail threshold of LFI 3.2. Filled circles indicate sarcopenia and open circles indicate the absence of sarcopenia. (D) LFI stratified by sarcopenia and myosteatosis status. Myosteatosis showed stronger separation by LFI than sarcopenia, although estimates should be interpreted in the context of small subgroup sizes.

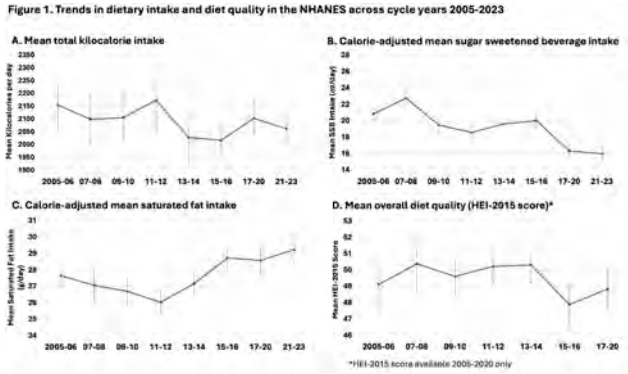
2622 | TRENDS IN DIET QUALITY, SUGAR SWEETENED BEVERAGE CONSUMPTION, AND CALORIE SOURCES AMONG US ADULTS WITH MASLD, 2005-2023



Ani Kardashian[1] Jennifer Dodge[1] Areny Tchalikian[1] Norah Terrault[1], [1]University of Southern California

Background: Poor diet quality (DQ) contributes to metabolic dysfunction-associated steatotic liver disease (MASLD); however contemporary trends in dietary intake and calorie sources are not established. Understanding trends is crucial to inform policies that

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

improve DQ and MASLD-related health. **Methods:** We performed a serial cross-sectional analysis using 24-hour dietary recall data from the National Health and Nutrition Examination Survey cycles 2005-2023 in adults ≥20 years with MASLD. MASLD was defined as US Fatty Liver Index >30 and ≥1 cardiometabolic risk factor in the absence of other causes of steatosis or excessive alcohol use (>30 g/day in men, >20 g/day in women). Total caloric intake, sugar-sweetened beverages (SSBs), saturated fats, and calorie sources were assessed across cycle years. Saturated fats and SSBs were calorie-adjusted to minimize measurement error in dietary estimates. DQ was assessed overall by the Healthy Eating Index-2015 (HEI-2015; range 0-100; >74=optimal; available 2005-2020) and by 13 individual components (score range: 0-5 or 0-10 each, higher=better DQ) across cycle years. **Results:** Among 5,872 adults with MASLD, mean age was 53 years, 44% were female, 68% were non-Hispanic White/19% Hispanic, 56% were employed, 40% had public or no insurance, 13% were living in poverty, and 68% had low/32% no alcohol use. From 2005-06 to 2021-23, mean caloric intake decreased from 2,154 to 2,061 kcals (trend $p=0.08$; **Fig 1A**), mean SSBs decreased from 20.8oz to 16.0oz ($p<0.001$; **Fig 1B**), and mean saturated fats increased from 27.6g to 29.2g ($p=0.007$; **Fig 1C**); %kcals from grocery stores decreased (70% to 65%; $p<0.001$) and from fast food increased (11.7% to 13.4%; $p=0.03$). From 2005-06 to 2017-20, mean HEI-2015 was suboptimal and unchanged (49.1 vs 48.8, $p=0.13$; **Fig 1D**). Mean DQ scores worsened for total vegetables (3.3 to 2.9 out of 5, $p=0.001$), total fruits (2.0 to 1.9 out of 5, $p=0.048$), and total dairy (5.2 to 4.8 out of 10, $p=0.04$). There were no changes to whole fruits, whole or refined grains, total or sea/plant protein, fatty acids, sodium, or added sugars. **Conclusion:** From 2005 to 2023, adults with MASLD consumed fewer calories and SSBs. The decline in SSB consumption temporally correlates with the first explicit USDA Dietary Guideline recommendation in 2010 to restrict SSBs, suggesting federal guidance can serve as a powerful public health tool to influence dietary intake. However, overall DQ has remained suboptimal, with increases in saturated fats, decreases in vegetable, total fruit, and dairy intake, no improvement in added sugars, and a shift from grocery to fast food calorie sources. These findings highlight remaining critical gaps between guideline recommendations and real-world dietary behaviors in MASLD, underscoring the need for policy-level strategies to reduce added sugar and saturated fat intake – key MASLD contributors – and for the integration of nutrition interventions into routine hepatology care.

2623 | LARGE REAL-WORLD GAPS IN NUTRITIONAL MONITORING BEFORE AND AFTER GLP-1 RECEPTOR AGONIST INITIATION IN MASLD/MASH

Yee Hui Yeo[1] Sheng-Yin Chen[2] Hanyou Loh[3] Vincent Chen[4] Daniel Huang[5] Hyunseok Kim[6] Ju Dong Yang[6] Peng-Sheng Ting[7] Chun-Ying Wu[8] Lingyu Bao[9], [1]Cedars Sinai Medical Center, [2]Massachusetts General Hospital and Harvard Medical School, [3]Canton Medical Education Foundation, [4]University of Michigan Health System, Ann Arbor, [5]National University Hospital, Singapore, [6]Cedars-Sinai Medical Center, [7]Tulane University School of Medicine, [8]National Yang Ming Chiao Tung University, [9]Children's Hospital at Montefiore

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are increasingly used in patients with metabolic dysfunction-associated steatotic liver disease (MASLD/MASH). Joint advisory of professional societies recommended screening for micronutrient deficiencies, yet real-world surveillance practices remain poorly characterized. We evaluated patterns of nutritional laboratory monitoring before and after GLP-1RA initiation in patients with MASLD/MASH. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network (66 healthcare organizations). Adults aged $\geq$18 years with MASLD/MASH initiating GLP-1RA therapy between 2020 and 2026 were included. Patients with prior GLP-1RA exposure, bariatric endoscopy/surgery, Roux-en-Y gastric bypass, colectomy, small bowel resection, other chronic liver diseases, cirrhosis, hepatic decompensation, or alcohol-related disorders were excluded. Nutritional laboratory testing within 120 days before and 180 days after GLP-1RA initiation was assessed for cobalamin, thiamine, calcidiol, iron, ferritin, iron-binding capacity, folate, calcium, magnesium, zinc, albumin, and prealbumin. Analyses were stratified by sex and BMI category. Repeat testing after GLP-1RA initiation was evaluated among patients with baseline deficiencies. **Results:** Among 111,314 patients initiating GLP-1RA therapy (mean age 53.3 ± 13.8 years; 62.0% female), nutritional testing rates were low overall before and after treatment initiation across all sex and BMI subgroups. Calcium and albumin were the most frequently assessed markers (55.7% before vs 55.8% after initiation, and 50.1% before vs 49.2% after initiation), while thiamine, zinc, and prealbumin were rarely tested (<1%), followed by folate (2.6%) and calcidiol (4.2%). Iron-related testing modestly increased after GLP-1RA initiation, including iron (6.8% vs 7.4%), ferritin (6.9% vs 7.5%), and iron-binding capacity (5.9% vs 6.6%). Similar patterns were observed across sex and BMI strata. Among patients with documented baseline deficiencies, less than half had repeat testing for calcidiol (34.4%), iron (36.2%), ferritin (39.6%), iron-binding capacity (38.1%), folate (31.8%), magnesium (47.7%), zinc (27.2%), and prealbumin (32.1%) within 180 days after GLP-1RA initiation. Repeat testing was higher for calcium (76.2%) and albumin (68.8%) deficiencies, and near universal for cobalamin and thiamine deficiencies. **Conclusion:** Nutritional laboratory surveillance was infrequently performed before and after GLP-1RA initiation in patients with MASLD/MASH, regardless of sex or BMI subgroup. Many patients with established deficiencies also lacked follow-up monitoring after treatment initiation. These findings support the need for standardized monitoring strategies in patients receiving GLP-1RA therapy.

2624 | GLUCAGON-LIKE PEPTIDE-1 (GLP-1) USE IS ASSOCIATED WITH REDUCTION OF HEPATIC STEATOSIS IN ADULTS WITH TYPE 2 DIABETES AND OBESITY

Shivaani Prakash[1] Jamie Dermon[1] Luke Sagers[1] Vincent La[2] Orit Wimpfheimer[3], [1]Dandelion Health, [2]Vincent La Consulting, [3]Nanox Vision

Background: Use of Glucagon-Like Peptide-1 Receptor Agonists (GLP-1s) has increased substantially among patients with type 2 diabetes (T2D) and/or obesity. Whether GLP-1 use affects progression of metabolic dysfunction-associated steatotic liver disease (MASLD) is less established. Changes in liver attenuation on CT, measured in Hounsfield Units (HU), have been shown to correlate with hepatic fat content, with increases indicating reductions in steatosis. We applied an AI-based algorithm to assess liver density in CT scans and evaluate changes in HUs among T2D and/or obese patients taking GLP-1s compared to matched controls, to understand the impact of GLP-1s on hepatic steatosis. **Methods:** The HealthFLD algorithm (Nanox AI) was applied retrospectively to patients within Dandelion Health (a longitudinal, multimodal clinical data platform) who (1) were diagnosed with T2D, obesity, or both; and (2) had at least 2 routine abdominal CT scans as part of clinical care, to quantify liver HUs per scan. Patients who initiated a GLP-1 after the first CT (N = 1,779) were in the treatment cohort, while those with no GLP-1 use at any time were in the control cohort (N = 19,970). Treatment and control patients were matched on baseline characteristics using propensity-score matching to create comparable groups. Difference-in-differences modeling assessed change in HUs pre- vs. post-GLP-1 initiation in the treatment cohort as compared to changes from the first (index) to second CT scan in the matched controls. Survival analyses assessed time to clinically meaningful increases in HUs (10+ units) in the treatment cohort among subgroups with T2D, obesity, or both. Within the treatment cohort, changes in A1C and BMI were assessed. **Results:** Difference-in-differences models showed a statistically significant increase in HUs (+5.5 units, $p < 0.05$) over time in the treatment cohort as compared to control patients, indicating a decrease in steatosis among GLP-1 users. Within the treatment cohort, median time to clinically significant increase in HUs was 746 days; at 1 year post GLP-1 initiation, 35% of the treatment cohort already showed this increase. Of the T2D-only subgroup, 43% achieved HU improvement by 24 months. The obesity-only and both-condition subgroups showed faster improvement, with 50-54% achieving 10+ unit increase in HUs by 24 months. Among GLP-1 users, statistically significant reductions in BMI and A1C were also observed pre vs. post GLP-1 initiation ($p < 0.01$), irrespective of magnitude of increase in HUs. **Conclusion:** T2D and obesity patients taking GLP-1s experienced reversal of MASLD as compared to matched controls. Half of GLP-1 patients achieved clinically meaningful improvement in liver density within 2 years of initiation. This study showcases a novel method

2625 | POOR AWARENESS OF FATTY LIVER DISEASE AMONG US PEOPLE WITH MASLD

Mindie Nguyen[1] Vy Nguyen[1] Bui Tam Chi Nguyen[1] Hong Fan[1] Xiaonan Su[1] Thanh Thuy Le[2], [1]Stanford University Medical Center, [2]Osaka Metropolitan University

Background: MASLD is the most common chronic liver disease globally and in the U.S., affecting about one in three Americans. However, prior studies suggested that only a small minority of people with non-alcoholic fatty liver disease, as defined by the U.S. Fatty Liver Index, were aware of having any liver disease. We evaluated the proportion of people who were aware of having a liver disease and more specifically "fatty liver" among a population-based cohort of participants with MASLD as defined by having hepatic steatosis and at least one metabolic dysfunction, with hepatic steatosis identified via Fibroscan. **Methods:** We conducted a cross-sectional analysis with MASLD from the National Health and Nutrition Examination Survey (NHANES) 2017-2023. MASLD was defined as controlled attenuation parameter (CAP) $\geq$263 dB/m, the presence of $\geq$1 cardiometabolic risk, and no significant alcohol use. Awareness was defined with a positive response ("yes") to a survey asking if the participant had ever been told she/he had fatty liver or any liver disease. All analyses were survey-weighted to estimate data representative of the general U.S. population. Multivariable logistic regression was performed adjusting for age, sex, race/ethnicity, birthplace, education, income-to-poverty ratio (IPR), insurance type, alcohol use, diabetes, hypertension, depression, hepatitis B, hepatitis C, liver stiffness, routine place for healthcare, and survey cycle. **Results:** Among 4,739 adults with MASLD with liver disease awareness data, 334 (6.2%) were aware of their diagnosis, including 128 (2.1%) reporting being aware of liver disease and 206 (4.1%) reporting being aware of fatty liver disease, while 4,405 (93.8%) were unaware of having any liver disease. On multivariable analyses, factors associated with lack of disease awareness included non-Hispanic Black race (vs White: aOR 5.53, $p<0.001$), absence of a routine place for healthcare (aOR 2.58, 95% CI 1.18–5.66; $p=0.021$), and higher income-to-poverty ratio (middle-income vs low-income group: aOR 1.70, 95% CI 1.12–2.58, $p=0.017$; high-income vs low-income group: aOR 1.90, 95% CI 1.10–3.28, $p=0.025$), while factors associated with less lack of awareness were liver comorbidities such as hepatitis C (aOR 0.07, 95% CI 0.02–0.18) and B infection (aOR 0.33, 95% CI 0.15–0.73), advanced liver fibrosis (LSM $\geq$12 kPa: aOR 0.32, 95% CI 0.20–0.50), and depression (aOR 0.52, 95% CI 0.32–0.85). **Conclusion:** Overall, 93.8% of the US adults with FibroScan-defined MASLD were unaware of their liver or fatty liver disease, with significant disparities by several demographic, socioeconomic, and clinical factors. Additional efforts are needed to improve screening, diagnosis, and disease awareness of people with MASLD, so appropriate evaluation and treatment can be implemented to prevent and curtail future MASLD-related medical morbidity and mortality.

***Table 1.** Characteristics of US Adults with MASLD by Disease Awareness Status, NHANES 2017–2023*

Characteristic	Overall (N = 4739)[1]	Aware (n = 334)[1]	Unaware (n = 4405)[1]	p-value[2]

2626 | BEYOND STEATOSIS: CONCURRENT LIVER STIFFNESS ELEVATION IDENTIFIES A HIGH-RISK METABOLIC PROFILE

Vishant Vikram Rajkonwar[1] Sakshi Mahesh Taori[1] Vedant Bawa[1] Arjun Jayakumar[1] Kalyanram Naidu Botsa[1], [1]Sri Ramachandra Institute of Higher Education and Research, Chennai, Tamil Nadu, India

Background: Transient elastography allows for the simultaneous assessment of liver stiffness and steatosis via Controlled Attenuation Parameter (CAP). Despite its growing clinical use, the metabolic correlates of combined hepatic steatosis and fibrosis remain incompletely characterised at the population level. Using a nationally representative U.S. adult population, we sought to identify distinct metabolic risk profiles using multimodal liver assessment. **Methods:** We analyzed NHANES 2017-2020 data in adults with valid liver assessments. We defined 'Elevated liver stiffness' as $\geq$8 kPa with IQR/median ratio $\leq$30% (reliable measurements only). Significant steatosis was defined as CAP $\geq$275 dB/m. We classified the participants into four groups: neither elevated, steatosis only, stiffness only, and both elevated. Survey-weighted prevalence estimates with bootstrapped 95% confidence intervals were calculated. Differences across groups were assessed using one way ANOVA and chi-square tests. Multivariable logistic regression helped us identify independent predictors of elevated liver stiffness. Large language model assistance (Claude, Anthropic) was used to improve readability and language of this abstract. **Results:** Among 8,318 adults, the survey weighted prevalence of elevated liver stiffness was 8.64%. Participants were classified as: neither (62.64%), steatosis only (35.1%), stiffness only (2.8%), and both elevated (7.25%). A stepwise metabolic gradient was observed: survey weighted mean BMI increased from 27.0 kg/m² (95% CI 26.7-27.2) in the neither group to 38.3 kg/m² (95% CI 37.5-39.1) in the both elevated group ($p < 0.0001$). Survey weighted diabetes prevalence followed the same pattern: 6.68% (95% CI 5.8-7.7%) in neither vs. 34.75% (95% CI 29.0-40.2%) in both elevated - a greater than 5 fold difference ($p < 0.0001$). On multivariable logistic regression, male sex (OR 1.93, 95% CI 1.65-2.26), diabetes (OR 2.06, 95% CI 1.73-2.46), and BMI (OR 1.10 per unit, 95% CI 1.09-1.11) were independent predictors of elevated liver stiffness (all $p < 0.0001$). **Conclusion:** Combined elastography based liver assessment identified a clinically distinct subgroup; those with concurrent steatosis and elevated stiffness; marked by substantially higher BMI and diabetes burden. These findings support population level screening strategies that incorporate both parameters to flag patients at greatest risk for progressive liver disease. **Disclosures:** Vishant Vikram Rajkonwar: Nothing to Disclose, Sakshi Mahesh Taori: Nothing to Disclose, Vedant Bawa: Nothing to Disclose, Arjun Jayakumar: Nothing to Disclose, Kalyanram Naidu Botsa: Nothing to Disclose.

2627 | LIVER FAT IN RELATION TO TOXICITIES OF CHEMOTHERAPY AMONG PATIENTS WITH STAGE II-III COLON CANCER

Deborah Ophoff[1] Nienke Zwart[1] Daniel Bos[2] N. Tjarda van Heek[1] Ben Witteman[1] Floor Lubberman[3] Henk van Halteren[4] Harm Westdorp[5] Renate Winkels[1] Fränzel van Duijnhoven[1] Edward Giovannucci[6] Ellen Kampman[1] Dieuwertje Kok[1], [1]Division of Human Nutrition and Health, Wageningen University and Research, The Netherlands, [2]Department of Radiology and Nuclear Medicine, Erasmus MC University Medical Center, The Netherlands, [3]Department of Clinical Pharmacy, Hospital Gelderse Vallei, The Netherlands, [4]Department of Internal Medicine, Admiraal de Ruyter Hospital, The Netherlands, [5]Department of Medical Oncology, Radboud University Medical Center, The Netherlands, [6]Department of Epidemiology, Harvard T.H. Chan School of Public Health, The United States of America

Background: The liver is involved in metabolism of many chemotherapeutic drugs. Hence, accumulation of liver fat may impact chemotherapy toxicity and efficacy. So far, there are hardly any data on liver fat in relation to chemotherapy-induced toxicities. Here, we evaluated associations between the amount of liver fat at time of diagnosis and toxicity-induced treatment modifications for capecitabine and oxaliplatin among 350 patients with stage II-III colon cancer. **Methods:** We used data from the COLON study, a prospective cohort study conducted among adults newly diagnosed with colorectal cancer (CRC). Liver fat was assessed using contrast-enhanced portal phase CT-scans routinely taken at diagnosis and categorized according to sex-specific tertiles. Data on toxicity-induced treatment modifications (yes/no, and in which cycle) were collected via participants' medical records and included dose reductions, regimen switches, and early discontinuation of treatment. Cox proportional hazards regression analyses adjusted for age, sex, hospital, and starting chemotherapeutic doses, were used to obtain hazard ratios (HRs) and 95% confidence intervals (95%CIs). **Results:** In total, 350 patients who received adjuvant chemotherapy consisting of capecitabine with or without oxaliplatin, were included. Median (Q1-Q3) age of the study population was 64 (60-69) years at diagnosis, 39% (n = 138) were women, and 91% (n = 318) had stage III colon cancer. Most patients received capecitabine combined with oxaliplatin (CAPOX) (n = 301, 86%) whereas 14% (n = 49) received capecitabine monotherapy. Toxicity-induced modifications of treatment were observed in 82% (n = 248) of the patients receiving oxaliplatin, and

51% (n = 179) of the patients were not able to complete the capecitabine regimen as planned. More liver fat was associated with a lower risk of toxicity-induced treatment modifications for oxaliplatin (HR_{T3vsT1} 0.66, 95%CI 0.44-0.99), whereas the association was not significant for capecitabine (HR_{T3vsT1} 0.73, 95%CI 0.48-1.12). **Conclusion:** Liver fat is associated with a lower risk of oxaliplatin-related toxicities in patients with colon cancer. Further studies are needed to investigate liver fat in relation to oxaliplatin metabolism and exposure.

2628 | THE MASH TREATMENT GAP; NATIONAL ESTIMATES OF ELIGIBILITY AND EXPECTED HISTOLOGIC RESPONSE TO FDA-APPROVED THERAPY: A BAYESIAN SIMULATION STUDY

Rahul Falodia[1] Maryum Shah[2] Ubaid Ahmed[3], [1]All India Institute of Medical Sciences, Jodhpur, [2]UAB SOM Montgomery Internal Medicine Residency Program, [3]Dow University of Health Sciences

Background: Resmetirom and semaglutide received FDA approval in 2024 and 2025, respectively, for metabolic dysfunction- associated steatohepatitis (MASH) with moderate-to-advanced fibrosis. The population-level histological benefit of these drugs and the potential incremental gain from expanding diagnostic thresholds or adopting pipeline therapies has not been quantified at a national level. **Methods:** We conducted a Bayesian simulation using NHANES 2017-March 2020 data (n = 7,339 adults aged 18-75 representing ~213M US adults). MASLD was defined by the 2023 Delphi consensus criteria. FIB-4 was calculated from NHANES data. Treatment eligibility was modelled under 4 scenarios: (A) current FDA label (FIB-4 1.30-2.67 + MASLD); (B) non-invasive identification (FIB-4 ≥ 1.30 + MASLD); (C) advanced fibrosis priority (FIB-4 ≥ 2.67); and (D) diabetes-enriched strategy (diabetes + FIB-4 ≥ 1.30). Fibrosis improvement probabilities were derived from the Souza et al. Hepatology 2025 network meta-analysis (29 RCTs, n = 9,324), propagating 4,000 posterior draws of the pooled FDA-approved therapy risk ratio (RR 1.56; pooled resmetirom RR 1.64 and semaglutide RR 1.51 from Figure 3A) through the NHANES population. Survey weights were applied throughout. Drug-specific sensitivity analyses additionally modelled tirzepatide (RR 1.77) and pegozafermin (RR 3.46). **Results:** Approximately 104M US adults are diagnosed with MASLD. Under the current FDA label (Scenario A), an estimated 16.7M adults met treatment eligibility criteria. Applying pooled FDA-approved therapy, 1,746 (95% CI 1,089-2,457) adults per 100,000 eligible were projected to achieve ≥ 1-stage fibrosis improvement per treatment course, equivalent to approximately 291,000 Americans if all eligible patients received therapy. Expanding the diagnostic threshold to FIB-4 ≥ 1.30 (Scenario B) identified 17.8 million eligible adults and yielded 1,865 (1,163-2,624) improvers per 100,000, an additional 119 (74-167) per 100,000 beyond current labelling, with 100% posterior probability of benefit. A diabetes-enriched strategy (Scenario D; 5.0 million eligible) yielded 525 (327-739) improvers per 100,000, representing a more efficient strategy than advanced fibrosis prioritisation alone (Scenario C: 119 [74-167] per 100,000; 1.1 million eligible). Drug-specific sensitivity analyses showed directionally greater projected benefit with tirzepatide (+312/100,000 vs pooled FDA-approved therapy; CrI -639 to +1,515) and pegozafermin (+2,574/100,000; CrI -369 to +6,466), although uncertainty remained substantial. **Conclusion:** Approximately 16.7M US adults meet current FDA eligibility criteria for approved MASH pharmacotherapy, yet real-world treatment rates remain below 1%, representing one of the largest treatment gaps in hepatology. Expanding non-invasive diagnostic thresholds could capture an additional 1.1M eligible patients.

2629 | IMPACT OF LONGITUDINAL HBA1C CHANGES ON LIVER FIBROSIS PROGRESSION AMONG GENERAL POPULATIONS WITH MASLD

Luchen Shi[1] Jie Wang[1] Qing Zhao[1] Wu Wei[1] Qi Xia[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: While diabetes is a known driver of fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD), the prognostic value of short-term HbA1c dynamics remains unclear. We aimed to characterize the stage-specific longitudinal association between annual HbA1c trajectories and 5-year liver fibrosis progression in a general MASLD population. **Methods:** In this multicenter retrospective cohort study, 1,810 individuals with MASLD from physical examination centers of four Chinese hospitals (2017-2020) were followed for 5 years. Participants were stratified by baseline HbA1c (normoglycemia, prediabetes, and diabetes). Liver fibrosis progression was defined as a $\geq$30% relative increase in FIB-4 index over 5 years, and assessed the association with one-year HbA1c change. Landmark analysis, multivariable Cox regression, restricted cubic spline (RCS) were performed, with subgroup and sensitivity analyses. **Results:** Among 1,810 individuals with MASLD, 484 participants developed fibrosis progression. Baseline HbA1c was not associated with 5-year fibrosis progression in any glycemic stratum. Contrarily, 1-year HbA1c elevation was independently associated with higher risk of fibrosis progression in the prediabetes group (aHR = 1.77, 95% CI: 1.25–2.50, P < 0.01), with no significant association in normoglycemia or diabetes. RCS revealed a striking non-linear risk relationship, with risk sharply increasing beyond a 0.1% annual rise in HbA1c. The association was more pronounced in individuals aged < 65 years, males, and those with normal/overweight BMI in the prediabetes group, and remained robust across sensitivity analyses using stricter fibrosis definitions. **Conclusion:** Short-term HbA1c elevation identifies prediabetic individuals with MASLD at increased risk of accelerated fibrosis progression, highlighting prediabetes as a critical intervention window before irreversible liver injury.

Table 2. Associations Between HbA1c change categories and Subsequent Risk of Fibrosis Progression

2630 | RISK ALLELES AND THEIR ASSOCIATION WITH FIBROSIS PROGRESSION IN A HIGHLY DIVERSE URBAN POPULATION

Alejandra Paredes-Marin[1] Julia Napoli[2] Xiaotao Zhang[1] Meena Bansal[3], [1]Icahn School of Medicine at Mount Sinai, [2]Ichan School of Medicine, [3]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: The Mount Sinai Steatotic Liver Disease (SLD) registry and biobank, is a longitudinal study aimed at identifying real-world factors related to fibrosis progression and cardiac clinical outcomes. This study aims to assess demographic and clinical correlates and examine the association between risk allele carriage, fibrosis progression, and cardiac risk factors from baseline in a diverse SLD cohort. **Methods:** Patients with SLD seen for standard of care were enrolled. Demographics, fibrosis, comorbidities, and laboratory values were evaluated. Fibrosis was assessed using Fib-4 or Vibration Controlled Transient Elastography (VCTE) (F2: 8-10kPa; F3: 10-14kPa; F4: >14kPa). Previously enrolled patients from the BioMe® BioBank Program at Mount Sinai Hospital were fully genotyped, and the gene PNPLA3 was analyzed. **Results:** As of April 2026, 1163 patients were enrolled in the SLD registry, only 209 of them were co-enrolled in the BioMe BioBank Program, and only 199 had PNPLA3 gene genotyped. Among 199 participants with PNPLA3 genotyping (Table 1), 64 (32.2%) had no risk alleles (CC) and 135 (67.8%) carried at least one risk allele (CG/GG). The cohort was predominantly female (64.8%) with a mean age of 55.5 years (SD = 14.9), and no significant differences in age or sex between groups. Risk allele carriers were significantly more likely to be Hispanic (69.6% vs 40.6%, p < 0.001), while non-carriers included a higher proportion of non-Hispanic White individuals. Geographic distribution also differed significantly (risk allele more prevalent among South Americans(95%) than Caribbeans(70%) p < 0.001). Lipids and liver enzymes were largely similar, although triglycerides were higher among risk allele carriers (142.8 vs 120.7 mg/dL, p = 0.065). Among patients with longitudinal data (n = 65, cross-sectional models used the full cohort), median follow-up was 25 months. In multivariable logistic regression adjusted for age, sex, diabetes, BMI, and ethnicity, PNPLA3 risk allele was not associated with ALT-defined progression (OR 1.84, 95% CI 0.48–6.91, p = 0.37) or dyslipidemia at enrollment (OR 1.02, 95% CI 0.51–2.03, p = 0.948). When fibrosis progression was analyzed as a continuous variable, multivariable linear regression models adjusted for age, sex, diabetes, BMI, ethnicity, and follow-up duration (kPa models only) showed that PNPLA3 risk allele was not significantly associated

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

with change in liver stiffness (β = 0.137, SE = 1.725, p = 0.937). PNPLA3 was also not associated with change in Fib-4 score over time (β = 0.397, SE = 1.854, p = 0.832). **Conclusion:** While PNPLA3 risk allele was significantly associated with demographic variation, no significant differences in fibrosis or metabolic markers were observed. Future work will focus on expanding the genetic scope of this analysis and exploring associations with cardiometabolic markers to better define the clinical impact of genetic risk in MASLD.

Table 1: *PNPLA3* cohort characteristics by risk allele presence and Multivariable Logistic Regression Analysis

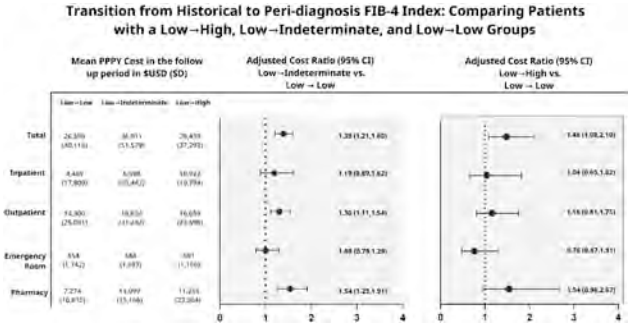
2631 | THE ECONOMIC BURDEN OF PATIENTS WITH METABOLIC DYSFUNCTION ASSOCIATED STEATOHEPATITIS STRATIFIED BY BASELINE AND CHANGES IN FIB-4 INDEX



David Shi[1] Abdalla Aly[1] Guanghao Zhang[1] Andres Quintero[1] Husam Albarmawi[1] Hashem El-Serag[2], [1]Novo Nordisk, [2]Baylor College of Medicine

Background: Fibrosis stage is the strongest predictor of long-term liver-related outcomes in patients with metabolic dysfunction-associated steatohepatitis (MASH). This study aimed to assess the impact of baseline and serial changes in Fibrosis-4 (FIB-4) score on subsequent healthcare costs among patients with MASH. **Methods:** This retrospective cohort study used Komodo Healthcare Map™ data from Jan 2017 to Nov 2023. We included patients with MASH diagnosis (ICD-10 code: K75.81; index date) who were ≥35 years old, with ≥12 months of pre- and post-index medical enrollment, and ≥2 calculable FIB-4 results for both: 1) a historical FIB-4 in the 1-2 years prior to diagnosis (hx-FIB-4) and 2) a peri-diagnosis FIB-4 in the ±90-day window from diagnosis (dx-FIB-4). Patients with other liver diseases or decompensation events were excluded. Changes from baseline in all cause per patient per year (PPPY) total costs (i.e., inpatient, outpatient, emergency room, and pharmacy) to follow up were reported by dx-FIB-4 risk categories. Adjusted cost ratios (CRs) were estimated using generalized linear models, using low risk dx-FIB-4 scores (L; <1.3) as a baseline for comparison to indeterminate (I; 1.3-2.67) and high (H; >2.67) risk dx-FIB-4 scores, after adjusting for demographics, comorbidities, liver disease severity, and baseline resource use. Similar analyses compared patients transitioning from L→I and L→H to patients with a consistently low FIB-4 index (L→L). **Results:** The study sample included 4,739 patients (median follow up: 2.8 y, median age: 57 y, male: 60%, mean BMI: 33.2). The most common comorbidities were hyperlipidemia (74%), hypertension (71%), and type 2 diabetes (47%). Changes in PPPY costs from baseline to follow up were largest in the H dx-FIB-4 group (L: $5,535; I: $7,084; H: $9,267). In adjusted models predicting healthcare costs, relative to patients from the L dx-FIB-4 group, those with I and H dx-FIB-4 scores had healthcare costs that were higher by 21% (CR: 1.21; 95% CI (1.10 - 1.34) and 44% (CR: 1.44; 95% CI (1.26 - 1.67), respectively. In patients with a L hx-FIB-4 index (n=3,373), 82% were L→L, 16% were L→I, and 2.5% were L→H. In adjusted models, relative

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

to the L→L group, the L→I and L→H groups had significantly higher healthcare costs (Figure). **Conclusion:** The economic burden is highest in patients with a high FIB-4 index at diagnosis. Similarly, compared to patients with a consistently low FIB-4 score, those with increased FIB-4 index had higher economic burden. Early detection is important to reduce advanced disease burden.

2632 | THE PREVALENCE OF DIABETES AND OBESITY COMORBIDITIES IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) IN THE UNITED STATES IN 2025

Ty Wallace[1] Ivane Gamkrelidze[1] Homie Razavi[1] Carolyn Wallace[1], [1]Center for Disease Analysis Foundation

Background: It is well established that comorbidities, mainly diabetes and obesity, serve as indicators strongly correlated with metabolic dysfunction-associated steatotic liver disease (MASLD) and its outcomes, such as progression to liver cirrhosis, hepatocellular carcinoma, cardiovascular events, liver failure, and a myriad of other life-threatening complications. As MASLD continues to surge worldwide, a pressing need for frequent observation of the disease and its comorbidities has risen to the vanguard. As such, extensive studies have been conducted into the prevalence of both diabetes and obesity in smaller MASLD cohorts; insights for the national population, however, remain more limited. The objective of this analysis was to estimate the prevalence of diabetes and obesity within the MASLD population and compare it to an independent evaluation of the diabetes and obesity populations with MASLD in order to best produce a lucid picture of the current interplay of these comorbidities in the United States in 2025. **Methods:** We conducted a systematic literature review on the prevalence of MASLD, diabetes, and obesity. Large, nationally representative surveys were prioritized and supplemented with robust regional data where necessary. A Markov model was used to estimate the current prevalence of MASLD in the US adult population, and the portion with diabetes and obesity was calculated using empirical data. Separately, populations with diabetes and obesity and comorbid MASLD were calculated using published data. The forecasts were compared to validate the accuracy of the projections. **Results:** Our model estimated the comorbid population in the US in 2025 of MASLD and diabetes as 23,924,000 whereas our analysis of the diabetes population with MASLD yielded 24,031,700. Triangulating the comorbidity resulted in a difference of less than 0.5%. The model estimated the 2025 population of MASLD with obesity as 60,888,300 whereas our analysis of the obesity population with MASLD yielded 61,453,800, resulting in a difference of 1%. **Conclusion:** The use of modeling substantiated by real-world data provides a consensus of the current disease burden of MASLD and diabetes and MASLD and obesity and establishes a framework for public health discussion to facilitate best policies and practices for optimal screening, diagnosis, and management of MASLD. Effective implementation of strategies targeted to these comorbid populations will markedly benefit the growing disease burden and reduce the risks that later stages of MASLD impose, potentially serving as a paradigm for the global population.

2633 | GENDER DISPARITIES IN MASLD SCREENING IN THE RURAL PRIMARY CARE SETTING

Dana Cornwell[1] Jonathan Hong[2] Nancy Kubiak[2] Adrian Singson[1], [1]Mountain Area Health Education Center, [2]Mountain Area Health and Education Center

Background: Primary care physicians in rural settings play a key role in early detection of Metabolic-Dysfunction Associated Steatotic Liver Disease (MASLD) through routine screening. The AASLD recommends screening high-risk patients for MASLD with calculation of FIB-4. Persistently elevated liver enzymes (>25U/L in women and >33U/L in men) can also be used as a surrogate marker in identifying MASLD and guiding management. MASLD is affecting patients at younger ages. ALT is particularly useful in patients younger than 35 years old for whom the FIB-4 score is less accurate. Many labs have higher thresholds for abnormal liver enzymes than the values defined by the AASLD. Women progress to cirrhosis sooner than men in established MASLD and MASLD is also the top cause of liver transplant in women. Gender disparities in screening tools and differing thresholds in local lab cutoffs may play a role in the poor identification of women with early MASLD. **Methods:** We conducted a retrospective, cross-sectional study in a single-center internal medicine residency primary care clinic in Western North Carolina to highlight gender disparities in high-risk patients affecting the identification of MASLD. Descriptive statistics were performed on average ALT and FIB-4 scores, and missed ALT separated by gender. Chi-square test was performed to compare differences in missed ALT percentages between men and women. A multivariable logistic regression was performed to evaluate the association between ALT status and gender and ethnicity. **Results:** 3458 individuals met inclusion criteria. 13% (272/2087) of women and 9% (125/1371) of men at high risk for MASLD had abnormal liver enzymes as defined by AASLD but were considered normal by local lab cutoffs. The proportion of missed ALT was significantly high among females compared to males ($\chi^2(1) = 9.99$, $p = 0.0016$). Mean FIB-4 scores were lower for females compared to males across all age groups (18-34: M = 0.53, F = 0.42; 35-64: M = 1.04, F = 0.90; 65+: M = 1.97, F = 1.73). A one-way ANOVA comparing FIB-4 across six age-matched sex groups revealed a statistically significant difference $F(5, 3353) = 235.19$, $p < 0.001$, $R^2 = 0.26$. Black race showed a trend toward lower odds of missed ALT, but this did not reach statistical significance (OR 0.62, 95% CI 0.38-1.01, $p = 0.055$). **Conclusion:** In our rural primary care clinic, we found women across all age groups and ethnicities were more likely than men to have abnormal liver enzymes despite appearing normal by local lab cutoffs. FIB-4 scores were not statistically different between men and women, which is consistent with the validation of FIB-4 cutoffs for both genders. Our study highlights that ALT cutoffs as a screening method can increase the likelihood of missing early MASLD, especially in women <35 years old where the FIB-4 is not as accurate. Our results highlight the importance of future studies focusing on creating and validating accurate screening methods for young patients.

2634 | CIRRHOSIS IN FAMILIAL MEDITERRANEAN FEVER IS LINKED TO DISEASE SEVERITY AND METABOLIC RISK RATHER THAN COLCHICINE TOXICITY

Yana Davidov-Derevyanko[1] Shiraz Scharf[2] Assaf Issachar[3] Eitan Giat[4] Amit Druyan[5] Merav Lidar[4] Ilan BenZvi[4], [1]The Center for Liver Diseases, Sheba Medical Center, Ramat Gan, Israel, [2]Gray Faculty of Medical and Health Sciences, Tel Aviv University, Tel Aviv, Israel., [3]Liver institute, Rabin Medical Center, Beilinson hospital, Petah Tikva,Israel., [4]The Rheumatology Unit, Sheba Medical Center, Ramat Gan, Israel., [5]The Rheumatology Unit, Sheba Medical Center, Ramat Gan, Israel

Background: FMF is an autosomal recessive disorder caused by mutations in the MEFV gene, which encodes pyrin, a key regulator of inflammatory pathways, including IL-1β. Although it primarily affects serosal membranes, systemic complications, such as AA amyloidosis, are common and may involve the kidneys, spleen, and liver. The specific causes of liver disease remain unclear. Possible contributors include long-term colchicine use and ongoing inflammation, which could lead to liver damage, including biochemical abnormalities, steatohepatitis, and cirrhosis. Our aim was to examine clinical, metabolic, inflammatory, and treatment-related factors linked to cirrhosis. **Methods:** We conducted a retrospective study of 150 FMF patients at a single center. We compared clinical features, metabolic conditions, inflammatory markers, genetic profiles, medications, and laboratory results between patients with and without cirrhosis. Propensity score matching was used to control for age, FMF severity, FMF mutation, diabetes, hypertension, and metabolic risk factors. The diagnostic performance of FIB-4 for detecting biopsy-confirmed cirrhosis and advanced fibrosis was evaluated using ROC analysis. **Results:** The median age was 58 years, and

49% were men. Patients with cirrhosis were older (64 vs. 54 years, p < 0.001) and had more metabolic comorbidities, including hypertension (65% vs. 36%, p < 0. 001), diabetes (36.7% vs. 21.3%, p = 0.04), cardiovascular disease (38.3% vs. 21.3%, p = 0.024), renal failure (18.3% vs. 6.7%, p = 0.029), and proteinuria (40.7% vs. 24.7%, p = 0.04). Cirrhosis correlated with FMF severity (r = 0.242, p = 0.003), ESR (r = 0.346, p < 0.001), SAA (r = 0.313, p = 0.017), duration of colchicine therapy (r = 0.252, p = 0.002), and total colchicine dose (r = 0.176, p = 0.035). After propensity matching, only older age and FMF severity score were independently associated with cirrhosis, whereas colchicine exposure and FMF mutation status were not. IL-1 receptor antagonists were prescribed less often to cirrhotic patients (11% vs. 25%, p = 0.034). Those treated had significantly lower transaminase levels after treatment; however, FIB-4 scores did not change during a median follow-up of 4.5 years. Baseline FIB-4 score predicted biopsy-confirmed cirrhosis with an AUC of 0.846 (p < 0.001); a cutoff of 2.07 provided 89.5% sensitivity and 82.4% specificity. **Conclusion:** In FMF patients, cirrhosis is strongly linked to metabolic health issues, inflammation, and disease severity rather than colchicine exposure after adjusting for confounders. The FIB-4 score shows good diagnostic accuracy for detecting advanced liver disease in FMF and could be a useful non-invasive screening tool.

2635 | PREVALENCE AND SEVERITY OF STEATOSIS AND FIBROSIS IN UNDIAGNOSED VERSUS DIAGNOSED DIABETES: A NATIONALLY REPRESENTATIVE ANALYSIS

Sai Vendidandi[1] Rohan Karkra[1] Himaja Vendidandi[2] Paul Gaglio[1] Diana Finkel[1], [1]Rutgers New Jersey Medical School, [2]Touro University California College of Osteopathic Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is common in Type 2 Diabetes (T2DM) and metabolic syndrome, increasing the risk of fibrosis and hepatocellular carcinoma. However, individuals with unrecognized insulin resistance or undiagnosed diabetes remain less characterized, even though current screening approaches largely focus on patients with established T2DM. This study used nationally representative data to quantify liver fibrosis burden in undiagnosed diabetes and evaluate FIB-4 performance compared with Vibration Controlled Transient Elastography (VCTE). **Methods:** We analyzed adults ≥18 years from the 2017–2020 NHANES with valid VCTE and complete diabetes status data. Participants were classified by HbA1c and self-reported diagnosis as No Diabetes, Pre-Diabetes, Undiagnosed Diabetes, or Diagnosed Diabetes; Undiagnosed Diabetes was HbA1c ≥ 6.5 without diagnosis.The primary outcome was VCTE-measured liver stiffness (LSM, kPa). Secondary outcomes were CAP score and FIB-4, calculated from age, AST, ALT, and platelets. Analyses used NHANES exam weights for national estimates. Multivariable linear regression assessed diabetes status and liver fibrosis, adjusting for age, sex, race/ethnicity, BMI, and waist circumference. Significance was p < 0.05. **Results:** Adults were stratified by diabetes status. Compared with the No Diabetes group, individuals with Undiagnosed Diabetes had higher BMI and waist circumference (34.3 kg/m² vs 27.8 kg/m²; 111.8 cm vs 94.6 cm; both p < 0.001). In fully adjusted models, liver stiffness was higher in the Undiagnosed group than the No Diabetes group (6.08 vs 5.00 kPa, p < 0.001) and was statistically similar to Diagnosed Diabetes (6.66 kPa, p = 0.07), suggesting comparable fibrosis burden. The Undiagnosed group also had the highest adjusted CAP score (288.7 vs 247.7 dB/m in No Diabetes, p < 0.001). Despite elevated stiffness and steatosis on VCTE, FIB-4 did not detect this risk; mean FIB-4 was not significantly different between the Undiagnosed and No Diabetes groups (1.15 vs 1.07, p = 0.17). **Conclusion:** Individuals with Undiagnosed Diabetes demonstrated a silent burden of liver fibrosis and steatosis, with higher adjusted liver stiffness than those without diabetes (6.08 vs 5.00 kPa, p < 0.001) and levels statistically similar to Diagnosed Diabetes (6.66 kPa, p = 0.07). This group also had the highest adjusted CAP score (288.7 vs 247.7 dB/m, p < 0.001) and the lowest proportion of Non-Hispanic White participants (44.8%), suggesting disproportionate risk among racial and ethnic minorities. Despite elevated VCTE-measured stiffness and steatosis, FIB-4 did not distinguish Undiagnosed Diabetes from No Diabetes (1.15 vs 1.07, p = 0.17), indicating that blood-based screening alone may miss fibrosis risk in this population. These findings

2636 | KILOGRAMS OR PERCENTAGE? WEIGHT LOSS METRICS IN MASLD

Sawsan Fathma[1] Harish Gopalakrishna[2] Natarajan Ravendhran[3] Yaron Rotman[4], [1]National Institutes of Health, [2]UTMB, [3]johns hopkins school of medicine, [4]National Institute of Diabetes and Digestive and Kidney Diseases; National Institutes of Health

Background: Metabolic dysfunction-associated steatotic liver disease is a leading cause of chronic liver disease impacting 30-40% of the general adult population globally. Weight loss is the primary intervention for MASLD and leads to improvement of hepatic steatosis, steatohepatitis and fibrosis. Weight loss recommendations in MASLD are typically geared towards a relative change (e.g. losing 5%) but it is unclear whether this is more relevant than an absolute change, especially at the extreme ends of baseline weight distribution. We aimed to determine whether percent weight change is a superior predictor of improvement in hepatic steatosis compared with absolute body mass index (BMI) reduction in patients with MASLD. **Methods:** We conducted a two-center retrospective cross-sectional study of 284 patients who underwent at least two FibroScan assessments with paired controlled attenuation parameter (CAP) and BMI measurements, with no pharmacological intervention between them. Weight loss was evaluated as both absolute BMI change (DBMI) and percent BMI change (%DBMI). Patients were stratified into six quantiles based on baseline BMI. The primary outcome was change in CAP as a surrogate for change in liver fat content. Linear regression analyses were performed to evaluate the association between weight loss metrics and changes in CAP values within each quantile. **Results:** Among 284 patients with MASLD, the median age was 63 years, 151/284 (53.2%) were female, median BMI was 32.1 kg/m^2 (range 21-54.8) and median CAP 318 dB/m (range 133-400). Median interval between VCTE tests was 287 days and 43.3% had significant fibrosis (TE > 8kPa). DBMI and %DBMI were similarly and linearly associated with improvement in CAP values across the entire cohort ($r = 0.28$ and 0.30, respectively, $p < 0.0001$ for both). To evaluate whether CAP response to changes in DBMI or %DBMI differed according to weight category, participants were stratified into six quantiles of baseline BMI. The effect of absolute BMI change on liver fat varied across BMI quantiles, with a diminishing effect at higher weight ranges. A decrease of 1kg/m^2 led to a 22.1db/m CAP decrease in the lowest BMI quantile but only 9.9dB/m in the highest quantile (p for trend < 0.01). In contrast, the effect of %DBMI on liver fat change remained remarkably consistent across all BMI quantiles, with similar slopes observed across groups (5.3-3.2 dB/m per 1% change, p = ns). **Conclusion:** Our findings suggest that relative weight change is a more physiological driver of liver fat reduction across the spectrum of baseline weights compared to absolute change. These findings support the use of percent weight loss targets when counseling patients with MASLD and monitoring therapeutic response.

2637 | METABOLIC LIVER DISEASE ON THE RISE: A GBD 2023 ANALYSIS OF MASLD BURDEN BY SEX AMONG US ADULTS AGED 15–49, 1990–2023

Mohammed Y. Youssef[1] Mohamed Eldesouki[2] EzzElDien A. Ibrahim[3] Hazem Abosheaishaa[4] Ahmed Salem[5] Sufiyan kamal[6] Ehab Faheid[1] Sherif Elhanafi[7], [1]Hunt Regional Medical Center, [2]New York Medical College at Saint Michael Medical Center, [3]University of Missouri-Columbia, [4]Brookly Hospital Center, [5]Gastroenterology and Hepatology Department Cleveland Clinic Florida Weston FL, [6]Internal Medicine Department, The University of Texas at Tyler Health Science Center, [7]Gastroenterology Division, The University of Texas at Tyler School of Medicine

Background: Nonalcoholic fatty liver disease (NAFLD), including its advanced manifestation as cirrhosis, is the most rapidly growing cause of chronic liver disease globally. Among working-age adults, NAFLD carries substantial implications for long-term hepatic and metabolic outcomes. This study aims to assess epidemiological trends and burden of NAFLD in the United States from 1990 to 2023 among individuals aged 15–49 years using the Global Burden of Disease (GBD) 2023 dataset. **Methods:** We assessed GBD 2023 estimates for the United States restricted to the 15–49 year age group from 1990–2023. Age-standardized incidence rates (ASIR), age-standardized prevalence rates (ASPR), age-standardized mortality rates (ASMR), and age-standardized disability-adjusted life year (DALY) rates per 100,000 population were analyzed by sex (male, female, both). Corresponding 95% uncertainty intervals (UIs) were obtained directly from the GBD database. **Results:** From 1990 to 2023, the ASMR for NAFLD among adults aged 15–49 years increased from 0.38 (95% UI: 0.24–0.59) to 0.46 (0.29–0.70) per 100,000. Among males, ASMR remained stable from 0.36 (0.22–0.57) to 0.37 (0.23–0.56) per 100,000, whereas in females it rose substantially from 0.40 (0.25–0.62) to 0.56 (0.35–0.88) per 100,000. ASIR increased markedly overall from 445.37 (387.57–508.91) to 550.84 (479.09–628.23) per 100,000, with male incidence rising from 526.17 (461.50–600.27) to 663.77 (583.84–757.48) and female incidence from 364.24 (313.91–416.02) to 434.82 (372.26–497.17) per 100,000. ASPR increased from 8196.58 (7244.61–9323.14) to 10088.60 (8841.63–11493.31) per 100,000 overall, with males rising from 9478.34 (8404.36–10792.29) to 12091.70 (10668.64–13727.69) and females from 6909.69 (6075.07–7831.47) to 8030.63 (6962.58–9177.68) per 100,000. DALY rates increased overall from 19.19 (11.95–29.52) to 22.76 (14.20–34.49) per 100,000, driven predominantly by a rise among females from 20.45 (12.79–30.98) to 27.57 (17.57–42.90) per 100,000, while male DALY rates remained nearly unchanged at 17.94 (11.10–28.35) to 18.07 (11.28–27.70) per 100,000. **Conclusion:** The burden of NAFLD among working-age Americans aged 15–49 years has increased substantially over three decades across all four burden metrics, with incidence and prevalence rising in parallel with the obesity and metabolic syndrome epidemics. Strikingly, the female-specific increases in ASMR and DALY rates, with male mortality essentially flat, suggest a feminizing shift in NAFLD-related disease burden in this age group, possibly reflecting hormonal transitions, reproductive-age metabolic changes, or differential rates of progression to advanced fibrosis. These findings underscore the urgent need for metabolic risk screening, early NAFLD identification, and sex-informed prevention strategies among working-age populations.

2638 | LOOKING BEYOND PLASMA CELLS: CLINICAL AND HISTOPATHOLOGIC CHARACTERISTICS OF OVERLAPPING AUTOIMMUNE HEPATITIS (AIH) IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Radhika Sekhri[1] Brent Sterling[1] Krutika Patel[1], [1]Vanderbilt University Medical Center

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a common cause of chronically elevated liver enzymes. A "biopsy-all" approach is neither appropriate nor applicable due to associated patient morbidity, and costs. MASH and autoimmune hepatitis (AIH) can have similar laboratory and histologic findings. In this clinicopathologic study, we aimed to elucidate the morphologic features of AIH, in patients with MASH. **Methods:** After IRB (Institutional Review Board) approval, we identified MASH and AIH cases in our clinical and pathology laboratory archives from 2020 to 2025. Demographic, serologic, biochemical, and histologic details were recorded. **Results:** We identified 610 patients with keyword search "MASH (or prior diagnosis of Non-alcoholic Steatohepatitis, NASH) and AIH" (Figure 1). 53 patients with concomitant features of MASH and AIH were identified (study cohort). Median age was 55 years with female predominance (85%, $P = 0.03$). Most patients showed increase in serum transaminases. ANA was positive in 79.4% patients. F-Actin was positive in 50% patients. 55% patients have a NAS score ≥ 5 with mild to moderate steatosis, ballooning, Mallory's hyaline, with moderate to severe lobular inflammation. Of the features suggestive of concomitant AIH, most prominent were portal inflammation ($P = 0.025$; mild 53% patients, moderate 38% patients, and severe 9% patients), interface activity ($P = 0.021$, 77% patients), lobular necroinflammatory activity ($P = 0.048$, 55% patients). Equivalent results were observed when accounting for other morphologic features of AIH like clustered plasma cells, acidophil bodies, multinucleation, emperipolesis, and cellular rosettes. Bridging fibrosis or cirrhosis was noted in 63% patients. Most patients responded to corticosteroids or azathioprine therapy. **Conclusion:** The prevalence of overlapping autoimmune hepatitis on index biopsy in patients with metabolic dysfunction-associated steatohepatitis is common. Morphologic features like moderate to severe portal inflammation, interface activity, and lobular necro-inflammatory activity should alert the pathologists to raise a possibility of an overlapping autoimmune hepatitis (AIH) in metabolic dysfunction-associated steatohepatitis (MASH) patients, even in the absence of serologic suspicion or lack of clustered plasma cells on histomorphology.

2639 | ◆ PRECLINICAL EFFICACY OF A PHASE 2-READY ASK1 INHIBITOR, SRT-015, TO TREAT BILIARY ATRESIA

Reena Mourya[1] Nithyananthan Subramaniyam[1] Pavithra Sudhakara[1] Bhargavi Mohan[1] Artur Plonowski[2] Advai Shivakumar[3] Kathleen Elias[4] Neil McDonnell[2] Pranavkumar Shivakumar[1], [1]Biliary Atresia Research and Cure (BARC) Program, GI Division, UTSW Medical Center, Dallas, TX., [2]Seal Rock Therapeutics Inc., Seattle, WA., [3]Northeast Ohio Medical University, Rootstown, OH., [4]Seal Rock Therapeutics, Inc

Background: Biliary atresia (BA) lacks effective pharmacotherapy despite identification of multiple relevant injury pathways and experimental interventions. We investigated signatures of apoptosis signal-regulating kinase 1 (ASK1), an oxidative stress-responsive MAP kinase, in human BA and determined efficacy of SRT-015, a phase 2-ready ASK1 inhibitor, to prevent bile duct atresia and liver pathology in neonatal experimental BA. **Methods:** ASK1-linked pathways were analyzed in RNA-seq and proteomic datasets from normal control (NC) and BA patient liver and serum specimens, patient liver cholangiocyte organoids (NCO/BACO), and murine BA liver RNA-seq. Liver sections from BA patients and murine model were stained for ASK1, p-ASK1, p38, and p-p38 and quantified by mean fluorescence intensity (MFI). Newborn mice received i.p. 0.9% saline or $1.2x10^6$ ffu rhesus rotavirus (RRV) to induce BA, followed by daily vehicle or SRT-015 (10 or 20 mg/kg) treatment. Serum ALT, AST, ALP, total/direct bilirubin, hepatic and organoid qPCR, intrahepatic immune cells by flow cytometry, and H&E/Sirius Red histology were assessed. **Results:** Human BA liver/organoids and experimental BA liver RNA-seq showed increased ASK1-linked

p38 (*MAPK11/12/13*), JNK (*MAPK9/10*), *CASP1*, *CCL2*, *CXCL3/5/6/8*, *CTGF*, *SPP1*, and *TNF* expression (1.5-15-fold; $P \leq 0.01$). BA livers at diagnosis and experimental BA showed enhanced cholangiocyte and immune-cell MFI for ASK1, p-ASK1, p38, and p-p38 (BA 259 ± 35 vs NC 83 ± 23; $P \leq 0.001$). To test whether ASK1 biology regulates duct atresia, portal inflammation, and biliary fibrosis in vivo, RRV-infected mice were treated daily with SRT-015 or vehicle. SRT-015 treatment reduced jaundice (23% vs 100% in controls) and acholic stools (15% vs 93%) and increased survival (100% vs 12%). Vehicle-treated mice developed segmental extrahepatic duct atresia, cystic malformation, intrahepatic portal inflammation, and biliary fibrosis; SRT-015 prevented duct atresia, maintained luminal continuity and bile flow (100% vs 0%), and attenuated portal inflammation and fibrosis. SRT-015 significantly improved liver biochemistry, decreasing ALT (74 ± 11 vs 164 ± 21), AST (244 ± 88 vs 783 ± 126), ALP (596 ± 159 vs 2170 ± 573), total (1.6 ± 0.6 vs 17 ± 3), and direct bilirubin (3 ± 1 vs 12 ± 2; all $P \leq 0.0001$). SRT-015 also reduced target-engagement transcripts (*Map3k5*, *Map2k3/4/7*, *Mapk13/14*), apoptotic markers (*Casp1/3/4*), and inflammatory markers (*Il1*β, *Tnf*α; $P \leq 0.01$). Flow cytometry showed fewer hepatic $CD45^+$ $COL1A1^+$ fibrocytes, $CD11b^+$ $F4/80^+$ macrophages, plasmacytoid DCs, and activated $TCR\gamma\delta^+$ T cells ($P \leq 0.001$). **Conclusion:** ASK1 is activated in human and experimental BA. SRT-015 improved survival, attenuated MAPK-driven cholestatic injury, inflammation, and apoptosis, while preserving biliary architecture, luminal continuity, and bile flow. These findings support clinical evaluation of ASK1 inhibition as a disease-modifying therapy for BA.

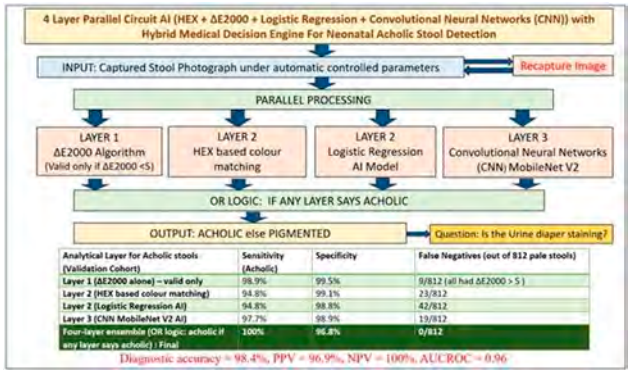
2640 | ◆ 4-LAYER PARALLEL CIRCUIT AI (HEX + ΔE2000 + LOGISTIC REGRESSION + CNN) WITH HYBRID MEDICAL DECISION ENGINE NAMED LIVERPOOP MOBILE APPLICATION ACHIEVES 100% SENSITIVITY FOR NEONATAL ACHOLIC STOOL WITH GLOBAL OUTREACH: 12-CENTER STARD VALIDATION



Piyush Upadhyay[1] Ritwik Dixit[1] Manisha Verma[2] Pankaj Kumar[3] Vipul Gautam[4] Aniket Deshmukh[5] Rizwan Ahmar[6] Arya Suchismita[7] Ishaq Maliq[8] Pranab Dey[9] Asritha A[10] Aashay Shah[11] Kalpana Panda[12], [1]Department of pediatrics, Dr RML INSTITUTE OF MEDICAL SCIENCES, [2]Department of Pediatrics, KGMU, Lucknow, [3]Department of Pediatrics, SNMC, Agra, [4]CLBS, Max Hospital, Saket, New Delhi, [5]Grant Medical College, Mumbai and Nanvati Max Hospital, Mumbai, [6]IGIMS, Patna, [7]Jai Prabha Medanta Super Speciality Hospital, Patna, [8]Government Medical College, Srinagar, [9]R.G. Kar Medical College, Kolkata, [10]Aster Hospitals, Bangalore, [11]Prism Pediatric Gastro centre, Ahemdabad, [12]IMS and SUM Hospital, Bhubneshwar

Background: Biliary atresiaBA) is fatal without timely Kasai. Paper stool cards miss up to 24% of cases & require huge logistics. We built a failsafe four-layer parallel Artificial Intelligence(AI) assisted Hybrid Medical Decision Engine(HMDE) using OR logic, with output as ACHOLIC if any layer says ACHOLIC. **Methods:** STARD-compliant, prospective consecutive enrolment of healthy newborns & BA patients across 12 Indian centres. Derivation cohort (used to build the mobile app): 7,247 captured images(6235 images of Pigmented stools and 1012 images of pale stools of biopsy proven cases of BA). Validation Cohort (12centres): 1,936 captured images (1124 images of Pigmented stools and 824 images of pale stools of biopsy proven cases of BA). The backend(python & the Flask web framework) did image preprocessing and normalization to reduce device & environmental variability. Four parallel layers for catching acholic stool colour includes: LAB-ΔE2000(CIEDE2000, valid only if <5), HEX based colour matching, logistic regression AI model, MobileNet V2 Convolutional Neural Networks (CNNs). HMDE integrates: Result is acholic stool if any of the layer detects it as acholic(Parallel circuit). Final step is a question on diaper staining urine an additional feature to also catch neonatal cholestasis disorders where stool is pigmented. **Results:** In the validation cohort, individual layer sensitivities for acholic stool were: Layer 1 (ΔE2000) sensitivity 98.9%, specificity 99.5% (9 false negatives, all $\Delta E2000 \geq 5$). Layer 2 (HEX) sensitivity 97.2%, specificity 99.1%. Layer 3 (logistic regression) sensitivity 94.8%, specificity 98.8% (42 false negatives). Layer 4 (CNN) sensitivity 97.7%, specificity 98.9%. Four-layer HMDE OR logic had a perfect 100% sensitivity (0/812 false negatives) . Final ensemble specificity was 96.8% (95% CI: 95.7–97.7%) , false-positive rate 3.2% , diagnostic accuracy 98.4%, PPV 96.9%, NPV 100%, AUROC 0.96. Critically, all cases with $\Delta E2000 \geq 5$ (borderline colorimetric matches) were successfully rescued by the other analytical layers (Figure 1). **Conclusion:** LiverPoop Mobile application, a 4-layer parallel circuit AI with HMDE achieves unprecedented

100% sensitivity for acholic stool detection across 12 centres. Zero missed acholic stool cases. The 3.2% false-positive rate is clinically justified to prevent BA. This 40-language (including languages of almost all low and medium income countries-LMIC of the world where implementation of paper based stool chart is near to impossible), cloud-based system with sharable results and already free to download (zero logistics) for usage is ready for global population-wide screening. This mobile application will not only narrow the gap between developed and developing LMIC countries in accessing the heathcare services but also reduce logistics significantlyeven in the developed part of the world, which can be utiliszed for the liver transplant in the diagnosed patients later.

★ 2641 | LONGITUDINAL URINARY METABOLOMIC PROFILING FOLLOWING KASAI PORTOENTEROSTOMY IN INFANTS WITH BILIARY ATRESIA

Elizabeth Wimborne[1] Jonathan Swann[1] Emma Alexander[2] Charlotte Burford[2] Mark McPhail[3] Antonio Riva[3] Mark Davenport[4] Anil Dhawan[2] Vandana Jain[2], [1]School of Human Development and Health, Faculty of Medicine, University of Southampton, UK, [2]Paediatric Liver, GI and Nutrition Centre, King's College Hospital, London, UK, [3]Roger Williams Institute of Liver Studies, London, UK, [4]Department of Paediatric Surgery, King's College Hospital, London, UK

Background: Urinary metabolomic profiling offers a a non-invasive tool to characterise disease-associated metabolic alterations in liver disease and cirrhosis. However its application in biliary atresia (BA) remains poorly defined. We aimed to characterise longitudinal urinary metabolomic changes in infants with BA following Kasai portoenterostomy (KPE) and evaluate clinical and prognostic outcomes including native liver survival at 12 months. **Methods:** Nineteen infants with BA undergoing intraoperative cholangiogram and KPE were prospectively enrolled at a quaternary paediatric liver centre. Urine and blood samples were collected at baseline prior to KPE (n = 11) and at 6 weeks (n = 15) and 6 months (n = 16) post-KPE. Samples from age-matched infants with non-BA cholestasis served as controls (n = 16). Metabolomic profiling was performed using liquid chromatography–mass spectrometry (LC-MS). Clinical and biochemical outcomes were assessed longitudinally. Multivariate modelling was performed using orthogonal partial least squares discriminant analysis (OPLS-DA). **Results:** Median age at KPE was 50 days (range 22–127) and 57% male. By 6 months post-KPE, 36% required liver transplantation (LT). At baseline, no urinary metabolomic signature discriminated BA from non-BA cholestasis, and no baseline metabolomic profile predicted subsequent jaundice clearance or need for LT. However, at 6 weeks post-KPE, a distinct urinary metabolomic signature emerged, characterised by elevated aromatic amino acids, acylcarnitines, and kynurenine, which was associated with subsequent LT ($Q^2 = 0.54$, $p = 0.02$). At this timepoint, Claudin-3 demonstrated a strong negative association with urinary symmetric dimethylarginine (SDMA), an amino acid derivative ($Q^2 = 0.75$, $p = 0.02$). By 6 months, infants requiring LT exhibited a metabolomic profile characterised by increased serotonin, long-chain acylcarnitines, trans-4-hydroxyproline, and persistent dysregulation of amino acid and lipid metabolism ($Q^2 = 0.61$, $p = 0.01$). **Conclusion:** Urinary metabolomic profiling may provide a non-invasive approach for identifying dynamic metabolic alterations in children with BA in the early post-KPE period. Increased urinary kynurenine, aromatic amino acids, and acylcarnitines are associated with poor native liver survival and may represent novel prognostic or mechanistic biomarkers in BA. Claudin-3, a hepatic and intestinal tight junction protein recently linked to poor BA outcomes, was associated with early circulating metabolomic alterations, further supporting its potential as an emerging biomarker. These findings are being validated in a larger cohort.

2642 | POST-NATAL CYP2C70-DEFICIENT MICE DEVELOP TRANSIENT SEVERE CHOLESTATIC LIVER INJURY ASSOCIATED WITH EARLY HEPATIC BILE ACID ACCUMULATION AND UPR ACTIVATION

Ryan Shaw[1] Saul Karpen[2] Paul Dawson[3] Brian LeCuyer[4] Richard Green[1] Alyssa Kriegermeier[4], [1]Northwestern Feinberg School of Medicine, [2]VCU Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, [3]Emory University, [4]Ann and Robert H. Lurie Children's Hospital of Chicago

Background: Cholestatic liver diseases are the leading indication for pediatric liver transplantation and lack therapies addressing disease progression. Toxic bile acid (BA) accumulation drives hepatic injury, ER stress, and the unfolded protein response (UPR). Our prior work showed that impaired hepatic XBP1 and UPR mediator expression contributes to neonatal liver injury, but traditional murine cholestasis models are limited by their hydrophilic BA pool. We used Cyp2c70 knockout (KO) mice, which possess a human-like hydrophobic BA profile, to investigate age-dependent ER stress, injury, and UPR activation in the post-natal period. **Methods:** Female Cyp2c70 KO and heterozygous control mice were assessed at 10 days, 16 days, 18 days, 21 days, and 8 weeks of age. Serum liver chemistries were measured and hepatic BAs quantified by LC-MS. Bulk hepatic RNA-seq was performed, with key ileal targets by qPCR. Data were compared by Welch's t-test or one-way ANOVA; $p < 0.05$ was considered significant. **Results:** At 10 days of age, serum ALT, ALP, and BAs in KO mice were similar to controls. Injury emerged at 16–18 days; ALT peaked at 21 days (4161 ± 1813 vs 37.5 ± 20 U/L) and lessened by 8 weeks (346 ± 157 vs 42 ± 11 U/L). Serum BAs were elevated at 21 days (> 700 vs < 5 µmol/L) and 8 weeks (38 ± 18 vs < 5 µmol/L). Hepatic TCDCA peaked at 21 days and remained elevated through 8 weeks, correlating with ALT. RNA-seq revealed a hepatic stress response at 21 days: induction of PERK/ATF4 (Atf4, Atf3, Ddit3) and IRE1/XBP1 (Xbp1, Hspa5, Dnajc10) arms, downregulation of BA homeostasis networks, and sustained upregulation of acute-phase reactants (Saa1, Saa2) and ductular marker Spp1 through 8 weeks. Ileal Asbt and Ibabp mRNA were nearly undetectable at day 10 and rose by 21 days in both genotypes, indicating normal developmental induction coincident with peak hepatic injury. **Conclusion:** Cyp2c70 KO mice, with a humanized hydrophobic BA pool, develop post-natal hepatic BA accumulation and age-dependent cholestatic liver injury that is most severe at 21 days and improves by 8 weeks. This is accompanied by PERK/ATF4 and IRE1/XBP1 UPR pathway activation and downregulation of BA homeostasis gene networks at 21 days, followed by a sustained acute-phase and ductular-reaction signature through 8 weeks. Notably, peak hepatic injury coincides with normal post-weaning maturation of ileal BA-uptake transporters, suggesting a developmentally timed surge in enterohepatic return of hydrophobic BAs imposes an acute burden on an immature hepatic BA-handling and UPR network. Improvement by 8 weeks parallels maturation of these hepatic defense pathways. Together, these findings define a hepatically driven phenotype of transient post-natal cholestatic injury within a developmentally vulnerable window, with relevance to neonatal- and infantile-onset pediatric cholestatic liver diseases, and identify the immature hepatic UPR and BA homeostasis network as a candidate therapeutic target.

2643 | PARENTERAL NUTRITION AND STARVATION SPECIFIC EFFECTS ON CIRCADIAN TRANSCRIPTION FACTOR EXPRESSION ALONG THE GUT LIVER AXIS

Colin Shearn[1] Aimee Anderson[1] Michael Devereaux[1] Ronald Sokol[2], [1]University of Colorado Anschutz Medical Campus, [2]University of Colorado School of Medicine

Background: We have developed a mouse model of Parenteral Nutrition Associated cholestasis (PNAC) in which total PN (TPN) infusion results in biochemical and immunohistochemical liver injury which is associated with discordant expression of circadian transcription factors between the ileum and liver. However, it is not clear if the effect of TPN is because of the lack of nutrition in the GI tract or due to other factors. The aim of this study was to examine the effect of 2-day PN compared to starvation on expression of ileal and hepatic circadian regulatory (CR) genes, Fxr signaling and bile acid homeostasis. **Methods:** WT adult C57/B6 mice were fed Chow alone, NPO except

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

for water (Starvation), or continuous soy oil lipid emulsion-based TPN (water was provided ad libitum, no enteral nutrition) through a central venous catheter for 2 days. On d2, mice were sacrificed at 7AM, and serum, ileal and hepatic tissue obtained. **Results:** Administration of 2d PN had no effect on hepatic injury. Compared to Chow fed controls, PN suppressed hepatic mRNA expression of *Cyp7a1, Cyp7b1, Cyp8b1* and *Cyp27a1*, whereas starvation only suppressed *Cyp7a1, Cyp7b1* and *Cyp27a1*. PN had no effect on hepatic mRNA expression of *Nr0b2* (Shp), *Abcc2* (Mrp2) or *Nr1h4* (Fxr) but did significantly increase *Abcb11* (Bsep). Starvation significantly suppressed *Nr0b2, Abcb11* and *Nr1h4* mRNA expression. Examining hepatic circadian transcription factor expression, PN significantly increased *Nr1d1* (Reverba), *Per1, Per2, Dbp, Bhlhe41* (Dec2) and suppressed *Arntl* (Bmal), whereas starvation significantly increased *Nr1d1* and *Per1* but suppressed *Arntl*, *Nr1f1* (Rora), *Nfil3, Bhlhe40* (Dec1) and *Bhlhe41*. In the ileum , PN increased expression of *Nr1d1* and *Nr1f1* but suppressed *Arntl, Cry1, and Bhlhe40*. Starvation significantly increased ileal *Dbp* and *Cry2* and suppressed *Nr1d1, Arntl, Clock, Cry1,* and *Bhlhe41*. PN administration significantly induced increased expression of FXR target genes *Fgf15, Nr0b2, Slc51a* (OSTa) and suppressed of *Slc10a2* (ASBT) whereas starvation had no effect. **Conclusion:** These data indicate that the effect of TPN on ileal and hepatic circadian gene expression is likely not related to the nutritional status of TPN mice. In the liver as well as the ileum, data support specific circadian regulatory genes that are regulated independent of nutritional status. In addition, short term PN is sufficient to activate ileal FXR thereby suppressing hepatic bile acid synthesis in the liver through Fgf15 signaling.

2644 | INEQUALITY IN HEALTHCARE ACCESS AND DISEASE BURDEN OF BILIARY ATRESIA IN SOUTHERN CHINA: A 12-YEAR MULTICENTER RETROSPECTIVE STUDY

Hanshi Zeng[1] Paul KH Tam[1] Yan Chen[1], [1]Macau University of Science and Technology

Background: Biliary atresia (BA) is a rare, progressive fibro-obliterative disease of the extrahepatic bile ducts in infants. Early surgical intervention is central to improving prognosis. Due to the uneven spatial distribution of healthcare resources, the potential role of socioeconomic disparities in the early detection of BA and healthcare utilization remains unclear. Using Guangdong Province (covering a population of 128.59 million) as the study area, this study systematically describes the epidemiological characteristics of BA in southern China and explores disparities in healthcare utilization across populations with different socioeconomic statuses. **Methods:** A multicenter retrospective cohort study of BA infants aged < 1 year was conducted in Guangdong Province from 2012 to 2024. The apparent population-based incidence was calculated. The Gini coefficient was used to assess the inequality of case distribution and healthcare resource allocation. The observed-to-expected (O/E) ratio was calculated to analyze the distribution of cases across regions with different economic levels. Multivariate logistic regression was used to identify factors associated with delayed surgery (> 60 days), and a Gamma regression model was employed to evaluate factors influencing hospitalization costs. **Results:** A total of 3,345 children were enrolled. The apparent incidence of BA was 22.42 per 100,000 live births. Cases showed significant clustering in high-economic-level areas (O/E = 2.02), while the number of cases in medium- and low-economic-level areas was lower than expected (O/E < 1). Both case distribution and healthcare resource allocation were highly unequal, with Gini coefficients of 0.855 and 0.886, respectively. Year of hospital admission was significantly associated with a reduced risk of surgical delay (OR = 0.91, 95% CI: 0.88–0.94), whereas socioeconomic level showed no independent association. Hospitalization costs were closely related to regional socioeconomic level, hospital tier, and length of hospital stay. **Conclusion:** The concentration of BA cases in high-socioeconomic areas more likely reflects disparities in healthcare accessibility and an imbalanced referral system rather than true differences in disease incidence. This study confirms significant inequality in healthcare utilization for BA. There is an urgent need to strengthen early diagnostic capacity for BA and establish a tiered referral system in underdeveloped regions to narrow healthcare disparities.

2645 | RESULTS OF AN INTERNATIONAL SURVEY DESCRIBING THE HUMANISTIC AND ECONOMIC IMPACT OF BILIARY ATRESIA ON PATIENTS AND THEIR CAREGIVERS

Emmanuelle Kaltenbach[1] Maria Mercadal-Hally[2] Elisa De Carvalho[3] Laure Dorey[4] Jennifer Lau[5] Michelle Wilkins[6] Lorraine Munetsi[7] Bethany Franks[7] Laura Francis[1] Shikha Sundaram[8], [1]Ipsen, London, UK, [2]University Hospital Vall d'Hebron, Barcelona, Spain, [3]Universidade do Distrito Federal, Brasília Childrens' Hospital, Brasília, Brazil, [4]Association Maladies du Foie depuis l'Enfance (AMFE), Paris, France, [5]Biliary Atresia Research & Education (BARE), New York, [6]Liver UK, Winchester, UK, [7]HCD Economics, Worcester, UK, [8]Digestive Health Institute, Department of Pediatrics, University of Colorado School of Medicine, CO,

Background: Complications from progressive liver damage and eventual liver transplant (LT) are devastating and have a profound impact on the lives of patients with biliary atresia (BA) and their caregivers. Published data on the burden of BA are scarce, and further research is needed to capture the disease-specific multidimensional impacts. We conducted an international survey of physicians, patients, and caregivers to describe and quantify the clinical, humanistic, and economic burden of BA; initial results are reported herein. **Methods:** Descriptive, retrospective, cross-sectional, and independent physician, patient, and caregiver surveys were conducted across Australia, Brazil, Canada, Denmark, France, Germany, Italy, Japan, the Netherlands, Poland, South Korea, Spain, Sweden, the UK, and US. Physician surveys collected data on patient symptoms, tests, consultations, medications, comorbidities, and hospitalizations. Patient surveys (≥18 years old) collected data on health-related quality of life (HRQoL; EQ-5D-5L), out-of-pocket costs related to disease management, and impact of disease on employment or education. Caregiver surveys collected data on HRQoL (self, and of the child they care for [proxy]; EQ-5D-5L), out-of-pocket costs related to disease management, and impact of disease (on their employment/education and on their child's education). Data were collected over 12 months for 4 cohorts, depending on disease stage: patients without LT/Kasai HPE in the past 5 years (data collected in the 12 months prior to survey); patients with Kasai HPE in the past 5 years (data collected in the 12 months post-Kasai HPE); and patients with LT in the past 5 years (data collected in the 6 months either pre-LT or post-LT). **Results:** At data cutoff (April 27, 2026), initial results were available from the US and UK. Questionnaires were collected from 47 caregivers (20 US + 27 UK; mean [SD] age, 40.2 [5.8] years]) and 6 UK patients (mean [SD] age, 19.8 [2.1] years). Mean (SD) EQ-5D-5L scores were lower for US/UK caregivers (index: US 0.74 [0.30], UK 0.76 [0.28]; visual analog scale [VAS]: US 73.5 [16.0], UK 67.8 [17.7]) and for UK patients (index: 0.75 [0.11]; VAS: 69.3 [13.3]) than the general population (index: US 0.86, UK 0.90–0.91; VAS: US 78.1–84.9, UK 73.8–86.8). A negative impact of BA on work was reported by caregivers, with 40.6% changing the number of hours they worked regularly. Twenty-two US clinicians and 7 UK clinicians completed 84 questionnaires (60 US + 24 UK) and clinical results are presented (**Table)**. **Conclusion:** Initial survey results from the US and UK indicate that BA adversely affects patient and caregiver QoL, potentially linked to the numerous symptoms and complications experienced by patients independent of their disease stage. BA also has a negative impact on caregiver work. Survey results for the rest of the world, as well as the economic impact of the disease,

2646 | CHANGING SOCIOECONOMIC PATTERNS IN BILIARY ATRESIA (BA): A MULTICENTER RETROSPECTIVE STUDY OF 1082 PATIENTS ACROSS THE COVID-19 PANDEMIC

Elise Kang[1] Pooja Reddy Spector[1] Mercedes Martinez[2], [1]Columbia University Irving Medical Center, [2]NewYork-Presbyterian

Background: Biliary atresia (BA) is a rare, fibro-obliterative disease of the extrahepatic biliary tree that requires timely surgical intervention with a Kasai Portoenterostomy (KP). Despite global disruptions to healthcare access during the COVID-19 pandemic, epidemiological studies of BA have not demonstrated delays in time to KP. We aimed to examine socioeconomic shifts in BA patient demographics that occurred across pre-, peri-, and post-COVID-19 pandemic eras. **Methods:** This is a retrospective analysis of BA patients who underwent KP between 2016–2024 using the Pediatric Health Information System database. Patient-level factors included age at diagnosis, sex, gestational age at birth, race, and ethnicity. Socioeconomic factors included payor type, median household income by census tract (deflated to 2024 dollars and analyzed in quartiles), and child opportunity index. Geographic variables included U.S. census region, urban versus rural residence, and distance to treating hospital. The cohort was stratified into three era-based groups including pre-pandemic era (2016-2019), pandemic (2020-2021), and the post-pandemic era (2022-2024), to examine temporal trends in demographics. **Results:** Amongst 1,082 BA patients who underwent KP, median household income distribution and Child Opportunity Index (COI) demonstrated significant shifts across pandemic eras (p = 0.008 and p < 0.001, respectively). Pre-pandemic (2016–2019), 29.3% (n = 151) of patients were from the lowest income quartile ($0–$58,791). The proportion of patients from this group declined to 18.5% (n = 41) during the pandemic and remained low at 20.3% (n = 58) in the post-pandemic period (2022–2024). In contrast, representation from the highest income quartile ($78,866+) increased from 23.8% (n = 123) pre-pandemic to 28.8% (n = 64) during the pandemic and 31.1% (n = 89) post-pandemic. The COI distribution showed notable shifts across pandemic eras (p < 0.001). Pre-pandemic (2016–2019), 26.3% (n = 135) of the patients came from "Very Low" opportunity neighborhoods. During the pandemic era (2020-2021), this proportion dropped to 18.6% (n = 41) with return to similar proportion in the post-pandemic era with 23.5% (n = 53) from very low COI. Conversely, the "High" and "Very High" COI categories combined increased to 38% (n = 86) during the pandemic era from 34.8% (n = 179) pre- and 35.4% (n = 80) post-pandemic eras. **Conclusion:** The proportion of BA patients from lower median household groups and lower COI decreased during the pandemic and post-pandemic era compared to pre-pandemic era. Vulnerable populations may have been underdiagnosed during the pandemic. Further research should be done on patients with delayed care or missed diagnoses during this time to explore barriers to care.

Select Variables of Biliary Atresia Patients Undergoing Kasai Portoenterostomy during Pre (2016-2019), Peri (2020-2021), and Post (2022-2024) COVID 19 Pandemic Eras

Variables	2016-2019 n = 516	2020-2021 n = 222	2022-2024 n = 344	p-value

2647 | THIOREDOXIN REDUCTASE 1 REGULATES THE NUCLEOTIDE BINDING OLIGOMERIZATION DOMAIN CONTAINING 2-RECEPTOR INTERACTING SERINE/THREONINE KINASE 2 SIGNALING PATHWAY DURING CHOLESTATIC LIVER INJURY

Colin Shearn[1] Aimee Anderson[1] Michael Devereaux[1] Edward Schmidt[2] Ronald Sokol[3], [1]University of Colorado Anschutz Medical Campus, [2]Montana State University, [3]University of Colorado School of Medicine

Background: The cholestatic liver disease primary sclerosing cholangitis (PSC), is characterized by periportal inflammation with progression to hepatic fibrosis and ultimately cirrhosis. Bacterial PAMPs have been shown to activate the Nucleotide Binding Oligomerization Domain Containing 2- Receptor Interacting Serine/Threonine Kinase 2 (Nod2-Ripk2) intracellular inflammatory signaling pathway in the intestine. Approximately 80% of PSC patients have an additional diagnosis of Crohn's disease, increasing the susceptibility of the liver to exposure of bacterial Pathogen-Associated Molecular Patterns (PAMPs) originating from the intestine. We have recently shown that Thioredoxin Reductase (TrxR1) signaling plays an important role in regulation of inflammation during cholestasis. The objective of this study was to determine if Nod2-Ripk2 signaling is upregulated in PSC and to examine the impact of pharmacological and genetic targeting of TrxR1 on Nod2-Ripk2 signaling in cell culture and a murine model of cholestatic liver injury. **Methods:** Protein and mRNA expression of the Nod2-Ripk2 signaling pathway was examined in liver tissue isolated from patients diagnosed with end stage PSC, Biliary Atresia as well as in murine models of cholestasis (3 day bile duct ligation (BDL) or 3day feeding of 0.1% 3,5-Diethoxycarbonyl-1,4-Dihydrocollidine (DDC)) compared to WT controls. In addition, the effect genetic ablation or pharmacological inhibition of TrxR1 (auranofin 10mg/kg/3d) on Nod2-Ripk2 signaling was analyzed in the bile duct ligation (BDL) model of cholestatic injury. Finally, the effect of pharmacological inhibition of TrxR1 on the Nod2-Ripk2 pathway was examined in cultured macrophages and primary hepatocytes. **Results:** Increased expression of the Nod2-Ripk2 signaling pathway was present in liver tissue isolated from human patients diagnosed with end stage PSC and Biliary Atresia. Similar results were also evident in mice subjected to bile duct ligation or feeding DDC for 3 days. Immunohistochemical analysis of livers from human cholestatic patients, 3d DDC fed and 3d BDL mice revealed increased hepatic Nod2 and Ripk2 staining. Hepatospecific deletion of TrxR1 as well as pharmacological targeting of TrxR1 inhibited BDL-dependent induction of hepatic Nod2-Ripk2 signaling, NFkB activation and proinflammatory cytokine production. In vitro, pharmacological targeting of TrxR1 inhibited Nod2-Ripk2 activation in RAW264.7 macrophages and primary hepatocytes. **Conclusion:** These data demonstrate that the Nod2-Ripk2 inflammatory pathway is activated in murine cholestasis as well as in human cholestasis and implicate TrxR1-signaling as an important regulator of Nod2-Ripk2 activation

2648 | PRURITUS IN CHILDREN WITH BILIARY ATRESIA: AN UNDERRECOGNIZED CLINICAL BURDEN

Natasha Dilwali[1] Shannon Vandriel[2] Nadia Ovchinsky[1] Jennifer Vittorio[1], [1]New York University Grossman School of Medicine, [2]Mirum Pharmaceuticals, Inc.

Background: Biliary atresia (BA) is a progressive, obstructive cholangiopathy and the leading indication for pediatric liver transplant (LT). In contrast to other pediatric cholestatic disorders, such as Progressive Familial Intrahepatic Cholestasis and Alagille Syndrome, pruritus has been less frequently recognized and characterized as a clinical feature of BA. This study aimed to describe the frequency and severity of pruritus in children with BA as reported by their caregivers and health-care providers (HCPs). **Methods:** Cross-sectional survey of caregivers (aged >18 years) and HCPs, including pediatric gastroenterologists, hepatologists, and advanced practice providers, caring for children with BA with native livers (>6 months). Caregivers of children who had undergone LT, had active acute cholangitis, and/or were enrolled in an ileal bile acid transporter (IBAT) inhibitor clinical trial were excluded. Quantitative variables are presented as medians [quartile 1 (Q1), quartile 3 (Q3)] and qualitative variables are reported as frequencies with percentages. **Results:** A total of 57 caregivers (92.3% female) and 67 HCPs participated. The median age of the children was 2 years (Q1, Q3: 0.8, 6), 40% were female and all had undergone a Kasai portoenterostomy (52/52). 19% (11/55) were listed or undergoing evaluation for LT.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Among caregivers, 41% (22/55) reported that their child had experienced itching related to BA. During the two weeks prior to survey completion, 52% (25/48) reported symptoms suggestive of pruritus in their child, including irritability/fussiness, blood on sheets, sleep difficulties, skin excoriation from scratching, and skin discoloration/hyperpigmentation. Notably, 40% of caregivers reported that their child's HCP had never informed them that itching could be related to BA. Among HCP respondents, the majority were hepatologists (55%; 37/67) and 43% (29/67) reported active involvement in the care of >40 BA patients over the preceding 5 years. Most HCPs (85%; 55/65) reported routinely screening for symptoms of pruritus in children with BA; however, only 15% (10/65) utilized a validated pruritus assessment scale. Despite the high prevalence of pruritus reported by caregivers, HCPs estimated that only 20% (Q1, Q3: 8%, 50%) of children with BA experience itching. 66% (44/67) of HCPs indicated that pruritus negatively impacts both children and caregiver sleep; however, 54% (25/46) of caregivers indicated that their child's HCPs do not routinely inquire about sleep difficulties or trouble falling asleep. Only 37% (25/67) of HCPs routinely measure serum bile acids in patients with BA. **Conclusion:** Collectively, these data indicate that pruritus is an underrecognized feature of BA and underscore the importance of routine screening using standardized assessment methods.

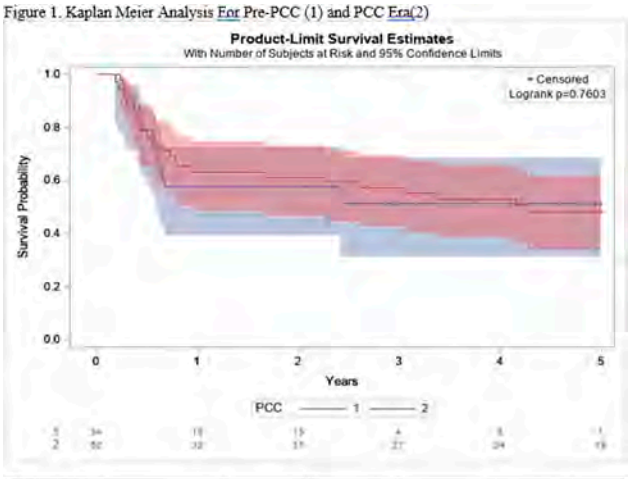
2649 | OUTCOMES OF KASAI PORTOENTEROSTOMY AFTER INCORPORATION OF PERCUTANEOUS CHOLECYSTOCHOLANGIOGRAPHY FOR DIAGNOSING BILIARY ATRESIA AT AN URBAN PEDIATRIC CENTER



Brooks Melnyk[1] Christopher Nemeh[1] Caitlin Cain-Trivette[1] Paul Park[1] Nicholas Schmoke[1] Chunhui Wang[1] Paul Kurlansky[1] Mercedes Martinez[2] Vincent Duron[1] William Middlesworth[1] Yeu Sanz Wu[3] Steven Stylianos[4] Pooja Reddy Spector[1], [1]Columbia University, [2]NewYork-Presbyterian, [3]University of Rochester, [4]Rutgers University

Background: Percutaneous cholecystocholangiography (PCC) is a minimally invasive tool that can help diagnose biliary atresia (BA). We evaluated the impact of incorporating PCC in the diagnostic algorithm for neonatal cholestasis on outcomes of Kasai Portoenterostomy (KP) before and after PCC was implemented. **Methods:** A single-institution retrospective review was performed for BA patients who underwent KP between January 2010 and July 2023 (n = 86). PCC was implemented in January 2019 and patients who underwent KP after implementation (PCC group) were compared to those who underwent KP in the preceding 9 years (pre-PCC group). Patient demographics, and preoperative and 3-month postoperative laboratory values were obtained as a marker for adequate biliary drainage. Survival with native liver (SNL) at 1 year and sequela of chronic liver disease including portal hypertension (HTN), failure to thrive (FTT) and cholangitis were assessed at one year follow up, in addition to readmission within 30 days. Categorical variables were compared using chi-square tests; continuous variables were reported as median and interquartile range (IQR) and were compared using Mann-Whitney tests, as they were evaluated as non-normal distribution by Shapiro-Wilk tests. Kaplan Meier curves were used to estimate SNL after KP. Univariable cox regression was used to evaluate factors associated with liver transplant or death. Multivariable cox regression model was fitted to assess the effect of PCC on SNL, adjusting for age, time to surgery, gender, prematurity, 3-month lab values, and portal HTN, FTT and cholangitis within 1 year. **Results:** Of the 86 patients included in the study, 46 were male (53.5%). Baseline preoperative laboratory values did not differ significantly between groups. There were 52 patients who underwent Kasai in pre-PCC era. SNL at one year was 63.2% in the pre-PCC era. For the 34 patients who underwent KP in the PCC era, overall SNL was 57.8%. Of these 34 patients, 25 patients (73.5%) underwent PCC and had a SNL of 64%. The median total bilirubin at 3 months post KP in the pre-PCC and PCC groups and the one-year outcomes including cholangitis, portal HTN and FTT had no significant difference between the two groups. Age at KP was significantly less in the PCC group ((51 days [IQR 37,62] vs. 61.5 days [IQR 53.5,72.5], (p = 0.002)). There was no significant difference in time from initial hepatology referral to KP in the Pre-PCC era ((7.5 days, IQR [4, 13.5]) compared to the PCC era (11.5 days [IQR 6,20], (p = 0.10)) **Conclusion:** Biliary drainage as assessed by total bilirubin and time to surgery from initial hepatology referral were not significantly different before and after PCC implementation. Age at KP was significantly lower in the PCC group. This data suggests that incorporating PCC in the diagnostic algorithm for BA is feasible without delaying surgery or affecting SNL.

2650 | DESIGN AND VALIDATION OF A CLINICAL CODING ALGORITHM FOR THE NATIONAL IDENTIFICATION OF BILIARY ATRESIA

Zeba Moin[1] Jill Haszard[1] Helen Evans[1] Cameron Grant[2], [1]Starship Child Health, Auckland, New Zealand, [2]The University of Auckland, New Zealand

Background: Coding systems such as the International Classification of Diseases (ICD) are used to identify research cohorts from health databases when large-scale chart review is impractical. Biliary atresia (BA) studies often utilise diagnosis or procedure codes for case identification, but this process has never been validated and may underrepresent deprived populations. **Methods:** New Zealand (NZ) has universal healthcare, an active ICD-10 coding system since 2000, a high BA incidence, and the centralisation of all BA care to a single national service in 2007. All NZ public and private hospital events from 2000 to 2025 for individuals born 2000 to 2024 with any code from ICD-10 chapter Q44 (congenital hepatobiliary malformations) were extracted from national databases. Operation codes and transplant codes were also extracted. All medical records were reviewed to confirm diagnoses and compared with national service records to obtain a complete list of true BA cases in NZ since 2000, against which to validate the health coding algorithm. Using these data, code combinations were assessed against the true diagnosis of BA to determine the coding accuracy for case identification. Diagnostic performance was assessed by sensitivity and specificity, and receiver operator curves. **Results:** There were 2,336 hospital events over the study years with any Q44 chapter code, comprising 510 individuals. The most used Q44 chapter code was Q44.2 (‘atresia of bile ducts’) for 224 individuals, of whom 177 had true BA and two were known cases of Alagille syndrome misdiagnosed as BA pre-centralisation (1% BA misdiagnosis rate with portoenterostomy). All BA cases were born and/or diagnosed and treated in NZ, with 87% from medium- to high-socioeconomic deprivation domiciles, and 43% indigenous Māori, 25% European, 20% Pacific Islander, and 11% Asian. BA birth incidence was 1 in 8,600 overall, but 1 in 5,000 in indigenous Māori and Pacific Islander, 1 in 11,000 in Asian, and 1 in 15,600 in European. Code Q44.2 identified the complete national series with 100% sensitivity (CI 98, 100), but 86% specificity (CI 82, 89) and 79% PPV (CI 73, 84). Step-wise combination of two hospital events coded by Q44.2, then one Q44.2 event plus operation code ‘portoenterostomy’, then one Q44.2 event plus either operation code ‘transplantation of liver’ or disease code Z94.4 (‘liver transplant status’), created the optimal algorithm for identifying the national series with 99% sensitivity (CI 96, 100), 98% specificity (CI 96, 99), 96% PPV (CI 92, 98), 99% NPV (CI 98, 100), and AUROC of 0.984. **Conclusion:** The ICD-10 code Q44.2, alone without chart review, lacks BA specificity but performs excellently when combined with disease-affiliated codes in an algorithm replicable in other settings. This algorithm was validated against a BA national series with a low misdiagnosis rate and a high burden in indigenous Māori, Pacific Islander and Asian populations from socioeconomically deprived areas.

Background: Patients with bile salt export pump (BSEP, *ABCB11*) deficiency have variable native liver survival (NLS) and serum bile acid (sBA) response to interruption of the enterohepatic circulation (iEHC) via surgical biliary diversion (SBD) or ileal bile acid transporter inhibition (IBATi). The missense variants p.E297G(E)and p.D482G (D) retain residual BSEP transport capacity. Patients who are homozygous or compound heterozygous for these two variants (ED/ED) have longer NLS after iEHC than other patients with BSEP deficiency. Apart from E and D, other missense mutations (MS) have been identified, but their severity and residual BSEP transport capacity remain unclear. Recently, we reported that residual BSEP transport capacity predicts sBA responsiveness to iEHC by IBATi (*Hepatology* 2026; 83: 708-20). We now aimed to grade the severity of different MS variants by assessing sBA responsiveness to surgical or medical iEHC in BSEP deficiency patients, based on their genotype. **Methods:** Patients from the NAPPED registry (NCT03930810) who were homozygous or compound heterozygous for disease-causing variant in *ABCB11* were included. Variants were categorized as ED, MS or truncating (T; variants leading to a truncated protein), and patients were categorized into one of seven genotype categories: ED/ED, ED/MS, ED/T, MS/MS heterozygous (Het), MS/MS homozygous (Hom), MS/T & T/T. sBA response to surgical or medical iEHC was defined as a post-iEHC sBA concentration <102 µmol/L or $\geq 75\%$ decrease of sBA concentration. **Results:** In 99 patients treated by iEHC (SBD: 67; IBATi: 32 [24 odevixibat, 8 maralixibat]), the percentage of sBA response could be calculated. ED/ED patients had the highest sBA response rate (67%; Figure A) and T/T patients the lowest (0%). ED/T patients rarely achieved an sBA response (20%), while 7 MS/T patients (39%) achieved an sBA response. In the MS/T sBA responder group 6 different MS variants were identified, and accordingly, these variants likely have a *higher* residual BA transport capacity than ED (Figure B). MS/MS Hom patients had an sBA response rate of 27%. In the MS/MS Hom sBA responder group, 3 different MS variants were identified, and these variants likely have a residual BA transport capacity *at least similar* to ED. In the MS/MS Hom sBA nonresponder group, 10 different MS variants were identified, and these variants likely have a residual BA transport capacity *lower* than ED (Figure B). **Conclusion:** Assessing the responsiveness of patients with BSEP deficiency to therapeutic interruption of the enterohepatic circulation allows grading of phenotypic severity and the expected residual transport function of specific *ABCB11* variants. This further detailing of genotype-phenotype will improve the predictability

Background: Growth failure is common in severe cholestatic liver diseases of childhood, but growth often improves after liver transplantation (LT). Patients with familial intrahepatic cholestasis 1 (FIC1) deficiency and bile salt export pump (BSEP) deficiency commonly experience growth failure. However, the effects of surgical biliary diversion (SBD) and LT on growth have only been partially characterized. In the largest study of patients with FIC1 and BSEP deficiency to date, integrating data from the global NAPPED and TreatFIC registries, we evaluated the effects of SBD and LT on growth outcomes. **Methods:** We analyzed demographic, growth, and clinical data, including surgical treatments, from patients in the NAPPED and TreatFIC registries with biallelic disease-causing variants in *ATP8B1* (FIC1) or *ABCB11* (BSEP). Height measurements recorded up to 10 years of age were converted into WHO-standardized height-for-age z-scores (HAZ), and analyzed before and after SBD or LT. We defined serum bile acid (sBA) responders to SBD as patients with sBA < 102 µmol/L or > 75% reduction from baseline within 12 months of SBD. We assessed within-patient changes after these events by comparing HAZ 0-12 months prior to surgery and up to 6 years after. LT after SBD was a censoring event. Growth stunting (GS) is defined as HAZ < −2. **Results:** We included 433 patients, 110 with FIC1 deficiency and 323 with BSEP deficiency. Of these patients, 49% with FIC1 and 27% with BSEP deficiency underwent SBD, with median HAZ before SBD of −2.1 (interquartile range [IQR] −3.1 to −1.2) and −1.9 (IQR −2.8 to −0.9), respectively. Patients with BSEP deficiency who had an sBA response to SBD (48%, 24/50 with available sBA) showed significant growth improvement after surgery compared with non-responders, with median HAZ difference of +1.4 ($p < 0.05$; Figure 1A). Patients with FIC1 deficiency had a low sBA response rate to SBD (32%, 7/22 with available sBA) and did not show significant growth improvement after SBD. Among patients who underwent LT, those with FIC1 deficiency had a significantly lower HAZ at LT than those with BSEP deficiency: −2.8 (IQR −3.7 to −1.2) vs. −1.9 (IQR −2.8 to −0.9), respectively ($p < 0.01$). No significant growth recovery was observed in patients with FIC1 deficiency after LT. In contrast, patients with BSEP deficiency showed significant growth improvement from 12 months after LT onwards ($p < 0.01$), which was sustained through 6 years (median HAZ of 0; IQR −1.5 to +1.3; Figure 1B). **Conclusion:** Most patients with FIC1 or BSEP deficiency who undergo SBD or LT are growth restricted at the time of surgery. SBD with sBA responsiveness and LT are associated with improved growth trajectories in children with BSEP deficiency, but not in those with FIC1 deficiency. We speculate that persistent growth failure in FIC1 deficiency is driven by extrahepatic ATP8B1 dysfunction.

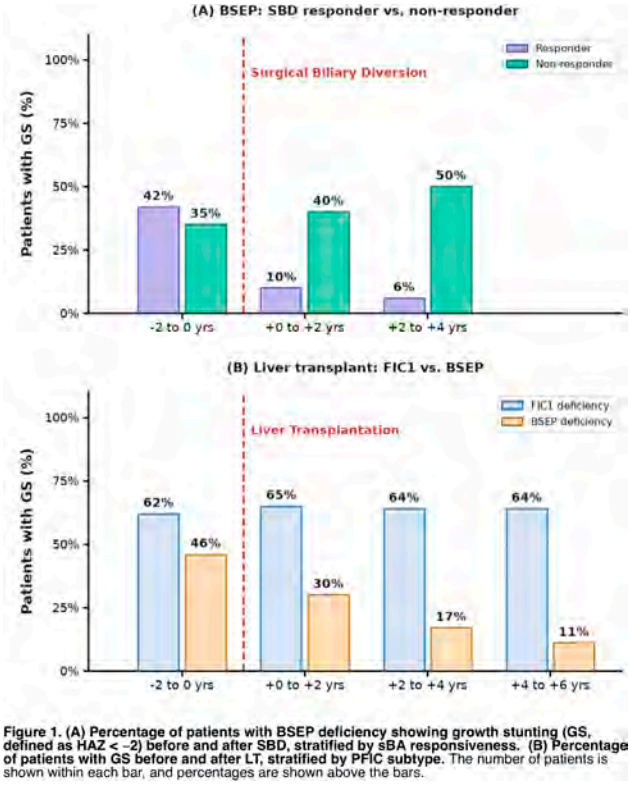

Figure 1. (A) Percentage of patients with BSEP deficiency showing growth stunting (GS, defined as HAZ < -2) before and after SBD, stratified by sBA responsiveness. (B) Percentage of patients with GS before and after LT, stratified by PFIC subtype. The number of patients is shown within each bar, and percentages are shown above the bars.

Hospital for Children, [2]Indiana University, [3]Indiana University School of Medicine

Background: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is rising in the pediatric population alongside obesity rates. While Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have shown efficacy in adults, pediatric data remain limited. This study aims to evaluate the impact of GLP-1RA therapy on anthropometric measures, biochemical markers, and liver stiffness in children with MASLD compared to a matched control group. **Methods:** We conducted a retrospective cohort study of 124 pediatric patients with MASLD, comparing those receiving GLP-1RA therapy due to obesity (n = 62) to those not on GLP-1RA (n = 62). Control group (non-GLP-1RA) was matched for age, sex, race, ethnicity and duration of follow up to GLP-1RA group. Baseline characteristics and treatment outcomes, including anthropometric assessment, liver enzymes, and FibroScan parameters (Controlled Attenuation Parameter; CAP and Liver Stiffness Measurement; LSM), were analyzed. The t -test was used to compare the continuous variables, and the chi-square test was used for categorical variables. **Results:** The average age at presentation was 12.88 years for the non-GLP-1RA group and 13.21 years (p = 0.13) for the GLP-1RA group, with mean follow-up durations of 13.36 and 11.20 months, (p = 0.22) respectively. Compared to the non-GLP-1RA cohort, the GLP-1RA group exhibited a significantly higher prevalence of obstructive sleep apnea (32.26% vs. 1.61%; p = 0.001) and pre-diabetes (24.19% vs. 4.84%; p = 0.001), whereas the prevalence of type 2 diabetes did not significantly differ between groups (8.1% vs. 4.8%; p = 0.26). Patients on GLP-1RA achieved a numeric reduction in mean BMI (43.81 to 41.83, p = 0.26) and BMI z-score (2.68 to 2.61), whereas mean BMI significantly increased in the non-GLP-1 RA group (33.28 to 36.32, p = 0.01). GLP-1RA-treated patients exhibited a significant reduction in ALT (61.98 ± 45.54 to 42.54 ± 33.80 U/L, p = 0.008) and AST (35.77 ± 22.15 to 26.44 ± 13.57 U/L, p = 0.008) at the last follow-up. GLP-1RA-treated patients who achieved 20% ALT reduction had significantly lower baseline BMI (41.02 vs. 46.27, p = 0.03) compared to non-20% ALT reduction. HbA1c, lipid profiles, CAP and LSM at recent follow up were not different in either the two groups. **Conclusion:** GLP-1RA therapy in pediatric MASLD is associated with significant improvements in transaminases and stabilization of BMI compared to traditional management. GLP-1RA therapy for MASLD may be more effective when initiated at an earlier stage of the disease before the development of severe obesity. Future clinical trials should incorporate more robust and sensitive endpoints, such as MRI-PDFF to accurately quantify changes in hepatic steatosis, or liver biopsy to assess histological improvements in inflammation and fibrosis.

Table Comparison of clinical outcomes at baseline and follow-up between pediatric MASLD patients receiving GLP-1 and non-GLP1 therapy.

Outcomes	At presentation	At last follow-up	P value
BMI			
Non-GLP1	33.29 ± 6.58	36.32 ± 6.54	**0.01**
GLP-1	43.81 ± 9.46	41.93 ± 9.31	0.26
BMI z score			
Non-GLP1	2.31 ± 0.38	2.38 ± 0.38	0.32
GLP-1	2.68 ± 0.33	2.61 ± 0.44	0.24
Weight (kg)			
Non-GLP1	86.58 ± 27.39	102.95 ± 27.01	**0.001**
GLP-1	124.96 ± 27.27	121.38 ± 28.32	0.48
Weight z score			
Non-GLP1	2.57 ± 0.74	2.61 ± 0.77	0.77
GLP-1	4.72 ± 12.21	2.83 ± 0.65	0.23
Aspartate Aminotransferase (U/L)			
Non-GLP1	46.16 ± 26.28	44.87 ± 41.10	0.83
GLP-1	35.77 ± 22.15	26.44 ± 13.57	**0.008**
Alanine transaminase (U/L)			
Non-GLP1	77.10 ± 54.42	77.83 ± 87.37	0.96
GLP-1	61.98 ± 45.54	42.54 ± 33.80	**0.008**
Total bilirubin (mg/dL)			
Non-GLP1 (n = 60, 58)	0.46 ± 0.28	0.56 ± 0.31	0.06
GLP-1 (n = 56, 41)	0.49 ± 0.21	0.53 ± 0.21	0.51
Albumin (g/dL)			
Non-GLP1 (n = 61, 57)	4.45 ± 0.62	4.62 ± 0.25	0.06
GLP-1 (n = 56, 41)	4.45 ± 0.33	4.48 ± 0.29	0.72
HbA1C (%)			
Non-GLP1 (n = 48, 53)	5.56 ± 0.51	6.87 ± 1.33	0.33
GLP-1 (n = 57, 46)	5.59 ± 0.39	5.42 ± 0.62	0.12
LDL (mg/dL)			
Non-GLP1 (n = 40, 47)	76.65 ± 4.38	80.72 ± 3.93	0.49
GLP-1 (n = 56, 38)	94.23 ± 27.61	93.21 ± 24.81	0.85
Cholesterol (mg/dL)			
Non-GLP1 (n = 40, 46)	150.47 ± 37.11	148.13 ± 38.90	0.78
GLP-1 (n = 53, 38)	163.72 ± 33.25	159.11 ± 31.17	0.50
Triglyceride (mg/dL)			
Non-GLP1 (n = 40, 46)	176.70 ± 106.31	168.65 ± 113.13	0.74
GLP-1 (n = 53, 38)	146.60 ± 66.22	148.26 ± 107.39	0.93
HDL (mg/dL)			
Non-GLP1 (n = 40, 46)	43.82 ± 7.15	44.96 ± 5.23	0.89
GLP-1 (n = 53, 38)	38.24 ± 6.73	44.61 ± 5.98	0.33
CAP from FibroScan (dB/m)			
Non-GLP1 (n = 23, 23)	309.74 ± 32.78	321.87 ± 41.51	0.28
GLP-1 (n = 32, 19)	338.63 ± 45.24	327.27 ± 59.64	0.48
LSM from FibroScan (kPa)			
Non-GLP1 (n = 23, 23)	7.00 ± 2.59	6.81 ± 2.89	0.81
GLP-1 (n = 32, 19)	7.48 ± 2.69	7.86 ± 3.22	0.66

Background: Fontan palliation is the primary treatment for patients with single ventricle cardiac abnormalities, but it results in high central venous pressure, decreased cardiac output and reduced hepatic oxygenation leading to Fontan-associated liver disease (FALD) which is characterized by liver congestion, fibrosis, and cirrhosis. To improve diagnosis and mechanistic understanding of FALD, we have established models of FALD in sheep from which circulating extracellular vesicles (EVs) are assessed for their molecular cargo components and bioactivities. **Methods:** To create Fontan models in sheep, an extracadiac conduit was used to join the inferior vena cava (IVC) to the main pulmonary artery (MPA) while the superior vena cava (SVC) remained in its normal anatomical position ("Glennless") or was connected to the MPA as part of the surgical procedure on the same day ("single stage") or ~12 months later ("two-stage"). Control animals received either no surgery or a procedure comprising a right thoracotomy through the 4th intercostal space followed by chest closure. EVs were isolated from plasma or serum over the ensuing 12-mo by differential centrifugation and analyzed by Nanosight tracking analysis and protein assay. EV total RNAs were isolated and subjected to small RNA-seq for miRNA and piRNA profiling. iPSC-derived human liver organoids (HLO) were used to assess regulation of fibrosis-related genes by 20ug/ml EVs or expression of candidate miRs. **Results:** As assessed histologically, mild hepatic fibrosis was present at ~6 months and moderate or severe fibrosis was present by 12 mo. Serum or plasma EVs from sham or Fontan sheep ($\leq$12 mo.) shared similar particle size, yield, or protein concentration. Serum and plasma EVs shared similar miRNA profiles but higher piRNA levels were evident in serum EVs compared to plasma EVs. Using regularized feature selection and ordinal logistic regression, 6 miRNAs and 3 piRNAs in serum EVs were identified that, together with time post-surgery, comprised a scoring system predictive of FALD severity. Four of these miRNAs underwent comparable changes in expression in TGF-β-treated HLOs as in serum/plasma EVs during FALD progression supporting a functional role in fibrosis. Plasma EVs collected 1 mo. from either a sham twin or its single stage Fontan twin counterpart suppressed TGF-β-induced fibrotic gene expression in HLOs; at 7mo post-surgery this suppression was maintained in plasma EVs from the sham twin but was lost from plasma EVs of the Fontan twin suggesting that circulating EVs lose anti-fibrotic activity during progression of FALD. **Conclusion:** Circulating EVs from a sheep FALD model exhibit dynamic changes in miRNA/piRNA payloads and fibrosis-related gene modulation. A select miRNA/piRNA panel was predictive of FALD severity and partially implicated in underlying fibrotic mechanisms.

Background: Accurate individualized prediction of native liver survival (NLS) is needed to support clinical monitoring and decision-making in children with Alagille syndrome (ALGS). Serum bile acids (sBA) and total bilirubin (TB) reflect cholestasis, whereas platelet count (PC) may capture changes in portal hypertension and the progression of liver disease. However, the extent to which longitudinal changes in these routinely collected markers predict NLS in ALGS remains unclear. This study aimed to address this question using a standard-of-care pediatric ALGS cohort. **Methods:** Data on an international cohort of 1562 patients from 81 centers across 34 countries were obtained from the Global Alagille Alliance Study. We included children with confirmed neonatal cholestasis, and we censored follow-up at biliary diversion, hepatocellular carcinoma diagnosis, participation in an IBAT inhibitor trial, or Kasai procedure, the latter in patients who underwent this surgery before ALGS was confirmed. Joint models were fitted to analyze longitudinal sBA, TB, and PC trajectories and the time of death or liver transplantation (LT), while accounting for left truncation due to delayed study entry. Models were compared using the Watanabe–Akaike information criterion, and their discriminative ability was evaluated using the in-sample time-dependent area under the curve (AUC). **Results:** The analysis included 1147 patients (58% male, 95% with *JAG1* mutation), who contributed 12,722 visits over a mean follow-up of 4.2 years. NLS at 18 years old was 34.5% (95% confidence interval [CI] 29.5–40.4). In univariate joint models, higher current values of sBA (per unit increase in log µmol/L: hazard ratio [HR] = 4.30, 95% CI 2.86–6.81) and TB (per unit increase in log mg/dL: HR = 4.59, 95% CI 3.67–5.77) were associated with an increased risk of death and LT. Increasing trajectories of sBA (per unit increase in log µmol/L over 6 months: HR = 1.55, 95% CI 0.93–2.64) and TB (per unit increase in log mg/dL over 1 year: HR = 1.82, 95% CI 1.26–2.66) were also associated with worse NLS. Figure 1 shows the fitted longitudinal sBA trajectories for a specific patient and their associated cumulative risk of death or LT. Conversely, higher PC values (per unit increase in square-root : HR = 0.75, 95% CI 0.72–0.79) and instantaneous increasing PC trajectories (HR = 0.84, 95% CI 0.79–0.91) were associated with improved NLS. At 6 years of age, the univariate time-dependent AUC over a 5-year horizon was 0.72 for sBA, 0.82 for TB, and 0.74 for PC. A multivariate model combining all three biomarkers showed the highest discriminative ability, with an AUC of 0.89. **Conclusion:** Longitudinal trajectories of TB, sBA, and PC, captured through current biomarker values and rates of change, provide information on NLS prognosis in this pediatric ALGS cohort. This model may support personalized risk stratification and inform the evaluation of these biomarkers as potential surrogate endpoints in ALGS.

2656 | VALIDATION OF FIBROSCAN-BASED NON-INVASIVE SCORES FOR THE DETECTION OF STEATOSIS, ADVANCED FIBROSIS AND FIBROTIC MASH IN CHILDREN WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Abdulmalik Kareem[1] Chao Jarasvaraparn[1], [1]Indiana University School of Medicine

Background: Identifying advanced fibrosis and fibrotic metabolic dysfunction-associated steatotic liver disease (MASH) is critical for pediatric clinical management. While liver stiffness measurement (LSM) is widely used, the performance of multi-parametric scores like AGILE 3 and FAST remains less defined in children. We evaluated the diagnostic accuracy of these scores against blinded histologic assessment in a pediatric cohort. **Methods:** We retrospectively studied 128 children with biopsy-confirmed MASLD who underwent FibroScan within 6 months of liver biopsy. Biopsies were re-read by a blinded pediatric pathologist using the NASH CRN system

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

(steatosis 0-3; ballooning 0-2; lobular inflammation 0-3; fibrosis 0-4). We compared the diagnostic performance of APRI, FIB-4, LSM, AGILE 3 and FAST. The FAST (FibroScan-AST) score is designed to identify patients with "at-risk" or fibrotic MASH (NAS $\geq$ 4 and F $\geq$ 2) and is calculated using a proprietary formula incorporating LSM, controlled attenuation parameter (CAP), and AST. The Agile-3 score is a multi-parametric model used to identify advanced fibrosis (Stage $\geq$ F3) by integrating LSM with clinical and laboratory variables, including AST, ALT, platelet count, age, sex, and diabetes status. Advanced fibrosis was defined as Stage 3–4. **Results:** The cohort (mean age 14.2 years; mean BMI 36.5 kg/m2) had an advanced fibrosis prevalence of 14.1%. The CAP was significantly higher in patients with steatosis compared to those without (327.0 ± 43.7 vs. 254.7 ± 47.0 dB/m, p = 0.001). LSM showed the strongest correlation with fibrosis stage (r = 0.57, p < 0.001), followed by AGILE 3 (r = 0.43, p < 0.001); APRI and FIB-4 were significantly weaker (r = 0.31 and 0.20). To detect advanced fibrosis, AGILE 3 $\geq$ 0.059) demonstrated the highest sensitivity (94.4%) and NPV (98.8%; AUC 0.840), while LSM $\geq$ 9.2 kPa) achieved 83.3% sensitivity and 96.3% NPV (AUC 0.771). Mean LSM was significantly higher in advanced fibrosis (15.3 vs. 9.2 kPa, p = 0.001). For fibrotic MASH, a FAST score $\geq$ 0.53 yielded 96.0% sensitivity and 98.0% NPV (p = 0.003). Notably, diagnostic accuracy for advanced fibrosis diminished significantly in patients with BMI $\geq$ 40, with AUCs declining to 0.600–0.646. **Conclusion:** FibroScan-derived scores, particularly AGILE 3 and LSM, provide superior diagnostic accuracy for identifying pediatric advanced fibrosis compared to simple biochemical markers. The high NPV of AGILE 3 and FAST makes them excellent tools to rule out advanced disease, though clinicians should exercise caution in patients with a BMI $\geq$ 40 due to reduced performance.

Table Cut-offs for non-invasive fibrosis scores indicating advanced liver disease on liver biopsy (stage 3-4) in children

	Cut-off	Sensitivity	Specificity	AUC (95% CI)	PPV (%)	NPV (%)	OR (95% CI)	P-value
LSM	≥ 9.2	83.3 (66.1, 100.0)	70.9 (62.4, 79.4)	0.771 (0.673, 0.870)	31.9 (18.6, 45.2)	96.3 (92.2, 100.0)	12.2 (3.30, 44.9)	<0.001
APRI	≥ 0.328358	94.4 (83.9, 100.0)	35.5 (26.5, 44.4)	0.650 (0.579, 0.720)	19.3 (11.1, 27.6)	97.5 (92.7, 100.0)	9.3 (1.20, 72.3)	0.033
FIB-4	≥ 0.253447	77.8 (58.6, 97.0)	50.9 (41.6, 60.3)	0.643 (0.534, 0.753)	20.6 (11.0, 30.2)	93.3 (87.0, 99.7)	3.6 (1.1, 11.7)	0.031
Agile-3	≥ 0.059	94.4 (83.9, 100.0)	73.6 (65.4, 81.9)	0.840 (0.772, 0.909)	37.0 (23.0, 50.9)	98.8 (96.4, 100.0)	47.5 (6.0, 372.8)	<0.001

Table Comparison of Fibroscan Prediction of Fibrosis Stage 3-4 using AUCs

	Overall (n=128)	BMI < 30 (n=29)	BMI 30 – 34.9 (n=32)	BMI 35 – 39.9 (n=27)	BMI 40+ (n=40)
Cut-Points					
LSM ≥ 9.2	0.771 (0.673, 0.870)	0.795 (0.464, 1.000)	0.926 (0.858, 0.994)	0.786 (0.571, 1.000)	0.600 (0.387,0.813)
AGILE 3 ≥ 0.059	0.840 (0.772, 0.909)	0.795 (0.464, 1.000)	0.907 (0.833, 0.982)	0.886 (0.797, 0.976	0.757 (0.673, 0.841)
Continuous Score

2657 | LOW SCREENING RATES AND UNEQUAL RISK OF ABNORMAL RESULTS IN PEDIATRIC MASLD

Doris Valenzuela Araujo[1] Jennifer Panganiban[2] Jeremy Michel[1] Katherine Yun[1], [1]Children's Hospital of Philadelphia, [2]The Children's Hospital of Philadelphia

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common pediatric liver disease and disproportionately affects Latino children. Despite this, screening rates remain low and patient-level differences in screening and abnormal results are not well described for Latino children and Spanish-Speaking families. **Methods:** We conducted a retrospective study to evaluate MASLD screening completion and prevalence of abnormal results in children ages 10–17 with BMI $\geq$ 95th percentile seen in primary care at a large academic center in 2023. Completion of screening was defined as having an alanine aminotransferase (ALT) level up to 2 years prior to or 1 year after their qualifying primary care visit, in alignment with American Academy of Pediatrics recommendations. We used logistic regression and adjusted models to evaluate for differences screening and in frequency of ALT value $\geq$ 80 U/L and how this varied by age, sex, ethnicity, language preference, and BMI. **Results:** Our cohort included 16,208 children ages 10-17 with obesity. The mean age was 13.1 years, mean BMI was 31.8 and 46.7% were female. 13.3% of children were Hispanic/Latino and the most prevalent races were White at 43% and Black at 40.1%. Spanish was the preferred language for 4.6%, and 1.5% preferred a non-English, non-Spanish language. Only 7,627 (47%) of children had ALT screening completed with the 17-year-old cohort having the highest screening rate at 54.3%. There were no differences in screening by ethnicity or by language group. An ALT $\geq$ 80 U/L occurred in 149 children (2% of screened), with higher prevalence among Hispanic/Latino (5.3%) and Spanish-speaking children (8.9%). Spanish-preference was associated with higher odds of ALT $\geq$ 80 U/L (aOR 5.58, 95% CI 3.64–8.53 vs English), as was Hispanic/Latino ethnicity (aOR 3.85, 95% CI 0.87–1.05 vs non-Hispanic/Latino). **Conclusion:** We found that less than half of children had screening for MASLD. Among those screened, rates of ALT $\geq$ 80 U/L were significantly higher for Hispanic/Latino children and preferred language of Spanish even after adjusting for confounders. Our findings highlight the need for interventions to

increase rates of screening particularly among patients with highest risk of abnormal results and poor disease outcomes.

2658 | MITOCHONDRIAL HEPATOPATHY: GENETIC ETIOLOGY AND CLINICAL SPECTRUM FROM OVER 100 CHILDREN

James Squires[1] Alexander Miethke[2] Kieran Hawthorne[3] Johan Van Hove[4] Simon Horslen[5] Rohit Kohli[6] Akihiro Asai[2] Mark Lovell[7] Estella Alonso[8] Saul Karpen[9] Kathleen Loomes[10] Steve Guthery[11] Jean Molleston[12] Pamela Valentino[13] Benjamin Shneider[14] Kasper Wang[6] Philip Rosenthal[15] John Magee[16] Ronald Sokol[17], [1]Children's Hospital of Pittsburgh, [2]Cincinnati Children's Hospital Medical Center, [3]Arbor Research Collaborative for Health, Ann Arbor, Michigan, United States, [4]Section of Clinical Genetics and Metabolism, Department of Pediatrics, University of Colorado, [5]UPMC Children's Hospital of Pittsburgh, [6]Children's Hospital Los Angeles, [7]Department of Pathology, Children's Hospital Colorado, [8]Ann and Robert H. Lurie Children's Hospital of Chicago, [9]VCU Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, [10]The Children's Hospital of Philadelphia, [11]Primary Children's Hospital, [12]Riley Hospital for Children, Indiana University School of Medicine, [13]University of Washington, [14]Texas Children's Hospital, [15]University of California, San Francisco, [16]University of Michigan Hospitals and Health Centers, [17]University of Colorado School of Medicine

Background: Alterations in mitochondrial structure and function result in a wide range of liver-based pathology termed mitochondrial hepatopathies (MH). Increasingly, MH diagnosis is made by genetic sequencing of both nuclear DNA and mitochondrial DNA (mtDNA). We aim to identify unique clinical features attributable to the underlying molecular etiologies of MH, linking these features with clinical phenotypes and disease course. **Methods:** We interrogated 2 NIDDK/NIH funded prospective studies – the Longitudinal Study of MH (MITOHEP) and the Pediatric Acute Liver Failure Study Group (PALFSG) - to collect and analyze demographic, clinical, laboratory, and outcome data on participants with MH phenotypes. Demographics and baseline characteristics are described using counts and percents or median and range and compared between phenotypic groups using chi-square or Wilcoxon rank sum tests. Time to event analyses were conducted using Kaplan-Meier methods. **Results:** Data from 115 participants (n = 93 MITOHEP, n = 22 PALF) were analyzed. Comprehensive genetic/enzymatic testing was performed in 65% with a final diagnosis in 73% of those tested. Three primary phenotypes were noted - acute liver failure (ALF, n = 43), chronic liver disease (Chronic, n = 62), and post-liver transplant (LT, n = 10). (**TABLE**) Comprehensive testing was performed more often in Chronic than ALF (77% vs 42%); however, etiology was identified more often in ALF (78% vs. 67%) with mtDNA depletion (*POLG*, *DGUOK*, *MPV17*) being most common (ALF: 79% vs Chronic: 41%). Overall, LT-free survival was 47% [95%CI: 36-57%] at 2 years. Those with ALF had worse LT- free survival (ALF15% [95%CI: 5-30%] vs. Chronic 65% [95%CI: 51-76%], $p < 0.001$). LT-free survival was also significantly lower in patients with a known genetic diagnosis (2-year survival 44% [95% CI: 28-58%] vs. 82% [95% CI: 54-94%], $p < 0.01$). Nineteen (17%) underwent LT (*TRMU* n = 5, *DGUOK* n = 3 Complex IV def n = 2, *POLG* n = 2, *TYMP* n = 1, Negative genetic testing n = 2, No genetic testing n = 4). With 99 patient-years of follow-up post-LT, 5 deaths were reported. **Conclusion:** Bi-allelic mutations in genes associated with mtDNA depletion syndromes were the most common identified cause of MH presenting with both ALF and Chronic phenotypes. LT-free survival is poor, with both an ALF phenotype and a known genetic diagnosis portending a poor outcome. In patients who underwent LT, long-term survival is possible highlighting areas for further investigation.

2660 | PAIRED EVALUATION OF BIOPSY AND NONINVASIVE TESTS FOR STAGING AND MONITORING ADOLESCENT MASLD ACROSS SLEEVE GASTRECTOMY AND LIFESTYLE INTERVENTION

Toshifumi Yodoshi[1] Nicholas Ollberding[2] Meghan McNeill[2] Sanita Ley[2] Shelley Kirk[2] David Kleiner[3] Ana Catalina Arce-Clachar[1] Kristin Bramlage[1] Thomas Inge[4] Michael Helmrath[2] Kim Cecil[2] Andrew Trout[5] Deborah Elder[2] Marialena Mouzaki[1] Stavra Xanthakos[1], [1]Cincinnati Children's Hospital Medical Center, [2]Cincinnati Children's Hospital Medical Center, [3]National Institutes of Health, [4]Northwestern University Feinberg School of Medicine, [5]Cincinnati Children's Hospital Medical Center, Cincinnati

Background: Pediatric metabolic dysfunction-associated steatotic liver disease (MASLD), including steatohepatitis (MASH), lacks well-validated noninvasive tests (NITs) for fibrosis staging and treatment monitoring. Pediatric-derived scores and imaging NITs have largely been evaluated cross-sectionally. **Methods:** In a prospective parallel-arm cohort, adolescents aged 12–19 with severe obesity and biopsy-confirmed MASLD underwent vertical sleeve gastrectomy (VSG) or comprehensive lifestyle intervention (CLI), with repeat biopsy at week-52. NITs evaluated were ALT, GGT, Fibro-PeN, pediatric fibrosis-c (pFIB-c), pediatric fibrosis-6 (pFIB-6), MRI proton density fat fraction (MRI-PDFF), and MR elastography (MRE). We assessed baseline and week-52 detection of significant fibrosis (stage ≥ 2), week-52 NIT values for histologic response, and correlation of NIT change with histologic change. Models adjusted for baseline value and treatment arm. **Results:** Of 42 enrolled (VSG = 17; CLI = 25), 27 completed paired biopsies (VSG = 12; CLI = 15). Histologic improvement favored VSG over CLI: NAFLD Activity Score (NAS) improvement 11/12 (92%) vs 3/15 (20%), MASLD resolution 7/12 (58%) vs 0/15 (0%), MASH resolution (among baseline MASH) 8/8 (100%) vs 4/11 (36%), fibrosis improvement (≥ 1 stage) 6/12 (50%) vs 1/15 (7%). At baseline, MRE best discriminated significant fibrosis (AUROC 0.80, 95% CI 0.61–0.94); at week-52, Fibro-PeN (0.85, 0.67–0.97) and GGT (0.85, 0.69–0.97) performed best. In

unadjusted cross-treatment analyses, the best week-52 NITs were Fibro-PeN for fibrosis improvement (0.90), MRI-PDFF for MASLD resolution (0.88), ALT for NAS improvement (0.86). NIT changes correlated only modestly with histologic change (Fibro-PeN with fibrosis stage, rho = 0.45, P = 0.02; MRI-PDFF with NAS, rho = 0.44, P = 0.03); after adjustment, no NIT-change term independently predicted any histologic outcome. Paired MRE trajectories diverged by arm and baseline stage: in VSG, the 2 with baseline F ≥ 2 (F3→F0, F4→F3) showed expected stiffness decrease, but those with low baseline fibrosis showed post-treatment increase (ΔMRE +0.30 to +0.71 kPa) despite stable or improved histology. Change in MRE was uncorrelated with change in MRI-PDFF in VSG (r = −0.04, P = 0.92), arguing against steatosis loss as explanation. **Conclusion:** Baseline MRE performed best for assessing fibrosis severity. Although week-52 Fibro-PeN, MRI-PDFF, and ALT showed strong unadjusted AUROCs for histologic response, NIT changes did not independently predict response after adjustment, indicating much of the unadjusted discrimination reflects treatment arm rather than biomarker-specific signal. Post-treatment MRE behaved discordantly in low-fibrosis VSG participants, unexplained by hepatic fat loss. Current pediatric NITs may be more useful as point-in-time markers than as change-based monitoring tools across treatments of differing intensity.

Table. Cross-sectional and Post-treatment Discrimination of Noninvasive Tests

Panel A. Cross-sectional discrimination of NITs for biopsy-confirmed significant fibrosis (F≥2)at baseline and week-52 assessment.

Marker	Baseline N	Baseline rho (P)	Baseline AUROC (95% CI)	Week-52 N	Week-52 rho (P)	Week-52 AUROC (95% CI)
ALT	42	0.20 (0.204)	0.54 (0.34–0.72)	27	0.19 (0.331)	0.67 (0.42–0.88)
GGT	42	0.35 (0.024)	0.70 (0.54–0.86)	27	0.42 (0.028)	0.85 (0.69–0.97)
pFIB-c	42	0.03 (0.857)	0.52 (0.35–0.71)	27	0.15 (0.450)	0.72 (0.49–0.91)
pFIB-6	42	-0.16 (0.306)	0.47 (0.29–0.66)	27	0.09 (0.656)	0.66 (0.44–0.85)
Fibro-PeN	42	0.39 (0.046)	0.65 (0.42–0.86)	27	0.38 (0.050)	0.85 (0.67–0.97)
MRI-PDFF	42	-0.06 (0.725)	0.54 (0.36–0.73)	27	0.24 (0.258)	0.69 (0.44–0.90)
MRE	42	0.66 (<0.001)	0.80 (0.61–0.94)	27	-0.07 (0.725)	0.38 (0.17–0.61)

Panel B. Unadjusted, cross-treatment discrimination of histologic response using absolute Week 52 NIT values.

outcome	marker	AUROC
Fibrosis improvement (baseline F≥1)	ALT	0.88 (0.61–1.00)
	GGT	0.80 (0.51–1.00)
	pFIB-c	0.78 (0.47–1.00)
	pFIB-6	0.70 (0.38–0.94)
	Fibro-PeN	0.90 (0.69–1.00)
	MRI-PDFF	0.88 (0.63–1.00)
MASLD resolution	ALT	0.86 (0.72–0.98)
	GGT	0.73 (0.50–0.93)
	pFIB-c	0.70 (0.43–0.92)
	pFIB-6	0.66 (0.38–0.91)
	Fibro-PeN	0.78 (0.54–0.95)
	MRI-PDFF	0.88 (0.61–1.00)
MASH resolution	ALT	0.80 (0.54–0.96)
	GGT	0.85 (0.64–0.98)
	pFIB-c	0.83 (0.60–1.00)
	pFIB-6	0.80 (0.57–0.97)
	Fibro-PeN	0.89 (0.73–1.00)
	MRI-PDFF	0.81 (0.54–0.97)
NAS improvement	ALT	0.86 (0.70–0.98)
	GGT	0.79 (0.61–0.94)
	pFIB-c	0.84 (0.65–0.95)
	pFIB-6	0.79 (0.60–0.93)
	Fibro-PeN	0.80 (0.61–0.95)
	MRI-PDFF	0.84 (0.62–1.00)

Panel B evaluates whether absolute NIT values at Week 52 distinguish participants with versus without histologic improvement or resolution; these AUROCs are not based on NIT change scores.

Abbreviations: AUROC, area under the receiver operating characteristic curve; CI, confidence interval; MASLD, metabolic dysfunction-associated steatotic liver disease; MRE, magnetic resonance elastography; MRI-PDFF, magnetic resonance imaging-proton density fat fraction; NAS, NAFLD Activity Score; pFIB-c, continuous pediatric fibrosis score; pFIB-6, simplified pediatric fibrosis score; pFIB-c, continuous pediatric fibrosis score.

2661 | REAL-WORLD EXPERIENCE WITH SWITCHING TO ODEVIXIBAT FROM MARALIXIBAT IN PATIENTS WITH ALAGILLE SYNDROME: A RETROSPECTIVE CHART REVIEW

Nadia Ovchinsky[1] Mathias Ruiz[2] Alice Tiret[3] Madeleine Aumar[4] Henry Lin[5] Muriel Girard[6] Cécile Artaud[7] Marie-Cécile Fournier[7] Frédérique Thoby[7] Etienne Quet[7], [1]Division of Pediatric Gastroenterology and Hepatology, Hassenfeld Children's Hospital at NYU Langon, [2]CHU de Lyon HCL, Lyon, and GH Est-Hôpital Femme Mère Enfant, Bron, France, [3]CHU de Rennes, Hospital Sud, Rennes, France, [4]CHU de Lille, Lille, France, [5]Department of Pediatrics, Oregon Health Science University School of Medicine, Portland, OR, US, [6]Unité d'Hépatologie, Hôpital Necker-Enfants Malades, Paris, France, [7]Ipsen, Paris, France

Background: Two IBAT inhibitors (odevixibat [ODX] and maralixibat [MRX]) are approved for treating cholestatic pruritus in patients (pts) with Alagille syndrome (ALGS). Some pts experience loss of clinical response or gastrointestinal (GI) adverse events (AEs) that require switching to an alternative IBAT inhibitor. Long-term ODX data demonstrate favorable tolerability, sustained improvements in pruritus, and reductions in serum bile acids in the phase III ASSERT/ASSERT-EXT studies (NCT04674761/NCT05035030); limited data are available in pts previously treated with MRX in whom

switching to ODX may be beneficial. This is particularly important in adolescents requiring transition of care between pediatric and adult hepatologists. In this interim analysis of retrospective chart data, we characterize real-world drivers of switching and post-switch clinical parameters in adolescents with ALGS (age at ODX initiation, 13–18 years). **Methods:** This is a real-world, non-interventional, multicenter, retrospective chart review of pts with ALGS conducted in France and the US. Eligible pts had a genetic diagnosis, ≥4-week treatment with MRX prior to switching, and ≥4-week treatment with ODX after switching. The primary objective was to describe the reasons for discontinuing MRX and reasons for initiating ODX. Secondary objectives included demographics and clinical characteristics prior to switch, and AEs. Data were collected from up to 12 months before the last visit prior to MRX discontinuation, through all visits on MRX and ODX and until the time of data collection or the end of ODX treatment. **Results:** At data cutoff (March 25, 2026), five pts had been recruited, including three adolescents (age at ALGS diagnosis, 5–21 months). MRX was discontinued between 11.5 and 17.1 years of age after median 12.5 weeks of treatment; the observed reasons for MRX discontinuation in these pts were GI AEs (n = 2) or poor adherence to treatment with uncontrolled pruritus (n = 1). Pruritus subsequently improved in all three pts after ODX initiation. The most common GI AEs (Grade 1 & 2) related to MRX included diarrhea (n = 2), vomiting (n = 3), abdominal pain (n = 3), and nausea (n = 1); fewer GI AEs were observed with ODX (diarrhea [n = 2] and abdominal pain [n = 2]), that were transient and resolved by data cutoff without discontinuation. **Conclusion:** In this small cohort of adolescents with ALGS, observed reasons for discontinuing MRX included GI AEs, poor adherence, and uncontrolled pruritus. Switching to ODX from MRX improved pruritus symptoms in all pts, with fewer GI AEs that resolved without discontinuation. These preliminary results suggest that patients with ALGS who experience GI intolerance or inadequate symptom control on MRX could clinically benefit from switching to ODX. This may potentially inform clinical decisions in adolescents with ALGS transitioning to adult hepatology care. Enrollment is ongoing and further analysis will be presented.

2662 | DISCORDANCE BETWEEN METABOLIC BURDEN AND FIBROSIS SEVERITY IN BLACK YOUTH WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Chaowapong Jarasvaraparn[1] Laura Wilson[2] Jeffrey Schwimmer[3] Stavra Xanthakos[4] Miriam Vos[5] Naga Chalasani[6] Jean Molleston[1], [1]Riley Hospital for Children, [2]Johns Hopkins University, [3]Rady Children's Hospital San Diego, [4]Cincinnati Children's Hospital Medical Center, [5]Michigan State University, Helen DeVos Children's Hospital Corewell Health, [6]Indiana University Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver condition in the pediatric population. Although racial and ethnic differences in pediatric MASLD prevalence are recognized, less is known about whether Black youth with MASLD differ in metabolic phenotype, genetic risk, or histologic severity. We compared metabolic and histologic features of Black and White pediatric participants enrolled in the NASH Clinical Research Network. **Methods:** We analyzed baseline characteristics of 1,248 pediatric participants (mean age 12.5 years) enrolled in the NASH CRN. Participants were categorized as non-Hispanic Black (NHB, n = 21), Hispanic Black (HB, n = 20), non-Hispanic White (NHW, n = 306), or Hispanic White/Other (HW/Other, n = 901). Clinical, metabolic, PNPLA3 genotype, and centrally reviewed liver histology data were compared across groups. Logistic regression evaluated the association of race/ethnicity with clinically significant fibrosis, defined as stage 2–4 versus stage 0–1. **Results:** NHB participants had the highest mean weight, BMI z-score, and prevalence of severe obesity; severe obesity was present in 67% of NHB participants compared with 41% of NHW and 25% of HW/Other participants ($p < 0.001$). Metabolic syndrome was significantly more prevalent in NHB and HB cohorts (45% for both) compared to HW (29%; $p < 0.001$). NHB also demonstrated the highest levels of insulin resistance (HOMA-IR median 8.8 vs 5.2 NHW, $p > 0.001$). Triglyceride levels were significantly lower in NHB vs. NHW children (median 116 vs. 140; $p = 0.006$). PNPLA3 risk genotype frequency differed substantially across groups: 36% of NHB participants carried the CG/GG genotype compared with 72% of NHW and 92% of HW/Other participants ($p < 0.001$). On biopsy, NAS and fibrosis scores did not differ between NHB and NHW children. (NAS 4.4 vs 4.2 $p = 0.44$) and fibrosis stage 0.8 vs 1.2, $p = 0.18$). Multivariable logistic regression analysis showed that NHB and HB participants had a lower odds of clinically significant

fibrosis compared to NHW, adjusted for age, sex, BMI z-score, Type 2 diabetes, hypertension, and triglyceride level (OR = 0.29 [95% CI 0.11, 0.77], p = 0.01), but this association was attenuated when adjusted for PNPLA3 genotype (OR = 0.35 [95% CI 0.11, 1.04), p = 0.06). **Conclusion:** Black youth with MASLD in the NASH CRN had greater obesity, and insulin resistance, but did not have greater histologic severity than White youth. Lower PNPLA3 risk genotype frequency may partly explain the lower adjusted odds of clinically significant fibrosis observed in Black participants. These findings illustrate heterogeneity in pediatric MASLD and support further study of how metabolic, genetic, and social determinants jointly shape disease severity across racial and ethnic groups.

Table Independent association of clinically significant fibrosis (stage 2-4 vs. stage 0-1) with race/ethnicity

	Unadjusted		Adjusted for Demographic and Clinical Covariates*		Adjusted for Demographic, Clinical, and PNPLA3†	
	OR (95% CI)	P	OR (95% CI)	P	OR (95% CI)	P
White, non-Hispanic (ref.)	1.0		1.0		1.0	
Black (combines Hispanic and non-Hispanic)	0.31 (0.12, 0.81)	0.02	0.29 (0.11, 0.77)	0.01	0.35 (0.11, 1.04)	0.06
Hispanic, white/other	0.85 (0.64, 1.13)	0.25	0.90 (0.66, 1.21)	0.47	0.80 (0.57, 1.14)	0.22

Logistic regression analysis with the outcome of fibrosis stage 2-4 vs. fibrosis stage 0-1. N=1,248 for unadjusted models.
* Models adjusted for age, sex, BMI z-score, Type 2 diabetes, hypertension, and triglyceride level; N=1,236 due to missingness in covariates.
† Models adjusted for age, sex, BMI z-score, Type 2 diabetes, hypertension, triglyceride level, and PNPLA3 genotype (CG/GG vs. CC). N=922 due to missingness in covariates, including unavailable genotyping.

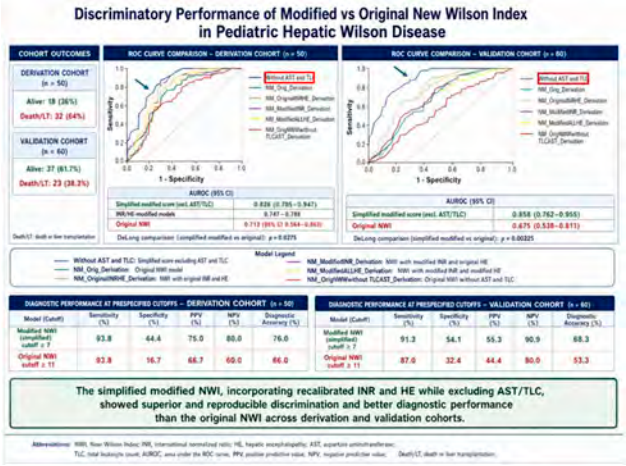
2663 | MODIFIED NEW WILSON INDEX FOR PEDIATRIC HEPATIC WILSON DISEASE WITH LIVER FAILURE: INCORPORATING ENCEPHALOPATHY SEVERITY AND RECALIBRATED INR IMPROVES PROGNOSTICATION



Anmol Anmol[1] Seema Alam[1] Rajeev Khanna[2] Vikrant Sood[1] Bikrant Biharilal Raghuvanshi[1], [1]Institute of liver and biliary sciences, [2]Institute of Liver and Biliary Sciences, Delhi

Background: The New Wilson Index (NWI) is widely used to predict outcomes in severe hepatic Wilson disease (WD), but its performance may vary in modern pediatric cohorts, especially with therapeutic plasma exchange. We assessed whether adjusting admission INR and including hepatic encephalopathy (HE) severity improves prediction of death or liver transplantation (Death/LT). **Methods:** In a single-center observational cohort of **110** children/adolescents with WD presenting with acute-on-chronic liver failure or decompensated chronic liver disease, outcomes were classified as alive versus Death/LT. Patients were split by UHID order into derivation (**n = 50**) and validation (**n = 60**) cohorts. Admission INR was re-categorized into five ordinal bands: $\leq$**2.50, 2.51–3.29, 3.30–3.99, 4.00–5.69,** $\geq$**5.70** . HE was scored as **0** for none, **2** for grade I–II, and **4** for grade III–IV. Candidate modified models were compared with original NWI using AUROC, fixed-cutoff classification, DeLong testing, calibration, reclassification indices, decision-curve analysis, and time-to-event discrimination. **Results:** In the derivation cohort, the simplified modified NWI with inclusion of HE and recalibrated INR cut-offs with exclusion of AST and TLC demonstrated significantly better discrimination than the original NWI, with AUROC improving from 0.713 for original NWI to 0.826 for the modified score (95% CI 0.705-0.947; DeLong p = 0.0275). This improvement was reproducible in the validation cohort, where the simplified modified NWI retained superior discrimination (AUROC 0.858; 95% CI 0.762-0.955) compared with original NWI (AUROC 0.675; 95% CI 0.538-0.811; DeLong p = 0.00225). Using a prespecified high-risk threshold of modified NWI 7, validation cohort sensitivity, specificity, positive predictive value, negative predictive value, and overall accuracy were 91.3%, 54.1%, 55.3%, 90.9%, and 68.3%, respectively. In comparison, the conventional original NWI 11 threshold yielded lower performance across all corresponding metrics (87.0%, 32.4%, 44.4%, 80.0%, and 53.3%, respectively), indicating improved classification of Death/LT risk with the modified score. The modified NWI also demonstrated better transported validation calibration, with a lower Brier score than original NWI (0.181 vs 0.253), substantial improvement in risk reclassification (continuous NRI 1.469; IDI 0.202), and higher decision-curve net benefit across clinically relevant threshold probabilities. In time-to-event analysis, the modified NWI showed superior validation discrimination for Death/LT-free survival compared with original NWI (C-index 0.795 vs 0.650), supporting its incremental prognostic value beyond fixed-time binary classification. **Conclusion:** A simplified modified NWI incorporating recalibrated INR and graded HE improves prognostic discrimination, classification, calibration,

Background: Growth failure is a frequent complication of pediatric cholestatic liver diseases, including familial intrahepatic cholestasis 1 (FIC1) deficiency and bile salt export pump (BSEP) deficiency. Although the severity of cholestasis is frequently similar in both these conditions, they are genetically distinct, and FIC1 deficiency also has extrahepatic manifestations. Global collaboration within the NAPPED consortium and the prospective TreatFIC registry has created the largest dataset for these rare diseases, enabling for the first time a large-scale, reliable analysis of the growth trajectories in patients with FIC1 and BSEP deficiency. **Methods:** We included demographic and clinical data from patients in the NAPPED and TreatFIC registries with available height measurements and biallelic disease-causing variants in *ATP8B1* (FIC1) or *ABCB11* (BSEP). Height measurements up to the age of 10 years were converted into WHO-standardized height-for-age z-scores (HAZ). Growth stunting (GS) was defined as HAZ < −2. Differences in HAZ over 24-month intervals from 0 to 10 years old between groups were assessed using median regression, adjusting for interruption of the enterohepatic circulation and liver transplantation. **Results:** We included 433 patients, of whom 110 had FIC1 deficiency (male/female 59/41%) and 323 had BSEP deficiency (male/female 52/48%). Median age at first presentation was 0.5 years (interquartile range [IQR] 0.2–1.5) in patients with FIC1 deficiency and 0.8 years (IQR 0.2–1.9) in those with BSEP deficiency. Median follow-up time was 4.8 years (IQR 2.5–7.4) and 5.6 years (IQR 2.5–8.1), respectively. By age 10, 49% of patients with FIC1 deficiency and 27% of those with BSEP deficiency had undergone surgical biliary diversion, 25% vs. 14% had received ileal bile acid transporter inhibitors, and 45% vs. 53% had undergone liver transplantation, respectively. The patients with FIC1 deficiency had a lower median HAZ during the first 10 years of life ($p < 0.05$; Figure 1A), and a higher proportion had GS (FIC1 59% vs. BSEP 42%, $p < 0.01$). In FIC1 deficiency, there were no significant sex differences in HAZ at any time point. In BSEP deficiency, however, growth trajectories differed between boys and girls, with girls aged 4–10 years having a significantly lower HAZ (Figure 1B). The prevalence of GS was 45.8% in girls and 38.1% in boys ($p < 0.05$). **Conclusion:** Children with FIC1 deficiency are shorter and a higher percentage has GS compared with children with BSEP deficiency, which may be related to extrahepatic deficiency of ATP8B1. In BSEP deficiency, girls have more pronounced pre-pubertal growth restriction than boys. Recognition of these disease- and sex-specific growth patterns, together

with improved understanding of the underlying mechanisms, may target approaches to optimize growth potential.

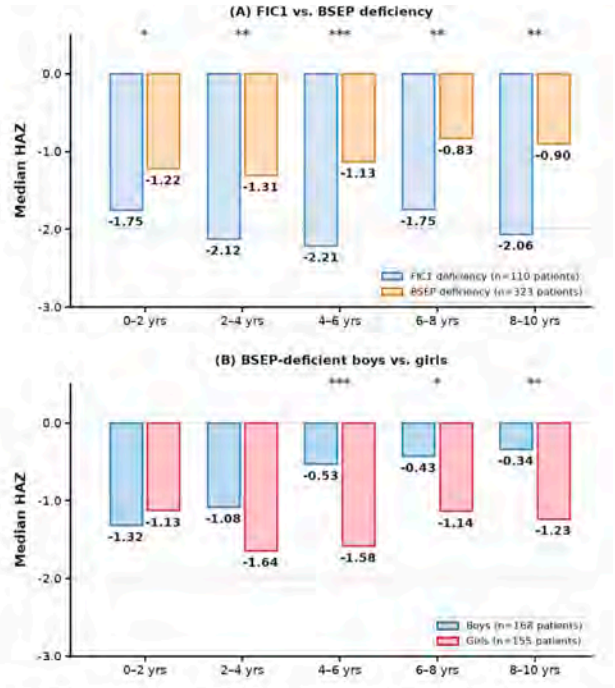

Figure 1. (A) HAZ by absolute age, stratified by PFIC subtype. (B) HAZ by absolute age for BSEP deficiency, stratified by sex. Groups were compared at each 24-month interval using median quantile regression, adjusted for interruption of the enterohepatic circulation (ileal bile acid transporter inhibitor therapy or surgical biliary diversion) and liver transplantation. *** $p < 0.001$, ** $p < 0.01$, * $p < 0.05$.

Pirogov", Sofia, [27]Erasmus MC Rotterdam

Background: Progressive Familial Intrahepatic Cholestasis (PFIC) is a group of rare cholestatic liver diseases in which impaired bile flow compromises intestinal absorption of fat-soluble vitamins A, D, E and K (FSV). Odevixibat, an ileal bile acid transporter inhibitor (IBATi), has demonstrated efficacy in reducing pruritus and serum bile acid levels in patients with PFIC. By interrupting the enterohepatic circulation, odevixibat may decrease FSV absorption. We evaluated the effect of odevixibat on serum FSV levels in patients with PFIC using the largest global prospective registry with real world data on PFIC, TreatFIC.
Methods: Patient data and serum concentrations of vitamin A, D and E were exported from TreatFIC (NCT06778174, May 2026) and normalized to center-specific lower limits of normal (LLN). For vitamin K deficiency, we used International Normalized Ratio (INR) as surrogate, with 1.2 as upper limit of normal (ULN). A linear mixed-effects model (LMM) was fitted for each FSV separately. Each model was adjusted for supplementation dose, age, sex and northern or southern hemisphere seasonal variation. We compared data from patient visits during odevixibat treatment to those without IBATi-treatment. Visits after liver transplantation were censored. The percentage of FSV deficient visits before and after odevixibat initiation was compared using paired Wilcoxon signed-rank tests. $P < 0.05$ was considered significant.
Results: A total of 132 PFIC patients (FIC1 = 28; BSEP = 56, MDR3 = 31, MYO5B = 6, TJP2 = 5, Other = 6) were included, with 68 patients receiving odevixibat (43 already on treatment upon entering TreatFIC and 25 patients starting treatment during follow-up). Total number of patient visits was 250. Irrespective of odevixibat treatment, 14-29% of all patient visits were below the LLN of vitamins A, D and E, and 15-16% above the ULN for INR (Figure). In line with this, odevixibat use was not significantly associated with decreased serum concentrations of vitamin A, D or E, nor with increased INR. Upon starting odevixibat, the FSV supplementation dosages were not changed in 78% of patients (n = 49 patient-vitamin pairs). Nevertheless, the percentage of visits with FSV deficiency did not change (16% vs. 17%, prior to and after starting odevixibat, resp., NS). Upon starting odevixibat, FSV supplementation dosages were changed in 22% of patients (median

changes: D, +800 IU/day; E, -77 mg/day; K, +0.8 mg/day; n = 14 patient-vitamin pairs). In these patients, the fraction of FSV deficient visits did not significantly change either (38% vs. 27%, prior to and after starting odevixibat, resp., NS). **Conclusion:** Odevixibat does not cause FSV deficiency in patients with PFIC, despite theoretical concerns related to interruption of the enterohepatic circulation and intestinal bile acid deficiency. Independent of odevixibat use, between 13 and 29% of patients with PFIC have biochemical FSV deficiency.

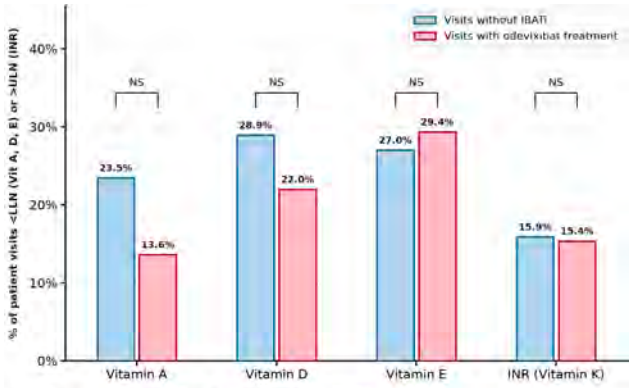

Figure. Percentage of patient visits indicating FSV deficiency

2666 | SURGICAL BILIARY DIVERSION EFFECTIVELY TREATS CHOLESTATIC PRURITUS IN FIC1 DEFICIENCY PATIENTS NOT RESPONDING TO IBAT INHIBITION

Willem Lexmond[1] Amala Alenchery[2] Alise de Groot[1] Winita Hardikar[3] Anna Orłowska[4] Piotr Czubkowski[4] Pamela Valentino[5] James Squires[2] Henkjan Verkade[1], [1]University Medical Center Groningen, [2]Children's Hospital of Pittsburgh, [3]Royal Children's Hospital, [4]The Children's Memorial Health Institute, [5]Seattle Children's Research Institute

Background: Progressive familial intrahepatic cholestasis (PFIC1) is caused by mutations in *FIC1*. For PFIC1 patients, cholestatic pruritus is usually the most burdensome hepatological symptom that may necessitate liver transplantation even in the absence of end-stage liver disease. The cornerstone of anti-pruritic therapy is interruption of the enterohepatic circulation (iEHC) of bile acids. With the advent of ileal bile acid transporter inhibitors (IBATi), iEHC can now be achieved pharmacologically, with obvious advantages over traditional surgical biliary diversion (SBD). Many PFIC1 patients, however, do not respond to IBATi. IBATi and SBD both interrupt the EHC, but only SBD results in pre-intestinal disposal of bile and conjugated bile acids from the body. In IBATi-treated patients, in contrast, conjugated bile acids remain available for microbial deconjugation and passive re-uptake in the colon. We investigated whether auxiliary treatment with SBD could effectively relieve cholestatic pruritus in IBATi-nonresponsive PFIC1 patients. **Methods:** We retrospectively analyzed data on 10 patients (6 boys) with bi-allelic mutations in *ATP8B1* (*FIC1*) who had undergone SBD while already on IBATi therapy. From these patients, we retrieved data on genetic testing, sex and age of the patients, timing of treatment with IBATi and biochemical and clinical characteristics from clinic visits before and after SBD. **Results:** SBD was performed at a median age of 3.1 years (IQR 1.7 – 5.0) and after a median treatment duration with IBATi of 2.9 years (IQR 1.1 – 3.5). Pruritus was present in all patients before SBD was undertaken. In 8 of 10 patients (80%), itch had resolved within 12 months after diversion. In 2 patients (20%), SBD did not improve pruritus, and one of these is

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

currently considered for liver transplantation. Interestingly, the pruritus response appeared to be independent of serum bile acid response. In 4 patients, IBATi therapy has been successfully stopped. The other 6 patients continue to be treated with a combined EHC interruption with both SBD as well as IBATi at a median follow-up time of 1.4 years (IQR 0.8 – 2.8) after SBD. **Conclusion:** Auxiliary SBD can successfully treat cholestatic pruritus in IBATi-nonresponsive PFIC1 patients. Combined surgical and pharmacological interruption of the enterohepatic circulation should be considered before committing PFIC1 patients to liver transplantation for intractable itch.

Background: Light microscopy (LM) and electron microscopy (EM) are routinely used in evaluating suspected mitochondrial hepatopathy (MH), a heterogeneous group of disorders for which definitive histopathologic correlates and genotype-phenotype relationships remain poorly defined. We assessed LM and EM features relative to genetic diagnoses in a prospectively enrolled pediatric cohort. **Methods:** Liver biopsies from 42 pediatric patients (median age 2.3 years, 73.8% male) clinically enrolled in the prospective MITOHEP mitochondrial hepatopathy study and 2 genetically confirmed cases from PROBE (a prospective database of infants with cholestasis) of the Childhood Liver Disease Research Network were analyzed (LM & EM n = 25; LM only n = 10; EM only n = 7). When available, genetic diagnosis served as the reference standard. Three expert reviewers independently evaluated anonymized LM and EM images blinded to genetic diagnosis, with interobserver discrepancies resolved by group consensus. Features were systematically evaluated using LM and EM and categorized as diagnostic, suspicious, or unlikely for MH, summarized using counts and percentages, and compared across genetic categories using Fisher's exact test. **Results:** Genetic diagnoses varied, most commonly *DGUOK* (n = 5), *POLG* (n = 5), *MPV17* (n = 4), and *TRMU* (n = 4). LM findings were heterogeneous and non-specific, with no significant genotype-phenotype correlations. Microvesicular and macrovesicular steatosis were variably present without significant differences across genetic categories. LM showed minimal inflammatory activity. LM was diagnostic in 5.9%, suspicious in 35.3%, and unlikely in 58.8% of cases. n contrast, EM frequently demonstrated mitochondrial abnormalities but was rarely diagnostic. EM was diagnostic in 3.1%, suspicious in 78.1%, and unlikely in 18.8% of cases. EM abnormalities were heterogeneous and overlapping across genetic groups, without reproducible genotype-specific patterns. LM more frequently classified cases as

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

unlikely, whereas EM more frequently classified cases as suspicious. See Table 1. **Conclusion:** LM and EM demonstrate limited utility for mitochondrial hepatopathies and do not reliably distinguish genetic subtypes. LM predominantly reflects nonspecific injury patterns; EM more often identifies mitochondrial abnormalities and increases diagnostic suspicion. These findings highlight the complementary but limited role of histologic and ultrastructural evaluation, with genetic testing remaining essential for definitive diagnosis.

Table 1 (a-d)

a. Histologic and Ultrastructural Features Evaluated

Modality	Features Evaluated
Light microscopy	Hepatocellular steatosis (microvesicular and macrovesicular) and hepatocyte necrosis; oncocytic hepatocytes; portal and lobular inflammation; fibrosis stage
Electron microscopy	Mitochondrial quantity, pleomorphism, cristae morphology, electron density, distribution, and matricial dense granules; hepatocytic lipid

b. Genetic Categories

Genetic Category	Genes	N
mtDNA depletion	*DGUOK, MPV17, POLG, POLG2*	15
RNA translation	*CARS2, MTFMT, TRMU*	6
mtDNA deletion	mtDNA deletion, *ATP6*	4
Enzymatic/FAO	Complex defects	5
Negative genetic testing	*NBAS*/none	9
No genetic testing	N/A	3

Legend: mt, mitochondrial; FAO, mitochondrial fatty acid oxidation defects; WES, whole exome sequencing; TGP, targeted gene panel; NBAS, neuroblastoma amplified sequence (not significant gene in mitochondrial hepatopathy), N/A, not applicable

c. Steatosis by Light Microscopy Across Genetic Categories

Genetic Category (N)	Microvesicular (% of cases)	Macrovesicular (% of cases)
mtDNA depletion (15)	Absent 64%; Present 36% (Rare, 7%; 5-66%, 29%)	Absent 50%; Present 50% (Rare, 21%; Mild, 21%; Moderate, 7%)
RNA translation (6)	Absent 75%; Present 25% (5-66%, 25%)	Absent 50%; Present 50% (Moderate, 25%; Severe, 25%)
mtDNA deletion (4)	Absent 75%; Present 25% (5-66%, 25%)	Absent 25%; Present 75% (Rare, 75%)
Enzymatic/FAO (5)	Absent 50%; Present 50% (Rare, 50%)	Absent 25%; Present 75% (Rare, 50%; Mild, 25%)

Legend: mt, mitochondrial; Absent (0%); Rare (<5%); Present (≥5%); Mild (5-33%); Moderate (>33-66%); Severe (>66%); FAO, mitochondrial fatty acid oxidation defects

d. Electron Microscopy Findings Across Genetic Categories

Genetic Category (N)	Electron Microscopic Findings (% of EM cases)
mtDNA depletion (15)	Increased mitochondria 20%; pleomorphism 30%; abnormal cristae 50%; abnormal electron density 60%; small droplet lipid 70%
RNA translation (6)	Increased mitochondria 40%; pleomorphism 40%; abnormal cristae 20%; abnormal electron density 80%; small droplet lipid 80%
mtDNA deletion (4)	Increased mitochondria 33%; pleomorphism 0%; abnormal cristae 67%; abnormal electron density 33%; small droplet lipid 100%
Enzymatic/FAO (5)	Increased mitochondria 25%; pleomorphism 0%; abnormal cristae 50%; abnormal electron density 25%; small droplet lipid 75%

Legend: mt, mitochondrial; FAO, mitochondrial fatty acid oxidation defects

2668 | PROSPECTIVE LONGITUDINAL CHARACTERIZATION OF A COHORT OF INFANTILE WILSON DISEASE

Rima Fawaz[1] Ayse Coskun[2] Sefa Keserci[1] Hatice Maras[1] Asim Ulcay[1] Pamela Valentino[3] Michael Schilsky[4], [1]Yale University School of Medicine, [2]Creighton University, [3]Seattle Children's Hospital, [4]Yale University Medical Center

Background: Objectives: To characterize the clinical and diagnostic evaluation, treatment and follow up in a cohort of infants with Wilson Disease (WD). **Methods:** Cohort: children with WD age <5 years (N=18, 12 females,12 White, 5 Asian ,1 mixed Asian/white) enrolled in a prospective registry (2018-2026). WD was defined by Leipzig score ≥4. **Results:** All 18 participants were asymptomatic and diagnosed by genetic screening due to parental carrier status, newborn screening or family history. Nine patients had 2 pathogenic(P) *ATP7B* mutations; five had 1P+1 likely pathogenic (LP), two had 2 LP, one had P and a variant of unknown significance. In this last patient, the ceruloplasmin was <3, ALT >3xULN, and they had a sibling with symptomatic WD. Ceruloplasmin was persistently <10 mg/dL in 3, <14 mg/dl in 6 and <20 mg/dl in 11 participants at diagnosis and during follow up. ALT was elevated in 12/16 before treatment (~1.5-2 x ULN). Liver ultrasound was obtained in 13 participants; 9 were normal and 4 had minimal changes reported as increased hepatic echogenicity or coarsened echotexture. One had liver

biopsy prior to start of therapy at age 5 years; liver copper was 789 mcg/g dry weight. Three did not receive any therapy due to age < 2 years. Zinc monotherapy was started in 15: at 5 months in 1, at 12-23 months in 5, 24-35 months in 7 and 36-50 months in 2. Initial dosages of zinc prescribed were 5 mg daily,12.5 mg bid and 25 mg daily. In one participant initiated on zinc 25 mg bid at 19 months, a year later developed signs of copper deficiency with undetectable serum copper, ceruloplasmin and neutropenia but no anemia. Zinc was stopped for 6 months then restarted as once daily treatment with resolution of neutropenia and slow improvement in serum copper. Liver enzymes continued to be elevated in 9/15 on treatment, but most had an improved trend. All participants on zinc monotherapy with available testing (8/18) had a 24-hour urine copper < 100 mcg. One participant had a liver biopsy at 5 years due to persistently elevated liver enzymes while on zinc monotherapy since age 1 year. Liver copper was 630 mcg/g dry weight. Though they were switched to trientine, liver enzymes were persistently elevated and 24-hour urine copper on therapy was 42 and 70 mcg, suggesting possible overtreatment. **Conclusion:** Genetic/Infantile WD presents a challenging paradigm with lack of clinical and diagnostic hallmarks to inform providers as to the optimal timing of treatment initiation, choice of medication and dosing, and frequency of monitoring. Further access to clinical diagnostic tools and studies to guide uniformity in managing this growing patient population are urgently needed as affordable expanded carrier screening of mothers during pregnancy and newborn screening for WD are becoming a reality.

Characteristics of the study population, with longitudinal laboratory work up with management

Pt	Sex	Age at Dx (m)	Reason for screening	ATP7B mutation (P/LP/VUS)	Age at Tx (m)	Zinc dose	ALT(U/L)	Ceruloplasmin (mg/dL)	Urine Cu (µg/24h)	Liver Biopsy (mcg/g dry weight)/ Ultrasound (age in months)/ Stiffness

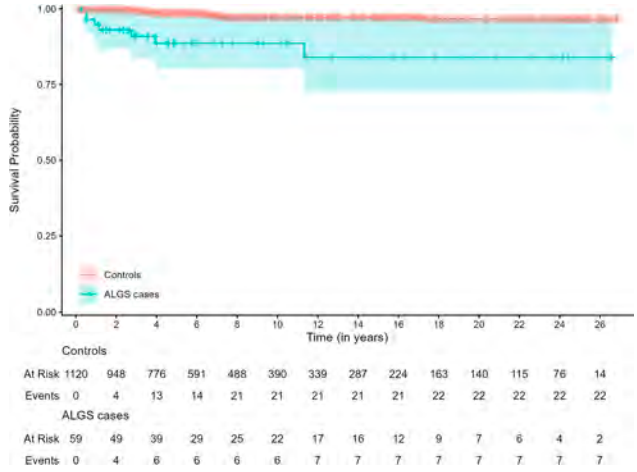
2669 | EPIDEMIOLOGY AND NATURAL HISTORY OF ALAGILLE SYNDROME: A POPULATION-BASED STUDY USING THE UTAH POPULATION DATABASE



Catalina Jaramillo[1] Brian Avery[2] Michael Madsen[2] Nicola Camp[2] Stephen Guthery[3], [1]University of Utah/ Primary Children's Hospital, [2]University of Utah, [3]University of Utah / Primary Children's Hospital

Background: Alagille Syndrome (ALGS) is an autosomal dominant, life-threatening, multiorgan disease caused by mutations in *JAG1* or *NOTCH2* genes, with variable expression and penetrance within families. Diagnosis is established either by the presence of these variants or by clinical criteria, defined as at least three characteristics, including liver, cardiac, ocular, musculoskeletal, and renal anomalies or typical facial features. To our knowledge, there are no prior studies describing the epidemiology and natural history of ALGS in population-based cohorts. We aimed to characterize the ALGS population in Utah. **Methods:** Patients with an established diagnosis of ALGS followed at our pediatric hepatology and cardiology clinics were identified. Additional cases were identified through an International Classification of Diseases (ICD) code-based search across the enterprise data warehouses of the 2 major health systems, which effectively cover the entire population of Utah. Structured chart reviews were performed to confirm the diagnosis. Individuals with ALGS were sent to the Utah Population Database (UPDB) for probabilistic linking. ALGS cases were compared to population-based controls obtained from the UPDB (1997-2023) and matched on age, sex, and place of birth. Cox proportional hazards regression was used to estimate hazard ratios (HR) with 95% confidence intervals (CI). Survival was assessed using the Kaplan-Meier method from the time of diagnosis to death or last follow-up. **Results:** A total of 69 individuals with ALGS were identified. A molecular diagnosis was available for 50 (47 *JAG1* and 3 *NOTCH2*), and 20 met established clinical criteria. Of the 69 individuals, 59 linked to UPDB and were residents of Utah; 49% were female and predominantly

white (88%). ALGS disease manifestations included liver involvement in 90% (n = 53), cardiac in 61% (n = 36), renal in 17% (n = 11), cerebrovascular in 15% (n = 9), ophthalmological in 6.8% (n = 4), and musculoskeletal in 6.8% (n = 4). Among those with liver disease, pruritus occurred in 56% (n = 19), and 27% (n = 16) underwent liver transplantation. ALGS had a 6-fold increased hazard of all-cause mortality (HR 6.19, 95% CI 2.64–14.49, p < 0.001). By the end of follow-up (26 years), estimated survival was 85% for cases versus 98% for controls. **(Figure 1)** Point prevalence of ALGS in Utah was estimated at 14.8 per 1 million in 2023 (eligible people were those residing in Utah at the start of 2023). **Conclusion:** We used the UPDB to evaluate the epidemiology and natural history of ALGS in a population-based cohort, showing prevalence estimates similar to those reported in the literature. Overall survival of ALGS cases in the Utah population is significantly lower than matched controls. Future studies using the UPDB may identify kindreds in which ALGS is segregating, may identify family members with subclinical disease, and may serve as a potential resource for future ALGS preventative health studies.

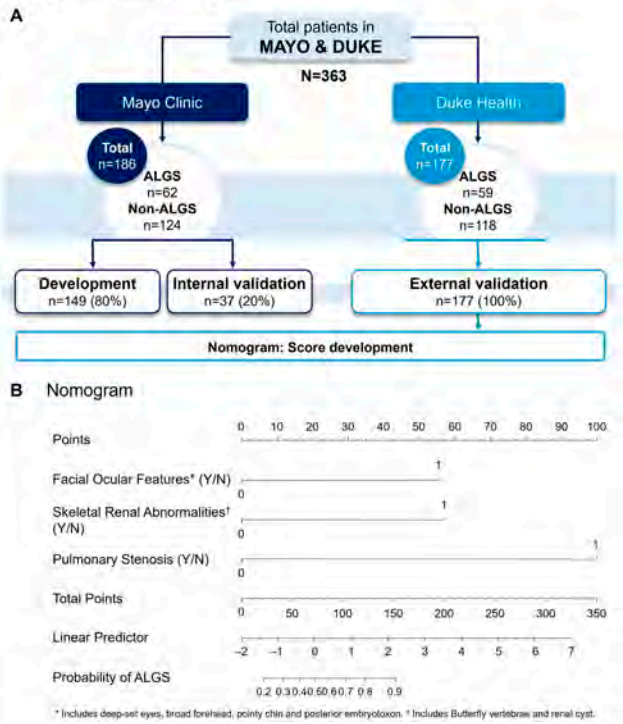
2670 | IMPROVING IDENTIFICATION OF PATIENTS WITH ALAGILLE SYNDROME USING A MACHINE-LEARNING ALGORITHM APPLIED TO ELECTRONIC HEALTH RECORDS FROM TWO US HEALTH SYSTEMS

Praveen Kumar-M[1] Seema Meloni[2] Jeeva Bharathi[1] Sara Hassan[3], [1]nference, Cambridge, MA, US, [2]Ipsen, Cambridge, MA, US, [3]University of Texas Southwestern, Children's Medical Center, Dallas, TX, US



Background: Neonatal and pediatric cholestasis can arise from a wide range of underlying conditions, including Alagille syndrome (ALGS). ALGS is a rare, genetically inherited disease linked to mutations in *JAG1* and *NOTCH2*. Clinical presentation is multifaceted, including characteristic facial features, debilitating pruritus, and life-threatening liver or cardiac disease. An autosomal dominant inheritance pattern and varied penetrance cause phenotypic heterogeneity, which can delay diagnosis. Here, we describe the development of an algorithmic tool to support healthcare practitioner decision-making and facilitate earlier diagnosis of ALGS by differentiating it from other rare cholestatic liver diseases with overlapping features; thereby, enabling earlier intervention. **Methods:** This retrospective, non-interventional study used a previously confirmed ALGS cohort (N = 121) derived from de-identified Mayo Clinic and Duke Health electronic health record data, covering the period from January 1, 2005 to November 15, 2024. The machine-learning algorithm was developed using the Mayo Clinic ALGS cohort and a 1: 2 propensity score–matched cohort of patients < 10 years old with non-ALGS cholestasis. ALGS-discriminating clinical features were evaluated as model inputs, either individually or grouped into clinical feature domains, and assessed for statistical significance using logistic regression. The algorithm was trained on 80% of the Mayo Clinic cohort, internally validated on the remaining 20%, and externally validated on the full Duke Health cohort (**Figure A**). **Results:** The output of the algorithm was a nomogram that scores probability of ALGS based on the presence of key clinical characteristics, including pulmonic stenosis, skeletal/renal abnormalities, and facial/ocular features (**Figure B**). Good discriminatory performance was confirmed in the external cohort with a sensitivity of 0.71 (95% confidence interval [CI]: 0.60 to 0.82) and a specificity of 0.91 (95% CI: 0.86 to 0.96). Precision-recall area under the curve (PR_{AUC}) was reported as 0.81 (95% CI: 0.73 to 0.88), indicating strong performance in identifying positive cases beyond overall classification accuracy. **Conclusion:** To our knowledge, this is the first study to develop and validate an algorithm-based nomogram that can support early identification of patients with a high probability of ALGS. Good discriminatory performance was demonstrated in a matched cholestatic population, with strong specificity, precision, and PR_{AUC} metrics, supporting its potential utility to identify a high-confidence ALGS cohort. This tool may support earlier identification and genetic confirmation of patients with ALGS, particularly for those

2671 | MANNOSE ATTENUATES HEPATIC STELLATE CELL ACTIVATION AND FIBROGENESIS IN BILIARY ATRESIA

John Hong[1] Poulomi Dey[1] Charles DeRossi[2] Jaime Chu[2], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Biliary atresia (BA) is a neonatal cholangiopathy characterized by progressive bile duct injury, inflammation, and fibrosis, with most affected children requiring liver transplantation. Although fibrosis drives disease progression, the role of hepatic stellate cell (HSC) activation (the principal fibrogenic cells of the liver) remains poorly defined in BA. Biliatresone (BT), a plant-derived isoflavone, models BA-related injury and induces glutathione depletion and oxidative stress in zebrafish and murine cholangiocytes. Mannose reduces stellate cell activation in multiple models of liver fibrosis, but its role in BA is unknown. **Methods:** For *in vitro* modeling, human HSCs (LX-2) were treated with BT (0.5 and 1.0 µg/mL) ± mannose (1 and 5 mM). Fibrotic gene expression (*PDGFRB, ACTA2, COL1A1, COL1A2*) was assessed by qPCR and protein levels (αSMA, COL1A2) were assessed by western blot and immunofluorescence. Oxidative stress was measured using CellROX assay. For *ex vivo* modeling, human precision-cut liver slices (hPCLS) from three BA patients were obtained at time of transplant and were treated with mannose (1 and 25 mM) for 24 and 48 hours. Fibrotic markers were quantified by qPCR. **Results:** BT induced dose-dependent increases in ROS generation and fibrogenic activation in HSCs, with significant upregulation at both transcriptional (*PDGFRB, ACTA2*, *COL1A1*) and protein (COL1A2) levels. Mannose treatment significantly attenuated BT-induced ROS accumulation and reduced expression of fibrotic markers in vitro. In *ex vivo* BA hPCLS, mannose consistently reduced *COL1A2* and *ACTA2* expressions across patient samples compared to vehicle-treated controls. **Conclusion:** BT induces oxidative stress and fibrogenic activation in human HSCs, supporting its utility as an in vitro model of BA-associated fibrosis. Mannose attenuates BT-induced oxidative stress and fibrogenic signaling in HSCs and reduces fibrotic marker expression in human BA liver tissue ex vivo. These findings identify mannose as a promising antifibrotic therapeutic candidate for BA with translational relevance.

2672 | CHOLANGIOCYTE-TARGETED AAV-ABCC12 GENE THERAPY PARTIALLY RESTORES MITOCHONDRIAL FUNCTION AND ATTENUATES BILIARY INJURY

Michelle Damen[1] Pervinder Choksi[2] Manavi Singh[1] Tanja Linnerz[1] Bryan Donnelly[1] Ramesh Kudira[1] Annika Yang Vom Hofe[1] Maria Fields (n.e Moreno-Fernandez)[1] Holger Willenbring[3] Alexander Miethke[4] Chunyue Yin[1], [1]Cincinnati Childrens Hospital Medical Center, [2]The University of California, San Francisco, [3]USCF, [4]Cincinnati Children's Hospital Medical Center

Background: We previously identified a homozygous truncating mutation in *ABCC12*, encoding the ABC transporter MRP9, in a child with idiopathic cholestasis and bile duct paucity. In zebrafish, loss of Abcc12 impairs mitochondrial function and predisposes to apoptosis and ferroptosis of cholangiocytes. We evaluated whether an adeno-associated viral (AAV) vector engineered for biliary epithelial cell (BEC)tropism and carrying full-length *ABCC12* restores cholangiocyte function in *Abcc12* knockout

(KO) mice. **Methods:** CRISPR-Cas9–edited H69 cholangiocytes harboring the deleterious mutation observed in the proband were transduced with AAV-BEC-m*Abcc12*. Transgene expression was assessed by qPCR and immunofluorescence. Mitochondrial function was evaluated using Seahorse assays. *Abcc12* KO and wild-type (WT) mice were evaluated at baseline (8wks old) and following 0.05% DDC diet for 14 days (10wks old). Male *Abcc12* KO mice received AAV-BEC-m*Abcc12* (1.6×10^{10} vg/g) at 4wks old prior to regular diet or 0.05% DDC exposure (14days, 8wks until 10wks old). Hepatobiliary injury was assessed by serum biochemistries, histology, and CK19 immunostaining. Ferroptotic stress was assessed by hyperoxidized PRDX3 staining. **Results:** AAV transduction induced robust *ABCC12* mRNA and protein expression in H69 cells and restored mitochondrial function by Seahorse assay in *ABCC12*-deficient cells. 8-week-old *Abcc12* KO mice exhibited increased serum alkaline phosphatase (ALP) levels, diminished well-formed and increased number of bile duct clusters on examination of CK19-stained liver sections which was accompanied by increased TUNEL staining of BECs compared with WT mice. *mAbcc12*-AAV treatment of *Abcc12* KO mice induced MRP9 expression in BECs (Fig 1A), lowered serum ALP levels (Fig 1B), decreased % area of CK19+ stained cells (Fig 1C) and number of BEC clusters (1D) while increasing number of well-formed bile ducts in portal tracts compared with untreated age-, sex- and genotype matched mice. AAV treatment prior to DDC challenge lowered serum total bilirubin levels (mean ± SEM of 5.97 vs 3.59 mg/dL in Abcc12KO vs *Abcc12* KO + AAV, ***: $p < 0.005$) and reduced cholangiocyte apoptosis in *Abcc12* KO mice by TUNEL staining. DDC induced accumulation of hyperoxidized PRDX3 in hepatocytes and cholangiocytes indicating ferroptotic stress; this effect was ameliorated by AAV-mAbcc12 treatment. **Conclusion:** AAV-mediated *ABCC12* delivery restores mitochondrial function of MRP9-deficient BEC *in vitro*. In *Abcc12* KO mice, it reduces BEC ferroptosis, decreases serum ALP levels, and promotes formation of well-formed bile ducts while preventing BEC cluster formation. Furthermore, it confers partial protection from xenobiotic injury in a model of sclerosing cholangitis. These findings support MRP9 as a regulator of mitochondrial functions and cell death in BEC and establish translational proof-of-concept for gene therapy in inherited cholangiopathies.

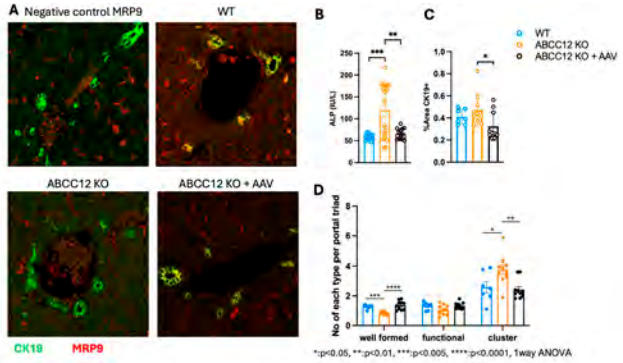

Figure 1. Administration of AAV-BEC-mAbcc12 vector to *Abcc12* KO mice prevents loss of well-formed bile ducts. Representative images of dual-immunofluorescence CK19 (green) and MRP9 (red) on liver sections from WT, Abcc12 KO and Abcc12 KO mice following AAV treatment, Single-plane confocal images 40x (A). Serum ALP was measured at time of harvest at 8 weeks (B). Percent area of CK19+ cells (C) and bile duct profiles classified as well-formed, functional, or clusters were enumerated on liver sections subjected to CK19 IHC (DC).

2673 | CONCURRENT CHANGES IN MACROPHAGE AND T CELL SUBSETS OVER TIME IN MURINE OBSTRUCTIVE CHOLESTASIS SUGGEST INTERPLAY BETWEEN MACROPHAGE AND T CELL FUNCTION IN PROMOTION OF HEPATIC INJURY

Lauren Maloney[1] *Ioannis Ziogas*[2] *Matthew Burchill*[3] *Sarah Taylor*[1], [1]*University of Colorado Anschutz*, [2]*University of Colorado*, [3]*University of Colorado - Anschutz*

Background: Macrophages (MΦ) play a key role in disease pathogenesis of both adult and neonatal obstructive cholestasis, however, their role in regulating the T cell response remains poorly defined. Regulatory T cells (Tregs) can protect against lymphocyte activation in immune-mediated bile duct injury, while CD8+ T

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

cells have been implicated in driving biliary injury and fibrosis. We aimed to define MΦ-T cell signaling networks over the disease course of obstructive cholestasis. **Methods:** We utilized the bile duct ligation (BDL) model of surgically induced obstructive cholestasis and sham surgical controls in adult Balb/c mice. Single cell RNA-sequencing analysis of hepatic MΦs from BDL and non-diseased controls defined MΦ heterogeneity at post operative day (POD) 7. Multiparameter flow cytometry profiled hepatic immune cell changes over the course of disease after BDL (POD0, 3, and 7). MΦs were characterized by expression of MerTK (receptor important in apoptotic cell engulfment), Ly6c (marker distinguishing recruited pro-inflammatory vs. tissue-repair subsets), and MHCII (indicator of activation and antigen presentation). T cells were identified by flow cytometry using standard sequential gating on singlets/live cells followed by CD45+ leukocytes, CD3+ T cells, and subsequent delineation into CD4+ and CD8+ subsets. Exhausted T-cell populations were defined as CD44+PD1+ cells. **Results:** Transcriptional analysis of BDL versus control MΦs at POD7 showed enrichment for antigen processing and presentation as well as the defense response including increased expression for *Ifitm2* (adjusted p-value = 0, log2FC = 1.9), a gene involved in Treg suppression (**Figure 1A**). Flow cytometry analysis of liver tissue demonstrated a significant increase in total F480+ MΦs in BDL POD 7 compared to BDL POD 3, Sham POD 3 and baseline ($p < 0.05$ for all). Among MΦ subsets, Ly6C+ MΦs had the greatest increase at POD7 from baseline ($p = 0.007$) although MerTK + MΦs and MHC2+ MΦs were also significantly increased (**Figure 1B**). Among T cells, CD8+ T cells were significantly higher in number at BDL POD 3 than in any other condition or timepoint ($p < 0.05$ for all). CD4 T cells were highest in BDL at both POD3 and 7 compared to sham ($p < 0.05$ for both), however, subset analysis demonstrated lower number of Tregs in BDL POD 3 and POD 7 compared to baseline ($p = 0.016$ and $p = 0.018$ respectively). A high proportion of CD4 and CD8 T cells demonstrated the exhausted phenotype at POD7 (**Figure 1C**). **Conclusion:** Our data support an important interplay between MΦs and T cells which may propagate cholestatic injury. We show evidence for increased MHCII+ MΦ antigen presentation, greater CD8 T cell exhaustion, and T regulatory cell inhibition over the disease course of BDL. Future studies defining the mechanism by which MΦs may inhibit T regulatory cells and promote T cell exhaustion in chronic obstructive cholestasis will improve our understanding of disease pathogenesis.

2674 | SHORT BOWEL SYNDROME ASSOCIATED CHOLESTATIC LIVER INJURY DISRUPTS PANCREATIC ENDOCRINE ARCHITECTURE

Shun Onishi[1] Aakash Nagarapu[1] Takahiro Ohkura[1] Chandrashekhara Manithody[1] Marzena Syn[1] Ajay Jain[1], [1]Saint Louis University

Background: Short bowel syndrome (SBS) causes intestinal failure, dependence on parenteral nutrition, and intestinal failure–associated liver disease (IFALD). Although SBS-associated cholestasis and disrupted enterohepatic signaling are well described, whether this gut–liver injury state affects pancreatic endocrine development is unknown. We hypothesized that neonatal SBS-associated cholestatic liver injury alters pancreatic islet cell cluster (ICC) morphology and endocrine cell composition, and that prebiotic modulation may partially preserve endocrine architecture. **Methods:** Neonatal piglets, 7–10 days old, received enteral milk feeding (EN) or underwent 75% small bowel resection with ileocolonic anastomosis and parenteral nutrition support (SBS). A subgroup of SBS animals received prebiotic supplementation. Cholestatic liver injury and intestinal adaptation were assessed by serum conjugated bilirubin, GGT, and distal gut linear density. Pancreatic sections were stained for insulin, glucagon, and chromogranin A. Five

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

representative 20× fields per sample were analyzed using QuPath to quantify ICC size, circularity, cell number, and endocrine cell distribution. **Results:** SBS piglets developed IFALD. Compared with EN controls, SBS animals had markedly elevated conjugated bilirubin, 3.89 ± 0.51 vs 0.036 ± 0.004 mg/dL, increased GGT, 129.97 ± 24.11 vs 19.56 ± 3.12 U/L, and reduced distal gut linear density, 0.11 ± 0.008 vs 0.30 ± 0.02 g/cm. Across groups, ICC frequency declined with increasing cluster size, while ICC circularity did not differ significantly, suggesting that IFALD associated with altered endocrine cellular composition rather than overall cluster shape. In large ICCs measuring 4001–5000 μm², insulin-positive cells were markedly reduced in SBS compared with EN, 6.12 ± 0.00% vs 40.59 ± 9.02%, p = 0.029. Within SBS animals, smaller ICCs, 1001–2000 μm², contained relatively higher insulin-positive and fewer glucagon-positive cells than ICCs measuring 2001–3000 μm², indicating size-dependent endocrine remodeling. Prebiotic supplementation was associated with partial preservation of insulin-positive cell proportions. **Conclusion:** Neonatal SBS-associated cholestatic liver injury is associated with altered pancreatic endocrine architecture, particularly reduced insulin-positive cells in larger ICCs. These findings suggest that IFALD may extend beyond the gut–liver axis to disrupt gut–pancreas endocrine signaling. Partial preservation with prebiotic supplementation supports microbiome modulation as a potential strategy to mitigate adverse effects.

2675 | SINGLE-NUCLEUS MULTIOME PROFILING REVEALS MACROPHAGE SUBTYPE-SPECIFIC CYTOKINE RESPONSES ASSOCIATED WITH FIBROSIS PROGRESSION IN PEDIATRIC AUTOIMMUNE LIVER DISEASE

Zi Yang[1] Ramesh Kudira[1] Annika Yang Vom Hofe[2] Mosab Alquraish[1] Cyd Castro-Rojas[1] Joseph Wayman[1] Pamela Sylvestre[2] Stacey Huppert[2] Anna Peters[2] Matthew Weirauch[1] Lee Denson[1] Leah Kottyan[1] Yunguan Wang[1] Alexander Miethke[2] Emily Miraldi[1], [1]Cincinnati Children's Hospital Medical Center, [2]Cincinnati Children's Hospital Medical Center

Background: Autoimmune liver diseases (AILDs) are a group of chronic immune-mediated disorders that include primary sclerosing cholangitis (PSC), autoimmune hepatitis (AIH), and overlap syndrome autoimmune sclerosing cholangitis (ASC). These rare conditions can lead to progressive liver fibrosis, cirrhosis, and liver failure, and may require liver transplantation at the end-stage. Development of targeted biologic therapies is limited by an incomplete understanding of the cellular programs driving tissue inflammation and fibrosis progression. **Methods:** To identify cellular and molecular drivers of AILD, we generated multiome-seq (tandem single-nuclei (sn)RNA-seq and chromatin accessibility (snATAC)-seq) of frozen explanted liver tissue and biopsy samples. The cohort included patients with PSC (n = 11), AIH (n = 8), ASC(n = 6) spanning multiple fibrosis stages and deceased liver donors serving as healthy controls (HC, n = 5). Cell types were annotated using curated markers and reference-based label transfer, followed by subclustering to resolve macrophage heterogeneity. Compositional changes of macrophage subtype were assessed using centered log-ratio transformation of cell proportions followed by t-test. Fibrosis-associated transcriptional changes were identified using pseudo-bulk differential expression analysis accounting for donor-level variability, tested for enrichment of the ligand-response signatures curated from experimentally derived sc-resolved immune cells dataset *in vivo* (PMID: 38057668). **Results:** Seven major epithelial and immune cell populations were identified across approximately 240,000 nuclei from 30 multiome-seq samples (Fig 1A). Subsequent subclustering of macrophages resolved five distinct subtypes that were reproducibly observed across donors and supported by both transcriptomic and chromatin accessibility profiles (Fig 1B). Composition analysis identified *MHCII*^{high} subtype significantly increased in early/established fibrosis stages compared to controls (Fig 1C). Pseudo-bulk analysis identified 1,350 fibrosis-associated genes that segregated into seven clusters with shared and subtype-specific patterns across diseases and fibrosis stages (Fig 1D). Notably, a fibrosis-associated gene module was selectively expressed in *MHCII*^{high} macrophages and enriched for expression of interferon (IFNG, IFNa1) and IL-1 (IL33, IL36) family response genes, implicating inflammatory cytokine signaling in disease progression (Fig 1E). **Conclusion:** Single-nucleus multiome profiling of pediatric-onset AILD reveals fibrosis stage-dependent changes in macrophage composition, gene expression, and cytokine response programs. These findings highlight a central role for *MHCII*^{high} macrophages in tissue inflammation and identify candidate pathways and therapeutic targets for next-generation biologic

interventions in AILD.

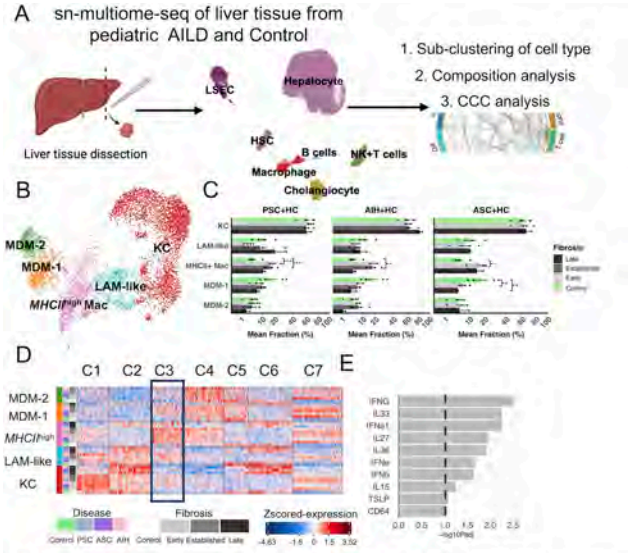

Fig 1. (A) Multiome-seq on cryopreserved tissue samples of explanted livers and clinical biopsies to generate tandem transcriptome and accessible chromatin data powering computational modelling to identify cytokine signals mediating liver inflammation and fibrosis progression in AILD. CCC = Cell-cell communication. (B) Integrated analysis of transcriptome and chromatin accessibility yielded 5 macrophage subtypes. (C) The compositions of macrophage subtypes across disease groups and fibrosis stages (*Padj<0.05, two-sided t-test on centered log-ratio transformed compositions). (E) Fibrosis-dependent differentially expressed genes (FDR ≤ 10%, |fold change| > 1.5) visualized across macrophage subtypes, disease groups, and fibrosis stages. Seven clusters reveal distinct cell type–specific expression patterns. (F) Bar plot of significantly enriched Immune Dictionary cytokine response genes in the MHCIIhigh macrophage–associated genes, which are upregulated in early and established fibrosis stages (cluster C3 of panel D). Pathway significance is shown as −log10(Padj), with multiple testing correction performed using the Benjamini–Hochberg procedure. The dotted line corresponds to Padj<0.1.

2676 | IMMUNOLOGICAL CHARACTERISATION OF PAEDIATRIC LIVER DISEASE: MAIT CELL REPROGRAMMING AND FALTERING GROWTH AS MARKERS OF IMMUNE SEVERITY

Eirini Kyrana[1] Tengfei Si[1] Qing Shao[1] Huihong Yu[1] Bethany Tucker[2] Xuan Luo[1] Zao-Hong Carmen Cai[1] Sinead Cunningham[2] Tassos Grammatikopoulos[2] Karishma Manwani[2] Anil Dhawan[2] Yun Ma[1], [1]King's College London, [2]King's College Hospital

Background: Mucosal-associated invariant T (MAIT) cells are innate-like lymphocytes with emerging roles in hepatic immunopathology. Their phenotypic characterisation across disease severity and relationship to clinical markers of nutritional status remains poorly defined in children with liver disease. **Methods:** Ninety-five children were studied: advanced liver disease (ALD, n = 39), stable liver disease (SLD, n = 34), and healthy controls (NLD, n = 22). Peripheral blood immunophenotyping assessed 61 parameters, including MAIT cell frequency and surface markers (CCR4, CD38, CD39, CXCR3). Spearman correlations with clinical predictors (bilirubin, MELD/PELD, weight z-score, platelet count, neutrophil: lymphocyte ratio) were performed with Benjamini-Hochberg false discovery rate correction across 300 tests. Group comparisons used the Mann-Whitney U and Kruskal-Wallis tests with Bonferroni-corrected post hoc analyses. **Results:** MAIT cell frequency was selectively depleted in ALD versus SLD and NLD (median 0.56% vs 1.84% vs 1.46%; $p < 0.001$), whilst phenotypic reprogramming occurred across all liver disease: MAIT %CCR4+, %CD38+, and %CD39+ were each significantly elevated in liver disease versus controls (all $p < 0.001$), and were highest in ALD, significantly exceeding SLD (all adjusted $p < 0.05$). This activation-exhaustion-homing triad was independently predicted by bilirubin ($\rho = +0.479$), MELD/PELD ($\rho = +0.425$), and weight z-score ($\rho = -0.463$; all FDR $q < 0.01$). Weight z-score ≤ -1 identified 27 children (all with liver disease; median age 2.0–6.5 years by severity subgroup), who demonstrated significantly lower peripheral MAIT frequency (0.55% vs 1.37%; $q = 0.011$) and higher sCD163 (1606 vs 544 ng/ml; $q = 0.005$) versus children with weight $z > -1$, with a stepwise gradient of MAIT frequency 1.37% / 0.65% / 0.31% and sCD163 level 544 / 951 / 1947 ng/ml across weight z-score thresholds of > -1 / -1 to -2 / < -2. Bilirubin thresholds of ≥ 17 and ≥ 50 µmol/L correspond to the immunological separation achieved by the weight z-scores of < -1 and < -2, respectively. **Conclusion:** Paediatric liver disease drives progressive MAIT cell depletion and phenotypic reprogramming — activation, exhaustion, and tissue homing — that tracks disease severity across biochemical and nutritional indices. Weight z-score is a sensitive clinical surrogate for immunological burden.

2677 | PERCUTANEOUS PORTAL VEIN RECANALIZATION IN CHILDREN WITH EXTRAHEPATIC PORTAL VEIN OBSTRUCTION WITHOUT UNDERLYING LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Douglas Miotto[1] Alexandra Salazar-Riaño[2] Sabrine Teixeira Ferraz Grunewald[3] Leticia Helena Caldas Lopes[4] Lilian de Carvalho[4] Thaís Silva Martins Shehan[5] Suelen Renoste[6], [1]Universidade Federal de São Paulo, Brazil, [2]Universidad CES de Medellín, Medellín, Colombia, [3]Universidade Federal de Juiz de Fora, [4]Universidade Federal de São Paulo, [5]Universidade Federal Fluminense, [6]Independent Researcher

Background: Extrahepatic portal vein obstruction (EHPVO) is the primary cause of pediatric portal hypertension. The Meso-Rex bypass is the surgical gold standard treatment but requires a patent Rex recessus, which is absent in approximately half of these patients. Percutaneous portal vein recanalization (PVR) restores physiological hepatopetal flow and is cited by Baveno VII and the 2026 European Association for the Study of the Liver (EASL) guidelines, yet no systematic synthesis of pediatric outcomes has been published. We evaluated the technical feasibility, safety profile, and clinical efficacy of PVR in children with EHPVO without underlying liver disease. **Methods:** Systematic review and proportional meta-analysis conducted according to the Cochrane Handbook v6.5 (PROSPERO CRD420261395918) and reported in compliance with the PRISMA 2020 guidelines. PubMed/MEDLINE, Embase, Cochrane and Web of Science were searched from inception to May 2026. Corresponding authors were contacted, yielding unpublished patient-level when necessary. Random-effects models with simple arcsine transformation, restricted maximum likelihood (REML) τ^2 and Hartung–Knapp adjustment yielded pooled proportions with 95% CI and prediction interval (PI). To assess heterogeneity and results robustness, sensitivity leave-one-out were performed for each outcome. Risk of bias was assessed with the Joanna Briggs Institute (JBI) tools. **Results:** Five retrospective single-center cohorts included 73 children undergoing PVR, with a median follow-up of 6–22 months. Pooled technical success reached 55.3% (95% CI 35.9–73.2; I^2 24.1%; PI 27.9–79.9) in the pooled analysis. No procedure-related or all-cause mortality occurred (0/57). Procedure-related hemorrhage was 11.8% (95% CI 4.5–21.9; I^2 0%). Furthermore, heterogeneity was substantially reduced (I^2 from 55% to 0%) after isolating a single outlying cohort sensitivity analysis. The proportion of portal-biliary fistula was 1.3% (95% CI 0–15.1). Among twenty children with technically successful PVR and imaging follow-up, late portal vein patency was achieved in 87.8% (95% CI 34.4–100; PI 15.6–100) of the pooled sample; though 50.8% required at least one endovascular re-intervention with no surgical conversion. The proportion of free-recurrent variceal or gastrointestinal bleeding was 100% (95% CI 100–100; PI 73.8–100) across 16 patients. **Conclusion:** Percutaneous PVR may be feasible in more than half of children with chronic native-vessel EHPVO, demonstrating zero procedure-related mortality and a predictable hemorrhage rate. Given the absence of recurrent variceal bleeding post-recanalization, PVR represents a legitimate first-line alternative to Meso-Rex bypass when Rex anatomy is unfavorable.

★ 2678 | LYMPHATIC INTERACTION WITH AND TRAFFICKING OF IMMUNE CELLS IS ALTERED IN CHOLESTATIC LIVER DISEASE

Alyssa Goldberg[1] William Hollenbach[2] Beth Tamburini[2], [1]Children's Hospital Colorado, [2]University of Colorado

Background: The liver lymphatic system supports organ health by draining interstitial fluid and immune cells to the lymph node. Patients with primary sclerosing cholangitis have increased lymphatic vessel density in the liver. These findings are replicated in murine models of cholestasis and are associated with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

increased immune cell infiltrate into the liver. Our study evaluates changes in intrahepatic lymphatic endothelial cells (LECs) in cholestatic liver disease, how lymphatic endothelial cells are affected by bile salts, and how bile salts lead to lymphatic induced changes in T cell activity, viability and changes in immune cell trafficking through the lymphatic vasculature. **Methods:** Using flow cytometry, we evaluate immune cell phenotypes in the liver and in liver draining lymph nodes of mdr2 *(Abcb4)-/-* and 3,5-diethoxycarbonyl-1,4-dihydrocollidine fed (DDC) cholestatic mice. Immune cell phenotypes are combined with histologic findings including liver injury, fibrosis, and spatial information resulting from immune staining and spatial transcriptomics of the liver tissue. *In vitro*, we treat cells with pro-inflammatory cytokine, IFNg, and bile salts to model the cholestatic environment. We evaluate lymphatic endothelial cell expression of immune regulatory markers, chemokines, bile acid signaling, and interferon stimulated genes. Further we co-cultured effector T cells with lymphatic endothelial cells to investigate T cell activation state, chemokinesis, viability, and the impact of immune check-point inhibition. **Results:** Liver lymphatics are expanded in a murine model of cholestasis and expansion is associated with an increase liver-draining lymph node size. T cell accumulation and activation in the liver and liver draining lymph nodes are increased during cholestasis. Spatial and transcriptional analysis of the liver and liver draining lymph nodes during cholestasis demonstrates unique transcriptional changes, particularly in LEC-T cell neighborhoods. In vitro analysis of human LECs with IFNg and bile salts leads to upregulation of the inhibitory molecule, PD-L1, on LECs. Co-culture of the bile treated LECs led to a striking reduction in T cell activation as assessed by decreased T cell activation marker expression and decreased T cell proliferation. Further, T cell adhesion and chemokinesis towards bile salt treated LECs were also affected. **Conclusion:** This study demonstrates LEC-T cell interactions may be an important immune regulatory process in cholestasis. Our *in vitro* data suggests that *in vivo*, intrahepatic LECs directly respond to bile acids and the infiltrating immune cells found within the cholestatic environment. In turn, lymphatic endothelial cells in the liver may drive changes in T cell proliferation and activation. These changes in lymphatics may contribute to the liver inflammation and injury in cholestatic liver disease.

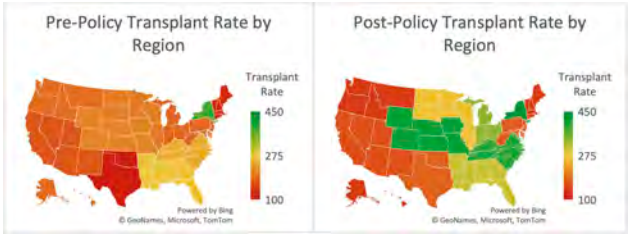
2679 | IMPACT OF NON-STANDARD EXCEPTION REQUESTS ON TRANSPLANT ACCESS IN PEDIATRIC LIVER TRANSPLANT CANDIDATES



Tess Coker[1] Ruiwen Zhou[2] George Blanco[3] Janis Stoll[4] Adeel Khan[2] Sakil Kulkarni[5], [1]Washington University St. Louis, School of Medicine, [2]Washington University St. Louis, [3]St. Louis University, [4]St. Louis Children's Hospital, [5]Washington University in St. Louis

Background: Non-standard exception requests (NSERs) allow pediatric liver transplant (LT) centers to seek increased allocation priority for candidates in whom priority scores are believed to underestimate true mortality risk, with the goal of facilitating timely LT. National Liver Review Board (NLRB) was established to standardize NSER review in 2019, and the acuity circles (AC) policy was implemented to expand organ sharing in 2020. We aimed to evaluate the impact of NSER use on transplant access among pediatric LT candidates. **Methods:** Using the SRTR database, we identified 1,973 pediatric (0-18 years) candidates listed between 2016 and 2024 for deceased donor LT, who were eligible for NSER, and had one of two outcomes (transplant or death/removal for being too sick). Fine-Gray competing risks models (with death treated as a competing event) were used to evaluate the association of listing with NSER approval with LT. Transplant centers were categorized into three clusters using k-means clustering (Cluster 1: high total and living donor (LD) volume, greater use of deceased-donor technical variant grafts (TVG); Cluster 2: medium-volume centers with lower TVG, lower LD; Cluster 3: low-volume centers with greater use of TVG, minimal LD volume). **Results:** 63.4% of eligible candidates were listed with NSER. Waitlist mortality did not differ between groups ($p = 0.5$). In the adjusted Fine-Gray model, NSER listing was associated with a 26% lower subdistribution hazard (sHR) of transplantation. Amongst other co-variates, higher priority score at outcome (sHR 1.01, $p < 0.001$) and listing in the post-NLRB/AC policy era (2021-24) (sHR 1.21, $p = 0.005$) vs. pre-NLRB/AC era (2016-19) were associated with higher access to LT. Age group 12–17 years (sHR 0.75, $p < 0.001$) and age group 1-5 years vs. infants (sHR 0.86, $p = 0.03$), blood group O (sHR 0.90, $p = 0.01$), LT at cluster 2 (sHR 0.80, $p < 0.001$) or cluster 3 (sHR 0.70, $p < 0.001$) vs. cluster 1 centers were associated with lower access to LT. Candidate sex, race, insurance status and diagnosis were not

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

associated with LT. Regional variation in transplant access pre/post NLRB/AC implementation is shown in Figure 1. **Conclusion:** After adjustment for patient-, policy-, and center-level factors, NSER listing was associated with a lower cumulative incidence of transplantation, suggesting that observed differences are influenced by allocation structure and center practices. Notably, regional disparities in transplant access persisted despite NLRB/AC policy.

2680 | DESIRABILITY OF OUTCOME RANKING (DOOR) IN PEDIATRIC LIVER TRANSPLANTATION: LIVING DONOR AND CENTER CAPABILITY

Toshifumi Yodoshi[1] Shuntaro Sato[2] Akihiro Asai[3] Tomohiro Tanaka[4], [1]Cincinnati Children's Hospital Medical Center, [2]Nagasaki University Hospital, [3]Cincinnati Children's Hospital Medical Center, [4]University of Iowa Carver College of Medicine

Background: In pediatric liver transplantation, prior work has compared outcomes between living donor (LDLT) and deceased donor (DDLT) recipients, and has linked higher cumulative center LDLT volume to better outcomes. These analyses share two limitations: recipient-only studies are restricted to children who actually received a transplant, missing those who died or deteriorated while waiting, and any single endpoint captures only one part of the candidate journey; and cumulative historical volume may not reflect a center's current capability for newly listed children. Desirability of Outcome Ranking (DOOR), an ordinal composite endpoint that ranks each patient's outcome from least to most desirable, can integrate competing outcomes into one patient-centered hierarchy. We applied DOOR within a unified framework to evaluate pediatric LDLT both from listing (current active vs historical cumulative center capability) and after transplant (LDLT vs DDLT).

Methods: Using SRTR liver files, we studied children <18 years at first listing and pediatric transplant recipients. Three DOOR comparisons were performed: (1) post-transplant outcomes for LDLT vs DDLT; and, at listing, candidate outcomes by (2) active recent LDLT capability (≥5 pediatric LDLTs at the listing center in the prior 5 years vs none) and (3) cumulative experience (≥20 vs none). Candidate DOOR used six ordered states; recipient DOOR used three (Figure). Results were expressed as DOOR probabilities, the adjusted probability that an LDLT or higher-capability child had a more desirable outcome (0.50 = no difference). Models adjusted for demographic, clinical, severity, exception, era, and center-volume factors with cluster bootstrap 95% CIs. **Results:** We studied 23,150 children at 146 centers and 17,227 recipients (2,019 LDLT) at 131 centers. After transplant, LDLT showed a modest but consistent advantage over DDLT: DOOR 0.512 (95% CI, 0.503-0.520), 0.518 (0.509-0.527), and 0.518 (0.508-0.528) at 1, 3, and 5 years. From listing, current active capability favored candidate DOOR in contemporary cohorts: 2018-or-later, DOOR 0.532 (0.500-0.570) at 1 year and 0.534 (0.505-0.569) at 3 years; 2020-or-later, 1-year 0.549 (0.517-0.586). Cumulative experience alone was not (1-year 0.495 [0.472-0.513]; 3-year 0.495 [0.476-0.512]). High-cumulative centers had more LDLT and less DDLT with similar transplantation and survival, consistent with substitution between donor sources rather than expanded access. **Conclusion:** Within a unified patient-centered framework, DOOR distinguished current programmatic LDLT capability from cumulative experience at listing, and confirmed the post-transplant advantage of LDLT over DDLT. Active recent capability, not cumulative volume, favored listed children. Cumulative volume alone may inadequately proxy current LDLT capability and should not be the sole metric for referral or center assessment.

2681 | MORTALITY AND LIVER TRANSPLANT ACCESS IN CHILDREN WITH BILIARY ATRESIA

Olabade Omole[1] Janet Wojcicki[1] Matthew Pantell[1] Emily Perito[1], [1]University of California San Francisco

Background: Biliary atresia (BA) is the leading cause of pediatric end-stage liver disease and the most common indication for liver transplantation (LT) in children. While outcomes among children with BA who are listed for LT are well described, it is not yet known whether all children with BA and end-stage liver disease are appropriately listed and have access to LT. This analysis aimed to identify children with BA with indication for LT who are not listed and evaluate mortality within this potentially vulnerable population. **Methods:** We performed a retrospective cohort study using the Pediatric Health Information System (PHIS) and Scientific Registry of Transplant Recipients (SRTR) databases. Children < 18 years old with BA between 2010-2020 were identified in PHIS and cross-referenced with SRTR transplant listing data to determine listing status using validated PHIS-SRTR linkage codes. Children were categorized as listed or unlisted for LT, based on PHIS-SRTR merge. Deaths were identified using PHIS mortality data 2010-2020, and listing status among children who died was verified through linkage with SRTR records. **Results:** Among 3,838 children with BA identified in PHIS, 1,171 (30.5%) were listed for liver transplantation in SRTR, while 2,667 (69.5%) were not listed. A total of 152 deaths (4%) occurred within this cohort. 136 deaths (89.5%) occurred among children who were never listed for transplant, whereas 16 deaths (10.5%) occurred among listed children. The 16 identified listed children who died did so during or after LT. Among children with BA who died, median age at death was 6 months (IQR 0–10) in unlisted versus 9.5 months (IQR 7.5–16.5) in listed ($p = 0.002$). Among listed children who died, 62.5% were white compared with 44.9% of unlisted children who died, while 22.1% of unlisted children who died were black compared with 6.2% of listed children who died ($p = 0.025$). Deaths occurred across 35 of 46 PHIS hospitals caring for children with BA. **Conclusion:** In our cohort of children with BA based on PHIS-SRTR merge, deaths occurred among children not listed for LT. Mortality occurred predominantly in infancy, raising concern for a vulnerable subgroup of children who may not be accessing LT evaluation or listing. Children who were not identified as listed for transplant died at younger ages than listed children, further emphasizing the vulnerability of this population. Differences in race distribution between listed and unlisted children who died suggest the possibility of disparities in LT listing process. Mortality was observed across many PHIS centers, suggesting a broadly distributed at-risk population. Further work aims to distinguish children who were not LT candidates from those potentially eligible but never referred or listed, and further characterize mortality outcomes, barriers to listing, and clinical trajectories preceding death.

2682 | THE 2023 OPTN PEDIATRIC MEDICAL URGENCY UPDATE INITIATED A DURABLE DECLINE IN WAITLIST FAILURE WITHOUT DISRUPTING TRANSPLANT OR EXCEPTION ACCESS: A NATIONAL INTERRUPTED TIME-SERIES EVALUATION

Toshifumi Yodoshi[1] Akihiro Asai[1] Tomohiro Tanaka[2], [1]Cincinnati Children's Hospital Medical Center, [2]University of Iowa Carver College of Medicine

Background: Legacy pediatric end-stage liver disease (PELD) underestimated short-term waitlist mortality in children younger than 12 years. In July 2023, Organ Procurement and Transplantation Network (OPTN) implemented a pediatric medical urgency update revising PELD, pediatric Status 1A/1B rules, and related National Liver Review Board guidance. National effects on waitlist outcomes and exception access have been understudied. **Methods:** We conducted a national interrupted time-series analysis of OPTN/UNOS STAR liver data linked to the formal exception file for children younger than 12 years listed from January 2019 through December 2024. June and July 2023 were excluded a priori as a transition period; August 2023 onward defined the post-policy era. Adjusted segmented Poisson models, with log person-days offset and two-way clustered standard errors, evaluated waitlist failure (death or removal for clinical deterioration) and transplant rate after adjustment for prespecified demographic and clinical covariates, calendar month, and region. Linked exception analyses used segmented Poisson models for first formal exception request and approval probability, and cause-specific Cox models for post-request outcomes. Supportive recipient analyses used adjusted pre/post models. **Results:** Among 14,639 person-months from 2,791 under-12 registrations, the policy was not associated with an immediate step change in waitlist failure (incidence rate ratio [IRR], 1.25; 95% confidence interval [CI], 0.61-2.57; $P = 0.548$) but was followed by a lower post-policy monthly slope (trend-change IRR, 0.94; 95% CI, 0.88-1.00;

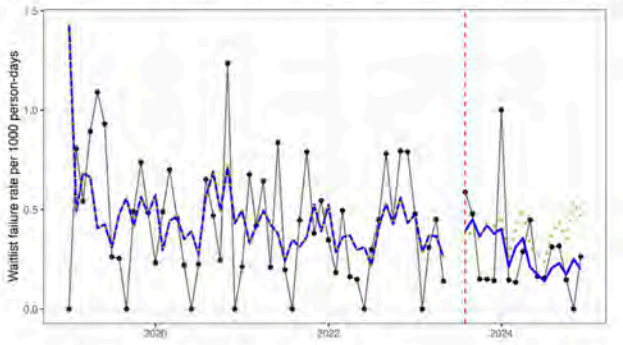
Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

P = 0.04). No insurance- or race/ethnicity-based differential effect on waitlist failure survived correction. Transplant rates remained stable (step IRR, 1.07; P = 0.54; trend IRR, 1.00; P = 0.81). There was no immediate post-policy change in first formal exception request rate (step IRR, 1.15; 95% CI, 0.84-1.58; P = 0.38), or approval probability among requests (step risk ratio [RR], 1.07; 95% CI, 0.98-1.18; P = 0.13). Post-request waitlist death was unchanged (hazard ratio, 1.00; P = 0.99), whereas post-request transplant hazard was lower (HR, 0.83; P = 0.025). In supportive pre/post recipient analyses, post-policy exception proxy use decreased (RR, 0.91; P = 0.03) and living donor use increased (RR, 1.22; P = 0.04) among recipients younger than 12 years, while 90-day mortality among recipients younger than 18 years did not increase (RR, 0.66; P = 0.18). **Conclusion:** The 2023 OPTN pediatric medical urgency update was associated with a durable decline in waitlist failure among children younger than 12 years without evidence of reduced transplant access or tightened formal exception pathways. Lower exception proxy use among recipients is consistent with improved calibration of urgency to clinical risk.

Figure. Interrupted time-series analysis of waitlist failure and transplant rate among pediatric liver transplant candidates younger than 12 years before and after the 2023 pediatric medical urgency update

Figure 1A. Adjusted monthly waitlist failure rate among candidates younger than 12 years



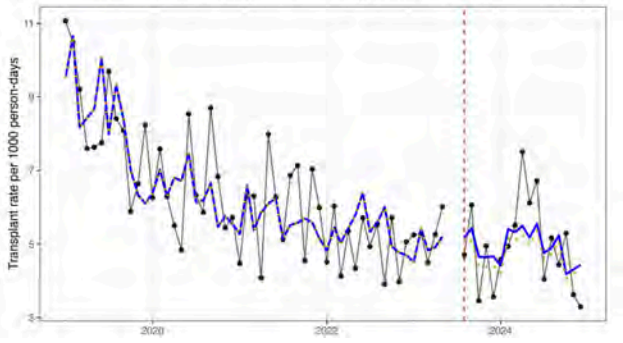


Figure 1B. Adjusted monthly transplant rate among candidates younger than 12 years

2683 | NONLINEAR ASSOCIATION OF DONOR AGE WITH GRAFT SURVIVAL AFTER PEDIATRIC LIVER TRANSPLANTATION FOR BILIARY ATRESIA

Ioannis Ziogas[1] Ryan Lavanchy[1] Charalampos Theocharopoulos[1] Dor Yoeli[1] Megan Adams[1] Jonathan Merola[1] Katie Rose Conover[1] Amy Feldman[1] Ronald Sokol[2] Susana Arrigain[1] Deena Brosi[1] Rocio Lopez[1] Jesse Schold[1] Sarah Taylor[1], [1]University of Colorado, [2]University of Colorado School of Medicine

Background: Biliary atresia (BA) is the leading indication for pediatric liver transplantation (LT). Donor age and graft type are important determinants of graft survival; however, their complex and potentially non-linear relationship warrants further investigation in pediatric BA. **Methods:** We performed a retrospective cohort study using the Scientific Registry of Transplant Recipients on children (< 18 years) with BA undergoing first isolated LT (02/2002-09/2025). Graft types included deceased donor whole graft (DDWG), deceased donor technical variant (DDTV), and living donor liver transplantation (LDLT). The primary outcome was graft survival. Multivariable Cox proportional hazards models with restricted cubic splines were used to evaluate the association between donor age and graft survival, stratified by graft type. **Results:** Among 3,910 children with BA, 1,879 received DDWG, 1,220 DDTV, and 811 LDLT. Recipient and donor characteristics differed by graft type: DDWG recipients were older and waited longer, DDTV recipients had the highest burden of growth failure, ascites, ICU status, and dialysis, while LDLT recipients were less critically ill and had shorter cold ischemia time. LDLT was associated with superior unadjusted graft survival (log-rank p < 0.001), with 5-year graft survival of 96.8% vs 92.1% for DDWG and 93.2% for DDTV. Donor age showed non-linear associations with graft loss (**Figure**). In DDWG, donor age < 1 year was associated with increased graft loss compared with age 18 years (adjusted HR 2.36, 95% CI: 1.32–4.23), whereas older donor age was not associated with excess risk. In DDTV, graft loss risk increased progressively with donor age, from HR 1.04 at 19 years (95% CI: 1.02–1.05) to 4.55 at 55 years (95% CI: 2.20–9.40). In LDLT, older donor age was associated with increased graft loss, with HR 3.92 at 64 years (95% CI: 1.00–15.29) and 4.54 at 67 years (95% CI: 1.06–19.48). Additional risk factors for graft loss by graft type included: growth failure, ICU status, and increasing cold ischemia time for DDWG, increasing INR for DDTV, and increasing recipient age, growth failure, and ICU status for LDLT. **Conclusion:** Donor age is a non-linear and graft type–dependent determinant of graft survival in children with BA, with age-related risk emerging later in LDLT than in DDTV.

These findings support the use of graft-specific, continuous risk assessment to optimize donor selection and improve outcomes. Further studies will assess the generalizability of these associations beyond BA.

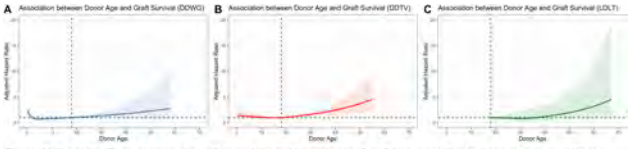

Figure. Multivariable Cox regression by graft type. Adjusted hazard ratio of graft loss according to donor age as a continuous variable using restricted splines with three knots for (A) DDWG, (B) DDTV, and (C) LDLT.

2684 | INCREASED RISK OF ADENOVIRUS INFECTION IN PATIENTS TREATED WITH BASILIXIMAB-CONTAINING IMMUNOSUPPRESSION FOLLOWING LIVER TRANSPLANTATION

Princess Ogundu[1] Julie Bonn[1] Teresa Ambrosino[1] Jessica Rogers[1] Mallory Rosinski[1] Kristen Gamm[1] Siobhan Cooper[1] Anna Peters[1], [1]Cincinnati Children's Hospital Medical Center

Background: The optimal immunosuppression (IS) protocol for pediatric liver transplantation (LT) which promotes allograft acceptance while avoiding IS-related end-organ damage and infections remains controversial. Our institution's IS protocol was revised from higher tacrolimus troughs combined with corticosteroids to a basiliximab-containing regimen with lower tacrolimus trough goals in 2022, with aims to improve patient outcomes. **Methods:** This retrospective case-control study aimed to determine the safety and efficacy of the revised IS protocol (RISP) for patients receiving isolated LT between 2022-2024. Historical IS protocol (HISP) were transplanted prior to 2022 and matched 1: 1 to RISP based on transplant age and indication. 1 year outcomes were analyzed with respect to: patient and graft survival; tacrolimus exposure; number, severity, and timing of biopsy-proven acute cellular rejection (BPAR) episodes; post-transplant lymphoproliferative disorder (PTLD), sepsis, viremia, renal function, hypertension, and hospital length of stay and readmissions. **Results:** RISP (n = 39 patients) compared to HISP (n = 35) had similar 1-year patient/graft survival (10% vs. 3%; p = 0.36) and rates of BPAR (46% RISP vs. 49% HISP, p = 0.82). Cystatin C at time of transplant was significantly lower for HISP patients (0.79) vs RISP patients (0.99; p < 0.05), indicating more severe pre-LT renal disease, however, there was no statistical significance in cystatin C values at one year post-LT. As expected, RISP patients had lower mean tacrolimus trough levels at d30 post-LT vs. HISP patients (12.7; p < 0.05). Rates of sepsis (29% HISP vs 21% RISP) and viremia (69% HISP vs 77% RISP) were not statistically different. However, there was a statistically significant increase in adenoviremia of 36% RISP vs. 11% HISP (p = 0.02; n = 4 in RISP treated with cidofovir), yet a decreased use of rituximab for EBV treatment in RISP (3% vs. 17%, p = 0.05). **Conclusion:** Overall, we demonstrate that the basiliximab-containing RISP had similar one-year post-LT outcomes to HISP despite decreased tacrolimus exposure. Surprisingly, there was increased risk of adenovirus infection, yet decreased severity of EBV infections requiring rituximab in RISP. Prospective analysis in a larger cohort with longer follow up is needed to determine whether these trends are durable.

2685 | TEMPORARY WITHDRAWAL OF IMMUNOSUPPRESSION IS ASSOCIATED WITH IMPROVED SURVIVAL WITHOUT INCREASED REJECTION IN PEDIATRIC PATIENTS WITH PTLD: A REAL-WORLD, PROPENSITY-MATCHED COHORT STUDY OF 1271 LIVER TRANSPLANT RECIPIENTS

Xu Fang[1], [1]Renji Hospital, Shanghai Jiao Tong University School of Medi

Background: Posttransplantation lymphoproliferative disorder (PTLD) remains a life-threatening complication of pediatric liver transplantation (p-LT), with a high mortality rate even after treatment with the current first-line therapy and a reduction in

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

immunosuppression (RIS). The optimal management strategy and effects of immunosuppression (WIS) remain unclear. **Methods:** We analyzed 1271 p-LT recipients from a single center. Management strategies (WIS vs. RIS) were evaluated in children who developed PTLD. To control for confounding by indication, 1: 2 propensity score matching (PSM) was performed between the WIS and RIS groups, and 1: 3 exact match was conducted between the WIS group and a routine follow-up (RF) cohort. Differences in liver function between the WIS and RF groups were evaluated using linear mixed-effects models (LMMs). Long-term liver function, graft survival, and biopsy-proven rejection rates were compared. **Results:** PTLD occurred in 5.98% (76/1271) of patients, with 82.89% being EBV positive. Among these, 49 received WIS (median duration: 93 days; 3 retransplantation patients were excluded) and 24 received RIS. The WIS group had a significantly higher overall survival rate than the RIS group did (95.92% vs. 75.00%, $P = 0.0052$). In the 1: 2 matched cohort, the survival and rejection rates remained comparable between the groups ($P = 0.21$), suggesting that there was no added risk from withdrawal. Furthermore, compared with the RIS group, the WIS group had significantly better liver function (lower DB levels) during follow-up ($P < 0.05$). Longitudinal analysis using linear mixed-effects models demonstrated that compared with the matched RF group, WIS treatment was associated with significantly improved liver function profiles, including lower TB, DB and ALT levels ($P < 0.05$). Crucially, the incidence of acute rejection in the WIS group was not significantly different from that in the RF group (11.76% vs. 10.39%, $P > 0.05$). **Conclusion:** A temporary WIS strategy combined with close clinical monitoring and anti-PTLD therapy was associated with superior patient survival and improved functional recovery without compromising graft safety.

2686 | EMOTIONAL-BEHAVIORAL FUNCTIONING AND QUALITY OF LIFE IN PEDIATRIC BILIARY ATRESIA LIVER TRANSPLANT RECIPIENTS AND THEIR CAREGIVERS: AN ITALIAN SINGLE-CENTER EXPERIENCE

Francesca Boldrini[1] Andrea Pietrobattista[1] Daniela Liccardo[1] Marco Spada[1] Deny Menghini[1], [1]Bambino Gesù Children's Hospital

Background: Biliary atresia (BA) is the leading indication for pediatric liver transplantation. Despite improved survival, BA is associated with complex neuropsychological and psychosocial outcomes. This study evaluates non-verbal cognitive abilities, emotional-behavioral functioning, and quality of life (QoL) in pediatric BA transplant recipients; parental anxiety and depressive symptoms were also considered. **Methods:** During routine post-transplant follow-up, 58 patients (56% F, 44% M; mean age 9.8 ± 3.7 years; mean age at transplant 2.98 ± 4 years; mean time since transplant 6.8 ± 2.8 years) and parents underwent a screening protocol. Patients' non-verbal cognitive abilities were assessed using Raven's Progressive Matrices (2023). Quality of life was measured using the PedsQL Transplant Module (Varni et al., 2000), behavioral difficulties with the SDQ (Goodman, 1997) in self- and parent-report form. Depressive and anxious symptoms were assessed in patients and parents using the PHQ-9 (Kroenke et al., 2001) and the GAD-7 (Spitzer et al., 2006). **Results:** Non-verbal cognitive abilities were homogeneous across the sample. Borderline or clinically significant behavioral problems were reported by 46% of patients and 31% of parents. Both patients and parents identified Physical Appearance and Communication as critical QoL domains. Additionally, patients reported Worry, while parents reported Anxiety, as impaired domains. Correlation analyses showed that higher emotional symptoms were associated with greater behavioral difficulties and poorer QoL. Patient-reported depressive symptoms strongly correlated with SDQ Conduct Problems ($p < 0.002$), Hyperactivity ($p < 0.01$), and Total Difficulties ($p < 0.001$), suggesting an association with broader behavioral dysregulation. Patient anxiety was inversely related to the Total PedsQL Index ($p = 0.03$), indicating lower QoL with higher anxiety. Parental anxiety and depression positively correlated with all SDQ subscales except Prosocial Behavior, suggesting greater perceived child difficulties. Higher parental depressive symptoms were associated with lower QoL scores in Medication Management and Social Relations ($p < 0.01$), Pain Perception ($p < 0.02$), Physical Appearance and Communication ($p < 0.001$). Parental anxiety showed similar correlations, with additional impact on the Anxiety scale ($p < 0.01$). **Conclusion:** Children with BA undergoing liver transplantation exhibit significant emotional-behavioral vulnerabilities despite preserved cognitive abilities. Parental psychological well-being is a relevant factor for child adjustment. Findings support systematic psychological screening and early interventions within multidisciplinary post-transplant care.

2687 | ALLOGENEIC HEMATOPOIETIC CELL TRANSPLANTATION IN CHILDREN WITH ADVANCED LIVER FIBROSIS AND CIRRHOSIS: A RETROSPECTIVE COHORT STUDY

Prakash Satwani[1] Mercedes Martinez[2], [1]Columbia University, NewYork, [2]NewYork-Presbyterian

Background: Advanced liver fibrosis and cirrhosis are traditionally considered contraindications to allogeneic hematopoietic cell transplantation (alloHCT) due to concerns for increased transplant-related mortality. Pediatric data in this high-risk population are limited. **Methods:** We conducted a retrospective single-center cohort study of pediatric patients (age 0-21 years) with biopsy-proven stage F3-F4 liver fibrosis or cirrhosis underwent HCT between January 2017 and March 2026 (Table). Clinical characteristics, transplant variables, hepatic outcomes, engraftment, graft versus host disease (GVHD), graft failure, and survival were analyzed. **Results:** Eight patients underwent 11 HCTs for malignant and nonmalignant disorders, including leukemia, transfusion-dependent thalassemia, sickle cell disease, sideroblastic anemia, Wolman's disease, chronic active Epstein–Barr virus infection, and Langerhans cell histiocytosis. Median age at transplantation was 15 years (range, 3–19). Donor sources included matched sibling, matched unrelated and haploidentical family members. Conditioning regimens were myeloablative (n = 8) and reduced intensity (n = 4). Median neutrophil and platelet engraftment occurred at 15 days and 25 days, respectively. At baseline, prior to initiation of conditioning, the median alanine aminotransferase (ALT) was 58 U/L (range, 14–163), and the median total bilirubin was 0.6 mg/dL (range, 0.2–7.2) (Table 1). From the start of conditioning through day +30 post-HCT, median ALT and direct bilirubin increased to 87 U/L (range, 30–248) and 1.6 mg/dL (range, 1.1–17), respectively. Between days +31 and +100, median ALT was 103 U/L (range, 31–596), and direct bilirubin was 1.1 mg/dL (range, 0.4–24) (Table 2). None of the patients received defibrotide for VOD prevention and only one patient was treated with defibrotide for presumed VOD. Acute GVHD occurred in 33% of patients and chronic GVHD in 11%. Two patients experienced graft failure after reduced-intensity conditioning and subsequently achieved durable engraftment following 2nd transplantation. One patient died from Streptococcus mitis sepsis complicated by liver failure. At a median follow-up of 3 years (range, 1–8), 7 of 8 patients were alive and disease-free with native liver. **Conclusion:** Although transient elevations in transaminases and bilirubin were observed after conditioning, most patients experienced only temporary hepatic worsening without progression to irreversible liver failure, suggesting that baseline fibrosis alone may not reliably predict post-HCT hepatic decompensation. Advanced liver fibrosis or cirrhosis should not universally exclude pediatric patients from HCT candidacy. With careful multidisciplinary management and individualized transplant strategies, favorable outcomes may be achievable in selected high-risk patients.

Table: Pre- hematopoietic cell transplant liver functions pathology and ultrasound findings

2688 | BASELINE VALUES OF APRI AND FIB-4 DO NOT ALLOW FOR PREDICTING THE DISEASE PROGRESSION IN FONTAN-ASSOCIATED LIVER DISEASE IN CHILDREN

Anna Mania[1] Katarzyna Mazur-Melewska[2] Magdalena Figlerowicz[2], [1]Poznan University of Medical Sciences;, [2]Poznan Univesity of Medical Sciences

Background: The growing need to manage patients with Fontan-associated liver disease (FALD) is being recognised. The Fontan circulation leads to altered hemodynamics, chronic hypoxia, and increased venous pressure, resulting in liver injury and progressive fibrosis. Methods of non-invasive monitoring are required in this group of patients.This study aims to evaluate the clinical utility of non-invasive markers of fibrosis in children with FALD. **Methods:** The study included 31 children (18 girls) who underwent a Fontan procedure (FP) due to inborn heart defects. The median time from FP was 6 years (IQR 3.25-8.00). Children were evaluated every 12 months for the three

following years in the outpatient hepatology clinic. Physical examination, blood CBC, ALT, AST, ALP, GTP levels, and liver stiffness (LS) by shear-wave elastography were evaluated. FIB-4 and APRI scores were calculated based on the laboratory results. All children received ursodeoxycholic acid at a dose of 15 mg/kg throughout the observation period. **Results:** After 3 years of observation, LS increased in 10 patients, while no progression (constant LS) or improvement (lower LS) was observed in 21 children. There was no difference between the groups in age or time from FP (10 vs 11 years, $p = 0.79$; 6 vs 5 years, $p = 0.95$, respectively). The baseline evaluation did not differ significantly between the groups with LS progression or improvement (7.9 vs 5.9 kPa; $p = 0.374$). Baseline APRI and FIB-4 were higher in children with LS improvement (0.54 vs 0.41; $p = 0.007$; 8.24 vs 5.28, $p = 0.04$). Other baseline parameters did not differ significantly between the groups. **Conclusion:** Liver stiffness monitoring is necessary in the management of children with FALD. Non-invasive markers of fibrosis are not helpful in predicting further outcomes of the diseases.

2689 | MULTI-CENTER COMPARISON OF "ADJUSTED MEAN ALT" IN THE 5TH YEAR AFTER PEDIATRIC LIVER TRANSPLANTATION (LT)

Elizabeth Raby[1] Sandy Feng[1] Emily Perito[1] SPLIT Society of Pediatric Liver Transplantation[2] Elizabeth Rand[3] Nitika Gupta[4] James Squires[5], [1]UCSF, [2]Society of Pediatric Liver Transplantation, [3]CHOP, [4]Emory University School of Medicine, [5]Children's Hospital of Pittsburgh

Background: Following previous single-center derivation of “adjusted mean ALT” in years 4-5 after LT as a more holistic representation of graft health than a single ALT value[1], we explored this metric and its association with immunosuppression (IS) practices in a multi-center cohort. **Methods:** In this retrospective analysis of children transplanted 2011-17 at 4 geographically diverse pediatric LT centers, all available ALT (IU/L) and tacrolimus trough (mg/dL) levels from each child’s medical record (EMR) were merged with outcomes data from the Society of Pediatric Liver Transplantation registry and the EMR. The mean adjusted ALT and tacrolimus trough levels representative of the 5th year after LT were derived by calculating, for each child, the median for each month of the 5th post-LT year and averaging all the median values.[1] Categorical variables were compared using the Chi-square test of significance, and continuous variables were compared using the Kruskal-Wallis test. **Results:** 321 children were included: 47% male; 33% non-White; median (IQR) age at LT 2 (1, 9) yrs; 40% biliary atresia; 76% deceased donor; race, LT indication, and donor type differed ($p < 0.001$ for all). At 5 yrs after LT, mean adjusted ALT distributions were similar across centers ($p = 0.46$; Fig 1A); means were 29.2, 29.0, 26.0, and 27.1 for sites 1, 2, 3, and 4, respectively. Use of induction and maintenance drugs, both early and late after LT, differed (Table). However, at 5 yrs, centers were similar in their use of monotherapy (62-82%; $p = 0.25$) versus dual therapy (15-31%; $p = 0.41$). **Conclusion:** Mean adjusted ALT distributions for children 5 years post-LT across 4 diverse LT centers were surprisingly similar, despite substantial variability in induction and maintenance IS drug use. Differential IS practices across LT centers appear to yield similar overall allograft health, reflected by a metric derived to holistically represent allograft health over time. Future directions should investigate the long-term outcomes of pediatric patients with the distinct IS regimens reflected in this cohort, as well as perform histological confirmation of allograft health in a similar cohort. [1] PMID: 37458328

2690 | ROLE OF LIVER TRANSPLANTATION IN LANGERHANS CELL HISTIOCYTOSIS IN CHILDREN: LARGEST SINGLE CENTRE EXPERIENCE AND AN ALGORITHM-BASED APPROACH

Jagadeesh Menon[1] Naresh Shanmugam[1] Naveen Bharathi[1] Julius Scott[1] Mukul Vij[1] Ashwin Rammohan[1] Rajesh Rajalingam[1] Mohamed Rela[1], [1]Dr Rela Institute & Medical Centre

Background: Langerhans cell histiocytosis (LCH) is a rare but important cause of end-stage liver disease in children. We describe the largest cohort of patients with LCH who underwent liver transplant (LT) and propose an algorithm to approach them based on our experience. **Methods: Methodology:** All patients aged < 18 years with LCH who underwent a liver transplant (LT) between January 2011 and June 2025 were analysed in this study. Their clinical profile, chemotherapy protocols and outcomes were described, and a therapeutic algorithm was proposed. **Results:** Twenty-three (2.7%) of 835 pediatric liver transplants performed in the aforementioned period were for LCH-related end-stage liver disease, and this included 16 males and 7 females. Diagnosis of LCH was made in the pre-LT period in 17 and post-LT from the explant liver in 6 children, whose pre-LT working diagnosis were Caroli's disease (n = 3) and primary sclerosing cholangitis (PSC) (n = 3). Patients were divided into *Category I* (n = 5), *Category II* (n = 12), and *Category III (n = 6)*. (Ref Figure 1 and notes). Indications for LT included decompensation and/or advanced portal hypertension and intractable pruritus. Median age at transplantation was 48 (11-216) months, and all were liver donor liver transplants (LDLT). Explant was positive for the *V600E BRAF* mutation in 4 patients. Chemotherapy was continued post-LT as per protocol (Figure 1). Trametinib was started for 2 patients, Dabrafenib for 1, and Vemurafenib for 3. There were no surgical complications, and none had rejection or post-transplant lymphoproliferative disorder (PTLD). After a median follow-up of 32 months (10-140 months), 22 (95.6%) patients are alive with normal graft function and in remission. One patient had a recurrence of LCH at the hepaticojejunostomy site post 20 months of LT, and is currently in remission following chemotherapy. **Conclusion:** We propose a therapeutic algorithm for patients with LCH based on our excellent post-LT outcomes. LCH should be strongly considered in patients suspected of Caroli's disease or PSC.

2691 | TOWARDS PRECISION IMMUNOSUPPRESSION: RISK-STRATIFIED TACROLIMUS WINDOWS IN PAEDIATRIC LIVER TRANSPLANTATION

Yang Yang Lee[1] Jan Sabo[2] Alba Bueno[3] Hector Vilca-Melendez[3] Evelyn Ong[3] Khalid Sharif[3] Jake Mann[4] Girish Gupte[3], [1]National University Hospital, Singapore, [2]Department of Pediatric Surgery, Uniklinikum Essen, Germany, [3]Birmingham Women's and Children's Hospitals NHS Foundation Trust, United Kingdom, [4]Institute of Biomedical Research Research, University of Birmingham, United Kingdom

Background: Tacrolimus based immunosuppression after paediatric liver transplantation should simultaneously prevent allograft rejection and avoid over-immunosuppresion that drives Epstein-Barr virus

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(EBV)-driven malignancies such as post-transplant lymphoproliferative disorder (PTLD) and EBV-associated smooth muscle tumour (EBV-SMT). Tacrolimus trough targets vary widely between centers, and no risk-stratified, paediatric-specific therapeutic window has been defined. We aim to define individualized tacrolimus trough windows that balance these opposing risks across different clinical recipient groups. **Methods:** We performed a retrospective analysis of paediatric liver transplant recipients in a single quaternary referral center over 10 years (2015 – 2024). The primary endpoint was EBV-related malignancy (both PTLD and EBV-SMT). Secondary endpoints were presence of biopsy-proven acute rejection, the Banff severity grade and the number of rejection episodes. Predictors for each endpoint were first quantified independently as odds ratios (Fisher exact test; Mann-Whitney U and Spearman correlation for continuous variables). The interaction of tacrolimus trough levels with both endpoints was examined to derived safe therapeutic windows for each risk group. **Results:** Between 2015 and 2024, 229 liver-only transplants were performed in 217 recipients. EBV-associated malignancies occurred in 10 patients (4.4%; 9 PTLD and 1 SMT). EBV malignancy was strongly correlated by viral load - peak PCR at or above 10000 copies/mL (OR 12.1, 95% CI 2.4-60.3) and sustained viraemia (OR 17.0, 95% CI 3.4-85.7; 25.8% vs 2.0% malignancy rate). Recipients with PTLD were also correlated with sustained, high-level EBV viraemia ($\geq$1000 copies/mL) over the first 12 months post-transplant, in contrast to transient viraemic episodes in non-PTLD patients. Tacrolimus trough variability was not correlated with rejection (OR 1.3, 95% CI 0.7–2.5) (Table 1). Recipients transplanted for autoimmune indications showed a trend toward higher rejection rates (89%) and moderate / severe rejection episodes (42% vs 15% in the general cohort). Tacrolimus trough windows were then derived for different clinical risk groups: 6-9 ng/mL for general-risk recipients, narrowed to 6-8 ng/mL where EBV-malignancy risk is higher (EBV-seronegative, R-/D+ mismatch, infancy) and raised to 7-10 ng/mL where rejection risk is higher (autoimmune aetiology, prior rejection) (Table 2). **Conclusion:** High-risk EBV mismatch (R −/D+) and sustained EBV viraemia above 1000 copies/mL are clinical indications to reduce tacrolimus trough targets and intensified EBV surveillance. EBV PCR $\log_{10} \geq 3.0$ (1000 copies/mL) should trigger tacrolimus trough review with target de-escalation if rejection risk is acceptable. We propose precision, risk-stratified tacrolimus windows to individualise immunosuppression and support more consistent decision-making across centres.

Table 1. Tacrolimus Trough Bands

Mean Tacrolimus trough POD 1-90 (ng/mL)	N	Rejection		EBV	
		Any rejection	Recurrent rejections	High EBV Viraemia	EBV Malignancy
≤5	6	4 (67%)	0 (0%)	1 (100%)	1 (17%)
5 – 6	14	9 (64%)	4 (29%)	6 (67%)	1 (7%)
6 – 7	43	34 (79%)	16 (37%)	23 (54%)	4 (9%)
7 – 8	80	57 (71%)	27 (34%)	59 (74%)	2 (2%)
8 – 9	56	36 (64%)	23 (41%)	35 (62%)	1 (2%)
9 – 10	19	14 (74%)	9 (47%)	11 (60%)	1 (5%)
10 – 12	9	6 (67%)	4 (44%)	7 (80%)	0 (0%)
>12	1	1 (100%)	0 (0%)	–	0 (0%)

Table 2. Risk-stratified Tacrolimus Therapeutic Windows

Risk group	Safe Therapeutic Window POD 1–90 (ng/mL)	Safe Therapeutic Window >POD 90 (ng/mL)	EBV PCR surveillance
General-risk liver transplant	6 – 9	4 – 7	Monthly EBV PCR × 12 months
EBV-seronegative recipient (R−)	6 – 8	3.5 – 6	Weekly × 3 mo, fortnightly × 3 mo, then monthly
R−/D+ high-risk mismatch	6 – 8	3 – 6	Weekly × 6 mo, then monthly to ≥24 months
Autoimmune aetiology (AIH / PSC)	7 – 10	5 – 8	Monthly EBV PCR × 12 months
Age <1 year at transplant	6 – 9	4 – 7	Weekly × 6 mo, then fortnightly
History of rejection	7 – 10	5 – 8	Monthly EBV PCR × 12 months

Background: Pediatric Primary Sclerosing Cholangitis (PSC) associates with inflammatory bowel disease (IBD) and autoimmune hepatitis (AIH) linking the gut-liver axis in pathogenesis. We hypothesized that the microbiome would differ in pediatric PSC between different disease phenotypes, treatments and fibrosis. **Methods:** Stool samples and clinical metadata were prospectively collected from 110 children with PSC through the Childhood Liver Disease Research Network's PSC Observational Study (NCT04181138) from 12 sites in North America. Whole genome shotgun metagenomic sequencing was performed. Statistical modeling was performed in ATIMA (Agile Toolkit for Incisive Microbial Analyses) and R (version 4.5.2), with coding input from Microsoft CoPilot. **Results:** 110 children with PSC (61.8% male) had stool samples sequenced (average age 15.1 years, range 7-25). 81 children had large duct PSC (73.6%) and 29 (26.4%) had small duct PSC. Eighty (72.7%) had IBD and 27 (25%) had PSC-AIH. 25 (23%) were treated with oral vancomycin (OV), and 22 of those had IBD. 59 (69.4%) had liver stiffness (kPa) <7.4, and 11 (12.9%) had kPa ≥ 14.4 as measured by Fibroscan. Children on OV had lower alpha diversity ($p<0.001$) and different overall community structure than those not on OV ($p=0.001$). Increased relative abundance (RA) of *Klebsiella pneumoniae* and *Escherichia coli* and decreased RA of *Bacteriodes vulgatus, B.uniformis* and *Faecalibacterium prausnitzil* were seen with OV use (FDR adj $p<0.001$). MaAsLIn2 analysis revealed 270 metagenomic pathways associated with OV (FDR adj $P<0.05$), including increased propionate synthesis and baiA KEGG ortholog, a bile acid modifier (FDR adj $p<0.001$). No significant differences were seen between large and small-duct PSC nor PSC-AIH vs PSC in alpha or beta diversity. Adjusting for OV, increased *Streptococcus mitis* and decreased *Barnesiella intestine hominis* RA were seen in large-duct PSC (FDR adj $p=0.02, 0.03$). *Veillonella* species had higher RA in PSC-AIH vs PSC, (FDR adj $p=0.03$) aligning with adult studies. Adjusting for OV, *Gemella morbillorum* negatively correlated with GGT level and platelet count (FDR adj $p=0.04, 0.02$). *Clostridium disporicum* and *Turicibacter sanguinis* negatively correlated with fibrosis severity (FDR adj $p=0.01, 0.03$) The methionine degradation pathway (PWY-5464) decreased with increasing fibrosis, suggesting a role in fibrosis-associated methionine disruption. **Conclusion:** OV was the strongest modifier of both the composition and function of the fecal microbiome in pediatric PSC, affecting microbial short chain fatty acid synthesis and bile acid metabolism. Differences across PSC categories and markers of severity were less marked, but linked to microbial mechanisms of hepatic dysfunction; together, these findings warrant further study.

Background: Activated T-cell pediatric acute liver failure (TC-PALF) is the most common cause of liver failure in children in North America. Work from the PALF Immune Response Network (PALF-IRN) described two distinct disease endotypes that differ by their CD8+ T-cell Perforin1 (Prf) expression: TC-PALF High Prf and TC-PALF Normal Prf (TC-PALF NL Prf). We aimed to identify novel non-invasive serum protein biomarkers of disease and recovery that characterize these TC-PALF groups. **Methods:** Serum samples from patients enrolled in the PALF-IRN clinical trial, TReatment for ImmUne Mediated PathopHysiology (TRIUMPH) (NCT04862221), from day 1, 7, 21, 90 and liver transplant were analyzed using a multiprotein assay measuring N = 5400 serum proteins (Olink 5400 HT explore). TRIUMPH patient samples from the TC-PALF High Prf and TC-PALF NL Prf groups were compared to samples of healthy children and other causes of PALF (Oth-PALF) from the PALF-Study Group biorepository (UO1-DK072146). Investigators remain blinded to patient study treatment arm, which included 3 arms- equine anti thymocyte globulin, methylprednisolone or supportive care. Statistical analysis was performed using R studio 4.4.0. **Results:** Healthy (n = 9, 55% male), Oth-PALF (n = 39, 53% male), TC-PALF High Prf (n = 20, 75% male), and TC-PALF NL Prf (n = 8, 50% male) were compared. Principal component analysis (PCA) showed migration of TC-PALF endotype clusters toward healthy over time (figure 1A). The highly expressed proteins driving PC1 included those associated with liver synthetic function: coagulation cascade and complement pathways. PC1 also contained Tumor Necrosis Factor Superfamily Member 11(TNFSF11) and Integrin Subunit Alpha 11 (ITGA11), proteins involved in extracellular matrix production. These markers normalized over time in patients recovering from PALF compared to those undergoing transplantation (figure 1B). Pathways that differentiated TC-PALF from Oth-PALF patients by gene set enrichment analysis (GSEA) involved proteins associated with interferon-ɣ signaling and T-cell cytotoxicity with downregulation of energy metabolism via oxidative phosphorylation (figure 1C). Leukotriene A4 hydrolase (LTA4H), an enzyme involved in activating innate immune responses, was significantly higher in Oth-PALF compared to TC-PALF High Prf patients (figure 1D). **Conclusion:** Patients recovering from TC-PALF have serum biomarkers associated with tissue regeneration, fibrosis and normalization of coagulation and complement pathways. LTA4H is a candidate biomarker for differentiation of etiologies of PALF. These may serve as useful biomarkers for diagnosis or trajectory of illness.

2694 | THE CHILDHOOD LIVER DISEASE RESEARCH NETWORK PROSPECTIVE CHARACTERIZATION OF PEDIATRIC PRIMARY SCLEROSING CHOLANGITIS

Cara Mack[1] Alexander Miethke[2] Kieran Hawthorne[3] Lisa Henn[3] Simon Horslen[4] Estella Alonso[5] Nitika Gupta[6] Shikha Sundaram[7] Rohit Kohli[8] Molly Bozic[9] Mark Deneau[10] Kathleen Loomes[11] Pamela Valentino[12] Mary Elizabeth Tessier[13] Benjamin Shneider[14] John Magee[15] Saul Karpen[16] Philip Rosenthal[17] Kasper Wang[18] Amanda Ricciuto[19] Ronald Sokol[20] Binita Kamath[21] ChiLDReN Childhood Liver Disease Research Network[22], [1]Medical College of Wisconsin, [2]Cincinnati Children's Hospital Medical Center, [3]Arbor Research Collaborative for Health, [4]UPMC Children's Hospital of Pittsburgh, [5]Ann and Robert H. Lurie Children's Hospital of Chicago, [6]Emory University School of Medicine, [7]Children's Hospital Colorado, [8]Children's Hospital Los Angeles, [9]Indiana University School of Medicine, [10]University of Utah, [11]The Children's Hospital of Philadelphia, [12]University of Washington, [13]Texas Children's Liver Center - Baylor College of Medicine, [14]Texas Children's Hospital, [15]University of Michigan Hospitals and Health Centers, [16]VCU Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, [17]University of California, San Francisco, [18]Hospital for Sick Children, University of Toronto, [19]Hospital for Sick Children, [20]University of Colorado School of Medicine, [21]Children's Hospital of Philadelphia, [22]NIH NIDDK

Background: Primary sclerosing cholangitis (PSC) is a rare biliary fibrosing disease that leads to significant morbidity and the need for liver transplantation. The Childhood Liver Disease Research Network is conducting a prospective, observational longitudinal study to define the natural history of pediatric PSC. The aim of this report is to characterize the clinical phenotypes of the first 175 children enrolled in the PSC study and to determine correlations of specific phenotypes with clinical and laboratory characteristics. **Methods:** Data collected included diagnostic MRCP/ liver histology, history of inflammatory bowel disease (IBD) and/or autoimmune hepatitis (AIH), IBD activity, medications, clinical blood tests, autoantibodies, and fasted liver stiffness measurements (LSM) per protocol. Comparison of phenotypes with/without IBD and/or AIH, and small duct versus large duct PSC was performed. **Results:** 90% of participants had been previously diagnosed with PSC, while 10% were newly diagnosed within 90 days of enrollment. The median age at enrollment was 16.1 years, 60% were male, 78% had large duct PSC and the median duration of PSC was 2.2 years. Frequent medication use at enrollment included ursodeoxycholic acid (51%) and oral vancomycin (27%). The predominant phenotype was PSC/IBD and 96% had quiescent/mild IBD. The majority had evidence of mild liver disease based on biochemistries and LSMs; < 10% had portal hypertension defined as ascites, splenomegaly or thrombocytopenia. Higher LSMs were associated with elevated liver biochemistries. There were no significant characteristics that differentiated the phenotypes, however there was frequent autoantibody positivity in the PSC/IBD cohort at enrollment (56%), despite the fact that the majority of these patients did not have a previous diagnosis of AIH. Furthermore, there was a trend towards a more severe phenotype in the PSC/AIH cohort with higher LSMs, and greater frequency of focal biliary strictures and concentric periductal inflammation based on diagnostic MRCP and histology, respectively. **Conclusion:** This prospective cohort of pediatric PSC revealed mild liver disease in the majority. Laboratory biomarkers of liver injury and fibrosis were associated with LSM elevation, suggesting LSM as a reliable tool to monitor PSC severity. The majority of participants with a positive autoantibody at enrollment were not previously diagnosed with AIH, suggesting that autoantibodies are associated with IBD and not necessarily classical AIH or PSC. This dataset encompasses a well-phenotyped cohort of children with PSC that will be followed prospectively for longitudinal assessment of progression of disease, as well as a model for stratification within future treatment trials.

2695 | EARLY BIOCHEMICAL AND CLINICAL PREDICTORS OF OUTCOMES IN PEDIATRIC AUTOIMMUNE HEPATITIS AND AUTOIMMUNE SCLEROSING CHOLANGITIS

Shelley Choudhury[1] Sakil Kulkarni[1] Rebekah Karns[2] Pooja Khonde[1] Adith Boloor[1] Cyd Castro-Rojas[2] Amy Taylor[2] Alexander Miethke[2], [1]Washington University in St. Louis, [2]Cincinnati Children's Hospital Medical Center

Background: In adults with autoimmune hepatitis (AIH), baseline disease characteristics and early biochemical response (EBR) are strong predictors of long-term outcomes. A recent study showed that adult patients who achieve EBR, defined as normalization of ALT, AST, and immunoglobulin G (IgG) levels at 6 months after diagnosis, have significantly improved transplant-free survival. EBR has emerged as a potential surrogate endpoint for clinical trials in adult AIH. However, the prognostic value of baseline disease features and EBR, including optimal definitions, remains unclear in pediatric AIH and autoimmune sclerosing cholangitis (ASC). **Methods:** We performed a retrospective multicenter cohort study of 191 patients aged 2–21 years with AIH (n = 180) or ASC (n = 11) treated at 9 pediatric tertiary centers between 2010–2020. Baseline demographic, clinical and laboratory data were analyzed. EBR at 6 and 12 months was defined using normalization of ALT, AST, IgG and total protein. Outcomes included liver-related events (ascites, encephalopathy, variceal hemorrhage, transplantation), steroid-related complications (obesity, growth impairment, hypertension, diabetes, cataracts), and treatment resistance (steroid dependence or flare within 18 months). **Results:** Among 191 patients with AIH and ASC (median follow-up 3.2 years), liver events occurred in 15.6%, steroid-related complications in 31.1%, and treatment resistance in 56.1%. Liver events were associated with higher baseline INR ($p < 0.001$), bilirubin ($p = 0.005$), APRI ($p = 0.03$), and FIB-4 ($p = 0.003$), and with lower albumin ($p < 0.001$) and platelet count ($p = 0.009$). Steroid-related complications were associated with younger age (median 11 vs 13.5 years, $p < 0.001$), higher alkaline phosphatase ($p = 0.02$), and lower albumin ($p = 0.02$) and creatinine ($p = 0.004$). Treatment resistance was associated with higher baseline IgG ($p = 0.02$) and INR ($p = 0.007$). EBR at 6 months showed limited predictive value (AUC 0.5–0.7). In contrast, EBR at 12 months predicted liver events and treatment resistance, with inclusion of IgG improving discrimination for treatment resistance. **Conclusion:** In pediatric AIH/ASC, early markers of synthetic dysfunction, noninvasive fibrosis indices at baseline, and incomplete biochemical response (abnormal ALT/AST) at 12 months post diagnosis identify patients at higher risk for adverse liver outcomes. Treatment resistance was associated with higher baseline serum IgG and lack of normalization of ALT, AST, and IgG at 12 months post diagnosis.

Parameters used for EBR	ALT and AST threshold for normal	Time after Diagnosis	Liver Event (AUC)	Steroid Complications (AUC)	Treatment resistance (AUC)
ALT and AST	≤ ULN	12 months	0.61	**0.63**	**0.74**
ALT and AST	Boys < 26 U/L Girls < 22 U/L	12 months	0.59	0.60	0.57
ALT, AST and IgG	≤ ULN	12 months	0.63	**0.71**	0.55
ALT, AST and IgG	Boys < 26 U/L Girls < 22 U/L	12 months	0.51	0.52	0.51
ALT, AST and protein	≤ ULN	12 months	0.54	**0.63**	**0.65**
ALT, AST and protein	Boys < 26 U/L Girls < 22 U/L	12 months	0.59	**0.67**	0.57

Table 1: Univariable analyses evaluating the predictive performance of early biochemical response (EBR) markers for clinical outcomes. ALT = alanine aminotransferase; AST = aspartate aminotransferase; U/L = units per liter; AUC = area under the receiver operating characteristic curve. Bolded values indicate statistically significant predictors ($p<0.05$); bolded red values indicate significant predictors with AUC >0.7.

2696 | PROTAC-MEDIATED DEGRADATION OF MMP-7 AS A POTENTIAL THERAPEUTIC STRATEGY FOR BILIARY ATRESIA

Shuiqing Chi[1] Mengxin Zhang[2] Yan Chen[1] Paul Tam[1] Shao-Tao Tang[2], [1]Macau University of Science and Technology, [2]Wuhan Union Hospital

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Matrix metalloproteinase-7 (MMP-7) is not only a diagnostic biomarker for biliary atresia (BA), but also a pathogenic mediator of biliary inflammation and liver fibrosis, making it a critical therapeutic target. Conventional MMP-7 inhibitors mainly suppress extracellular enzymatic activity, whereas they may not effectively reduce the intracellular MMP-7 pool available for continuous secretion by injured cholangiocytes. This study aimed to develop a novel MMP-7-targeting PROTAC, compound 3C-V1, and evaluate whether targeted MMP-7 degradation could provide a protein-level strategy for alleviating BA progression. **Methods:** The MMP-7 degradation efficacy and cytotoxicity of 3C-V1 were first evaluated in vitro. Its functional effects were then assessed in cholangiocyte organoid models derived from rhesus rotavirus (RRV)-induced BA mice, bile duct ligation (BDL) mice, and human BA patients. The in vivo therapeutic efficacy of 3C-V1 was further investigated using the RRV-induced BA mouse model. **Results:** Compound 3C-V1 induced potent MMP-7 degradation in cholangiocyte-derived organoids, with a DC50 of 3 nM and minimal cytotoxicity, as indicated by an IC50 of 16.32 μM. Across RRV, BDL, and human BA organoid models, 3C-V1 consistently reduced intracellular MMP-7 expression, enhanced organoid growth, and attenuated apoptosis. Notably, 3C-V1 decreased MMP-7 secretion in RRV and human BA organoids, suggesting that degradation of the intracellular MMP-7 pool may limit subsequent extracellular release. In contrast, marked MMP-7 secretion was not observed in BDL-derived organoids, indicating that extracellular MMP-7 detection may be influenced by disease-specific epithelial polarity, barrier integrity, and compartmentalized release. In human BA organoids, 3C-V1 reduced the secretion of inflammatory cytokines, including IL-6, IL-8, and IL-17A. In BDL and human BA organoids, 3C-V1 further reversed epithelial-mesenchymal transition-related protein changes, characterized by preservation of epithelial features and reduced cytoplasmic redistribution of β-catenin. In vivo, 3C-V1 delayed the onset of jaundice, reduced the mean jaundice rate by 65%, and improved the 14-day survival rate by 60% in RRV-induced BA mice. These therapeutic effects were accompanied by decreased hepatic MMP-7 expression and reduced inflammatory responses. **Conclusion:** The MMP-7-targeting PROTAC 3C-V1 alleviates BA-associated cholangiocyte injury by degrading intracellular MMP-7, reducing its extracellular availability, and attenuating downstream inflammatory and EMT-associated fibrotic responses. These findings support PROTAC-mediated MMP-7 degradation as a promising strategy to suppress cholangiocyte-derived MMP-7 at the protein level and alleviate BA progression.

2697 | A PROSPECTIVE MULTINATIONAL STUDY OF A FEEDING ULTRASOUND APPROACH TO IDENTIFY BILIARY ATRESIA

Tebyan Rabbani[1] Ashley Upton[2] Ming-Wei Lai[3] Bikrant Lal[4] Pamela Valentino[5] Orith Waisbourd-Zinman[6] Jia-Feng Wu[7] Seema Alam[4] Pazit Bar-Gil[8] Niviann Blondet[5] En-Shuo Chang[3] Mei-Hwei Chang[7] Chieh-Chang Chen[3] Huey-Ling Chen[7] Peace Dike[1] J. Alberto Hernandez[2] Noorie Javer[9] Rajeev Khanna[4] Osnat Konen[8] Nadia Kryvol[1] Amar Mukund[4] Amrita Narang[1] Katelyn Saarela[10] Benjamin Shneider[2] Sanjiv Harpavat[11], [1]Stanford Children's, Stanford University, [2]Texas Children's Hospital, [3]Chang Gung Memorial Hospital, [4]Institute of Liver and Biliary Sciences, [5]Seattle Children's, University of Washington, [6]Schneider Children's Medical Center, [7]National Taiwan University, [8]Schneider Children's Medical Center, [9]Seattle Children's, Washington University, [10]Seattle Children's Hospital, [11]Texas Children's Liver Center - Baylor College of Medicine

Background: We recently reported a single-center experience with a novel feeding ultrasound approach that identifies biliary atresia (BA) based on the absence of a common hepatic duct. This study aimed to assess the approach on a larger scale, by applying it prospectively in a multinational investigation. **Methods:** The feeding ultrasound approach

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

was performed prospectively on infants presenting with cholestasis at ≤180 days of life at seven centers across four countries. Each site followed a previously published four-step protocol to visualize a structure consistent with the common hepatic duct, referred to as the "duct at the hilum" or "DaH." Operators at sites were trained through a virtual 30-minute didactic presentation, a 5-minute demonstration video, and, depending on operators' requests, direct instructions during clinical care through live video conferencing. Data for completion of the protocol, as well as demographic information and final diagnoses, were entered into a centralized database by investigators at each site. **Results:** The feeding ultrasound approach was performed on 251 infants between January 2025 and May 2026, including 48 infants eventually diagnosed with BA. The approach's sensitivity, specificity, positive predictive value, and negative predictive value for biliary atresia were 0.96 (95%CI 0.85-0.99), 0.94 (95%CI 0.90-0.97), 0.79 (95%CI 0.66-0.88), and 0.99 (95% CI 0.96-1.00), respectively (Figure 1A). Of the 58 cases in which a DaH was not visualized, 46 infants were eventually diagnosed with BA (true-positives) and 12 infants without BA (false-positives). Eight of the 12 false-positive cases were from a single center at a time before all operators had completed training. In comparison, of the 193 cases in which a DaH was visualized, two infants were eventually diagnosed with BA (false-negatives) and 191 infants without BA (true-negatives). In these infants, the approach was completed in a median of 3.0 minutes (interquartile range 1.0-5.9 minutes). Both false-negative cases had a duct structure labeled as the DaH; however, the structure did not extend into the liver and likely represented the common bile duct instead of the common hepatic duct (Figure 1B). **Conclusion:** This study demonstrates that a novel feeding ultrasound approach can be performed in diverse clinical settings with high diagnostic accuracy, often in <5 minutes. Visualizing the DaH structure both inside and outside the liver could improve the accuracy even more. Taken together, the approach is a simple first-line test with the potential to streamline the evaluation of cholestatic infants by quickly identifying those who may have BA while excluding the majority of infants who have another disorder.

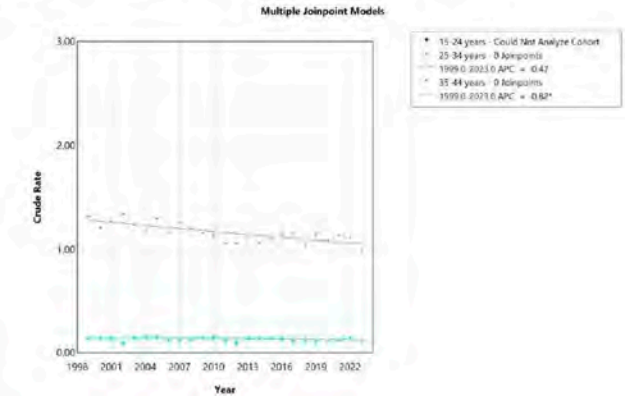
★ 3001 | ◆ TEMPORAL TRENDS IN MORTALITY BURDEN OF ALCOHOL-ASSOCIATED LIVER DISEASE AND EARLY-ONSET PANCREATIC CARCINOMA IN YOUNG ADULTS (15-44): A CDC WONDER ANALYSIS OF AGE, RACIAL, SEX AND GEOGRAPHIC DISPARITIES 1999-2023



Adnan Zafar[1] Mohammed Misbahuddin[2] Afzal Ahmed[2] Abdul Rehman[2] Abdul Shafi[2] Harleen Chela[3], [1]Magnolia Regional Health Center, [2]Deccan College of Medical Sciences, Hyderabad, India, [3]Charleston Area Medical Center

Background: The rising incidence of early-onset hepatobiliary and gastrointestinal ailments in young adults is a growing public health challenge. However, the intersection of increasing alcohol consumption and mortality in the pre-screening population, particularly following the COVID-19 pandemic, remains under-characterized. **Methods:** We utilized the CDC WONDER Underlying Cause of Death database (1999-2023) to analyze mortality trends for alcohol-associated liver disease (ICD-10 :K70) and early-onset pancreatic carcinoma (ICD-10: C25) in American young adults aged 15-44. Age-adjusted mortality rates (AAMR) per 100,000 were stratified by race/ethnicity, sex, and census region. Annual Percent Change (APC) and 95% Confidence Intervals (CI) were calculated using Joinpoint regression to assess temporal trends. Racial trends were studied separately for 1999-2020 Bridged-race and 2021-2023 Single-race datasets due to incompatible summation of datasets. **Results:** From 1999-2023, a total of 74,298 deaths due to ALD and 13,964 due to EOPC were identified in young American adults. The overall AAMR for ALD decreased from 1999 to 2013 (APC: -1.14%,C.I: -1.72, -0.54; $p < 0.001$) and then dramatically increased from 2013 to 2023 (APC: +4.13; C.I: +2.49, +5.80; $p < 0.001$) with an overall significant AAPC +0.78 (C.I: +0.02, +1.21; $p < 0.05$). In contrast, EOPC mortality exhibited a stable gradual deceleration (AAPC: -0.95, CI: -1.28, -0.614; $p < 0.01$). The 35-44 age group had the highest ALD mortality with significant rise during 2019-2023 (APC: +25.3), while all age groups had a stable decrease in AAMR due to EOPC. Geographically, Western US populations exhibited the highest AAMR due to ALD but the highest rise in AAMR was identified in the Midwest from 2019-2023. Notably, American Indian/Alaska Native adults had the highest AAMR as well as the steepest rise in ALD mortality (APC: +28.48), signaling a hyper-acute mortality crisis. **Conclusion:** Although the decreasing mortality of EOPC is reassuring, the accelerating mortality of ALD in young adults, plausibly exacerbated by pandemic-era behavioral shifts, necessitates urgent public health intervention. The persistence of age, racial, gender and geographic disparities suggest that the current 'one-size-fits-all' screening guidelines fail to capture high-risk minority populations, warranting risk-adapted surveillance strategies.

Age-wise stratification of Mortality due to ALD 1999-2023

Age-wise stratification of EOPC Mortality 1999-2023

★ 3002 | ◆ ELEVATED FGF21 IN *TGR5*$^{-/-}$ MICE DIFFERENTIALLY REGULATES ALCOHOL AND SWEET PREFERENCE VIA METABOLIC-REWARD PATHWAYS

Shifat-E Ferdous[1] *Titilayo Olotu*[1] *Elliot Arazi*[1] *Jessica Ferrell*[1], [1]*Northeast Ohio Medical University*

Background: Takeda G-protein coupled receptor 5 (TGR5), a bile acid receptor, regulates metabolism and inflammatory signaling in a tissue-specific manner. We previously reported *TGR5*$^{-/-}$ mice were protected from alcohol-induced liver injury via upregulation of fibroblast growth factor 21 (FGF21), a hepatokine that suppresses alcohol consumption in a negative feedback mechanism via liver, adipose tissue and brain. We also demonstrated that a single ethanol gavage increased hepatic and serum FGF21 2-3-fold in *TGR5*$^{-/-}$ mice compared to wild type-control (WT) mice. When presented with a 2-bottle-choice paradigm, *TGR5*$^{-/-}$ mice showed a reduced preference for ethanol drinking. However, since continuous free access to ethanol rarely induces dependence, we used an intermittent access 2-bottle choice model to better mimic excessive alcohol consumption. As FGF21 is also induced by sugar intake, we tested whether TGR5 deficiency alters FGF21-mediated sugar preference similar to alcohol. **Methods:** 3 different cohorts of chow diet-fed female WT and *TGR5*$^{-/-}$ mice were subjected to 2-bottle choice paradigm with intermittent access to either 10% ethanol (cohort 1, intermittent alcohol choice, IAC), 1% sucrose (cohort 2, intermittent sugar choice, ISC) and 10% ethanol & 1% sucrose combined (cohort 3, intermittent sugar-alcohol choice, ISAC) along with continuous water access for 4 weeks. Upon termination, metabolic, central reward seeking, and inflammatory pathways in the liver and brain were assessed. **Results:** Under IAC, the *TGR5*$^{-/-}$ mice exhibited reduced alcohol consumption and preference compared to WT mice. During ISC, *TGR5*$^{-/-}$ mice initially increased sucrose intake but later declined towards WT drinking levels. In ISAC, the combined ethanol-sucrose consumption was also reduced in *TGR5*$^{-/-}$ mice. Calorie intake from food was reduced in all *TGR5*$^{-/-}$ cohorts with a decreasing trend in the calorie intake from ethanol in IAC. Surprisingly, the calorie intake from sucrose was increased in ISC *TGR5*$^{-/-}$ mice, which showed no change when combined with ethanol (ISAC). Across all cohorts, hepatic *Fgf21* gene expression was significantly increased in *TGR5*$^{-/-}$ mice. Dopamine receptor D1 (*Drd1*), classically associated with positive reinforcement and reward, was decreased in *TGR5*$^{-/-}$ mice of both IAC and ISAC cohorts but not in the ISC group. This may indicate that FGF21-mediated suppression of sugar intake in *TGR5*$^{-/-}$ mice occurs through dopamine-independent pathways. **Conclusion:** Collectively, the persistence of elevated hepatic *Fgf21* with reduced alcohol and sugar preference in *TGR5*$^{-/-}$ mice across all the paradigms TGR5-regulated liver-brain signaling. The molecular mechanism directing TGR5-FGF21 interaction is under investigation which will represent TGR5 as a druggable receptor to induce FGF21-mediated regulation of alcohol use disorder.

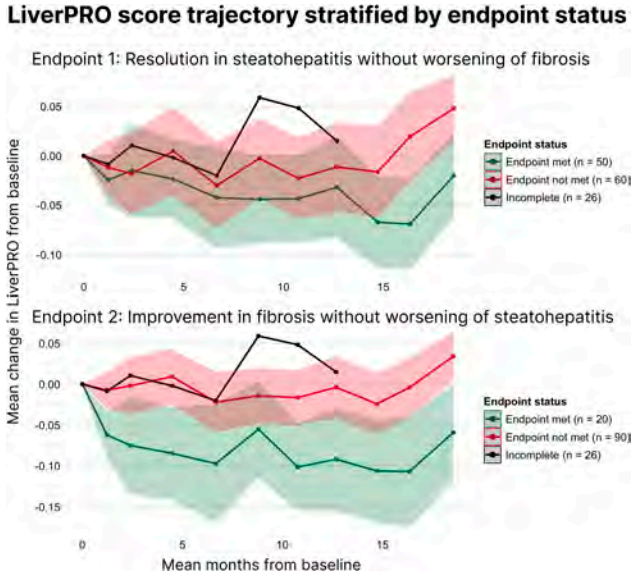
3003 | ◆ LIVERPRO AS A NON-INVASIVE MARKER OF HISTOLOGICAL RESPONSE TRAJECTORIES IN STEATOTIC LIVER DISEASE



Julie Astono[1] *Nikolaj Torp*[2] *Stine Johansen*[3] *Camilla Hansen*[3] *Sönke Detlefsen*[4] *Peter Andersen*[3] *Johanne Hansen*[3] *Katrine Thorhauge*[3] *Katrine Lindvig*[1] *Morten Karsdal*[5] *Maja Thiele*[1] *Aleksander Krag*[6] *Mads Israelsen*[3], [1]*Evido Health, Copenhagen, Denmark,* [2]*Center for Liver Research, Odense University Hospital, Denmark,* [3]*Liver Research Center, Odense University Hospital, Denmark,* [4]*Department of Pathology, Odense University Hospital, Odense, Denmark,* [5]*Nordic Bioscience Biomarkers and Research, Herlev, Denmark,* [6]*Liver Research Center, Odense University Hospital, Denmark*

Background: Non-invasive tests (NITs) for the assessment of treatment response are essential for clinical trials and treatment of patients with steatotic liver disease (SLD). We evaluated four different NITs as markers of histological endpoints in patients with a current or previous alcohol overuse. **Methods:** We conducted a post-hoc analysis in participants from the phase II GALA-Rif trial randomized (1:1) to 18-months of rifaximin-α or placebo. We pooled all participants and evaluated the regulatory required histological endpoints in MASH trials: 1) resolution in steatohepatitis without worsening of fibrosis, 2) improvement in fibrosis without worsening of steatohepatitis. Associations between histological endpoints and changes in LiverPRO, VCTE, PRO-C3, and FIB-4 from baseline to end-of-study (EOS) were assessed using ANCOVA adjusted for baseline values and treatment assignment. LiverPRO is a flexible blood-based NIT for liver fibrosis risk assessment with scores ranging from 0.0-1.0. **Results:** The study randomized 136 participants of whom 108 completed the study per protocol. 110 had biopsy at EOS and were therefore included. 26 had incomplete

data to determine endpoint status. 84% were male, median age 60 years (IQR 55-66) and BMI 29.4 kg/m^2 (25.8-32.6). Endpoint 1 was met by 50 patients (45%), 20 (18%) met endpoint 2, and 18 (16%) met both endpoints. Of the 110 patients, LiverPRO was processable in 107, VCTE was available in 107, PRO-C3 in 106, and FIB-4 in 90. Achievement of histological endpoints was associated with lower LiverPRO values at EOS. Participants meeting endpoint 1, endpoint 2, or both endpoints had significantly lower LiverPRO values compared with non-responders (endpoint 1: $\beta = -0.07$; endpoint 2: $\beta = -0.10$; both endpoints: $\beta = -0.10$). The three other NITs likewise showed statistically significant decreases in participants meeting endpoint 1, endpoint 2 and both endpoints compared with non-responders. VCTE) endpoint 1: $\beta = -5.46$; endpoint 2: $\beta = -3.85$; both endpoints: $\beta = -3.78$. PRO-C3) endpoint 1: $\beta = -2.88$; endpoint 2: $\beta = -3.64$; both endpoints: $\beta = -2.50$. FIB-4) endpoint 1: $\beta = -0.62$; endpoint 2: $\beta = -0.57$; both endpoints: $\beta = -0.53$LiverPRO demonstrated distinct trajectories according to endpoint status. Participants meeting endpoints showed a decrease from baseline during the first month, followed by continued decline until ~6 months then stabilisation until an incline at EOS. While non-responders also showed an initial decrease but subsequently a more variable trajectory until increase at EOS. VCTE, PRO-C3, and FIB-4 had only 2-3 repeated measurements, limiting trajectory analysis. **Conclusion:** LiverPRO demonstrated dynamic longitudinal changes associated with histological improvement over time in individuals with SLD and alcohol history. These findings support LiverPRO as a promising non-invasive tool for assessing treatment response and disease progression in alcohol-related liver disease trials.

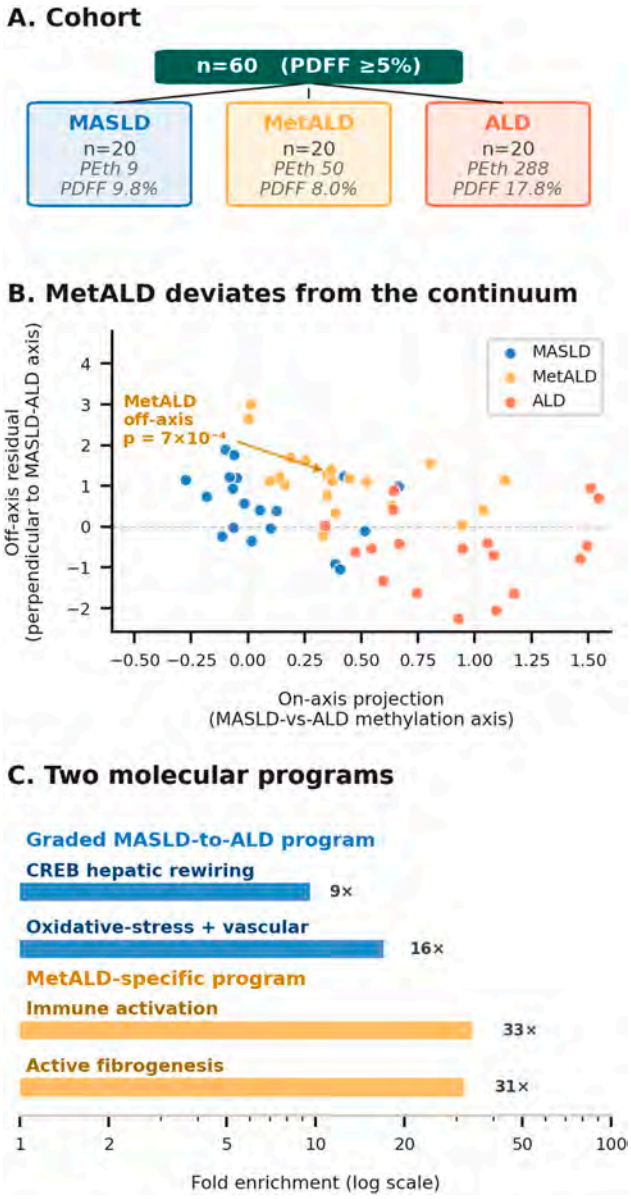
3004 | ◆ PLASMA CELL-FREE DNA METHYLATION RESOLVES THREE MOLECULAR SUBTYPES OF STEATOTIC LIVER DISEASE AND REVEALS METALD AS BIOLOGICALLY DISTINCT FROM A MASLD-TO-ALD CONTINUUM



Rohit Loomba[1] Soheil Damangir[2] Egbert Madamba[1] Seema Singh[1] Chong Lu[2] Amin Naghdloo[2] Leila Bazargan[2] Hamed Amini[2], [1]University of California, San Diego, [2]Hepta Bio, Inc.

Background: The 2023 AASLD multi-society nomenclature created MetALD as a mixed metabolic-and-alcohol category of steatotic liver disease (SLD) by alcohol-exposure thresholds, but whether MetALD carries its own molecular biology or only a clinical-history label remains unresolved. Subtype assignment relies on patient-reported alcohol history; no blood test molecularly characterizes these categories. We tested whether plasma cfDNA methylation can resolve this. **Methods:** Sixty patients with hepatic steatosis (MRI-PDFF $\geq$5%) were classified as MASLD (n = 20), MetALD (n = 20), or ALD (n = 20) using phosphatidylethanol (PEth) thresholds aligned with AASLD-2023 categories. Plasma cfDNA whole-methylome sequencing was processed with LiquidTransformer. We tested for an ordinal MASLD-MetALD-ALD methylation gradient with sequential adjustment for age, sex, BMI, and MRI-PDFF. We also tested whether MetALD methylation carries biology distinct from a MASLD-to-ALD continuum using a half-split projection test with permutation calibration. All reported results were significant at $p < 0.01$. **Results:** The population had a mean age 52 ± 12 years; BMI 33 ± 3 kg/m²; 40% female. PEth cleanly separated classes (medians 9, 50, 288 ng/mL); MRI-PDFF was higher in ALD (median 17.8%) than MASLD (9.8%) or MetALD (8.0%).Regions changing across the gradient enriched for hepatic lipid handling (FGF21, ANGPTL4, LIPC), xenobiotic metabolism (ADH4, CES2, BCHE), and hepatocyte tissue identity. After adjusting for level of steatosis, the signal shifted to the canonical alcohol-injury response: CREB-driven rewiring of the hepatic fed/fasted transcriptional program (10 CREB-target genes; CREB Q3 and CREB 02 motifs), oxidative-stress defense (CAT), and sinusoidal vascular destabilization (BDKRB2, ANGPT2), an alcohol-specific signal beyond steatosis severity.The regions best discriminating MASLD from ALD

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

define a methylation axis. MetALD samples were significantly deviated from this MASLD to ALD axis. Regions distinguishing MetALD from the MASLD to ALD continuum were enriched for immune activation (CD40, IFNA13, TPO, IL16) and active fibrogenesis (periostin/POSTN). **Conclusion:** Plasma cfDNA methylation distinguishes MASLD, MetALD, and ALD through two molecularly distinct signatures: a graded MASLD-to-ALD signature dominated by hepatic metabolism that resolves to the canonical alcohol-injury response after steatosis adjustment; and a MetALD-specific immune-fibrotic signature absent from this continuum. This is the first molecular characterization of MetALD as biologically distinct from a MASLD-to-ALD continuum, and identifies plasma cfDNA methylation as an objective subtyping tool complementing patient-reported alcohol history, showing the need for a precision approach to SLD management and positioning cell free DNA methylation as noninvasive readout of SLD molecular state.

Health + Hospitals Elmhurst / Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai, [3]Montefiore Einstein College of Medicine

Background: Alcohol use disorder (AUD) is a leading cause of liver-related hospitalization in the United States.[1] Despite strong evidence that medications for AUD (MAUD) reduce hospital readmissions, MAUD remains underutilized.[2-4] Prior electronic medical record (EMR)-based interventions have increased MAUD initiation.[5-6] We evaluated the impact of an EMR-based intervention on MAUD prescribing in hospitalized patients on CIWA protocol. **Methods:** We conducted a retrospective pre-post quality improvement study of hospitalized patients admitted on CIWA protocol from March 2024 to March 2026 at an academic medical center. An EMR-based intervention, proposed by internal medicine and supported by hepatology, launched in March 2025 and consisted of: 1) a modified inpatient CIWA order set with oral naltrexone and acamprosate orders, 2) a best practice advisory for MAUD initiation prior to discharge, and 3) a discharge order set with oral naltrexone and acamprosate prescriptions and specialty referral. Providers were educated on MAUD best practices. Rates of inpatient orders and discharge prescriptions were tracked for one year post-intervention. Demographics, comorbidities, and clinical variables associated with MAUD prescribing were analyzed using chi-square and t-tests. ChatGPT was used solely for language editing and improving conciseness. **Results:** A total of 2,058 CIWA-associated admissions were analyzed. Following implementation, inpatient MAUD initiation increased from 1.7 to 4.4% ($p < 0.001$) and discharge MAUD prescriptions increased from 5.0 to 11.7% ($p < 0.001$). Both increases were primarily driven by naltrexone. Patients aged 40–65 had the highest MAUD prescribing rates (9.7%, $p = 0.018$), with no significant difference by sex ($p = 0.889$). There were no significant differences in AST (65.7 vs 71.0 U/L, $p = 0.689$), ALT (44.7 vs 51.1 U/L, $p = 0.654$), or hospital length of stay (6.31 vs 6.30 days, $p = 0.986$) between patients who did and did not receive MAUD. The increase in prescribing was sustained over the post-intervention year. Importantly, cirrhosis diagnosis and comorbidities were not associated with lower MAUD prescribing rates. **Conclusion:** An EMR-based intervention was associated with a significant increase in MAUD prescribing among hospitalized patients with AUD. Despite improvement, prescribing rates remained low, highlighting persistent barriers to inpatient MAUD initiation. The lack of significant differences in cirrhosis and other comorbidities between the pre- and post-intervention groups suggests the increase was not driven by changes in patient complexity or liver disease severity. Further studies are needed to better understand age-related differences and other barriers to treatment initiation. EMR-based interventions are scalable, low-cost strategies to improve evidence-based care in hospitalized patients with AUD.

Table 1. Impact of EMR-Based Intervention and Characteristics Associated With MAUD Prescribing

Characteristics Associated With MAUD Prescribing				
Variable	Category/Group	No MAUD given n (%) or Mean ± SD	MAUD given n (%) or Mean ±SD	p-value
Age Category	<40 years	502 (90.9%)	50 (9.1%)	0.018
	40-65 years	963 (90.3%)	103 (9.7%)	
	>65 years	417 (94.8%)	23 (5.2%)	
Sex	Male	1338 (91.4%)	126 (8.6%)	0.889
	Female	544 (91.6%)	50 (8.4%)	
AST	Mean ± SD	71.0 ± 162.4	65.7 ± 89.4	0.689
ALT	Mean ± SD	51.1 ± 181.5	44.7 ± 102.0	0.654
Length of Stay (days)	Mean ± SD	6.30 ± 9.62	6.31 ± 6.03	0.986
Comorbidities	Cardiovascular	99 (5.3%)	5 (2.8%)	0.161

Background: Patients with alcohol-associated cirrhosis (AAC) are highly vulnerable to infection-triggered sepsis and progression to septic shock. Alcohol-induced gut microbial dysbiosis linked microbial metabolites may contribute to immune dysregulation, exaggerated inflammatory responses, and multi-organ failure. We studied the role of gut-derived microbial metabolites in immune dysregulation in genesis of septic shock. **Methods:** Untargeted metabolomic/metaproteomic of plasma, stool, and neutrophils from healthy (n = 50), non-septic AAC (n = 50), and septic-shock patients (n = 100) identified hippurate as shock-associated microbial metabolite validated in independent AAC cohort (n = 250), benchmarked for outcome stratification. Alcohol-induced gut microbiota–mediated benzoate-to-hippurate metabolism was evaluated in AAC patients and NIAAA mice model. Functional studies for hippurate mediated inflammation with/without PS1145 (TLR-inhibitor) in primary neutrophils, HepG2, HUVECs, and NIAAA mice model was studied, and the efficacy of plasma exchange (plex) in reducing systemic hippurate levels was evaluated in AAC patients. **Results:** Stool metaproteome and plasma metabolome analyses identified > 278 bacterial species and > 293 metabolites specific to septic shock ($p < 0.05$), including Vibrio parahaemolyticus, Staphylococcus aureus and others, converging on a benzoate-hippurate inflammatory axis (FC > 2, $p < 0.05$). Integrated omics cross correlation analysis identified hippurate as the top predictor (FC > 25, $r^2 > 0.89$, $p < 0.05$, AUC > 0.9), validated in an independent cohort (AUC > 0.95; Cox-HR > 3), outperforming SOFA/MELD scores. Plasma hippurate > 415uM segregated Non-survivors (log-rank < 0.02). Alcohol-driven microbiome activity enhanced metabolites and linked enzymes for phenylalanine to benzoate conversion (FC > 1.5, $p < 0.05$) in septic shock patients, further validated in the plasma, stool, intestine and liver of NIAAA mice model. Plasma benzoate/hippurate levels correlated with impaired clearance (AKI > grade2/3). Hippurate at shock-associated concentrations (> 415µM) triggered TLR-mediated neutrophil activation, ROS generation, and degranulation, while promoting hepatic and endothelial inflammatory and oxidative responses ($p < 0.05$); these effects were further amplified in the presence of LPS ($p < 0.05$). TLR inhibition with PS1145 attenuated these responses showing therapeutic validation, while plex significantly reduce circulating hippurate levels, supporting both PS1145 and plex as potential therapeutic strategies for AAC patients. **Conclusion:** Alcohol induced Microbiome drive hippurate accumulation and induces septic shock in AAC via TLR-mediated neutrophil dysfunction and hyper-inflammation. Its diagnostic value and attenuation by PS1145 or plasma exchange highlight a targetable microbiome-neutrophil therapeutic axis.

Legend: Gut-derived Hippurate Pathway and Neutrophil Activation in Shock.

In shock patients, gut dysbiosis promotes the conversion of phenylalanine to benzoic acid. Once in circulation, benzoic acid is metabolized by the liver enzyme GLYAT into hippuric acid. Due to impaired kidney clearance, hippuric acid accumulates and binds to Toll-like Receptors (TLRs) on neutrophils. This triggers excessive ROS production and degranulation, leading to systemic organ injury and shock. The inhibitor PS1145 blocks TLR signaling, reducing this hyper-inflammatory immune response. This pathway represents a potential therapeutic target for mitigating neutrophil-mediated organ damage during shock.

3007 | ◆ CHRONIC ETHANOL FEEDING DRIVES GUT MICROBIOME REMODELING AND INFLUENCES CHOLESTATIC LIVER INJURY IN MICE

Jenna Copes[1] Xiao-Ming Yin[1] Shengmin Yan[1], [1]Tulane University School of Medicine

Background: Alcohol-associated liver disease (ALD) is a leading cause of liver-related mortality worldwide and includes a spectrum of disorders ranging from steatosis to cirrhosis and alcohol-associated hepatitis (AH). AH is commonly accompanied by cholestasis, defined by impaired bile flow or bile acid homeostasis. Although accumulating evidence links ALD progression, cholestatic injury, and gut microbiome dysbiosis, the functional role of the gut microbiome in alcohol-associated cholestasis remains unclear. This study investigated the contribution of gut microbiome alterations to ALD

progression and cholestatic liver injury. **Methods:** Mice were subjected to chronic ethanol (EtOH) feeding or pair feeding for 4 weeks. Fecal samples were collected at 10 days and 4 weeks for shotgun metagenomic sequencing. To evaluate the functional impact of microbiome alterations, cecal contents from male mice after 4 weeks of EtOH or pair feeding were used for fecal microbiota transplantation (FMT). Recipient mice received an antibiotic-containing control diet for 5 days during liquid diet acclimatization, followed by 10 days of EtOH feeding with oral gavage of FMT from EtOH-fed or pair-fed donors every other day. Forty-eight hours before sacrifice, mice were challenged with ANIT at 25 mg/kg to induce cholestatic liver injury. Liver injury, cholestasis, and inflammation were evaluated by biochemical and histological analyses. **Results:** EtOH feeding, but not pair feeding, produced time-dependent changes in the gut microbiome. While ANIT induced only mild cholestatic liver injury in 10-day EtOH-fed female mice in previous experiments, FMT from 4-week pair-fed donors unexpectedly exacerbated liver injury in both male and female EtOH-fed recipient mice. This was evidenced by increased markers of hepatocellular injury, cholestasis, and hepatic inflammation. In contrast, FMT from EtOH-fed donors did not significantly alter liver injury compared with non-FMT controls. **Conclusion:** EtOH exposure is the major factor driving gut microbiome alterations in this model. Moreover, the microbiome established after chronic EtOH feeding may represent an adaptive response that protects against additional cholestatic insults. These findings highlight a complex, context-dependent role of the gut microbiome in alcohol-associated cholestatic liver injury.

3008 | ◆ PHOSPHATIDYLETHANOL POSITIVITY IDENTIFIES UNREPORTED ALCOHOL USE AND IS ASSOCIATED WITH ADVERSE OUTCOMES IN PATIENTS BEING EVALUATED FOR LIVER TRANSPLANTATION

Madeleine Hu[1] Courtney Sherman[1] Aryana Far[1] Jin Ge[1] Jennifer Lai[1] Michael Li[1], [1]University of California, San Francisco

Background: Phosphatidylethanol (PEth) is a highly sensitive and specific biomarker for detection of recent alcohol use. While its use is increasingly widespread in clinical hepatology, there is limited data on the influence of PEth results on outcomes in patients being evaluated for liver transplantation. **Methods:** We extracted all available PEth results from patients enrolled in the FrAILT study, a prospective cohort study of individuals undergoing evaluation for liver transplantation at the University of California San Francisco. Starting in mid-2022, all subjects underwent PEth testing at the outset of transplant evaluation, then received routine testing at pre-specified toxicology screening intervals based on assessment of risk. The primary outcome was the time to first occurrence of an adverse pre-transplant event (death, declined for listing, delisting, or deactivation). The Fine Gray model was used to create a cumulative incidence curve for transplant outcomes. Competing risks regression (with transplant as a competing outcome) was used to adjust for potential confounders. **Results:** Of 1,345 patients who received at least one PEth test, 65 (4.8%) had a positive PEth at their initial pre-transplant evaluation, with a median PEth 16:0/18:1 of 75 ng/dL (SD 210.1). 14 (22%) patients with a positive initial PEth did not have alcohol documented as a contributor to their liver disease. Similarly, 78 (5.8%) patients had a positive PEth on routine testing after initial transplant evaluation; 19 of which (24%) did not have alcohol listed as a liver disease etiology. 81% (n = 93) of patients with a positive PEth at any time prior to transplant experienced an adverse pre-transplant event, as compared to 56% (n = 687) of patients without a positive pre-transplant PEth. The cumulative incidence of adverse pre-transplant events at one year was 59% in those with positive PEths and 28% in those with negative PEths. After adjusting for age and MELD at time of initial transplant evaluation, positive PEth remained significantly associated with adverse pre-transplant outcomes (Figure 1; SHR 2.1, 95% CI 1.6 - 2.8, $p < 0.001$). Rate of being declined for listing was higher in individuals with positive PEths at initial evaluation as opposed to those with subsequent positive PEths (56% vs 44%, RR = 0.92, $p = 0.75$), whereas rate of delisting or listing removal/deactivation for psychosocial reasons was higher in the latter group (19% vs 81%, RR = 3, $p = 0.01$). **Conclusion:** PEth is a highly sensitive marker for alcohol use and can be used to identify unreported alcohol use; over 20% of patients who had positive PEths while being considered for transplant did not have alcohol listed as a contributor to their liver disease. Individuals found to have positive PEth results during the transplant evaluation process were significantly more likely to experience adverse pre-transplant events such as death, being declined for listing, or removal or deactivation from the waitlist.

★ 3009 | ◆ AUTOPHAGY REPORTER LC3B MICE ARE PROTECTED FROM ALCOHOL-INDUCED LIVER INJURY THROUGH SUPPRESSION OF ADIPOSE LIPOLYSIS

Ahmed Bakheet[1] Murugadas Anbazhagan[1] Robert Judd[1] Sieun Yoo[1] Paul Thomes[1], [1]Auburn University

Background: Alcohol-associated liver disease (ALD) is driven in part by adipose–liver crosstalk, where alcohol-induced adipose lipolysis elevates circulating free fatty acids (FFAs) and promotes hepatic steatosis and hepatocellular injury. LC3B-based autophagy reporter mice, widely used to monitor autophagic flux, express fluorescent LC3B fusion proteins resulting in LC3B overexpression; however, the physiological impact of LC3B overexpression during chronic alcohol exposure remains unknown. Given the central role of LC3B in autophagy regulation and lipid homeostasis, we investigated whether LC3B reporter mouse models exhibit altered susceptibility to alcohol-induced adipose dysfunction and liver injury. **Methods:** Male and female Wild-type (WT) and two independent LC3B-overexpressing reporter strains, CAG-EGFP-RFP-LC3B (Jackson Laboratory) and GFP-LC3B (RIKEN), were subjected to chronic-binge ethanol feeding. Inguinal white adipose tissue (iWAT) explants were analyzed ex vivo for lipolysis by glycerol release. Hepatic steatosis was assessed by blinded histopathologic scoring of H&E-stained liver sections, and liver injury was evaluated by serum alanine aminotransferase (ALT) levels. Hepatic hormone-sensitive lipase (HSL) activation and adipose/liver PPARα expression were measured by immunoblotting and qPCR. **Results:** Compared with ethanol-fed WT mice, ethanol-fed male CAG-EGFP-RFP-LC3B mice exhibited ~2-fold lower adipose lipolysis, measured by glycerol release from iWAT explants. Ethanol-fed CAG-EGFP-RFP-LC3B mice of both sexes also showed ~2-fold reduced hepatic steatosis and significantly lower serum ALT levels (2.7-fold in males; 1.6-fold in females) relative to ethanol-fed WT mice. In WT female mice, ethanol increased hepatic pHSL/HSL, whereas this response was absent in ethanol-fed CAG-EGFP-RFP-LC3B females. In adipose tissue, ethanol-fed CAG-EGFP-RFP-LC3B mice exhibited ~2-fold higher PPARα mRNA expression compared with ethanol-fed WT mice, while hepatic PPARα expression remained unchanged between genotypes. Similarly, ethanol-fed female GFP-LC3B mice showed a ~1.6-fold reduction in ALT levels compared with ethanol-fed WT mice, with a trend toward significance ($p = 0.08$). **Conclusion:** LC3B-overexpressing autophagy reporter mice are protected against alcohol-induced adipose lipolysis, hepatic steatosis, and liver injury. These findings indicate that LC3B overexpression alters adipose–liver metabolic responses to alcohol and confers protection from liver injury, although the contribution of the reporter construct itself warrants further evaluation.

3010 | ◆ GLP-1 RECEPTOR AGONIST USE AND LIVER-RELATED OUTCOMES IN PATIENTS WITH METABOLIC AND ALCOHOL-RELATED LIVER DISEASE

Karim Besir[1] Don Rockey[1], [1]Medical University of South Carolina (MUSC)

Background: Metabolic and alcohol-related liver disease (MetALD) is increasingly recognized as a major contributor to liver-related morbidity and mortality, with limited therapies available despite the substantial burden of hepatic decompensation and liver-related complications associated with the disease. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

demonstrated favorable metabolic effects and have recently shown potential benefit in steatotic liver disease; however, their impact in patients with MetALD is not well understood. **Methods:** We performed a retrospective cohort study using the TriNetX Global Collaborative Network, including adult patients with MetALD between 2010 and 2026. MetALD was defined as alcohol-related liver disease in the presence of at least one metabolic risk factor, including type 2 diabetes mellitus (T2D), obesity, hypertension, or dyslipidemia. Patients receiving GLP-1 RAs were compared with patients not receiving GLP-1 RAs. The index event was defined as the first GLP-1 RA prescription occurring after the diagnosis of MetALD. Outcomes were assessed beginning 90 days after the index event to reduce early event misclassification. Propensity score matching was performed for demographics, comorbidities, medications, and baseline laboratory values. Outcomes included ascites, hepatic encephalopathy (HE), portal hypertension, esophageal variceal bleeding (EVB), hepatorenal syndrome (HRS) and all-cause mortality. **Results:** Before propensity score matching, 11,711 patients receiving GLP-1 RAs and 300,642 patients without GLP-1 RA exposure were identified. After propensity score matching, 6,190 patients remained in each cohort. The matched population had a mean age of 57 years, was predominantly male (66%) and White (71%), and, as expected, had a high prevalence of cardiometabolic risk factors and alcohol-related liver disease. GLP-1 RA use was associated with significantly lower risks of ascites, HE, portal hypertension, EVB, and HRS compared with no GLP-1 RA use **(Table 1):** . GLP-1 RA use was also associated with a significantly lower risk of all-cause mortality compared with no GLP-1 RA use (9% vs 28%: HR 0.41, $p < 0.001$). In addition, patients receiving GLP-1 RAs demonstrated lower rates of positive alcohol-related biomarkers, including ethanol and phosphatidylethanol (PEth), compared with patients not receiving GLP-1 RAs (HR 0.81, $p = 0.043$). **Conclusion:** Among patients with MetALD, GLP-1 RA use was associated with significantly lower risks of hepatic decompensation and mortality. The mechanism of this effect is likely multifactorial, but one possibility is that GLP-1 RA use may be associated with reduced ETOH consumption.

Table 1. Clinical Outcomes After Propensity Matching

Outcome	GLP-1 RA (n, %)	No GLP-1 RA (n, %)	HR	p-value
Ascites	428/4,807 (9)	557/4,033 (14)	0.78	<0.001
Hepatic encephalopathy	327/5,518 (6)	472/5,391 (9)	0.84	<0.001
Esophageal variceal bleeding	95/5,960 (1.6)	125/5,900 (2)	0.93	0.003
Portal hypertension	405/4,491 (9)	597/4,038 (15)	0.70	<0.001
Hepatorenal syndrome	119/6,006 (2)	278/5,803 (5)	0.51	0.001
All-cause mortality	527/6,083 (9)	1567/5,667 (28)	0.41	<0.001

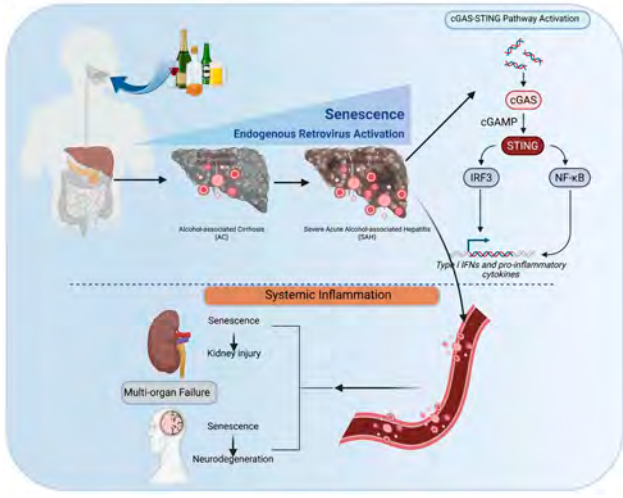
3011 | ◆ TARGETING PEPTIDYL-PROLYL CIS-TRANS ISOMERASE NIMA-INTERACTING 1 (PIN1)–METHIONINE ADENOSYLTRANSFERASE α1/α2 INTERACTIONS PROTECTS AGAINST ETHANOL-INDUCED LIVER INJURY

Guo Zhang[1] Sibiao Su[1] Jiaohong Wang[1] Manisha Dagar[1] Lucía Barbier-Torres[1] Ramachandran Murali[1] Jyoti Chhimwal[1] sonal sinha[1] Maria Lauda Tomasi[1] Heping Yang[1] Shelly Lu[1], [1]Cedars-Sinai Medical Center

Background: Alcohol-associated liver disease (ALD) is characterized by mitochondrial dysfunction, oxidative stress, inflammation, and fibrosis. Methionine adenosyltransferase (MAT) catalyzes synthesis of the methyl donor S-adenosylmethionine (SAMe). Normal hepatocytes express MATα1 while nonparenchymal cells express MATα2. We showed MATα1 targets the mitochondria and this pool is depleted in ALD as MATα1-S114 is phosphorylated, which allows PIN1 to bind and block its mitochondrial entry, causing mitochondrial dysfunction. MATα2 is a driver of liver inflammation and fibrosis, shares the PIN1 motif but whether PIN1 interacts and affects its function in ALD is unknown. Here we examined whether pharmacologic disruption of PIN1 interaction with MATα1/MATα2 can protect from ALD. **Methods:** We used the NIAAA chronic-plus-binge ethanol (EtOH) feeding model. Eight compounds were screened for their ability to disrupt endogenous PIN1–MATα1 interaction induced by EtOH using co-immunoprecipitation (co-IP) in human hepatocytes and effects on viability, ATP, reactive oxygen species, release of alanine aminotransferase were measured. PIN1–MATα2 interaction was measured in Kupffer cells (KCs) and hepatic stellate cells (HSCs) by co-IP, immunoblotting, and immunofluorescence. Intracellular SAMe levels and MAT activity were measured using commercial kits. Liver injury, inflammation, fibrosis, and metabolic dysfunction were assessed by histology, immunohistochemistry, and biochemical analyses. **Results:** Among the eight compounds screened, compounds #4 and #7 were equally effective in disrupting PIN1– MATα1 interaction and raising MATα1 level in EtOH-treated human hepatocytes. MATα2 expression, phosphorylation, and interaction with PIN1 were all induced in KCs and HSCs isolated from NIAAA livers. Mechanistically, EtOH activated ERK, phosphorylating MATα2 and promoting PIN1 binding. Compounds #4 and #7 selectively attenuated PIN1-MATα1/α2 interaction without affecting other PIN1 substrates. In vitro EtOH treatment reduced intracellular SAMe levels and MAT activity in hepatocytes, KCs, and HSCs, all of which were attenuated by compounds #4 and #7. EtOH increased MATα2 content in the nuclei and mitochondria of KCs and HSCs, which was attenuated by compound #7 without affecting total MATα2 level. In vivo,

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient



© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

compound #7 markedly protected against EtOH-induced liver injury, steatosis, oxidative stress, macrophage infiltration, inflammatory cytokine expression, and profibrogenic gene induction, while restoring hepatic ATP and SAMe levels. **Conclusion:** The PIN1–MATα1/MATα2 axis is a major driver of EtOH-induced metabolic dysfunction and liver injury. Pharmacologic disruption of PIN1–MATα1/MATα2 restores hepatic metabolic homeostasis and suppresses inflammation and fibrosis, identifying this as a novel therapeutic approach in ALD.

3012 | ◆ HEPATOCYTE SENESCENCE ACTIVATES ENDOGENOUS RETROVIRUSES TO PROMOTE THE SYSTEMIC INFLAMMATORY RESPONSE SYNDROME AND MULTI-ORGAN FAILURE IN SEVERE ACUTE ALCOHOL-ASSOCIATED HEPATITIS

Anna Mae Diehl[1] Rajesh Dutta[1] Kuo Du[2] Niansheng Ren[1] Seh-Hoon Oh[1] Raquel Maeso-Diaz[1], [1]Duke University, [2]University of Kansas Medical Center

Background: Mortality in severe acute alcohol-associated hepatitis (SAH) results from multi-organ failure (MOF) caused by the systemic inflammatory response syndrome (SIRS). Previously, we showed that accumulation of senescent hepatocytes parallels risk for SAH mortality in humans. Reducing senescent hepatocytes improves alcohol-associated liver disease (ALD) in mice. Thus, the senescence-SIRS axis may be a novel therapeutic target in SAH. Senescent cells often express endogenous retroviruses (ERVs) that are normally repressed in healthy cells. ERVs propagate and sustain inflammation by triggering RIG-I and cGAS-STING signaling that globally up-regulates production of inflammatory cytokines and growth inhibitors. We asked whether senescent hepatocytes activate ERV expression in SAH as ERV expression can be blocked by FDA-approved drugs to provide a novel treatment for SAH. **Methods:** We analyzed bulk RNA-seq and single-nucleus RNA-seq from healthy human livers and explants with alcohol-associated cirrhosis (AC) or SAH to define ERV activation across disease states and liver cell populations. To validate HERVK induction, we assessed expression of HERVK Envelope (Env) protein by Western blotting normal and SAH liver tissues. To determine if inducing senescence activates HERVK in hepatocytes, we treated Huh-7 cells with Palbociclib and performed Western blot analysis of HERVK Env. **Results:** Compared to controls, human liver explants with AC or SAH had increased expression of several endogenous retroviral RNAs, including HERVK, HERVE, HERVL and HERVH. Consistent with this transcriptomic evidence of ERV activation, Western blotting confirmed increased HERVK Env protein expression in SAH liver tissue. Single-nucleus RNA-seq analysis validated expansion of HERVK(+) populations in diseased livers, with the greatest enrichment observed in SAH. Across liver cell populations, hepatocytes showed the highest proportion of HERVK(+) cells. HERVK(+) cells were particularly enriched with TBK1, IRF3, NFKB1 and REL, transcription factors that transduce innate immune signaling by the RIG-I and cGas-STING pathways. HERVK(+) hepatocytes localized to the hepatocyte subpopulation that was most enriched in senescent hepatocyte gene signature (SHGS) positive cells, linking ERV activation to hepatocyte senescence. Treating Huh-7 cells with Palbociclib to induce senescence increased HERVK Env protein expression, confirming that hepatocyte senescence promotes HERVK activation. **Conclusion:** Activation of endogenous retroviral elements (ERVs) in senescent hepatocytes is a feature of life-threatening alcohol-associated liver disease that may propagate and sustain the systemic inflammatory response that leads to progressive multi-organ failure. Targeting the hepatocyte senescence-ERV-SIRS axis may offer a new therapeutic approach for severe alcohol-associated liver disease.

3013 | ◆ SPHK2 DEFICIENCY DRIVES SEX-DIMORPHIC METABOLIC AND INFLAMMATORY REPROGRAMMING IN ALCOHOL-ASSOCIATED LIVER INJURY

Nan Wu[1] Grayson Way[1] Hongkun Lu[1] Derrick Zhao[1] Yun-Ling Tai[1] Chen Chen[1] Meiyi Song[1] Xuan Wang[1] Emily Gurley[1] Phillip Hylemon[1] Huiping Zhou[1], [1]Virginia Commonwealth University

Background: Alcohol-associated liver disease (ALD) exhibits prominent sex dimorphism. Sphingosine kinase 2 (SphK2) regulates sphingolipid metabolism, but its sex-specific role in alcohol-induced liver injury remains unclear. We evaluated how SphK2 deficiency modulates phenotypic, metabolic, and transcriptomic responses to ethanol in both sexes. **Methods:** Male and female WT and SphK2 knockout (KO) C57BL/6J mice (24 weeks old; n = 3-5/group) underwent the NIAAA chronic-binge model (10-day ethanol/control diet plus binge). Phenotypes included body weight and body weight change, liver/body weight (LW/BW) ratio, histology, and liver/serum triglycerides (TG) and cholesterol (Chol). Hepatic transcriptomes were analyzed by RNA-seq and Ingenuity Pathway Analysis (IPA). **Results:** Alcohol upregulated hepatic SphK2 in WT mice, suggesting SphK2 is part of the hepatic adaptive response to ethanol. Under alcohol stress, WT mice gained weight, whereas KO mice showed blunted weight gain or weight loss, increased LW/BW ratio, and worse steatosis. Biochemically, KO males had elevated hepatic Chol/TG with reduced serum Chol/TG, whereas KO females had increased hepatic TG and reduced serum Chol. IPA of ethanol-fed KO versus WT livers revealed shared KO stress signatures: EIF2 signaling (female z = +2.67; male z = +2.50), acute-phase response (female z = +1.61; male z = +1.57), and MYC activation (female z = +4.08; male z = +4.36), consistent with translational stress, inflammatory adaptation, and altered hepatic growth/metabolic programs. Downstream signatures diverged by sex. Females showed IL-1 (z = +2.31) and IL-6 signaling (z = +2.67), with anabolic signaling via MLXIPL/ChREBP (z = +3.70), SCAP (z = +2.94), and cholesterol biosynthesis (z = +2.83), plus macrophage alternative activation (z = +1.80) and fibroblast IL-17A signaling (z = +2.89). Males showed upstream IL1B (z = +2.21) and IL6 (z = +2.42) activation with NF-kB signaling (z = +1.71), phagosome formation (z = +3.35), complement cascade (z = +2.89), NET signaling (z = +2.04), LPS/IL-1-mediated RXR inhibition (z = +1.67), and hepatocyte proliferation (z = +2.14). **Conclusion:** SphK2 deficiency promotes hepatic lipid retention and amplifies ethanol-associated stress responses in a sex-dependent manner. Both sexes share EIF2/acute-phase/MYC activation, but female KO mice preferentially display lipid/cholesterol anabolic and stromal immune signatures, whereas male KO mice exhibit IL1B/IL6-associated inflammatory injury-repair remodeling, innate immune clearance, RXR suppression, and hepatocyte proliferation. These findings identify SphK2 as a sex-dependent regulator of metabolic and inflammatory adaptation in alcohol-associated liver injury.

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Alcohol-associated hepatitis (AH) is an acute inflammatory presentation of alcohol-related liver disease (ALD) that often occurs with advanced liver fibrosis or cirrhosis. Because AH and decompensated alcohol-related cirrhosis may overlap clinically, biomarkers capturing acute injury beyond chronic ALD cirrhosis can help the diagnosis of AH and understanding its pathogenesis. As hepatocyte-derived very low-density lipoprotein (VLDL) particles carry lipid cargo only from liver cells, their per-particle composition may capture disease-specific information. We aimed to determine whether untargeted, particle-normalized VLDL lipidomics identifies lipid-class and acyl-chain signatures distinguishing AH from cirrhosis. **Methods:** VLDL plasma fractions from patients with AH (n = 66) and ALD cirrhosis (n = 59) underwent untargeted LC-MS lipidomics. Signal drift was corrected by LOESS, and abundances were normalized to VLDL particle number. Differential abundance of lipids in positive and negative ESI modes was tested using Limma; significant species were defined by FDR < 0.05 and $|Log_2FC| > Log_2(1.25)$. Lipid set enrichment analysis combined Kolmogorov-Smirnov and fgsea algorithms. Structurally aware acyl-chain remodeling was assessed using easyLSEA. **Results:** VLDL carries a distinct lipidome compared to low density lipoprotein (LDL), high density lipoprotein (HDL) or bulk plasma (FIG 1A). Across both ESI modes, 439 unique lipid species met combined significance and effect-size thresholds (FDR < 0.05 and |log2FC| > log2[1.25]), with 21 species independently confirmed in both modes, providing cross-ionization validation. Cirrhosis-enriched species predominated in positive mode (123 vs 57), whereas AH-enriched species predominated in negative mode (188 vs 92), indicating that single-mode profiling substantially underestimates AH-associated lipid dysregulation (FIG 1B). AH was characterized by enrichment of triacylglycerols, ceramides, diacylglycerols, short-chain acylcarnitines (C2:0–C4:0), saturated short-chain phosphatidic acids (C8:0–C13:0), oxylipins ($FDR = 1.3\times10^{-7}$), and conjugated bile acids ($FDR = 2.6\times10^{-7}$), supporting steatotic, mitochondrial, oxidative, and cholestatic lipid stress. In contrast, cirrhosis was characterized by robust SM and PC enrichment across modes, plus PUFA-containing PC, PI, and PE remodeling with unsaturated sn-2 chains including C18:2, C20:4, and C22:6, consistent with chronic membrane lipid remodeling. **Conclusion:** AH and cirrhosis show distinct particle-normalized VLDL lipidomic fingerprints, reflecting acute oxidative/cholestatic lipid stress versus chronic membrane remodeling. AH-enriched oxylipins, conjugated bile acids, and short-chain lipid species, together with cirrhosis-enriched SM/PUFA-glycerophospholipid remodeling, warrant validation as candidate non-invasive biomarkers in severe ALD.

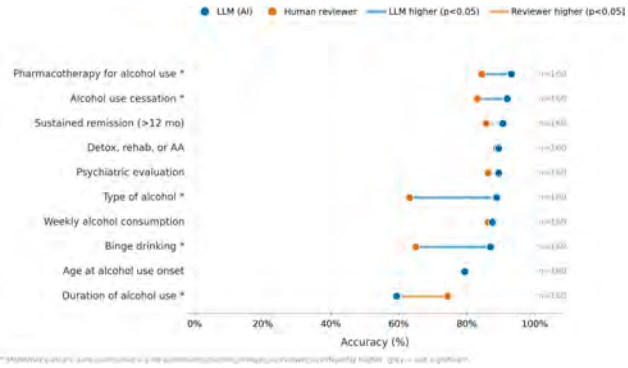
3015 | ◆ LARGE LANGUAGE MODEL PIPELINE FOR EXTRACTION OF LONGITUDINAL ALCOHOL USE FROM ELECTRONIC HEALTH RECORDS MATCHES OR EXCEEDS MANUAL CHART REVIEW



Yigit Yazarkan[1] Alberto Calleri[1] Federico Mastroleo[2] Diego Durmond Westgeest e Sousa[1] Kamalpreet Hara[1] Victoria Kusztos[3] Miguel Gomez[3] Gabriel Prusch Fernandes[4] Mark Waddle[2] Tiffany Wu[1] Patrick Kamath[1] Vijay Shah[1] Douglas Simonetto[1], [1]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, [2]Department of Radiation Oncology, Mayo

Clinic, Rochester, [3]Department of Internal Medicine, Mayo Clinic, Rochester, [4]Department of Internal Medicine, Montefiore Medical Center, New York

Background: Longitudinal alcohol use assessment from medical records requires labor-intensive chart review across years of unstructured documentation, limiting registry and observational research in alcohol-associated liver disease (ALD). Conventional NLP has historically struggled with the temporal and narrative complexity of alcohol histories. Thus, we developed and validated a large language model (LLM) pipeline for automated extraction of longitudinal alcohol use phenotypes from EHR notes, benchmarked against trained reviewers. **Methods:** A cohort of 160 patients with ALD was assembled from the Mayo Clinic data lake (BigQuery), sampled to reflect the temporal distribution of ALD diagnoses from 1995–2022. Notes were converted to structured JSON and processed by a prompt-engineered, HIPAA-compliant Gemini 2.5 Flash, developed iteratively on a 40-patient training subset and applied to the full cohort to extract 30 variables per patient (4,800 data points) covering demographics, ALD features, and longitudinal alcohol use (pattern, type, quantity, duration, cessation, treatment). Four reviewers each extracted 40 unique patients, with a shared 20-patient subset to assess inter-rater reliability. LLM–reviewer discrepancies were adjudicated by a blinded second reviewer to establish the reference standard against which both LLM and reviewer accuracy were scored. **Results:** Inter-rater reliability across the 4-reviewer overlap was Fleiss' $\kappa = 0.48$ (objective variables $\kappa = 0.82$; alcohol-quantification variables $\kappa = 0.38$). Overall LLM accuracy was 89.7% (95% CI 88.8–90.5): 93.6% demographics, 88.8% ALD features, 85.6% longitudinal alcohol use. Using a paired analysis with a 5% non-inferiority margin, LLM accuracy was non-inferior or superior to reviewer accuracy for 18 of 30 variables and significantly higher for 5, including type of alcohol (+25.6%; 16.1–35.2), binge drinking (+21.9%; 12.0–31.8), family history of alcohol use (+8.8%; 1.5–16.0), alcohol use pharmacotherapy (+8.8%; 1.3–16.2), and alcohol use cessation (+8.8%; 1.3–16.2). Human reviewer accuracy was significantly higher for 7 variables; the largest difference was alcohol use duration category (−15.0%; −25.4 to −4.6), with the remaining 6 differences $\leq 8.8\%$. Mean extraction time was 2.9 vs 13.8 min/patient (LLM vs manual). **Conclusion:** A prompt-engineered LLM pipeline extracted longitudinal alcohol use and ALD phenotypes with 89.7% accuracy, matching or exceeding trained reviewers on all alcohol history variables except duration, while reducing extraction time ~5-fold. Notably, poor inter-rater agreement on alcohol-quantification ($\kappa = 0.38$) suggests the LLM may add reproducibility, not just efficiency, on tasks where humans themselves disagree. The pipeline supports alcohol use phenotyping at scale.

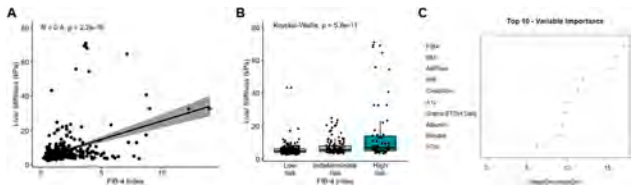
3016 | ◆ AN INTEGRATED FIB-4 AND METABOLIC MODEL OPTIMIZES FIBROSIS SCREENING IN SEVERE ALCOHOL USE DISORDER



Berenice Ramirez Leal[1] Amelia Orgill[1] Maryam Soltani[2] Heather Patton[3] Cynthia Hsu[3], [1]University of California San Diego, [2]University of California San Diego, & VA San Diego Healthcare System, [3]University of California San Diego & VA San Diego Healthcare System

Background: Screening for early detection of advanced liver disease in severe alcohol use disorder (AUD) is critical, but universal vibration-controlled transient elastography (VCTE/FibroScan) screening is resource-intensive. Fibrosis-4 (FIB-4) index is recommended for risk stratification, but its optimal implementation in AUD remains poorly defined. At the VA San Diego Substance Abuse Residential Rehabilitation Treatment Program (SARRTP), a pilot VCTE initiative

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

revealed that 5% of screened individuals had cirrhosis. However, most did not have clinically significant fibrosis (LSM ≥ 8 kPa). Here, we aim to evaluate the performance of FIB-4 index, alone or integrated with metabolic comorbidities and biochemical markers, in identifying patients at risk for elevated LSM. **Methods:** We conducted a retrospective cohort study of 601 patients with severe AUD who underwent VCTE. Random Forest machine learning analysis was utilized to extract features driving advanced fibrosis risk and identify top noninvasive predictors. Optimal thresholds were determined using Youden index optimization. Exploratory multivariable logistic regression models incorporating a FIB-4 threshold of 1.3 alongside metabolic and Random Forest-identified variables were evaluated to optimize the prediction of significant fibrosis. **Results:** In individuals with AUD, though FIB-4 index correlated with LSM by VCTE, substantial diagnostic misclassification persisted (Fig 1a). Among patients with FIB-4 ≥ 1.3, 68% had a false positive result (LSM < 8 kPa) (Fig 1b). FIB-4 cutoff of 1.3 demonstrated poor predictive performance (sensitivity 72%, specificity 62%, accuracy 64%). Random Forest analysis identified alkaline phosphatase (AP), body mass index, INR, creatinine, and hemoglobin A1c, as the top five parameters alongside FIB-4 index differentiating low and high-risk individuals (Fig 1c). Youden index optimization identified an AP threshold of 91 U/L for predicting elevated LSM. A multivariable logistic regression model incorporating a FIB-4 threshold of 1.3 alongside key clinical parameters (obesity, hypertension, diabetes mellitus, and AP) significantly enhanced diagnostic accuracy for predicting LSM ≥ 8 kPa (AUROC 0.81; 95% CI: 0.75-0.87), compared with FIB-4 threshold alone (AUROC 0.67; 95% CI: 0.62-0.73). In this multivariable analysis, elevated AP (OR 3.74, $p < 0.001$), obesity (OR 3.51, $p < 0.001$), FIB-4 ≥ 1.3 (OR 3.42, $p < 0.001$), and hypertension (OR 2.26, $p = 0.027$) were robust independent predictors of elevated liver stiffness, whereas type 2 diabetes mellitus was not significantly associated. **Conclusion:** Standard FIB-4 thresholds alone are insufficient to stratify fibrosis risk in severe AUD. Integrating metabolic comorbidities (obesity, hypertension) and AP significantly improves diagnostic accuracy (AUROC 0.81 vs 0.67), supporting a sequential screening approach to guide VCTE referral.

3017 | ◆ LIVER TRANSPLANTATION FOR ALCOHOL-RELATED HEPATITIS VERSUS ALCOHOL-RELATED CIRRHOSIS IN THE UNITED STATES FROM 2000–2025: DISEASE SEVERITY AND CLINICAL OUTCOMES

Maria Stepanova[1] Giacomo Germani[1] Adrian Gadano[1] Patrizia Burra[1] Rohit Satoskar[2] Linda Henry[1] Zobair Younossi[1], [1]The Global NASH/MASH Council, [2]Georgetown University Hospital

Background: Alcohol-related liver disease (ALD) is the most common cause of cirrhosis in the US. Within the ALD spectrum, severe alcohol-related hepatitis (AH) carries a higher short-term mortality risk compared to ALD cirrhosis (AC). We assessed trends and outcomes of liver transplantations (LT) for AH and AC in the U.S. **Methods:** Adult LT candidates and recipients with primary listing diagnoses of ALD were identified from the U.S. Scientific Registry of Transplant Recipients (SRTR) from 2000-2025. **Results:** Among 274,868 adult LT candidates, 25.4% were listed for AC and 1.7% for AH. LT listings for AC increased from 16.6% (2000) to a peak of 40.7% (2022), followed by a decline to 38.5% (2025). AH listings remained under 100 cases annually until 2018 (< 1%), then increased sharply to 3.7% (2022) and 7.5% (2025). Compared to AC, AH candidates demonstrated higher disease severity with elevated MELD scores (29.4 ± 10.4 vs. 22.7 ± 10.0), and greater life support requirement (9.0% vs. 4.5%) (all $p < 0.01$) but were of younger age (45.9 ± 11.2 vs. 52.7 ± 10.5 years), less commonly male (64.4% vs. 68.3%) with higher private insurance coverage (58.3% vs. 52.9%).Among all ALD candidates, 78.0% of AH vs. 70.2% of AC received LT ($p < 0.0001$). In addition, 4.6% of AH vs. 5.1% of AC candidates died on the list, 2.6% vs. 4.0% were removed due to deterioration, and 4.7% vs. 5.8% improved clinically. In multivariate time-to-event analysis, with LT as a competing risk, AH was independently associated with lower waitlist mortality vs. AC (aHR [95% CI] = 0.77 [0.66–0.88]). Additional independent predictors of waitlist mortality included earlier listing year, advanced age, Medicare/Medicaid coverage, higher MELD scores, life support dependence, encephalopathy, transjugular intrahepatic portosystemic shunt (TIPSS), type 2 diabetes (T2D), and hepatocellular carcinoma (HCC) ($p < 0.01$).Post-transplant survival was comparable between groups: 1-year mortality 5.1% (AH) versus 5.0% (AC), 3-year 9.2%

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

versus 10.1%, and 5-year 13.3% versus 15.9% (all $p > 0.05$). Multivariate analysis showed AH was not independently associated with post-LT mortality (aHR [95% CI] = 1.06 [0.93–1.21]). Rather, independent predictors of higher post-LT mortality included earlier transplant era, advanced age, lack of college education, Medicare/Medicaid insurance, T2D, reduced functional status, higher MELD score, HCC, encephalopathy, TIPSS, and re-transplantation ($p < 0.01$). **Conclusion:** Liver transplantations for both alcohol-related cirrhosis and alcohol-related hepatitis have expanded substantially, with particularly marked growth since 2018. Despite presenting higher disease severity at listing, patients with alcohol-related hepatitis achieved superior waitlist outcomes and comparable post-transplant survival to those with cirrhosis, suggesting appropriate patient selection and management strategies.

3018 | ◆ PREVALENCE OF CIRRHOSIS AND ALCOHOL-RELATED CONDITIONS, INCLUDING MET-ALD AND ALCOHOL-ASSOCIATED HEPATITIS, BY INSURANCE TYPE IN THE UNITED STATES, 2017–2024

Arun Jesudian[1] Arthur Voegel[2] Hannah Han[2] Fengyi Jiang[2] Patrick Gagnon-Sanschagrin[2] Annie Guerin[2] Olamide Olujohungbe[3] Aarth Sheth[3] Leonardo Passos Chaves[3], [1]Weill Cornell Medicine, [2]Analysis Group, [3]Bausch Health

Background: Cirrhosis is an increasing public health burden in the United States, with alcohol-related etiologies contributing substantially. Metabolic dysfunction-associated alcohol-associated liver disease (MET-ALD) reflects the overlap between metabolic and alcohol-related risk factors. Alcohol-associated hepatitis (AH) is a severe manifestation of alcohol-related liver disease. This study assessed recent trends in the prevalence of cirrhosis and alcohol-related conditions among patients with cirrhosis across different insurance populations. **Methods:** This retrospective observational study used administrative claims data from the Komodo Research Database (January 1, 2016–December 31, 2024), including commercially insured, Medicaid, and Medicare Advantage patients. For each calendar year (2017–2024), prevalence of cirrhosis was estimated among patients with continuous enrollment throughout the year, separately by insurance type. Among patients with cirrhosis, the annual prevalence of MET-ALD, defined by the co-occurrence of metabolic dysfunction-associated steatotic liver disease (including fatty liver) and alcohol-associated liver disease, and AH were assessed. **Results:** From 2017 to 2024, the prevalence of cirrhosis increased across all insurance types, rising from 0.21% to 0.35% in Commercial populations, from 0.77% to 1.08% in Medicaid, and from 0.99% to 1.81% in Medicare Advantage. Among patients with cirrhosis, the prevalence of MET-ALD more than doubled across all payer types, increasing from 9.12% to 21.02% in Commercial populations, from 11.96% to 30.47% in Medicaid, and from 5.16% to 14.15% in Medicare Advantage. Similarly, the prevalence of AH increased across all populations, with the highest levels consistently observed in Medicaid (11.92% to 20.55%), compared with Commercial (7.03% to 12.18%) and Medicare Advantage populations (1.62% to 3.02%) **(Figure 1). Conclusion:** Between 2017 and 2024, the prevalence of cirrhosis and alcohol-related etiologies **:** increased substantially across all insurance types in the United States. The increasing burden of alcohol-related conditions, particularly in Medicaid and commercially insured populations, highlights a growing population at risk of severe liver-related outcomes. Given the limited therapeutic options available for certain alcohol-related liver disease manifestations, including AH, these findings underscore an increasing need for improved management strategies in this population.

3019 | ◆ MECHANISTIC INSIGHTS INTO N-3 PUFA-MEDIATED ATTENUATION OF LIVER INJURY IN EXPERIMENTAL METABOLIC DYSFUNCTION-ASSOCIATED ALCOHOL-RELATED LIVER DISEASE (MET-ALD).

Irina Kirpich[1] Dennis Warner[1] Yasmeen Abdelfadil[1] Craig McClain[1] Jingzhi Wang[1], [1]University of Louisville

Background: Metabolic dysfunction-associated alcohol-related liver disease (Met-ALD) is an increasingly recognized condition in which metabolic abnormalities and alcohol consumption may synergistically worsen liver injury. Clinical evidence indicates that nearly 50% of patients with early-stage alcohol-related liver disease (ALD) have a BMI > 25 kg/m2, highlighting the strong association between excess adiposity and alcohol-induced liver damage. n3 polyunsaturated fatty acids (n3 PUFAs) have overall beneficial health effects, including anti-inflammatory, lipid-lowering, and hepatoprotective properties. The current study evaluated the therapeutic potential of endogenous n3 PUFA enrichment in experimental Met-ALD and explored the underlying molecular mechanisms. **Methods:** Male and female C57BL/6J wild-type (WT) and fat-1 transgenic mice, which endogenously produce elevated n3 PUFAs, were exposed to a 12-week high-fat diet (HFD) combined with 10% ethanol supplementation in drinking water to induce metabolic alterations and liver injury Met-ALD phenotype. Metabolic and liver injury markers, inflammatory mediators, and hepatic transcriptomic changes were evaluated. Liver RNA-seq was performed to identify differentially regulated genes, signaling pathways, and immune-cell responses. **Results:** HFD+EtOH induced progressive body weight gain in both WT and fat-1 mice, greater in males. Plasma triglyceride and glucose levels increased significantly in WT but not fat-1 female mice, while both male genotypes showed these metabolic alterations. HFD +EtOH-induced liver injury, as indicated by ALT elevation, was less in fat-1 vs WT females, whereas no genotype-dependent differences were observed in males. However, ALT levels were significantly higher in males overall, indicating sex-dependent differences in liver injury severity. Liver RNAseq analysis revealed that reduced liver injury in fat-1 mice was associated with significant down-regulation of Tnfsf19, a gene implicated in injury-associated inflammatory and stress signaling. Among the 16 up-regulated genes, several were involved in anti-inflammatory responses, tissue repair and resolution of liver injury, including Slpi, Jag2, and Gpc3. In addition, several up-regulated genes were associated with a ductular/progenitor-cell regenerative program, including Krt19. Immune-cell deconvolution analysis revealed increased macrophage infiltration and reduced T-cell signatures, particularly CD8 lymphocytes, in WT male Met-ALD mice compared with controls. **Conclusion:** Endogenous n3 PUFA enrichment in fat-1 mice attenuated liver injury in experimental Met-ALD, with stronger protective effects in females. Transcriptomic findings suggest activation of anti-inflammatory and regenerative pathways, supporting a potential therapeutic role for n3 PUFAs in Met-ALD.

3020 | ◆ CANNABIS EVER-USE IS INDEPENDENTLY ASSOCIATED WITH LOWER HEPATIC STEATOSIS IN HEAVY ALCOHOL DRINKERS: A CROSS-SECTIONAL ANALYSIS OF NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (NHANES) DATA

Calvin Tan[1] Rachan Narala[2] Brian Lee[3], [1]University of Southern California, [2]Stanford University, [3]Keck School of Medicine

Background: Alcohol-associated liver disease (ALD) is a major cause of liver-related morbidity and mortality. Cannabis use is common among individuals who drink heavily, yet its hepatic effects in this population remain understudied. Cannabinoid

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

receptors CB1 and CB2 are expressed in the liver and are implicated in lipid metabolism and inflammatory regulation, providing a plausible mechanism for cannabis-liver interactions. We evaluated the association between cannabis use and hepatic steatosis, measured by controlled attenuation parameter (CAP), in a nationally representative sample of heavy alcohol drinkers. **Methods:** We analyzed cross-sectional data from the National Health and Nutrition Examination Survey among adults aged 18-79. Heavy drinkers were defined as consuming ≥ 4 drinks/day or drinking ≥ 3 to 4 times/week. The primary exposure was cannabis ever-use. Outcomes were CAP score and severe steatosis, defined as CAP ≥ 280 dB/m. Covariates included age, sex, income, and binge drinking frequency. Income and binge drinking were converted to ordinal numeric scales for adjustment. Analyses included nonparametric testing, logistic regression, and linear regression with interaction modeling. **Results:** Among 951 heavy drinkers, 594 (62.5%) reported cannabis ever-use. Median age was 40.0 years [IQR 29-55], 638 (67%) were male, median income was 7.0 [IQR 5-11] and median binge drinking frequency was 1.0 [IQR 0-4], both on an ordinal scale. Median CAP was 267.0 dB/m [IQR 218-307.5], and 382 participants (40.2%) had severe steatosis. Cannabis users had lower median CAP than non-users (258 vs. 278; $p < 0.0001$). Severe steatosis was less common among cannabis users (36.8% vs. 48.9%; OR = 0.61, 95%CI = 0.47-0.80; $p = 0.0003$). After adjusting for age, sex, and income, cannabis ever-use remained independently associated with a lower CAP score ($\beta = -15.82$, 95%CI = -27.05 to -4.60; $p = 0.006$). Cannabis ever-use remained independently associated with lower odds of severe steatosis (OR = 0.65, 95%CI = 0.45-0.93; $p = 0.019$). After adjusting for binge drinking, the association strengthened (OR = 0.57, 95%CI = 0.40-0.83; $p = 0.003$). A significant cannabis x drinks-per-day interaction was observed ($\beta = -3.01$, 95%CI = -5.95 to -0.07; $p = 0.045$), indicating cannabis use attenuates the positive association between drinks-per-day and CAP. **Conclusion:** Cannabis ever-use is independently associated with lower CAP score and severe steatosis in heavy drinkers, with the association remaining across multiple adjustment strategies. This effect persisted after adjusting for age, sex, and income, and strengthened after accounting for binge drinking frequency. Interaction modeling suggests cannabis may weaken the relationship between daily alcohol consumption and CAP in heavy drinkers. These findings suggest a possible cannabis-liver interaction relevant to hepatic steatosis risk in heavy drinkers.

Predictor / Test	Estimate (β or OR)	SE	95% Confidence Interval	p-value
Model A - Logistic Regression: Severe Steatosis (Adj: age, sex, income; n = 865)

3021 | PEGYLATED IFN-α-2B AMELIORATES ALCOHOL-ASSOCIATED LIVER DISEASE BY REMODELING THE GUT MICROBIOTA–BILE ACID–INTESTINAL FXR-FGF15 AXIS

Tuo Shao[1] Qian Zhu[1] Enfei Qiang[2] Weifeng Zhao[1] Raymond Chung[3], [1]The First Affiliated Hospital of Soochow University, [2]1The First Affiliated Hospital of Soochow University, [3]Division of Gastroenterology and Hepatology, Mass General Brigham, Boston

Background: Alcohol-associated liver disease (ALD) is driven by hepatic lipid accumulation, inflammation, gut dysbiosis, intestinal barrier disruption, and altered bile acid metabolism. Type I interferon has immunomodulatory and metabolic effects, but its role in ALD remains poorly defined. We investigated whether pegylated interferon-α-2b (PEG-IFN-α-2b) protects against alcohol-induced liver injury through modulation of the gut–

liver axis. **Methods:** A mouse model of alcohol-associated fatty liver disease was established using the NIAAA chronic-plus-binge ethanol feeding protocol. Mice were treated with PEG-IFN-α-2b, followed by assessment of liver injury, serum biochemistry, hepatic lipid metabolism and inflammatory gene expression, intestinal barrier markers, gut microbiota composition by 16S rRNA sequencing, metabolomics, and hepatic transcriptomic analysis. **Results:** PEG-IFN-α-2b markedly attenuated alcohol-induced liver injury, as shown by reduced liver-to-body weight ratio, decreased hepatic triglyceride accumulation, lower serum ALT, AST, and triglyceride levels, and increased HDL-C. PEG-IFN-α-2b also suppressed hepatic inflammatory mediators, including IL-6, TNF-α, and MCP-1, downregulated lipogenic genes such as SREBP-1c and ACC1, and improved intestinal barrier integrity by restoring tight-junction, mucin, and antimicrobial defense markers.16S rRNA sequencing showed that alcohol feeding induced gut dysbiosis, whereas PEG-IFN-α-2b restored microbial homeostasis by reducing potentially pathogenic bacteria and enriching bile salt hydrolase-producing taxa. Bile acid profiling further showed increased unconjugated and secondary bile acids and decreased conjugated bile acids after PEG-IFN-α-2b treatment. Correlation and transcriptomic analyses suggested that these microbiota-derived bile acid changes suppressed intestinal FXR-FGF15 signaling, promoted hepatic bile acid synthesis and secretion, enhanced fecal bile acid excretion, and thereby facilitated cholesterol-to-bile acid conversion and reduced hepatic lipid accumulation. **Conclusion:** PEG-IFN-α-2b protects against alcohol-associated liver injury by restoring intestinal barrier function, reshaping gut microbiota, enriching BSH-producing bacteria, increasing FXR-antagonistic bile acids, and suppressing the intestinal FXR-FGF15 axis. These findings identify a previously unrecognized gut microbiota–bile acid mechanism underlying the therapeutic potential of PEG-IFN-α-2b in ALD.

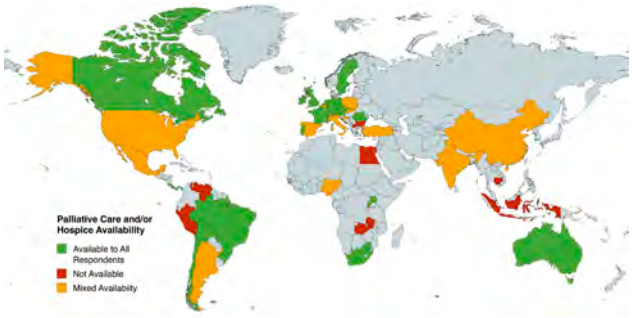
3022 | PALLIATIVE CARE IS UNDERUTILIZED IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS: FINDINGS FROM AN INTERNATIONAL SURVEY STUDY



Hanna Blaney[1] Marta Tejedor[2] Jasmohan Bajaj[1] Simone Strasser[3] Svetlana Adamcova Selcanova[4] Lubomir Skladany[5] Marina Berenguer[6] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]University of Iowa, [3]New South Wales, [4]Jefferson University Hospital, [5]Roosevelt Univeristy Hospital, [6]University of Valencia

Background: Alcohol-associated hepatitis (AH) has a high short-term mortality. The use of palliative care (PC) or hospice services (HS) in AH is unknown. This study aims to describe current practice patterns and variation in both consultation service use and perceptions of PC and HS in AH. **Methods:** This is an international survey study conducted between January and May 2026. The survey contained four questions on PC and HS in AH. The survey was sent out to 208 hepatologists and surgeons identified through Global AlcHep and International Liver Transplant Society contacts. **Results:** The response rate was 66.8% (139/208) with responses from 46 unique countries. 75.5% of respondents practiced at a liver transplant (LT) center. PC and HS are not universally available: just 63% of respondents have access to PC and HS, while 37% do not, with geographic variability shown in **Figure 1**. Interestingly, 60% of respondents at LT centers had PC or HS services available, compared to 46.9% of those not at an LT center. Consulting habits for PC and HS in AH were variable, with 18.4% regularly consulting regardless of transplant candidacy, 46% regularly consulting only if the patient was not a transplant candidate, 14.9% only consulted at the request of the patient or family, and 17.2% did not consult PC and HS. Perceptions regarding the benefit of PC and HS in AH also varied, with 70.5% of respondents agreeing that all patients with severe AH could benefit from PC and/or HS regardless of whether they were a transplant candidate, and 28.1% felt that only patients with severe AH who were not transplant candidates would benefit. A minority (1.4%) felt that patients with severe AH would not benefit from PC or HS. In LT centers with PC and HS available, 76.2% of participants felt that all patients with severe AH would benefit, compared to 55% at LT centers without these services. When asked about perceived barriers to PC and HS, 45.2% felt that patients or families may not be agreeable to a PC and/or HS consult, 39.3% felt that patients with AH were typically young and may recover, 39.3% felt that PC and HS have a negative connotation, 32.6% cited discomfort with discussing PC and HS, 17.8% believed that patients receiving PC or HS could not receive other treatment, with 5.9% of respondents feeling that PC and HS were the same thing. A minority (11.1%) felt confident in managing end-of-life symptoms in patients with AH and did not need additional help, while 7.4% did not think there was a role for PC or HS care in AH. Additional costs associated with PC and/or HS consultations and care were cited by 14.1% of respondents. **Conclusion:** Availability of and use of PC and/or HS in AH vary globally. Multiple real and perceived barriers exist, including a sizable portion of

LT centers not having access to these services, discomfort with discussing PC and HS, and several respondents equating PC with HS. This study highlights opportunities to improve complex symptom and end-of-life care in AH.

3023 | P300-MEDIATED ACETYLATION STABILIZES HIF1A AND PROMOTES SKELETAL MUSCLE MITOCHONDRIAL DYSFUNCTION IN ALCOHOL ASSOCIATED LIVER DISEASE (ALD)

Pugazhendhi Kannan[1] Seshu Pothabathula[1] Saurabh Mishra[1] Annette Bellar[1] Inna Serganova[2] Abhishek Chakraborty[1] Srinivasan Dasarathy[1] Nicole Welch[1], [1]Cleveland Clinic, [2]Cornell University

Background: Sarcopenia in ALD is severe, persistent, and does not reverse after abstinence or liver transplantation. In ethanol-treated (ET) C2C12 myotubes, human induced pluripotent stem cell-derived myotubes (hiPSCm), mouse ALD (mALD) muscle, and human ALD muscle, HIF1a protein and acetylation increased during normoxia. We tested whether ethanol stabilizes HIF1a through p300-mediated acetylation. **Methods:** C2C12 myotubes and hiPSCm were treated with 100 mM ethanol. 10-wk-old mice received Lieber-DeCarli ethanol or pair-fed (PF) control diet for 10 days, followed by ethanol (5 g/kg) or control gavage on study day. Vastus lateralis muscle was obtained from humans with cirrhosis and heavy drinkers. Myotubes and mALD and human muscle were analyzed for HIF1a protein, target gene mRNA/protein, acetylated (Ac) HIF1a, hydroxylated (OH) HIF1a^{Pro564}, p300. Cycloheximide (CHX) chase and in vivo imaging system HIF1a reporters (GFP-HIF1a-luciferase); GFP-HIF1a-oxygen dependent domain deleted-luciferase) were used to quantify stability. HIF1a acetylation and candidate sites were measured by immunoprecipitation/immunoblotting for Ac-lysine and liquid chromatography-mass spectrometry (LC-MS). p300 inhibitor C646, genetic manipulation, and other acetyltransferases were tested. mTORC1 signaling/protein homeostasis, autophagy, and senescence markers were quantified. **Results:** ET or ALD increased HIF1a stability in all models, with stable HIF1a in myotubes after CHX chase compared with near-complete loss in controls by 30-60 min (**Fig 1a**). HIF1a luciferase activity increased 2-fold in ET myotubes ($p < 0.01$) (**Fig 1b**). HIF1a targets, including PDK1, PDK4, REDD1, and VEGF, increased 1.5- to 2-fold ($p < 0.01$). ET increased Ac-HIF1a 2- to 3-fold in myotubes and mALD muscle ($p < 0.05$ to $p < 0.01$) and reduced OH-HIF1a^{Pro564} by 50% ($p < 0.01$), despite preserved HIF1a degradation components. PHD2 expression did not prevent ethanol-induced HIF1a signaling. p300 protein increased in ET myotubes and mALD and human muscle (6-8-fold, 2-3-fold, and 3-4-fold, respectively; $p < 0.01$ to $p < 0.001$) with no change in GCN5. p300 mRNA increased 1.7-fold after ET ($p < 0.01$). Molecular docking (**Fig 1c**) and LC-MS identified HIF1a$^{K709/K719}$ as a candidate p300-responsive acetylation site. C646 reduced Ac-HIF1a and HIF1a stabilization by 50%, while GCN5 deletion (KO) did not change Ac-HIF1a (**Fig 1d**). In vivo, ALD reduced gastrocnemius weight in HIF1a^{flox} mice from 0.34 g to 0.25 g ($p < 0.01$), while muscle-specific HIF1a KO preserved muscle weight (vs mALD HIF1a^{flox} ,$p < 0.01$). HIF1a KO restored mTORc signaling and reduced autophagy with ET. **Conclusion:** Ethanol stabilizes skeletal muscle HIF1a through p300-mediated acetylation that bypasses canonical degradation. Ac-HIF1a promotes mitochondrial dysfunction, impaired proteostasis, mtROS, and senescence-associated injury, identifying p300-Ac-HIF1a as a targetable pathway in ALD sarcopenia.

3024 | DUF6383-DOMAIN CONTAINING PROTEIN FROM *PARABACTEROIDES DISTASONIS* PREDICTS SURVIVAL IN PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS

Henriette Kreimeyer[1] Carlos Gonzalez[2] Marcos Fondevila[3] AlcHepNet Investigators[4] Ali Canbay[5] Peter Stärkel[6] David Gonzalez[2] Bernd Schnabl[7], [1]Universitätsklinikum Knappschaftskliniken Bochum, [2]Department of Pharmacology University of California San Diego, La Jolla, California, USA, [3]Department of Medicine, University of California San Diego, La Jolla, California, USA, [4]IU School of Medicine, Division of Gastroenterology/Hepatology, [5]Universitätsklinikum Knappschaftskrankenhaus Bochum, [6]Department of Hepatology and Gastroenterology, Cliniques Universitaires Saint Luc, Brussels, Belgiu, [7]University of California, San Diego

Background: Alcohol-associated hepatitis is the acute form of alcohol-associated liver disease linked to low short-term survival. Intestinal dysbiosis is a hallmark of alcohol-associated liver disease characterized by a higher abundance of unfavorable species and a reduction of beneficial species. **Methods:** In this study, we aimed to analyze the bacterial proteome of stool samples from patients with alcohol-associated hepatitis (n = 80), alcohol use disorder (n = 20) and controls (n = 19) from an international multicenter cohort using quantitative tandem mass tag (TMT)-based metaproteomic profiling. We validated our results in an independent multicenter cohort of 72 patients with alcohol-associated hepatitis at the genomic level using qPCR. **Results:** Fecal metaproteomic analysis of revealed significantly different bacterial proteomic signatures across all three groups. Fecal samples of patients with alcohol-use disorder and alcohol-associated hepatitis were characterized by a loss of *Firmicutes*-derived proteins and enrichment of proteins from *Bacteroidetes*, *Proteobacteria*, and *Actinobacteria*, accompanied by shifts in specific genera. We identified 18 bacterial proteins that increased with liver disease severity, predominantly produced by Veillonella, Bifidobacterium, and Clostridium-related taxa, including multifunctional "moonlighting" proteins such as enolase and hexokinase (Figure A). The DUF6383 domain-containing protein from *Parabacteroides distasonis* correlated significantly with 90-day mortality and with histological injury and inflammatory cell infiltration (Figure B). Patients with high DUF6383 domain containing protein levels showed significantly worse 90-day survival ($p < 0.05$), independent of the MELD score. This was validated in an independent cohort using qPCR (n = 72, p = 0.045). DUF6383 domain containing protein correlated positively with neutrophil degranulation, autophagy, and mitophagy pathways. We analyzed mortality patterns by taxonomic origin. Proteins from Firmicutes were more closely tied to 30-day outcomes and Proteobacteria proteins dominating 90-day risk. **Conclusion:** Our study reveals that changes in the abundance of specific fecal bacterial proteins are associated with disease severity and progression in alcohol-associated liver disease. Even though, the function of DUF6383 domain containing protein from *P. distasonis* is still unknown, it is a potential prognostic biomarker for short-term mortality in alcohol-associated hepatitis.

3025 | PHOSPHATIDYLETHANOL RESPONSE FOLLOWING BINGE DRINKING IN PATIENTS WITH STEATOTIC LIVER DISEASE

Nikolaj Torp[1] Marianne Bergmann[2] Markus Maagaard[1] Ellen Lyngbeck Jensen[1] Stine Johansen[1] Mette lehmann Andersen[3] Peter Andersen[1] Katrine Bech[1] Helle Schnefeld[1] Maria Fogt[1] Ea Kyed[1] Charlotte Gjoel[1] Gunilla Calov[1] Ida Villesen[1] Katrine Thorhauge[1] Johanne Hansen[1] Camilla Dalby Hansen[1] Torben Hansen[4] Mads Israelsen[1] Aleksander Krag[1], [1]Odense University Hospital, [2]Lillebaelt Hospital-University Hospital of Southern Denmark, [3]Herlev Hospital, [4]University of Copenhagen

Background: Phosphatidylethanol (PEth) is a direct alcohol biomarker, where homologues with distinct fatty acid compositions and detection windows can be quantified simultaneously to reflect alcohol consumption patterns. Whether the PEth homologue response to binge drinking differs in patients with steatotic liver disease remains unknown. We therefore aimed to characterize PEth response following controlled binge drinking in patients with SLD compared with healthy controls. **Methods:** We conducted an intervention study of a controlled binge drinking episode in 29 patients with asymptomatic SLD (MASLD: n = 15, MetALD/ALD: n = 14) and 10 healthy individuals serving as controls. Alcohol abstinence was required 48 hours prior to the study visit with confirmation by blood alcohol concentration (%BAC) at baseline. All participants underwent a standardized binge drinking episode consisting of 1 mL ethanol/kg body weight (adjusted for overweight), administered via nasogastric tube over 30 minutes. Two whole-blood PEth homologues with different half-lives (16:0/18:1, $T_{1/2}$ = 8 days and 16:0/18:2, $T_{1/2}$ = 6 days) were quantified by LC-MS/MS and expressed as change from baseline (ΔPEth, ng/mL). Serial systemic venous blood samples were collected at T = 0, 15, 30, 60, 90, 120, 150, and 180 minutes. **Results:** Participants had a median age of 55 years, and 62% were male. Baseline PEth 16:0/18:1 concentrations were median 14 ng/mL (IQR: 6-693 ng/mL) for SLD and median 16 ng/mL (IQR: 8-39 ng/mL) for healthy controls. Prior to binge drinking, PEth 16:0/18:1 had the highest relative abundance in both treatment groups (16:0/18:1 to 16:0/18:2 ratio: 1.33 in SLD and 1.15 healthy controls). Weight-adjusted ethanol dosing to simulate binge drinking ranged from 40 to 98 grams. The resulting serum ethanol peaked after 60 minutes with a mean %BAC of 0.16 (SD: ±0.03) and no difference in %BAC between groups (p = 0.562) (Figure). The PEth 16:0/18:1 response to binge drinking was ≥200 ng/mL in 28 of 29 patients with SLD (97%), while the peak PEth 16:0/18:1 response was comparable between patients with SLD and healthy controls (p = 0.085). Binge drinking induced a selective shift in PEth homologue abundance, where PEth 16:0/18:2 became the dominant homologue (16:0/18:1 to 16:0/18:2 ratio: 0.80 in SLD and 0.55 in healthy controls). Adjusting for peak % BAC, the PEth 16:0/18:1 response was independent of age (p = 0.790), sex (p = 0.547), hemoglobin levels (p = 0.877) and diabetes status (p = 0.581) with similar independencies for the 16:0/18:2 homologue. **Conclusion:** In patients with SLD, a single binge drinking episode leads to substantial PEth elevations with a selective relative shift in homologue abundance. Measuring several PEth homologues with different response and detection windows can provide insights into alcohol consumption beyond quantity alone.

3026 | CUMULATIVE LIFETIME ALCOHOL EXPOSURE AND ADVANCED LIVER FIBROSIS IN BIOPSY-PROVEN MASLD

Alexander Rueda[1] Jennifer Dodge[1] Brian Lee[1], [1]Keck School of Medicine, University of Southern California, Los Angeles, CA

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Current steatotic liver disease (SLD) nomenclature, clinical risk stratification, and MASH trial enrollment criteria rely on alcohol intake assessed over short look-back windows. The contribution of cumulative lifetime alcohol exposure to fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD) is understudied. We examined the association between cumulative lifetime alcohol exposure and advanced fibrosis in MASLD. **Methods:** We conducted a cross-sectional analysis of adults enrolled in the prospective NASH Clinical Research Network (NASH-CRN) with lifetime alcohol exposure and liver histology. Participants had a diagnosis of MASLD by liver biopsy and average intake of $\leq$14 drinks/week in men or $\leq$7 drinks/week in women at cohort entry. Lifetime alcohol exposure was quantified using the validated Lifetime Drinking History (Skinner). The primary exposure, drink-years (drinks/day × duration, summed across drinking phases), was modeled per 10-unit increase. The primary outcome was advanced liver fibrosis (F3-F4 vs. F0-F2). Multivariable logistic regression adjusted for sex, race/ethnicity, and diabetes. Dose-response and effect modification by sex, age, and beverage type were examined. **Results:** Among 840 participants (mean age = 50.2 years, 50.1% male), 24.3% had advanced fibrosis. Lifetime drinking trajectories revealed that 143 participants (17.0%) had previously crossed MetALD-level drinking threshold ($\geq$140 g/week women; $\geq$210 g/week men) and 65 (7.7%) had crossed ALD-level threshold ($\geq$350 g/week women; $\geq$420 g/week men). In multivariable analysis, each 10 drink-year increase was associated with higher odds of advanced fibrosis (aOR = 1.06, 95% CI: 1.00, 1.11; p = 0.040). A dose-response relationship was observed: compared to the lowest quartile median (1.07 drink-years), aOR was 1.17 (1.01, 1.37) at 30 drink-years and 1.31 (1.01, 1.70) at 50 drink-years. In exploratory sex-stratified analyses, the dose-response trend appeared steeper in males than females, though the sex interaction was not significant (p = 0.55). **Conclusion:** Cumulative lifetime alcohol exposure is associated with higher odds of advanced fibrosis in MASLD, with a dose-response relationship. Nearly one in five had previously exceeded the MetALD drinking threshold, exposing a measurement gap in current SLD nomenclature that relies on recent intake. Routine assessment of lifetime drinking history may improve fibrosis risk stratification, refine SLD subclassification and clinical trial design beyond current consumption alone.

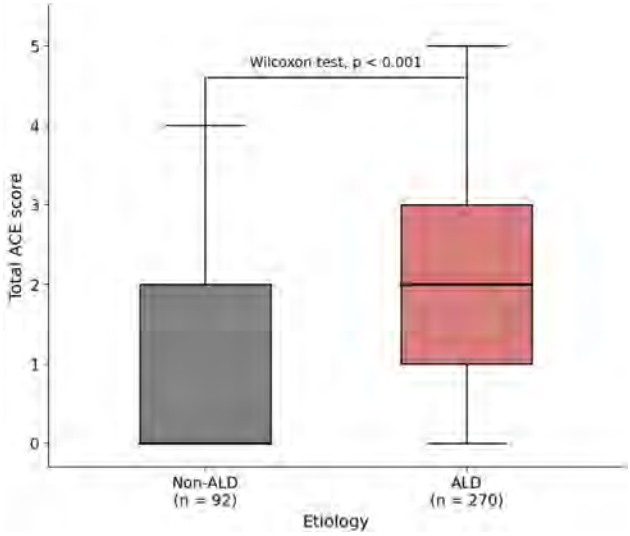
3027 | ADVERSE CHILDHOOD EXPERIENCE SCORE IS ELEVATED IN ALCOHOL-ASSOCIATED BUT NOT NON-ALCOHOL-ASSOCIATED CIRRHOSIS: EVIDENCE FOR AN ACE&RARR; AUD&RARR;ALD CASCADE FROM A PROSPECTIVE REGISTRY



Svetlana Adamcova Selcanova[1] Lubomir Skladany[1] Daniela Zilincanova[1] Karolina Kristina Sulejova[1] Daniel Jan Havaj[2] Ivana Ihnatova[3], [1]F. D. Roosevelt University Hospital, Banská Bystrica, Slovakia, [2]University Hospital of F. D. Roosevelt, [3]Institute of Biology and Ecology, Faculty of Science, Pavol Jozef Safarik University in Kosice

Background: Adverse childhood experience (ACE) score is an established upstream driver of adult alcohol use disorder (AUD). Whether this cascade extends to its end-organ consequence, alcohol-associated liver disease (ALD), at the level of advanced chronic liver disease (ACLD), and whether ACE score tracks ALD phenotypic severity, has not been

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

investigated. **Methods:** Single-center analysis within a prospective cirrhosis registry (RH7; NCT04767945). Consecutive ACLD patients (n = 362) received the 10-item ACE questionnaire (ACE-Q) at bedside and were classified as non-ALD (n = 92; including MASLD, autoimmune, viral and metabolic etiologies), ALD without severe alcohol-associated hepatitis (ALD-noSAH; n = 184), and ALD-SAH (n = 86). ACE score was compared by Kruskal-Wallis/Dunn's test with Bonferroni correction and benchmarked against a geographically matched healthy student cohort (n = 3,647; Šulejová et al., 2022) by one-sample Wilcoxon tests. Logistic regression assessed individual ACE items as predictors of ALD etiology. **Results:** ACE score formed a clear stepwise hierarchy across four groups: healthy students (median = 1) and non-ALD patients (median = 0; IQR 0–2) were statistically indistinguishable (p = 0.899), while ALD-noSAH (median = 2; IQR 1–3) and ALD-SAH (median = 2.5; IQR 1–3) both scored significantly above this shared healthy baseline (p < 0.00001 each). Both ALD groups differed markedly from non-ALD (p < 0.00001 each); 51% of non-ALD patients reported zero childhood adversity versus 16% and 15% in ALD groups. The two ALD subgroups did not differ from each other (p = 0.812), indicating ACE score associates with ALD etiology but not with phenotypic severity within ALD. Physical neglect (OR 8.47; 95% CI 1.75–153) and emotional neglect (OR 4.38; 95% CI 2.35–8.80) were the strongest individual predictors of ALD etiology, exceeding all the other abuse-related ACE items. **Conclusion:** Non-ALD cirrhosis patients — including those with MASLD — carry ACE score equivalent to healthy controls, while both ALD phenotypes show a more than twofold elevation. ACE score marks ALD as a category but does not stratify its severity, suggesting childhood adversity is a permissive upstream factor in the ACE→AUD→ALD cascade rather than a modulator of acute disease expression. The predominance of neglect over abuse points to chronic relational deprivation as the key driver. These findings support routine ACE-Q screening in hepatological ALD care.

3028 | HEPATIC STELLATE CELL-DERIVED FSTL3 DEFINES AN ACTIVIN A-ACTRII AXIS AS A TARGET FOR REPURPOSING CLINICAL-STAGE ANTIBODIES IN ALCOHOL-RELATED LIVER DISEASE

Gloria Alvarez Sola[1] Wei Zhang[1] Jay Luther[1] Esperance Schaefer[2] Russell Goodman[1], [1]Massachusetts General Hospital, [2]Brigham and Women's Hospital

Background: Alcohol-related liver disease (ALD) lacks effective medical therapies. To identify possible new therapeutic targets, we combined a bioinformatics screen of the ethanol-induced hepatic secretome with a human proteomics screen to identify circulating follistatin-like 3 (FSTL3) — a TGF-β superfamily antagonist with no prior role in ALD — as robustly elevate across the spectrum of human disease and in mouse models of ALD. We aimed to define FSTL3's cellular origin, influence on ALD, and therapeutic tractability. **Methods:** We applied cell-type deconvolution of single-cell and spatial transcriptomics to identify the hepatic FSTL3 source, with follow up mechanistic studies employing murine models of ALD, human liver organoids, serum from ALD patients, and bioinformatics analysis of human ALD liver biopsies. **Results:** Spatial and single-cell transcriptomics identified hepatic stellate cells (HSCs) as the dominant source of FSTL3 which was confirmed in HSC cell lines. *in vivo,* FSTL3 overexpression attenuated and knockout exacerbated ALD in mouse models. Mechanistically, FSTL3 exerted its affect via neutralization of hepatocyte-secreted activin A which signals activin type II receptors, with a transcriptional rescue signature highly enriched in human ALD biopsies. We tested three late-stage clinical or FDA approved antibodies targeting different nodes of this pathway: garetsomab, sotatercept, and bimagrumab, all of which phenocopied FSTL3s protective effect in ALD. **Conclusion:** HSC-derived FSTL3 protects against ALD by antagonizing a hepatocyte-autonomous Activin A–ActRII–p21 axis. Three distinct clinical-stage antibodies each recapitulate the protective effects of FSTL3, providing

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

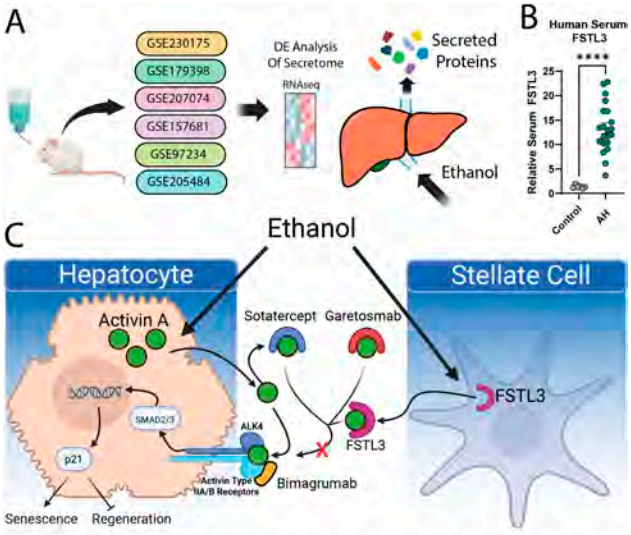
preclinical rationale to repurpose an existing pharmacologic pipeline as a novel therapeutic approach for a disease with no effective medical treatments.



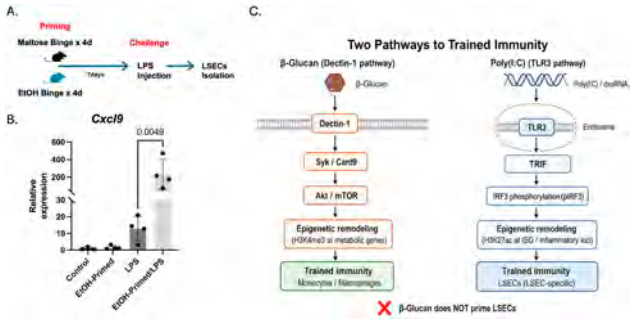


Figure 1. Identification of FSTL3 as a candidate therapeutic target in ALD and its mechanism of action. (A)Analysis of the hepatic secretome across mouse liver RNA-seq datasets identifies ethanol-regulated secreted proteins, converging on FSTL3. (B) Serum FSTL3 is significantly elevated in patients with alcohol-related hepatitis (AH) compared to healthy controls (C) Ethanol drives hepatocyte-autonomous Activin A secretion, which signals through SMAD2/3 to induce p21, impairing regeneration and promoting senescence. Hepatic stellate cell-derived FSTL3 antagonizes this axis. Three clinical-stage antibodies — sotatercept, garetosmab, and bimagrumab — recapitulate FSTL3's protective effect by targeting distinct nodes of the pathway.

3029 | LIVER SINUSOIDAL ENDOTHELIAL CELLS TRAINED IMMUNITY AMPLIFIES INFLAMMATION IN ALCOHOL-ASSOCIATED HEPATITIS

Weizhe Zhong[1] Rafael Ricci de Azevedo[1] Benjamin Swartzwelter[1] Fiona Xhafi[1] Mengfei Liu[1], [1]YALE University

Background: Alcohol-associated hepatitis (AH) is a highly morbid inflammatory liver syndrome with no effective therapy. Liver sinusoidal endothelial cells (LSECs) are angiocrine hubs mediating hepatic immune trafficking and inflammatory amplification. We hypothesize that LSECs undergo trained immunity — a form of innate immune memory in which a primary stimulus induces durable epigenetic and metabolic reprogramming that enhances responses to subsequent challenges, driving a sustained hyperinflammatory state triggered by alcohol-induced endogenous retrovirus reactivation. **Methods:** Bulk RNA-seq deconvolution (BayesPrism) of human AH liver biopsies (GSE136103) quantified LSEC proportions and transcriptional activation. A murine priming–rest–challenge binge alcohol model assessed trained immunity: mice received repeated alcohol binges, 7-day rest, then LPS rechallenge. LSEC Cxcl9 expression, liver injury and inflammation gene expression were measured. CUT&TAG profiled H3K27ac in sorted LSECs from primed versus unprimed mice. PolyI:C or β-glucan were used as defined trained immunity primers followed by LPS rechallenge. ERV reactivation was assessed by qPCR in primary human and mouse LSECs, and phospho-IRF3 by Western blot in ethanol-treated SV40 mouse LSECs. **Results:** Deconvolution of human AH liver revealed marked LSEC inflammatory signaling expansion, with significantly elevated interferon-stimulated and NF-κB-induced signaling, indicating concurrent IRF3 and NF-κB activation in human AH LSECs. In the murine binge model, alcohol-primed LSECs showed greater than 10-fold increase in Cxcl9 upon LPS rechallenge compared to unprimed controls, accompanied by upregulation of liver injury and inflammation gene expression. CUT&TAG demonstrated H3K27ac enrichment at inflammatory gene loci including the Cxcl9 promoter in primed versus unprimed LSECs, confirming priming-induced epigenetic reprogramming. Hepatocytes from the same mice did not exhibit trained responses, establishing LSEC specificity. PolyI:C, but not β-glucan, priming recapitulated alcohol-induced trained immunity with augmented Cxcl9 upon alcohol rechallenge, implicating the TLR3–IRF3 axis. ERV reactivation was confirmed by qPCR in ethanol-treated primary human and mouse LSECs, and phospho-IRF3 was increased by Western blot, identifying ERV-derived nucleic acids as endogenous TLR3 ligands initiating LSEC training. **Conclusion:** LSECs undergo trained immunity in AH, driven by an ERV–TLR3–IRF3 axis that epigenetically programs durable inflammatory hyperresponsiveness across inflammatory gene loci. This represents a previously unrecognized mechanism of sustained hepatic inflammation and a novel therapeutic target in AH.

3030 | GLP-1 RECEPTOR AGONIST USE AND ALCOHOL-RELATED HOSPITALIZATION AND LIVER OUTCOMES IN ALCOHOL USE DISORDER: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Jashanveer Johal[1] Archana Salek[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Bianca Patel[1] Abdallah Hussein[1] Yecheskel Schneider[1] Jason Hyman[2] Simona Rossi[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: GLP-1 receptor agonists (GLP-1 RAs) have demonstrated signals of reduced alcohol craving and consumption in preclinical and early clinical studies, yet real-world data on their impact on alcohol-related hospitalizations, liver disease progression, and mortality in patients with alcohol use disorder (AUD) are lacking. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised adults with AUD prescribed a GLP-1 RA within one year of diagnosis. Cohort 2 comprised AUD patients with no GLP-1 RA use. Both cohorts excluded prior cirrhosis, HCC, liver transplant, and chronic viral hepatitis. 1:1 PSM yielded 32,572 patients per arm over a 6–60 month follow-up. Outcomes included alcohol-related inpatient admissions, alcoholic cirrhosis, new-onset ascites, incident HCC, need for secondary AUD pharmacotherapy, inpatient encounter burden, and all-cause mortality. **Results:** GLP-1 RA use was associated with dramatically lower rates of alcohol-related admission (4.8% vs. 14.1%; HR 0.38, 95% CI 0.35–0.40; $p < 0.001$) and all-cause mortality (2.8% vs. 9.9%; HR 0.36, 95% CI 0.33–0.39; $p < 0.001$). Alcoholic cirrhosis was significantly lower in the GLP-1 arm (0.5% vs. 1.2%; HR 0.56, 95% CI 0.47–0.68; $p < 0.001$), as was new-onset ascites (0.9% vs. 2.1%; HR 0.55, 95% CI 0.48–0.64; $p < 0.001$). Incident HCC was lower on cumulative risk analysis (RR 0.38; $p = 0.004$) but did not reach significance on KM analysis (HR 0.51; $p = 0.052$), likely reflecting low event counts (11 vs. 29 events). Need for secondary AUD pharmacotherapy was modestly lower by risk ratio (4.8% vs. 5.6%; RR 0.87; $p = 0.0001$) but non-significant on KM analysis (HR 1.06; $p = 0.097$). Inpatient burden was significantly lower in the GLP-1 arm (25.2% vs. 45.9% with any encounter; mean 6.4 vs. 9.2 encounters; $p < 0.001$). **Conclusion:** In this large propensity-matched cohort, GLP-1 RA use within one year of AUD diagnosis was associated with dramatically lower rates of alcohol-related hospitalization, cirrhosis, ascites, and all-cause mortality. While confounding by indication cannot be fully excluded, the breadth and magnitude of these associations support a clinically meaningful role for GLP-1 RAs in reducing alcohol-related harm. These findings complement emerging evidence examining GLP-1 RAs in alcoholic hepatitis, further situating this drug class as a promising intervention across the spectrum of alcohol-related liver disease. Prospective trials are warranted to establish causality and define the populations most likely to benefit.

3031 | OUTCOMES AND THE LIMITS OF PSYCHOSOCIAL RISK STRATIFICATION IN LIVER TRANSPLANT EVALUATION FOR ALCOHOL-ASSOCIATED LIVER DISEASE

Darine Daher[1] Hassan Azhari[2] Omar Mousa[3] Kymberly Watt[4] William Sanchez[4] Timucin Taner[4] Terry Schneekloth[4] Douglas Simonetto[4], [1]Mayo Clinic, [2]Memorial Sloan Kettering Cancer Center, [3]Mayo Clinic Florida, [4]Mayo Clinic Rochester

Background: Alcohol-associated liver disease (ALD) is a leading indication for liver transplant (LT) evaluation, yet predictors of post-transplant abstinence largely derive from transplanted cohorts. Existing tools, such as the SALT score, are therefore subject to selection bias and cannot characterize patients deferred or denied listing. We evaluated the natural history of patients undergoing LT evaluation for ALD, with particular attention to those deferred or denied. **Methods:** We conducted a multisite observational cohort study of patients evaluated for LT at three Mayo Clinic sites between 1/1/2018 and 1/1/2025. Patients with ALD and alcohol use disorder were included; hepatobiliary or metastatic cancers were excluded. Return to alcohol use was defined as any positive phosphatidylethanol (PEth), ethyl glucuronide, or ethanol test following evaluation. High psychosocial risk was defined by validated instruments (PACT score 0–1, SIPAT score ≥ 40, or SIPAT Section IV score 6–8). **Results:** We identified 2,309 patients (mean age 53.6 years; 63.5% male; 89.1% White); 438 (19.0%) were approved, 1,284 (55.6%) deferred, and 587 (25.4%) denied at initial evaluation. Initial decisions were frequently revised: 434/1,284 (33.8%) deferred and 27/587 (4.6%) denied patients ultimately underwent LT, with 805 (34.9%) transplanted overall. There were 399 deaths (28.3%) among non-transplanted deferred/denied patients ($n = 1,410$) with median follow up time of 433 days.Biochemical return to

alcohol use was common and similar in observed proportion between non-transplanted denied/deferred (189/786; 24.0%) and transplanted patients (195/765; 25.5%);p = 0.54), despite substantially less frequent testing in the former (56% vs 95% with biomarker data). Of 1,089 patients with available psychosocial evaluation data, 596 (55%) were classified as high risk. High psychosocial risk was associated with greater mortality (HR 1.78, 95% CI 1.40-2.25) and higher rates of return to alcohol use (100/339; 29.4% vs 64/315; 20.3%; p = 0.008), including 41/339 (12.1%) within 90 days of evaluation. Notably, the majority of high-risk patients (239/339; 70.6%) had no detected return to alcohol use. **Conclusion:** Return to alcohol use was common across the evaluation pathway and not confined to transplant recipients, suggesting that listing status alone does not identify relapse risk. While psychosocial risk stratified both mortality and return to alcohol use, the majority of high-risk patients showed no detected alcohol use, suggesting that a high-risk designation has limited individual-level predictive value and, used as a categorical exclusion, may forgo transplant access for many patients who do not return to drinking. These findings support dynamic, biomarker-anchored reassessment, and identify high-risk patients as a group warranting continued surveillance and targeted interventions.m close monitoring or targeted interventions.

3032 | GALECTIN-3 BINDING PROTEIN UPREGULATED IN ALCOHOL-ASSOCIATED CIRRHOSIS PROMOTES BROAD TRANSCRIPTIONAL CHANGES IN HEPATIC STELLATE CELLS, INCLUDING MONOCYTE CHEMOTAXIS AND PROFIBROTIC SIGNALING

Andrea Paola De La Lama Flores[1] Ainsley Baker[2] Rolando Garcia-Milian[3] Yasuko Iwakiri[3] Matthew McConnell[3], [1]Yale University School of Medicine, Section of Digestive Diseases, [2]Yale University School of Medicine, Section of Digestive Diseases (Yale Liver Center), [3]Yale University

Background: Platelets promote metabolic-associated steatotic liver disease (MASH) and other inflammatory liver diseases, but their role in alcohol-associated cirrhosis (AC) remains unclear. We previously showed that platelet-derived microparticles carrying Galectin-3 binding protein (Gal3BP) are significantly upregulated in AC patients, but their pathological role remains unknown. **Methods:** Public liver single-cell RNAseq data from alcohol-associated cirrhosis patients was analyzed for Gal3BP receptor expression and hepatic stellate cell (HSC)-monocyte crosstalk. Primary HSCs were treated with Gal3BP, and their conditioned media was used to treat primary human monocytes. Bulk RNAseq was performed on Gal3BP-treated HSCs and conditioned medium-treated monocytes. THP-1 chemotaxis to Gal3BP-treated HSCs was assessed. qPCR was used to assess key genes in HSCs and monocytes. **Results:** Analysis of publicly available single-cell RNAseq data from AC and control human livers (GSE 136103) revealed that HSCs and myofibroblasts express high levels of the Gal3BP receptors CD248, LGALS3, and LGALS1. To study Gal3BP signaling, HSCs were treated with Gal3BP *in vitro* followed by bulk RNAseq. Ingenuity pathway analysis (IPA) revealed significant upregulation of pathways associated with immune cell chemotaxis, including movement and activation of phagocytes and myeloid cells. qPCR from HSCs confirmed upregulation of chemokines CXCL2 (fold-change 1.8, p < 0.01) and CXCL8 (fold-change 2.2, p < 0.01), along with inflammatory cytokine IL-1β (fold-change 1.6, p < 0.01).To determine whether these transcriptional changes promoted monocyte migration, we performed a transwell migration assay using Gal3BP- or vehicle-treated HSCs in the lower chamber and labeled THP-1 monocytes in the upper chamber. Immunofluorescence showed a significant increase in migrated THP-1 cells over 24 hours in the Gal3BP-treated group compared to control (95.5 cells vs 67.6 cells, p < 0.01), indicating enhanced chemotactic activity induced by Gal3BP.Conditioned medium from Gal3BP-treated HSCs was then used to treat primary human monocytes followed by bulk RNAseq. IPA showed significant upregulation in the monocytes of fibrotic, inflammatory, and immune recruitment pathways, including hepatic fibrosis signaling, collagen trimerization, leukocyte migration, and mononuclear leukocyte activation.To assess *in vivo* relevance, we re-analyzed AC single-cell RNAseq data and found increased HSC expression of CCL2, CXCL2, and IL-1β. We observed increased macrophage abundance along with upregulated mesenchymal-macrophage crosstalk mediated by IL-1β. **Conclusion:** Gal3BP is upregulated in platelet-derived microparticles in AC. Gal3BP signaling to HSCs promotes crosstalk with

3033 | RENAL OUTCOMES AFTER LIVER TRANSPLANTATION FOR ALCOHOL-ASSOCIATED HEPATITIS

Claire Durkin[1] Shari Rogal[1] Ravy Vajravelu[1], [1]University of Pittsburgh

Background: Early liver transplantation (LT) for alcohol-associated hepatitis (AAH) has increased over the past decade, yet long-term renal outcomes and kidney transplant utilization remain poorly characterized in this population. Understanding the impact of current policies, including simultaneous liver-kidney (SLK) transplantation and the kidney-after-liver transplant (KALT) safety net, may inform strategies to optimize renal preservation and organ allocation. **Methods:** This was a retrospective cohort study of the United Network for Organ Sharing (UNOS) database of adults ($\geq$18 years) undergoing first-time LT alone (LTA) or SLK for AAH (1/1/2018-12/31/2024). AAH was identified using primary/secondary diagnosis codes on initial waitlist application. Clinical and demographic characteristics were compared between SLK recipients and LTA recipients who met SLK acute kidney injury (AKI) thresholds (CrCl < 25mL/min or dialysis) at LT. Among patients undergoing LTA, Cox multivariable regression was used to identify predictors of subsequent KALT listing. Follow-up extended from LT to KALT, death, or end of follow-up. Models adjusted for age, sex, race/ethnicity, body mass index, diabetes, Model for End-Stage Liver Disease (MELD) score, ascites, encephalopathy, ventilator use, life support, and LT year, as well as calcineurin inhibitor (CNI) exposure as a binary time-varying covariate. **Results:** Of the 2,528 patients transplanted for AAH, 2,417 (95.6%) underwent LTA and 111 (4.4%) underwent SLK. Renal dysfunction at LT was common with 38.9% of LTA recipients requiring dialysis and over half (51.2%) having CrCl < 30mL/min. Following LT, 298 (12.3%) of LTA recipients were waitlisted for KALT and 165 (6.8%) received a kidney transplant. Nearly all (90.3%) KALT listings occurred within 1 year of LT under the UNOS safety net policy. Compared to SLK recipients, LTA recipients meeting SLK AKI listing thresholds had higher MELD scores (40 vs 34, p < 0.001) and rates of Child Pugh class C (94.6% vs 81.8%, p < 0.001), but were younger (41 vs 45, p < 0.001) and less likely to have diabetes (6.3% vs 14.1%, p = 0.003). Among LTA recipients, predictors of subsequent KALT listing included greater severity of renal dysfunction at LT (**Figure**), CNI exposure (adjusted hazard ratio [aHR] = 7.96, p < 0.001), use of life support (aHR = 1.71, p = 0.019), and class III obesity (aHR = 2.01, p = 0.040). **Conclusion:** Renal dysfunction is highly prevalent among patients undergoing LT for AAH, and approximately one in six ultimately require SLK or KALT. Given the acute presentation of AAH, patients may undergo urgent LT before meeting sustained renal dysfunction criteria for SLK, underscoring the importance of the UNOS safety net in preserving kidney access. Baseline renal dysfunction, post-LT CNI exposure, life support, and severe obesity predict progression to KALT, highlighting opportunities for risk stratification and renal-sparing management following LT.

Figure:
(A) Adjusted probability of waitlisting for kidney-after-liver transplant in alcohol-associated hepatitis by renal function at liver transplant

Note: Kidney waitlisting is shown through 365 days post-liver transplant, as most events (90.3%) occurred within 1 year.

B) Cox multivariable model for waitlisting for kidney-after-liver transplant in alcohol-associated hepatitis

Background: Alcohol-associated liver disease (ALD) features progressive ductular reaction and cholangiocyte expansion. The origin of these cholangiocytes—whether via hepatocyte transdifferentiation, cholangiocyte proliferation, or stem cell differentiation—remains controversial. Clarifying this origin and its governing mechanisms is essential for developing ALD therapeutic targets. **Methods:** We performed single-nucleus RNA sequencing (snRNA-seq) on liver samples from normal controls, alcoholic hepatitis (AH), and alcoholic cirrhosis (AC) patients. Using Seurat and Slingshot, we conducted cell type, transitional state, and pseudotime trajectory analyses. Transitioning cells were identified via KLF4, KLF6, SOX4, and KRT23. Differential gene expression, pathway enrichment, and marker co-expression were analyzed across disease states. Findings were validated in an independent snRNA-seq cohort (GSE256398). **Results:** We observed significant cholangiocyte expansion in AH and AC with corresponding hepatocyte depletion. Transitioning cell populations also increased in AH and AC. Co-expression analysis revealed normal transitioning cells co-expressed hepatocyte (ALB, APOA1, CYP3A4, HNF4A) and transition markers (KLF4, KLF6), whereas AH and AC transitioning cells showed dramatic loss of hepatocyte markers, suggesting aggressive transdifferentiation. Proliferation markers (MKI67, TOP2A, STMN1) were absent in cholangiocytes, indicating limited contribution from cholangiocyte proliferation. Pseudotime confirmed a continuous hepatocyte-to-cholangiocyte transition, with progressive upregulation of cholangiocyte and downregulation of hepatocyte markers. Mechanistically, transitioning cells showed a transcriptional signature of TGFB2-driven fate switching: TGFB2 was the most upregulated TGF-β ligand across comparisons and datasets, co-occurring with SMAD3 upregulation and loss of inhibitory regulators (SMAD6, SMAD7, SKI, SKIL). This coincided with downregulation of ID1, ID2, and ID3, which normally repress the biliary transcription factor SOX9 in hepatocytes. These findings suggest TGFB2-SMAD3-ID1/2/3 signaling contributes to hepatocyte fate loss and cholangiocyte differentiation in ALD progression. **Conclusion:** ALD cholangiocyte expansion predominantly arises from hepatocyte transdifferentiation, rather than proliferation or stem cell differentiation. This identity loss is an alcohol-induced adaptive response driven by TGFB2-SMAD3-ID1/2/3 signaling, which dismantles hepatocyte identity while de-repressing biliary fate determinants. Targeting this transition and its upstream regulators offers a potential strategy to prevent ALD ductular reactions

3035 | BIDIRECTIONAL ASSOCIATION BETWEEN DIABETES MELLITUS AND DISEASE SEVERITY AND LONG-TERM PROGNOSIS IN ALCOHOLIC LIVER DISEASE: A MULTICENTER COHORT STUDY

Yingying Zhao[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: To investigate the bidirectional relationship between diabetes mellitus (DM) and alcoholic liver disease (ALD) in a large cohort of patients with ALD. **Methods:** A total of 2,724 patients with confirmed ALD from five centers were enrolled and divided into two groups based on the presence of diabetes(DM) at baseline. Cross-sectional analysis was performed to compare parameters of liver disease severity (Child-Pugh class, Model for End-Stage Liver Disease(MELD) score, and cirrhosis-related complications) between the two groups. Multivariate logistic regression was used to identify factors associated with severe ALD (e.g., Child-Pugh class B/C), with a specific assessment of the independent contribution of DM. Longitudinal survival data were analyzed using the Kaplan-Meier method and Cox proportional hazards model to evaluate the impact of DM on 1-to 4-year all cause mortality. In the subgroup without DM at baseline, we explored the association between baseline liver disease severity indicators and the risk of incident hyperglycemia or new-onset DM. **Results:** The prevalence of DM among ALD patients was 27.3% (813/2,724). Cross-sectional analysis showed that patients with concomitant DM had significantly higher baseline Child-Pugh scores ($P = 0.037$) and MELD scores ($P = 0.048$), as well as higher rates of complications: ascites (47.4% vs. 16.5%) and hepatic encephalopathy (14.2% vs. 8.6%). The presence of DM was positively correlated with the incidence of hepatic encephalopathy ($r = 0.094$, $P < 0.001$), esophagogastric variceal bleeding ($r = 0.096$, $P < 0.001$), hepatocellular carcinoma ($r = 0.048$, $P = 0.012$), and ascites ($r = 0.117$, $P < 0.001$), but was negatively correlated with the proportion of Child-Pugh class C ($r = -0.040$, $P = 0.039$). Multivariate analysis confirmed that, in addition to age and low serum albumin, DM was an independent risk factor for severe liver disease at baseline (adjusted OR 1.373, 95%

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

CI 1.095-1.722). Survival analysis indicated that DM was an independent predictor of long-term mortality in ALD patients (adjusted HR 1.1, 95% CI 0.839–1.445). Alcohol abstinence was negatively correlated with incident DM during follow-up (r = -0.309, P < 0.001). Moreover, more severe liver disease at baseline, as reflected by the ABIC score (r = 0.059, P = 0.03), was associated with worsening glycemic control or an increased risk of new-onset DM during follow-up. **Conclusion:** This study reveals a significant bidirectional adverse relationship between DM and ALD. DM not only serves as a marker and promoter of ALD severity but also as an independent risk factor for poor prognosis. Conversely, severe ALD may exacerbate glucose metabolism disorders. These findings underscore the critical importance of systematic screening and management of DM in ALD care, as well as the assessment of liver status in patients with DM. An integrated management strategy is essential to improve overall patient outcomes.

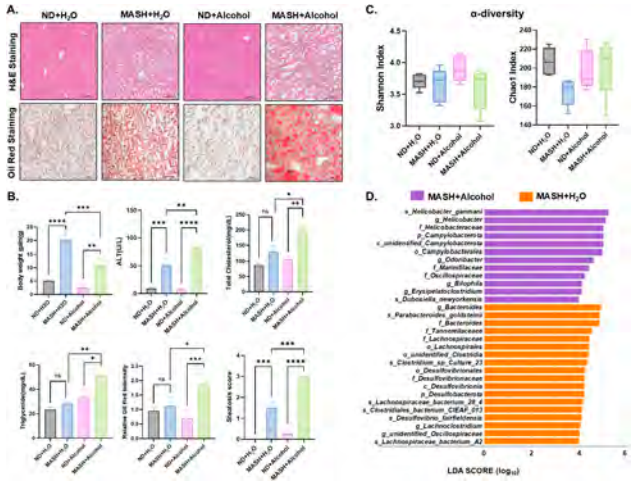
3036 | METALD EXACERBATES HEPATIC STEATOSIS AND RESHAPES THE GUT MICROBIOTA COMPARED WITH MASLD IN MURINE MODELS



Ning Ma[1] Saisai Zhang[1] Zhe Zhang[1] Fung Yu Huang[1] Man-Fung Yuen[1] Lung-Yi Mak[1] Wai-Kay Seto[1], [1]The University of Hong Kong

Background: Metabolic dysfunction-associated alcohol-related liver disease (MetALD) is defined by the presence of metabolic dysfunction with concurrent alcohol intake. The differences of MetALD with metabolic dysfunction associated steatotic liver disease (MASLD) in hepatic histopathology and gut microbiome profiles remain incompletely understood. This study aimed to characterize these differences using mouse models of MASLD and MetALD. **Methods:** Eight-week-old male C57BL/6J mice were randomly assigned to four groups (n = 4 per group). Mice were initially fed either a high-fat, high-cholesterol, high-sucrose diet (metabolic associated steatohepatitis [MASH] diet) or a standard chow diet and subsequently subdivided into alcohol- or water-treated subgroups for 12 weeks. Mice in the alcohol groups received 10% (v/v) ethanol in drinking water along with weekly oral gavage of ethanol (5g/kg), while control mice received regular water and weekly gavage of water. Mice fed with the MASH diet with alcohol exposure were defined as the MetALD group. Fecal samples were collected for PacBio Full-length 16S rRNA sequencing. **Results:** MetALD mice, when compared with MASLD mice, exhibited significantly lower body weight gain (10.76 ± 2.44 g vs 20.21 ± 2.97 g), but higher serum ALT (82.72 ± 15.37 U/L vs 51.77 ± 11.61 U/L), triglycerides (197.65 ± 26.94 mg/dL vs 132.36 ± 29.56 mg/dL), and total cholesterol (51.67 ± 6.03 mg/dL vs 28.37 ± 1.76 mg/dL) levels (all $p < 0.05$). Histological examination showed MetALD mice having increased steatosis grade (3.00 ± 0.00 vs 1.50 ± 0.50) and Oil Red O-stained area (1.87 ± 0.37 vs 1.13 ± 0.25) (all $p < 0.05$). Gut microbiota analysis based on 16S rRNA sequencing revealed no significant differences in α-diversity between MetALD and MASLD groups. Although principal coordinate analysis (PCoA) indicated that the MASH diet was the dominant factor shaping microbiota variation, with alcohol exposure exerting a comparatively modest effect, permutational multivariate analysis of variance (PERMANOVA) based on Bray-Curtis distance still revealed a significant difference in gut microbial composition between MetALD and MASLD mice (Adonis, R^2 = 0.214, p = 0.036). Linear discriminant analysis effect size (LEfSe) identified enrichment of

Helicobacter and *Bilophila* at the genus level, as well as *Helicobacter ganmani* at the species level, in the MetALD group. Both *Helicobacter* and *Bilophila* have been reported to promote inflammation, intestinal barrier impairment and bile acid dysmetabolism, exacerbating hepatic steatosis. **Conclusion:** MetALD mice develop more severe hepatic injury, steatosis, and dyslipidemia than MASLD mice. The enrichment of *Helicobacter* and *Bilophila* at the genus level, as well as *Helicobacter ganmani* at the species level, in MetALD mice may contribute to the progression of hepatic steatosis and dyslipidemia. *Supported by the Innovation and Technology Commission, HKSAR Government (ITS/046/22MS).*

3037 | LONGITUDINAL ALCOHOL CONSUMPTION TRAJECTORIES AND INCIDENT CHRONIC LIVER DISEASE AMONG MIDDLE-AGED AND OLDER CHINESE ADULTS: A NATIONAL COHORT STUDY

Bowen Qin[1] Yue Zhang[1] Ruiyuan Zhang[1] Qiaoman Fei[1] Xiao Liang[1] Qian Wang[1] Huan Deng[1] Qi Shang[1] Yujiao Deng[1] Yi Liu[1] Haidan Shi[1] Yee Hui Yeo[2] Fanpu Ji[1], [1]The Second Affiliated Hospital of Xi'an Jiaotong University, [2]Cedars-Sinai Medical Center

Background: Alcohol consumption is a major modifiable risk factor for chronic liver disease (CLD), but most epidemiologic studies rely on single-time-point drinking assessments. Whether long-term drinking trajectories are associated with incident CLD among aging Chinese adults remains unclear. We examined the incidence of CLD and the associations of drinking history, drinking frequency, longitudinal drinking trajectories, and alcohol dose with incident CLD in a nationally representative cohort. **Methods:** This cohort study used nationally representative data from the China Health and Retirement Longitudinal Study (CHARLS). Middle-aged and older adults without baseline CLD or hepatitis B were followed from 2011 to 2018. Alcohol-related exposures included drinking history, drinking frequency, and longitudinal drinking trajectories across four survey waves, based on the presence or absence of moderate-to-heavy drinking (>210 g/week for men and >140 g/week for women). Incident CLD was defined as self-reported physician-diagnosed CLD identified through structured interviews. Multivariable logistic regression and restricted cubic spline models were used to estimate associations. **Results:** Among 10,384 participants without CLD at baseline, 698 developed CLD during follow-up, yielding a 7-year cumulative incidence of 6.7%. Among 10,384 participants without CLD at baseline, 698 developed CLD during follow-up, yielding a 7-year cumulative incidence of 6.7%. Kaplan–Meier analyses showed significantly higher cumulative incidence among ever drinkers than never drinkers (7.8%

vs. 6.2%; log-rank P = 0.002), among daily drinkers than less-than-daily drinkers, and among participants with stable or escalating high-level and fluctuating drinking trajectories compared with those with stable low-level trajectories (Figure).After full adjustment, ever drinking (OR, 1.26; 95% CI, 1.04-1.52) and daily drinking (OR, 1.30; 95% CI, 1.02-1.66) were associated with higher odds of incident CLD. Compared with stable low-level drinking trajectories, stable or escalating high-level drinking (OR, 1.39; 95% CI, 1.02-1.90) and fluctuating drinking trajectories (OR, 1.34; 95% CI, 1.04-1.73) had higher odds of incident CLD. Restricted cubic spline analysis indicated a nonlinear dose–response association between alcohol intake and incident CLD (P-overall = 0.023; P-non-linearity = 0.040), with a more evident pattern in men but not women (Figure). Associations were generally consistent in subgroup and sensitivity analyses. **Conclusion:** Among middle-aged and older Chinese adults, the 7-year cumulative incidence of CLD was 6.7%. Drinking history, daily drinking, and unfavorable long-term drinking trajectories were associated with increased CLD risk. These findings support the value of incorporating dynamic alcohol-use patterns into liver disease risk assessment and prevention strategies in aging populations.

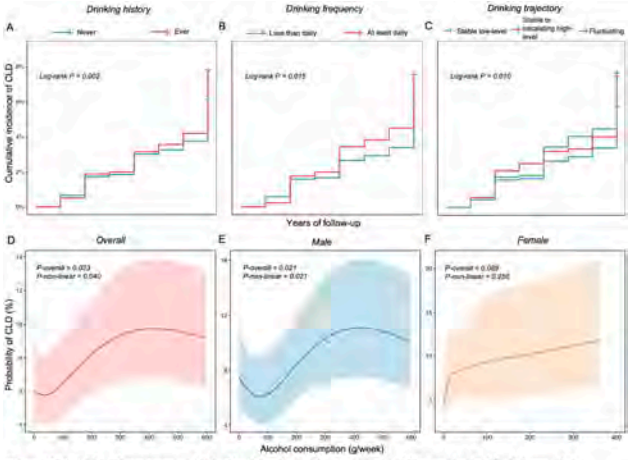

Figure. Alcohol-related exposures and risk of incident chronic liver disease in middle-aged and older Chinese adults.
(A–C) Kaplan–Meier cumulative incidence curves for incident chronic liver disease according to drinking history (A), drinking frequency (B), and drinking trajectory (C) in the overall population. Log-rank P values are shown in each panel. (D–F) Restricted cubic spline curves showing the dose–response association between average weekly alcohol consumption and the predicted probability of incident chronic liver disease in the overall population (D), men (E), and women (F). Shaded areas indicate 95% confidence intervals. Spline models were adjusted for age, sex, body mass index, diabetes, number of chronic conditions, marital status, educational attainment, place of residence, and smoking status. Participants with zero alcohol intake across all four survey waves were excluded from spline analyses.

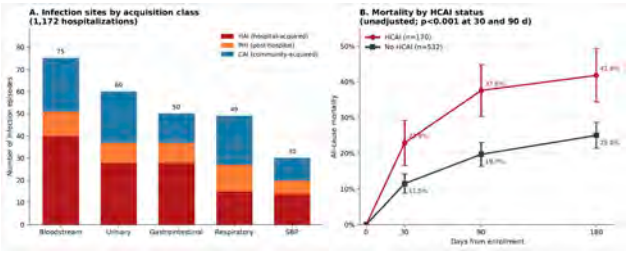
3038 | HEALTHCARE-ASSOCIATED INFECTIONS ARE COMMON AND ASSOCIATED WITH EARLY MORTALITY IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS: A CONTEMPORARY MULTICENTER STUDY



Douglas Simonetto[1] Wanzhu Tu[2] Srinivasan Dasarathy[3] Ashwani Singal[4] Amon Asgharpour[5] Juan Pablo Arab[5] Qing Tang[2] Nicole Welch[3] Vatsalya Vatsalya[4] Jacqueline O'Leary[6] Wanyu Zhang[4] Maiying Kong[4] Patrick Kamath[7] Ramon Bataller[8] Gyongyi Szabo[9] Craig McClain[4] Vijay Shah[1] Naga Chalasani[10] Mack Mitchell[11] Arun Sanyal[5] Samer Gawrieh[2], [1]Mayo Clinic Rochester, [2]Indiana University, [3]Cleveland Clinic, [4]University of Louisville, [5]Virginia Commonwealth University, [6]University of Texas Southwestern, [7]Mayo Clinic, [8]University of Pittsburgh, [9]Beth Israel Deaconess Medical Center, [10]Indiana University Medical Center, [11]University of Texas Southwestern Medical Center

Background: Patients with severe alcohol-associated hepatitis (sAH) are highly susceptible to infection due to immune dysfunction, frequent hospitalization, and exposure to immunomodulatory therapies. However, contemporary multicenter data describing the epidemiology, timing, and clinical risk factors for infection, particularly healthcare–associated infections (HCAI), remain limited. We aimed to characterize the burden and patterns of infection in sAH and identify factors associated with the development of HCAI. **Methods:** We performed a secondary analysis of two NIH-funded multicenter prospective studies (AlcHepNet and TREAT). Adults with sAH (MELD $\geq$ 20) and at least one hospitalization were included. All infections were systematically reviewed and categorized as community-acquired (CAI), hospital-acquired (HAI), or post-hospital (PHI); HCAI was defined as HAI plus PHI. Episode-level infection rates were calculated for all hospitalizations, while patient-level analyses assessed HCAI risk within 90 days. Multivariable logistic regression models evaluated associations between demographic and clinical factors and HCAI risk. **Results:** The cohort consisted of 702 subjects (mean age 45.0 ± 10.3 years; 59.4% male; MELD 27.8 ± 6.6), with 71.7% having ascites and 44.6% receiving corticosteroids, contributing to 1,172 hospitalizations. At the subject level, 35.9% of patients developed at least one infection, and 24.2% had at least one HCAI. Among 170 subjects with HCAI, 128 (75%) had a single episode, and 25% had two or more. Infections were predominantly bacterial (14.5%), followed by fungal (1.5%). Across 1,172 hospitalizations, HAI occurred in 11.1% of hospitalization episodes, CAI in 8.9%, and PHI in 4.6%. The most frequent HCAI sites were

bloodstream (4.3%), urinary and gastrointestinal (3.2% each), respiratory (2.3%), and spontaneous bacterial peritonitis (1.7%). In multivariable logistic regression analyses, higher MELD score (OR = 1.05 per point, 95% CI: 1.01–1.08), elevated white blood cell count (OR = 1.03, 1.00–1.05), diabetes (OR = 2.88, 1.25–6.65), and higher body mass index (OR = 1.03 per kg/m², 1.00–1.06) were independently associated with increased risk of HCAI, whereas recent alcohol and corticosteroid use were not. In an unadjusted comparison, patients who developed HCAI had substantially higher short-term mortality than those without HCAI: 22.9% vs. 11.5% at 30 days and 37.6% vs. 19.7% at 90 days (both $p < 0.001$). **Conclusion:** In this contemporary multicenter cohort of sAH, infections were common and predominantly bacterial. One in four patients with HCAI experienced recurrent infection, and HCAI was associated with nearly 2-fold higher mortality at 30 and 90 days. Overall, infection risk appeared to be driven primarily by host and disease factors, including MELD, diabetes, and obesity, underscoring the need for better risk-stratified surveillance and prevention strategies.

3039 | REVISITING THE LILLE SCORE: HOW BASELINE CHARACTERISTICS MODIFY THE BILIRUBIN DECLINE REQUIRED TO DEFINE "CORTICOSTEROID RESPONSE"

Yee Hui Yeo[1], [1]Cedars Sinai Medical Center

Background: The Lille score is used to guide corticosteroid management in severe alcohol-associated hepatitis (AH), with the score ≤ 0.45 interpreted as a corticosteroid response. However, the model was originally developed as a mortality prediction tool. We hypothesized that the bilirubin decline required to achieve the conventional Lille threshold varies substantially across baseline characteristics, potentially conflating prognosis with biological treatment response. **Methods:** We performed an algebraic iso-threshold analysis of the 7-day Lille model by inverting the equation to estimate the bilirubin decline required to achieve Lille = 0.45 across values of age, albumin, baseline bilirubin, renal function, and prothrombin time (PT). Analyses used a reference patient with age 50 years, baseline bilirubin 17.5 mg/dL, albumin 3.0 g/dL, PT 20 seconds, creatinine 1.0 mg/dL, and no renal insufficiency. Required bilirubin decline was defined as baseline minus day-7 bilirubin. **Results:** In a reference patient aged 21 years, day-7 bilirubin could increase by up to 11.1 mg/d, and still meet the Lille response threshold, whereas at age 75, bilirubin needed to decrease by 8.2 mg/dL. Each additional year increased the required bilirubin decline by approximately 0.36 mg/dL. Albumin exerted a similarly large effect: each 1 g/dL increase reduced the required bilirubin decline by approximately 5.2 mg/dL. Patients with albumin 3.9 vs. 4.4 g/dL required markedly different bilirubin trajectories despite being within normal range. Renal dysfunction was modelled as a binary variable, producing an abrupt threshold effect with minimal additional penalty for severe renal failure beyond creatinine >1.3 mg/dL. Baseline bilirubin also modified the threshold, with each 10 mg/dL higher baseline bilirubin requiring approximately 3.9 mg/dL greater bilirubin decline. PT had a relatively narrow active interval. **Conclusion:** The bilirubin decline required to achieve Lille ≤0.45 varies substantially according to age, albumin, baseline bilirubin, renal insufficiency, and PT. The Lille score should be interpreted as a dynamic prognostic model rather than a measure of corticosteroid responsiveness. Clinicians should interpret Lille as a prognostic tool incorporating bilirubin or MELD score kinetics. To avoid unnecessary use of corticosteroids and increased risk of infection, shared decision making should be performed in those with a Lille score ≤ 0.45 but presents escalating bilirubin levels.

Disclosures: Yee Hui Yeo:Nothing to Disclose.

3040 | A DEEP-LEARNING MODEL DISTINGUISHES ALCOHOL-ASSOCIATED STEATOHEPATITIS FROM METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS ON ROUTINE H&E LIVER BIOPSY

Chady Meroueh[1] Vijay Shah[2] Samar Ibrahim[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Distinguishing alcohol-associated steatohepatitis (ASH) from metabolic dysfunction-associated steatohepatitis (MASH) on liver biopsy is challenging since there are no pathognomonic features. We developed a patch-based ResNet50 convolutional neural network using progressive layer unfreezing and evaluated it on an independent holdout cohort. **Methods:** A transfer learning approach using a ResNet50 model with MoCo v2 contrastive self-supervised learning was fine-tuned on 441 whole slide images (WSI) from H&E stained liver biopsies with steatohepatitis (441 patients, ASH n = 161, MASH n = 280; 40× magnification) using patient-level 5-fold cross-validation. The model was trained in 3 stages:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Phase 1 updates only the final classification layer, Phase 2 updates layer 4 and classifier, and Phase 3 further updates layer 3, 4, and classifier. Performance was assessed on a separate, never-seen set of 140 WSI (140 patients, ASH n = 43, MASH n = 97). A WSI-level diagnosis was obtained by averaging the model's predictions across all patches, and were compared using DeLong's test (for AUROC) and McNemar's test (for changes in correct classification); effect size was quantified with Cohen's d. **Results:** Phase 1 achieved AUROC 0.587 ± 0.245 and balanced accuracy 0.557 ± 0.129. Phase 2, did not improve metric compared to phase 1. Phase 3 achieved an AUROC 0.863 ± 0.005, balanced accuracy 0.764 ± 0.045, sensitivity 0.651, specificity 0.866, PPV 0.724, and NPV 0.858 (AUROC improvement of +0.277, a large effect size [Cohen's d = 1.14]; DeLong p < 0.0001), outperforming Phase 1 in these metrics. Phase 3 corrected 25 biopsies and introduced 10 errors, a net gain of 15 (McNemar p = 0.018). Performance was strongly stage-dependent: advanced fibrosis (NASH CRN fibrosis stage 3 and 4: AUROC 0.907, balanced accuracy 0.862) outperformed early fibrosis (fibrosis stage < 3: AUROC 0.754, balanced accuracy 0.660), where early-stage ASH was sparse (training n = 54/441; holdout n = 10/140). **Conclusion:** Progressive fine-tuning of a MoCo v2-pretrained ResNet50 achieved an AUROC of 0.86 for ASH versus MASH discrimination on routine H&E at 40× in an independent 140-slide test set, a meaningful level of accuracy for a distinction that lacks pathognomonic features. This model will augment rather than replace a pathologist interpretation. Additional potential application include providing independent adjudication in diagnostically uncertain cases, and supporting patient selection for clinical trial enrollment. Discrimination was strongest in advanced fibrosis where ASH and MASH diverge most architecturally. Key limitations include the single-institution design and the small number of early-stage ASH biopsies. Future work will prioritize enrichment of early-stage ASH cases and multi-site, multi-scanner validation to establish reliability in the low-fibrosis setting and support prospective clinical integration.

Figure 1

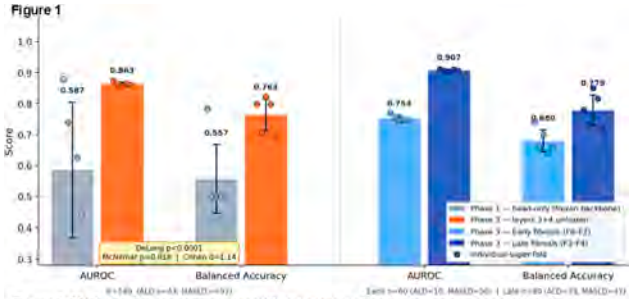

Figure 1. Model performance improves with progressive fine-tuning and varies by fibrosis stage. Compared with Phase 1, which showed variable and often near-chance performance, Phase 3 demonstrated substantially stronger discrimination between ASH and MASH on the separate holdout set of biopsies, with higher AUROC and balanced accuracy. Within Phase 3, performance was better in biopsies with advanced fibrosis than in early fibrosis, particularly for AUROC. This stage-dependent pattern suggests that disease-related histologic differences may be more visually pronounced in advanced fibrosis, whereas early-stage ASH and MASH may overlap more in appearance and fewer early-stage ASH cases were available for the model to learn from. Dots represent individual cross-validation results; bars summarize average performance.

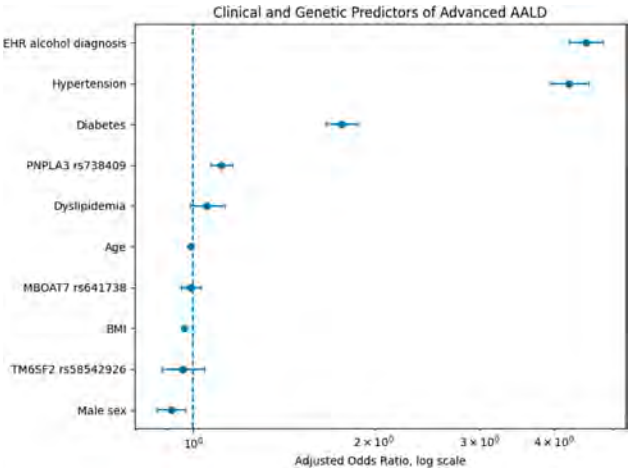
3041 | PNPLA3 RS738409 AND CLINICAL MODIFIERS OF ADVANCED ALCOHOL-ASSOCIATED LIVER DISEASE IN THE ALL OF US RESEARCH PROGRAM



Ihunanya Kanu[1] Sarpong Boateng[2] Chimezirim Ezeano[3] Oladoyin Ogunbayo-Jolaoye[4] Omar Ebrahim Ibrahim[5] Peng-Sheng Ting[6], [1]Baptist Memorial Hospital- Golden Triangle, [2]Yale New Haven Health, Bridgeport Hospital, [3]Advocate Aurora Healthcare, [4]University of illinois College of Medicine, Chicago, IL, [5]Baptist Memorial Hospital - Golden Triangle, [6]Tulane University School of Medicine

Background: Alcohol-associated liver disease (AALD) is a growing cause of cirrhosis-related morbidity and mortality in the United States, yet only a subset of individuals with alcohol exposure progress to advanced disease. This variability suggests that clinical, metabolic, and genetic modifiers influence susceptibility. Variants in PNPLA3 rs738409, TM6SF2 rs58542926, and MBOAT7 rs641738 have been associated with hepatic steatosis, fibrosis, and alcohol-related cirrhosis, with PNPLA3 rs738409 being the most consistently replicated risk locus. However, their independent associations with advanced AALD in large U.S. cohorts with linked EHR, lifestyle survey, and WGS data remain incompletely characterized. We evaluated whether PNPLA3 rs738409 and other candidate variants modify advanced AALD risk in the All of Us Research Program. **Methods:** We conducted a retrospective cohort study using the All of Us Controlled Tier CDR v8. Adults aged ≥ 18 years with EHR data, lifestyle survey responses, and short-read WGS were included. Advanced AALD was defined using EHR diagnosis codes for cirrhosis, alcoholic hepatitis, portal hypertension, ascites, esophageal varices, hepatic encephalopathy, or hepatic failure. Alcohol exposure was assessed using AUDIT-C-derived survey responses and EHR-documented alcohol-related diagnoses. PNPLA3 rs738409, TM6SF2 rs58542926, and MBOAT7 rs641738 were extracted from short-read WGS data using Hail and modeled additively. The primary analytic cohort excluded competing liver disease etiologies. Data extraction used SQL/BigQuery, and analyses were performed in Python using pandas, NumPy, and statsmodels. Multivariable

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

logistic regression adjusted for age, sex at birth, race, ethnicity, BMI, diabetes, hypertension, dyslipidemia, and EHR-documented alcohol-related diagnosis. **Results:** The primary analytic cohort included 259,549 adults, with 5,759 advanced AALD cases. EHR-documented alcohol-related diagnosis was strongly associated with advanced AALD (aOR 4.52, 95% CI 4.24–4.83, p < .001). Hypertension (aOR 4.23, 95% CI 3.93–4.56, p < 0.001) and diabetes (aOR 1.77, 95% CI 1.66–1.88, p < 0.001) were independently associated with advanced disease. Among candidate variants, PNPLA3 rs738409 remained independently associated with advanced AALD (per-allele aOR 1.11, 95% CI 1.07–1.16, p < 0.001). In contrast, TM6SF2 rs58542926 was not significantly associated (aOR 0.96, 95% CI 0.89–1.04, p = 0.334), and MBOAT7 rs641738 remained null (aOR 0.99, 95% CI 0.95–1.03, p = 0.608) **Conclusion:** PNPLA3 rs738409 remained independently associated with advanced AALD after excluding competing liver disease etiologies and adjusting for clinical, metabolic, alcohol-related, and sociodemographic factors. EHR-documented alcohol-related diagnosis, hypertension, and diabetes were the strongest clinical predictors, supporting combined clinical-genetic risk stratification for advanced AALD.

3042 | AN ELECTRONIC HEALTH RECORD-BASED HONEST BROKER STRATEGY TO IDENTIFY AND ENGAGE PATIENTS AT RISK FOR ALCOHOL-ASSOCIATED LIVER DISEASE FOR AUD TREATMENT

Allison Kwong[1] John Mendelson[2] Ethan Akama-Garren[1] Amy Chieng[1] Molly Bowdring[1] Judith Prochaska[1], [1]Stanford University, [2]Ria Health

Background: Early identification and linkage to treatment for alcohol use disorder (AUD) can prevent progression to alcohol-associated liver disease (ALD). However, engaging patients with AUD in treatment remains challenging. We describe the novel implementation and yield of an electronic health record (EHR)-based honest broker recruitment strategy to identify and engage patients at risk for ALD for a telehealth AUD treatment trial. **Methods:** From 2024-2025, EHR screening criteria were used to identify adult participants at our institution who within the previous 14-90 days: (a) had at least one elevated ALT, AST, or GGT 1-3x ULN (AST/ALT 45-135 U/L, GGT 100-300 U/L) or (b) had a medical encounter with an associated AUD diagnosis. After initial demonstration of safety and acceptability, the range of abnormal ALT, AST or GGT was expanded to include abnormal values up to 5x ULN. The honest broker, serving as a confidential third party independent of the research team, sent a single study invitation to patients via the Epic MyHealth research portal, indicating their potential eligibility for a study providing telehealth-based AUD treatment (NCT #05747703). Given the sensitive nature of the study, our institutional Research Compliance, Privacy, and Patient Experience offices vetted the recruitment language prior to deployment. Patients who indicated interest were provided a link to complete a screening questionnaire to assess eligibility. Outcomes included the volume of invitations, rate of response, and rate of enrollment based on trial eligibility criteria (i.e. presence of AUD, exclusion of prior AUD treatment, and ability to engage in study procedures). **Results:** Honest Broker study invitations for the AUD treatment study were sent to 60,140 patients (17,739 based on elevated liver tests 1-3x ULN, 38,306 for liver tests 1-5x ULN, and 4,095 for an AUD-related encounter). In total, 471 (0.8%) expressed interest and were provided a link to the screening survey, 335 completed screening, 86 met study eligibility criteria, and 66 ultimately enrolled. Among eligible patients, the median age was 47 years (IQR 37-60), 70% were male, and the median AUDIT-C was 7 (IQR 4-12). Among those who enrolled and completed a MINI interview for alcohol use, 50% had severe AUD, 36% moderate AUD, and 14% mild AUD, with a median baseline PETH of 115 ng/mL (IQR 44-257). **Conclusion:** An EHR-wide honest broker recruitment strategy successfully identified and engaged patients at risk for ALD for participation in a clinical trial. This approach identified several hundred patients interested in AUD treatment and enrolled 66 participants with predominantly moderate-to-severe AUD, without any reported patient complaints. Beyond research recruitment, EHR-based screening using laboratory abnormalities or AUD diagnoses may represent a scalable strategy to improve AUD treatment uptake and reduce the burden of ALD.

3043 | NEUROPSYCHIATRIC BURDEN ACROSS THE STEATOTIC LIVER DISEASE SPECTRUM: ALCOHOL-ASSOCIATED LIVER DISEASE IS INDEPENDENTLY ASSOCIATED WITH HIGHER DEPRESSIVE SYMPTOM BURDEN

Omar Albhaisi[1] Ayah Albhaisi[2] Lea Assaf[3] Ali Khan[1] Krishan Patel[1] Butros Fakhoury[1] Hannah Blaney[1] Luis Antonio Diaz[4] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Alexandria Faculty of Medicine, [3]American University of Beirut, [4]Pontificia Universidad Católica de Chile

Background: The neuropsychiatric burden across steatotic liver disease (SLD) phenotypes defined by the 2023 Delphi nomenclature remains poorly characterized. Whether depressive symptom burden differs across MASLD, MetALD, and alcohol-associated liver disease (ALD) independent of metabolic comorbidity, fibrosis severity, and binge drinking patterns is unknown. **Methods:** We analyzed 13,066 adults aged 18–80 years with vibration-controlled transient elastography from NHANES 2017–2023. SLD subtypes were classified using 2023 Delphi criteria. Primary outcomes were PHQ-9 total score and moderate-severe depression (PHQ-9 $\geq$10). Secondary outcomes included item-level depressive symptom domains and sleep characteristics. Survey-weighted regression models adjusted for demographics, BMI, diabetes, smoking status, and socioeconomic status. Fibrosis-adjusted models additionally incorporated liver stiffness measurement (LSM). Sensitivity analyses additionally adjusted for annual binge drinking status. **Results:** The analytic cohort included 5,732 MASLD, 286 MetALD, and 154 ALD participants (No SLD reference N = 6,894). Mean PHQ-9 scores progressively increased across No SLD (3.24), MASLD (3.54), MetALD (3.81), and ALD (4.91). After full adjustment, ALD was independently associated with higher depressive symptom burden versus No SLD (β = 1.45, 95% CI 0.50–2.41; p = 0.006), whereas MASLD showed a borderline association (β = 0.21; p = 0.057) and MetALD was not independently associated (β = 0.33; p = 0.386). Adjustment for fibrosis severity did not attenuate the ALD association (β = 1.46; p = 0.006; LSM p = 0.70). Additional adjustment for annual binge drinking status produced minimal attenuation (β = 1.43; p = 0.006), while binge drinking itself was independently associated with higher PHQ-9 score (β = 0.36; p = 0.011). Item-level analyses identified depressed mood (β = 0.32; p = 0.002), sleep disturbance (β = 0.29; p = 0.023), and diminished self-worth (β = 0.29; p = 0.008) as dominant symptom domains. **Conclusions:** Alcohol-associated liver disease is associated with disproportionately greater depressive symptom burden independent of fibrosis severity and binge drinking. These findings suggest neuropsychiatric burden in ALD extends beyond hepatic injury alone and support broader integration of neuropsychiatric assessment into alcohol-associated liver disease care pathways.

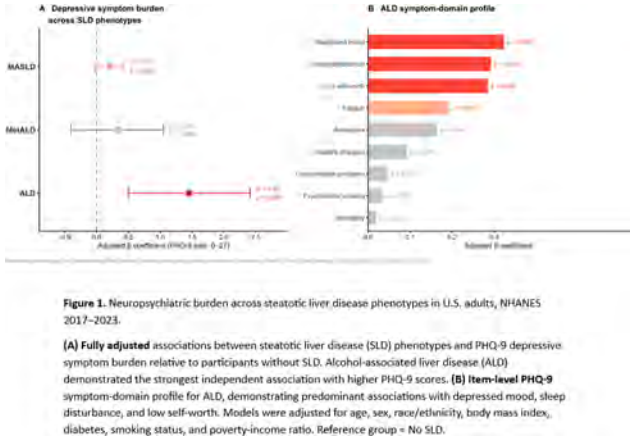

Figure 1. Neuropsychiatric burden across steatotic liver disease phenotypes in U.S. adults, NHANES 2017–2023.

(A) Fully adjusted associations between steatotic liver disease (SLD) phenotypes and PHQ-9 depressive symptom burden relative to participants without SLD. Alcohol-associated liver disease (ALD) demonstrated the strongest independent association with higher PHQ-9 scores. **(B) Item-level PHQ-9** symptom-domain profile for ALD, demonstrating predominant associations with depressed mood, sleep disturbance, and low self-worth. Models were adjusted for age, sex, race/ethnicity, body mass index, diabetes, smoking status, and poverty-income ratio. Reference group = No SLD.

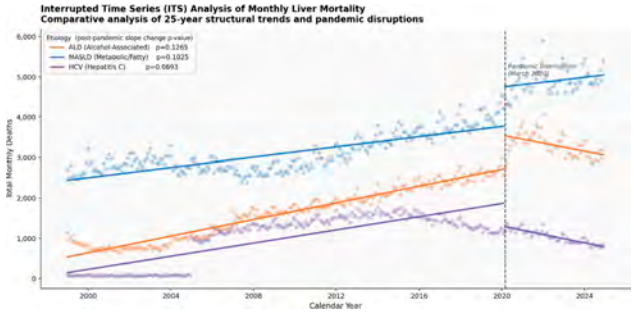
3044 | THE POST-PANDEMIC "NEW NORMAL" IN U.S. LIVER MORTALITY: INTERRUPTED TIME-SERIES AND YEARS OF POTENTIAL LIFE LOST ANALYSES OF ALCOHOL-ASSOCIATED LIVER DISEASE, MASLD, AND HEPATITIS C, 1999–2024



Nafiz Rashid[1] Sumaiyya Syeda[2] Sana Shaik[3] Muhammad Roshaan[4], [1]Dalian Medical University, [2]Gerogia National University, [3]Tbilisi State Medical University, [4]King Edward Medical University, Lahore

Background: Chronic liver disease mortality in the United States significantly changed in the face of COVID-19, but with incomplete definitions of the long-term post-pandemic trajectories of major causes. In this regard, we examined interrupted time-series (ITS)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

trends and years of potential life lost (YPLL) for alcohol-associated liver disease (ALD), metabolic dysfunction-associated steatotic liver disease (MASLD), and hepatitis C virus (HCV) mortality from 1999–2024. **Methods:** Monthly trends in US liver mortality were determined by ITS over 312 months (out of a total of 936 stand alone observations). Changes in structure after the pandemic were evaluated for ALD, MASLD and HCV mortality trajectories. YPLL analyses were also conducted to assess the burden of premature mortality among the different etiologies. **Results:** ITS analysis showed clear structural disruption from 2020, which stabilized mortality trajectories through 2024. Upon the peak mortality observed in 2021, there appeared no substantial downward recovery trend of ALD and MASLD post-pandemic and the overall reductions were plateauing period (ALD: $\chi^2 = 2.33$, $p = 0.1265$; MASLD: $\chi^2 = 2.67$, $p = 0.1025$). HCV mortality likewise could not recover its previous steep decline during the direct-acting antiviral period, an indication that prior enhancement trends had been disrupted ($\chi^2 = 3.30$, $p = 0.0693$). YPLL analyses showed that while MASLD was significant contributor to total number of people dying prematurely compared with ALD by absolute mortality in old age, ALD accounted for the largest proportion of premature mortality burden nationally. ALD accounts for almost half of total relative YPLL burden, indicating the high proportion of deaths among young & middle age populations. **Conclusion:** Post-pandemic liver mortality trends of mortality in the U.S. in the United States have stabilized under stable and consistently altered levels of death caused by major etiologies in the USA post-pandemic. ALD was reported to remain the leading factor for premature mortality burden, while prior improvements in HCV mortality did not fully recover until 2024. Such results could provide insights into future prevention and public health strategies for better liver disease outcomes for the population.

3045 | QUANTIFYING CUMULATIVE EXCESS ALCOHOL-ASSOCIATED LIVER DISEASE MORTALITY IN THE UNITED STATES, 2020–2024: A FORMAL INTERRUPTED TIME-SERIES ANALYSIS

Shabi Mohammadi[1] Muhammad Roshaan[2] Sumaiyya Syeda[3] Sana Shaik[4], [1]Shadan Institute of medical sciences, [2]King Edward Medical University, [3]Georgian National University, [4]Tbilisi State Medical University

Background: Mortality among alcohol-associated liver disease (ALD) patients increased in the United States in recent years, with worries that the COVID-19 pandemic may have led to further changes in mortality trajectories. This paper quantified cumulative excess ALD mortality between 2020 and 2024 and assessed trends by using interrupted time series (ITS) analysis to evaluate demographic differences. **Methods:** CDC WONDER mortality data of ALD (ICD-10: K70) were analyzed from 2010–2024. Expected mortality rates for 2020–2024 were estimated using pre-pandemic trends for 2010–2019. Excess mortality was calculated as the difference between observed and expected mortality. ITS regression was used to assess level and slope changes post 2020. Stratified analyses were performed by sex, age group, race/ethnicity. Overall, sex, and race analyses applied age-adjusted rates, and age-group analyses employed crude. **Results:** In the United States, an estimated 14,757 excess ALD deaths occurred between 2020 and 2024, translating to an overall excess mortality of 9.8%. The results of ITS analysis indicated that mortality level increased massively at 2020 (+2.35 per 100,000; $p < 0.001$) followed by gradual attenuation in the years to the next decade. The excess mortality rate peaked in 2021 and went higher than projected through 2023 with rates hovering even until 2023, nearing expected trends by 2024. Females had a proportional excess mortality that was larger than males, reflecting greater females (12.1% compared to 9.0%). Compared to all other age groups, the greatest proportional increase was seen in people aged 15–24 years (41.8%), followed by people aged 35–44 years (27.3%) with a proportionally higher increase, and in people aged 25–34 years (23.3%). American Indian/Alaska Native individuals had the most proportionate excess mortality (24.4%), whereas Asian/Pacific Islander individuals had the lowest positive excess mortality (8.3%) according to race/ethnicity. No sustained excess mortality was observed for adults aged ≥ 85 years. **Conclusion:** ALD mortality in the United States increased significantly above projected pre-pandemic trends during 2020–2024 and greater burden occurred among younger adults, females, and American Indian/Alaska Native populations. These

results might support the need for targeted public health and preventive policies for high risk populations for ALD-related mortality.

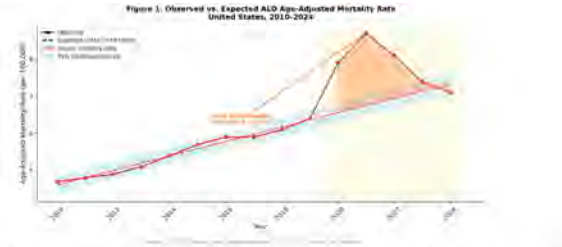

Figure 1. Observed versus expected alcohol-associated liver disease (ALD) age-adjusted mortality rates in the United States, 2010–2024. A solid line denotes observed ALD mortality rates from CDC WONDER data; the dashed line is expected mortality projected from the 2010–2019 pre-pandemic linear trend. The orange shaded area denotes excess mortality from 2020–2024, and the blue shaded band is the 95% prediction interval for expected rates. The total number of excess ALD deaths during this period was estimated at 14,757. Mortality rates were reported per 100,000 population and were age-adjusted to the 2000 U.S. standard population. ALD deaths were identified using ICD-10 code K70.

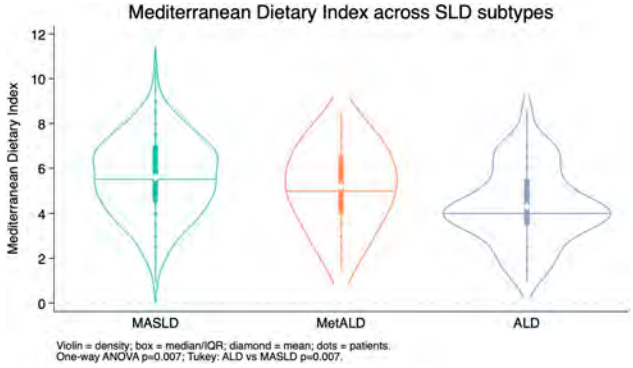
3046 | HIGHER MEDITERRANEAN DIET ADHERENCE IS ASSOCIATED WITH LOWER LIVER FIBROSIS RISK ACROSS STEATOTIC LIVER DISEASE SUBTYPES



Luis Antonio Diaz[1] Francisco Idalsoaga[1] Mario Pessoa[2] Claudia Oliveira[3] Patricia Ziteli[3] Scherezada Mejia[4] Ezequiel Ridruejo[5] Mirta Peralta[6] César Castro[7] Jorge Garavito[7] Rommel Zambrano-Huailla[7] Gustavo Ayares Campos[1] Nancy Solis López[1] María Paz Orellana[1] Sebastian Marciano[8] Adrián Gadano[8] Jorge Martínez[8] Maria Jose Acosta[8] Martin Tagle[9] Hugo Cedron[9] Ismael Yepes[10] Dalis Perez[10] MaríaFernanda SaavedraChacón[11] Samuel Perez[11] Ignacio Garcia Juarez[12] Orfanel Sebastian Pineda-Arzate[13] Liz Toapanta-Yanchapaxi[13] Aline Sorribas[14] Manuel Mendizabal[14] Lorena Castro Solari[15] Loreto Aguilar Barría[16] Samantha Wu[16] Catalina Roa[16] Fabiana Nina[17] Estefanía Liza Baca[18] Javier Diaz Ferrer[18] Roberto Pérez Ravier[19] María Belen Martinez[19] Natalie Vilcinskas[19] Daniza Alexandra Contreras[20] Daniela Simian[21] Juan Roblero[22] Pamela Gil[21] Arun Sanyal[23] Juan Pablo Arab[23] Marco Arrese[1], [1]Pontificia Universidad Católica de Chile, [2]University of São Paulo, [3]Universidade de São Paulo, [4]Hospital Juárez de México, [5]Centro de Educación Médica e Investigaciones Clínicas Norberto Quirno "CEMIC, [6]Hospital Francisco J Muñiz, [7]Hospital Nacional Arzobispo Loayza, [8]Hospital Italiano de Buenos Aires, [9]Clínica Anglo Americana, [10]Centro Médico Gastropack, [11]Clínica CES, [12]The National Institute of Medical Science and Nutrition, [13]The National Institute of Medical Sciences and Nutrition, [14]Hospital Universitario Austral, [15]Clínica Universidad de los Andes, [16]Universidad de los Andes, [17]Universidad del Alba, [18]Hospital Nacional Edgardo Rebagliati Martins, [19]Hospital Central de Mendoza, [20]National Institute of Diabetes, Nutrition, and Endocrinology (INDEN), [21]Hospital Clínico Universidad de Chile, [22]University of Chile, [23]Virginia Commonwealth University

Background: The Mediterranean diet may play a protective role in steatotic liver disease (SLD), but this relationship remains poorly characterized in Latin America. This multinational study aims to identify the association between Mediterranean diet adherence and the risk of liver fibrosis across the SLD subtypes in Latin America. **Methods:** Cross-sectional analysis of prospectively enrolled adults with SLD (2023 criteria) at 16 tertiary centers in seven countries (Argentina, Brazil, Chile, Colombia, Dominican Republic, Mexico, and Peru). We recorded self-reported alcohol intake and the Chilean Mediterranean Dietary Index (MDI, adapted for regional use). Fibrosis was assessed by liver biopsy and/or vibration-controlled transient elastography (VCTE). Significant fibrosis was defined as $\geq$F2 on biopsy or VCTE $\geq$8 kPa (if biopsy unavailable). Analysis included a binary logistic regression, adjusted for age, sex, ethnicity, body mass index (BMI), type 2 diabetes mellitus (T2DM), MDI, and SLD subtype. **Results:** We included 491 participants (median age 59 [50–60] years; 52.8% women; 78.8% self-reported Hispanic). A total of 81.6% had MASLD, 9.6% MetALD, and 8.8% ALD. Significant fibrosis prevalence was 40.6%. The mean MDI was 5.5 ± 1.8, while by using predefined categories, 35.6% had low adherence, 62.7% had moderate adherence, and only 1.6% had high adherence. Mean MDI differed significantly across SLD subtypes (MASLD: 5.6 ± 1.7, MetALD: 5.2 ± 1.8, and ALD: 4.3 ± 1.7; $p < 0.001$) (**Figure**). In pairwise comparisons, MDI was significantly lower in ALD than in MASLD (mean difference −1.3; Bonferroni-adjusted $p < 0.001$) and MetALD (mean difference −0.9; Bonferroni-adjusted $p = 0.048$). Higher MDI adherence was independently associated with lower odds of significant fibrosis, with each 1-point increase linked to a 17% reduction in odds after adjustment (aOR 0.83; 95% CI 0.74–0.94; $p = 0.003$). **Conclusion:** In this well-characterized multinational Latin American cohort of adults with SLD, Mediterranean diet adherence was suboptimal and differed significantly across SLD subtypes, with the lowest adherence observed in ALD. Higher MDI was independently associated with lower odds of significant fibrosis, supporting the potential role of Mediterranean diet as a modifiable factor across the

3047 | HEAVY DRINKING PATTERNS AND MULTISYSTEM ALCOHOL-ASSOCIATED DISEASE: A GLOBAL ECOLOGICAL STUDY

Denisse Rubio Cruz[1] Ximena Parraga[2] Kriti Soni[2] Tulio Correa[3] Hyundam (Dami) Gu[2] Rylyn Reyes[2] Adelina Horhat[4] Joshua Chen[2] S. Fisher Rhoads[2] Vinay Jahagirdar[2] Kavin Parmar[2] Krishan Patel[2] Stephen Hoang[2] Luis Díaz[5] Juan Pablo Arab[2], [1]Lahey Hospital; Virginia Commonwealth University, [2]Virginia Commonwealth University, [3]University of Pittsburgh, [4]Department of Hepatology, Henri Mondor University Hospital, [5]Pontificia Universidad Católica de Chile

Background: Alcohol consumption contributes to multisystem cellular injury and has been associated with several malignancies and cardiovascular diseases, including hepatocellular carcinoma (HCC), laryngeal cancer, esophageal cancer (EC), colorectal carcinoma (CRC), and alcohol-associated cardiomyopathy (ACM). Global sex-specific drinking patterns and their relationship with the distribution of these diseases remain incompletely characterized. **Methods:** An ecological analysis including 184 countries across World Health Organization (WHO) regions was conducted for the aforementioned diseases. Heavy episodic drinking (HED), heavy continuous drinking (HCD), and sex-related differences in alcohol exposure patterns were evaluated. Radar plots and correlation heatmaps were used to reveal regional drinking profiles and explore potential relationships between alcohol exposure patterns and disease prevalence. **Results:** HED and HCD stratified by sex demonstrated distinct regional patterns. Male HED represented the most pronounced drinking behavior globally, whereas female HCD had the lowest overall prevalence and the least regional variability. Male HED, female HED, and male HCD were most prevalent within the European Region and the Region of the Americas. Correlation analyses exhibited overall modest relationships, where HCD in both sexes showed relatively stronger correlations with HCC compared with HED. A modest alignment was observed for female HCD with CRC and female HED with ACM. In contrast, EC showed minimal correlation with all the evaluated drinking patterns. Interestingly, geographic concordance between alcohol exposure patterns and disease prevalence was more pronounced among conditions with stronger established epidemiologic associations with alcohol use. **Conclusion:** This study provides an exploratory ecological characterization of sex-related drinking patterns and alcohol-associated disease burden across multiple organ

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

systems. Despite subtle correlations, it is a close insight to global patterns integration. More studies are needed to better characterize the mechanisms underlying these relationships.

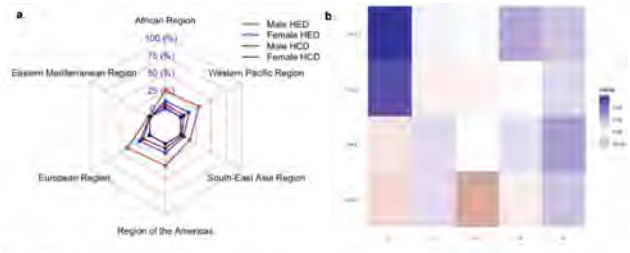

Figure 1a. Regional drinking patterns stratified by sex; each level represents a different percentage of the prevalences per zone. **b.** Correlation between sex-specific patterns and disease burden for different conditions. Drinking patterns include: heavy continuous drinking for females (hcd_f), heavy continuous drinking for males (hcd_m), heavy episodic drinking for females (hed_f), heavy episodic drinking for males (hed_m). Diseases evaluated include: hepatocellular carcinoma (hc), laryngeal cancer (lc), esophageal cancer (ec), colorectal cancer (cc), alcoholic cardiomyopathy (ac); darker colours represent stronger associations between each other.

3048 | AI-DRIVEN HISTOPATHOLOGY AND MACHINE LEARNING FOR MORPHOLOGICAL ANALYSIS OF DUCTULAR REACTION AND PREDICTING HEPATIC VENOUS PRESSURE GRADIENT IN ALCOHOL-ASSOCIATED HEPATITIS

Ankita Srivastava[1] Meritxell Cots[2] Ramon Bataller[3] Rajanikanth Vadigepalli[4], [1]Thomas Jefferson University, [2]Vall d'Hebron Institute of Research, Universitat Autònoma de Barcelona, [3]Hospital Clinic of Barcelona, University of Barcelona, Barcelona, Spain, [4]University of New Mexico School of Medicine

Background: Alcoholic Hepatitis (AH) is a clinical syndrome characterized by acute-onset jaundice and liver enzyme abnormalities in the setting of long-term heavy alcohol use with high short-term mortality and limited therapies. AH is a frequent complication of alcohol-associated liver disease (ALD) that accounts for ~40% of liver transplantations. AH is characterized by hepatocellular insufficiency, immune activation, and aberrant proliferation of a biliary phenotype (cholangiocyte-like cells), referred to as the ductular reaction (DR). DR is both a hallmark of AH and a contributor to fibrotic remodeling and portal hypertension. Hepatic venous pressure gradient (HVPG) is the gold-standard measure of portal hypertension and a crucial prognostic indicator in cirrhosis; however, its role in AH is less defined. Since portal hypertension is a key consequence of AH, and DR has a characteristic morphology, we hypothesized that quantifiable morphological features of DR, extracted from histopathology images of the liver needle biopsies, could be used to predict HVPG levels in AH patients. **Methods:** We analyzed Cytokeratin 7 (CK7-DAB) stained whole slide images from 53 AH patients (fibrosis F1-F4) for general CK7+ objects, and 41 AH patients (F3-F4 fibrosis) for specific elongated and circular DR. We developed image analysis workflows, including AI-based U-Net segmentation for refined DR morphologies, to extract numerous shape and size parameters. Feature selection was based on correlation with HVPG. Tabular Prior-data Fitted Network (TabPFN) models, augmented with linear corrections, were used to predict HVPG. Models were evaluated using 80-20 train-test splits over 10 runs and compared to randomized data. **Results:** We identified CK7+ cellular objects with larger than 100 µm2 area and collated data on 43602 CK7+ cellular objects (751.76 ± 509.41; mean ± s.d. per image) across 53 images. For all CK7+ objects, the proportion of CK7-DAB area correlated with HVPG (r = 0.48), with poor prediction performance in model testing. When focusing on elongated and circular DR, the proportion of CK7-DAB area (r = 0.46) and elongated DR count (r = 0.31) also correlated with HVPG. This refined approach significantly improved prediction performance in testing (p-value = 0.0068), outperforming the general CK7+ model. **Conclusion:** Our machine learning approach demonstrates the potential to quantitatively relate the histopathological aspects of AH liver tissue to physiological variables associated with portal hypertension. These findings establish a link between histological remodeling and physiological dysfunction, opening new avenues for risk stratification and therapeutic decision-making in AH.

3049 | C5 COMPLOSOME IN HEPATIC MACROPHAGES IS REQUIRED FOR IMMUNOMETABOLIC SWITCHING REQUIRED FOR PROINFLAMMATORY POLARIZATION IN MODELS OF ALD

Shannon Kirkpatrick[1] James Roede[2] Rebecca McCullough[3], [1]University of Colorado, Anschutz

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Medical Campus, [2]CU Anschutz Medical Campus, [3]University of Colorado - Anschutz

Background: Complement activation and hepatic macrophages (HMs), including the resident Kupffer Cells (KCs) and monocyte-derived macrophages (MDMs), play critical roles in alcohol-associated liver disease (ALD) pathogenesis by initiating and maintaining non-resolving hepatic inflammation. During ALD, HMs respond to ethanol (EtOH) and gut-derived microbial-associated molecules [MAP; i.e. lipopolysaccharide (LPS)] by undergoing glycolytic shift required for proinflammatory polarization. The mechanisms underlying how immunometabolic switching initiates and sustains inflammatory HM phenotypes remain unclear. Intracellular complement activation (complosome) has emerged as a mediator of glycolytic switching required for inflammatory macrophage functions. We have shown that the C5 complosome contributes to inflammatory polarization by EtOH and MAP exposure. It is unclear if EtOH-induced C5 complosome activation can impact mitochondrial function following metabolic stress in models of EtOH exposure. **Methods:** C5 complosome components in HMs were assessed by scRNA-seq data from severe alcohol-associated hepatitis (sAH) and healthy control (HC) patients and from EtOH exposed mice. C5/C5aR1 KO immortalized mouse KCs (ImKCs) and C5aR1 antagonists (PMX205, cell-impermeable; JPE1375, cell-permeable) were used to interrogate the C5 complosome in EtOH- and LPS-driven glycolytic shift. Seahorse XF mitochondrial stress testing and Western blotting of glycolytic enzymes assessed metabolic shifts, and MitoSOX was used to quantify mitochondrial superoxide. **Results:** Cell clustering defined by HM lineage markers revealed that sAH macrophages exhibit enhanced expression of C5aR1, with the highest expression in MDMs and neo-KCs when compared to other AH HMs and HC MDMs. HMs from mice exposed to 5% EtOH feeding had increased proportions and mean expression of C5aR1. In human and mouse, C5aR1 expression in HMs were positively associated with proinflammatory and glycolytic gene expression. In WT ImKCs, LPS alone, and with EtOH, suppressed basal, maximal, and ATP-linked respiration but all parameters were restored in EtOH- and LPS-treated C5 KO and C5aR1 KO ImKCs. C5 KO and C5aR1 KO ImKCs were protected against EtOH- and LPS-induced expression of glycolytic enzymes, PFKb3 and TPI. C5aR1 antagonist pretreatment suppressed EtOH- and LPS-induced superoxide production; notably, the JPE1375 achieved greater suppression than the PMX205, implicating intracellular C5aR1 signaling in superoxide generation. **Conclusion:** In summary, human and mouse ALD is defined by enhanced HM C5aR1 expression. Pharmacologic blockage and genetic deficiency indicate a pivotal role for the C5 complosome in glycolytic shift by alcohol. Future directions include profiling how HMs specific expression of the C5 complosome influences downstream effects of mitochondrial dysfunction in models of ALD.

3050 | IMPROVING ENGAGEMENT IN ALCOHOL USE DISORDER TREATMENT THROUGH A MULTIDISCIPLINARY ALD CLINIC

Rebecca Roediger[1] Yael Belinkie[2] Melanie Hundt[2] Katherine Myers[1] Lisa Teh[3] Hamza Sadhra[4] Jessica Jang[5] Alexander Vogel[4] Brett Fortune[6] Kristina Chacko[4], [1]Weill Cornell Medicine, [2]Montefiore Medical Center, [3]Montefiore Einstein Medical Center, [4]Montefiore Einstein, [5]Albert Einstein School of Medicine, [6]Miami Transplant Institute/Jackson Health

Background: Treatment for alcohol-related liver disease (ALD) requires abstinence and therefore addressing alcohol use disorder (AUD). Nationally only 14% of patients with ALD enroll in alcohol treatment and only 10% receive medications for alcohol use disorder (MAUD)[1] . Of ALD patients referred to AUD treatment by a hepatologist, only 35% get connected with care[2] . Multidisciplinary ALD clinics allow patients to receive concurrent ALD and AUD treatment, however time and staffing constraints limit the frequency and extent of targeted interventions. Montefiore Einstein has created the METRIC clinic, which provides multidisciplinary care for ALD within a transplant program while connecting patients to partner AUD treatment programs where they receive more extensive outpatient care. **Methods:** METRIC was implemented to support patients with high-risk alcohol use throughout the liver transplant process. METRIC includes a hepatologist, psychologist, psychiatrist, pharmacist, social workers, dietitian, and certified recovery peer. All METRIC patients are offered MAUD and referred to AUD treatment, which provides counseling, peer support, psychiatry, and psychotherapy services. METRIC has undergone iterative improvements to better serve our patients. We first targeted engagement with our partner outpatient AUD program by implementing weekly meetings to address barriers before missed appointments. Once patients were reliably attending our partner program in the Bronx, we created a network of alcohol treatment centers throughout our catchment area to broaden access. We then sought to address the nearly 25% of our patients whose preferred language is Spanish by creating a variant of METRIC where all providers speak Spanish fluently, allowing the entire visit to be conducted in the patient's preferred

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

language. **Results:** METRIC served 82 patients from December 2023 to December 2025. They reflect our diverse community with 65% male, 50% Hispanic, 29% Caucasian and 13% Black. We have a 78% attendance rate and reschedule all missed or cancelled appointments. 69% of our patients have verified attendance at an alcohol treatment program and 76% are taking MAUD. Of METRIC patients referred to our partner AUD program in the Bronx, 82% completed an intake assessment compared to 37% of referrals from non-METRIC sources. After completing an intake, 94% of METRIC referrals enrolled in treatment, and of those 40% have successfully completed their AUD treatment and 43% remain actively engaged.Of patients who attended METRIC pre-transplant, 45% have undergone liver transplant, 21% remain listed for transplant, and 18% became too well for transplant as a result of abstinence. **Conclusion:** We have created a successful multidisciplinary clinic which treats transplant pathway patients with AUD by both integrating alcohol use treatment into the transplant team and bridging patients to outpatient AUD treatment programs.

3051 | MODELING HEPATIC DYSFUNCTIONS CAUSED BY METALD USING A HUMAN MICROPHYSIOLOGICAL SYSTEM

Owen Lally[1] Salman Khetani[2], [1]University of Illinois Chicago, [2]University of Illinois at Chicago

Background: Rising rates of obesity combined with prevalent alcohol use have increased the prevalence of metabolic dysfunction-associated steatotic liver disease with increased alcohol intake (MetALD), a disease classification associated with faster disease progression and poor clinical outcomes. However, animal models do not always suffice to investigate the progression of human MetALD, thereby necessitating in vitro human-relevant models. Thus, we utilized micropatterned cocultures (MPCCs) of primary human hepatocytes (PHH) and fibroblasts to investigate the synergistic effects of ethanol (EtOH) and fatty acids (FA) on hepatic function and disease phenotypes. **Methods:** MPCCs were fabricated using established protocols. Briefly, polydimethylsiloxane (PDMS)-based soft lithography was used to pattern collagen I into circular domains (500 µm diameter, 800 µm spacing center-to-center) within multiwell plates. PHHs adhered to the collagen domains and were subsequently surrounded by stromal fibroblasts to stabilize functions for 3+ weeks. MPCCs were exposed to metabolic stressors associated with MASLD, including glucose, insulin, a mixture of saturated and unsaturated fatty acids (FA), and pharmacologically relevant EtOH concentrations for 2 weeks. To reduce EtOH evaporation during daily media exchange, a PDMS sheet was bonded to the plate lid to minimize the air space between the plate bottom and lid; furthermore, EtOH at 1.35X the concentration used for cell treatment was placed in cell-free wells (Fig. 1A). Hepatic CYP450 activity, albumin and urea secretions, steatosis, insulin resistance, and oxidative stress were measured using established assays, while RT-qPCR was used for gene expression analysis. **Results:** While excess glucose induced hepatic steatosis, it did not affect insulin sensitivity or CYP450 activities (not shown). EtOH and FAs, individually, however, did induce steatosis, caused insulin resistance, and altered CYP450 activities. A combination of these triggers (MetALD) produced significantly greater steatosis than either condition alone (Fig. 1B) and resulted in the greatest induction of CYP450 activities and expression (Fig. 1C, D). MetALD also altered EtOH metabolism (not shown), elevated mitochondrial membrane potential (Fig. 1E), increased oxidative stress (Fig. 1E, F), and increased the expression of oxidative stress markers Nrf2 and NQO1 (Fig. 1G). **Conclusion:** MPCCs exposed to physiologically relevant concentrations of FAs and EtOH exhibited additive effects on lipid accumulation and CYP450 induction, as well as synergistic disruption of EtOH metabolism and mitochondrial function, effects not observed with either treatment alone. These findings implicate oxidative stress as a key driver of MetALD-associated hepatocyte dysfunction and position MPCCs as a human-relevant platform for investigating MetALD mechanisms and evaluating therapeutic strategies.

3052 | RISING MENTAL HEALTH AND SUBSTANCE USE COMBINED MORTALITY WITH ALCOHOL-ASSOCIATED LIVER DISEASE IN THE UNITED STATES, 2008–2024

William Oles[1] Jessica Rubin[1] Courtney Sherman[1], [1]University of California, San Francisco (UCSF)

Background: Alcohol-associated liver disease (ALD) is a leading cause of liver-related mortality in the United States. Despite clinical recognition of the psychiatric and substance use comorbidity burden in ALD, contributions to combined mortality have not been characterized nationally. **Methods:** Using the CDC WONDER database (2008–2024) and associated ICD-10 codes, we identified all-cause deaths for which ALD and leading mental health diagnoses (depression, anxiety disorders, bipolar disorder, PTSD, schizophrenia) or substance use (opioid, stimulant, sedative-hypnotic; alcohol excluded) were listed as contributing causes. Annual percent change (APC; 95% CI) in age-adjusted mortality rate (AAMR) was calculated using Joinpoint regression to analyze temporal trends. Analyses were stratified by gender, age, race and ethnicity, and region. **Results:** Co-morbid mental health conditions and substance use accounted for 7,762 and 8,016 ALD deaths between 2008 and 2024, respectively. During this period, the AAMR for mental health mortality increased from 0.10 to 0.23 (APC: 6.5%; 5.2–7.8), while the AAMR for substance use mortality increased from 0.09 to 0.23 (APC: 8.0%; 6.4–9.7). Mortality associated with both mental health and substance use significantly increased in 2019 before plateauing in 2021 (Figure). Depression accounted for 60% of mental health mortality; however, acceleration was greater for anxiety disorders (APC: 15.8%; 13.7–17.9) than depression (APC: 6.3%; 4.4–8.2). Opioid use accounted for 53% of substance use mortality; however, acceleration was greater for stimulant use (APC: 13.7%; 10.5–16.9) than opioid use (APC: 6.1%; 4.2–7.9), with associated AAMR surpassing opioids by 2017. Maximum AAMR for mental health mortality was seen in males, Non-Hispanic Whites, ages 55–64, and those in the West. Maximum AAMR for substance use mortality was similarly distributed, with the exception of Hispanic or Latino and American Indian or Alaska Native (AIAN) populations experiencing greater mortality than Non-Hispanic Whites. The steepest increases across all co-involved mortality occurred in females, ages 65–74, those in the South, and AIAN individuals. **Conclusion:** Mortality from ALD with co-morbid mental health conditions or substance use increased between 2008 and 2024. Temporal analyses suggest that rates rose steadily before increasing rapidly after 2019, likely reflecting COVID-19-era care disruptions. While attention should be paid to historically predominant co-morbidities—such as depression and opioid use—we identified greater acceleration from stimulant use and anxiety disorders, with disproportionate impacts among females, older adults, those in the South, and Hispanic or AIAN individuals. These trends highlight the need for holistic ALD care and targeted interventions, particularly for underserved populations and regions.

3053 | DIAGNOSTIC ACCURACY OF ICD-10 CODES FOR ALCOHOL USE DISORDER IN A REAL-WORLD CIRRHOSIS COHORT: A MANUAL CHART VALIDATION STUDY

Maaz Arif[1] Eric Orman[2] LaKeisha Boyd[1] Yang Li[1] Deborupa Pal[1] Jing Su[1] Wanzhu Tu[1] Naga Chalasani[3] Archita Desai[1] Samer Gawrieh[1], [1]Indiana University

School of Medicine, [2]Indiana University, [3]Indiana University Medical Center

Background: The accuracy of ICD-based AUD identification in administrative cirrhosis cohorts and real-world data is poorly characterized. We aimed to measure the performance of ICD-10–based AUD identification in the Indiana Cirrhosis Cohort (ICC), a statewide real-world cirrhosis registry derived from a large health information exchange. **Methods:** The total cohort included 10,227 subjects with compensated cirrhosis. ICD code-based AUD diagnosis was compared to manual chart review on a stratified sample from the ICC: 243 adults with an ICD-10 F10.x AUD code and 244 without. Clinical documentation including medication list, medical history, or AUD treatment history when available was reviewed for 18 months before and after the AUD diagnosis date (cases) or index cirrhosis date (non-cases). 200 charts were reviewed by 2 reviewers and the remaining by 1 reviewer. Reviewers were blinded to the AUD code status. A structured form covering 8 keyword categories was used to classify each chart on a 6-point ordinal scale, with "Definitely Yes" or "Probably Yes" treated as AUD-positive. Inter-rater reliability was assessed using weighted Cohen's kappa. A sensitivity analysis restricted AUD classification to 'Definitely Yes' and 'Definitely No' designations only. Subgroup analyses examined ICD performance by sex and race. **Results:** Among 487 patients, ICD-coded patients were younger (53.6 vs 61.9 years), more often male (62% vs 47%), more often had alcoholic etiology (55% vs 13%), and more often had Medicaid (43% vs 27%) with less Medicare (16% vs 35%) coverage than ICD-negative patients (all $p < 0.001$). During chart review, 77 (16%) had insufficient data for determination. Of the remaining 410, 238 (58%) were AUD-positive: 204 of 224 ICD-coded patients (91%) and 34 of 186 ICD-negative patients (18%). Inter-rater reliability on the dually reviewed subset was high (weighted Cohen's kappa 0.90, 95% CI 0.85–0.95). ICD-10 F10.x codes demonstrated an AUROC of 87% (95% CI 84–90%), sensitivity of 85.7% (95% CI 81.3–90.2), specificity of 88.4% (95% CI 83.6–93.2). Performance was preserved across sensitivity analysis that included "Definitely Yes" cases (sensitivity 88.0%, specificity 93.6%) and in males/females (sensitivities 84.8% and 86.9%, specificities 87.5% and 88.8%, respectively); estimates were similar in the Black subgroup (Panel A). AUD ICD-10 F10.x codes showed consistently high (>97%) negative predictive value (NPV) for AUD when applied to the entire ICC (F10.x AUD prevalence 13%) and across subgroups, but moderate positive predictive value (PPV) (48–68%) (Panel B). **Conclusion:** In a real-world cirrhosis cohort, ICD-10 F10.x codes are highly reliable to exclude AUD but when present show only moderate positive predictive value for AUD. Additional methods such as artificial intelligence or large language models may help improve the accuracy of AUD identification in structured administrative data of cirrhosis cohorts.

Table 1. Diagnostic accuracy of ICD-10 F10.x codes for alcohol use disorder identification across sensitivity and subgroup analyses.

Panel A. Sensitivity and specificity from the chart-reviewed sample (n=487)

	Primary	Sensitivity	Subgroup analyses			
Metric	Definitely or Probably Yes n = 410	Definitely Yes only n = 242	Male n = 223	Female n = 187	Black n = 30	Non-Black n = 355
Sensitivity, % (95% CI)	85.7 (81.3–90.2)	88.0 (83.6–92.4)	84.8 (78.6–90.5)	86.9 (79.7–94.1)	90.0 (78.3–100)	84.9 (80.0–89.8)
Specificity, % (95% CI)	88.4 (83.6–93.2)	93.6 (89.2–97.9)	87.5 (79.8–95.1)	88.8 (82.1–95.6)	85.0 (69.4–100)	88.7 (83.6–93.7)

Panel B. PPV and NPV when applied to the Indiana Cirrhosis Cohort, (compensated cirrhosis, n=10,227)

	Primary	Sensitivity	Subgroup analyses			
Metric	Definitely or Probably Yes	Definitely Yes only	Male	Female	Black	Non-Black
PPV, % (95% CI)	53.07 (47.73–63.41)	67.66 (52.95–85.89)	50.99 (35.62–66.81)	54.29 (40.82–68.26)	47.93 (27.75–74.13)	53.86 (47.23–64.69)
NPV, % (95% CI)	97.58 (94.85–98.55)	98.07 (95.55–98.91)	97.40 (95.49–98.89)	97.79 (94.19–98.99)	98.23 (94.13–100)	97.45 (94.63–98.97)

Arrese[5] Winston Dunn[16] Ashwani Singal[17] Ramon Bataller[18] Luis Díaz[5] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Texas Tech University Health Sciences Center, [3]Western University, [4]Amrita Institute of Medical Sciences and Research Centre, [5]Pontificia Universidad Católica de Chile, [6]Pontificia Universidad Católica de Chile, Santiago, [7]Escuela de Medicina Universidad de Chile, [8]Hospital Civil de Guadalajara Fray Antonio Alcalde, [9]Hospital General Manuel Gea González, [10]Hospital Universitario Austral, [11]Hospital Italiano Buenos Aires, [12]Montefiore Medical Center, [13]Slovak Medical University, [14]University Hospital in Kraków, [15]Mayo Clinic, [16]University of Kansas Medical Center, Kansas City, [17]University of Louisville School of Medicine, [18]Hospital Clínic de Barcelona

Background: This prospective, multinational cohort study from the Global AlcHep Database stratified AH patients into three phenotypes: no AKI, prevalent AKI (at admission), and incident AKI (hospital-acquired). 90-day mortality was analyzed via multivariable competing-risks regression (liver transplantation as a competing event). A 7-day landmark analysis among survivors not receiving renal replacement therapy (RRT) evaluated early trajectory. Progression was defined as day 7 creatinine increasing $\geq$50% or $\geq$0.3 mg/dL from admission. **Methods:** This prospective, multinational cohort study from the Global AlcHep Database stratified AH patients into three phenotypes: no AKI, prevalent AKI (at admission), and incident AKI (hospital-acquired). The primary outcome was 90-day mortality, analyzed via multivariable competing-risks regression (treating liver transplantation as a competing event), adjusting for age, nadir creatinine, Child-Pugh score, circulatory/respiratory failure, and infection. A 7-day landmark analysis among 7-day survivors evaluated early renal trajectory. Progression was defined as day 7 creatinine increasing $\geq$50% or $\geq$0.3 mg/dL from admission; patients requiring renal replacement therapy were excluded from the landmark analysis to avoid trajectory confounding. **Results:** Among 581 patients (median age 48; 92% male), 52.5% had no AKI, 36.5% had prevalent AKI, and 11.0% developed incident AKI. Overall 90-day mortality was 18.2%. 42 patients (15.2% of those with AKI) required RRT, with 90-day mortality of 45.2%. Prevalent AKI was predominantly functional (84.4%), while incident AKI had significantly higher rates of structural/acute tubular necrosis (43.8% vs 10.4%, $p < .001$). Despite lower admission disease severity (median MELD 23.5 vs 31.7), incident AKI conferred an independent mortality risk (sHR 2.18, 95% CI 1.19–3.99) comparable to prevalent AKI (sHR 1.80, 95% CI 1.02–3.16). In the 7-day landmark analysis ($N = 457$), patients with prevalent AKI without progression (67.4%) had a mortality hazard statistically similar to those without AKI (sHR 1.27, $p = .52$). Conversely, progressive prevalent AKI carried the worst prognosis (sHR 3.34, 95% CI 1.44–7.77, $p = .005$). Infection and respiratory dysfunction strongly predicted mortality alongside progressive AKI. **Conclusion:** Both prevalent and incident AKI independently drive mortality in AH. Incident AKI confers equivalent risk despite lower baseline severity, enriched for intrinsic renal injury. Early renal trajectory provides essential prognostic discrimination: the absence of progression by Day 7 approximates outcomes of those without AKI, while progressive AKI identifies the highest-risk subgroup. These findings highlight the critical need for dynamic renal monitoring to guide early liver transplant evaluation and RRT considerations.

(A): The Baseline CIF Curve (Prevalent vs. Incident vs. No AKI). (B): The Landmark 7-Day CIF Curve (Progressive vs. Non-Progressive).

3055 | HEPATOCYTE-INTRINSIC FKBP5 DRIVES ALCOHOL-ASSOCIATED HEPATIC STEATOSIS THROUGH HSD17B7 STABILIZATION AND LIPID DROPLET BIOGENESIS

Hui Gao[1] Ge Zeng[2] Themis Thoudam[1] Yanchao Jiang[1] Nazmul Huda[1] Zhihong Yang[1] Jing Ma[1] Suthat Liangpunsakul[1], [1]Indiana University, [2]Indiana University; Southern Medical University

Background: Alcohol-associated liver disease (ALD) is a leading cause of liver-related morbidity and mortality worldwide. FK506-binding protein 5 (FKBP5) is a stress-responsive co-chaperone and scaffolding protein that modulates glucocorticoid receptor signaling, protein stability, and metabolic homeostasis. Notably, FKBP5 is robustly induced by both alcohol and cellular stress, and has emerging roles in lipid metabolism, insulin signaling, and the regulation of protein turnover via chaperone-assisted degradation pathways. We previously identified FKBP5 as a pathological driver of alcohol-induced liver injury; however, its hepatocyte-intrinsic mechanisms remain undefined. **Methods:** Hepatocyte-specific *Fkbp5* knockout (*Fkbp5*$^{\Delta Hep}$) mice and wild-type (WT) littermates underwent the chronic-plus-binge ethanol feeding model. Liver, blood, and and other relevant tissues were harvested 9 hours post-gavage for histological, biochemical, and transcriptomic analyses. FKBP5-interacting proteins were identified by co-immunoprecipitation coupled with mass spectrometry. Mechanistic studies employed overexpression and siRNA knockdown in AML12 hepatocytes, and in vivo rescue via AAV8-mediated hepatic Hsd17b7 reconstitution in *Fkbp5*$^{\Delta Hep}$ mice. **Results:** *Fkbp5*$^{\Delta Hep}$ mice were markedly protected from ethanol-induced hepatic steatosis, exhibiting significantly reduced liver triglyceride content and lipid deposition alongside suppression of the lipogenic program (ACC, FASN, CD36, cleaved SREBP1) at both mRNA and protein levels. Proteomic screening identified hydroxysteroid 17-beta dehydrogenase 7 (HSD17B7) as a novel FKBP5 partner: FKBP5 directly binds and stabilizes HSD17B7 by inhibiting ubiquitin-proteasome-mediated degradation. In AML12 cells, HSD17B7 overexpression exacerbated, while knockdown attenuated, ethanol-induced lipid accumulation in parallel with lipogenic gene expression. AAV8-mediated hepatic HSD17B7 restoration in *Fkbp5*$^{\Delta Hep}$ mice fully reversed the reductions in triglycerides and lipogenic proteins, abolishing the protective phenotype. Interestingly, confocal microscopy and lipid droplet (LD) fractionation revealed that HSD17B7 redistributes to and localizes to the LD surface under metabolic stress, an association that was markedly diminished in *Fkbp5*$^{\Delta Hep}$ livers and restored upon HSD17B7 reconstitution, implicating HSD17B7 as a FKBP5-dependent participant in LD membrane biogenesis (**Fig 1**). **Conclusion:** These findings establish a hepatocyte-intrinsic FKBP5–HSD17B7 signaling axis that coordinately drives lipogenesis and lipid droplet biogenesis in ALD. Targeting this pathway represents a novel therapeutic strategy for alcohol-associated hepatic steatosis.

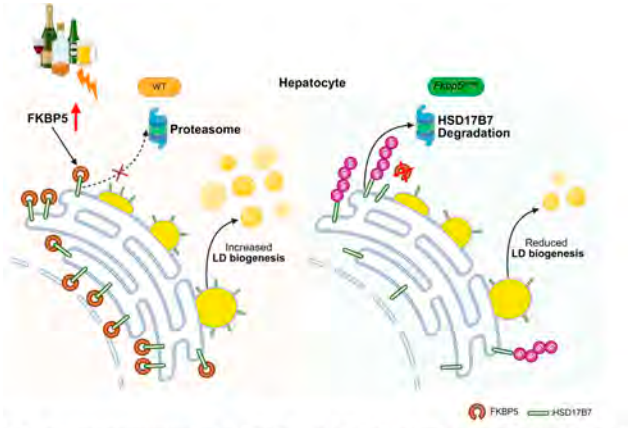

Fig 1. Mechanism of hepatocyte-intrinsic FKBP5–HSD17B7 axis in alcohol-associated hepatic steatosis. Alcohol consumption robustly induces FKBP5 expression, which directly interacts with and stabilizes HSD17B7 by inhibiting its ubiquitin-proteasome-mediated degradation. The stabilized HSD17B7 subsequently localizes to and enriches within lipid droplets (LD), driving LD biogenesis. Conversely, hepatocyte-specific deficiency of FKBP5 (*Fkbp5*$^{\Delta Hep}$) disrupts this interaction, compromising HSD17B7 stability and its enrichment on LDs, which ultimately attenuates lipid accumulation and protects against ethanol-induced steatosis.

Medical University Cancer Institute & Hospital, [5]Medical University of Gdańsk, [6]Fukushima Medical University, [7]Sapporo Medical University, [8]Cedars-Sinai Medical Center

Background: Genetic polymorphisms in Fas-associated factor family member 2 (FAF2) have been reported as protective factors that reduce the risk of liver cirrhosis in heavy drinkers. This study aimed to clarify the pathophysiological role of FAF2 in alcohol-associated liver disease (ALD). **Methods:** (1) RNA-sequencing data from liver tissues of patients with ALD were obtained from the NCBI Gene Expression Omnibus (GEO) database. Hepatic *FAF2* mRNA expression levels were compared between control and ALD groups. The datasets were integrated and stratified into high and low *FAF2* expression groups to identify gene expression profiles associated with differences in *FAF2* expression.(2) To further investigate the role of FAF2 in ALD pathogenesis, hepatocyte-specific FAF2 knockout mice (FAF2-LKO) generated using the LoxP-Cre system and their littermate controls were subjected to a chronic ethanol feeding plus binge administration model (NIAAA model). Both male and female mice were analyzed at 12 weeks of age. To evaluate the impact of aging-related metabolic changes, the same analyses were also performed in 12-month-old mice. **Results:** (1) Across all GEO datasets analyzed (GSE142530, GSE143318, GSE155907), hepatic *FAF2* mRNA expression was significantly higher in the ALD group than in controls. Integrated dataset analysis indicated that elevated *FAF2* mRNA expression was most strongly associated with modulation of the steroid biosynthesis pathway in the liver of patients with ALD. **:** (2) In the mouse model, FAF2-LKO mice exhibited a significantly increased liver-to-body weight ratio compared with control mice, along with elevated serum levels of free fatty acids and free cholesterol. Histopathological analysis revealed significantly exacerbated steatosis, predominantly in zone 2, in both male and female FAF2-LKO mice (male 4% vs. 16%; female 2% vs. 13%; both $P < 0.05$%), whereas no significant differences in liver fibrosis were observed. Similar findings were obtained in 12-month-old mice, in which steatosis was significantly more severe in FAF2-LKO mice (male 5% vs. 22%; female 4% vs. 24%; both $P < 0.05$), with no significant differences in fibrosis. RNA-sequencing of liver tissues demonstrated significant downregulation of *Stard4* (cholesterol transport-related) and *Hsd11b* and *Hsd17b* (steroid metabolism-related), along with suppression of the steroid biosynthesis pathway in FAF2-LKO mice. Metabolomic analysis further revealed alterations in lipid metabolism accompanied by broader reprogramming of amino acid metabolism, particularly involving aromatic amino acid pathways. **Conclusion:** These findings suggest that FAF2 promotes the steroid biosynthesis pathway, thereby suppressing lipid accumulation in hepatocytes during ALD progression. FAF2 may represent a novel therapeutic target for ALD through its role in regulating steroid metabolism.

3057 | ALCHEPNET DIGITAL TWINS ENABLE HIGH-FIDELITY SYNTHETIC CONTROL ARMS FOR IN-SILICO TRIALS IN ALCOHOL-ASSOCIATED HEPATITIS

Joseph Ahn[1] Mingzhao Hu[1] Sonam Palmo[1] Soheil Rasoolzadegan[1] Sori Lundin[1] Xinyue Hu[1] Avanti Bhandarkar[1] AlcHepNet Investigators[2] Douglas Simonetto[3] Patrick Kamath[1] Wanzhu Tu[4] Cui Tao[1] Vijay Shah[3], [1]Mayo Clinic, [2]AlcHepNet Consortium, [3]Mayo Clinic Rochester, [4]Indiana University

Background: Clinical trials in alcohol-associated hepatitis (AH) are hampered by slow recruitment, attrition, and ethical barriers to placebo or standard-care control arms. Synthetic data can provide virtual replicas, or digital twins, of individual patients that preserve the statistical patterns and clinical relationships of the original cohort. Digital twins are a promising approach increasingly relevant to FDA/EMA interest in externally controlled and model-informed trial designs and may reduce reliance on placebo. We developed and validated a generative model for AH digital twins and tested whether an in-silico corticosteroid trial could reproduce treatment-effect estimates from the source cohort. **Methods:** A tabular denoising diffusion probabilistic model (TabDDPM) was trained on multisite AlcHepNet consortium trial data from 788 patients with AH, spanning demographics, day-0/day-7 labs, baseline and in-hospital complications, and 90-day death-or-transplant. Fidelity was assessed via marginal distributions, joint relationships, derived severity scores, and stratified survival patterns. A two-stage diffusion model then generated baseline cohorts and simulated 90-day outcomes under randomized corticosteroid assignment across 50 Monte Carlo trials of 2,000 patients. The in-silico hazard ratio (HR) was compared with unadjusted Cox, propensity-score matching, inverse-probability weighting (IPW), and augmented IPW in the real

cohort. **Results:** Synthetic patients closely matched the real cohort: numerical features differed by < 2% using normalized Wasserstein distance, categorical proportions by < 4%, with complete real/synthetic overlap on visual clustering. Derived MELD/Maddrey DF/ABIC scores, though not modeled directly, were reproduced with fidelity comparable to measured inputs. Survival curves preserved complication risk gradients: 90-day survival was 83% without HRS vs 58% with HRS, with similar gradients for HE and infection. Day-0 to day-7 lab trajectories reproduced the classic AH prognostic divergence: 90-day survivors showed falling bilirubin and stable renal function, while decedents showed rising bilirubin and creatinine with persistent coagulopathy. The in-silico RCT estimated a 90-day mortality HR of 0.78 (95% CI 0.69–0.90; 67.7% vs 61.8% survival, 5.9-point absolute benefit, NNT ~17), directionally consistent with real-cohort methods (HR 0.71–0.86). **Conclusion:** A diffusion-based generative model produced high-fidelity AH digital twins that preserved clinical phenotypes, severity scores, complications, survival trajectories, longitudinal lab dynamics, and corticosteroid treatment-effect patterns. With further validation in prospective trials, synthetic control arms may help address ethical and practical barriers in AH trials by reducing recruitment burden and limiting reliance on placebo or standard-care arms in a high-mortality population.

3058 | MARIJUANA USE AND ALCOHOL CO-USE AMONG ADULTS WITH CIRRHOSIS: A REPEATED CROSS-SECTIONAL STUDY

Stephanie Mrowczynski[1] Alexander Siebert[2] Brigham Walker[2] Lixian Chen[1] Meghana Vankina[1] Peng-Sheng Ting[1] Allison Ju-Chen Hu[2], [1]Tulane University School of Medicine, [2]Tulane University

Background: Marijuana use is becoming more prevalent as its legalization expands. Individuals with alcohol-associated liver disease (ALD) who are interested in alcohol cessation may perceive marijuana as a safer, less addictive alternative. One recent study suggests alcohol craving acutely decreased following cannabis consumption. However, the landscape of marijuana use, including its combination with alcohol use among patients with cirrhosis, remains understudied. We examine the prevalence and patient characteristics associated with marijuana use and co-use of marijuana and alcohol among this patient population. **Methods:** This study uses a repeated cross-sectional, nationally representative, sample from the 2021-2024 National Survey on Drug Use and Health (NSDUH), which includes 519 adults with cirrhosis. The survey includes questions that assess whether the patient used, at any point within the prior 12 months: (1) marijuana, (2) alcohol, and (3) both marijuana and alcohol. We use logistic regression to examine the association between patient characteristics and each outcome. All estimates are adjusted for complex survey design and sampling weights. **Results:** Among patients with cirrhosis, 25.2% used marijuana, 43.7% used alcohol, and 15.1% used both substances in the past year. Females were less likely than males to use marijuana (OR [odds ratio] = 0.38, 95% CI = 0.18-

0.80, p = 0.012). Compared to patients aged 18-34, those aged 35-49 years were more likely to use marijuana (OR = 5.8, 95% CI = 1.36-24.69, p = 0.018) but less likely to use alcohol (OR = 0.08, 95% CI = 0.02-0.3, p < 0.001). Compared to Non-Hispanic White patients, Non-Hispanic Black (OR = 3.21, 95% CI = 1.33-7.22, p = 0.01) and Hispanic patients (OR = 11.64, 95% CI = 2.05-66.03, p = 0.006) were more likely to use both marijuana and alcohol. Patients with past-year alcohol use disorder were more likely to use both marijuana and alcohol in comparison to those without alcohol use disorder (OR = 7.93, 95% CI = 3.34-18.80, p < 0.001). **Conclusion:** Using a nationally representative sample of cirrhotic individuals, we find that male patients and those aged 35-49 were more likely to use marijuana. Hispanic and Black patients, as well as patients with alcohol use disorder, were more likely to use both alcohol and marijuana. These results demonstrate marijuana use has disparate prevalence among individuals with cirrhosis. This may help guide further public health screening and interventions for patients with cirrhosis, particularly in the context of liver transplant evaluation.

3059 | ASPIRIN ATTENUATES HEPATIC STEATOSIS AND SUPPRESSES INFLAMMATORY TRANSCRIPTIONAL PROGRAMS IN AN ALCOHOL-ASSOCIATED HEPATITIS MODEL

Nima Fattahi[1] Fallyn Kirlin[2] Yasuko Iwakiri[1] Matthew McConnell[1], [1]Yale University, [2]Internal medicine department, yale school of medicine

Background: Alcohol-associated liver disease (ALD) is a leading cause of liver-related morbidity and mortality worldwide. Platelet-mediated inflammatory signaling has emerged as an important contributor to hepatic injury and liver disease progression. Aspirin (ASA), an irreversible cyclooxygenase inhibitor with anti-inflammatory and antiplatelet properties, has demonstrated hepatoprotective effects in chronic liver disease; however, its role in alcohol-associated liver injury remains incompletely understood. We investigated the effects of ASA treatment on hepatic histologic and transcriptional responses in a murine model of alcohol-associated hepatitis (AH). **Methods:** Female mice aged 10–13 weeks underwent the 10-day NIAAA chronic-plus-binge ethanol feeding protocol consisting of a 5% Lieber-DeCarli ethanol diet followed by a single 31.5% ethanol binge gavage on the final day. Mice received either daily ASA treatment (1 mg/mL aspirin in PBS, 100 µL by gavage) or PBS vehicle control throughout the experiment. Liver tissues were collected for hematoxylin and eosin (H&E) staining and bulk liver RNA sequencing analysis (n = 7-8/group). Differential gene expression and pathway enrichment analyses were performed using an FDR threshold of < 0.05. **Results:** ASA-treated mice demonstrated significantly reduced hepatic steatosis on H&E staining compared with vehicle-treated controls (log2 steatotic area 15.79 vs 14.98, p < 0.05). Bulk liver RNA-seq analysis revealed distinct transcriptional alterations associated with ASA treatment, including modulation of inflammatory and metabolic pathways. Differential expression analysis identified significant upregulation of metabolic-associated genes including Aldob, Acly, Slc2a4, Gpi1, and Espn in ASA-treated livers, suggesting altered glucose and lipid metabolic regulation. In contrast, inflammatory-associated genes including Ikbke and Jam2 were significantly downregulated following ASA treatment. Hallmark pathway enrichment analysis demonstrated suppression of multiple inflammatory and stress-response pathways in ASA-treated mice, including TNFα signaling via NF-κB, inflammatory response, IL6-JAK-STAT3 signaling, apoptosis, epithelial-mesenchymal transition, and KRAS signaling pathways. Gene ontology analyses additionally demonstrated downregulation of immune-related pathways associated with T-cell activation and differentiation. **Conclusion:** ASA treatment reduces hepatic steatosis and suppresses inflammatory transcriptional signaling in a AH model. These findings support a potential hepatoprotective role for ASA in alcohol-associated liver injury and suggest that modulation of inflammatory and platelet-associated pathways may represent a therapeutic strategy in ALD.

3060 | GLP-1 RECEPTOR AGONISTS AND ALCOHOL-RELATED HEALTHCARE UTILIZATION IN ADULTS WITH AUD: REAL-WORLD EVIDENCE FROM A MATCHED COHORT

Suthat Liangpunsakul[1] Chi Mai Nguyen[2] Yi Zhao[2] Yining Li[2] Shihui Jiang[2] Jing Su[2] Samer Gawrieh[1] Wanzhu Tu[2], [1]Division of Gastroenterology and Hepatology, Indiana University School of Medicine, Indianapolis, IN, [2]Department of Biostatistics and Health Data Science, Indiana University School of Medicine, Indiana.

Background: GLP-1 receptor agonists (GLP-1RAs) are widely prescribed for type 2 diabetes (T2DM) and obesity. Preclinical and clinical evidence suggests GLP-1 signaling modulates reward pathways and may reduce alcohol intake. A substantial proportion of patients initiating GLP-1RAs carry a concurrent alcohol use disorder (AUD) diagnosis, yet real-world associations between GLP-1RA exposure and alcohol-related healthcare utilization remain uncharacterized. the objective of this study is to estimate the association between GLP-1RA initiation and alcohol-coded healthcare utilization and direct medical costs over 12 months in adults with comorbid AUD and metabolic disease. **Methods:** We conducted a matched cohort study using IBM MarketScan Commercial databases (2016–2024). Eligible adults (ages 21–64) had AUD with coexisting T2DM, obesity, or both, and continuous enrollment ≥6 months pre- and ≥12 months post-index. The exposed cohort comprised new GLP-1RA initiators (dulaglutide, exenatide, liraglutide, semaglutide, or tirzepatide) with ≥4 weeks dispensed. Controls received no GLP-1RA or AUD pharmacotherapy. Patients were matched 1:1 via logit propensity score with exact matching on clinical strata. Alcohol-coded outpatient, ED, and inpatient encounters and direct medical costs (2024 USD) were assessed over 12 months. Matched-pair differences were evaluated using Wilcoxon signed-rank tests. **Results:** The analytic sample comprised 1,203 matched pairs. Exposed patients had a median age of 51 years (IQR 44–56), and 68.8% were male. Metabolic comorbidities included T2DM alone (44.4%), obesity alone (28.9%), and both conditions (26.7%); 22.9% had baseline liver disease, and 96.1% initiated therapy in the outpatient setting.Over 12 months, GLP-1RA initiators had significantly fewer alcohol-coded encounters than controls, including outpatient visits (mean 1.5 vs. 3.0), ED visits (0.03 vs. 0.06), and inpatient admissions (0.04 vs. 0.11; all $p < 0.01$). Despite lower encounter counts, mean direct costs were higher in the GLP-1RA arm across all settings: outpatient ($2,037 vs. $1,820), ED ($359 vs. $119), and inpatient ($7,120 vs. $5,298; all $p < 0.001$), reflecting greater per-encounter spending. Mean GLP-1RA pharmacy expenditure was $7,699 over the same period. **Conclusion:** Among adults with AUD and coexisting metabolic disease, GLP-1RA initiation was associated with fewer alcohol-coded healthcare encounters over 12 months; however, per-encounter and pharmacy costs were higher, and the net economic implications remain uncertain. These claims-based findings are hypothesis-generating, as confounding by indication, differential coding of alcohol-related care, and unmeasured AUD severity cannot be excluded. Prospective studies evaluating the effects of GLP-1RA on alcohol consumption and downstream healthcare utilization are warranted.

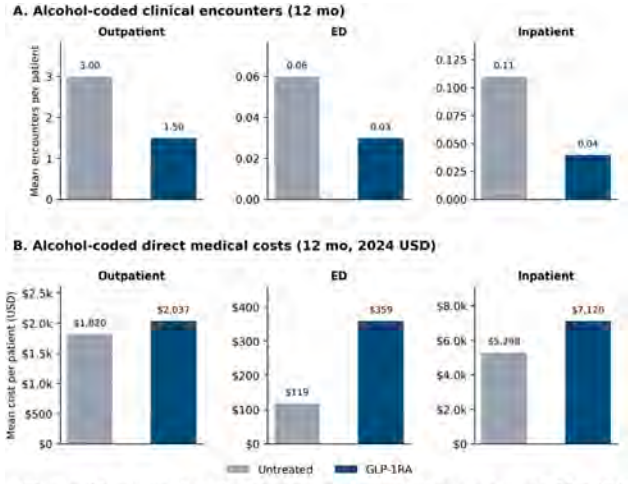

Figure. Alcohol-related utilization and medical costs among GLP-1RA users and non-users. All comparisons are significant with p<0.001.

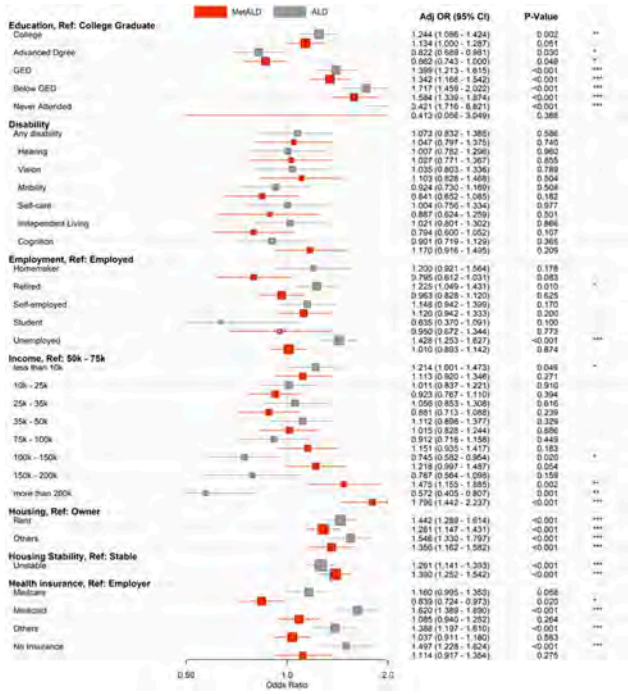
3061 | SOCIAL DETERMINANTS OF HEALTH DIFFERENTIALLY ASSOCIATED WITH MASLD, METALD, AND ALD: A NATIONAL REAL-WORLD ANALYSIS



Chenxi Xiong[1] Wanzhu Tu[2] Baijian Yang[3] Suthat Liangpunsakul[4] Jing Su[5], [1]Department of Biostatistics and Health Data Science, Indiana University School of Medicine, Indiana, [2]Department of Biostatistics and Health Data Science, Indiana University School of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Medicine, Indiana,, [3]School of Applied and Creative Computing, Purdue University, Indiana, USA, [4]Division of Gastroenterology and Hepatology, Indiana University School of Medicine, [5]Department of Biostatistics and Health Data Science, Indiana University School of Medicine

Background: Social determinants of health (SDoHs) play a critical role in the development, progression, and management of steatotic liver disease across the metabolic and alcohol-related spectrum, yet their associations with the newly defined metabolic dysfunction–associated alcohol-related liver disease (MetALD) remain poorly characterized in real-world populations. The NIH-sponsored All of Us (AoU) Research Program, with its deliberate inclusion of historically underrepresented groups, offers a unique national platform to examine these relationships. We aimed to identify SDoHs differentially associated with MetALD compared with metabolic dysfunction–associated steatotic liver disease (MASLD) and alcohol-related liver disease (ALD). **Methods:** This cross-sectional study leveraged AoU Research Program data (data release: April 18, 2023; N = 413,376). Eligible participants had liver disease per the Charlson Comorbidity Index with available AUDIT-C survey responses and longitudinal electronic medical record (EMR) data. MetALD was defined as meeting cardiometabolic criteria with alcohol consumption (AUDIT-C ≥ 5 in men, ≥ 4 in women); MASLD as meeting the same cardiometabolic criteria below the alcohol threshold; and ALD by ICD codes 571.0–.3/K70 without cardiometabolic criteria. Covariates included demographics, cardiometabolic variables (physical measurements, laboratory values, drug exposures, diagnoses, and procedures), and SDoHs (insurance type, housing stability, educational attainment, income, disability status, and employment). Multivariable logistic regression assessed differential SDoH associations across disease groups, with MASLD as the reference. **Results:** A total of 30,407 participants were included (median age 59 years; 57% female; 40% from racial/ethnic minority groups, including 19% Hispanic), comprising 2,776 MetALD, 24,655 MASLD, and 2,976 ALD cases. Compared with MASLD, both MetALD and ALD were independently associated with rental housing versus homeownership (aOR: 1.28–1.44), housing instability (aOR: 1.26–1.39), and lower educational attainment including GED certification (aOR: 1.34–3.42). Income showed a divergent pattern: higher annual income (>$100,000) was more prevalent in the MetALD group (aOR: 1.21–1.80) but less prevalent in ALD (aOR: 0.57–0.79) relative to MASLD. Non–employer-provided insurance was significantly associated with ALD (aOR: 1.16–1.62) but not MetALD (aOR: 0.84–1.11), indicating distinct socioeconomic patterning between these two alcohol-associated phenotypes (**Figure 1**). **Conclusion:** In this real-world cohort, MetALD and ALD had greater housing instability and lower education than MASLD, but differed in income and insurance. MetALD emerged as a distinct phenotype in employed, insured, higher-income patients, supporting tailored screening for steatotic liver disease.

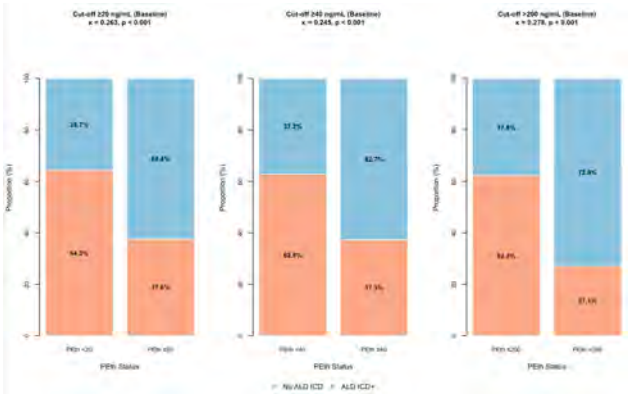
3062 | ALIGNMENT BETWEEN PHOSPHATIDYLETHANOL (PETH) AND ALCOHOL-ASSOCIATED LIVER DISEASE (ALD) ICD CODING IN A US-BASED STEATOTIC LIVER DISEASE COHORT



Hyundam (Dami) Gu[1] Samuel Rhoads[1] Stephen Hoang[1] Ronnie Li[1] Butros Fakhoury[1] Krishan Patel[1] Juan Pablo Arab[1], [1]Virginia Commonwealth University

Background: Phosphatidylethanol (PEth) is a sensitive and specific biomarker of alcohol consumption, yet its administration and utilization in clinical settings are limited. Currently in SLD, it is believed that using Peth testing can play in favor of correctly placing individuals in each disease category, overcoming existing reporting issues including recall and social desirability bias. In this study, we evaluated the matching rate between PEth levels and ALD ICD coding at baseline across multiple clinically relevant thresholds, and to

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

identify patient factors associated with discordance. **Methods:** Among 415 patients in a US-based SLD registry who have MASLD-related or ALD-related ICD codes with available PEth measurements, agreement between PEth positivity and ALD ICD coding was assessed at three thresholds ($\geq$20, $\geq$40, and >200 ng/mL) using Cohen's kappa. ALD ICD positivity was defined as the presence of any of the following diagnoses in the electronic medical record: 'alcohol-induced mental disorders', 'acute alcohol intoxication', 'alcohol dependence', 'alcohol abuse', 'personal history of alcoholism', 'alcoholic fatty liver', 'acute alcoholic hepatitis', 'alcoholic cirrhosis', 'alcoholic liver damage', or 'alcoholic liver disease'. MASLD was defined by the presence of 'chronic nonalcoholic liver disease', 'unspecified chronic liver disease', 'hepatic steatosis', or 'nonalcoholic steatohepatitis (NASH)' (ICD-9/10). Logistic regression was performed to identify predictors of discordance (PEth-positive but ICD-negative, or vice versa), adjusting for age, sex, and race. **Results:** The cohort included patients with codes of MASLD (386, 93%) and ALD (195, 47%). The mean value of Peth was 184ng/mL. Agreement between PEth and ALD ICD coding was fair but statistically significant across all thresholds (κ = 0.263, 0.245, and 0.278 for $\geq$20, $\geq$40, and >200 ng/mL cutoffs respectively, all p < 0.001). Of those who had PEth $\geq$ 20 ng/mL, 37.6% were not coded properly. When the $\geq$ 40 ng/mL cut-off was applied, similar results of 37.3% were observed. Using the >200 ng/mL threshold, 72.9% of heavy drinkers had an ALD ICD code, yet 27.1% lacked ALD documentation despite biochemical evidence of heavy alcohol use. Overall, 34.7% of patients (n = 144) showed discordance between PEth and ALD ICD coding. In logistic regression, older age was the only significant predictor of discordance (OR = 1.06 per year [1.00–1.12], p < 0.05), while sex and race were not independently associated. **Conclusion:** A significant portion of MASLD patients have records of significant alcohol consumption. Moreover, the overall discordance rate was up to 38%, demonstrating that PEth utilization can be used to set more accurate diagnosis, as well as raising awareness that the temporality of biomarkers should be taken account when establishing a proper SLD diagnosis.

3063 | ASSOCIATION OF AUTOMATED LIVER AND SPLEEN MEASUREMENTS WITH TRANSPLANT-FREE SURVIVAL IN ALCOHOL-ASSOCIATED HEPATITIS

Previn Ganesan[1] Richie Manikat[1] Ethan Akama-Garren[1] Ashley Jowell[2] Weiyu Wu[1] Paul Kwo[3] Nishita Kothary[1] Akshay Chaudhari[1] Robert Boutin[1] Vivek Charu[1] Allison Kwong[3], [1]Stanford University School of Medicine, [2]Duke University Medical Center, [3]Stanford University Medical Center

Background: Alcohol-associated liver disease (ALD) is a leading indication for liver transplantation. Yet, spontaneous hepatic recovery has been observed in 10-35% of patients with alcohol-associated hepatitis (AH). Liver transplantation poses unique risks and requires significant resource allocation. It is imperative to identify those who will spontaneously recover from those who are unlikely to survive without transplantation. We aim to assess whether (1) an automated deep-learning algorithm can reliably measure liver/spleen volume and (2) these radiographic parameters are associated with survival without transplant in AH. **Methods:** We identified patients hospitalized with AH [AK1] at our center between 2018 and 2023 that underwent abdominal computed tomography (CT) during admission. Demographic and anthropometric data were collected. Liver/spleen volumes were measured manually and with an automated deep learning algorithm for body composition analysis (*Comp2-Comp*). Liver and spleen size were normalized to body surface area; hepatomegaly was defined by established nomograms. Attenuation (in Hounsfield units, HU) was estimated by the algorithm; steatosis was defined as mean liver attenuation <40 HU on non-contrast CT or difference in liver-spleen attenuation >10 HU. Correlation between manual and automated measurements was assessed using intraclass correlation (ICC) and Bland-Altman analysis. One-year survival was assessed using Fine-Gray competing risk analysis, with liver transplant considered as a competing risk. **Results:** A total of 196 patients were included with a median age of 43 years (IQR 38-52) and MELD of 32 (IQR 25-38). Median liver volumes by manual and automated measurement were 2177 cm^3 (IQR 1473-3124) and 2087 cm^3 (IQR 1416-3006), respectively (ICC coefficient 0.95, p < 0.01). Median spleen volumes by manual and automated measurement were 565 cm^3 (IQR 383-853) and 543 cm^3 (IQR 360-808),

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

respectively (ICC 0.94, p < 0.01). Bland-Altman analysis confirmed agreement between measurements. Automated measurement of liver and spleen volumes was lower than manual measurement (mean percent difference of 4.9% and 5.7%, respectively). Increased liver volume was associated with improved survival, independent of age, sex, MELD, and steatosis (sHR 0.45, 95% CI 0.26-0.79, p < 0.01). The presence of hepatic steatosis was associated with increased mortality (sHR 1.91, 95% CI 1.10-3.32, p = 0.02), whereas the liver/spleen ratio and spleen volume were not independently associated with survival (p > 0.05). **Conclusion:** This study validates the use of a deep-learning algorithm — which may be applied at scale — to measure radiographic parameters that may predict outcomes in liver disease. In patients with AH, greater liver volume and the absence of radiographic steatosis is associated with higher transplant-free survival and may help identify those who are more likely to spontaneously recover.

Table – Competing risk analysis (fine-gray) for 1-year survival.

	Univariable (sHR, 95% CI)	Multivariable (sHR, 95% CI)*
Liver volume †	0.56 (0.34-0.92)	0.45 (0.26-0.79)
Spleen volume†	0.10 (0.02-0.67)	0.29 (0.03-2.42)
Liver/spleen ratio†	1.01 (0.94-1.08)	1.00 (0.93-1.08)
MELD‡	1.03 (1.00-1.06)	1.05 (1.02-1.08)
Liver steatosis§	1.29 (0.79-2.11)	1.91 (1.10-3.32)

3064 | STIMULATING SURVIVAL: G-CSF AS A LAST RESORT IN ALCOHOL-ASSOCIATED HEPATITIS

Madeline Hathoot[1] Alicia Clum[1] Maiying Kong[1] Wanyu Zhang[1] Luis Marsano-Obando[1] Ashwani Singal[1], [1]University of Louisville

Background: Alcohol-associated hepatitis (AH) has a potential for mortality of up to 50% within a month in a severe episode (sAH), MELD score ≥ 20. Corticosteroids, the only available treatment is limited by ineligibility in 40-50%, non-response in 50-60% in eligible patients, survival benefit limited to a short-term period of 28 days in responders (day 4-7 Lille score ≤ 0.45), and infection risk in non-responders. Granulocyte colony-stimulating factor (G-CSF) is studied as an alternative therapy for steroid nonresponders or those with contraindications. Data on the survival benefit of G-CSF are conflicting. **Methods:** We conducted a retrospective study (07/2023-07/2025) at a tertiary center in sAH patients aged 18-65 yrs. Each patient receiving G-CSF (cases) s/c at 5 mcg/kg twice daily (300-480 mcg/dose) were matched with two patients not receiving G-CSF (controls) on baseline MELD score. Kaplan-Meier analysis with stratified long-rank testing and Cox regression were used to evaluate overall survival and liver transplant (LT)-free survival during hospitalization, and at 90 and 365 days. **Results:** Of 185 patients with sAH, 18 (10%) were treated with G-CSF (9 each for ineligibility and for non-response to steroids). Patients with vs. without G-CSF differed in disease severity, with a higher baseline MELD score and its variables (Table). Of 36 controls, 13 received steroids during hospitalization (5 responders), with a mean Lille score of 0.38 on day 4 and 0.32 on day 7. Baseline characteristics were similar between cases and controls (Table). A total of 28 patients died (11 cases) within a year, 25 within 90-d (11 cases), and 23 during hospitalization (11 cases). One of the controls underwent a liver transplant during the hospitalization. Patients receiving G-CSF had a 1.46-fold hazard of death vs. controls, which was not statistically significant (95% CI 0.485-4.395). Of the 11 deaths in cases, all had acute kidney injuries (AKI) due to hepatorenal syndrome (HRS), and 6 had a concomitant bacterial infection. Of 12 deaths in the control group during hospitalization, 11 had AKI (7 HRS), and 8 had a concomitant bacterial infection. **Conclusion:** In this limited retrospective study, G-CSF

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

did not demonstrate a survival benefit in sAH. Multicenter randomized studies with a uniform population and the regimen are needed in the Western world to investigate the benefit of G-CSF in patients with sAH.

Table. Baseline characteristics in patients with severe alcohol-associated hepatitis: G-CSF vs no G-CSF treatment

	Unmatched patients			Propensity score matched for MELD score		
	No G-CSF (n=167)	G-CSF (n=18)	P-value	No G-CSF (n=36)	G-CSF (n=18)	P-value
Mean Age, SD	45.5 (±11.2)	49.0 (±9.1)	0.16	47.7 (±9.9)	49.0 (±9.1)	0.71
% Males	65.9%	66.7%	1.00	66.7%	66.7%	1.0
% White	78.4%	94.4%	0.12	86.1%	94.4%	0.53

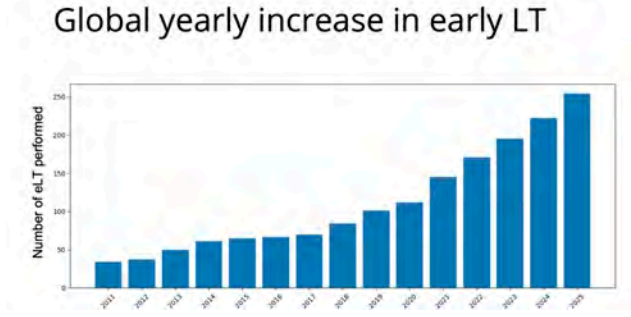
3065 | VARIABILITY IN ACCESS TO EARLY LIVER TRANSPLANTATION FOR ALCOHOL-ASSOCIATED HEPATITIS: A GLOBAL SURVEY STUDY



Hanna Blaney[1] Marta Tejedor[2] Rym Yousfi[3] Simone Strasser[4] Svetlana Adamcova Selcanova[5] Lubomir Skladany[6] Marina Berenguer[7] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]University of Iowa, [3]Virginia Common Wealth University, [4]New South Wales, [5]Roosevelt Teaching Hospital, [6]Roosevelt Univ. Hospital, [7]University of Valencia

Background: Alcohol-associated hepatitis (AH) is a severe form of liver disease with limited medical management and a high short-term mortality. Early liver transplant (LT) without a prescribed period of sobriety is increasingly performed, with excellent survival benefit. However, early LT is not universally available. This study aims to understand global access and barriers to early LT for AH. **Methods:** This is an international survey study conducted between January and May 2026. The survey was sent to 208 hepatologists and surgeons identified through Global AlcHep and International Liver Transplant Society contacts. **Results:** The response rate was 66.8% with responses from 46 unique countries, and 75.5% of respondents practiced at a transplant center. LT was offered in 94.9% of respondent countries; however, only 71.4% of respondents at transplant centers offered early LT for AH (Figure 1a). 46.7% of respondents at LT centers not offering early LT cited local or national policies prohibiting early LT as the reason that early LT was not offered. Living donation LT (LDLT) was performed at centers of 40.3% of respondents, with just 22.3% respondents offering LDLT for AH. Early LT for AH has become increasingly available, with most programs started in 2022 (Figure 1b). The median MELD at transplant for AH was 28. A majority of 96.4% of respondents agreed that selected patients with severe AH should be offered early LT. Frequency of perceived barriers to early LT included 77% concerned about return to drinking post-LT, 45.3% concerned over the impact on other patients waiting for LT, 38.8% concerned over the potential for poor post-LT outcomes, 36% concerned about the recovery and survival without LT, 23% concerned about lay perception and effect on organ donation,16.5% had uncertainty about the need for LT, and 7.9% felt that patients with severe AH did not deserve LT. Return to alcohol use was tracked by 89.9% of respondents. However, phosphatidylethanol was only available to 32.4% of respondents. The estimated return to any alcohol use at 1 year was 16.5%, with return to heavy use at 1-year of 5.6%. Estimated mean survival was 88.75% (SD 14.4), with a 5-year mean survival of 77% (SD 13.6). **Conclusion:** There is marked geographic variation in access to early LT. While a majority of hepatologists agree that early LT should be considered in AH, multiple barriers to early LT for AH exist, including local and national policy as well as overwhelming concern regarding return to alcohol use.

3066 | BURDEN AND DRIVERS OF ALCOHOL-ASSOCIATED CIRRHOSIS AMONG WOMEN OF REPRODUCTIVE AGE, 1990–2023: IMPLICATIONS FOR REPRODUCTIVE HEALTH- A GLOBAL BURDEN OF DISEASE 2023 ANALYSIS

Yeshika Thapa[1] Carson Creamer[2] Tony Brar[1] Yaseen Perbtani[1], [1]UCF/HCA Florida North Florida, [2]University of Central Florida, HCA Healthcare GME

Background: Alcohol-associated cirrhosis among women of reproductive age has implications for liver-related morbidity, pregnancy outcomes, and fetal alcohol spectrum disorder prevention. We evaluated global trends and drivers of burden among women aged 15–49 years using GBD 2023 estimates. **Methods:** We performed a secondary analysis of GBD 2023 estimates for females aged 15–49 years with alcohol-associated cirrhosis from 1990–2023. Outcomes included DALYs and deaths with 95% uncertainty interval (UI), and corresponding crude rates. Trends were assessed by estimated annual percentage change (EAPC). Absolute burden changes were partitioned into population growth, age structure, and age specific rate contributions using Das Gupta decomposition. Geographic Variation in 2023 was assessed by SDI, GBD region, and country. **Results:** Among women aged 15–49 years, global DALYs rose from 444,951 (95% UI 289,880–656,333) to 517,058 (95% UI 348,080–739,910) (+16.2%) and deaths from 8,857 (95% UI, 5,833–12,930) to 10,451 (95% UI, 7,078–14,857) (+18.0%). In contrast, the DALY rate declined from 33.22 to 26.21 per 100,000 (−21.1%), and the death rate declined from 0.66 to 0.53 (−19.9%). EAPC showed significant annual declines in DALY rate (−0.84%/year, 95% CI −1.05 to −0.63, $p < 0.001$) and death rate(−0.80%/year, 95% CI −1.01 to −0.58, $p < 0.001$). Decomposition showed that rising DALYs were driven by population growth (+190,832) and age-structure shift toward older reproductive ages (+96,298), partially offset by declining age-specific rates (−215,023); deaths showed the same pattern. In 2023, the highest reproductive-age DALY rate was in High SDI settings (36.36 per 100,000), inverting the all-age GBD pattern, followed by Eastern Europe (202.06 per 100,000) and the Republic of Moldova (231.91 per 100,000), likely reflecting high alcohol exposure in several high-income and post-Soviet settings. **Conclusion:** Despite declining reproductive-age rates, absolute burden of alcohol-associated cirrhosis in women aged 15–49 rose from 1990 to 2023. This rise was largely demographically driven rather than worsening underlying risk, supporting earlier alcohol-use screening and integration of hepatology, addiction, and reproductive-health services for this population.

3067 | GREATER SEX-ADJUSTED SKELETAL MUSCLE DEFICIT IS ASSOCIATED WITH INCREASED MORTALITY IN ACUTE ALCOHOL-ASSOCIATED HEPATITIS

Beatriz Sordi Chara[1] Anahita Rabiee[2] Gabrielle Pakravan[2] Praveena Narayanan[3] Pramod Mistry[2] Guadalupe Garcia-Tsao[2], [1]Yale New Haven Hospital/ Yale School of Medicine, [2]Yale University, [3]UW-Madison

Background: Sarcopenia is recognized as a marker of frailty and poor outcomes in advanced liver disease, but its prognostic significance in alcohol-associated hepatitis (AAH) remains incompletely characterized. Given the catabolic and inflammatory

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

milieu of AAH, we hypothesized that lower skeletal muscle mass would be associated with increased mortality. We evaluated the association between sex-adjusted skeletal muscle deficit and mortality in patients with confirmed AAH and advanced fibrosis/cirrhosis. **Methods:** We performed a retrospective cohort study of patients with biopsy-confirmed AAH and bridging fibrosis/cirrhosis with decompensation (ascites, variceal bleeding, or hepatic encephalopathy) at a tertiary care hospital between 2013–2022. Patients without baseline CT imaging were excluded. Skeletal muscle index (SMI) was measured on baseline CT imaging. We derived a continuous sex-adjusted SMI deficit variable relative to cirrhosis-specific sarcopenia thresholds: < 50 cm²/m² in men and < 39 cm²/m² in women. The primary outcome was mortality, with liver transplantation treated as censoring. Multivariable Cox proportional hazards models adjusted for age, MELD-Na, and fibrosis stage used restricted cubic splines to evaluate nonlinear associations between sex-adjusted SMI deficit and mortality. **Results:** Among 107 patients, median age was 47 years (IQR 36–55), median MELD-Na was 27 (IQR 22–32), 60% were male, and median follow-up was 1.6 years (IQR 0.2–3.1). During follow-up, 49 (46%) deaths and 5 transplants occurred. Sixty-four patients (60%) met criteria for sex-specific sarcopenia. Most patients (85%) had cirrhosis (F4), while 15% had bridging fibrosis (F3). In multivariable Cox models adjusted for MELD-Na, age, and fibrosis stage, restricted cubic spline analysis demonstrated a nonlinear association between greater sex-adjusted SMI deficit and increased mortality risk, approaching significance ($p = 0.054$). Mortality risk appeared to rise disproportionately at greater muscle deficits. In secondary analyses using a binary sarcopenia definition, sarcopenia was associated with higher mortality risk, although this did not reach significance (HR 1.49, 95% CI 0.82–2.72, $p = 0.19$). Older age (HR 1.03/year, 95% CI 1.00–1.06, $p = 0.028$), higher MELD-Na (HR 1.05/point, 95% CI 1.01–1.09, $p = 0.010$), and F4 fibrosis (HR 4.39, 95% CI 1.35–14.34, $p = 0.014$) were independently associated with mortality. Model concordance was 0.714. **Conclusion:** Spline modeling suggested a nonlinear association between lower sex-adjusted skeletal muscle reserve and mortality risk in AAH after adjustment for MELD-Na, age, and fibrosis stage. Risk appeared to rise disproportionately at greater SMI deficits, suggesting CT-derived muscle depletion may capture physiologic vulnerability not reflected by liver disease severity alone. These findings support further evaluation of skeletal muscle metrics as prognostic biomarkers in AAH.

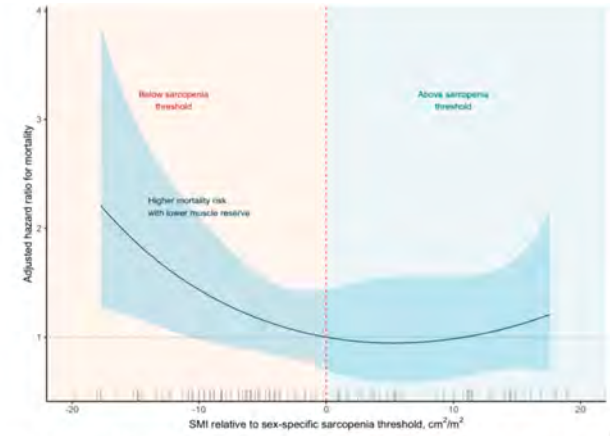

Figure 1: Adjusted association between sex-adjusted skeletal muscle deficit and mortality risk in acute alcohol-associated hepatitis. Restricted cubic spline modeling demonstrates higher predicted mortality risk at greater skeletal muscle deficits after adjustment for MELD-Na, age, and fibrosis stage.

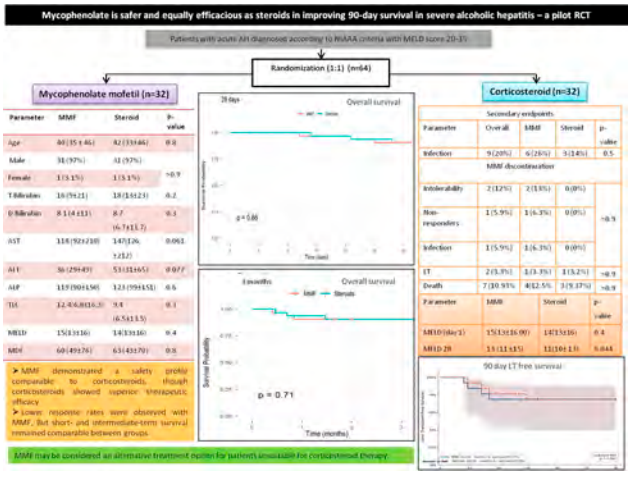
3068 | MYCOPHENOLATE MOFETIL IS SAFER AND EQUALLY EFFICACIOUS AS STEROIDS IN IMPROVING 90-DAY SURVIVAL IN SEVERE ALCOHOLIC HEPATITIS – A PILOT RCT



Ananthu Narayan[1] Saggere Muralikrishna Shasthry[1] Satender Pal Singh[1] Vinod Arora[1] Sanda Kavitha[1] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences, Delhi

Background: Corticosteroids continue to be the primary treatment for severe alcoholic hepatitis (SAH), despite controversial efficacy and an increased risk of infections. Additionally, many patients are either non-responsive or unsuitable for steroid therapy, highlighting the need for alternative treatments. Mycophenolate mofetil (MMF), an immunomodulatory agent with established safety in liver diseases, has shown safety in steroid non-responsive AH patients in an initial trial. However, comparative evidence on their efficacy and safety in AH remains limited. **Methods:** Patients with SAH was identified based on national institute on alcohol abuse and alcoholism criteria and a MELD score of 20-35 were randomized to receive either MMF or corticosteroid. MMF group received 750 mg twice daily, while steroid

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

group received prednisolone 40 mg/day. Patients were followed for 90 days with assessments on days 4, 7 and 28. Steroids were discontinued in non-responders based on Lille score on days 7. Primary end point was survival at 28 days. Clinical outcomes, including hospitalization, liver related events, and survival at 90 days have been evaluated. **Results:** A total of 64 patients with SAH were randomized equally to receive MMF (n = 32) or steroids (n = 32). Baseline MELD (15 vs 14, p = 0.4) and MDF (60 vs 63, p = 0.8), were comparable between groups. The 28-day transplant-free survival was 90.3% in the MMF group and 93.5% in the steroid group, while the 90-day transplant-free survival was 90.3% in both groups. Kaplan–Meier analysis showed no significant difference in survival between MMF and steroid groups at 28 days (p = 0.66) or 90 days (p = 0.71).Overall incidence of infection was 20%, with no significant difference between MMF and steroid groups (26% vs 14%, p = 0.5). Among patients receiving MMF, 76% completed therapy without interruption; treatment discontinuation occurred due to intolerance (12%), clinical non-response (5.9%), and infection (5.9%).Steroid-treated patients also had lower day-28 INR (1.51 vs 1.82, p = 0.031) and MELD scores (11 vs 13, p = 0.044). Death occurred in 7 patients (4 vs 3), while liver transplantation was done in 2 patients (1 patient each). **Conclusion:** MMF demonstrated an acceptable safety profile comparable to corticosteroids with respect to survival and liver related events. Short- and intermediate-term survival were comparable between groups, suggesting that MMF may be considered as an alternative treatment option in patients with alcoholic hepatitis.

3069 | RISING DISCORDANCE BETWEEN ADMINISTRATIVE CODING AND CLINICAL PHENOTYPE OF ALCOHOLIC HEPATITIS AMONG LIVER TRANSPLANT RECIPIENTS AFTER 2020: A UNOS MACHINE LEARNING ANALYSIS

Wen Hui Lim[1] Eunice Tan[1] Nicole Tang[1] Ken Liu[2] Karn Wijarnpreecha[3] Mohammad Siddiqui[4], [1]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, [2]Gastroenterology and Liver Centre, Royal Prince Alfred Hospital, SLHD and University of Sydney, Camp, [3]University of Arizona College of Medicine-Phoenix, [4]Division of Gastroenterology and Hepatology, Department of Medicine, University of Virginia

Background: Alcohol-associated liver disease (ALD) has emerged as an increasingly common indication for liver transplantation in the United States, particularly following 2019. However, it remains unclear whether these changes were driven disproportionately by alcoholic hepatitis (AH) compared with chronic alcohol-associated liver disease, and whether the clinical phenotype and severity of affected transplant recipients have evolved over time. Administrative diagnosis codes are frequently used to identify AH in large transplant datasets, although coding practices and diagnostic classification may change over time. We therefore aimed to evaluate temporal changes in alcohol-related liver transplantation patterns before and after 2019 within the UNOS registry, assess changes in AH-like clinical phenotype and disease severity, and determine the extent of discordance between administrative diagnosis coding and phenotype-defined disease in the post-2020 era. **Methods:** Adult liver transplant recipients in the UNOS database with a primary diagnosis of alcohol-associated liver disease (ALD) or AH were identified, while recipients with multiple etiologies were excluded. A logistic classification model was trained using the pre-2020 cohort, with AH diagnosis code as the outcome variable. Clinical and demographic predictors included MELD score, bilirubin, INR, creatinine, sodium, albumin, age, BMI, sex, ethnicity, diabetes, and obesity. The trained model was subsequently applied to the post-2020 cohort to identify an AH-like clinical phenotype. Model discrimination was evaluated using area under the receiver operating characteristic curve (AUC). A prevalence-calibrated probability threshold derived from the pre-2020 AH prevalence was used to classify AH-like phenotype. Discordance was defined as mismatch between administrative diagnosis coding

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and model-predicted phenotype. **Results:** The classifier demonstrated good discrimination in the post-2020 test cohort (AUC 0.836). Patients coded with AH exhibited a clinically distinct phenotype characterized by higher MELD score (OR 1.32, p = 0.017), bilirubin (OR 2.15, p < 0.001), creatinine (OR 1.24, p < 0.001), and sodium (OR 1.21, p = 0.012), alongside lower albumin (OR 0.82, p = 0.003), younger age (OR 0.52, p < 0.001), and lower prevalence of diabetes mellitus (OR 0.48, p = 0.014). Male sex (OR 0.65, p = 0.004) and Hispanic ethnicity (OR 0.53, p = 0.007) were associated with lower odds of AH coding. From the pre-2020 to post-2020 era, the proportion of transplant recipients demonstrating an AH-like clinical phenotype increased from 4.7% to 7.1%. Concurrently, discordance between administrative diagnosis coding and phenotype-defined disease increased from 6.0% to 9.9%. In multivariable analysis, the post-2020 era was independently associated with greater discordance between coded diagnosis and clinical phenotype (OR 1.71). **Conclusion:** Alcohol-related liver transplant recipients demonstrated an increasingly AH-like clinical phenotype following 2020, suggesting that post-2019 increases in alcohol-related transplantation may have been driven disproportionately by more acute and severe alcohol-associated liver disease. However, this was accompanied by substantially greater discordance between administrative diagnosis coding and phenotype-based classification. These findings suggest evolving diagnostic classification and/or shifts in disease presentation in the post-2020 era, with important implications for epidemiologic and transplant outcomes studies relying on administrative definitions of alcoholic hepatitis.

Regression Analysis Table

Variable	OR (95% CI), p-value

3070 | GLP-1 RECEPTOR AGONISTS AND LIVER OUTCOMES IN METABOLIC DYSFUNCTION-ASSOCIATED ALCOHOL-RELATED LIVER DISEASE: A PROPENSITY SCORE-MATCHED COHORT STUDY

Islam Mohamed[1] Basil Jalamneh[2] Walid Hazem[3] Mohamad Ali Ibrahim[4] Mohamed Nadeem[2] Prasun Jalal[4], [1]The Cleveland Clinic Foundation-Fairview hospital, [2]Cleveland Clinic Foundation, [3]University hospitals of Cleveland, [4]Baylor College of Medicine

Background: Metabolic dysfunction-associated alcohol-related liver disease (MetALD) represents a growing clinical challenge. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) show promise in managing metabolic dysregulation and addictive behaviors, but their impact on clinical outcomes in patients with MetALD remains poorly defined. We evaluated the impact of GLP-1 RA exposure on hepatic decompensation and alcohol-related outcomes in this population. **Methods:** We conducted a retrospective 1:1 propensity score-matched cohort study using the TriNetX Research Network (106 healthcare organizations; N = 117,955,548). MetALD was defined by ICD-10 codes for alcoholic liver disease (K70) and hepatic steatosis (K76.0) with BMI $\geq$ 27 kg/m^2 or diabetes. Patients with hepatocellular carcinoma, type 1 diabetes, prior liver transplantation, or pregnancy were excluded. The GLP-1 cohort required documented use of semaglutide, tirzepatide, dulaglutide, exenatide, liraglutide, or lixisenatide. Matching variables included demographics, liver disease severity, metabolic comorbidities, cardiovascular disease, chronic kidney disease, psychiatric disease, medication exposure, and laboratory values. Outcomes were assessed from 90 days to 5 years post-index. **Results:** Of 5,018 GLP-1 RA-exposed and 69,567 non-exposed MetALD patients initially identified, 3,525 and 56,670 remained after exclusions, respectively. Following 1:1 propensity score matching on 40+ covariates (all post-match SMDs < 0.06), 2,703 patients were included per cohort. Compared to non-GLP-1 patients, GLP-1 RA use was associated with lower rates of: listing for liver transplant (1.0% vs 1.8%; HR 0.56, 95% CI 0.35–0.90; p = 0.015), all-cause hepatic decompensation (3.1% vs 8.4%; HR 0.36, 95% CI 0.28–0.47; p < 0.001), alcohol-associated hepatitis (4.1% vs 9.5%; HR 0.41, 95% CI 0.33–0.52; p < 0.001), cirrhosis progression (3.4% vs 7.6%; HR 0.46, 95% CI 0.35–0.61; p < 0.001), alcohol withdrawal (3.0% vs 7.9%; HR 0.36, 95% CI 0.28–0.47; p < 0.001), alcohol intoxication (1.8% vs 6.4%; HR 0.28, 95% CI 0.20–0.39; p < 0.001), and all-cause hospitalization (1.5% vs 4.9%; HR 0.30, 95% CI 0.21–0.43; p < 0.001). GLP-1 RA users also had lower rates of alcohol use remission coding (11.4% vs 13.6%; HR

0.83, 95% CI 0.71–0.97; p = 0.018), potentially reflecting reduced severity of active alcohol use in this group. **Conclusion:** In a large, propensity-matched real-world cohort of patients with MetALD, GLP-1 RA therapy was associated with a profound reduction in all-cause hepatic decompensation, liver disease progression, hospitalizations, and severe alcohol-related clinical events. These findings suggest that GLP-1 RAs may serve as a powerful therapeutic strategy to modify the clinical trajectory of MetALD.

3071 | INPATIENT ADDICTION MEDICINE SERVICE IMPROVES ANTI-CRAVING PHARMACOTHERAPY AND MULTIDISCIPLINARY CARE IN ALCOHOL-ASSOCIATED LIVER DISEASE: AN AUSTRALIAN COHORT STUDY

James Chen[1] Kavindya Perera[1] Damien Foo[2] Kavita Seth[1] Ashleigh Kapnoullas[1] Simon Hazeldine[1], [1]Fiona Stanley Hospital, [2]Curtin University

Background: Anti-craving pharmacotherapy and integrated multidisciplinary care for alcohol use disorder (AUD) are markedly underutilised in inpatients with alcohol-associated liver disease (ALD), despite consistent evidence of benefit. The clinical impact of a the introduction of a hosptial inpatient addiction medicine service (IAMS) on hepatology patients is poorly understood. We evaluated whether IAMS implementation improved adherence to British Association for the Study of the Liver (BASL)/British Society of Gastroenterology (BSG) alcohol-related liver disease (ArLD) quality standards and short-term clinical outcomes. **Methods:** Single-centre retrospective pre–post cohort study at a Western Australian tertiary referral centre. Consecutive adult inpatients admitted under hepatology with ALD and active alcohol use (or < 60 days' abstinence) were identified across two 6-month study periods: pre-IAMS (2021; n = 50) and post-IAMS (2024; n = 60). Seven BASL/BSG quality domains and clinical outcomes were assessed. Comparisons used logistic regression and log-binomial generalised linear models, adjusted *a priori* for age, sex, Model for End-Stage Liver Disease (MELD) score and Charlson Comorbidity Index (CCI). **Results:** Cohorts were balanced for age (51.3 ± 10.4 years), MELD (22.7 ± 8.0), CCI (4.0 ± 1.7) and length of stay (7.9 days); 11.8% identified as Aboriginal and/or Torres Strait Islander. Post-IAMS, adjusted process metrics improved markedly: AUDIT-C screening 0% to 56.7%; inpatient alcohol and other drug (AOD) referral 44% to 83.3% (aOR 8.27, 95% CI 2.94–23.26) and review 40% to 71.7% (aOR 4.40, 1.83–10.63); and any anti-craving pharmacotherapy 10% to 58.3% (aOR 19.18, 5.52–66.70). Addiction medicine initiated 38.3% of post-IAMS prescriptions versus 2% pre-IAMS, directly implicating the service model. Outpatient mental health/AOD linkage rose 34% to 58.3% (aOR 3.22, 1.33–7.82). Pre-existing care domains — withdrawal protocol use (78% to 86.7%), dietetic review (90% to 90%) and education/harm reduction (56% to 51.7%) — showed no significant change. Favourable but underpowered trends were observed for post-discharge 30-day readmission (14% to 6.7%), 30-day mortality (10% to 3.3%) and 90-day mortality (20% to 8.3%). **Conclusion:** Introduction of a dedicated inpatient addiction medicine service for hepatology produced a near 20-fold adjusted increase in anti-craving pharmacotherapy and substantial gains in screening, multidisciplinary engagement and outpatient linkage for ALD inpatients, without disrupting existing care domains. This study demonstrates that integrated addiction–hepatology pathways can rapidly close a longstanding evidence–practice gap in AUD pharmacotherapy, with clinical outcomes trending favourably and warranting powered prospective evaluation.

3072 | NALTREXONE VERSUS ACAMPROSATE IN COMPENSATED ALCOHOL-ASSOCIATED CIRRHOSIS: A PROPENSITY-MATCHED ANALYSIS OF MORTALITY AND LIVER-RELATED OUTCOMES

Davis Kuruvilla[1] Elan Adhami[1] Amanda Julia-Rios[1] Paul Alvarez[1] John Nahas[1] Aya Akhras[1] Waseem Wahood[2] Samer Wahood[3] Bernardo Reyes[1], [1]HCA Aventura Florida, [2]University of Miami, [3]Warren Alpert Medical School

Background: Alcohol use disorder (AUD) drives progression of alcohol-associated liver disease (ALD), yet pharmacotherapy remains underutilized in cirrhosis. The 2019 AASLD Practice Guidance suggests acamprosate or baclofen in ALD but does not endorse naltrexone due to historical hepatotoxicity concerns, despite the FDA removing its black box warning in 2013. The 2024 ACG guideline conditionally suggests both agents in compensated ALD. No study has directly compared liver-specific outcomes between naltrexone and acamprosate in compensated alcohol-associated cirrhosis. This study compared hepatic decompensation, all-cause mortality, and hospitalizations between these agents in this population. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network, identifying adults ≥18 years with compensated alcoholic cirrhosis and concurrent AUD. Patients with decompensation, viral hepatitis coinfection, hepatocellular carcinoma, or prior liver transplant were excluded. Cohorts were defined by receipt of naltrexone or acamprosate after cirrhosis diagnosis; cross-over patients were excluded. Propensity score matching (1:1) balanced demographics, comorbidities, and laboratory values. Outcomes over 5 years included hepatic decompensation, all-cause mortality, alcohol-related hospitalizations, and liver-related hospitalizations. Kaplan-Meier survival analysis and Cox proportional hazards models were used. $P < 0.05$ was significant. **Results:** After matching, 801 patients were included per cohort. Mean age (51.3 ± 12.0 vs 51.6 ± 11.8 years; p = 0.536) and sex (71.2% male both) were comparable. Baseline comorbidities and labs were well-balanced (all standardized differences < 0.05). Mean follow-up was 700 ± 619 vs 657 ± 621 days. Hepatic decompensation rates were similar (5.6% vs 5.4%; OR 1.02, 95%CI 0.65-1.62, p = 0.922; HR 0.95, 95%CI 0.61-1.49, p = 0.836). Naltrexone was associated with lower all-cause mortality (9.5% vs 13.1%; RR 0.72, 95%CI 0.55-0.96, p = 0.022; HR 0.68, 95%CI 0.50–0.91, log-rank p = 0.009). Alcohol-related hospitalizations did not differ (79.3% vs 76.3%; OR 1.19, 95%CI 0.94-1.51, p = 0.149). Liver-related hospitalizations were comparable (64.7% vs 65.3%; OR 0.97, 95%CI 0.79-1.20, p = 0.793), though survival analysis trended toward naltrexone (HR 0.89, 95% CI 0.78-1.00, p = 0.050). **Conclusion:** In this propensity score-matched cohort with compensated alcohol-associated cirrhosis, naltrexone was associated with a 28% relative reduction in all-cause mortality compared to acamprosate, with similar rates of hepatic decompensation and hospitalizations. These findings challenge historical reluctance to prescribe naltrexone in cirrhosis and support its consideration as first-line AUD pharmacotherapy in compensated ALD. Prospective trials are warranted.

3073 | MAPPING GLOBAL VARIATION IN STANDARD DRINK DEFINITIONS AND THEIR RELATIONSHIP WITH ALCOHOL-RELATED OUTCOMES

Kriti Soni[1] Rylyn Reyes[1] Ximena Parraga[1] Denisse Rubio Cruz[2] Joshua Chen[3] Adelina Horhat[4] Hyundam (Dami) Gu[1] S. Fisher Rhoads[1] Vinay Jahagirdar[1] Kavin Parmar[1] Krishan Patel[1] Stephen Hoang[1] Luis Díaz[5] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Lahey Hospital; Virginia Commonwealth University, [3]Virginia Commonwelath University, [4]Department of Hepatology, Henri Mondor University Hospital, [5]Pontificia Universidad Católica de Chile

Background: Alcohol-related risk assessment, surveillance, and public health guidance rely on standardized definitions of alcohol exposure; however, national "standard drink" definitions vary substantially across countries. Because drinking behaviors, heavy drinking thresholds, and risk communication are frequently reported in units of drinks rather than grams of ethanol, inconsistent definitions may limit cross-country comparisons and distort the interpretation of alcohol-related risk. Despite the World Health Organization (WHO) recommendation of a 10-g ethanol benchmark, the global distribution of standard drink definitions and their relationship with alcohol-related outcomes remain poorly characterized. **Methods:** A cross-sectional ecological analysis was conducted using data from the 2024 WHO Global Status Report on Alcohol and Health, the WHO Global Information System on Alcohol and Health, the World Bank, national guidelines, and published literature across 185 countries. The exposure of interest was the national standard drink definition (grams of ethanol). Primary outcomes included heavy episodic drinking (HED), alcohol use disorder (AUD), and cirrhosis mortality rates (per 100,000). Alcohol per capita (APC) was assessed as a potential confounder.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Bivariate relationships were evaluated using Spearman's rank correlation. **Results:** Among 185 countries, 64 (34.6%) had available standard drink definitions (M = 11.8g, SD = 2.9), ranging from 4-25 g. Missing formal definitions were non-random and concentrated in African and Eastern Mediterranean regions. The analytic sample was dominated by the Americas (63.6%) with a median of 14 g and Europe (53%) with a median of 10 g. HED prevalence ranged from 0.2-48.5% (M = 20.2%), AUD prevalence averaged 2.3%, and cirrhosis mortality averaged 7.4 per 100,000. APC was strongly correlated with HED (ρ = 0.78). Standard drink size displayed weak-to-modest associations with HED (ρ = 0.02), AUD (ρ = 0.07, and cirrhosis mortality (ρ = 0.16). Regional clustering was identified as a primary source of confounding, limiting the interpretability of bivariate associations. **Conclusion:** Wide variation in standard drink definitions globally limits the comparability of alcohol surveillance and risk communication. The observed regional clustering and weak bivariate associations highlight the need for more robust analytical approaches to clarify their public health implications.

3074 | SMALL ACTIVATING RNA RESTORES HNF4α DYSREGULATION IN ALCOHOL ASSOCIATED HEPATITIS

Susmita Bhattarai[1] Sehrish Naz[1] Shanshan Su[1] Hua Xu[1] Nezam Afdal[1] Pooja Dua[2] Zhenghui Jiang[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, [2]OliX Pharmaceuticals

Background: Alcohol-associated hepatitis (AH) represents a severe form of alcohol-associated liver disease (ALD) with high mortality and limited effective medical therapies. Hepatocyte Nuclear Factor 4 Alpha (HNF4α), a master hepatocyte transcription factor, maintains liver function, metabolic homeostasis, hepatocyte differentiation and maturation. Driven by distinct promotors, HNF4α has two major isoforms: HNF4α -P1 (P1) found in normal adult liver maintaining mature liver function and HNF4α –P2 (P2) predominantly in fetal, supporting proliferation and regeneration. Oxidative stress and inflammation in AH lead to dysregulation of HNF4a isoforms, loss of P1 dominance and liver function. Long noncoding antisense RNA: HNF4α-AS1 may contribute to P1 and P2 balance. We hypothesize: restoring P1 expression in AH will enhance hepatocyte maturation and function. Thus, we aim to develop a novel therapeutic strategy that can modulate P1 expression using small activating RNA (saRNA) targeting HNF4α-AS1. **Methods:** P1 and P2 isoforms were analyzed in liver tissues from AH and control patients using RT-PCR and *in situ* hybridization (ISH). Screenings in Huh7 cells were performed to identify saRNA that upregulate P1 expression. Transforming growth factor-beta 1(TGFβ1) was used to treat Huh7 cells and induce HNF4α dysregulation as seen in AH patients. RNA sequencing was performed to define transcriptomic changes. GalNAc conjugated saRNA was validated in precision cut liver slices (PCLS) derived from ALD patients. **Results:** P1 and HNF4a-AS1 levels were significantly reduced in AH livers compared to control human livers, shown by both mRNA and isoform-specific ISH via Basescope. TGFβ1 induced P1 down-regulation and P2 upregulation in Huh7 cells *in vitro* in both RNA and protein analyses. Large-scale screening identified multiple saRNAs that significantly upregulate P1 expression. Efficacy of HNF4α-saRNA was validated by enhanced P1 (Fig.1), HNF4α-AS1 expressions, significantly upregulated downstream genes (OTC, CYP3A4, CYP27A1, CYP7A1 and HNF1a). RNAseq showed elevated epithelial cell proliferation pathways upon saRNA treatment. *ex vivo* PCLS from ALD patients, showed robust GalNAc-HNF4α saRNA uptake by hepatocytes and upregulation of P1 along with downstream genes, similar to findings *in vitro*. **Conclusion:** Dysregulation of HNF4α isoforms represents a key pathogenic factor in AH leading to the loss of hepatocellular maturity and liver function. saRNA targeting HNF4α-AS1 induces P1 expression, restoring P1-specific transcriptome linked to normal liver function in both *in vitro* and *ex vivo* human models. GalNAc-HNF4α-saRNA may represent a novel therapeutic strategy for the treatment of AH.

3075 | NATIONAL TRENDS, INPATIENT OUTCOMES, AND RESOURCE UTILIZATION AMONG ALCOHOL-ASSOCIATED HEPATITIS, ALCOHOL-ASSOCIATED CIRRHOSIS, AND NON-ALCOHOL CIRRHOSIS IN THE UNITED STATES, 2016–2023

Talal Bhatti[1] Wanyu Zhang[2] Mangesh Padala[3] Jamil Abdo[2] David Maundu[4] Suthat Liangpunsakul[5] Maiying Kong[2] Ashwani Singal[2] Fatima Elmustafa[6], [1]Northwell Health, [2]University of Louisville, [3]Liver Institute -Methodist Dallas Medical Center, [4]KUMC Wichita,, [5]Indiana University, [6]Henry Ford Warren

Background: Cirrhosis, including alcohol-associated liver disease, remains a major cause of liver-related hospitalization in the United States, yet contemporary national data comparing alcohol-associated hepatitis (AH), alcohol-associated cirrhosis (AC), and non-alcohol cirrhosis (NAC) are limited. We evaluated temporal trends, inpatient outcomes, and resource utilization across these phenotypes. **Methods:** Weighted hospitalizations from the National Inpatient Sample (2016–2023) were analyzed using ICD-10 codes to identify patients with AH, AC, and NAC. Trends were examined between 2016 and 2023. Healthcare resource utilization was compared for 2023 using survey-weighted statistical tests with Bonferroni-adjusted pairwise analyses **Results:** From 2016 to 2023, hospitalizations increased across all cohorts, with AH admissions increasing from 116,880 to 163,220 (+39.6%), AC from 291,240 to 392,490 (+34.8%), and NAC from 403,870 to 546,925 (+35.4%). Mean hospitalization charges also increased from $53,527.58 to $84,712 in AH, from $66,662.65 to $101,585 in AC, and from $65,001 to $98,394 in NAC. In 2023, compared with AC and NAC, hospitalizations with AH had higher rates of intensive care for mechanical ventilation (2.9%), management of shock (0.9%), and continuous renal replacement therapy, or CRRT (1.3%). Inpatient mortality was 6.2% in AC vs. 5.6% in NAC and 4.5% in AH. AC also had the longest average hospitalization (6.62 days) with the total charges ($100,049). Disposition among survivors of hospitalization, AH had the highest rates of discharge to home and leaving against medical advice in 69% and 6.2%, respectively. In contrast, AC and NAC were more likely to be transferred to another hospital or use home health care. During the hospital stay, NAC had the highest rates of dialysis at 7.0%, whereas AC had the highest rates of paracentesis (27.9%) and of liver transplant (1.1%). Palliative care was used most often in AC and NAC at 9.0 and 9.3%, respectively (**Table**). **Conclusion:** Inpatient burden of advanced liver disease of cirrhosis and AH is increasing in the US. The healthcare and resource utilization in 2023 varied, with the highest a) inpatient mortality and resource utilization in AC, b) palliative care, dialysis, and transfer to another facility and home health care in NAC, and c) ICU care, discharge to home, and leaving against medical advice in AH. These differences in healthcare and resource use are relevant in building strategies to optimize inpatient care and transition to outpatient management, with the long-term goal of improving morbidity and mortality in hospitalized patients with advanced liver disease.

Table. Healthcare Burden and Resource Utilization in 2023: Alcohol-Associated Hepatitis vs. Alcohol-Associated Cirrhosis vs. Non-Alcohol-Associated Cirrhosis

	Alcohol-Associated Hepatitis n=163,220	Alcohol-Associated Cirrhosis n=332,500	Non-Alcohol Cirrhosis n=536,545	P value
Survival				
Inpatient mortality	7,265 (4.5)[a]	20,570 (6.2)[a]	30,150 (5.6)[a]	<0.001
Liver Care Procedures / Resources				
Paracentesis	25,700 (15.7)[a]	92,685 (27.9)[a]	93,795 (17.5)[a]	<0.001
Liver transplant	750 (0.5)[a]	3,760 (1.1)[a]	3,985 (0.7)[a]	<0.001
Dialysis	3,225 (2.0)[a]	13,100 (3.9)[a]	37,725 (7.0)[a]	<0.001
Palliative care consultation	8,810 (5.3)[a]	30,100 (9.0)[a]	50,025 (9.3)[a]	<0.001
Intensive Care Unit Management				
Mechanical ventilation	4,680 (2.9)[a]	9,250 (2.5)[a]	8,765 (1.6)[a]	<0.001
Shock	1,405 (0.9)[a]	2,740 (0.8)[a]	3,570 (0.7)[a]	0.0001
CRRT	2,050 (1.3)[a]	3,570 (1.1)[a]	4,520 (0.8)[a]	<0.001
Resource Utilization				
Length of stay in days (mean, SE)	6.34 (0.06)[a]	6.62 (0.06)[a]	6.46 (0.05)[a]	<0.001
Total charges in $ (mean, SE)	84,711.98 (1,911.24)[a]	100,048.80 (2,063.34)[a]	98,355.53 (1,616.56)[a]	<0.001
Disposition of Survivors				<0.001
Routine discharge to home	112,425 (69.0)	186,560 (56.2)	267,945 (50.0)	
Transfer to a short-term hospital	4,285 (2.6)	10,070 (3.0)	15,160 (2.8)	
Transfer to another facility	17,215 (10.6)	54,386 (16.4)	102,955 (19.2)	
Home health care	11,755 (7.2)	47,575 (14.3)	107,375 (20.0)	
Against medical advice	10,055 (6.2)	13,020 (3.9)	12,625 (2.4)	

For categorical variables, weighted counts and percentages are shown. For continuous variables, weighted means and standard errors are shown

[a] Significant difference between alcohol-associated hepatitis and alcohol-associated cirrhosis, excluding alcohol-associated hepatitis.

[b] Significant difference between alcohol-associated hepatitis and non-alcohol-associated cirrhosis.

[c] Significant difference between alcohol-associated cirrhosis excluding alcoholic hepatitis and non-alcohol-associated cirrhosis.

3076 | THE DESIGNER CYTOKINE IC7FC ATTENUATES ALCOHOL-ASSOCIATED LIVER DISEASE THROUGH IL-22–STAT3–DRIVEN LIVER REGENERATION

Fernanda Raya Tonetti[1] Phillipp Hartmann[2] Hui Han[1] Noemi Cabre[1] Marcos Fondevila[1] Alvaro Eguileor[1] Abraham Meijnikman[1] Yuxuan Jiang[1] Peter Starkel[3] Michael Karin[1] Mark Febbraio[4] Bernd Schnabl[2] Cristina Llorente[2], [1]University of California San Diego, [2]University of California, San Diego, [3]Cliniques Universitaires Saint-Luc, Brussels, Belgium, [4]Monash Institute of Pharmaceutical Sciences, Monash University, Melbourne, Victoria, Australia

Background: Alcohol-associated liver disease (ALD) is a leading cause of chronic liver disease worldwide and is characterized by hepatocyte injury, inflammation, steatosis, and impaired regenerative responses. Although activation of IL-22–STAT3 signaling promotes hepatocyte survival and tissue repair, therapeutic approaches targeting this pathway remain limited. IC7Fc is a designer gp130 agonist engineered to selectively activate regenerative signaling while avoiding the pro-inflammatory effects associated with IL-6 trans-signaling. However, its therapeutic potential in ALD has not been explored. **Methods:** Here, we investigated whether IC7Fc protects against ethanol-induced liver injury through hepatocyte-intrinsic IL-22–STAT3 signaling. Alcohol-associated liver disease was induced using the chronic-plus-binge NIAAA ethanol feeding model in wild-type (WT), hepatocyte-specific Stat3-deficient (*Stat3*$^{\Delta hep}$), and hepatocyte-specific Il22ra1-deficient (*Il22ra1*$^{\Delta hep}$) mice. During the final 7 days of ethanol feeding, mice received daily intraperitoneal injections of IC7Fc (1 mg/kg/day) or vehicle control. **Results:** IC7Fc markedly attenuated ethanol-induced liver injury in WT mice, as demonstrated by reduced plasma alanine aminotransferase levels, decreased hepatic steatosis, and attenuation of hepatic inflammation and fibrosis. Mechanistically, IC7Fc increased hepatic STAT3 phosphorylation and elevated hepatic IL-22 protein expression, accompanied by induction of hepatoprotective genes including Mcl1 and Bcl-xL and increased hepatic PCNA protein expression. Bulk liver RNA sequencing further revealed enrichment of regenerative and STAT3-associated transcriptional programs in IC7Fc-treated mice. In contrast, the protective effects of IC7Fc were completely abolished in *Stat3*$^{\Delta hep}$ and *Il22ra1*$^{\Delta hep}$ mice, demonstrating that IC7Fc promotes a hepatocyte IL-22–STAT3 regenerative program required for protection against ALD. Analysis of publicly available human liver RNA-seq datasets from patients with alcohol-associated hepatitis confirmed dysregulation of regenerative and STAT3-related pathways in human disease. **Conclusion:** Together, these findings identify IC7Fc as a potent therapeutic activator of hepatocyte IL-22–STAT3 signaling that promotes liver regeneration and protects against alcohol-associated liver disease. Our study establishes selective gp130 pathway activation as a promising regenerative strategy for ALD while avoiding the inflammatory liabilities associated with conventional IL-6 signaling.

3077 | INTEGRATED SPATIAL LIPIDOMICS AND PROTEOMICS REVEAL REGION-SPECIFIC LIPID COMPARTMENTALIZATION AND DISTINCT LIPID METABOLIC REPROGRAMMING IN ALCOHOL-ASSOCIATED CIRRHOSIS AND HEPATITIS

Le Day[1]; [1]Pacific Northwest National Laboratory

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Alcohol-associated liver disease (ALD) encompasses a spectrum of progressive injuries, including alcohol-associated hepatitis (AH) and alcohol-associated cirrhosis (AC). Despite the significant morbidity and mortality associated with ALD, the molecular mechanisms underlying the progression of these conditions remain poorly understood and spatial molecular heterogeneity is increasingly recognized as a driver of disease progression. **Methods:** We applied matrix-assisted laser desorption/ionization mass spectrometry imaging (MALDI-MSI) at 20 μm resolution to generate high-plex spatial lipidomics maps of human liver explants from healthy controls (HC) and patients with AC and AH. The spatially resolved lipid signatures were subsequently used to guide laser capture microdissection (LCM) for precise sampling of three distinct micro-environments: lipid-rich/fibrotic regions, the border of lipid-rich and lipid-depleted regions, and the center of lipid-depleted/non-fibrotic areas. Captured material underwent microscale proteomics sample preparation (microPOTS) followed by data-independent acquisition (DIA) analysis on the Orbitrap Astral mass spectrometer. **Results:** In AC, unsupervised clustering and region-of-interest analysis identified discrete lipid species selectively enriched within fibrotic septa versus non-fibrotic parenchyma. In contrast, the lipids that distinguish fibrosis and non-fibrosis regions in AC exhibited markedly more dispersed, non-specific distributions across AH tissue, losing clear spatial segregation. The spatial lipidomics informed spatial proteomics analysis yielded deep proteome coverage (>6,000 proteins) from ~100 cells. Quantitative proteomics demonstrated distinct lipid metabolism between AH and AC. AC samples showed coordinated upregulation of lipid mediators and extracellular matrix-remodeling enzymes within lipid-rich/fibrotic and border regions, whereas AH tissue exhibited broader dysregulation of mitochondrial β-oxidation, peroxisomal lipid catabolism, and phospholipid remodeling enzymes across the regions. Pathway enrichment further highlighted AH-specific enrichment of pro-inflammatory signaling that was absent in AC. **Conclusion:** Taken together, MALDI-MSI-guided spatial proteomics demonstrates that lipid compartmentalization is preserved in AC but disrupted in AH, corresponding to distinct proteomic reprogramming of lipid metabolic networks. This integrated spatial multi-omic approach provides mechanistic insight into ALD progression and identifies spatially restricted therapeutic targets linked to lipid dysregulation in ALD.

3078 | SIPAT SUBSTANCE DOMAIN, NOT OVERALL SIPAT SCORE, IS PREDICTIVE OF SUSTAINED ALCOHOL RECIDIVISM AT 1-YEAR POST-LIVER TRANSPLANT AMONG PATIENTS WITH ALCOHOL ASSOCIATED CIRRHOSIS

Chung-Heng Liu[1] Manida Wungjiranirun[2] Dekey Lhewa[1] Arnab Mitra[2], [1]Oregon Health & Science University, [2]Oregon Health And Science University

Background: The Stanford Integrated Psychosocial Assessment for Transplantation (SIPAT) offers a standardized method for psychosocial evaluation for liver transplant. Current data suggest SIPAT is predictive of mortality and medication adherence post- liver transplant. However, data on SIPAT in predicting return to alcohol use, using objective markers, among those with alcohol-related cirrhosis is limited. The primary aim of this study is to evaluate whether overall SIPAT score or individual SIPAT domains are predictive of alcohol recidivism, measured by an objective method like phosphatidylethanol (PEth). **Methods:** This was a retrospective analysis of liver transplant performed at a large transplant center from 2015-2024. All patients with alcohol-associated cirrhosis (AC) who underwent pre-transplant evaluation and transplant with PEth within 1-year post-liver transplant were included. Primary outcome was PEth positivity, defined as more than 20ng/mL from 2 or more consecutive follow-ups, within 1-year after liver transplant. Individual domain within the SIPAT (readiness, social support, psychological, and substance use), total SIPAT score, and SIPAT $\geq$ 21 (suggestive of high psychosocial risk) were evaluated as predictors of PEth positivity. Logistic regression was used to assess the associations between SIPAT score and PEth positivity. Kaplan-Meier was performed to evaluate time to first PEth positivity stratified by SIPAT $\geq$ 21. **Results:** A total of 187 patients with alcohol-associated cirrhosis who underwent liver transplant were included. 62% were male, 72% white and 12% Latinx, median age 52 (IQR 45-59), median MELD 29 (IQR 25-34), and 15% had positive PEth within 1 year of liver transplant. Among SIPAT domains, higher substance use scores were significantly associated with increased odds of alcohol recidivism (OR 1.13, p= 0.016). After adjusting for gender, age at transplant, MELD, race/ethnicity, insurance type, each 1-point increase in the SIPAT substance use domain score was associated with a

13% increase in odds of 1-year PEth positivity (p = 0.042) (Figure 1). In addition, there was no significant difference in time to PEth positivity between patients with total SIPAT < 21 and those SIPAT ≥ 21 (p = 0.266) (Figure 2). **Conclusion:** Less than a quarter of patients with alcohol-related cirrhosis had sustained alcohol relapse. Total SIPAT score and individual SIPAT domains of readiness, social support, and psychological were not independently associated with alcohol use post liver transplant. Substance use domain is a predictor of recidivism of alcohol within 1 year of transplant among patients with alcohol-associated cirrhosis. These findings suggest the substance use domain may provider greater utility than total SIPAT score in predicting post-transplant alcohol use. Further studies are needed to further validate psychosocial assessments in predicting recidivism.

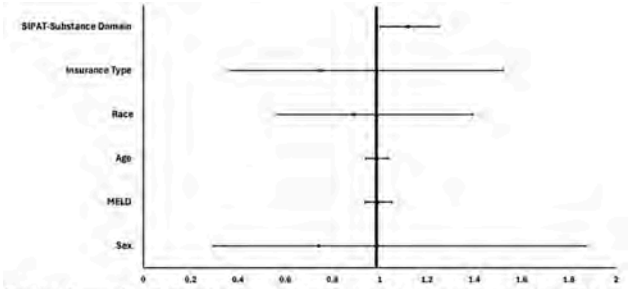

Figure 1. Forrest plot of adjusted odds ratio for predictors of 1-year post liver transplant PEth positivity

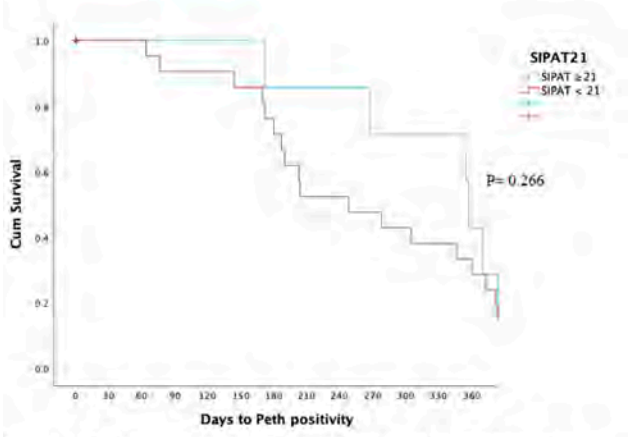

Figure 2. Time to PEth positivity after liver transplantation by SIPAT risk category: high risk (total SIPAT ≥21) and low risk (total SIPAT < 21).

3079 | TRENDS AND DISPARITIES IN ALCOHOLIC CIRRHOSIS MORTALITY IN THE UNITED STATES, 1999–2024: A 25-YEAR CDC WONDER ANALYSIS INCLUDING THE POST-COVID ERA

Faraz Waheed[1], [1]Benefis Health System

Background: Alcoholic cirrhosis is a leading cause of liver-related mortality in the United States, with rates rising over the past two decades. Prior analyses have ended at 2022, leaving the post-pandemic recovery period uncharacterized. We examined alcoholic cirrhosis mortality trends from 1999 through 2024, with particular attention to the COVID-19 era and subsequent recovery, and stratified findings by sex, race and ethnicity, age group, and US census region **Methods:** We conducted a retrospective cross-sectional analysis using the CDC WONDER Multiple Cause of Death databases. Decedents aged 25 years and older with alcoholic cirrhosis (ICD-10 K70.3) listed as the underlying cause of death were identified using the Bridged-Race database (1999–2020) and the Single-Race expanded database (2018–2024). Age-adjusted mortality rates (AAMRs) were calculated per 100,000 population using the year 2000 US standard population. Joinpoint regression was used to identify inflection points and to compute annual percent change (APC) and average annual percent change (AAPC) with 95% confidence intervals. **Results:** Between 1999 and 2024, 351,453 alcoholic cirrhosis deaths were recorded. The AAMR for alcoholic cirrhosis more than doubled from 4.1 to 8.7 per 100,000 (AAPC +3.2%). Joinpoint analysis identified three inflection points (2009, 2018, 2021) with the steepest acceleration during 2018–2021 (APC +11.88%, 95% CI 7.49–13.82, p < 0.001). After peaking at 10.1 per 100,000 in 2021, mortality declined through 2024 (APC −4.40%, p = 0.006) but remained 19% above the 2019 baseline. Disproportionate increases were observed among adults aged 25–34 years (COVID-era APC +25.53%) and 35–44 years (+23.39%); among American Indian and Alaska Native individuals (2021 AAMR 39.9, nearly four times the national rate); and among women, whose male-to-female AAMR ratio narrowed from 3.5:1 in 1999 to 2.2:1 in 2021. Geographic acceleration was greatest in the Midwest (+14.89%) and Northeast (+12.79%) during 2018–2021. **Conclusion:** Alcoholic cirrhosis mortality

surged dramatically during COVID-19 and remains elevated through 2024, with no major subgroup recovering to pre-pandemic levels. The disproportionate burden in young adults, women, and AIAN populations represents an evolving public health crisis requiring targeted prevention, expanded access to alcohol use disorder treatment, integration of liver disease screening into primary care, and culturally tailored interventions in high-risk communities.

3080 | EFFICACY AND SAFETY OF TERLIPRESSIN IN PATIENTS INELIGIBLE FOR LIVER TRANSPLANT WITH HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY AND ALCOHOL-ASSOCIATED HEPATITIS: AN EXPLORATORY ANALYSIS OF THE CONFIRM TRIAL

Todd Frederick[1] Nancy Reau[2] Laurie Larson[3] HoChong Gilles[4] Nneka Ufere[5] Kevin Regner[6] Anooj Shah[7] Richard Wu[8] Christopher White[8] Kavish Patidar[9], [1]California Pacific Medical Center, San Francisco, CA, [2]Rush University Medical Center, Chicago, IL, [3]University of Minnesota Physicians, Minneapolis, MN, [4]Central Virginia VA Health Care System, Richmond, VA, [5]Massachusetts General Hospital, Boston, MA, [6]Medical College of Wisconsin, Milwaukee, WI, [7]formerly affiliated with Mallinckrodt Hospital Products, Inc (A Keenova Therapeutics Company), [8]Mallinckrodt Hospital Products, Inc (A Keenova Therapeutics Company), Bridgewater, NJ, [9]Houston Methodist Hospital, Houston, TX

Background: Hepatorenal syndrome-acute kidney injury (HRS-AKI) is a functional renal failure caused by hemodynamic changes in patients (pts) with ascites and portal hypertension. The standard of care for treatment of HRS-AKI is vasoconstrictor therapy, preferably terlipressin, which is FDA-approved for use in adults with HRS with rapid reduction in kidney function. Liver transplant (LT) is a curative treatment, but pts with HRS-AKI and alcohol-associated hepatitis (AH) are often ineligible for LT and have a poor prognosis, particularly if HRS-AKI remains untreated. In the phase 3 CONFIRM trial (NCT02770716), alcohol/substance use was the most common reason for LT ineligibility (terlipressin, 53.5%; placebo [PBO], 59.5%). Here, we performed an exploratory analysis using CONFIRM data to understand the benefits of terlipressin use in pts with HRS-AKI and AH who were LT-ineligible. **Methods:** In CONFIRM, pts with HRS-AKI were randomized 2:1 to terlipressin or PBO, and concomitant albumin was strongly recommended if clinically appropriate. This exploratory analysis evaluated efficacy and safety of terlipressin in the overall LT-ineligible population with AH and an LT-ineligible subpopulation with AH excluding pts with serum creatinine $\geq$5 mg/dL and/or acute-on-chronic liver failure grade 3. Primary and secondary endpoints from CONFIRM, safety, and incidence of renal replacement therapy (RRT) in pts alive from Day 14 to 90 were analyzed. **Results:** There were 120 pts in CONFIRM with HRS-AKI and AH (n = 81 terlipressin, n = 39 PBO), 53 of whom were LT-ineligible (n = 35 terlipressin, n = 18 PBO). Among pts with AH who were LT-ineligible, 31 pts were also in the subpopulation (n = 20 terlipressin, n = 11 PBO). The percentage of pts with AH with verified HRS reversal was higher for terlipressin vs PBO in both the LT-ineligible population (28.2% vs 5.6%) and subpopulation (35.0% vs 9.1%). Pts with AH who received terlipressin vs PBO also demonstrated better response for all secondary endpoints (Figure). Incidence of RRT in pts with AH who were alive through Day 90 was lower with terlipressin vs PBO (LT-ineligible, 14.3% vs 40.0%; subpopulation, 12.5% vs 25.0%). The percentage of pts with AH experiencing adverse events in the LT-ineligible population receiving terlipressin (88.6%) was similar to the subpopulation (85.0%) and consistent with the overall CONFIRM population (88.0%). Abdominal pain, dyspnea, and respiratory failure were reported in $\geq$10% of pts treated with terlipressin. **Conclusion:** For pts with HRS-AKI and AH in the LT-ineligible population and subpopulation in CONFIRM, terlipressin was more effective than PBO for improving outcomes, including reducing incidence of RRT. The safety profile in these populations was also consistent with the overall CONFIRM population. These results suggest that pts with HRS-AKI and AH who are LT-ineligible may benefit from terlipressin treatment.

3081 | IGA-TARGETED DYSBIOSIS AND COMPARTMENTALIZED IGA RESPONSES ARE ASSOCIATED WITH DISEASE SEVERITY IN ALCOHOL-ASSOCIATED LIVER DISEASE

David Schöler[1] Cynthia Hsu[2] Takao Miwa[1] Linton Freund[1] Sonja Lang[3] Derrick Fouts[4] Peter Starkel[5] AlcHepNet Investigators[6] Bernd Schnabl[2], [1]Medicine, University of California, San Diego, CA, USA, [2]Medicine, University of California and VA San Diego Healthcare System, San Diego, CA, USA, [3]Gastroenterology and Hepatology, Faculty of Medicine and University Hospital, Cologne, Germany, [4]Human Genomic Medicine, J. Craig Venter Institute, Rockville, MD, USA, [5]Hepatology and Gastroenterology, St. Luc Univ. Hosp., UCLouvain, Brussels, Belgium, [6]Alcoholic Hepatitis Network Investigators

Background: Alcohol-associated liver disease (ALD) is characterized by intestinal dysbiosis, impaired gut barrier function, and microbial translocation that contribute to hepatic inflammation. Immunoglobulin A (IgA), the dominant mucosal antibody, plays a central role in intestinal homeostasis by coating luminal bacteria. We aimed to define fecal and serum IgA responses and characterize IgA-bound bacterial communities across the spectrum of ALD. **Methods:** We included 617 individuals (healthy controls (HC) n = 107, patients with alcohol use disorder (AUD) n = 150, patients with alcohol associated hepatitis (AH) n = 360). Stool IgA was measured in 199 individuals and IgA-bound microbiota in a subset, while serum IgA was measured in 522 individuals. Paired samples from a subset of patients with AUD was available following abstinence. IgA-bound bacteria were isolated using magnetic activated cell sorting (MACS) and analyzed by 16S rRNA gene sequencing. **Results:** Fecal IgA increased with disease severity (AH > AUD > HC) and were associated with distinct microbial compositions. IgA-bound microbial diversity was reduced in AH and partially recovered after abstinence. Beta diversity analyses demonstrated clear separation of IgA-bound bacterial communities by disease state, with enrichment of pathobiontic genera (e.g., *Streptococcus*, *Enterococcus*, *Escherichia/Shigella*) and depletion of beneficial and short chain fatty acid producing families including *Lachnospiraceae* and *Ruminococcaceae*. IgA-bound taxa were associated with disease severity, with commensal bacteria inversely and *Campylobacteraceae* positively correlated with MELD-Na scores. Serum IgA levels were markedly elevated in AH, decreased after abstinence, and were not correlated with fecal IgA, indicating compartmentalized regulation. While fecal IgA was not associated with survival, higher serum IgA was independently associated with reduced 6-month survival in patients with AH. **Conclusion:** ALD is associated with altered mucosal IgA responses and IgA-targeted dysbiosis, characterized by reduced diversity and enrichment of IgA-bound pathobionts. Distinct regulation of

3082 | ATRIAL FIBRILLATION AS A PREDICTOR OF ADVERSE HOSPITAL OUTCOMES IN CIRRHOSIS: FINDINGS FROM A NATIONWIDE DATABASE

Frank Lin[1] Brett Cohen[1] Nishanth Eluri[1] Kimberly Chaput[1] Noel Martins[1], [1]St. Luke's University Health Network

Background: Atrial fibrillation (AF) is a common arrhythmia associated with increased mortality, particularly in patients with liver cirrhosis, which exacerbates cardiovascular risks through inflammation and coagulopathy. Alcohol-associated cirrhosis and metabolic-dysfunction associated steatohepatitis (MASH)-related cirrhosis represent distinct etiologies, yet their impact with AF outcomes remains understudied. We aimed to evaluate in-hospital mortality and other outcomes in AF patients with alcohol-associated, MASH, or metabolic-dysfunction and alcohol associated liver disease (MetALD) using a large national database. **Methods:** We analyzed the 2018–2022 National Inpatient Sample (NIS), representing 20% of U.S. hospitalizations. Adult AF patients were stratified by cirrhosis type: alcohol-associated, MASH, and MetALD. Primary outcome was in-hospital mortality. Multivariable logistic regression adjusted for age, sex, race, income, Charlson comorbidity index, hospital characteristics, and comorbidities. ORs with 95% CIs were reported. Analyses used Stata 17. **Results:** Among 22.9 million weighted AF hospitalizations, 190,395 (0.8%) had alcohol-associated cirrhosis, 505,645 (2.2%) had MASH cirrhosis, and 691,820 (3.0%) had MetALD cirrhosis (Table 1). Patients with alcohol-associated cirrhosis were younger (mean age 64.9 years) than those with MASH (71.1 years) or no cirrhosis (75.1 years), with higher male predominance (80.3% vs. ~58% in no cirrhosis). Comorbidity burdens were elevated in cirrhosis groups, with Charlson index ≥ 3 in 82.8% (alcohol-associated), 87.2% (MASH), and 86.0% (MetALD) vs. 56.4% in no cirrhosis. In-hospital mortality was higher in alcohol-associated cirrhosis (9.2%, 17,485 deaths) and MASH (7.9%, 39,860 deaths) compared to no cirrhosis (5.4%, 1.2 million deaths) (Figure 1). OR for mortality was 1.76 (95% CI 1.69-1.82) for alcohol-associated cirrhosis vs. no cirrhosis, 1.26 (95% CI 1.23-1.29) for MASH, and 1.37 (95% CI 1.35-1.40) for MetALD. After full adjustment including comorbidities, ORs attenuated to 1.53 (95% CI 1.47-1.59) for alcohol-associated, 1.23 (95% CI 1.20-1.26) for MASH and 1.23 (95% CI 1.20-1.26) for MetALD. Mean LOS and charges were higher in cirrhosis groups (7.1-7.5 days, $89k-$95k) vs. no cirrhosis (6.1 days, $81k) (Figure 2). **Conclusion:** Cirrhosis significantly elevates in-hospital mortality in AF patients with alcohol-associated etiology conferring the highest risk. Attenuated post-adjustment ORs suggest comorbidities such as malnutrition and ESRD mediate much of the excess risk, highlighting opportunities for targeted interventions including nutritional support and renal management. MASH's rising prevalence underscores its growing public health burden. Limitations include administrative data biases and lack of longitudinal follow-up. Future studies should explore outpatient outcomes and strategies to mitigate cirrhosis-AF interactions.

3083 | EARLY MEDICATION FOR ALCOHOL USE DISORDER AFTER SEVERE ALCOHOL-ASSOCIATED HEPATITIS: PORTAL HYPERTENSION-RELATED EVENTS AND ACUTE-CARE UTILIZATION IN A PROPENSITY-MATCHED TRINETX COHORT

Nourhan Saleh[1] EzzElDien A. Ibrahim[1] Bjorn Rodriguez[1] Mahmoud Majed Mansour[1] Darian Fard[1] Khulood Ahmed[1], [1]University of Missouri

Background: Severe alcohol-associated hepatitis (AH) carries high short-term mortality, readmission, and downstream decompensation. Fewer than 6% of post-AH patients receive FDA-approved medication for alcohol use disorder (MAUD) at discharge despite guideline endorsement. Whether early post-discharge MAUD changes 6-month liver-event trajectories in real-world data remains unsettled while ITAALD recruits. **Methods:** TriNetX US Collaborative Network. Adults ≥18 with severe AH (AH diagnosis plus AST 50–<400 U/L, total bilirubin ≥3 mg/dL, and INR ≥1.5 within ±7 days of index) required a day-30 observability landmark and 365-day MAUD washout. Cohort A initiated FDA-approved MAUD (naltrexone, acamprosate, or disulfiram) in days 0–30 post-AH; Cohort B initiated none. Exclusions: prior transplant, viral/competing liver disease, ESRD, pregnancy, warfarin. 1:1 propensity matching at caliper 0.10 SD logit balanced demographics, binned severity labs, baseline decompensation, acute AH treatment, psychiatric and substance-use comorbidity, healthcare engagement, and concomitant medications (estimable post-match SMDs <0.10). Primary outcome: hepatic decompensation burden/progression composite over days 31–180. Secondary: acute-care utilization and recurrent AH code reappearance. Sensitivities: stricter severe-AH (bilirubin ≥5) and any-MAUD (adding baclofen, gabapentin, topiramate). Cox models estimated HRs. **Results:** 509 FDA-MAUD initiators matched to 509 no-MAUD comparators. Early MAUD was associated with directionally lower 180-day decompensation burden (composite HR 0.88, 95% CI 0.76–1.01, p = 0.07), driven by lower ascites/paracentesis (HR 0.84, 0.72–0.99, p = 0.03) and esophageal varices (HR 0.78, 0.63–0.97, p = 0.03); hepatic failure/encephalopathy, hepatorenal syndrome, and SBP were null. MAUD was associated with lower 180-day inpatient readmission (HR 0.78, 0.65–0.95, p = 0.01), consistent across segments (HR 0.69 days 31–60; 0.71 days 61–120; 0.74 days 121–180). The bilirubin ≥5 cohort showed favorable ascites and hospitalization estimates (N = 577 pairs: ascites HR 0.87, p = 0.06; hospitalization HR 0.77, p = 0.004). The any-MAUD cohort also favored MAUD (N = 1,937 pairs: ascites HR 0.89, p = 0.008; varices HR 0.85, p = 0.008; ED visit HR 0.88, p = 0.05). Recurrent AH code reappearance was null across cohorts, arguing against coding persistence as the main explanation. Mortality and negative-control outcomes were uninterpretable due to event suppression. **Conclusion:** Early FDA-approved MAUD within 30 days after severe AH was associated with lower portal hypertension-related decompensation burden and inpatient utilization within 6 months, with directionally consistent sensitivity analyses. Findings support real-world post-AH MAUD pathways while awaiting ITAALD efficacy data.

Background: The disease burden of alcohol-related liver disease (ALD) is increasing, and its disease spectrum and clinical outcomes are highly heterogeneous. Currently, there is a lack of systematic characterization of clinical features in large-scale Chinese ALD populations. This study aimed to: (1) describe the baseline characteristics and disease spectrum distribution in a multicenter Chinese ALD cohort; (2) identify independent factors influencing disease severity; (3) explore predictors associated with 4-year survival. **Methods:** This was a multicenter observational study, enrolling a total of 2724 diagnosed ALD patients from five medical centers. Baseline clinical, laboratory, and imaging data were collected, and 4-year survival follow-up was conducted. Disease severity was assessed using a Model for End-Stage Liver Disease (MELD) score ≥ 21 (defined as severe ALD). Logistic regression analysis was used to identify factors influencing disease severity, and Cox proportional hazards models were used to analyze factors influencing survival. **Results:** The cohort was predominantly male (97.1%), with a mean age of 54.51 ± 10.65 years. Disease spectrum distribution showed that decompensated alcoholic cirrhosis was the most prevalent (70.8%). Multivariate logistic regression analysis indicated that ascites (OR = 1.672, p = 0.009), decreased hemoglobin (OR = 0.992, p = 0.002), thrombocytopenia (OR = 0.991, p < 0.001), AST/ALT ratio > 1.5 (OR = 1.068, p = 0.007), and elevated GGT (OR = 1.000, p = 0.003) were independent factors influencing disease severity. Among 807 patients with complete follow-up data, the cumulative 4-year survival rate was 55.2%. Multivariate Cox analysis revealed that failure to abstain from alcohol at baseline (HR = 2.129, p < 0.001),presence of ascites (HR = 1.314, p = 0.047), hepatic encephalopathy (HR = 0.387, p < 0.001), elevated white blood cell count (HR = 1.034, p = 0.001), decreased hemoglobin (HR = 0.96, p = 0.044), AST/ALT ratio > 1.5 (HR = 1.055, p < 0.001), MELD score ≥ 21 (HR = 3.088, p < 0.001), and comorbid diabetes (HR = 0.405, p < 0.001) were independent predictors of 4-year survival. **Conclusion:** This study delineates a disease spectrum in Chinese ALD patients that is predominantly decompensated cirrhosis. It identifies key clinical determinants of disease severity and long-term prognosis, highlighting the prognostic significance of baseline inflammatory markers and continued alcohol use. These findings provide a basis for risk stratification and individualized patient management.

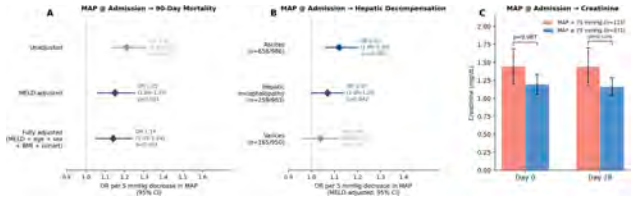
3085 | MEAN ARTERIAL PRESSURE IS INDEPENDENTLY ASSOCIATIED WITH 90-DAY MORTALITY IN



Samer Gawrieh[1] Wanzhu Tu[2] Qing Tang[2] Merixtell Ventura Cots[3] Srinivasan Dasarathy[4] Mack Mitchell[5] Vijay Shah[6] Arun Sanyal[7] Craig McClain[8] Gyongyi Szabo[9] Juan Pablo Arab[7] Ashwani Singal[8] Suthat Liangpunsakul[2] Ramon Bataller[10] Naga Chalasani[11] AlcHepNet Investigators[12], [1]Indiana University School of Medicine, [2]Indiana University, [3]Barcelona Clinic, [4]Cleveland Clinic, [5]University of Texas Southwestern Medical Center, [6]Mayo Clinic Rochester, [7]Virginia Commonwealth University, [8]University of Louisville, [9]Beth Israel Deaconess Medical Center, [10]University of Pittsburgh, [11]Indiana University Medical Center, [12]AlcHepNet

Background: The existing prognostic scores for alcohol-associated hepatitis (AH), such as MELD, are derived from biochemical markers of hepatic and renal failure and do not capture hemodynamic status. Mean arterial pressure (MAP) is a proxy for circulatory dysfunction and reflects effective arterial underfilling, a central feature of AH pathophysiology. Whether MAP carries independent prognostic value beyond the biochemistry markers in AH remains poorly studied. **Methods:** We analyzed data from two prospective cohorts: the Alcoholic Hepatitis Network Observational Study cohort (AHNOBS; N = 706) and the TREAT cohort (N = 271). The primary outcome was 90-day all-cause mortality. The association between MAP at admission and mortality was examined in three sequential logistic regression models: MELD alone, MELD + MAP, and a fully adjusted model (MELD + MAP + age + sex + BMI + cohort). MAP's association with baseline decompensation symptoms and its influence on renal function were examined as secondary analyses. **Results:** The analytic sample included 943 patients (184 deaths, 19.5%). Non-survivors had lower MAP than survivors (80.0 ± 12.1 vs. 84.7 ± 11.2 mmHg). Each 5 mmHg decrease in MAP was associated with

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

increased 90-day mortality after adjusting for MELD (OR 1.15, 95% CI 1.06–1.24, p = 0.001) and after full covariate adjustment (OR 1.13, 95% CI 1.04–1.23, p = 0.003). MAP added significant prognostic value beyond MELD (likelihood ratio test p = 0.001). The cohort indicator was not significant (p = 0.74). Lower MAP was associated with ascites (OR 1.13 per 5 mmHg decrease, p < 0.001) and hepatic encephalopathy (OR 1.08, p = 0.027) but not varices (p = 0.22). The prognostic effect of MAP was amplified in patients with concurrent renal impairment (creatinine ≥ 1.2 mg/dL; OR 1.23, p = 0.001) compared with those with preserved renal function (OR 1.06, p = 0.35), **:** suggesting an interaction between hemodynamic compromise and renal dysfunction. In AHNOBS, the low-MAP group (MAP < 75 mmHg) had persistently higher creatinine through day 28 (1.44 vs. 1.16 mg/dL, p = 0.058). **Conclusion:** MAP at admission is independently associated with 90-day mortality in patients with AH. MAP effects are amplified in patients with concurrent renal impairment.

3086 | IMPACT OF RENAL DYSFUNCTION ON CLINICAL OUTCOMES IN PATIENTS HOSPITALIZED WITH ALCOHOL-ASSOCIATED HEPATITIS

Ahmed Ibrahim[1] Don Rockey[2], [1]San Joquin General Hospital, [2]Medical University of South Carolina

Background: Alcohol-associated hepatitis (AH) is associated with high morbidity and mortality, particularly in patients with renal dysfunction. While acute kidney injury (AKI) and hepatorenal syndrome (HRS) are recognized complications, their impact on clinical outcomes in AH remains incompletely defined. We aimed to evaluate the association of AKI and HRS at presentation with liver-related outcomes and mortality in patients hospitalized with AH. **Methods:** We conducted a cohort study using the TriNetX multicenter database (n = 114,456,231 patients in total), including adult patients hospitalized with AH between 2010 and 2025. Patients were stratified into three groups: AH with AKI (AKI-AH), AH with AKI caused by HRS (HRS-AH), and AH without AKI (control). Baseline characteristics were assessed prior to propensity score matching. The primary outcome was all-cause mortality.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Secondary outcomes included hepatic decompensation events (ascites, hepatic encephalopathy, variceal hemorrhage). Outcomes were analyzed using Kaplan–Meier survival analysis, and Cox proportional hazards models were reported as hazard ratios (HR) with 95% confidence intervals (CI). **Results:** A total of 2,324 patients with AKI-AH, 1,447 patients with HRS-AH, and 22,567 control patients were included (**Table 1A**). At baseline, patients had similar demographic features, and the majority of patients were White males. Patients with HRS more frequently had ascites (38%) and hepatic encephalopathy (HE) (34%) compared to other groups. HRS patients also had more abnormal laboratory parameters, including higher bilirubin, INR, and creatinine levels. After propensity matching, at 90 days post-admission, mortality was significantly higher in patients with AKI-AH than controls, and patients with HRS-AH had the highest mortality, **Table 1B**). Additionally, hepatic decompensation, including ascites and HE occurred more frequently in patients with AKI-AH as compared to controls, with the highest rates of decompensation occurring in those with AKI caused by HRS). HE was the most common decompensation event followed by ascites. Interestingly, variceal hemorrhage occurred in less than 5% of patients and rates were not significantly different between groups. Finally, KM analysis showed that survival rates at 90 days were the lowest in those with AKI caused by HRS as compared to AKI-AH and controls. **Conclusion:** AKI at presentation identifies a high-risk phenotype in patients hospitalized with AH and is associated with an increased risk of hepatic decompensation and mortality. HRS confers the highest risk of adverse outcome, suggesting a distinct and more severe disease phenotype.

Table 1A. Demographics and baseline characteristics before propensity score matching

Variable	AKI-AH (N=2,324)	HRS-AH (N=1,447)	No AKI-HRS-AH (N=22,567)
Age (yrs, mean ± SD)	46 ± 11	46 ± 11	47 ± 11
Female, n (%)	832 (36%)	540 (37%)	7,772 (34%)
White, n (%)	1,716 (74%)	1,072 (74%)	16,998 (75%)
Black, n (%)	195 (8%)	95 (7%)	1,987 (9%)
Hispanic, n (%)	253 (11%)	167 (12%)	2,492 (11%)
Cirrhosis, n (%)	887 (38%)	653 (45%)	7,838 (35%)
Ascites, n (%)	732 (32%)	545 (38%)	5,933 (26%)
HE, n (%)	533 (23%)	488 (34%)	3,240 (14%)
Platelets	150 ± 93	133 ± 89	152 ± 90
Albumin (g/dL)	2.6 ± 0.7	2.5 ± 0.6	2.9 ± 0.7
T bilirubin (mg/dL)	16 ± 10	22 ± 11	10 ± 7

3087 | INTEGRATION OF CLINICAL PARAMETERS AND CYTOKINE PROFILES TO PREDICT 90-DAY OUTCOMES IN ADULTS WITH ALCOHOL-ASSOCIATED HEPATITIS

Stephen Samuel[1] Prashanth Thevkar Nagesh[1] Yun-Cheng Hsieh[1] - AlcHepNet Clinical Centers investigators[2] Yunpeng Yu[3] Wanzhu Tu[3] Gyongyi Szabo[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, [2]-, [3]Indiana University

Background: Alcohol-associated hepatitis (AH) has high short-term mortality. Conventional clinical scores incompletely capture systemic inflammation, a major contributor to pathogenesis and outcomes, prompting integration of cytokines with clinical variables to improve 90-day mortality prediction. **Methods:** Retrospective analysis of the AlcHepNet multicenter study (NCT03850899). Adults ≥21 years with AH (NIAAA) treated with prednisone (40 mg/d; n = 71) or anakinra (100 mg s.c./d) plus zinc (220 mg/d; n = 72) were included. Cytokines were measured using a 48-plex Luminex assay (8-time points: days 0, 3, 7, 14, 28, 60, 90, 180). The primary endpoint was 90-day mortality. Predictors were assessed by univariable analysis, Cox-LASSO with bootstrapping, and multivariable Cox regression adjusting for treatment arm. Model performance was evaluated via the C-index and internally validated using bootstrap resamples. A weighted scorecard was derived from Cox model beta-coefficients. **Results:** Among 144 patients, 90-day mortality was 18%. Mortality was higher with anakinra+zinc vs. prednisone (72% vs. 28%, P < 0.001). Non-survivors had higher MELD (27 vs. 24, P = 0.005) and lower hemoglobin (8.65 vs. 9.85 g/dL, P = 0.014), platelets (124 vs. 151×10³/μL, P = 0.031), and alkaline phosphatase (121 vs. 177 U/L, P = 0.012) when compared to survivors. No baseline cytokines differed; however, day-7 log changes in eotaxin, IL-13, IL-17A, IL-17F, and VEGF-α were greater in non-survivors when compared to survivors. In the anakinra + zinc group, non-survivors had lower baseline IL-1RA (P = 0.04) and IL-2 (P = 0.01). Univariable predictors in 90-day non-survivors included MELD, hemoglobin, INR, BUN, bilirubin, alkaline phosphatase, IL-3, IL-6, M-CSF and prednisone when compared to anakinra+zinc. LASSO regression model identified IL-1RA, IL-3, and IL-6. After adjusting for treatment arm, we identified independent predictors of 90-day mortality: INR (HR 2.44; 95% CI, 1.29 to 4.61; P = 0.006), BUN (HR 1.04; 95% CI, 1.01 to 1.07; P = 0.019), total bilirubin (HR 1.07; 95% CI, 1.02 to 1.11; P = 0.004), and $\log_{10}$ IL-6 (HR 2.33; 95% CI, 1.14 to 4.76; P = 0.021). No significant interaction was observed between treatment arm

and IL-6 (P > 0.05). A 4-variable score card (bilirubin, BUN, INR, IL-6) had numerically higher AUC vs. MELD (73.3% vs. 68%, P = 0.24), with sensitivity 84.6%, specificity 56.3%, and NPV 93.9%. It also demonstrated an apparent C-index of 0.779 and an optimism-corrected C-index of 0.746; outperforming MELD score, which yielded an optimism-corrected C-index of 0.679 in this cohort. Calibration analysis showed high agreement between predicted and observed survival (mean absolute error of 0.11). **Conclusion:** Cytokine dysregulation is associated with mortality in AH; IL-6 found to be an independent predictor of 90-day mortality. A combined clinical–cytokine model may show promise in improving risk stratification.

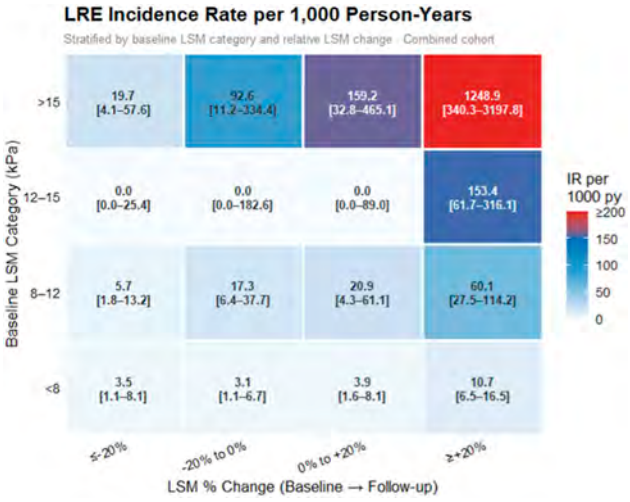
3088 | DYNAMIC LIVER STIFFNESS MEASUREMENT CHANGES PREDICT LIVER-RELATED EVENTS ACROSS FIBROSIS STRATA IN STEATOTIC LIVER DISEASE



Hyundam (Dami) Gu[1] Luis Díaz[2] Natalia Baeza[2] Francisco Idalsoaga[3] Cristiane Villela-Nogueira[4] Natalia Balassiano Wajsbrot[4] Ana Carolina Cardoso[4] Nathalie Leite[4] Gil Salles[4] Claudia Cardoso[4] Anand Kulkarni[5] Ramagundam Ramyasri[6] William Alazawi[7] Wenhao Li[7] Laura Temperley[7] Maria Poca[8] Berta Cuyas[8] Terry Cheuk-Fung Yip[9] Vincent Wai-Sun Wong[9] Grace Wong[9] Jimmy Che-To Lai[9] Jose Velarde Ruiz Velasco[10] Juan Roblero[11] Daniela Simian[12] Pamela Gil Galleguillos[12] Mohamed El-Kassas[13] Claudia Couto[14] Guilherme Grossi Cancado[15] Sebastian Marciano[16] Jorge Martínez[16] Maria Jose Acosta[16] Adrián Gadano[16] Ismael Yepes[17] Luis Molina Barrios[17] Argemiro Lara[17] MaríaFernanda SaavedraChacón[18] Eira Cerda Reyes[19] Stefanny Cornejo Henández[19] Graciela Castro-Narro[20] Sheel Patel[21] Ashwani Singal[21] Katrina Pekarska[22] Richard Parker[22] Mohamad Ali Ibrahim[23] Prasun Jalal[23] Mazen Noureddin[24] Naim Alkhouri[25] Winston Dunn[26] Patrick Kamath[27] Arun Sanyal[1] Richard Sterling[1] Maraco Arrese[2] Ramon Bataller[28] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Pontificia Universidad Católica de Chile, [3]Pontificia Universidad Católica de Chile; Western University, [4]Universidade Federal do Rio de Janeiro, [5]Asian Institute of Gastroenterology, [6]AIG Hospitals, [7]Blizard Institute, Queen Mary University of London, [8]Institut de Recerca Hospital de Sant Pau-IIB Sant Pau, Universitat Autònoma de Barcelona, [9]The Chinese University of Hong Kong, [10]Hospital Civil de Guadalajara, [11]University of Chile, [12]Universidad de Chile, [13]Capital University, [14]Federal University of Minas Gerais, [15]Universidade Federal de Minas Gerais, [16]Hospital Italiano de Buenos Aires, [17]Universidad de Cartagena, [18]Clínica CES, [19]Central Military Hospital, [20]Hospital Médica Sur, Ciudad de México. Instituto Nacional de Ciencias Médicas y Nutrición, [21]University of Louisville, [22]Leeds Teaching Hospitals NHS Trust, [23]Baylor College of Medicine, [24]Houston Methodist Hospital, [25]Summit Clinical Research, [26]University of Kansas Medical Center, [27]Mayo Clinic, [28]University of Pittsburgh

Background: Serial vibration-controlled transient elastography (VCTE) offers a practical, non-invasive approach for longitudinal monitoring of hepatic fibrosis in patients with steatotic liver disease (SLD); however, the prognostic significance of interval liver stiffness measurement (LSM) changes across baseline fibrosis strata remains incompletely defined. We aimed to evaluate whether the magnitude of LSM percentage change between serial measurements predicts liver-related events (LREs) across baseline fibrosis strata in a large combined international cohort. **Methods:** We analyzed 2,978 patients with MASLD or MetALD/ALD from an international cohort (n = 2,320) and US-based SLD registry (n = 658) with ≥ 2 VCTE measurements. LSM change was categorized as ≤ -20%, -20–0%, 0–+20%, and ≥ +20%. The composite LRE endpoint included incident cirrhosis, hepatic decompensation, hepatocellular carcinoma (HCC), and liver transplantation, whichever occurred first. LRE incidence rates (per 1,000 person-years) were stratified by baseline LSM category (< 8, 8–12, 12–15, and > 15 kPa) and LSM change category. Pairwise rate ratios were estimated using Poisson regression with Holm correction for multiple comparisons. **Results:** The cohort included patients with MASLD (2815, 94.2%), MetALD/ALD (172, 5.8%). [HG1] Median age and baseline LSM were 54 years and 6.3 kPa, respectively. Median time between VCTEs were 2.2 and 3.5 years in the SLD and International cohorts, respectively. 94 LREs occurred during follow-up. Across all baseline LSM categories, ≥ +20% worsening was associated with the highest LRE incidence. ≥ 20% improvement conferred an 11-fold lower LRE incidence compared with ≥ 20% worsening (RR = 0.09 [95% CI:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

0.03–0.28], p < 0.001) in the 8–12 kPa group. In the > 15 kPa group, ≥ 20% improvement showed similar signal of lower LRE incidence (RR = 0.02 [95% CI: 0.00–0.07], p < 0.001). In subgroup analysis of more improvement groups, substantial LSM reduction of ≥ 30% was associated with 88% lower LRE incidence compared to stable LSM in baseline advanced fibrosis (LSM > 15 kPa, both p < 0.05). **Conclusion:** Serial LSM improvement of ≥ 20% was associated with substantially lower LRE risk across different baseline fibrosis strata. These findings support the prognostic value of LSM dynamics and reinforce the utility of serial VCTE monitoring to identify patients who may benefit from continued or escalated therapeutic intervention in SLD.

3089 | BASELINE AND LONGITUDINAL CHANGES IN SERUM BASED NON-INVASIVE TESTS (NITS) FOR PREDICTING MAJOR ADVERSE LIVER OUTCOMES IN PATIENTS WITH METABOLIC AND ALCOHOL ASSOCIATED STEATOTIC LIVER DISEASE (METALD)

Binu John[1] Dustin Bastaich[2] Bassam Dahman[2], [1]University of Miami and Miami VA, [2]Virginia Commonwealth University

Background: Metabolic and alcohol-associated steatotic liver disease (MetALD) represents a distinct and emerging entity within the steatotic liver disease spectrum, yet optimal fibrosis risk stratification strategies for this population remain poorly defined. We evaluated the prognostic performance of serum based non-invasive tests (NITs) (FIB-4, APRI, NAFLD fibrosis score, and SAFE score), using standard MASLD risk categories, for predicting major adverse liver outcomes (MALO: hepatocellular carcinoma (HCC), decompensation, liver transplantation, or liver-related death) in patients with MetALD. **Methods:** This retrospective cohort study utilized data from the Veterans Health Administration Corporate Data Warehouse (January 2013-June 2025). MetALD was identified using a validated algorithm combining natural language processing of abdominal imaging reports with cardiometabolic risk factor and alcohol use data ($\kappa = 0.87$). Patients were excluded for alternative etiologies of liver disease, < 6 months of follow-up, death within 12 months of steatosis, or with MALO within 6 months of steatosis identification. NITs were classified as low, intermediate, or high based on established thresholds. NIT risk categories were included in univariable Cox proportional hazard models predicting MALO. The C-statistics (c) of these models were evaluated for predictive performance, and p-values for differences in Uno's concordance statistics were used to test for significant differences in predictive performance. We also examined the performance of the 3-year trajectory of NITs for predicting following MALOs compared to using risk groups at the 3-year landmark alone. **Results:** There were 114,833 participants with MetALD in the analytic sample after exclusions (median age 62 years (IQR 18), 92.3% male). Among baseline NITs, FIB-4 demonstrated superior discrimination for MALO (C-statistic 0.70; 95% CI 0.69–0.72) compared to APRI (0.65; $p < 0.0001$), NFS (0.66; $p = 0.0006$), and SAFE score (0.66; $p < 0.0001$). Relative to low FIB-4 (< 1.3), intermediate (1.3–2.67) and high-risk (> 2.67) categories conferred markedly elevated MALO risk (HR 2.21 [95% CI 2.06–2.38] and HR 7.13 [6.64–7.66], respectively; $p < 0.0001$). Three-year FIB-4 trajectory significantly outperformed baseline classification (C-statistic 0.72 [0.70–0.73]; $p < 0.0001$). Patients with persistently elevated FIB-4 carried the highest MALO risk (HR 12.48 [10.68–14.59]), followed by those progressing from low-to-high (HR 10.20 [7.50–13.88]) and intermediate-to-high (HR 6.95 [5.76–8.37]). (**Figure 1**). **Conclusion:** In this large national MetALD cohort, FIB-4 was the most accurate serum-based NIT for MALO prediction. Serial FIB-4 monitoring with trajectory-based risk stratification substantially improved prognostic accuracy over single-time-point measurement, supporting its integration into longitudinal surveillance strategies for patients with MetALD.

3090 | ETHANOL ACTIVATES YAP SIGNALING AND DRIVES PRO-INFLAMMATORY MACROPHAGE POLARIZATION UNDER METABOLIC STRESS IN METALD

Swastika Tripathi[1] Zeinab Heidariyan[1] Wenyu Lin[1] Yongtao Wang[1] Raymond Chung[1] Shadi Salloum[1], [1]Massachusetts General Hospital

Background: Hepatic macrophages are key amplifiers of liver injury, capable of shifting between pro-inflammatory and pro-fibrotic polarization states central to the progression from steatosis to cirrhosis. In Metabolic dysfunction and alcohol-associated liver disease (MetALD), alcohol superimposed on metabolic stress accelerates fibrosis and increases liver-related mortality. Critically, ethanol and free fatty acids, the dual stressors defining MetALD, are established inducers of Hippo pathway dysregulation; whether these signals converge on YAP activation to reprogram macrophage polarization and amplify fibrogenic signaling remains unexplored. Here, we interrogated YAP-associated transcriptional programs across complementary human macrophage platforms, including our novel iPSC-derived macrophages (MACs), to define how ethanol and lipid stress shape macrophage-driven fibrogenic crosstalk. **Methods:** To simulate the dual metabolic-alcoholic stress of MetALD, primary monocyte-derived macrophages (MDMs), U937 cells, and MACs were exposed to ethanol (0–2%) ± free fatty acid cocktail for 5 days. YAP activation, pro-inflammatory, and pro-fibrotic polarization were assessed by qRT-PCR and Western blot. Conditioned media from ethanol-treated macrophages were applied to iPSC-derived hepatic organoids to investigate paracrine fibrogenic capacity. **Results:** Across all three platforms, ethanol consistently activated YAP signaling in a dose-dependent manner, establishing it as a downstream effector of ethanol stress in human macrophages. When the ethanol treatment was paired with free fatty acid treatment to model the dual-stressor environment of MetALD, YAP target gene induction was attenuated under combined exposure. In parallel, ethanol treatment preferentially induces macrophages toward a pro-inflammatory polarization state, rather than a more pro-fibrotic state, across all cell lines, identifying inflammation as the dominant macrophage response to ethanol stress. Most compellingly, conditioned media from ethanol-stimulated macrophages induced fibrogenic gene expression in hepatic organoids at levels comparable to TGF-β, demonstrating that an inflammatory macrophage state retains full paracrine fibrogenic capacity. **Conclusion:** These findings reveal that fibrosis in MetALD may not require macrophages to adopt a classical pro-fibrotic identity. Combined alcohol and metabolic stress may instead sustain an inflammatory state capable of driving fibrogenesis via paracrine crosstalk. This work positions macrophage YAP signaling as a mechanistic bridge between metabolic injury, alcohol exposure, and fibrosis amplification thereby highlighting a tractable therapeutic axis for progressive MetALD.

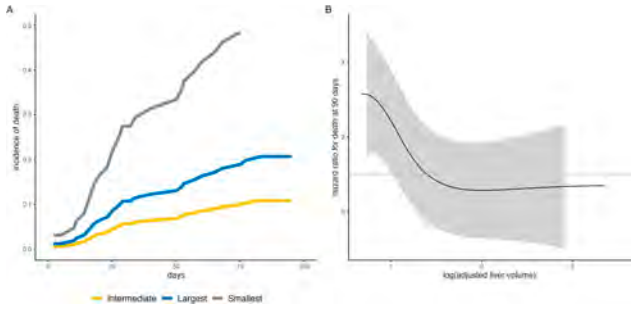
3091 | LIVER VOLUME IS ASSOCIATED WITH MORTALITY IN ALCOHOL ASSOCIATED HEPATITIS



Francisco Idalsoaga[1] Amy Hicks[2] Nawaz Safdar[3] Darwish Khizindar[4] Vincent Haghnejad[4] Joaquin Hevia-Morel[5] Ashwani Singal[6] Juan Pablo Arab[7] Richard Parker[8], [1]Western University, Canada, [2]Leeds Liver Unit, St James's University Hospital, Leeds, UK., [3]School of Medicine, Faculty of Medicine and Health, University of Leeds, Leeds, UK, [4]Department of Hepatology and Gastroenterology, University Hospital of Nancy, Nancy, France., [5]Departamento de Radiología, Escuela de Medicina, Pontificia Universidad Católica de Chile, Santiago,, [6]University of Louisville, [7]Virginia Commonwealth University School of Medicine, Richmond, VA, USA., [8]Leeds Teaching Hospitals NHS Trust

Background: Alcohol-associated hepatitis (AH) is associated with high short-term mortality, but prognostic assessment relies mainly on clinical and laboratory variables. Imaging-based markers may provide additional risk stratification. We evaluated whether computed tomography (CT)-derived liver volume and steatosis were associated with clinically relevant outcomes in patients hospitalized with AH. **Methods:** We conducted a multicenter retrospective cohort study of patients hospitalized with AH between 2009 and 2023 who underwent abdominal CT within 5 days of admission. Liver volume was measured by CT volumetry and compared with the predicted liver volume based on body surface area. Hepatic steatosis was assessed using the liver-to-spleen attenuation ratio. The primary outcome was 90-day mortality. Secondary

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

outcomes were 30-day mortality, corticosteroid response, and infection. Associations were assessed using Cox regression and logistic regression models. **Results:** We included 122 patients with AH. Median age was 46 [41-53] years, 40 (33%) were women, and median MELD score was 22 [19-26]. Median liver volume was 2,535 [1,908-3,304] cm^3, and the median observed-to-predicted liver volume ratio was 1.61 [1.17-2.11]. Ninety-day mortality occurred in 28 patients (23%). Body surface area-adjusted liver volume was inversely associated with 90-day mortality (HR 0.32, 95% CI 0.12-0.83, p = 0.019), and this association remained significant after adjustment for age, sex, and MELD (HR 0.24, 95% CI 0.07-0.87, p = 0.029). Compared with the smallest tertile, patients in the intermediate and largest liver volume tertiles had significantly lower 90-day mortality. Liver volume was also associated with 30-day mortality in univariable analysis (HR 0.20, 95% CI 0.06-0.89, p = 0.034), but was not associated with corticosteroid response or infection. Hepatic steatosis was not associated with mortality, infection, or corticosteroid response. Liver volume showed moderate discrimination for 90-day mortality (AUROC 0.70). **Conclusion:** In this multicenter cohort of patients hospitalized with AH, a smaller CT-derived liver volume was independently associated with higher 90-day mortality, whereas CT-assessed steatosis was not associated with outcomes. CT-derived liver volume may provide additional prognostic information in AH and warrants validation in larger prospective cohorts.

3092 | PREVALENCE AND RISK FACTORS OF RENAL IMPAIRMENT IN PATIENTS WITH ALCOHOLIC LIVER DISEASE: A MULTICENTER STUDY IN CHINA

Wei Li[1]; [1]Beijing Ditan Hospital, Capital Medical University

Background: Alcoholic liver disease (ALD) has become a common chronic liver disease in China. Current research on ALD, both domestically and internationally, has largely focused on liver pathology, whereas studies on renal impairment in ALD patients remain insufficient, lacking large-sample, multicenter epidemiological data. The prevalence of renal impairment in Chinese ALD patients, its independent risk factors, and its impact on patient survival are still unclear. **Methods:** This study is a cross-sectional analysis combined with retrospective follow-up. A total of 2,724 ALD patients from four medical centers were enrolled. Renal impairment was defined as an estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m^2 (calculated using the CKD-EPI equation based on serum creatinine). Baseline demographic data, alcohol consumption history, laboratory parameters (liver and kidney function, blood count, coagulation profile), and complications were collected. Baseline characteristics were compared between the renal impairment group and the non-renal impairment group. Multivariable logistic regression analysis was performed to identify independent risk factors for renal impairment. The Kaplan-Meier curve was used to preliminarily assess the effect of renal impairment on 1-year survival. **Results:** The prevalence of renal impairment (eGFR < 60) in this cohort was 7% (101/1,442). Multivariable logistic regression identified age, abstinence from alcohol, aspartate aminotransferase, total bilirubin, and white blood cell count as independent risk factors for renal impairment in ALD patients (Table1). Univariate analysis showed that factors such as presence of cirrhosis, cirrhotic complications (ascites, hepatic encephalopathy, portal hypertensionrelated gastrointestinal bleeding), diabetes mellitus, hypoalbuminemia, Maddrey discriminant function, MELD score, and ChildPugh score were associated with renal impairment (P < 0.05); however, these independent associations disappeared after adjusting for confounders (P > 0.05). Patients with baseline renal

impairment had a significantly lower estimated 12-month survival rate than those with normal renal function (P < 0.001)(Figure1). **Conclusion:** Renal impairment is not uncommon in ALD patients and represents an important component of systemic damage in this disease. Its occurrence is driven by multiple factors. Early identification of high-risk patients and intervention on modifiable factors may be of great significance for improving the overall prognosis of ALD patients.

Table 1. Multivariable logistic regression analysis of factors associated with renal impairment in ALD patients.

Step 1[a]	Variable	B	S.E.	Wald	df	Sig.	Exp(B)	95% C.I. for Exp(B)

3093 | PROGRESSION TO SEVERE ALCOHOL-ASSOCIATED HEPATITIS (AH) IS COMMON IN PATIENTS WITH MODERATE AH AND IS ASSOCIATED WITH A HIGHER RISK OF MAJOR ADVERSE LIVER OUTCOMES

Ashwani Singal[1] Wanzhu Tu[2] Yunpeng Yu[2] Vatsalya Vatsalya[1] Nicole Welch[3] Douglas Simonetto[4] Juan Pablo Arab[5] Jacqueline O'Leary[6] Srinivasan Dasarathy[3] Suthat Liangpunsakul[2] Mack Mitchell[7] Arun Sanyal[5] Naga Chalasani[8] Gyongyi Szabo[9] Ramon Bataller[10] Craig McClain[1] Samer Gawrieh[8], [1]University of Louisville, [2]Indiana University, [3]Cleveland Clinic, [4]Mayo Clinic Rochester, [5]Virginia Commonwealth University, [6]UTSW, [7]University of Texas Southwestern Medical Center, [8]Indiana University Medical Center, [9]Beth Israel Deaconess Medical Center, [10]University of Pittsburgh

Background: Data on the natural history of moderate alcohol-associated hepatitis (mAH, MELD score < 20) and its progression to severe AH (sAH) are limited **Methods:** In a prospective multicenter AlcHepNet (AHN) observational study, participants with mAH were enrolled and followed for 6 months. The primary outcome was progression to sAH (MELD ≥ 20) within 6 months, stratified by return to drinking (RTD). The effect of RTD on outcomes was estimated using Cox proportional hazards models with RTD as a time-varying covariate. Progression to sAH by RTD status was compared cross-sectionally using Fisher's exact test. **Results:** Of 712 participants with AH (2020-2024), 148 (20.8%) had mAH at enrollment (mean age 45.0 ± 11.5 years, 44.6% females, 82% white, mean MELD 16.7 ± 2.1). Among those with available follow-up data on MELD and RTD, the overall rate of progression to sAH was 22.1% (19/86). Cross-sectional progression rates were 14.3% (10/70), 19.1% (9/47), and 19.6% (10/51) at 1, 3, and 6 months, respectively. Progressors vs. non-progressors had a higher baseline MELD (17.7 ± 1.6 vs. 16.6 ± 2.1, p = 0.033), with no differences in demographics, comorbidities, and alcohol use. Participants with RTD (n = 30, 34.9%) had a higher frequency of progression to sAH than those without RTD: 46.7% vs 6.3% at 3 months (p = 0.002) and 35.0% vs 9.7% at 6 months (p = 0.036) (**Figure**). MELD score comparing progressors vs. non-progressors was 21.2 ± 5.3 vs. 10.9 ± 3.5 at 3 months (p < 0.001) and 20.3 ± 6.1 vs. 10.6 ± 5.2 at 6 months (p < 0.001). Major adverse liver outcome (MALO) at 6 months (decompensation, mortality, liver-related hospital admission, or liver transplantation) was more frequent in progressors (68.4% vs. 28.4%, p = 0.001). Of 6 deaths, 3 each occurred in progressors and non-progressors, 15.8% vs. 4.5%, p = 0.119. In time-varying Cox models adjusted for age, sex, race, body mass index, MELD, albumin, WBC, and mean arterial pressure, RTD was associated with a 4.4-fold (95% CI 1.6–12.3; p = 0.005), 2.2-fold (1.0-4.5, p = 0.04), and 9.4-fold (1.2-73.3, p = 0.032) hazard of progression to sAH, MALO, and mortality at 6 months. **Conclusion:** About 22% of participants with mAH are at risk of progression to sAH within 6 months. This progression is associated with RTD and increased risk of MALO. These findings support a close follow-up, integrated management of liver disease and of alcohol-use disorder, and highlight an unmet need for drug development in patients with mAH.

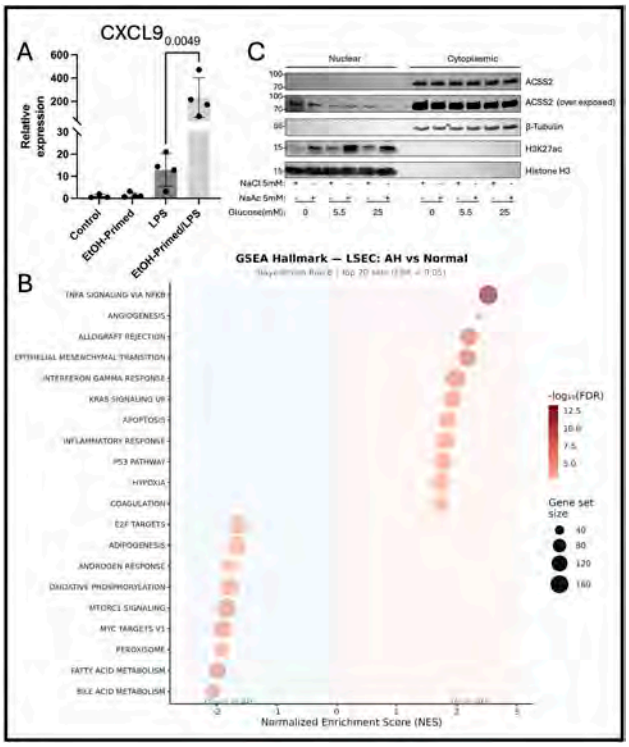
3094 | ALCOHOL-INDUCED METABOLIC STRESS ACTIVATES AN ACETATE–ACSS2 EPIGENETIC AXIS IN LIVER SINUSOIDAL ENDOTHELIAL CELLS



Rafael Ricci de Azevedo[1] Weizhe Zhong[1] Mengfei Liu[1],
[1]Yale

Background: Alcohol-associated hepatitis (AH) features metabolic reprogramming and sustained hepatic inflammation with no effective therapy. Alcohol metabolism generates millimolar circulating acetate while impairing glucose utilization. In innate immune cells, nuclear acetyl-CoA drives histone acetylation underlying trained immunity — durable epigenetic reprogramming that amplifies inflammatory responses upon rechallenge. Liver sinusoidal endothelial cells (LSECs) are angiocrine gatekeepers of hepatic immune trafficking, but whether acetate-derived acetyl-CoA via ACSS2 contributes to epigenetic reprogramming in LSECs under the metabolic conditions of AH is unknown. **Methods:** A murine priming–rest–challenge binge alcohol model assessed LSEC trained immunity: mice received 4-day alcohol binges, 7-day rest, then LPS rechallenge, with Cxcl9 as the inflammatory recall readout. Bulk RNA-seq deconvolution (BayesPrism) of human AH liver biopsies quantified LSEC transcriptional programs. Primary human LSECs were subjected to glucose deprivation and 5 mM acetate treatment to model alcohol-induced metabolic stress. ACSS2 subcellular localization and global H3K27ac were assessed by Western blot of nuclear and cytoplasmic fractions. **Results:** Alcohol-primed LSECs showed greater than 10-fold increase in Cxcl9 upon LPS rechallenge compared to unprimed controls, demonstrating robust trained immunity in LSECs in vivo. Deconvolution of human AH liver revealed upregulated TNF and interferon signaling alongside suppressed mTOR, oxidative phosphorylation, pyruvate metabolism, and fatty acid oxidation in LSECs, indicating inflammatory activation

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

concurrent with broad metabolic stress. In primary human LSECs, glucose deprivation increased ACSS2 nuclear translocation, and acetate treatment increased global H3K27ac, demonstrating that the metabolic conditions of AH are sufficient to activate the ACSS2-dependent histone acetylation axis in LSECs. **Conclusion:** LSECs in AH exhibit a trained-immunity phenotype accompanied by broad metabolic suppression. Glucose deprivation drives ACSS2 nuclear translocation and acetate increases histone acetylation in primary human LSECs, implicating the acetate–ACSS2 axis as a metabolic mechanism supporting epigenetic inflammatory reprogramming in LSECs during AH.

3095 | PYRUVATE DEHYDROGENASE KINASE 4 LINKS ALCOHOL METABOLISM TO MONOCYTE/MACROPHAGE-MEDIATED INFLAMMATION IN ALCOHOL-ASSOCIATED LIVER DISEASE

Jianguo Wu[1] Zhiwei Guo[1], [1]Northeast Ohio Medical University

Background: Mitochondria harbor key alcohol-metabolizing enzymes and serve as active mediators of alcohol-induced toxicity. Canonically regulating glycolysis and exhibiting higher activity than its paralogues, pyruvate dehydrogenase kinase 4 (PDK4) plays a pivotal role in metabolic reprogramming and tissue homeostasis. Hepatic PDK4 is overexpressed in murine models of alcohol-associated liver disease (ALD) and in patients with alcohol-associated hepatitis (AH), implicating it in disease progression. However, its precise role in the pathogenesis of ALD remains incompletely understood. Here, we investigate the potential role of PDK4 in hepatic alcohol metabolism and monocyte/macrophage-mediated inflammatory responses in ALD. **Methods:** PDK4-interacting proteins in PDK4-overexpressing cells were identified by immunoaffinity purification followed by LC-MS/MS. Acetaldehyde-induced oxidative stress, with or without the PDK4 inhibitor diisopropylamine dichloroacetate (DADA), was assessed by measuring reactive oxygen species (ROS) production using a DCF-DA assay. Inflammatory gene expression in murine models of acute and chronic liver injury was quantified by qPCR and ELISA. Expression of signal transducers and activators of transcription (STATs), known regulators of PDK4 expression, was analyzed in monocyte subclusters from peripheral blood mononuclear cells (PBMCs) of patients with AH using a single-cell RNA-seq dataset. **Results:** Immunoaffinity purification revealed that ALDH2, a key enzyme in the oxidative pathway of alcohol metabolism, co-immunopurified with PDK4 in PDK4-overexpressing cells. Pharmacological inhibition of PDK4 by DADA increased ROS levels following acetaldehyde exposure in hepatocytes, suggesting a role for PDK4 in hepatic alcohol detoxification. PDK4 deficiency in mice altered inflammatory gene expression in both acute and chronic liver injury models. Analysis of scRNA-seq data demonstrated increased STAT expression in monocytes from patients with AH. Specifically, STAT2, STAT3, and STAT6 were upregulated across monocyte subclusters, while STAT1 was increased in most clusters except CD16^{+} monocytes, suggesting a possible role of the downstream PDK4 in response to STATs to regulate monocyte/macrophage-driven inflammatory responses in ALD. **Conclusion:** PDK4 may coordinate alcohol metabolism and monocyte/macrophage-mediated inflammatory activation in the pathogenesis of ALD. These findings provide insight into regulators linking alcohol metabolism, mitochondrial function, and innate immune activation in ALD.

3096 | MATRIX-BOUND NANOVESICLES AS MODULATORS IN ALCOHOL-RELATED LIVER DISEASE

Yekaterina Krutsenko[1] Bashar Al Matour[1] Jiang Li[1] Jia-Jun Liu[1] Lorien Walker[1] Michael Merchant[2] Silvia Liu[1] George Hussey[1] Melanie Scott[1] Gavin Arteel[1], [1]University of Pittsburgh, [2]University of Louisville

Background: Alcohol-related liver disease (ALD) lacks effective therapies, and understanding extracellular matrix (ECM) remodeling during disease progression may reveal novel therapeutic targets. Matrix-bound nanovesicles (MBVs) are ECM-embedded vesicles enriched in bioactive proteins and microRNAs that regulate cell-matrix signaling and tissue repair in multiple injury settings. However, the contribution of MBVs to ALD pathogenesis has not been yet examined. In the present study, we not only characterized how alcohol alters hepatic MBV composition, but also evaluated therapeutic effects of exogenous healthy MBVs in alcohol-induced liver injury. **Methods:** Using the NIAAA chronic-plus-binge ethanol model, we first isolated hepatic MBVs and performed LC-MS/MS proteomic analysis with pathway enrichment to define alcohol-induced cargo alterations. We then administered MBVs from healthy porcine urinary bladder matrix to ethanol-exposed mice and assessed therapeutic effects through histopathological evaluation and bulk RNA sequencing. **Results:** Chronic ethanol exposure induced marked remodeling of hepatic MBV cargo, with enrichment of proteins associated with metabolic stress responses and detoxification pathways. Administration of healthy MBVs attenuated ethanol-induced steatosis, and lipid peroxidation, while partially normalizing transcriptional programs related to oxidative stress, inflammation, and metabolic regulation. Transcriptomic analyses further demonstrated that MBV administration partially reversed ethanol-induced pathways associated with oxidative stress, inflammatory signaling, cytokine responses, and metabolic dysfunction. Interestingly, MBV treatment improved hepatocellular injury despite persistent neutrophil-associated inflammatory responses, suggesting selective immunomodulation rather than broad immunosuppression. **Conclusion:** These findings identify hepatic MBVs as dynamic components of the ECM microenvironment in ALD. MBVs appear to modulate hepatic homeostasis in a context-dependent manner rather than acting as direct immunosuppressive agents, supporting their potential utility as both biomarkers of ECM remodeling and therapeutic modulators in alcohol-related liver disease.

3097 | CONTEXT-DEPENDENT FEATURES OF SENESCENT HEPATIC STELLATE CELLS IN LIVER DISEASE

Daniel Lin[1] Hye Yeon Choi[2] Yixin Bai[2] Yoann Daniel[2] Stephanie Pan[2] Qihong Yang[2] Hyun Young Kim[3] Sadatsugu Sakane[3] Meng Li[2] Linda Sher[2] Satoshi Haneda[4] Zhaoli Sun[5] Tatiana Kisseleva[3] Hidekatzu Tsukamoto[2], [1]University of Southern Callifornia, [2]University of Southern California, [3]University of California, San Diego, [4]Sekisui Chemical Co. Ltd., [5]Johns Hopkins University

Background: Hepatic stellate cells (HSCs) undergo senescence to contribute to liver inflammation, regeneration and HCC development. However, single cell transcriptomic profiling of senescent HSCs in liver disease of different etiology, is yet to be assessed. Further, the relationship of HSC senescence with cell activation state, vitamin A content, and ECM scaffold, are elusive. This study aimed to address these knowledge gaps. **Methods:** *Col1a1-GFP* mice underwent alcohol associated-hepatitis (AH); liver fibrosis by bile duct ligation or CCl4; or HCC induced by DEN and alcohol western diet. HSCs were FACS-sorted into VitA+GFP- quiescent HSCs, VitA+GFP+ and VitA-GFP+ activated HSCs (aHSCs). Senescence was assessed by *Glb1+Cdkn2a+* expression via scRNA-seq and SA-β-gal staining in culture. AH or HCC patient livers analyzed by snRNA-seq and/or Visium spatial analysis. ALD patient-derived HSCs and etoposide-induced senescent LX2 cells were cultured on wells coated with chemically defined scaffold Ceglu™ vs. plastic wells to assess its effects. **Results:** scRNA-seq of *Glb1+Cdkn2a+* HSCs across the 4 disease models identifies a common set of induced core senescence markers including *Cdkn1a*, *Serpine1*, and *Atm*. Concurrently, AH senescent HSCs uniquely over-express inflammatory (*Cxcl2*, *Cxcl5*, *Spp1*, *Saa3, C3, Cd5l*) and lipid metabolism (*Ptgs2*, *Pla2g4a*, *Vps13c*, *Apoc1)* genes while HCC senescent HSCs distinctly upregulate immunosuppressive (*Fcgr2b, Dnase1l3*) and tumor-promoting (*Col6a5*,*Stab1, Sox18*) genes. Cross-species conservation is supported by upregulation of *VPS13C*, *APOC1*, *C3*, and *CXCL2* in senescent HSCs in patient AH. Spatial analysis reveals enrichment of senescent HSCs within *AFP+* regenerative nodules in AH patient liver and within patient HCC nodules with *AFP+* cancer cells and *CD4+FOXP3+* Tregs. The senescence rate assessed by *Glb1+Cdkn2a+* is low in control mouse HSCs including VitA+GFP- quiescent HSCs. However, VitA+GFP- cells from AH have a higher senescence rate (3.22%) than VitA+GFP+ (2.30%) or VitA-GFP+ (1.04%) *Lrat+* aHSCs. This surprising result is confirmed by SA-β-gal staining showing 10.67% positivity in the former vs. 2.41%

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and 2.55% in the latter two. *Glb1+Cdkn2+* vs. *Glb1-Cdkn2-* VitA+GFP- HSCs have higher expression of genes previously shown to be associated with inactivated HSCs (*Csf1r, Csf2rb, Il7r, Ly86, Aft3*). VitA+GFP + senescent aHSCs have higher expression of inflammatory genes vs. VitA-GFP+ senescent aHSCs that express immunosuppressive genes. Ceglu™ coated vs. plastic wells reduces etoposide-induced LX2 senescence and partially rescues the senescence of ALD patient HSCs. **Conclusion:** These results suggest HSC senescence is context-dependent and shaped by disease etiology, activation state, vitamin A content, and ECM microenvironment. VitA+GFP- senescent HSCs identified in AH mice, may constitute inactivated HSCs which were once activated.

3098 | CONTINGENCY MANAGEMENT FOR PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE FOLLOWING LIVER TRANSPLANTATION: A PILOT STUDY

Vanessa Ryan[1] Nicole Prause[1] Akshay Shetty[1] Jasleen Singh[1] Trent Ford[2] Natalie Cohen[2] Steven Shoptaw[1] Arpan Patel[1], [1]University of California, Los Angeles, [2]RELIVE

Background: Alcohol-associated liver disease (ALD) is a leading indication for liver transplantation, yet 20-40% of recipients return to alcohol use after transplant, with harmful drinking linked to graft injury, morbidity and mortality. Contingency Management (CM), an evidence-based behavioral intervention that uses escalating rewards to reinforce abstinence, is effective in many substance use disorders but has not been well-studied among post-liver transplant patients with ALD. This pilot study evaluated the feasibility and acceptability of CM among post-liver transplant patients with ALD and explored preliminary effects on alcohol use and quality of life. **Methods:** This pilot randomized clinical trial aimed to enroll 30 post-liver transplant patients with ALD; only 10 participants were enrolled and randomized to either 10 weeks of CM or treatment as usual (TAU). Eight participants completed all study procedures (CM = 4, TAU = 4), including weekly visits assessing alcohol use with blood and urine biomarkers. Both groups were compensated for study visits; CM participants received escalating incentives (from $5 to up to $70 per week) for negative alcohol biomarkers. CM participants also completed weekly Client Satisfaction Questionnaire (CSQ-8) and semi-structured interviews at Week 2, 5, and 10. All participants completed the PROMIS-29+2 Profile (PROPr) at baseline and study completion. **Results:** Retention among enrolled participants was high (80%). CM participants reported that CM was very acceptable to them (CSQ-8 mean = 30.9 ± 0.6, out of 32). Two participants (one in each arm) reported alcohol use during the study. Although underpowered for efficacy analyses, improvements were observed across 7 of 8 PROPr domains (except physical function). Themes that emerged during interviews included improved accountability, trust, and self-motivation. Reported barriers included laboratory testing burden and limited incentive variety. Participants recommended peer involvement, extended follow-up, and incentive options for future CM programs **(Table):** . **Conclusion:** CM was feasible and highly acceptable among enrolled post-live transplant patients with ALD, though recruitment proved challenging. Exploratory findings suggest potential benefits for patient engagement, increasing abstinence, and improving health-related quality of life. Future studies should focus on optimizing recruitment strategies and reducing participation burden while evaluating CM effectiveness across larger post-liver transplant populations.

Table: Interview Themes and Representative Quotes

	Theme	Quote
CM Acceptability	Trust	"I think as far as making it a **no judgement and a safe space, that was huge, and I really feel like it is a safe space**. So, I think the way that was approached was really important. Because being a transplant recipient, there is a lot of judgement that comes with it once they hear liver."
	Accountability	"For me it is **accountability**, knowing I am part of this study, and it is a good motivator too."
	Internal Motivation And Self Awareness	"I haven't had to give up anything for the program. It's **just a way of life**. I know what I have to do for me and the program is just a reminder of what I need to do to keep me right." "This program has **kept me focused** on what's ahead of me. Not trying to recall what was behind me…" "Overall, the program has opened my eyes to lot of things **Making myself aware of certain things** even as far as what I eat because there are meals where they use cooking wine and sherry and stuff like that…"
	External Support	"Believe in yourself and have a **great support system**. "You can go through a lot of pressure and not give in if you want to live…"
CM Program Suggestions	Contributions from those who completed CM	"Finding out from people who already did it. **I think maybe if you have people like that, who have done it and experienced it**, and have people reach out to those people and ask them what they think… Sometimes, people take it more personally from a person rather than staff, a doctor, a nurse, or an administrator."
	Flexibility in incentives	"But what if **some people don't go to Target**, and maybe some people go to Walmart? Maybe some people shop at other grocery stores or other clothing stores. Maybe it's an option maybe to mix up with the Target gift cards, because some things at Target is more expensive than other places." "Maybe instead of something where they have to go to a certain store, **$25.00 cash might can have them to go to buy something that they might need medically.**"
	Lab Draws	"I wish there was **some way that we could have a home test** afterward so that I could check myself periodically, even though I know what I am doing, just to check myself periodically."
	Create longer follow up	"No. Like I said, **the program is awesome**. It is excellent. I am open to if you guys want to call me in **30, 60, 90 days just** for a **checkup**. That is how good the program was to me, and for me to open up myself to say at your will, come check me, I think that says a whole lot because you guys did a whole lot for me."

3099 | ADMISSION NEUTROPHIL-TO-LYMPHOCYTE RATIO IS ASSOCIATED WITH 90-DAY MORTALITY IN ALCOHOL-ASSOCIATED HEPATITIS: AN INTERNATIONAL MULTICENTER COHORT STUDY

Gabriel Prusch Fernandes[1] Hamza Sadhra[1] Kristina Chacko[1] Ronnie Li[2] Stephen Hoang[2] S. Fisher Rhoads[2] Mark Thursz[3] Winston Dunn[4] Ashwani Singal[5] Yanhang Gao[6] Roberta Araújo[7] Fatima Higuera-de la Tijera[8] Rakhi Maiwall[9] Ramon Bataller[10] Lubomir Skladany[11] Luis Antonio Diaz[12] Juan Pablo Arab[2], [1]Montefiore Einstein, [2]Virginia Commonwealth University, [3]Imperial College London, [4]University of Kansas Medical Center, [5]University of Louisville, [6]The First Hospital of Jilin University, [7]Hospital das Clínicas da Faculdade de Medicina de Ribeirão Preto, [8]General Hospital of Mexico, [9]Institute of Liver and Biliary Sciences, [10]Hospital Clínic de Barcelona, [11]F.D. Roosevelt University Hospital, [12]Pontificia Universidad Católica de Chile

Background: The neutrophil-to-lymphocyte ratio (NLR) is an inexpensive marker of systemic inflammation derived from routine complete blood counts. NLR reflects the balance between innate (neutrophil-driven) and adaptive (lymphocyte) immune responses and rises during the prominent neutrophilic inflammation and systemic inflammatory response characteristic of alcohol-associated hepatitis (AH). Its prognostic role at hospital admission has not been well evaluated in large international cohorts. We evaluated the association between admission NLR and 90-day mortality in hospitalized patients with AH. **Methods:** We conducted a retrospective multicenter cohort study of 1,433 patients hospitalized with AH from 14 centers in 8 countries within the GlobalAlcHep collaboration. Admission NLR was categorized as low (<3), moderate (3 to <6), or high (≥ 6). Missing data were handled with multiple imputation across 30 datasets. Kaplan-Meier survival curves and multivariable Cox proportional hazards regression were used to assess 90-day all-cause mortality. **Results:** Median age was 46 years (IQR 38–54); 70.8% were male. Median admission NLR was 6.6 (IQR 3.8–11.1), and 90-day mortality was 28.6% (410/1,433). Kaplan-Meier analysis demonstrated significantly worse 90-day survival across rising NLR categories (log-rank $p<0.001$). In multivariable analysis, high admission NLR was independently associated with 90-day mortality compared with low NLR (HR 1.55, 95% CI 1.09–2.21; $p=0.02$); moderate NLR did not differ from low (HR 1.13, 95% CI 0.77–1.66; $p=0.54$). Admission MELD was also independently associated with 90-day mortality (HR 1.50 per 5-point increase, 95% CI 1.41–1.61; $p<0.001$). **Conclusion:** In a large international multicenter AH cohort, high admission NLR was independently associated with increased 90-day mortality. As a simple day-0 biomarker derived from the complete blood count, admission NLR may provide additional risk stratification at the time of presentation but should be considered an adjunct rather than a replacement for established prognostic tools.

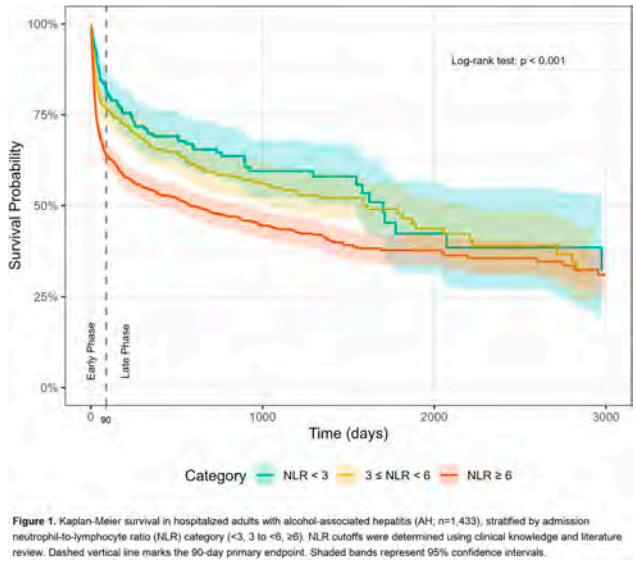

Figure 1. Kaplan-Meier survival in hospitalized adults with alcohol-associated hepatitis (AH; n=1,433), stratified by admission neutrophil-to-lymphocyte ratio (NLR) category (<3, 3 to <6, ≥6). NLR cutoffs were determined using clinical knowledge and literature review. Dashed vertical line marks the 90-day primary endpoint. Shaded bands represent 95% confidence intervals.

3100 | METABOLIC AND MOLECULAR PERTURBATIONS UNDERLYING METABO-INFLAMMATORY-NECROTIC ACTIVITY INDUCED BY ALCOHOL EXPOSURE IN THE PRESENCE OF OBESITY WITH METABOLIC DYSFUNCTION AND PNPLA3^{I148M} MUTATION

Isabel Veloso Alves Pereira[1] Gamze Bulut[2] Faridoddin Mirshahi[2] Mulugeta Seneshaw[3] Shailaja Lakshmana Reddy[3] Stephen Hoang[3] Thomas Andl[3] Ekaterina Smirnova[2] Arun Sanyal[2], [1]Universidade de São Paulo, [2]Virginia Commonwealth University, [3]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health

Background: Alcohol-associated liver disease (ALD) and obesity with metabolic dysfunction often co-exist. The PNPLA3^{I148M} variant increases the risk of cirrhosis in both ALD and MASLD. The metabolic-molecular perturbations when all three co-exist are not known. **Aim:** To define the impact of (1) alcohol consumption on metabo-inflammatory pathways when obesity and PNPLA3^{I148M} are already present, and (2) PNPLA3^{I148M} on background of obesity and alcohol use. **Methods:** The following interventions were performed on 8wk old male DIAMOND mice: (Group (Gp) 1) high fat diet (HFD), (Gp 2) HFD + AAV-PNPLA3^{I148M} for liver-specific overexpression, (Gp 3) HFD + 20% alcohol (v/v) in drinking water, and (Gp 4) HFD + AAV-PNPLA3^{I148M} + 20% alcohol. Histological, laboratory, tissue SnRNAseq and metabolomic analyses were performed after 16 weeks of treatment. Pseudo-bulked snRNAseq datasets were batch-corrected and integrated with metabolomics data. Gene expression across cell types in the entire liver was constructed using Stouffer weighting with cell-type proportions. For joint pathway analysis, the maximum p value was used to combine metabolites with genes using gene or metabolite set enrichment analysis (ssGSEA GenePattern Module), and a similar enrichment analysis was performed using the KEGG database and custom functions in R Studio. Significance was set to alpha = 0.05 and FDR to 0.1. **Results: Results:** ***A: Effect of alcohol on background of obesity + PNPLA3^{I148M} (Gp 4 vs 2)*****:** Group 4 had the highest histological and molecular metabo-inflammatory activity. 13 pathways were concordantly (gene + metabolite) significantly upregulated (Fig. 1 below) including cysteine-methionine metabolism (FDR 0.05), glycine, serine and threonine (FDR 0.03), one-carbon folate (FDR 0.03). Arachidonic acid (FDR 0.48) and linoleic acid metabolism (0.58) were down-regulated driven by suppression of Cyp4a10 and Cyp2e1 (CT-weighted logFC = -2.78 and -0.8 respectively). Necroptosis was activated by alcohol in this but not in mice without PNPLA3^{I148M} (gp 3). ***B: Effect of PNPLA3^{I148M} on background of obesity + alcohol*****:** A signature of altered AMPK signaling was noted as the only concordant (transcription/metabolite) change (FDR 0.04). **Conclusion:** Alcohol alters amino acid metabolism and transcriptionally activates necroptotic pathways in the background of obesity + PNPLA3^{I148M} . In the presence of obesity and alcohol use, PNPLA3^{I148M} increases AMPK signaling.

3101 | BIOMARKER-BASED CLASSIFICATION IDENTIFIES POTENTIAL UNDER-RECOGNITION OF ALCOHOL-ASSOCIATED STEATOTIC LIVER DISEASE IN A NATIONALLY REPRESENTATIVE U.S. COHORT

Katharine Tippins[1] Adnan Said[2], [1]University of Wisconsin Hospitals and Clinics, [2]University of Wisconsin School of Medicine and Public Health

Background: Classification of steatotic liver disease (SLD) relies on self-reported alcohol intake to distinguish metabolic dysfunction-associated steatotic liver disease (MASLD) from alcohol-associated phenotypes.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

However, self-report may underestimate alcohol exposure. The MetALD-ALD Prediction Index (MAPI), incorporating routinely available laboratory parameters, was developed to identify alcohol-associated SLD using objective biomarkers. We applied this framework to a nationally representative U.S. cohort to evaluate potential misclassification of alcohol-associated disease. **Methods:** We conducted a cross-sectional, survey-weighted analysis of adults ≥20 years in NHANES 2017–2020 with vibration-controlled transient elastography and complete MAPI components (sex, mean corpuscular volume, GGT, HDL cholesterol, hemoglobin A1c) and alcohol quantity-frequency questionnaires. SLD was defined by controlled attenuation parameter (CAP) ≥280 dB/m and categorized using AASLD-aligned alcohol intake thresholds. Participants were stratified by MAPI risk categories (rule-out ≤0.09, indeterminate 0.09-0.33, rule-in ≥0.33). Primary outcomes were distribution of MAPI risk across self-reported alcohol phenotypes and discordance between self-reported classification and biomarker-based risk. Survey weights were applied to generate nationally representative estimates. **Results:** Among 2,883 adults with SLD, metabolic dysfunction, and complete MAPI variables, 32.5% were classified as MAPI rule-out, 48.7% as indeterminate, and 18.7% as rule-in for alcohol-associated disease. Among participants with MASLD-range self-reported alcohol intake, 18.8% met MAPI rule-in criteria for MetALD-ALD and 68.7% were classified as indeterminate or high-risk for alcohol-associated disease, indicating discordance between self-report and biomarker-based risk. MAPI classification demonstrated a graded increase across self-reported alcohol categories, with rule-in prevalence rising from 18.8% in MASLD-range intake to 51.2% in MetALD-range and 75.7% in ALD-range intake, supporting biological plausibility. Weighted to the U.S. population, these findings correspond to approximately 10.1 million adults with MASLD-range self-reported alcohol intake who meet MAPI rule-in criteria for alcohol-related disease, with 37.0 million classified as indeterminate or high-risk for alcohol-related disease. **Conclusion:** In a nationally representative U.S. cohort, biomarker-based classification using MAPI identifies a substantial subset of individuals with SLD who may have under-recognized alcohol-associated disease despite low self-reported intake. These findings highlight potential limitations of reliance on self-reported alcohol exposure in current SLD classification frameworks and support further evaluation of objective, biomarker-based approaches in population-based liver disease research.

3102 | SARCOPENIA AND MALNUTRITION ARE ASSOCIATED WITH HEPATIC DECOMPENSATION AND MORTALITY IN HOSPITALIZED PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS: A MULTICENTER PROPENSITY-MATCHED ANALYSIS

Ahmed Ibrahim[1] Eisha Mohsin[2] David Maundu[3] Sajid Jalil[4] Ashwani Singal[5], [1]San Joquin General Hospital, [2]Agha Khan Univeristy, [3]University of Kansas School of Medicine–Wichita, [4]Stanford University, [5]University of Louisville

Background: Alcohol-associated hepatitis (AH) is associated with substantial morbidity and mortality. Sarcopenia and malnutrition reflect diminished physiologic reserve and impaired ability to recover from acute illness, yet their impact on outcomes in hospitalized AH is not well described. We aimed to evaluate the association between sarcopenia/malnutrition and hepatic decompensation, as well as mortality among patients hospitalized with AH. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network to identify adults hospitalized with AH between 2010 and 2025. Adult patients hospitalized with AH and coexisting sarcopenia/malnutrition were identified using validated ICD diagnosis codes. Patients with AH and sarcopenia and/or malnutrition were propensity matched (1:1) with those without sarcopenia/malnutrition. Variables for matching were demographics, comorbidities, and laboratory values. The primary outcome was all-cause mortality. Secondary outcomes included new onset hepatic decompensation [ascites, hepatic encephalopathy (HE), variceal hemorrhage (VH)]. Hazard ratios (HR) with 95% confidence intervals (CI) were calculated using Cox regression models to measure outcomes at 90 days post-admission. **Results:** Among 27,649 patients hospitalized with AH, 6,099 (22%) had sarcopenia/malnutrition. After 1:1 propensity score matching, 5,987 patients remained in each cohort. Matched cohorts were well balanced with respect to age (48.0 ± 11.6 vs 48.3 ± 11.4 years), sex (female: 37.6% vs 38.4%), race, chronic kidney disease, INR, and platelet count (**Table 1**). Sarcopenia/malnutrition was associated with increased risk of hepatic decompensation and adverse outcomes. Compared with patients without sarcopenia/malnutrition, affected patients had significantly had higher risk of ascites (28.9% vs 21.0%; HR 1.436, 95%CI 1.287–1.602; $p < 0.001$), HE (19.7% vs 8.9%; HR 1.333, 95%CI 1.299–1.579; $p < 0.001$), VH (4.2% vs 3.1%; HR 1.370, 95%CI 1.119–1.678; $p = 0.002$), and all-cause mortality (26.9% vs 20.0%; HR 1.349, 95%CI 1.251–1.453; $p = 0.001$) (**Table 2**). **Conclusion:** Sarcopenia/malnutrition is associated with increased hepatic

3103 | PEPTIDYL-PROLYL CIS-TRANS ISOMERASE NIMA-INTERACTING 1 (PIN1) REGULATES C/EBPβ-MEDIATED TRANSCRIPTIONAL RESPONSES IN ALCOHOLIC LIVER DISEASE

Manisha Dagar[1] *Manisha Dagar*[1] *Jyoti Chhimwal*[1] *Jiaohong Wang*[1] *Maria Lauda Tomasi*[1] *Shelly Lu*[1], [1]*Cedars-Sinai Medical Center*

Background: Alcohol-associated liver disease (ALD) from excessive alcohol intake can lead to steatosis, inflammation, cirrhosis, and hepatocellular carcinoma. PIN1 binds to target proteins phosphorylated at consensus binding motifs (p-S/T-P) that can affect the proteins' stability, subcellular targeting, interactome, and activity. We reported nuclear PIN1 content is higher in ALD, and this contributed to induction of FOXM1. Here, we analyzed PIN1 nuclear interactome in ALD to better understand how an increase in nuclear PIN1 affects ALD. **Methods:** We used the NIAAA protocol for murine ALD model and human hepatocyte spheroids treated with 100mM ethanol (EtOH) for 24 hours to confirm human relevance. Total liver protein lysates from NIAAA-fed and pair-fed control mice (n = 3 per group) were subjected to co-immunoprecipitation (co-IP) with an anti-PIN1 antibody, followed by mass spectrometry to identify PIN1-interacting proteins. Proteins annotated as nuclear were selected for Network analysis using Cytoscape with ReactomeFIViz. *In silico* analysis using NetPhos and ClusPro identified potential PIN1-binding motifs. RT-qPCR and western blotting measured gene and protein expression, respectively. Functional regulation of C/EBPβ was measured using a stable C/EBPβ GFP reporter cell line via lentiviral transduction of AML12 mouse hepatocytes, with or without PIN1 silencing by siRNA and 100mM EtOH treatment for 24 hours. **Results:** Mass spectrometry identified 84 PIN1-interacting nuclear proteins enriched in NIAAA livers (fold change > 2), with C/EBPβ being one of the top 10 proteins. Network analysis suggested shared clustering of C/EBPβ and PIN1 in a transcriptional regulation module, and in silico docking predicted PIN1 binding to phosphorylated serine/threonine-proline motifs on C/EBPβ (S231/P232, T235/P236, S237/P238), which are known to be phosphorylated by MAPKs and GSK3β. C/EBPβ protein expression was increased 2.6-fold ($p = 0.04$) in NIAAA livers, and in primary human hepatocyte spheroids treated with EtOH (1.6-fold increase). RNA expression of C/EBPβ target genes showed significant elevation in NIAAA livers: *Il6* (2.93-fold, $p = 0.002$), *Il1β* (2.85-fold, $p = 0.04$), and *Pparg* (6.14-fold, $p = 0.02$). C/EBPβ transcriptional activity as measured by the GFP reporter was significantly higher following EtOH treatment, which was mitigated by prior PIN1 silencing (49.8 versus 23.3 RFU, $p = 0.002$), suggesting involvement of PIN1 in the regulation of C/EBPβ transcriptional activity. **Conclusion:** Our findings suggest that in ALD there is increased nuclear PIN1 interaction with C/EBPβ and this activates C/EBPβ's transcriptional activity. C/EBPβ has been implicated in dysregulated inflammatory and fibrotic responses. Our findings suggest a novel role of PIN1 in regulating C/EBPβ transcriptional responses in ALD, which warrants further investigation as a potential therapeutic target.

3104 | CHANGING MORTALITY PATTERNS IN ALCOHOL-ASSOCIATED LIVER DISEASE WITH CONCURRENT ISCHEMIC HEART DISEASE IN THE UNITED STATES: CDC WONDER ANALYSIS FROM 1999 TO 2024

Neha Singh[1] Manish KC[1], [1]North Alabama Medical Center

Background: Alcohol associated liver disease(ALD) and Ischemic Heart disease(IHD) are major causes of morbidity and mortality in the United States. Long-term alcohol use and its effect on hypertension, cardiomyopathy, and atherosclerosis can affect both liver and cardiac conditions at the same time. With a change in population and changing drinking patterns, the burden of concurrent IHD and ALD needs to be explored. This study focuses on trends and demographic disparities in age-adjusted mortality (AAMR) for adults (25-85+) with comorbid ALD and IHD from 1999 to 2024. **Methods:** We performed a retrospective national level mortality analysis with the help of CDC WONDER cause of Death Database from 1999-2024 among patients aged 25-85 and above for Alcoholic liver disease (ICD-10 code: K70) and Cardiovascular disease (ICD code: I20-I25). Data were stratified by Race (Non-Hispanic [NH] American Indian or Alaska Native, NH Asian or Pacific Islander, NH Black or African American, NH White, Hispanic or Latino), sex and age groups. We calculated age-adjusted mortality rates per 100,000 population based on the 2000 US standard population. Temporal trends were assessed using Joinpoint regression to calculate annual percent change (APC), with statistical significance defined by $p < 0.05$. **Results:** From 1999 to 2024, total 37496 deaths were observed and ALD associated IHD mortality showed a statistically significant increase with a steeper recent slope. AAMRs for males exhibited a biphasic statistically significant increase (APC = 5.2%, $p < 0.05$) with upward shifts noted after 2017. Females showed a similar pattern in mortality, but acceleration was observed earlier than males in 2015 and persisted through 2021 (APC = 8.8%, $p < 0.05$) before reaching stabilization. According to racial analysis, AAMRs for NH White population was consistently increasing with statistical significance (APC = 4.9%, $p < 0.05$) while a significant inflection point was observed for the NH Black or African American population in 2012 (APC = 6.2%, $p < 0.05$) after which mortality rates increased significantly. Among Hispanic or Latino populations, mortality rate increased significantly after 2010 (APC = 5.8%, $p < 0.05$). These findings suggest that the coexistence of ALD and IHD represents a widespread and worsening public healthconcern across all demographic groups, without significant long-term improvement throughout the study period. **Conclusion:** Mortality associated with coexisting ALD and IHD has significantly increased since 1999, becoming more prominent over the last decade. The lack of any clear stabilization or decline in mortality trends, especially in recent years, suggests that current screening and management approaches are still falling short of addressing the true burden of these coexisting diseases in the population.

3105 | REPRODUCTIVE HEALTH CARE UTILIZATION AMONG REPRODUCTIVE-AGED WOMEN WITH ALCOHOL-ASSOCIATED VERSUS NON–ALCOHOL-ASSOCIATED CIRRHOSIS

Katherine Cooper[1] Ami Patel[2] Rachael Mahle[3] Jordan Tralins[4] Jay Luther[3] Deepika Devuni[5], [1]Massachusetts General Hospital, Harvard Medical School, [2]Univeristy of Massachusetts, [3]Massachusetts General Hospital, [4]Harvard Medical School, [5]UMass Chan Medical School

Background: The burden of cirrhosis among reproductive-aged women is rising, driven in part by alcohol-associated liver disease (ALD). Although reproductive counseling and preventive care are essential in this population, little is known about whether reproductive health care utilization differs between women with ALD and non–alcohol-associated liver disease. **Methods:** We identified females diagnosed with cirrhosis between the ages of 18-45 from 2020–2023 with ≥ 1 healthcare

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

visit in the year before and after diagnosis using TriNetX. Patients were categorized by etiology: ALD or non-ALD. The index date was the first qualifying cirrhosis/decompensation event. Outcomes were assessed from 1 day through 1095 days after index. Propensity score matching was performed on age, race, ethnicity, menopausal/perimenopausal disorders, and hysterectomy history The primary outcomes were routine women's health related care, including cervical cancer screening, mammography, sexually transmitted infection/HIV screening, and well-woman examination/ referral to a gynecologist. Secondary outcomes included pregnancy, emergency contraception use, and sterilization procedures. Comparisons were made using logistic regression within the matched cohorts. **Results:** A total of 2,978 matched patient pairs, mean age 36 years, were analyzed. Compared with women with non-ALD cirrhosis, women with ALD had lower documented pregnancy (6.0% vs 7.6%; OR 0.78, 95% CI 0.64-0.95; p = 0.016), mammography (12.5% vs 14.9%; OR 0.81, 95% CI 0.70-0.94; p = 0.005), and well-woman/OB-GYN care (10.9% vs 12.8%; OR 0.84, 95% CI 0.72-0.98; p = 0.028). Cervical cancer screening was higher among women with ALD (18.6% vs 15.6%; OR 1.24, 95% CI 1.08–1.42; p = 0.002) as was screening for sexually transmitted infections (STI) (8.2% vs 6.9%; OR 1.21, 95% CI 1.00–1.47; p = 0.05). Emergency contraception (4.2% vs 4.9%; OR 0.86, 95% CI 0.67-1.09; p = 0.214), and sterilization (3.3% vs 3.9%; OR 0.84, 95% CI 0.64-1.10; p = 0.210) did not differ significantly. Interestingly, liver/abdominal cross-sectional imaging was more common in ALD (30.7% vs 26.2%; OR 1.24, 95% CI 1.11-1.39; p < 0.001). **Conclusion:** In a large multi-institutional cohort of reproductive-aged women with cirrhosis, women with ALD demonstrated a selective preventive care pattern. Higher rates of cervical cancer and STI screening may reflect greater attention to infection-related screening in ALD, while routine women's preventive health services remain comparatively underused. These findings highlight an opportunity to broaden ALD care beyond liver monitoring and targeted infectious-risk screening to include routine gynecologic, breast cancer screening, and contraceptive care.

Outcome	ALD, N (%)	Non-ALD, N (%)	OR (95% CI)	p-value
Well-woman/OB-GYN care	326 (10.9)	381 (12.8)	0.84 (0.72–0.98)	0.028
Cervical cancer screening	553 (18.6)	464 (15.6)	1.24 (1.08–1.42)	0.002
Mammography	371 (12.5)	445 (14.9)	0.81 (0.70–0.94)	0.005
STI/HIV screening	245 (8.2)	205 (6.9)	1.21 (1.00–1.47)	0.05
Pregnancy	179 (6.0)	226 (7.6)	0.78 (0.64–0.95)	0.016
IUD or implant	130 (4.4)	141 (4.7)	0.92 (0.72–1.17)	0.494
Emergency contraception	126 (4.2)	146 (4.9)	0.86 (0.67–1.09)	0.214
Sterilization	98 (3.3)	116 (3.9)	0.84 (0.64–1.10)	0.210
Liver imaging	913 (30.7)	781 (26.2)	1.24 (1.11–1.39)	<0.001

3106 | COMPARING HEPATIC OUTCOMES FOLLOWING TIPS IN ALCOHOL-ASSOCIATED VERSUS NON-ALCOHOL-ASSOCIATED CIRRHOSIS: A RETROSPECTIVE COHORT STUDY

Laith Alomari[1] Zaid Al-Fakhouri[2] Daniel Simadibrata[2] Ghideon Ezaz[3], [1]Jefferson Einstein Philadelphia Hospital, Thomas Jefferson University, Philadelphia, PA, [2]The MetroHealth System, Case Western Reserve University, Cleveland, OH, [3]Jefferson Einstein Philadelphia Hospital, Philadelphia, PA

Background: Given the divergent natural histories of cirrhosis etiologies and the potential reversibility of alcohol-associated liver injury with abstinence, post-transjugular intrahepatic portosystemic shunt (TIPS) outcomes may differ by underlying etiology, yet comparative data remain limited. We compared one-year post-TIPS hepatic outcomes between patients with alcohol-associated cirrhosis (ALD-cirrhosis) and non-alcohol-associated cirrhosis, with prespecified subgroup analyses against metabolic dysfunction-associated steatotic liver disease (MASLD)-related and viral hepatitis-related cirrhosis. **Methods:** Using the TriNetX US Collaborative Network, we identified adults with cirrhosis who underwent TIPS placement between 2015 and 2025. Cirrhosis etiology was defined using ICD-10 diagnostic codes. The index date was the date of TIPS placement. Patients with ALD-cirrhosis were compared with patients with non-alcohol-associated cirrhosis using 1:1 propensity score matching on demographics, prior hepatic decompensation, and MELD components (bilirubin, INR, and creatinine), with parallel matched comparisons against MASLD- and viral hepatitis-related subgroups. The primary endpoint was a one-year composite of hepatic decompensation, comprising ascites, spontaneous bacterial peritonitis (SBP), hepatorenal syndrome, variceal hemorrhage, or hepatic encephalopathy. Hazard ratios (HR) with 95% confidence intervals (CI) were estimated using Cox proportional hazards models, with patients censored at loss to follow-up or one year. **Results:** In the primary matched analysis (n = 2,148 pairs), ALD-cirrhosis was associated with a lower one-year risk of composite hepatic decompensation versus non-alcohol-associated cirrhosis (58.2% vs. 65.2%; HR 0.85, 95% CI 0.78–0.91; p < 0.001), driven by lower risks of ascites (43.8% vs. 55.7%; HR 0.72, 95% CI 0.66–0.79), SBP (HR 0.72, 95% CI 0.56–0.93), and variceal hemorrhage (HR 0.77, 95% CI 0.64–0.93; all p < 0.01). Conversely, ALD-cirrhosis was associated with a higher risk of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hepatic encephalopathy (HR 1.23, 95% CI 1.08–1.39; p = 0.002). In prespecified subgroup analyses, ALD-cirrhosis remained associated with lower one-year hepatic decompensation versus MASLD-related cirrhosis (HR 0.87, 95% CI 0.78–0.96; p = 0.006) and viral hepatitis-related cirrhosis (HR 0.84, 95% CI 0.73–0.96; p = 0.008). **Conclusion:** In this large multicenter cohort, ALD-cirrhosis was associated with lower one-year rates of post-TIPS hepatic decompensation but a higher risk of hepatic encephalopathy compared with non-alcohol-associated cirrhosis, including MASLD- and viral hepatitis-related subgroups. These findings suggest cirrhosis etiology may modify post-TIPS outcomes and may reflect, in part, the potential reversibility of alcohol-associated liver injury with abstinence, warranting prospective investigation with granular data on post-TIPS alcohol use.

3107 | SOCIODEMOGRAPHIC AND PSYCHOSOCIAL PREDICTORS OF RECOMPENSATION IN PATIENTS WITH DECOMPENSATED STEATOTIC LIVER DISEASE REFERRED FOR LIVER TRANSPLANT EVALUATION

Mohamad Ali Ibrahim[1] Nagham Ramadan[1] Allan Zhang[1] Hannah Wani[1] That Hein[1] Fareen Dhuka[1] Prachi Kaur[1] Mazen Elsheikh[1] Sherry Fares[1] Karim Adhem[1] Humberto Nieves-Jiménez[1] Youseph Karouni[1] Ximena Ramirez Morales[1] Megha Bhongade[1] Prasun Jalal[1], [1]Baylor College of Medicine

Background: Recompensation is increasingly recognized as a clinically meaningful outcome in patients with decompensated steatotic liver disease (SLD). However, the impact of sociodemographic and psychosocial factors on recompensation after liver transplant (LT) evaluation remains poorly defined. We aimed to identify predictors of recompensation among patients with decompensated SLD referred for LT evaluation. **Methods:** We conducted a retrospective cohort study of 175 patients with decompensated SLD, including alcohol-associated liver disease (ALD) and MetALD, referred for LT evaluation at a single U.S. transplant center. Sociodemographic predictors included age, sex, race, ethnicity, education, insurance, income, social support, and Area Deprivation Index (ADI). Psychosocial and substance-use predictors included psychiatric comorbidity, tobacco use, history of drug use, active alcohol use, and prior alcohol use disorder treatment. Recompensation was defined according to the BAVENO VII expanded definition (Tonon et al.). Cox regression analysis was performed to assess the predictors of recompensation. **Results:** Among 175 patients, the median age was 51 years, 61.7% were male, 87.4% were White, 31.0% were Hispanic, the median ADI was 57, and the median MELD 3.0 was 28. Overall, 23/171 patients (13.5%) achieved recompensation, 72/175 (41.1%) underwent LT, and 69/174 (39.7%) died. On univariable analysis, higher ADI was associated with lower recompensation (HR 0.979, p = 0.021), White race was associated with lower recompensation hazard (HR 0.301, p = 0.012), and some college or higher education was associated with higher recompensation hazard (HR 2.823, p = 0.029). On multivariable analysis, lower MELD 3.0 (aHR 0.891, p = 0.002), non-white race (aHR 0.085, p < 0.001), and lower ADI (aHR 0.975, p = 0.013) were independently associated with increased recompensation hazard. **Conclusion:** In patients with decompensated SLD referred for LT evaluation, lower deprivation index, lower MELD 3.0, and non-white race were associated with higher rates of recompensation. These findings suggest that both disease severity and social determinants of health may significantly influence recovery trajectories following LT evaluation and may help identify patients with a greater likelihood of recompensation.

3108 | TRANSCRIPTOMIC FINGERPRINTING REVEALS DISTINCT IMMUNE, SECRETORY, AND METABOLIC SIGNATURES IN ALCOHOL-ASSOCIATED HEPATITIS

Brandon Peiffer[1] Zhe Deng[1] Ali Reza Ahmadi[2] Yongchun Wang[1] Yukun Guan[3] Heng Zhu[1] Russell Wesson[1] Jiang Qian[1] Andrew Cameron[1] Bin Gao[3] Zhaoli Sun[1], [1]The Johns Hopkins University School of Medicine, [2]MedRegen LLC, [3]NIH/NIAAA

Background: Alcohol-associated hepatitis (AH) is a severe inflammatory liver disease characterized by immune dysregulation and impaired hepatic function. However, the molecular pathways distinguishing AH from other chronic liver diseases remain incompletely understood. We performed comprehensive transcriptomic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

profiling to identify disease-specific cellular, inflammatory, and metabolic signatures associated with AH. **Methods:** Bulk RNA sequencing data from liver tissues of patients with AH and comparator liver diseases, including alcohol-associated cirrhosis (AC), metabolic dysfunction-associated steatohepatitis (MASH), hepatitis B virus (HBV), hepatitis C virus (HCV), primary biliary cholangitis (PBC), and autoimmune hepatitis (AIH), were analyzed using differential gene expression, cellular deconvolution, pathway enrichment, and secretome-focused analyses. Chemokine/cytokine signaling pathways, receptor expression, growth factor networks, and liver-derived secreted proteins were systematically evaluated. **Results:** Transcriptomic fingerprinting identified molecular features that distinguished AH from other liver diseases. Cellular deconvolution demonstrated increased proportions of adipocytes, common lymphoid precursors, pericytes, and eosinophils in AH livers, whereas plasma cells and megakaryocyte–erythroid precursors were reduced. Chemokine and cytokine analyses revealed upregulation of CCL11, CCL28, CXCL6, IL33, FLT1, and multiple TNF superfamily members. Several immune-related receptors, including CXCR4, CXCR7, CCR3, IL6R, IL10RB, IFNAR2, and IFNGR2, were also increased, indicating enhanced inflammatory signaling in AH. Secretome analysis demonstrated reductions in proteins involved in hepatic synthetic function, including ALB, HPX, APOB, and APOF, as well as coagulation-related proteins (SERPINC1, FGA, FGG, PLG, F2, F7, F11, and F12) and complement components (C2, C6, C8A, C8B, and C9). Growth factor profiling showed increased TGFB1, BMP1, FGF7, FGF12, and FGF13, whereas HDGF and BMP10 were decreased. Pathway enrichment analysis revealed activation of cytoskeletal remodeling, extracellular matrix interactions, infection-related pathways, and immune cell functional programs, while pathways associated with peroxisome activity, metabolic processes, and responses to chemically induced DNA adducts were suppressed. **Conclusion:** Compared with other liver diseases, AH exhibits a distinct transcriptomic signature characterized by altered cellular composition, enhanced inflammatory and chemokine signaling, impaired hepatic synthetic and complement functions, and profound metabolic dysregulation. These findings provide new insights into the molecular pathogenesis of AH and identify potential biomarkers and therapeutic targets for disease progression and treatment.

3109 | PROTEOSTASIS CHAPERONES AND PERIPHERAL IMMUNE CELL ALTERATIONS IN PATIENTS WITH ALCOHOL ABUSE AND ALCOHOL-ASSOCIATED HEPATITIS

Abhishek Mandal[1] Jeevitha Thanikasalam[1] Alessandro Colletta[1] Deepika Devuni[1] Rachel Gerstein[1] Pranoti Mandrekar[1], [1]University of Massachusetts Chan Medical School, Worcester, MA, USA

Background: Chronic alcohol consumption induces systemic physiological stress and compromises host immune function. Elucidating immune cell frequencies, and stress mediated proteostasis chaperones in patients with alcohol-associated hepatitis (AH) and alcohol abuse (AA) without any liver disease is critical to unraveling mechanisms related to immune function and liver disease. **Methods:** Peripheral blood mononuclear cells (PBMC) were isolated from healthy volunteers (n = 17), AA (n = 7) and AH (n = 21) patients. Immunophenotyping was performed via flow cytometry. The expression of proteostasis chaperones and cytokines was analyzed by RT-PCR. PBMCs were treated in-vitro with Hsp90 inhibitor (17-DMAG) and immune cell frequencies and pro-inflammatory cytokines were measured. **Results:** Proteostasis chaperones Hsp90AA1, Hsp90AB1, Hsp90B1/GP96, Hsp70, BiP/GRP78, but not HSP90L/TRAP1, are induced in PBMC of AH but not AA patients compared to healthy. Immunophenotyping exhibits increased intermediate monocytes ($p < 0.05$) and decreased non-classical monocytes ($p < 0.05$) without any change in classical monocytes in AH patients but not in AA patients compared to healthy. CD206+ intermediate monocytes are increased in AH patients compared to healthy or AA patients, whereas antigen-presentation markers, HLA-DR and CD86 on non-classical monocytes are reduced in AH compared to healthy and AA patients. Frequency of CCR2+ classical monocytes and CCR5+ intermediate monocytes remain unchanged between healthy, AH and AA patients. Interestingly, in-vitro 17-DMAG treatment reduced the intermediate monocytes ($p < 0.05$) in AH, suggesting decreased inflammatory phenotype. CD3+ CD4+ T cells ($p < 0.001$) and CD4+CD45RO+ memory T cells ($p < 0.05$) were increased whereas CD8+T cells ($p < 0.005$) and Treg cells ($p < 0.05$) decreased in AA and AH patients compared to healthy. However, no significant change in the frequency of T cells was observed after treatment with 17-DMAG. Notably, percentage of intermediate monocytes positively correlated with CD3+CD4+ T cells in AH patients. While baseline mRNA expression of pro-inflammatory TNFα, CCL2, IL-1β and IL-6 was not altered in PBMCs of AA and AH patients, LPS induced IL-1β was higher whereas LPS induced TNFα was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

lower in AH PBMC compared to healthy controls. Further, 17-DMAG significantly reduced ($p < 0.05$) LPS-induced TNFα and IL-1β in AH patients compared to healthy controls. **Conclusion:** Our data show that stress mediated proteostasis chaperones are increased in AH patients but not AA. Further, increased intermediate monocytes and CD4+T cells indicate pro-inflammatory responses in AH whereas reduced CD86 and HLA-DR in non-classical monocytes suggest immunosuppressive phenotypes. Finally, inhibition of Hsp90 in-vitro reduced intermediate monocytes and pro-inflammatory cytokines in AH, suggesting a role for Hsp90 in pro-inflammatory responses in AH.

3110 | BUILDING A PATIENT-INFORMED FRAMEWORK FOR ALD THERAPEUTIC DEVELOPMENT THROUGH THE EXTERNALLY LED PATIENT-FOCUSED DRUG DEVELOPMENT (EL-PFDD) PROCESS

Neeraj Mistry[1] Jenn Jones[2] Lindsey Moore[2], [1]Fatty Liver Foundation, [2]Sober Livers

Background: Despite growing research interest in ALD, there remains a significant unmet need in patient-centered outcomes research and approved therapies, especially as recent therapeutic advances across the Steatotic Liver Disease (SLD) spectrum create a timely opportunity to ensure ALD patient perspectives are included in the evolving drug development landscape. The EL-PFDD is a specialized forum where patient advocacy organizations and disease communities engage directly with the US FDA, pharmaceutical developers and researchers, to share lived experiences, challenges, and treatment priorities. The EL-PFDD process is intended to help the FDA and other stakeholders better understand patient experiences, treatment priorities, and risk tolerance relevant to drug development. **Methods:** Under the leadership and coordination of Sober Livers, an initiative housed at the Steatotic Liver Foundation, an EL-PFDD meeting letter of intent (LOI) was submitted and accepted in 2025, for hosting late 2026/early 2027. The preparation in advance of the EL-PFDD forum is a representative and participatory process to ensure that patient perspectives on ALD are represented equitably, commensurate with the burden of disease and etiology, and reflect the heterogeneous social conditions of people living with ALD. The process will highlight qualitative issues surrounding the patient experience, which will then be assessed and stratified by the Expert Steering Committee, for further qualitative research on patient perspectives and priorities. **Results:** The preparation for the EL-PFDD process has commenced, and various tools are being employed to engage patients, including: a discussion framework to capture their day-to-day experiences, current and future concerns, and wishes; multi-media platforms such as blogs, videos, and surveys; leveraging various patient support and advocacy networks; and a lean planning committee and multistakeholder steering committee. The intended outputs of these processes are: 1. A participatory and representative voice of the ALD patient in the drug development process at the EL-PFDD forum 2. A concise and workable document capturing patient perspectives for consideration in the FDA approval process and to inform the bio-life-science research and development sector. **Conclusion:** As therapeutic innovation in SLD accelerates, there is a growing need to better understand ALD-specific patient priorities, treatment goals, and acceptable benefit-risk tradeoffs to support development of safe, effective, and patient-centered therapies. ALD stakeholders have a timely and important opportunity to capture patient priorities and concerns for drug development in a clearly defined space. Given the overlap in lifestyle risks and liver pathology, it is hoped that patient perspectives on research into and approval of ALD therapies can inform and accelerate access to safe and effective treatment options.

3111 | MECHANISM STUDY ON THE ROLE OF GUT HCBP6 IN ALCOHOL-RELATED HEPATOCELLULAR CARCINOMA PROGRESSION VIA THE GUT-LIVER AXIS

Xuanxuan Niu[1] Huichun Xing[1] Xiaoxue Yuan[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: The occurrence and development of alcohol related hepatocellular carcinoma (AR-HCC) are closely associated with gut-liver axis dysfunction and gut microbiota dysbiosis. However, the role and regulatory mechanism of gut HCBP6 in this process are not yet clear. **Methods:** Six-week-old SPF mice were divided into CCl4 and ETOH+CCl4 groups to establish an AR-HCC model. MRI, HE staining, TEM, FITC-dextran assays, Alcian blue staining, and Western blot were used to evaluate liver injury, intestinal barrier function, and HCBP6/Occludin expression. Fecal metagenomic sequencing and AKK gavage were

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

further performed to assess microbiota-mediated effects on tumor progression. **Results:** MRI results demonstrated obvious tumor-like nodules in the livers of mice in the ETOH+CCl4 group. HE staining revealed marked dysplasia and tumor-like lesions in liver tissues, accompanied by destruction of intestinal villi, disorganized villus arrangement, and inflammatory cell infiltration.TEM analysis showed that intestinal microvilli in the CCl4 group were relatively intact with clear tight junction structures, whereas the ETOH+CCl4 group exhibited disorganized microvilli and widened intercellular junctions. FITC-dextran assays demonstrated significantly increased intestinal permeability in the ETOH+CCl4 group. Alcian blue staining further revealed damage to the intestinal mucus layer.Western blot analysis showed that the expression levels of HCBP6 and Occludin were significantly downregulated in intestinal tissues from the ETOH+CCl4 group.Fecal metagenomic sequencing demonstrated a significant reduction in the abundance of Akkermansia muciniphila in the ETOH+CCl4 group. Following AKK intervention, liver tumor burden was reduced, intestinal inflammation was alleviated, and villus architecture was partially restored. TEM analysis demonstrated improved microvillus integrity, while FITC-dextran assays indicated reduced intestinal permeability. Metagenomic analysis further showed that AKK treatment remodeled the gut microbiota composition. Meanwhile, the expression levels of HCBP6 and Occludin were upregulated in the ETOH+AKK group compared with the ETOH+PBS group. **Conclusion:** HCBP6 may be involved in the regulation of intestinal barrier function during alcohol-related liver cancer, and together with changes in gut microbiota, participate in disease progression through the gut liver axis. AKK intervention can partially improve intestinal barrier damage and reduce tumor burden, suggesting that intestinal HCBP6 and related microbiota may become potential targets for alcohol-related liver cancer intervention.

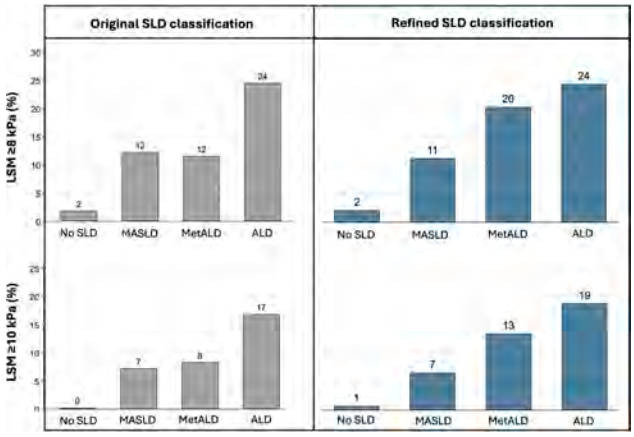
3112 | A REFINED SLD CLASSIFICATION IMPROVES FIBROSIS RISK STRATIFICATION IN METALD



Camilla Dalby Hansen[1] Charlotte Mary Bastida Gjøl[1] Helle Lindholm Schnefeld[1] Katrine Tholstrup Bech[1] Ellen Lyngbeck Jensen[1] Nikolaj Torp[1] Stine Johansen[1] Peter Andersen[1] Ida Falk Villesen[1] Katrine Thorhauge[1] Johanne Hansen[2] Mads Israelsen[1] Aleksander Krag[3], [1]Centre for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, [2]Odense University Hospital, [3]University of Southern Denmark

Background: Current evidence suggests that the Steatotic Liver Disease (SLD) subgroup metabolic- and alcohol related steatotic liver disease (MetALD) do not provide additional risk stratification for liver fibrosis beyond MASLD, as fibrosis prevalence appears similar between the two groups in several population-based cohorts. We therefore evaluated a refined exposure-based SLD classification incorporating both current and historical high-risk alcohol consumption to assess its association with liver fibrosis across SLD. **Methods:** Cross-sectional analysis from a large community-based cohort with metabolic and/or alcohol-related risk factors. Hepatic fibrosis was assessed using transient elastography. Participants were classified according to the current SLD nomenclature and according to a refined exposure-based classification incorporating current and historical high-risk alcohol exposure. Historical high-risk alcohol exposure was defined as alcohol consumption >50 g/day in women or >60 g/day in men for more than five years. Beyond the prevalence of hepatic steatosis, ALD was refined as having both a current and a historical high-risk alcohol exposure, MetALD as either current or a historical high-risk alcohol exposure in the presence of cardiometabolic risk factors (CMR), and MASLD as the absence of both current and historical high-risk alcohol exposure in the presence of CMR. **Results:** We included 3,123 participants, age of 56,5 years (SD, 9.6), 50.1% males, BMI of 31 kg/m^2 (IQR, 27-35). The refined classification of SLD resulted in a marginal reduction in the overall prevalence of diagnosed SLD (n = 2,197 (70.3%) vs. n = 2,181 (69.8%)), a higher prevalence of MASLD (n = 1,603 (51.3%) vs. n = 1,766 (56.6%)), and a corresponding lower prevalence of both MetALD (n = 398 (12.7%) vs. n = 306 (9.8%)) and ALD (n = 196 (6.3%) vs. n = 109 (3.5%)). Interestingly, the refined classification substantially altered the distribution of fibrosis across SLD subgroups, resulting in a markedly higher fibrosis burden within the MetALD phenotype (LSM ≥8 kPa: 11.6% to 20.3%), whereas the fibrosis burden remained largely unchanged in both MASLD (LSM ≥8 kPa: 12.2% to 11.3%) and ALD (LSM ≥8 kPa: 24.5% vs. 24.3%). The observed redistribution of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

fibrosis burden remained consistent when applying LSM ≥10 kPa. In a multivariable model adjusted for CMR, age and sex the reclassification resulted in adjusted odds of significant fibrosis in the MetALD subgroup from OR 5.6 ((95%CI; 3.13-10.18), p < 0.001) to OR 8.8 (95%CI; 5.1-15.1, p < 0.001) while fibrosis risk estimates for MASLD and ALD changed only modestly. **Conclusion:** Incorporating historical alcohol consumption appeared to enrich the MetALD phenotype for individuals with clinically relevant fibrosis risk, suggesting that this might better capture the cumulative hepatic injury than the current classification.

3113 | UBC9 TRANSCRIPTIONAL REGULATION REWIRES NF-κB SIGNALING IN ALCOHOL-ASSOCIATED LIVER DISEASE

Swati Chandla[1] Youngyi Lim[2] Manisha Dagar[2] Joshua Martinez[2] Komal Ramani[3] Maria Lauda Tomasi[2],
[1]Cedars Sinai Medical Center, [2]Cedars Sinai Medical Center, Los Angeles, [3]Cedars-Sinai Medical Center

Background: Alcohol abuse promotes alcoholic-associated liver disease (ALD) by increasing gut-derived endotoxin translocation, which activates Kupffer cells (KCs) and NF-κB–dependent inflammatory signaling. UBC9, the sole E2 enzyme for SUMOylation, regulates transcriptional responses by modulating nuclear factor activity. We previously showed that alcohol induces SRC-mediated phosphorylation of UBC9 at Y68 in KCs, thereby promoting hepatocyte lipogenic gene expression. Here, we investigated how UBC9 phosphorylation remodels its interactome and inflammatory signaling in ALD. **Methods:** RAW 264.7 and THP-1 cells were used for in vitro studies, with validation by CRISPR/Cas9-CD68–mediated UBC9 Y68 editing in the NIAAA mouse model. UBC9-interacting proteins were identified in KCs lysates from ethanol-fed and pair-fed mice by anti-UBC9 antibody via co-immunoprecipitation (co-IP) and mass spectrometry (MS), followed by Omics Playground network analysis. Additional assays included RT-qPCR, UBC9 promoter reporter, chromatin immunoprecipitation (ChIP), CHX chase, and proteasome inhibition. **Results:** LPS stimulation of RAW 264.7 and THP-1 cells reduced UBC9 promoter activity and mRNA expression, resulting in lower total UBC9 protein levels. Despite this reduction, LPS induced phosphorylation of the remaining UBC9 pool, with phosphorylated UBC9 accounting for approximately 95% of detectable UBC9 protein. ChIP analysis revealed LPS-mediated binding of HIF-1 to the UBC9 promoter, which is known to be a negative regulator of UBC9 when hypermethylated. CHX chase assays showed that UBC9 has a half-life of approximately 9 hours without enriching phosphorylated UBC9. This indicates that phosphorylation is not a simple passive consequence of UBC9 loss but rather requires active, translation-dependent processes. We also found that MG132 prevented LPS-induced reduction of UBC9, indicating proteasome-dependent degradation. MS interactome analysis revealed that phosphorylated UBC9 preferentially associated with NF-κB family members, including p65, p52, and p50, as validated by co-IP. Mechanistically, we found that NF-κB family members were SUMOylated in a paralog-specific manner: p65 and p52 were modified by SUMO1, whereas p50 was modified by SUMO2/3. These findings identify NF-κB subunits as plausible SUMO-sensitive transcriptional mediators linking phosphorylated UBC9 to cytokine secretion in activated macrophages. **Conclusion:** These findings identify UBC9 as a regulatory switch in ALD, whereby reduced UBC9 mRNA level and SRC-mediated Y68 phosphorylation reprogram SUMOylation-related signaling toward NF-κB activation in KCs. Targeting upstream pathways that link UBC9 mRNA loss to UBC9 phosphorylation may provide novel therapeutic strategies for ALD.

3114 | ALCOHOL EXPOSURE IDENTIFIES INDIVIDUALS AT HIGH-RISK OF INCREASED LIVER STIFFNESS MISSED BY FIB-4 IN ALCOHOL USE DISORDER

Omar Albhaisi[1] Monica Melmer[1] Anna Peyton[1] Hannah Kissel-Smith[1] Brandon Wills[1] Matthew Way[1] Megan Lemay[1] Andy Pinson[1] Crystal Watts[1] Chareece Williams[1] Tara Kilman[1] Brian Singh[1] James White[1] Gerry Moeller[1] Juan Pablo Arab[1], [1]Virginia Commonwealth University

Background: Background & Aims: FIB-4 is commonly used to screen individuals for liver fibrosis, but its role as a gatekeeper for vibration-controlled transient elastography (VCTE) in alcohol use disorder (AUD) is uncertain. We evaluated whether a high-FIB-4-only strategy would miss clinically meaningful increased liver stiffness in an integrated AUD clinic cohort. **Methods:** We analyzed patients with AUD who underwent VCTE with paired FIB-4 at the MOTIVATE Clinic, an integrated addiction program at Virginia Commonwealth University. LSM was categorized as <8 (low-risk/rule-out range), 8–11 kPa (indeterminate/elevated stiffness), and ≥ 12 kPa (high-risk stiffness suggestive of advanced fibrosis) per AASLD 2025 NIT guidelines. FIB-4 was grouped as <1.30 (low), 1.30–2.67 (intermediate), and ≥ 2.67 (high). Patients with FIB-4 <2.67 but LSM ≥ 12 kPa were classified as potentially missed by high-FIB-4-only gating. Drinking pattern, PEth, liver biochemistries, and platelets were compared between missed and non-missed patients using Mann-Whitney U and Fisher's exact tests. **Results:** We included 94 patients with AUD and paired VCTE/FIB-4 data; mean age was 50 years; 60% were male; 72% met DSM-5 criteria for severe AUD. Median LSM increased across FIB-4 categories: 5.9 kPa for FIB-4 <1.30, 6.9 kPa for FIB-4 1.30–2.67, and 32.7 kPa for FIB-4 ≥ 2.67. Among 71 patients with FIB-4 <2.67, 12 (16.9%) had LSM ≥ 12 kPa and would have been missed by a high-FIB-4-only strategy. Most missed cases were in the intermediate FIB-4 subgroup: 10/36 (27.8%) with FIB-4 1.30–2.67 had LSM ≥ 12 kPa. Compared with non-missed patients ($n=59$), missed patients had higher AUDIT-C (median 12 vs 8, $p<0.001$), more often had the maximum AUDIT-C score of 12 (83% vs 22%, $p<0.001$), higher alcohol use (11 vs 3 standard drinks/day, $p=0.013$), and more frequent ≥ 10 drinks/day (75% vs 29%, $p=0.006$). Missed patients also had higher AST (45 vs 29 U/L, $p=0.008$), higher ALT (48 vs 22 U/L, $p=0.008$), and lower platelets (176 vs 261 $\times 10^9$/L, $p<0.001$). PEth >200 ng/mL and beverage type did not significantly differ between groups. **Conclusion:** In AUD patients, high-risk FIB-4 alone may miss a clinically important subgroup with LSM ≥ 12 kPa. Intermediate FIB-4 combined with higher questionnaire-defined alcohol exposure and platelet/aminotransferase abnormalities may identify patients who should proceed directly to VCTE rather than being excluded by FIB-4 gating alone.

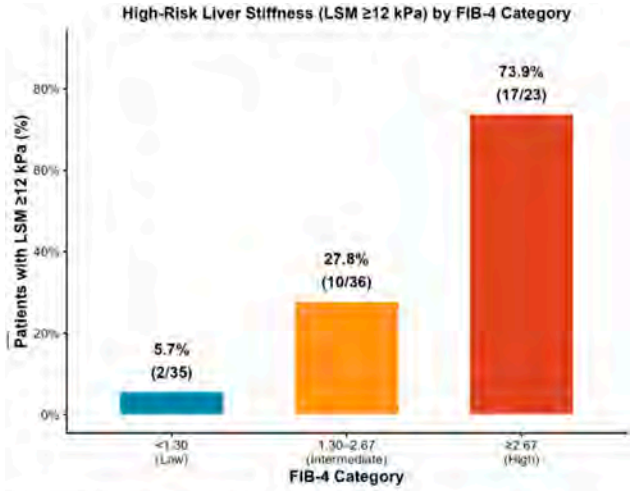

Figure 1. High-risk liver stiffness by FIB-4 category.

Proportion of patients with alcohol use disorder who had high-risk liver stiffness, defined as liver stiffness measurement (LSM) ≥12 kPa, across FIB-4 risk categories. High-risk LSM was present in 5.7% of patients with FIB-4 <1.30, 27.8% with FIB-4 1.30–2.67, and 73.9% with FIB-4 ≥2.67.

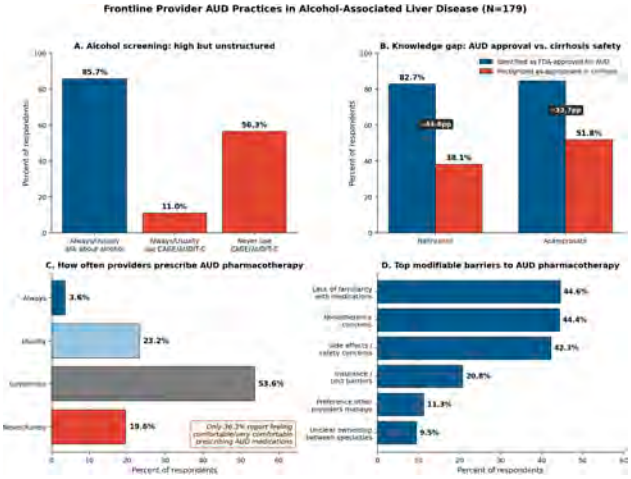
3115 | FRONTLINE PROVIDER ATTITUDES, PRACTICES, AND BARRIERS TO ALCOHOL USE DISORDER PHARMACOTHERAPY IN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE: A MULTISPECIALTY SURVEY



James Vu[1] Lindsey Immers[2] Jordan Holliday[2] Robert Pecha[2] Vikrant Rachakonda[2], [1]UC Davis Medical Center, [2]University of California Davis Medical Center

Background: Alcohol use disorder (AUD) drives mortality in alcohol-associated liver disease (ALD), yet AUD pharmacotherapy remain underutilized in this

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

population. Prior AASLD ALD Special Interest Group (SIG) survey data showed the majority of GI/Hepatology providers had never prescribed AUD pharmacotherapy due to low comfort. Because most ALD patients first present outside hepatology, we examined frontline provider attitudes, practices, and modifiable barriers to AUD pharmacotherapy. **Methods:** A 34-item survey adapted from the AASLD ALD SIG instrument was distributed across frontline specialties at a tertiary academic center to assess respondent demographics, AUD pharmacotherapy prescribing patterns, knowledge of FDA-approved AUD medications and their safety in liver disease and cirrhosis, and perceived barriers to screening and pharmacotherapy. Responses were summarized with descriptive statistics; open-ended responses were reviewed qualitatively for recurring themes. **Results:** 179 providers responded across internal medicine (62.0%), emergency medicine (22.9%), family medicine (7.3%), psychiatry/addiction medicine (7.3%), and GI/hepatology (5.0%); 53.1% were trainees and 44.1% attendings with 86.6% stating they encountered ALD patients at least monthly. Only 36.3% felt comfortable/very comfortable prescribing AUD pharmacotherapy, and only 26.8% reported being regular prescribers. 66.1% incorrectly believed there is a safe level of alcohol use in liver disease. While most recognized FDA approved AUD medications (naltrexone 82.7%, acamprosate 84.5%), recognition of their utility in cirrhosis dropped to 38.1% and 51.8% respectively. 35.7% agreed/strongly agreed that the risks of AUD pharmacotherapy outweigh the benefits in ALD cirrhosis. Top reasons therapy was not initiated by providers included: patient refusal (77.6%), outpatient deferral (55.8%), and AUD not addressed during hospitalization (45.8%). Top medication specific barriers included lack of familiarity (44.6%) and concern about side effects/safety (42.3%). The majority of providers (47.1%) felt ownership of AUD pharmacotherapy should fall to the primary internal medicine team during hospitalizations, versus being deferred to primary care (17.2%) or addiction medicine (16.7%). **Conclusion:** Despite frequent contact with ALD patients, frontline providers harbor misconceptions about safe alcohol use and AUD pharmacotherapy in ALD cirrhosis, and rarely initiate AUD pharmacotherapy. Primary inpatient teams, while identified as primarily responsible for inpatient AUD treatment, reported the greatest knowledge deficits. Modifiable barriers include gaps in knowledge and lack of treatment pathways and protocols. These findings extend the AASLD SIG findings beyond the GI/Hepatology specialty, and targeted educational and systematic interventions are warranted to improve the quality of care of AUD in the ALD population.

3116 | PSYCHOTHERAPY AUGMENTATION OF MEDICAL ALCOHOL DETERRENT THERAPY AND 90-DAY OUTCOMES IN ALCOHOLIC HEPATITIS AND ALCOHOL USE DISORDER: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Bianca Patel[1] Jashanveer Johal[1] Archana Salek[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Abdallah Hussein[1] Jason Hyman[2] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center

Background: Pharmacologic relapse-prevention therapy (naltrexone, acamprosate, or disulfiram) is standard in alcohol use disorder (AUD), yet recidivism remains common. The impact of adding structured psychotherapy on clinical and hepatic outcomes in alcoholic hepatitis is unclear. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised patients with alcoholic hepatitis (K70.1), alcohol abuse (F10.1), or alcohol dependence (F10.2) who received pharmacologic alcohol deterrent therapy (naltrexone, acamprosate, or disulfiram) within one month of diagnosis and had structured psychotherapy (CPT codes 99408, 99409, G0442, G0443, 90832, 90834, or 90853) documented concurrently. Cohort 2 comprised patients receiving deterrent pharmacotherapy alone without any structured psychotherapy. Both cohorts excluded prior CKD stage 5 or ESRD, liver transplant status, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hepatocellular carcinoma. Cohorts were balanced via 1:1 PSM, yielding 16,477 patients per arm. Pre-specified 90-day outcomes included repeat alcoholic hepatitis or acute hepatic failure, progression to cirrhosis, alcohol withdrawal, ICU admission, inpatient encounters, and all-cause mortality. **Results:** Recurrent alcoholic hepatitis/hepatic failure (3.6% vs. 3.6%; HR 0.95, p = 0.41) and cirrhosis progression (0.6% vs. 0.7%; HR 0.84, p = 0.21) were similar between groups. Alcohol withdrawal was more frequent with psychotherapy (11.3% vs. 9.6%; HR 1.12, p = 0.0006), as were inpatient encounters (4.5 vs. 3.0 mean encounters; p < 0.001). ICU admissions were absent in both groups. All-cause mortality was significantly lower with psychotherapy (0.58% vs. 0.85%; HR 0.63, p = 0.0005). **Conclusion:** In this propensity-matched real-world cohort, combining structured psychotherapy with pharmacologic alcohol deterrent therapy was not associated with lower rates of repeat alcoholic hepatitis, hepatic failure, or cirrhosis over 90 days, but was associated with significantly lower all-cause mortality. The paradoxical increase in withdrawal events and inpatient encounters in the psychotherapy arm most likely reflects greater healthcare engagement and detection bias rather than clinical worsening. These findings support psychotherapy integration as a mortality-reducing complement to pharmacologic AUD therapy and highlight the need for prospective studies with longer follow-up.

3117 | PREDICTING ALCOHOL RELAPSE AFTER LIVER TRANSPLANTATION FOR ALCOHOL-ASSOCIATED LIVER DISEASE: TWO-YEAR OUTCOMES OF THE SALT AND HALT SCORES AT A SINGLE ACADEMIC CENTER

Alex Chang[1] Anwesha Satapathy[2] Nishi Joshi[2] James Park[2] Sanjaya Satapathy[3], [1]Brown University, [2]Northwell Health, [3]Northshore University Hospital/Northwell Health

Background: Accurate prediction of post-transplant alcohol relapse is critical for patient selection, organ stewardship, and implementation of targeted harm-reduction strategies. Although the Sustained Alcohol Use Post-Liver Transplant (SALT) and Harmful Alcohol Use Post-Liver Transplant (HALT) scores have been proposed as relapse prediction tools, external validation data remain limited. We evaluated the performance of SALT and HALT scores in predicting post-transplant alcohol relapse in a single-center cohort of patients transplanted for alcohol-associated liver disease (ALD). **Methods:** We conducted a retrospective study of adults who underwent liver transplantation for ALD between December 2019 and August 2023, with minimum follow-up of 2 years. Clinical and psychosocial variables were obtained through chart review, and SALT and HALT scores were retrospectively calculated. Alcohol relapse wasFig defined by self-reported alcohol use or positive phosphatidylethanol (pETH) testing. Relapse was categorized as either any relapse (including slips) or harmful relapse, defined as alcohol consumption exceeding 3 drinks per week post-transplant or alcohol use resulting in hospital readmission. Receiver operating characteristic (ROC) analyses were performed using SAS 9.4. **Results:** A total of 82 patients were included, incuding 51 patients with < 6 months of abstinence. In the overall cohort, the HALT score demonstrated moderate performance for predicting harmful relapse (AUC 0.70, 95% CI 0.56–0.83), whereas the SALT score showed limited discrimination (AUC 0.57, 95% CI 0.43–0.72). Among patients transplanted with < 6 months of abstinence, predictive performance improved substantially for both scores, with HALT achieving an AUC of 0.78 (95% CI 0.60–0.96) and SALT an AUC of 0.71 (95% CI 0.54–0.89) for harmful relapse within 1 year post-transplant.Both scores performed poorly in predicting any relapse, including slips (HALT AUC 0.53; SALT AUC 0.53). However, among patients with < 6 months of abstinence, HALT demonstrated improved discrimination for any relapse (AUC 0.72, 95% CI 0.56–0.88). Using established thresholds, HALT $\leq$ 0.30 demonstrated better negative predictive value than SALT $\leq$ 5, particularly among patients transplanted with shorter abstinence periods. **Conclusion:** Both HALT and SALT scores demonstrated improved predictive performance among patients transplanted with < 6 months of abstinence and for identifying harmful relapse within the first year after transplantation. HALT appeared to have stronger predictive ability in identifying clinically significant relapse when including patients with > 6 months of abstinence. However, neither score reliably predicted isolated slips, limiting their utility as standalone selection tools. These findings support the

use of relapse risk stratification models as adjunctive tools to guide post-transplant monitoring and targeted behavioral interventions.

Table 1

	PPV	NPV	Sensitivity	Specificity
All Patients (n = 82)				
SALT ≥ 5	25%	79%	21%	87%
HALT ≥ 0.30	54%	83%	37%	90%
<6 months of abstinence (n =51)				
SALT ≥ 5	50%	84%	30%	93%
HALT ≥ 0.30	55%	90%	60%	88%

3118 | HIGH AREA DEPRIVATION INDEX IS ASSOCIATED WITH INCREASED NINETY-DAY MORTALITY IN ALCOHOL-ASSOCIATED HEPATITIS: A RETROSPECTIVE COHORT STUDY

Lindsey Immers[1] James Vu[1] Robert Pecha[1] Jordan Holliday[1] Vikrant Rachakonda[1], [1]University of California Davis Medical Center

Background: Alcohol associated hepatitis (AH) is a severe form of alcohol-related liver disease (ALD) associated with disparate outcomes based on socioeconomic factors. The Area Deprivation Index (ADI) is a validated composite measure of neighborhood-level socioeconomic disadvantage. This study evaluated the association between ADI and clinical outcomes in patients hospitalized with alcohol associated hepatitis. **Methods:** This was a single-center retrospective cohort study of 572 patients admitted with AH (October 2017–July 2024), defined by NIAAA criteria. National ADI scores were obtained using the University of Wisconsin Neighborhood Atlas based on patient addresses and divided into tertiles (low [1, N = 218], intermediate [2, N = 166] and high [3, N = 188] risk), with tertile 3 being the most disadvantaged population; unhoused patients (N = 29) were assigned national ADI score of 99 and placed in the third tertile. Baseline demographic, clinical, and socioeconomic characteristics were compared across ADI tertiles. The primary outcome was 90-day survival, and secondary analyses examined predictors of survival. **Results:** While there were no differences in age between ADI tertiles, fewer female (34.0% vs. 46.3% in low-risk, $p = 0.038$), white (40.4% vs. 59.6%, $p < 0.001$), and non-English speaking (87.2% vs. 98.6%, $p < 0.001$) patients were observed in tertile 3. There were no significant differences across ADI tertiles in MELD 3.0, ascites, gastrointestinal bleeding (GIB), acute kidney injury, or hepatic encephalopathy. Patients in tertile 3 had higher rates of Medicaid insurance (75.5% vs. 45.9%, $p < 0.001$) and lower rates of private insurance (6.9% vs. 21.1%, $p < 0.001$). Alcohol use disorder (AUD) medications were less frequently prescribed to tertile 3 (16.0% vs. 26.6%, $p = 0.004$), with no differences in substance use navigator utilization. Kaplan Meier analysis demonstrated significantly lower 90-day mean survival in tertile 3 compared to tertiles 1 and 2 [tertile 3: 73 (95% CI 69 – 77) vs tertile 2: 76 (72 – 80) vs tertile 1: 81 (78 – 84) days, $p = 0.012$]. Multivariate Cox proportional hazards models showed that ADI tertiles 2 [aHR 2.007 (95% CI 1.204 – 3.346), $p = 0.008$] and 3 [aHR 2.371 (95% CI 1.465 – 2.837), $p < 0.001$] were associated with increased 90-day mortality independent of MELD 3.0, ascites, GIB, age, and ICU admission. **Conclusion:** This study demonstrated that higher neighborhood-level socioeconomic disadvantage, as measured by ADI, is independently associated with lower 90-day survival in patients hospitalized with AH. As a freely available and easily ascertained metric, ADI may serve as a practical tool to identify high-risk populations and complement existing prognostic models. Future prospective studies should evaluate whether ADI-guided early interventions targeting modifiable social determinants can improve outcomes in this vulnerable population.

3119 | LIVER-DERIVED IGFBP1 DRIVES ALCOHOL-ASSOCIATED OSTEOPENIA BY INHIBITING OSTEOBLAST DIFFERENTIATION

Guangyu Liu[1], [1]National Institutes of Healthy

Background: Alcohol-associated bone loss is traditionally attributed to the direct toxic effects of ethanol on bone. However, whether liver-derived endocrine signaling contributes to alcohol-induced osteopenia remains largely unknown. In this study, we investigated the liver-bone crosstalk in alcohol-associated bone loss and explored the contribution of acetaldehyde to this process. **Methods:** We used a chronic-plus-binge ethanol feeding model in mice to assess the effects of alcohol exposure on bone mass and osteoblast function, and combined micro-CT, histology, serum analysis, transcriptomics, in vitro osteoblast assays, and trans-genetic mice model to identify and validate liver-derived mediators of bone injury. **Results:** Alcohol induced significant osteopenia in wild-type mice, as demonstrated by reduced bone mineral density and decreased newly formed trabecular bone. This phenotype was associated with impaired osteoblast differentiation. To determine whether ethanol or acetaldehyde aggravate skeletal injury, we utilized ALDH2 knock-in (KI) mice which have slower ALDH2 enzyme activity and therefore accumulate more acetaldehyde. Compared with wild-type controls, ALDH2 KI mice developed more severe bone loss. Transcriptomic analysis of liver tissue from ethanol-fed wild-type and ALDH2 KI mice identified insulin-like growth factor binding protein 1 (IGFBP1) as a prominently upregulated liver-derived factor. Consistently, circulating IGFBP1 levels increased after ethanol exposure, with a greater increase in ALDH2 KI mice. Functional studies demonstrated that recombinant IGFBP1 directly suppressed osteoblast differentiation in vitro. Importantly, deletion of IGFBP1 significantly attenuated alcohol-induced bone loss, including in the ALDH2 KI background, establishing a causal role for IGFBP1 in mediating skeletal deterioration. **Conclusion:** Alcohol-associated osteopenia is driven not only by the direct toxic effects of alcohol, but also by a liver-derived endocrine mechanism. Alcohol, particularly in the setting of impaired acetaldehyde metabolism, induces hepatic IGFBP1, which acts through a liver-bone endocrine axis to suppress osteoblast differentiation and promote bone loss. These findings identify IGFBP1 as a key mediator of alcohol-induced liver-bone crosstalk and suggest that targeting IGFBP1 may represent a promising therapeutic strategy for preventing skeletal complications associated with alcohol exposure.

University, [5]South Texas Health System, [6]University Of California, Riverside, [7]Yale New Haven Health, Bridgeport Hospital, [8]Yale University

Background: Acute kidney injury (AKI) is one of the most common and devastating extrahepatic complications of acute **:** alcohol associated hepatitis (AH), a potentially severe subtype of alcohol associated liver disease. We aimed to quantify the pooled impact of AKI on 28-day and 90-day all-cause mortality, severity risks and clinical markers in patients with AH. **Methods:** A systemic search utilizing PubMed, Embase, Web of Science, and Scopus database were used to search for articles. Data from five studies (n = 2306) were pooled. The primary outcomes were mortality at 28 days and 90 days. Secondary outcomes included hepatic encephalopathy, Systemic Inflammatory Response Syndrome (SIRS), infection, and upper GI bleed. Additional analysis assessed laboratory data including total bilirubin, creatinine, albumin, INR, Maddrey's discriminant function (MDF), and ABIC score and study demographic (Age, Sex). Mean difference (MD) was calculated for continuous variables for individuals with versus without AKI. OR and MD were calculated using common-effect and random-effect models. We reported the random-effect model analysis. Heterogeneity was assessed using Cochran's Q, I^2, and τ^2 statistics. A leave one out meta-analysis was conducted to assess the influence of each individual study on the pooled estimate and to explore potential contribution to heterogeneity. **Results:** Five studies with 2306 total population were included in the analysis. Serum creatinine was significantly higher in the AKI vs non-AKI group (MD of 0.51, $p < 0.0001$; $I^2 = 2.3\%$). AKI was significantly associated with increased short-term mortality at day 28 (OR 2.37, $p < 0.0001$; $I^2 = 1\%$) and day 90 (OR = 2.39, $p < 0.0001$; $I^2 = 62.7\%$). AKI was also significantly associated with higher rate of hepatic encephalopathy (OR = 2.78, $p < 0.0001$; $I^2 = 80\%$), SIRS (OR = 2.39, $p < 0.004$; $I^2 = 62.7\%$), and infection (OR = 1.81, $p < 0.0001$; $I^2 = 61\%$); no significant association was observed with upper GI bleeding (OR = 1.02, $p = 0.8$; $I^2 = 27.8\%$). Patients with AKI demonstrated significantly higher levels of total bilirubin (MD = 6.80, $p < 0.0001$; $I^2 = 13.2\%$), MDF score (MD = 16.67, $p < 0.0001$; $I^2 = 51\%$), MELD score (MD = 5.85; $I^2 = 94.4\%$), and INR (MD = 0.24, $p < 0.0001$; $I^2 = 18\%$). **Conclusion:** AKI is associated with significantly increased 28- and 90-day mortality in patients with AH. AKI is also associated with higher rates of hepatic encephalopathy, SIRS, infection, higher INR, total bilirubin, and MDF. Our findings highlight the critical prognostic impact of AKI and emphasize the need for early detection and targeted management strategies to improve patient outcomes.

3121 | MULTIDISCIPLINARY HEPATOLOGY AND ADDICTION PSYCHIATRY CARE FOR ALCOHOL-ASSOCIATED LIVER DISEASE (ALD) AND ALCOHOL USE DISORDER (AUD): A DESCRIPTIVE ANALYSIS

Danielle Morelli[1] Stephanie Rutledge[1] Gilbert Vasquez[1] Mashal Khan[1] Danielle Brandman[2] Rebecca Roediger[2], [1]Weill Cornell Medical Center-New York Presbyterian, [2]Weill Cornell Medicine

Background: ALD affects 3.5% of the general population and 55% among those with AUD. AUD is increasing in young adults, women, racial/ethnic minorities, yet longitudinal care engagement for ALD-AUD remains low. Nationally, behavioral therapy engagement is 10% and medication for alcohol use disorder (MAUD) use is < 1.5%. Meta-analysis data show integration of hepatology and addiction care improves outcomes. Barriers include resource limitations, care sustainability, lack of provider awareness, and engagement. We describe the successful implementation of the Center for Alcohol & Liver Medicine (CALM), an integrated hepatology and addiction psychiatry clinic that delivers patient-centered care, tailored to disease stage and motivational readiness in a diverse urban environment. **Methods:** CALM operates one half-day weekly, enrolling patients across the spectrum of ALD-AUD. The care team includes a Hepatologist, Addiction Psychiatrist, and Credentialed Alcoholism and Substance Abuse Counselor. Care is grounded in motivational interviewing and patient-driven goals, with same-day individualized care plans for liver disease management, MAUD use, mental health treatment, and linkage to alcohol treatment programs. **Results:** Intake engagement rate after referral was 78% (n = 80/102). Intake cohort demographics: average age 52 (SD 12.2); 37% female, 63% male; 52% publicly insured. A large proportion had cirrhosis: n = 45/80, of which 35% were decompensated. MAUD use in CALM was 69% (n = 55/80). Mean intake PETH was 492 (SD 527.8). Intake PETH was significantly higher among patients who initiated MAUD vs those who did not (median 455 vs 13.5 ng/mL, U = 754.0, $p = 0.004$). Intake PETH level ≥ 200

is strongly associated with abstinence outcome at follow up: Fisher Exact, OR = 0.07, $p < 0.001$. Clinic follow-up rate (defined as at least one follow-up visit) was 71%, with a lower rate in the compensated cirrhosis subgroup of 53%. Referral rates to alcohol treatment programs were high at 79% (n = 63/80) with a 60% (n = 38/63) engagement rate. No statistically significant associations were identified between patient sex, age, ALD severity, insurance type for follow-up rate, MAUD use, or enrolling in treatment programs (all $p > 0.05$). **Conclusion:** We have demonstrated that patients with ALD had high levels of engagement in an integrated clinic, with similar rates of engagement across liver disease severity and insurance types, including 52% of the cohort with public insurance suggesting equitable program reach. The observed follow-up rate and MAUD use were similar regardless of sex, age, liver disease severity, and insurance type, suggesting that CALM's care model may reduce barriers to engagement that typically disadvantage higher-risk or publicly insured patients. Future research will focus on the impact of CALM on liver-, AUD- and patient-related outcomes, with attention on program methodology to optimize outcomes.

3122 | ALCOHOL EXPOSURE IMPAIRS KUPFFER CELL–MEDIATED ANTIBACTERIAL DEFENSE THROUGH ZONAL REMODELING RATHER THAN SUPPRESSION OF ANTIMICROBIAL GENE PROGRAM

Tiantian Yao[1]; [1]Peking University First Hospital

Background: Alcohol use is a major risk factor for severe bacterial infections in humans, yet the cellular and molecular mechanisms underlying alcohol-induced susceptibility remain incompletely understood. Hepatocytes, neutrophils and Kupffer cells (KC) play essential roles in hepatic antibacterial defense, but how alcohol reshapes these responses during infection remains unclear. **Methods:** We established a mouse model of alcohol acceleration of bacterial infection by using alcohol-plus-binge and *K. pneumoniae* (*K. P.*) infection. We performed survival studies, bacterial burden analysis, histology, immunostaining, bulk and single-cell RNA sequencing, acetaldehyde-accumulation experiments (Aldh2*1/*2 KI), and zonal quantification of KC distribution. Neutrophil-specific antimicrobial pathways were interrogated using *Ncf1*–KO, *Mrp8*–KO, *Cxcl1*–KO, and IL-8 transgenic mice. **Results:** Alcohol exposure markedly reduced survival following *K. P.* infection, despite comparable bacterial loads and hepatic injury markers between pair-fed and ethanol-fed mice. Single cell RNA-seq demonstrated that a large number of hepatocyte-derived acute phase protein (APP) genes were upregulated during infection; however, chronic-plus-binge ethanol did not affect hepatic expression of these APP genes. Alcohol exposure did not alter the induction of neutrophil-associated antimicrobial genes, nor did it affect hepatic neutrophil recruitment. Functionally, *Ncf1* deficiency impaired survival in control-fed mice but not in ethanol-fed mice, whereas *Mrp8*–KO, *Cxcl1*–KO, and IL-8 transgenic mice showed no differences from WT controls under either dietary condition, indicating that alcohol overrides individual neutrophil effector pathways. Alcohol exposure remodels Kupffer cell morphology and impairs phagocytic function. Alcohol feeding also profoundly disrupted the zonal organization of hepatic KC, reflected by a marked loss of zone 1 KC and an aberrant accumulation of KC in zone 3. *Aldh2*1/2 KI* mice showed survival rates comparable to *WT* mice, indicating that acetaldehyde accumulation is not the primary driver of alcohol-induced mortality. **Conclusion:** Alcohol exposure increases susceptibility to bacterial infection not by suppressing APP expression or neutrophil antimicrobial gene programs, but by inducing zone-specific remodeling and altering the morphology of KC. These findings identify a previously unrecognized mechanism by which alcohol disrupts

3123 | CARDIOMETABOLIC RISK FACTOR SPECIFICITY AND ALCOHOL INTERACTION IN LIVER FIBROSIS ACROSS SLD SUBTYPES: A POPULATION-BASED ANALYSIS

Rylyn Reyes[1] Hyundam Gu[2] Samuel Rhoads[3] Juan Pablo Arab[4], [1]Virginia Commonwealth University, [2]VCU Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, [3]Stravitz Sanyal Institute for Liver Disease and Metabolic Health, [4]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health

Background: SLD has emerged as a leading cause of chronic liver disease globally, with liver fibrosis representing a critical determinant of liver-related morbidity and mortality. However, prior studies have focused predominantly on aggregate cardiometabolic risk factor count rather than the independent effect of the contribution of individual risk factors, and have largely been restricted to MASLD populations. This study examined the associations between individual cardiometabolic risk factors and alcohol consumption with significant and advanced liver fibrosis in MASLD and MetALD/ALD populations. **Methods:** This cross-sectional study used 2017-2018 NHANES data. Significant and advanced fibrosis were defined as LSM $\geq$ 8 kPa and LSM $\geq$ 12 kPa, respectively, measured by VCTE; hepatic steatosis was defined as a CAP $\geq$280 dB/m. Alcohol consumption was expressed in grams of ethanol per week (14g per standard drink) and modeled continuously and categorically using sex-specific thresholds. Multivariable logistic regression evaluated associations between individual cardiometabolic risk factors and liver fibrosis outcomes, adjusting for covariates. All analyses accounted for NHANES complex survey design. **Results:** A total of 1,955 adults with SLD were included: 1,864 (95.3%) with MASLD and 91 (4.65%) with MetALD/ALD across very low, low, moderate, and increased alcohol consumption groups. Significant fibrosis prevalence was 20.9% in MASLD and 16.5% in MetALD/ALD; advanced fibrosis prevalence was 11.7% in MASLD and 9.89% in MetALD/ALD, respectively. In adjusted models, elevated fasting glucose was independently associated with significant fibrosis (aOR: 5.52, 95% CI: 1.28-23.9, p = 0.030). Dyslipidemia was independently associated with advanced fibrosis (aOR: 3.94, 95% CI: 1.20-12.9, p = 0.031), as well as in unadjusted models (OR: 4.01, 95% CI: 1.98-8.10, p < 0.001). A significant interaction was identified between obesity and alcohol consumption of significant fibrosis (OR: 0.86 95% CI: 0.84-0.88, p < 0.001), suggesting the association between obesity and significant fibrosis attenuates with increasing alcohol consumption. **Conclusion:** Among U.S. adults with SLD, elevated fasting glucose and dyslipidemia emerged as the primary cardiometabolic drivers of significant and advanced fibrosis, respectively, independent of alcohol consumption level. However, a significant interaction between obesity and alcohol consumption for significant fibrosis indicates that increasing alcohol consumption may attenuate the effect of obesity on fibrosis risk, warranting further investigation into the relationship between metabolic and alcohol-related pathways across the SLD spectrum in larger data or prospective study.

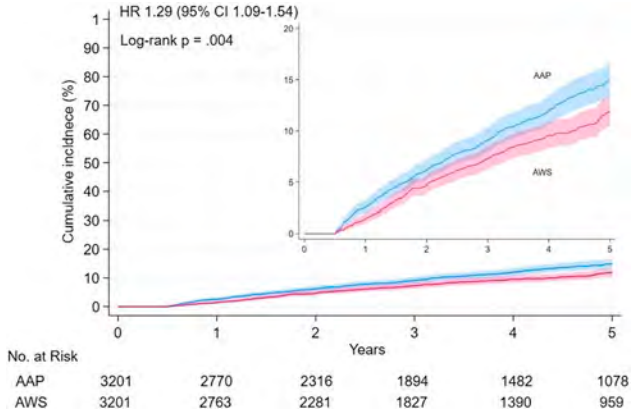
3124 | DIFFERENTIAL RISK OF ADVANCED LIVER DISEASE FOLLOWING ALCOHOL-ASSOCIATED PANCREATITIS VS ALCOHOL WITHDRAWAL SYNDROME



Butros Fakhoury[1] Leandro Sierra[2] Krishan Patel[1] Hyundam Gu[1] Luis Díaz[3] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Cleveland Clinic Foundation, [3]Pontificia Universidad Católica de Chile

Background: Unhealthy alcohol use is a leading cause of preventable mortality, with alcohol-associated liver disease (ALD) frequently presenting late as decompensated cirrhosis. Extrahepatic presentations requiring acute care, such as alcohol-associated pancreatitis (AAP) and alcohol withdrawal syndrome (AWS), indicate significant alcohol exposure but reflect fundamentally different pathophysiologic processes. We hypothesized that AAP, representing direct alcohol-mediated tissue toxicity, differentially predicts progression to advanced chronic liver disease (ACLD) compared to AWS, identifying a high-risk phenotype for targeted intervention. **Methods:** This retrospective cohort study utilized the federated TriNetX US Collaborative Network. We identified adults with a first diagnosis of AAP or AWS (2016-2023) without pre-existing liver disease.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

To ensure clinical severity, AWS cases required benzodiazepines or phenobarbital within 2 days of index. To isolate incident disease, patients with baseline or 6-month post-index diagnoses of any liver disease, fibrosis, or decompensation were excluded. Analysis was restricted to complete cases with available baseline laboratories within 6 months of index. Propensity score matching (1:1) balanced cohorts across demographics, metabolic comorbidities, social determinants of health, and baseline laboratories. The primary outcome was incident ACLD (composite of hepatic fibrosis, cirrhosis, or decompensation). Secondary outcomes included all-cause mortality and prescriptions for medications for alcohol use disorder (MAUD). **Results:** After matching, 3,201 patients per cohort were analyzed (median age 50-51 years). Over a median follow-up of 3.5-3.7 years, patients with AAP demonstrated a significantly higher cumulative incidence of ACLD compared to AWS (9.3% vs 7.0%; HR 1.29; 95% CI 1.09-1.54; $p = 0.004$). This was primarily driven by a higher rate of hepatic decompensation in the AAP cohort (7.0% vs 4.6%; HR 1.50; 95% CI 1.22-1.85; $p < 0.001$). Conversely, patients with AWS experienced higher all-cause mortality (12.7% vs 9.5%; HR 0.72; $p < 0.001$) and were nearly twice as likely to receive MAUD prescriptions during follow-up (15.1% vs 7.7%; HR 0.47; 95% CI 0.40-0.54; $p < 0.001$). Sensitivity analyses restricting AWS to severe phenobarbital-treated cases (HR 1.45; $p = 0.002$) and negative control exposure (appendicitis) and control outcome (osteoarthritis) confirmed the specificity of these findings. **Conclusion:** Among heavy drinkers without pre-existing liver disease, AAP is associated with a 29% higher risk of developing ACLD compared to AWS, yet these patients receive significantly less pharmacological addiction treatment. AAP represents a critical sentinel event and a distinct hepatotoxic phenotype that warrants prioritized systematic liver surveillance and aggressive linkage to AUD care to prevent decompensated ALD.

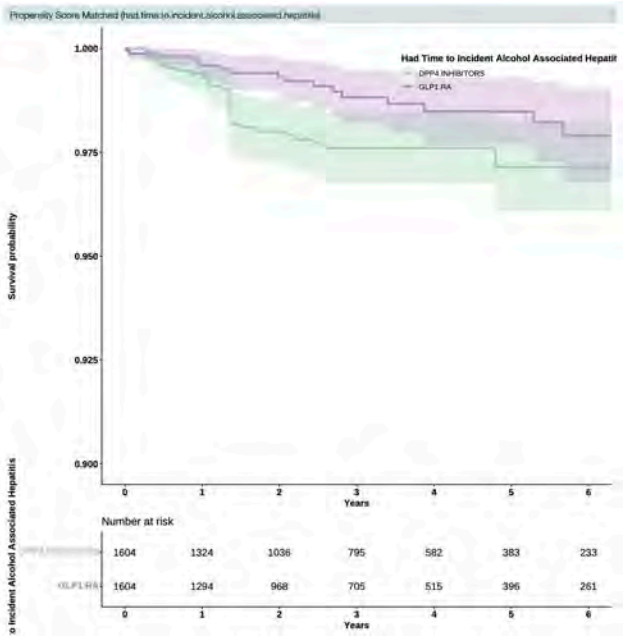
3125 | GLP-1 RECEPTOR AGONISTS MAY REDUCE RISK OF ALCOHOL-ASSOCIATED HEPATITIS



Judah Kupferman[1] Aparna Goel[1] Amir Hossein Gougol[1] Sajid Jalil[1] Allison Kwong[1] Ashwani Singal[2] Natalie Torok[1] Saurabh Gombar[3] Paul Kwo[1], [1]Stanford University Medical Center, [2]University of Louisville, [3]Atropos Health

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RA) and dipeptidyl peptidase-4 inhibitors (DPP-4i) are established treatments for glycemic control for patients with type 2 diabetes mellitus (T2DM). GLP-1 RAs also demonstrate effectiveness in reducing alcohol craving and consumption among people with alcohol use disorder (AUD). Whether GLP-1 RAs can reduce the risk of complications from AUD, such as alcohol-associated hepatitis (AH), remains uncertain. We aimed to assess the effect of GLP-1 RA in patients with T2DM and AUD. **Methods:** Using data from the Apollo Atropos Evidence Network, we performed a retrospective cohort study to evaluate whether GLP-1 RA therapy is associated with reduced incidence of AH in adults with T2DM and AUD. Subjects were 18 years or older with both T2DM and AUD and newly treated with either GLP-1 RAs (lixisenatide, albiglutide, dulaglutide, semaglutide, tirzepatide, liraglutide, exenatide) (exposure) or DPP-4i (linagliptin, alogliptin, sitagliptin, vildagliptin, saxagliptin) (controls) from 2015 to 2025. T2DM and AUD were defined by ICD-9/10 codes within 1 year prior to medication initiation. AH was defined by ICD-9/10 codes or laboratory-confirmed criteria. Patients with cirrhosis or chronic liver disease, hepatocellular carcinoma, liver transplant, prior AH, or those undergoing treatment for AUD were excluded. Continuous medication use for at least 90 days was required for inclusion. Propensity score matching was performed to balance baseline characteristics. **Results:** 5147 GLP-1 RA users and 2173 DPP-4i users (30.6% vs 22.5% female) were compared. Ages ranged from 18 to 89 years (mean 57.5 +/- 11.9 y vs 60.1 +/- 12.0 y). GLP-1 RA users had greater rates of emergency room visits (20.7% vs 10.3%), obesity (76.1% vs 52.1%), mean BMI (35.9 vs 31.7), and outpatient visits (42.4% vs 19.1%), compared to the DPP-4i group. After propensity score matching, GLP-1 RA exposure was associated with reduced incidence of AH (HR 0.55, 95% CI 0.30-0.99; $p = 0.046$) (Figure 1). **Conclusion:** In patients with T2DM and AUD, GLP-1 RA use was associated with reduced risk of AH compared to DPP-4i use. These real-world data

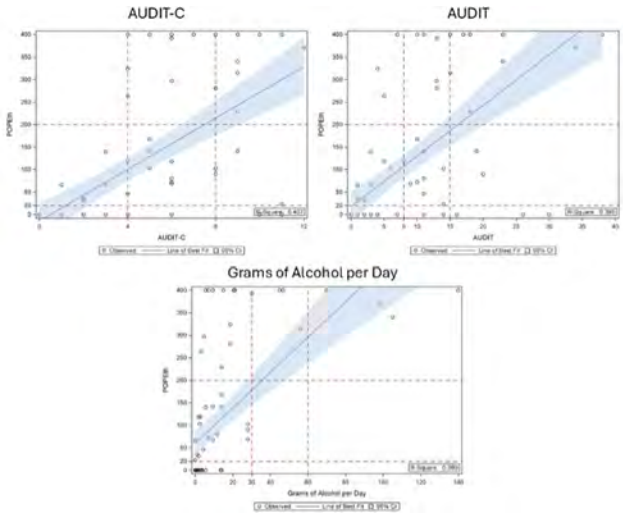
3126 | ALCOHOL CESSATION AFTER DEVELOPMENT OF ALD INDUCES RAPID EMERGENCE OF NEW MONOCYTE DERIVED KUPFFER CELLS WITHIN HEPATIC CROWN-LIKE STRUCTURES

Isabel Aranzazu Pulido Ruiz[1] Kyle Yuquimpo[2] Sheetalnath Rooge[2] Ayobami Dare[1] Irina Tikhanovich[2] Steven Weinman[2], [1]The University of Kansas Medical Center, [2]University of Kansas Medical Center

Background: Resolution of alcohol-associated liver disease (ALD) is often slow and incomplete, even after alcohol cessation. Hepatic macrophages are central regulators of ALD recovery through their roles in lipid handling and tissue remodeling. However, the mechanisms and spatial niches that support effective resolution remain poorly understood. Preliminary data suggest that alcohol cessation promotes the emergence of specific macrophage populations with defined spatial organization, which may promote disease recovery. We investigated the identity and spatial localization of macrophage populations emerging during ALD resolution. **Methods:** C57BL/6J and Cx3cr1-Cre×ROSA-CAG-LSL-TdTomato mice were fed a high-fat Western diet with ad libitum 10–20% alcohol in drinking water (WDA) for 16 weeks, then transitioned to chow and water for 3, 7 or 28 days. Liver tissue was analyzed by immunofluorescence (IF), flow cytometry, and qPCR. Cx3cr1 lineage TdTomato positive cells (TdT+) identified infiltrating monocyte derived macrophages (moMac) at the time of stopping WDA. **Results:** Cessation of high fat and alcohol consumption resulted in a progressive loss of liver fat and inflammation over the course of 28 days. Alcohol cessation induced a loss of Kupffer cell (KC) gene expression and an increase in moMac gene expression within 3 days of stopping WDA. By 7 days, KC gene expression was restored. Crown-like structures (CLS) were present in the liver, and these consisted largely of macrophages expressing both KC and lipid associated macrophages (LAM) markers. We performed lineage tracing using a tamoxifen pulse to label monocytes and moMac with TdT. In mice that remained on the WDA diet, there was minimal TdT incorporation into KCs by 7 days. In mice that stopped alcohol after the tamoxifen pulse, both flow cytometry and IF showed that TdT abundantly labeled a subset of VSIG4+ KCs that were found exclusively in CLS. Ki67 staining demonstrated that these newly formed TdT labeled KCs were proliferating

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



within the CLS. By 28 days after WDA stopped, CLS became more abundant but were primarily composed of LAMs expressing GPNMB and CD11c. The TdT+ VSIG4+ newly formed KCs were no longer restricted to CLS and were observed in the sinusoids throughout the liver parenchyma. **Conclusion:** These findings demonstrate that sudden cessation of high fat diet and alcohol induces a rapid change in hepatic macrophage populations. Existing KCs are lost, and new monocyte-derived KCs rapidly form and proliferate. Early during disease resolution, the CLS are the sites of new KC formation. These cells eventually distribute throughout the liver parenchyma. We speculate that the unique lipid rich environment of the CLS supplies the extrinsic signals necessary to imprint developing KC with the phenotype necessary to optimally dispose of excess lipid and promote disease resolution.

3127 | AUDIT-C OUTPERFORMS SELF-REPORTED ALCOHOL CONSUMPTION FOR STEATOTIC LIVER DISEASE CLASSIFICATION: VALIDATION AGAINST PHOSPHATIDYL ETHANOLAMINE (PETH)

Binu John[1] Dustin Bastaich[2] Flavia Carneiro[3] Gregory Bigford[3] Mina Shaker[3] Alexander Sy[4] Gema Casco[3] Olga Medina[3] Bassam Dahman[2], [1]University of Miami and Miami VA, [2]Virginia Commonwealth University, [3]Miami VA Health System, [4]Bruce W Carter VAMC

Background: Steatotic liver disease (SLD), including metabolic-associated steatotic liver disease (MASLD), metabolic and alcohol-related liver disease (MetALD), and alcohol-related liver disease (ALD), is classified based on self-reported alcohol use, which is susceptible to recall bias, potentially leading to misclassification. Phosphatidylethanol (PEth), while objective, is limited by costs (> $100/test) while AUDIT and AUDIT-C are validated, structured inexpensive screening tools. We examined whether AUDIT and AUDIT-C more accurately classify SLD compared to self-reported alcohol use, using PEth as the objective reference. **Methods:** This prospective study recruited consecutive U. S Veterans whose self-reported alcohol consumption corresponded to a diagnosis of MASLD, MetALD, or ALD. All participants provided IRB approved written informed consent, completed a questionnaire capturing self-reported grams of alcohol per day, AUDIT, and AUDIT-C, and underwent PEth measurement during a single visit. PEth was categorized as low (< 20), intermediate (20–200), or high (> 200 ng/mL), while AUDIT-C cut-offs were Male (M) < 4/Female (F) < 3 (MASLD), M4–8/F3–6 (MetALD), and M > 8/F > 6 (ALD) as previously validated. AUDIT cut-offs defined low (0–7), moderate (8–15), and heavy (> 15) use. Alcohol use thresholds followed the Delphi consensus (M < 30/F < 20, M30–60/F20–50, M > 60/F > 50). Agreement with PEth was assessed via weighted kappa and classification accuracy; continuous associations were evaluated using R^2 from linear regression. **Results:** Of 93 recruited participants, 87 were retained after excluding those with a failed PEth assay due to drug interference. AUDIT-C demonstrated moderate agreement with PEth ($\kappa = 0.58$, 95% CI 0.44–0.71) with 69.0% classification accuracy. AUDIT performed similarly ($\kappa = 0.56$, 95% CI 0.41–0.71; 71.3% accuracy). Among AUDIT-C discordant cases, 16 participants under-reported and 11 over-reported; notably, no participant with a high PEth category had a low AUDIT-C. Self-reported alcohol use showed weak agreement ($\kappa = 0.25$, 95% CI 0.10–0.40) and lower (60.5%) accuracy, with all discordant cases reflecting under-reporting. In continuous analyses, AUDIT-C modestly outperformed AUDIT and self-reported alcohol use in predicting PEth ($R^2 = 0.41$ vs. 0.40 vs. 0.39). **Conclusion:** AUDIT and AUDIT-C outperformed self-reported alcohol consumption in classifying SLD etiology against the objective standard of PEth. Self-reported alcohol use consistently underestimated consumption, likely reflecting recall and social desirability bias, while AUDIT and AUDIT-C demonstrated more balanced over- and under-reporting. These findings support adopting AUDIT-C to categorize SLD with cut-offs of < 4/ < 3 for MASLD, 4–8/3–6 for MetALD, > 8/ > 6 for ALD in males and females respectively, given the superior accuracy over self-reported alcohol use, ease of administration, and cost-effectiveness relative to PEth

3128 | PROGNOSTICATION OF OUTCOMES IN ALCOHOL-RELATED LIVER DISEASE (ALD) USING ELECSYS® PRO-C3, A NON-INVASIVE TEST MEASURED ON A FULLY AUTOMATED IN VITRO DIAGNOSTIC ANALYZER

Andressa de Zawadzki[1] Maja Thiele[2] Stine Johansen[3] Ida Villesen[3] Peter Andersen[3] Morten Karsdal[1] Aleksander Krag[4] Diana Leeming[5], [1]Nordic Bioscience, [2]Evido.health, [3]Odense University Hospital, [4]University of Southern Denmark, [5]Nordic Bioscience A/S

Background: Diagnosis of alcohol-related liver disease (ALD) is often made when liver fibrosis becomes irreversible. Therefore, prognostication in patients using high-throughput non-invasive tests (NITs) has become increasingly important. The prognostic performance of PRO-C3 using ELISA technology has been widely demonstrated in chronic liver diseases. The current study aimed to investigate the prognostic utility of Roche Elecsys® PRO-C3 for ALD risk stratification. **Methods:** Elecsys® PRO-C3 (N-terminal pro-peptide of type III collagen) was measured on the fully automated CE marked Roche COBAS® e801 in vitro diagnostic (IVD) analyzer in serum of 450 biopsy-proven F0-F4 ALD patients from the GALAXY consortium derived "GALA-ALD" cross-sectional cohort having 5 years of follow-up. PRO-C3 was also measured in the same samples using a fully validated enzyme-linked immunosorbent assay (ELISA). Risks of hepatic decompensation were estimated using Fine–Gray competing-risk models, while Kaplan–Meier and Cox regression analyses were used for mortality. Patients were stratified into tertiles (T) or quartiles (Q) according to baseline PRO-C3 levels, and a cut-off value was defined based on the category with the highest hazard ratio (HR). Prognostic performance of Elecsys® PRO-C3 was compared to PRO-C3 ELISA Generation 2. **Results:** Elecsys® PRO-C3 demonstrated good prognostic utility to stratify ALD patients at risk of all-cause mortality (hazard ratio for mortality (HRM) of 3.75 [95% CI 2.53-5.54], $p < 0.001$) and decompensation (hazard ratio for decompensation (HRD) of 10.5 [95% CI 5.86-18.8], $p < 0.001$) using a cut-off of 63 ng/mL which was defined as the upper quartile (Q4) of Elecsys® PRO-C3 concentrations, showing similar prognostic performance in comparison to PRO-C3 ELISA (HRM of 5.10 [95% CI 2.60-10.0], $p < 0.001$; HRD of 13.2 [95% CI 4.79-36.2], $p < 0.001$ using a predefined cut-off of 12.6 ng/mL. **Conclusion:** Roche Elecsys® PRO-C3 within the ADAPT score has previously demonstrated diagnostic utility in steatotic liver diseases (SLD) and PRO-C3 as a single marker has been incorporated in clinical trials for evaluation of therapeutic efficacy on fibrogenesis. The present study suggests Roche Elecsys® PRO-C3 as an efficient NIT for risk stratification in ALD, offering patient prognostication in a high-throughput CE marker IVD platform intended for use in routine clinical laboratories in the future.

★ 3129 | DNASE I PROTECTS AGAINST ALCOHOL-INDUCED INTESTINAL BARRIER FAILURE AND ENDOTOXEMIA

Scott Minchenberg[1] Marti Ortega-Ribera[1] Alejandro Hionides Gutierrez[1] Siddharth Ghosh Roy[1] Aditi Ashish Datta[1] Viliam Brezani[1] Bruna Santos[1] Prashanth Thevkar Nagesh[1] Gyongyi Szabo[1], [1]BIDMC - Harvard Medical School

Background: Alcohol binges inflict significant damage to the proximal small intestine (PSI), driving epithelial dysfunction, increased intestinal permeability, and systemic exposure to gut-derived microbial products, key events that drive alcohol-associated inflammation. In the context of alcohol associated liver disease (ALD), binge drinking disrupts the gut barrier and may contribute to infections from gut-derived pathogens. Despite the central role of early intestinal mucosal disruption in alcohol-related pathology, effective therapeutic strategies remain limited. Emerging evidence suggests that extracellular DNA released from alcohol-induced tissue injury amplifies inflammation after alcohol exposure. DNase I is an extracellular DNA–degrading enzyme with established clinical use in other disease states. We hypothesize that DNase I treatment mitigates PSI injury and prevents downstream endotoxemia due to alcohol binges. **Methods:** Eight to twelve week female C57BL/6J mice ($n = 4$-8 per group) received daily oral alcohol gavages (3.5 g/kg) for 3 days. DNase I (5 mg/kg) was administered I.P. 1 h before each binge. The intestines were collected 3 h after the final binge to evaluate for histologic injury, neutrophil recruitment, cytokine expression, and innate immune signaling. Serum was also collected for quantification of endotoxin. **Results:** Alcohol binges induce a PSI enteropathy with a 3-fold

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

reduction in villous height:crypt depth ($p < 0.001$), a 100-fold increase in Ly6G$^+$ neutrophil infiltration ($p < 0.01$), and a 2.5-fold increase in citrullinated histone H3 ($p < 0.001$) consistent with neutrophil extracellular trap (NET) formation. These changes were accompanied by a 2-fold elevation in serum endotoxin levels ($p < 0.01$) 3 hours after the third binge. DNase I pre-treatment conferred mucosal protection with a 2-fold increase in villous height:crypt depth ($p < 0.05$) while reducing Ly6G$^+$ neutrophil infiltration by 3.5-fold ($p < 0.05$) and NET formation by 2-fold ($p < 0.01$) compared to vehicle-treated alcohol binged mice. DNase I pre-treatment also reduced serum endotoxin levels by 2-fold ($p < 0.05$), consistent with improved intestinal barrier integrity. **Conclusion:** DNase I pre-treatment confers robust protection against alcohol-induced PSI enteropathy and microbial translocation, reflected by decreased serum LPS and preserved villous height–crypt depth ratios. These findings propose DNase I as a novel therapeutic strategy to disrupt early gut-derived inflammatory pathways that contribute to alcohol-associated liver disease.

3130 | DEFINING CLINICALLY MEANINGFUL CHANGES IN TRANSIENT ELASTOGRAPHY FOR ENDPOINT DESIGN IN METALD AND ALD TRIALS

Ellen Lyngbeck Jensen[1] Stine Johansen[2] Nikolaj Torp[2] Katrine Tholstrup Bech[2] Helle Schnefeld[2] Katrine Thorhauge[2] Ida Villesen[2] Mette Lehmann Andersen[2] Markus Maagaard[2] Peter Andersen[2] Johanne Kragh Hansen[2] Camilla Dalby Hansen[2] Aleksander Krag[2] Mads Israelsen[2], [1]Centre for Liver Research, Odense University Hospital, [2]Centre For Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital

Background: Vibration-Controlled transient elastography (VCTE) is increasingly used for monitoring and may serve as surrogate endpoint in clinical trials in patients with MetALD and ALD. The thresholds for changes in VCTE best reflecting risk of a liver-related outcome are debated, but it remains uncertain whether higher thresholds provide better prognostic value. Furthermore, therapeutic efficacy in steatotic liver disease trials has traditionally been defined by inducing fibrosis regression, while the clinical relevance of preventing progression remains less well established. We evaluated the association between changes in VCTE and subsequent hepatic decompensation, comparing different VCTE response thresholds. **Methods:** We performed a prospective longitudinal cohort study including individuals with MetALD and ALD who underwent two valid VCTE measurements at least 6 months apart and were subsequently followed for hepatic decompensation.The study evaluated candidate decrease/increase thresholds of $\geq 20\%$, $\geq 25\%$, $\geq 30\%$, $\geq 35\%$ and $\geq 40\%$ in VCTE. For decrease thresholds, hazard ratios were inverted to reflect the risk associated with not achieving the decrease threshold. Cox regression analyses adjusted for age, sex, BMI, type 2 diabetes and baseline VCTE were used to evaluate correlation between changes in VCTE and hepatic decompensation (defined by Baveno VII criteria). Subgroup analyses were performed according to baseline VCTE (< 10 and ≥ 10 kPa) and active alcohol intake status. **Results:** This study included 539 patients with baseline VCTE of 6.2 [IQR 4.7-10.6] and 34 developed hepatic decompensation during a median follow-up of 2.3 years [IQR 1.8-2.9]. The multiple candidate thresholds (20-40%) for increases in VCTE were consistently associated with subsequent hepatic decompensation with adjusted HRs ranging from 5.4-6.7 and higher response thresholds did not substantially improve prognostic discrimination. A $\geq 20\%$ increase in VCTE resulted in HR of 6.7 (95% CI: 2.6-17.5) whereas the $\geq 40\%$ threshold showed similar prognostic performance (HR 5.4, 95% CI 2.1-14.1). Similarly, across the same candidate thresholds, failure to achieve VCTE decrease thresholds was associated with increased risk of hepatic decompensation across candidate thresholds (HRs 2.3-6.3) and event rates were consistently higher in individuals with VCTE progression compared with those without progression. Associations were strongest among individuals with baseline VCTE ≥ 10 kPa and similar trends were observed among individuals with active alcohol intake.

Conclusion: Changes in VCTE reflected the risk of subsequent hepatic decompensation across multiple candidate response thresholds. More stringent response thresholds did not improve prognostic discrimination. These findings support paired VCTE measurements as clinically meaningful monitoring tools and may help inform potential surrogate endpoint definitions in MetALD and ALD trials.

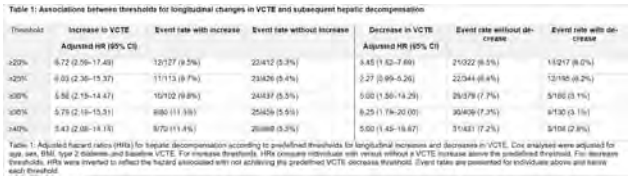

Table 1: Associations between thresholds for longitudinal changes in VCTE and subsequent hepatic decompensation

Threshold	Increase in VCTE Adjusted HR (95% CI)	Event rate with increase	Event rate without increase	Decrease in VCTE Adjusted HR (95% CI)	Event rate without decrease	Event rate with decrease
≥20%	6.72 (2.59–17.49)	12/127 (9.5%)	22/412 (5.3%)	3.45 (1.62–7.69)	21/322 (6.5%)	13/217 (6.0%)
≥25%	8.03 (2.36–15.37)	11/113 (9.7%)	23/426 (5.4%)	3.27 (0.99–6.26)	22/344 (6.4%)	12/195 (6.2%)
≥30%	5.56 (2.15–14.47)	10/102 (9.8%)	24/437 (5.5%)	5.00 (1.56–14.29)	29/379 (7.7%)	5/160 (3.1%)
≥35%	5.79 (2.16–15.51)	8/80 (11.3%)	25/459 (5.5%)	8.25 (1.79–20.00)	30/409 (7.3%)	4/130 (3.1%)
≥40%	5.43 (2.08–14.18)	8/70 (11.4%)	25/469 (5.3%)	5.00 (1.45–19.67)	31/431 (7.2%)	3/108 (2.8%)

Table 1: Adjusted hazard ratios (HRs) for hepatic decompensation according to predefined thresholds for longitudinal increases and decreases in VCTE. Cox analyses were adjusted for age, sex, BMI, type 2 diabetes, and baseline VCTE. For increase thresholds, HRs compare individuals with versus without a VCTE increase above the predefined threshold. For decrease thresholds, HRs were inverted to reflect the hazard associated with not achieving the predefined VCTE decrease threshold. Event rates are presented for individuals above and below each threshold.
