Background: The safety, tolerability, and efficacy of medications for alcohol use disorder (MAUD) in patients with alcohol-associated cirrhosis (AC) and -hepatitis (AH) in real-world settings are largely unknown. **Methods:** This was a retrospective cohort analysis of AC and AH patients newly initiated on MAUD with a minimum of 6-month follow-up from ALD-CORE, a multicenter collaborative of five centers in New York, Tennessee, and Massachusetts from 2020-2025. The outcomes were MAUD-related adverse events, DILI, discontinuation rates, change in alcohol use, and liver decompensation events. Regression analysis was completed after adjusting for medication type, history of rehabilitation, age, sex, and decompensation. **Results:** 271 patients with AC (60%), AH (15%), AC+AH (24%) were included, with a mean age of 50 years, mostly male (64%) and White (78%), and high baseline rates prior decompensation (69%). 56% of patients were on acamprosate, followed by oral naltrexone (24%), gabapentin (9%), and baclofen (3%). Most MAUD (76%) was initiated while patient was hospitalized. The overall adverse event rate from MAUD was 16%, most commonly nausea/vomiting (7.4%), without statistical difference across all MAUD or AC/AH designation. There were no significant changes in liver tests during MAUD treatment consistent with DILI. 40% of patients discontinued MAUD at six months due to self-discontinuation (39%), adverse events (27%), other MAUD therapy (20%), and lack of efficacy (11%); there was no association between reason for discontinuation and medication type, provider specialty, inpatient/outpatient setting, or duration of therapy. Per patient report, 35% patients had total abstinence and 65% had ongoing alcohol intake. AH and prior decompensation may increase likelihood of total abstinence on multivariate analysis (OR 2.71 (0.93 -7.93), p = 0.07; OR 2.3 (0.98-5.43), p = 0.06). 19.4% of patients experienced new/worsening ascites, 15.8% with new/worsening hepatic encephalopathy, and 5.2% with portal hypertensive bleeding. Though MAUD subtype and MELD were not associated with decompensation events on multivariate analysis, AH and higher albumin levels were associated with reduced decompensation rates (OR 0.1 (0.02-0.48)) while abstinence was associated with hepatic decompensation (OR 3.21 (1.07-9.61)). **Conclusion:** In this multicenter, real-world analysis, MAUD appears to be safe and reasonably tolerated in AC and AH patients, though with high rates of discontinuation. History of decompensation and AH diagnosis may increase likelihood of total abstinence by 6 months. While AH or higher albumin levels decrease decompensating events, we observed a paradoxical increase in hepatic decompensation with abstinence, which may be explained by discontinued alcohol intake with clinical decline. Future studies should investigate efficacy of MAUD with a matched cohort of AH and AC patients not on MAUD with the additional of PETH results.

3132 | HEPATOCYTE SOD1 DEFICIENCY ACCELERATES ALCOHOL-ASSOCIATED LIVER DISEASE VIA OXIDATIVE STRESS AND NEUTROPHIL ACTIVATION

Saraswathi Viswanathan[1] Vinothkumar Rajamanickam[1] Weilun Ai[1] Carol Casey[1], [1]University of Nebraska Medical Center

Background: Liver is a primary organ involved in ethanol metabolism and is highly susceptible to ethanol-induced organ injury. Evidence suggests that superoxide dismutase 1 (SOD1) plays a crucial role in protecting against alcohol-associated liver disease (ALD). Although a link exists between SOD1 and ALD, the role and mechanisms by which hepatocyte SOD1 alters liver injury upon ethanol exposure is yet to be determined. We hypothesize that deletion of SOD1 specifically in hepatocytes aggravates alcohol-induced hepatocyte oxidative stress which, in turn, enhances the progression of ALD. **Methods:** We developed conditional knock-out mice lacking SOD1 specifically in hepatocytes (Hepato-SOD$^{-/-}$ hereafter referred to as KO mice) by breeding SOD1$^{flox/flox}$ with Albumin^{Cre} mice. The littermate wild type mice (Hepato-SOD$^{+/+}$ hereafter referred to as WT mice) were used as controls. Mice were fed a Lieber-DeCarli control diet or ethanol (EtOH) diet for 1, 4 or 6 wk. **Results:** We observed an increase in plasma markers of liver injury in KO mice compared to WT mice as early as 1 week of EtOH exposure, and this increase was sustained through 6 weeks. We also noted a profound increase in the mRNA levels of inflammatory genes in the KO:EtOH mice, compared to WT:EtOH group. Moreover, Sirius red staining of liver sections revealed a pronounced increase in fibrotic lesions in KO:EtOH mice, compared to all groups, indicating that deletion of SOD1 only in hepatocytes leads to an aggravated liver injury upon EtOH exposure. The proteomics analysis in the liver samples shows that the top canonical pathways altered in KO:EtOH mice include neutrophil degranulation and NRF2-mediated oxidative stress response. The significantly altered proteins in KO:EtOH mice represent various diseases and disorders including cancer, gastrointestinal disease, and hepatic system disease. Regarding hepatotoxicity, we noted that proteins regulating hepatocellular carcinoma, liver hyperplasia/hyperproliferation, and liver steatosis are altered significantly between groups. NRF2-mediated oxidative stress response was identified as the top toxicity response in KO:EtOH mice, compared to WT:EtOH mice. **Conclusion:** Taken together, our data suggest that hepatocyte SOD1 plays an indispensable role in protecting the liver against ALD by regulating ethanol-induced oxidative stress and neutrophil

activation. Therefore, targeting SOD1 may represent a promising strategy to attenuate ALD

3133 | A CIRCULATING PROTEOMIC SIGNATURE PREDICTS DISEASE PROGRESSION IN ALCOHOL-ASSOCIATED LIVER DISEASE

Brooke Rice[1] Jay Luther[1] Wei Zhang[1] Russell Goodman[1] Esperance Schaefer[1], [1]Massachusetts General Hospital

Background: Alcohol-associated liver disease (ALD) encompasses a broad spectrum of clinical phenotypes from mild steatosis to decompensated cirrhosis. While emerging data suggest that a combination of metabolic and genetic factors may help assess risk of advanced ALD, there remains significant uncertainty in identifying those with at-risk drinking who will progress. We have previously identified a proteomic signature correlating with disease severity in ALD. In this study, we sought to determine whether circulating markers predict progression of liver disease during follow-up. **Methods:** From our cohort of 93 patients with at-risk drinking, we identified those who did not have decompensated liver disease at baseline (defined as decompensated cirrhosis and severe alcohol-associated hepatitis [AH]); we excluded those without follow-up. This discovery cohort included 46 patients (compensated cirrhosis n = 11, mild or moderate AH n = 19, and alcohol use disorder without clinically evident liver disease n = 16), with mean follow-up of 3.8 years. Disease progression was defined as decompensation of known cirrhosis, or new diagnosis of cirrhosis or severe AH. Our previously published proteins associated with ALD were quantified using the SomaScan proteomics aptamer-based platform. Analysis was performed using logistic regression and Wilcoxon Rank Sum testing. **Results:** In the discovery cohort of 46 patients, there were a total of 10 progressors identified during follow-up. Six proteins, assayed at baseline, were found to be significantly associated with disease progression: TIMP1 (OR 1.78, 1.12-2.82, p = 0.014), LTBP4 (OR 1.51, 1.05-2.16, p = 0.025), THBS2 (OR 1.07, 1.01-1.13, p = 0.029), NTN4 (OR 2.34 1.06-5.17, p = 0.036), FSTL3 (OR 1.37, 1.02 – 1.84, p = 0.037), and CXCL6 (OR 1.43, 1.01-2.01, p = 0.044). In a subgroup analysis based on index disease severity, CXCL6 was a significant predictor of development of incident cirrhosis or severe AH in patients with alcohol use disorder (OR 21.42, 1.10-418.19, p = 0.043). **Conclusion:** Circulating proteins may lend an important and clinically viable tool for risk assessment of disease progression in ALD. Importantly, these proteins also lend critical insights into the biological underpinnings of disease severity. In particular, several of these proteins (TIMP1, CXCL6, LTBP4, THBS2) have been associated with hepatic stellate cell activation, and thus represent promising candidates to non-invasively determine risk of advancing fibrosis and guide early intervention.

Protein	B1	OR (95% CI)	p value
TIMP1	0.5762	1.78 (1.12 - 2.82)	0.014

3134 | FK506 DECREASES MITOCHONDRIAL INJURY AND RELEASE OF MITOCHONDRIAL DAMAGE-ASSOCIATED MOLECULAR PATTERNS (MTDAMPS) AFTER CHRONIC-BINGE ETHANOL (CBE) TREATMENT IN MICE

Devadoss Samuvel[1] Amir Richardson[1] Li Li[1] John Lemasters[1] Zhi Zhong[1], [1]Medical University of South Carolina

Background: A pattern of chronic plus binge drinking is observed in many alcohol-associated hepatitis patients. Our previous study showed that chronic-binge ethanol treatment (CBE) leads to mitochondrial depolarization (mtDepo), dysregulation of mitophagic processing, and release of mtDAMPs. In this study we examined whether FK506 (tacrolimus), a drug that decreases mitochondrial dysfunction after acute ethanol treatment, protects the liver during CBE. **Methods:** Mice were fed a liquid diet containing 5% ethanol for 10 days and then gavaged once with ethanol (5 g/kg)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

on day 11. FK506 (1mg/kg, i.g.) was given once daily during CBE treatment. **Results:** CBE increased serum ALT from a basal level of 40 U/L to 310 U/L at the end of treatment and caused moderate hepatic steatosis, scattered necrotic cell death, and leukocyte infiltration histologically. FK506 decreased serum ALT by ~75% and also decreased steatosis, cell death, and leukocyte infiltration. After CBE, mtDepo occurred in ~80% hepatocytes. Moreover, many microvesicular and some macro-vesicular fat droplets appeared in hepatocytes. More and larger fat droplets developed in hepatocytes with mtDepo. FK506 decreased mtDepo and fat droplets after CBE. mtDepo drives Type 2 mitophagy. After CBE, mitophagic burden was high as indicated by increased PINK1 and LC3. Lysosomal degradation is needed to remove damaged mitochondria after CBE. However, TFEB, the master regulator of lysosomal enzyme expression, and LAMP2, a marker of lysosomes, decreased, suggesting suppressed lysosomal processing of mitophagosomes after CBE, which may result in release of cytotoxic, pro-inflammatory, and/or profibrotic mtDAMPs. As evidence of mtDAMP release after CBE, serum mtDNA/nuclear DNA ratios increased ~940%, and serum cytochrome *c* increased from 1.0 to 3.3ng/ml. FK506 increased TFEB and LAMP2 expression. Moreover, with FK506 treatment, serum mtDNA/nDNA ratios only increased 140%, and cytochrome *c* only increased to 1.2ng/ml. Associated with increased mtDAMP release after CBE, expression of NLRP3 (inflammasome activation) in the liver increased by ~250%, and hepatic myeloperoxidase (MPO, neutrophil marker) increased by ~370% after CBE. FK506 blunted these inflammatory reactions. **Conclusion:** Taking together, these data demonstrated that FK506 decreases liver injury and inflammation after CBE, at least in part, by suppressing mtDepo and inhibiting mtDAMP release.

3135 | ALCOHOL POTENTIATES PANOPTOSIS IN HIV-INFECTED HEPATOCYTES THROUGH ZBP1-ASSOCIATED SIGNALING PATHWAYS

Lukman Adepoju[1] Anup Pathania[1] Grace Bybee[1] Natalia Osna[1], [1]University of Nebraska Medical Center

Background: Alcohol use disorder accelerates liver disease progression in people living with HIV (PLWH), yet the mechanisms driving hepatocyte injury remain poorly understood. PANoptosis pathways, including apoptosis, necroptosis, and pyroptosis, contribute to inflammatory liver injury. Z-DNA-binding protein 1 (ZBP1), an innate immune sensor involved in inflammatory and lytic cell death signaling, may regulate these pathways during HIV-alcohol hepatotoxic stress. This study investigated activation of oxidative stress and programmed cell death signaling in alcohol-pretreated HIV-infected hepatocytes and evaluated the role of ZBP1. **Methods:** Huh7.5-CYP2E1 were pretreated with acetaldehyde-generating system (AGS) and infected with HIV-1 $_{ADA}$ at a multiplicity of infection (MOI) of 0.1. Cells were harvested at days 1, 3, and 5 post-infection to assess hepatocyte injury and regulated cell death signaling. Cell viability, cytotoxicity, and reactive oxygen species (ROS) assays were evaluated using MTT, lactate dehydrogenase (LDH) release, DCFDA-based assays respectively. Expression of cleaved caspase-3, cleaved PARP, RIPK3, pMLKL, NLRP3, caspase-1, gasdermin D, IL-1β, and IL-18 was analyzed by immunoblotting and molecular assays. Based on timed profiling, days 1 and 3 were selected for mechanistic studies using caspase-1, caspase-3, necrostatin-1 inhibitors and ZBP1 gene silencing. **Results:** AGS pretreatment increased HIV infected hepatocyte injury compared with HIV infection alone. MTT assays reduced viability, while LDH release assays showed increased cytotoxicity at day 3 post-infection. DCFDA analysis revealed significantly elevated ROS production in AGS-pretreated HIV-infected hepatocytes. Analysis demonstrated peak activation of PANoptosis pathways at day 3 by increased cleaved caspase-3 and cleaved PARP expression. Necroptotic activation was confirmed by elevated RIPK3 and pMLKL expression, while pyroptotic activation was associated with increased NLRP3 signaling, caspase-1 activation, gasdermin D cleavage, and elevated IL-1β and IL-18 expression. Caspase-3 inhibition attenuated apoptotic activation, caspase-1 inhibition reduced pyroptotic responses, and necrostatin-1 decreased necroptotic signaling. Importantly, ZBP1 silencing significantly attenuated oxidative stress, inflammatory signaling, and PANoptosis activation **Conclusion:** These findings demonstrate that alcohol-associated stress potentiates HIV-induced hepatocyte injury through coordinated activation of oxidative stress and multiple regulated cell death pathways. Peak hepatotoxic signaling at day 3 post-infection suggests a critical temporal window for inflammatory liver injury progression. ZBP1 silencing identifies ZBP1 as a key upstream mediator of HIV/alcohol-associated hepatocyte injury and a potential therapeutic target for reducing liver disease progression in PLWH with alcohol use disorder.

3136 | EXPLORING THE ROLE OF RECEPTOR-INTERACTING PROTEIN KINASE 1 UBIQUITINATION IN INFLAMMASOME ACTIVATION IN ALCOHOL-ASSOCIATED LIVER DISEASE

Uttam Ojha[1] Megan McMullen[1] Emily Huang[1] Vai Pathak[1] Adam Kim[2] Srinivasan Dasarathy[1] Laura Nagy[3], [1]Cleveland Clinic, [2]UConn Health, [3]Cleveland Clinic Foundation

Background: Alcohol-associated liver disease (ALD) is driven by inflammation and regulated cell death, but effective therapies remain limited. Receptor-interacting protein kinase 1 (RIP1) regulates inflammatory signaling and cell fate through scaffold and kinase functions controlled by post-translational modifications, including ubiquitination, and operates in coordination with RIP3 in necroptotic signaling pathways. Although RIP1 is classically activated through TNF-α/TNFR1 and non-canonically through TLR4, the role of RIP1 ubiquitination in inflammasome activation in ALD remains unclear. We investigated RIP1 ubiquitination and its regulatory mechanisms in ALD, focusing on immune cells and inflammasome signaling. **Methods:** Murine ALD models and liver samples from patients with alcohol-associated hepatitis (AH) were analyzed using tandem ubiquitin-binding entity (TUBE) pull-down assays to assess RIP1 ubiquitination. Bulk and single-cell RNA sequencing datasets were used to define E3 ligases and deubiquitinases regulating RIP1 signaling in liver and peripheral blood mononuclear cells (PBMCs). Mechanistic studies were performed in THP-1 monocytes stimulated with TNF-α ± ethanol. Inflammasome activation was assessed by ASC speck formation in THP1-ASC-GFP cells and IL-1β ELISA in THP-1 cells. siRNA knockdown and pharmacologic inhibition were used to define the downstream functional outcomes. **Results:** RIP1 ubiquitination was reduced in murine ALD and AH patient livers compared with healthy controls. Transcriptomic analysis revealed dysregulation of RIP1-associated ubiquitin enzymes in liver and PBMCs, identifying TNFAIP3/A20 as a potential candidate. In THP-1 cells, A20 knockdown decreased TNF-α–induced RIP1 ubiquitination and enhanced inflammasome activation, with increased ASC speck formation and IL-1β release, further amplified by ethanol. RIP1 knockdown or RIP1 kinase inhibition with necrostatin-1 suppressed inflammasome activation, whereas RIP3 kinase inhibition had no effect, indicating a RIP3-independent role for RIP1. **Conclusion:** RIP1 ubiquitination is disrupted in ALD and regulates inflammasome activation in immune cells via a RIP3-independent mechanism. These findings identify ubiquitination-dependent RIP1 signaling as a potential therapeutic target in alcohol-associated liver inflammation.

3137 | HOW PATIENTS WITH ALCOHOL-RELATED LIVER DISEASE FEEL AND FUNCTION: TOWARD A LITERATURE-INFORMED PATIENT-REPORTED OUTCOME

Yekaterina Poloz[1] Farrah Pompilus[1] Helen Smith[1] Samantha Linton[2] Nina Galipeau[2] Benjamin Banderas[2] Daniella Olonilua[2] Nikhil Vergis[1] Dharmraj Sauriyal[1], [1]GSK, [2]Adelphi Values

Background: Patients with alcohol-related liver disease (ALD) experience numerous signs, symptoms, and health-related quality of life (HRQoL) impacts, such as physical function decline. However, a validated patient-reported outcome (PRO) in ALD does not exist. We aimed to characterize the patient experience of ALD via a literature-based conceptual model to inform development of a novel PRO. **Methods:** A targeted, concept-focused literature review was conducted in OvidSP (supplement searches: Google, Google Scholar, PubMed) to identify and synthesize evidence on ALD-relevant concepts and PROs. Eligible publications describing ALD-related signs, symptoms, and HRQoL impacts underwent full-text review. Identified concepts were mapped to existing PROs and used to create a conceptual model, which informed initial development of a novel PRO for ALD. **Results:** The OvidSP search identified 251 abstracts (n = 6, full-text review); supplemental searches identified 16 publications (n = 3, full-text review). Across 9 publications, 38 signs and symptoms were identified; 18 were deemed suitable for PRO report. Most frequently reported were: fatigue and jaundice (n = 6/9 publications each, 66.7%), ascites (n = 5/9, 55.5%), and encephalopathy (n = 4/9, 44.4%). Among 41 identified HRQoL impacts, the most frequently reported were: depression (n = 4, 44.4%), feeling stigmatized, and cognitive impairment (n = 3 each, 33.3%). The search yielded 46 PROs: 36 from the targeted OvidSP instrument-identification search (172 screened abstracts) and 10 from the supplemental search. Five underwent concept mapping: Chronic Liver Disease Questionnaire (CLDQ; 29 items), PRO Measurement Information System version 29 (PROMIS-29), Liver Disease Symptom Index version 2.0 (LDSI 2.0), Liver Cirrhosis Patient-Reported Outcome Measure (LC-PROM; 55 items), and Sickness Impact Profile 68 (SIP-68; 68 items). LC-PROM provided the most conceptual coverage of signs and symptoms (n = 10/18 concepts, 55.6%), followed by CLDQ (n = 7/18, 39.4%).

SIP-68 provided the most conceptual coverage of HRQoL impacts (n = 14/41 concepts, 34.2%), followed by LC-PROM (n = 12/41, 29.3%), and PROMIS-29 (n = 10/41, 24.4%). Of the identified concepts, 33 (18 signs and symptoms, 15 HRQoL impacts) were included in a draft novel PRO. **Conclusion:** Existing PROs do not adequately capture the identified ALD-related signs, symptoms, and HRQoL impacts. Qualitative research is underway to further understand the patient experience of ALD and evaluate the novel PRO.

3138 | SASP PROFILING REVEALS SHARED AND ETIOLOGY-SPECIFIC SENESCENCE SIGNATURES IN ALD AND MASLD BEFORE AND AFTER LIVER TRANSPLANTATION

Kianna Nguyen[1] Douglas Simonetto[2] Timucin Taner[2] Ethan Leitschuh[2] Marissa Schafer[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Cellular senescence and its proinflammatory secretome, the senescence-associated secretory phenotype (SASP) contribute to chronic liver diseases pathogenesis across etiologies. Whether circulating SASP profiles attenuate after restoration of hepatic function, and whether they differ by underlying etiology remains unexplored. Thus, we characterized the SASP before and after liver transplantation in patients with alcohol-associated liver disease (ALD) and metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** Plasma samples from patients with ALD (n = 24) and MASLD (n = 21) pre-transplant and one-year post-transplant were profiled using the Luminex Discovery Assay to assess a panel of 31 SASP proteins. Pre-and post-transplant protein levels were analyzed by paired analysis with Benjamini-Hochberg FDR-adjusted p-values to account for multiple hypothesis testing. **Results:** Baseline characteristics were similar between the ALD and MASLD groups with a median age of 56 years, 73% male sex, and a median MELD score of 21. Compared with paired pre-transplant baseline, 9 proteins were differentially expressed post-transplant in the plasma of patients with MASLD and 13 proteins in patients with ALD. Both groups showed down regulation of CCL20, GDF-15, HGF, IL-6, MMP-2, MMP-8, and MMP-10 (median fold change 0.41 to 1.54) with increased detection of IGFBP-3 (fold change 1.85). IL-8 was also downregulated in patients with MASLD (fold change 1.14). In ALD, MMP-9 and TRAIL were additionally downregulated while PDGF-AA, PDGF-AB/BB, and TRAIL were upregulated (fold change 0.26 to 3.54). **Conclusion:** Attenuation pro-inflammatory (IL-6, CCL20), matrix remodeling (MMP-2, MMP-8, MMP-10) and hepatocyte injury-associated (HGF, GDF-15) SASP factors after transplantation suggest a core senescence signature of advanced liver disease. Etiology-specific findings, particularly persistent upregulation of pro-fibrogenic PDGF isoforms in ALD, implicate distinct, residual senescence biology that endures beyond removal of the diseased liver. SASP profiling helps define etiology-targeted senolytics or senomorphic strategies in cirrhosis.

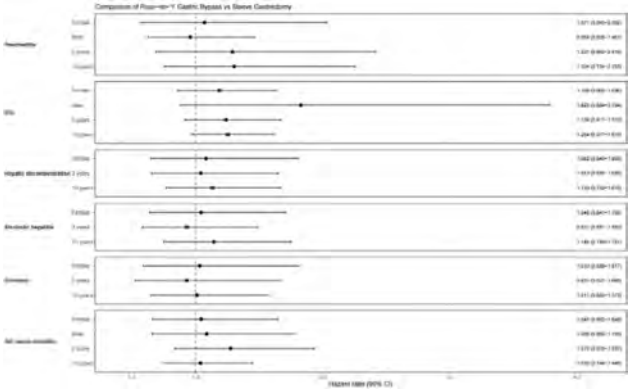
3139 | IMPACT OF BARIATRIC SURGERY TYPE ON LIVER OUTCOMES IN ALCOHOL USE DISORDER



Donghyun Ko[1] Muhammad Khalid[2] Denisa Costea[3] Jose Porres[4] Sonaal Singla[5] Do Han Kim[3] Frank Lukens[6] Lamia Haque[7], [1]Bridgeport Hospital, [2]Department of Medicine, Bridgeport Hospital, Yale New Haven Health, Bridgeport, CT, [3]Department of Medicine, Mount Sinai Morningside and West, Icahn School of Medicine at Mount Sinai, [4]Universidad Francisco Marroquin, School of Medicine, Guatemala City, Guatemala, [5]Department of Medicine, University of California Riverside, Riverside, CA, [6]Division of Gastroenterology and Hepatology, Mayo Clinic Florida, Jacksonville, FL, [7]Yale School of Medicine

Background: The benefits of bariatric surgery (Roux-en-Y gastric bypass [RYGB] and sleeve gastrectomy [SG]) are well-known, including substantial weight loss and improvements in complications related to obesity. However, physiological and anatomical changes that result from this surgery affect alcohol absorption and metabolism, leading to adverse effects in patients with alcohol use disorder (AUD). There is little known regarding whether the impact of these changes varies based on the type of bariatric surgery. This study aims to compare liver-related outcomes among patients with AUD who underwent RYGB versus SG. **Methods:** This retrospective cohort study was performed using TriNetX. The study population consisted of adult patients

with a diagnosis of AUD according to ICD 10 codes identified on or before December 31, 2020. Patients with underlying chronic liver disease according to ICD 10 codes before the index events were excluded. Demographic characteristics, comorbidities, medications, and laboratory variables were included for balancing both groups using propensity score matching. Primary outcomes were mortality, incidence of cirrhosis, and alcohol-associated hepatitis. Secondary outcomes were hepatic decompensation, critical care admission, and acute alcohol-associated pancreatitis. Cox proportional hazards models were used for all analyses. **Results:** Initial search yielded a total of 2,452 patients with AUD, of whom 965 patients had a history of RYGB and 1,487 had a history of SG. At 5-year follow-up, there were no statistically significant differences in mortality (HR 0.970; 95% CI, 0.682—1.378), cirrhosis (HR 0.934; 95% CI, 0.588—1.484), and alcohol-associated hepatitis (HR 1.045; 95% CI, 0.670—1.630). Secondary outcomes did not demonstrate statistically significant differences. Subsequent sensitivity analyses were consistent with the primary findings. **Conclusion:** Patients with AUD who underwent RYBG and SG had similar rates of mortality and liver-related complications. These findings suggest that procedure type alone may not independently determine risk of adverse liver-related outcomes in this population. Further research measuring patterns of alcohol consumption via self-report and direct alcohol biomarkers is needed to further characterize the association between bariatric surgery type and liver-related outcomes among patients with AUD.

3140 | DECOMPOSING THE POST-PANDEMIC RISE IN LIVER FIBROSIS BURDEN IN THE UNITED STATES: STRUCTURAL RATHER THAN POPULATION COMPOSITION EFFECTS

Omar Albhaisi[1] Ayah Albhaisi[2] Lea Assaf[3] Ali Khan[1] Krishan Patel[1] Butros Fakhoury[1] Hannah Blaney[1] Luis Antonio Diaz[4] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Alexandria Faculty of Medicine, [3]American University of Beirut, [4]Pontificia Universidad Católica de Chile

Background: Liver fibrosis burden increased in the United States following the COVID-19 pandemic; however, the relative contributions of alcohol exposure, metabolic dysfunction, demographic composition, and changing fibrosis-risk relationships remain unclear. We quantified contributors to rising fibrosis burden using formal decomposition methods in a nationally representative cohort. **Methods:** We analyzed adults aged 18–80 years undergoing vibration-controlled transient elastography (VCTE) in NHANES 2017–2023. Significant fibrosis was defined as liver stiffness measurement (LSM) $\geq$8 kPa and advanced fibrosis as LSM $\geq$12 kPa. Steatotic liver disease phenotypes were classified according to 2023 multi-society nomenclature criteria (No SLD, MASLD, MetALD, ALD). Survey-weighted analyses assessed trends in metabolic burden, alcohol exposure, and fibrosis prevalence. Three-component Oaxaca-Blinder decomposition quantified fibrosis changes attributable to shifts in population risk-factor distribution versus changes in fibrosis-risk associations. The analytic cohort included 13,167 adults; decomposition analyses were restricted to 11,127 participants with complete covariate data. **Results:** Significant fibrosis increased from 9.0% pre-pandemic to 11.4% post-pandemic (+2.43 percentage points [pp]), while advanced fibrosis increased from 3.4% to 4.4% (+1.06 pp). Alcohol exposure increased substantially across periods, including annual binge drinking and severe episodic drinking, whereas overall metabolic burden remained stable. For significant fibrosis, population composition changes did not explain the observed increase (composition effect: −0.36 pp, 95% CI −0.95 to 0.23; p = 0.23), whereas amplified associations between established risk factors and fibrosis accounted for the entirety of the increase (structure effect: +2.84 pp, 95% CI 1.24 to 4.45; p = 0.0005). Structural effects explained 117.0% of the observed fibrosis increase, while compositional shifts contributed −14.9%. Similar patterns were observed for advanced fibrosis (composition: −0.05 pp [−5.2%]; structure: +1.23 pp [116.0%]). Sensitivity analyses

incorporating binge drinking demonstrated consistent findings. **Conclusion:** Rising liver fibrosis burden in the United States was not primarily explained by changes in population composition, alcohol exposure distribution, or metabolic burden. Instead, strengthened associations between established risk factors and fibrosis accounted for most of the observed increase. These findings suggest that post-pandemic fibrosis trends may reflect evolving susceptibility to established risk factors — potentially including synergistic alcohol-metabolic interactions — and highlight the need to identify emerging determinants of fibrosis progression.

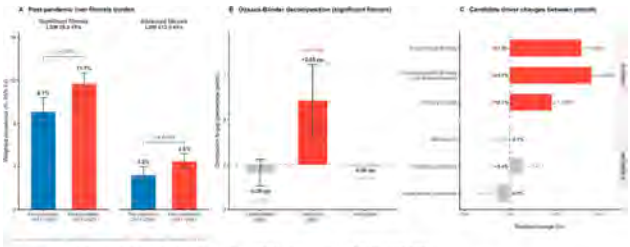

Figure 1. Post-pandemic liver fibrosis burden and Oaxaca-Blinder decomposition — NHANES 2017–2023.
(A) Weighted prevalence of significant fibrosis (LSM ≥8.0 kPa) and advanced fibrosis (LSM ≥12.0 kPa) in pre-pandemic (2017–2020) and post-pandemic (2021–2023) NHANES cycles (N = 13,167). Error bars represent 95% confidence intervals. **(B)** Three-component Oaxaca-Blinder decomposition of the observed significant fibrosis increase (+2.43 percentage points) into composition effects (changes in population risk factor distribution), structural effects (changes in associations between risk factors and fibrosis), and interaction. Decomposition N = 11,127 complete cases; bootstrap standard errors (R = 300). Error bars represent 95% confidence intervals for composition and structural effects. **(C)** Relative percent change in candidate drivers between periods. Red bars indicate statistically significant increases (p < 0.05); gray bars indicate non-significant changes.
LSM = liver stiffness measurement; **SLD** = steatotic liver disease; **pp** = percentage points.

3141 | PROTON PUMP INHIBITORS USE IN HOSPITALIZED PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS IS ASSOCIATED WITH HIGHER RATES OF LIVER DECOMPENSATION, MORTALITY, AND INFECTIOUS COMPLICATIONS COMPARED TO H2-RECEPTOR ANTAGONISTS: A PROPENSITY SCORE-MATCHED ANALYSIS

Karim Adhem[1] Osamah Salim[2] Hamza Salim[3] Mazen Elsheikh[1] Sherry Fares[1] Mohamad Ali Ibrahim[1] Youseph Karouni[1] Megha Bhongade[1] Ximena Ramirez Morales[1] Prasun Jalal[1], [1]Baylor College of Medicine, [2]Sam Houston State University College of Osteopathic Medicine, [3]Department of Gastroenterology and Hepatology, University of Texas Medical Branch, Galveston, TX

Background: Proton Pump Inhibitors (PPIs) are frequently prescribed during inpatient hospitalizations, often initiated empirically for stress ulcer prophylaxis. In patients hospitalized with Alcohol-associated Hepatitis (AH), the choice of acid suppression carries particular significance given the compromised hepatic reserve, systemic inflammation, and susceptibility to infectious complications. Despite the prevalence of PPI prescribing in this setting, comparative effectiveness data against H2-receptor antagonists (H2RAs) in AH remain limited. **Methods:** Using TriNetX (111 healthcare organizations), we identified adult patients hospitalized with AH (ICD-10 K70.1) between January 2015 and January 2026 receiving either a PPI (n = 6,008) or H2RA (n = 677) within 7 days of admission. Patients with prior GI bleeding, peptic ulcer disease, or prior use of the comparator agent were excluded. Propensity score matching on 33 characteristics—including demographics, sepsis, liver fibrosis/cirrhosis, disease severity markers (bilirubin, INR, creatinine, sodium), and baseline medications—yielded matched cohorts of 673 patients each with standardized mean difference (SMD) < 0.1. Outcomes including composite hepatic decompensation, ascites, hepatic encephalopathy (HE), mortality, pneumonia, and renal impairment were assessed at 90 days, 6 months, and 1 year. **Results:** PPI-treated patients demonstrated significantly worse outcomes across all time points. At 90 days, PPI use was associated with higher risks of ascites (RR 2.74, p < 0.001) and mortality (RR 1.57, p = 0.001). At 6 months, PPI patients had higher rates of composite decompensation (RR 1.87, p = 0.039), ascites (RR 2.86, p < 0.001), HE (RR 3.22, p < 0.001), mortality (RR 1.46, p = 0.002), pneumonia (RR 3.00, p = 0.001), and renal impairment (RR 3.72, p < 0.001). At 1 year, all differences remained significant, with notably elevated risks of renal impairment (RR 4.03), HE (RR 3.30), and pneumonia (RR 2.40). Kaplan-Meier analysis confirmed lower event-free survival in the PPI cohort across all outcomes (log-rank p < 0.05). **Conclusion:** In a large propensity-matched cohort of hospitalized AH patients, PPI use was associated with substantially worse hepatic, infectious, and renal outcomes compared to H2RAs at all follow-up intervals. These findings suggest H2RAs may represent a safer alternative for acid suppression in this population and challenge the routine empiric use of PPIs during AH hospitalizations.

3142 | RISK OF DEVELOPING ALCOHOL-ASSOCIATED LIVER DISEASE IN PATIENTS WITH ALCOHOL USE DISORDER IN THE UNITED STATES

George Cholankeril[1] Robert Taylor[2] Ramzi Argoubi[2] Fasiha Kanwal[3] Aaron Thrift[1] Hashem El-Serag[1], [1]Baylor College of Medicine, [2]Oracle Health and Life Sciences, [3]Michael E. DeBakey VA Medical Center

Background: Patients with alcohol use disorder (AUD) are at elevated risk for alcohol-associated liver disease (ALD), but real-world estimates of ALD incidence and determinants are limited. We estimated risk of developing ALD among patients with AUD and identified factors associated with incident ALD. **Methods:** We used the Oracle Health Real World Data, a nationally representative database comprising over 100 million U.S. adults, to identify adults with hospital or outpatient encounters for alcohol use disorder (AUD) and/or alcohol-associated liver disease (ALD) between January 2015 and April 2025. For incidence analyses, adults with AUD were identified using ICD-9/10 codes, and AUD index dates were defined as the first qualifying encounter. Adults with prior ALD and those with AUD or ALD evidence during a 12-month baseline period before the index date were excluded. Non-AUD controls were matched 3:1 to AUD patients by age, sex, U.S. region, and race/ethnicity. Incident ALD was assessed after the AUD index date. Annual age-adjusted prevalence estimates of ALD and cardiometabolic risk factors were calculated. Cumulative incidence, incidence rates per 100 person-years, and Fine-Gray subdistribution hazard ratios (sHRs) were estimated, with death and liver transplantation treated as competing events. **Results:** The matched cohort included 1,106,101 AUD patients and 3,318,303 non-AUD controls. Among AUD patients, ALD developed in 231,987 (20.9%) compared with 175,966 (5.3%) controls. The crude ALD incidence rate was 1.69 per 100 person-years (95% CI, 1.67–1.70). Compared with AUD patients who did not develop ALD, those who developed ALD were more frequently male (67.6% vs 55.0%), aged 40–64 years (58.7% vs 47.3%), and had higher prevalences of chronic hepatitis C (12.4% vs 4.8%), diabetes (19.8% vs 14.9%), and hypertension (43.7% vs 37.9%).In multivariable analyses among patients with AUD (Table 1), the strongest predictors of developing ALD were chronic hepatitis C (aHR 2.45, 95% CI 2.31–2.59), age 40–54 years (aHR 1.78, 95% CI 1.74–1.82), American Indian race/ethnicity (aHR 1.68, 95% CI 1.62–1.74), chronic hepatitis B (aHR 1.41, 95% CI 1.13–1.76), and heart failure (aHR 1.31, 95% CI 1.26–1.37). Diabetes and hypertension were also associated with increased risk. Conversely, GLP-1–based therapies (aHR 0.50, 95% CI 0.45–0.56) and statin use (aHR 0.58, 95% CI 0.57–0.60) were associated with lower ALD risk. **Conclusion:** In a nationally representative US real-world cohort, more than 7% of patients with AUD developed ALD within 5 years. Chronic viral hepatitis and cardiometabolic comorbidities were major risk factors, whereas GLP-1–based therapies and statin use were associated with substantially lower ALD risk. These findings identify potentially modifiable factors that may help guide risk stratification and prevention efforts and warrant prospective evaluation of metabolic therapies for ALD risk

3143 | GRAPHENE OXIDE NANOPARTICLES MITIGATE ETHANOL-INDUCED LIVER INJURY BY MODULATING MIR 21, MIR-122 AND MIR-214–ASSOCIATED AUTOPHAGY PATHWAYS

Hiral Aghara[1] Palash Mandal[2], [1]P D Patel Institute of Applied Science, [2]P D Patel Institute of Applied Sciences

Background: Alcohol-associated liver disease (ALD) is characterized by hepatic lipid accumulation, inflammation, and impaired autophagy, leading to progressive liver injury. Dysregulation of microRNAs (miRNAs), including miR-21, miR-122, and miR-214, plays a key role in regulating lipid metabolism and inflammatory responses during ethanol-induced liver damage. Graphene oxide nanoparticles (GNPs) have emerged as biologically active nanomaterials with the potential to modulate cellular stress responses. This study aimed to evaluate whether GNPs mitigate ethanol-induced liver injury by restoring autophagy through miRNA modulation. **Methods:** In vitro studies were performed using HepG2 hepatocyte cells exposed to ethanol, followed by GNP treatment. The protective effects of GNPs were assessed using Oil Red O staining and analysis of autophagy and inflammation-associated mRNA expression. To assess in vivo relevance, male Wistar rats were fed a liquid diet containing 5% ethanol for 28 days. During the ethanol-feeding period, rats received oral administration of GNPs (10 mg/kg, water suspended) at 5-day intervals. Hepatic injury was evaluated using serum biochemical parameters, histopathological assessment, and lipid staining. Hepatic mRNA expression of autophagy- and inflammation-related genes, along with miRNA expression profiling (miR-21, miR-122, and miR-214), was performed at the end of the study. **Results:** Ethanol exposure induced significant lipid accumulation and suppression of autophagy associated mRNA expression in HepG2 cells, accompanied by increased inflammatory gene expression. GNP treatment markedly reduced intracellular lipid accumulation and restored autophagy-related mRNA expression. In vivo, chronic ethanol feeding resulted in hepatic steatosis, elevated serum biochemical markers of liver injury, and histological evidence of liver damage. GNP administration significantly attenuated these effects, reducing hepatic lipid accumulation and improving liver histology. Ethanol-induced dysregulation of hepatic miRNAs, characterized by decreased miR-122 and increased miR-21 and miR-214 expression, was normalized following GNP treatment. These changes were associated with restoration of autophagy-related mRNA expression and attenuation of inflammatory signalling. **Conclusion:** Graphene oxide nanoparticles mitigate ethanol-induced liver injury by modulating miR-21, miR-122, and miR-214–associated autophagy pathways. These findings support GNPs as a protective nanoplatform for limiting disease progression in alcohol-associated liver disease.

3144 | TRENDS AND CLINICAL CORRELATES OF PHOSPHATIDYLETHANOL TESTING DURING LIVER TRANSPLANT EVALUATION

Natalia Salinas Parra[1] Marina Serper[2] Nadim Mahmud[1], [1]Hospital of the University of Pennsylvania, [2]University of Pennsylvania Health System

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Phosphatidylethanol (PEth) is a highly sensitive direct biomarker of recent alcohol use and is increasingly used during liver transplant evaluation. However, patterns of PEth testing and associations with transplant evaluation outcomes remain incompletely described. We evaluated PEth testing practices, patient-level predictors of testing, and associations between PEth results and waitlisting/transplantation among adults undergoing liver transplant evaluation at a large academic transplant center. **Methods:** We performed a retrospective cohort study of adults undergoing initial liver transplant evaluation from 2016-2026. PEth testing was defined as any PEth assay obtained within ±90 days of evaluation. PEth results were categorized as no PEth, negative/<20 ng/mL, 20-199 ng/mL, and ≥200 ng/mL. Patient demographics, metabolic comorbidities, liver disease etiology, evaluation setting, waitlisting, and transplantation outcomes were extracted from institutional transplant and EHR data. Multivariable logistic regression assessed predictors of PEth testing and associations between PEth category and transplant outcomes. **Results:** Among 3,028 liver transplant evaluation patients, 874 (28.9%) underwent PEth testing within ±90 days. Among tested patients, 719 (82.3%) were negative/<20 ng/mL, 97 (11.1%) had PEth 20-199 ng/mL, and 55 (6.3%) had PEth ≥200 ng/mL; 3 results were uninterpretable. PEth testing was more common among patients with ALD or MetALD and among those evaluated in inpatient/recent inpatient settings. In multivariable analysis, compared with HCV, PEth testing was more likely among patients with MASLD, ALD, MetALD, and other/unknown liver disease, and less likely among outpatient evaluations. Listing decreased stepwise with increasing PEth category: 26.6% of patients with negative/<20 PEth were listed compared with 15.5% with PEth 20-199 ng/mL and 1.8% with PEth ≥200 ng/mL (**Table 1**). Transplantation similarly declined across PEth categories: 12.1%, 6.2%, and 0%, respectively. After adjustment, PEth ≥20 ng/mL was associated with lower odds of listing (OR 0.28, 95% CI 0.15-0.52) and transplantation (OR 0.20, 95% CI 0.07-0.56) among tested patients. **Conclusion:** In this single-center cohort of adults undergoing liver transplant evaluation, PEth testing was performed in approximately one-third of patients and was strongly associated with alcohol-related liver disease phenotypes and evaluation setting. Positive PEth results were associated with markedly lower likelihood of waitlisting and transplantation. These findings highlight the growing role of PEth in transplant evaluation and support further study of how biomarker-based alcohol assessment influences candidate selection, equity, and transplant outcomes.

Table - PEth Testing Results and Transplant Outcomes Among Adults Undergoing Liver Transplant Evaluation

Key measure	Result
Total liver transplant evaluations	3,028
PEth checked within ±90 days	874 / 3,028 (28.9%)
No PEth checked	2,154 / 3,028 (71.1%)
Negative / <20 ng/mL among tested	719 / 874 (82.3%)
PEth 20–199 ng/mL among tested	97 / 874 (11.1%)
PEth ≥200 ng/mL among tested	55 / 874 (6.3%)
Listed: negative / <20	26.6%
Listed: PEth 20-199	15.5%
Listed: PEth ≥200	1.8%
Transplanted: negative / <20	12.1%
Transplanted: PEth 20-199	6.2%
Transplanted: PEth ≥200	0.0%
Adjusted OR for listing, PEth ≥20 vs <20	0.28 (95% CI 0.15-0.52)
Adjusted OR for transplant, PEth ≥20 vs <20	0.20 (95% CI 0.07-0.56)

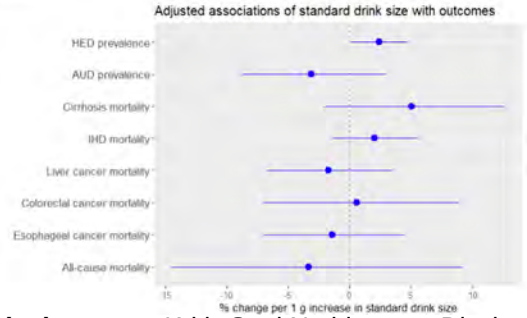
3145 | DOES STANDARD DRINK SIZE INFLUENCE HEAVY EPISODIC DRINKING? A CROSS-NATIONAL MULTIVARIABLE ECOLOGICAL ANALYSIS

Kriti Soni[1] Rylyn Reyes[1] Ximena Parraga[1] Denisse Rubio Cruz[2] S. Fisher Rhoads[1] Adelina Horhat[3] Hyundam (Dami) Gu[1] Joshua Chen[1] Vinay Jahagirdar[1] Kavin Parmar[1] Krishan Patel[1] Stephen Hoang[1] Luis Díaz[4] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]Lahey Hospital; Virginia Commonwealth University, [3]Department of Hepatology, Henri Mondor University Hospital, [4]Pontificia Universidad Católica de Chile



Background: Standard drink definitions are central to quantifying alcohol exposure in epidemiologic surveillance, clinical guidance, and alcohol control policies, yet they vary widely across countries. Because thresholds for heavy drinking and self-reported alcohol intake are commonly framed in “drinks,” larger national drink definitions may alter population-level estimates of alcohol exposure and drinking behavior. Whether variation in standard drink size is associated with heavy episodic drinking and alcohol-related outcomes has not been systematically evaluated. **Methods:** Data were obtained from the 2024 WHO Global Status Report on Alcohol and Health,the WHO Global Information System on Alcohol and Health, the World Bank, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

national guidelines. Disease prevalence and mortality data were obtained from the Global Health Data Exchange from the years 2017-2023, excluding 2020 and 2021. Unadjusted and multivariable linear regression models were used to assess the relationship between national standard drink size (in grams of ethanol) and the following outcomes across 64 countries: heavy episodic drinking (HED) prevalence, alcohol use disorder (AUD) prevalence, cirrhosis mortality, and other alcohol-attributable outcomes. Multivariable models adjusted for alcohol per capita consumption (APC), GDP per capita (log-transformed), GINI coefficient, and WHO region. Robust standard errors were used to address heteroskedasticity in the regression. Within-region analyses were conducted to evaluate whether associations were driven by between-region variation. **Results:** In the unadjusted models, standard drink size was not significantly associated with any outcome. After multivariable adjustment, standard drink size was positively associated with HED prevalence (?? = 0.651, robust p = 0.048). The HED estimate was minimally impacted by APC adjustment (?? = 0.702 without vs. ?? = 0.651 with APC included), suggesting independence from total consumption volume. The cirrhosis mortality association was positive in the conventional model (?? = 0.049, p = 0.039) but attenuated to non-significance with robust standard errors (robust p = 0.178). No significant associations were observed for AUD prevalence, IHD, liver cancer, colorectal cancer, esophageal cancer, or all-cause mortality. Within-region analyses indicated no significant association between standard drink size and HED in any WHO region, indicating overall association was driven by between-region variation. **Conclusion:** Our findings show that a 1g increase in a country's standard drink definition is associated with an increase in HED prevalence by 0.65%. There is an association between a country's standard drink size and cirrhosis mortality.

Figure 1. Forest plot for adjusted association of standard drink definition (per 1 g increase) with each outcome.

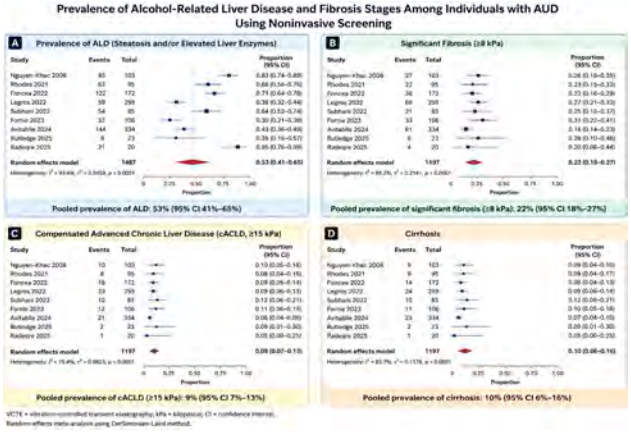
3146 | DETECTING ALCOHOL-RELATED LIVER DISEASE IN INDIVIDUALS WITH ALCOHOL USE DISORDER: A SYSTEMATIC REVIEW AND META-ANALYSIS



David Maundu[1] Mohamed Omar[2] Manisha Verma[3] Aleksander Krag[4] Zobair Younossi[5] Mary Rinella[6] Winston Dunn[7] Ashwani Singal[8], [1]University of Kansas School of Medicine–Wichita,, [2]University of Kansas School of Medicine–Wichita, [3]SKMC, Thomas Jefferson University, [4]University of Southern Denmark, [5]The Global NASH/MASH Council, [6]The University of Chicago, [7]University of Kansas Medical Center, [8]University of Louisville

Background: Alcohol-associated liver disease (ALD) in individuals with alcohol use disorder (AUD) frequently presents at an advanced stage with cirrhosis and /or complications. Detecting ALD at an early stage and controlling AUD prevents the development of cirrhosis. This systematic review and meta-analysis aims to determine the prevalence and stage of inapparent ALD through noninvasive screening in individuals with AUD **Methods:** A literature search using Embase and PubMed through April 2026 was performed for studies on adults with AUD receiving noninvasive fibrosis assessment (kilopascals, kPa), primarily by vibration-controlled transient elastography (VCTE), were included. Data were pooled for a) prevalence of ALD defined by steatosis and/or elevated liver enzymes, b) ALD fibrosis stage [significant fibrosis, ≥8 kPa; compensated advanced chronic liver disease or cACLD, ≥15 kPa; and cirrhosis], c) follow-up in a liver clinic, d) abstinence, and e) mortality. Random-effects meta-analysis was performed using Der Simonian–Laird models. Heterogeneity was evaluated using the I^2 statistic. **Results:** 24 studies (12 abstracts) on 53,156 individuals with AUD were included. The pooled prevalence of ALD was 53% (95% CI 41%–65%). Fibrosis stage, assessed with VCTE, was 22% (18–27%) for significant fibrosis, 9% (7–13%) for cACLD, and 10% (6–16%) for cirrhosis. The detection yield was higher in inpatient settings compared to addiction services (48% versus 35%). All analyses showed heterogeneity (I^2 > 50%), which was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

reduced after excluding outliers, and when comparing abstracts vs. full-text publications, with the estimates remaining similar. Further, screening for ALD was associated with liver clinic follow-up in 68% (49–82%) of cases and abstinence at follow-up in 38% (31–45%) of cases. In three studies, a repeat VCTE after abstinence showed a mean reduction of 0.62 (0.34-0.91) kPa. The mortality rate, based on two studies with a median follow-up period of 10.5 months, was 40 per 1000 person-years. Screening was consistently associated with reductions in alcohol consumption; however, heterogeneity among studies prevented pooled quantitative estimates (Figure 1). **Conclusion:** Noninvasive fibrosis screening among individuals with AUD offers benefits beyond detection by facilitating linkage to care and encouraging behavioral change. These results support an approach to enable earlier disease detection and potentially modify disease progression.

3147 | PREDICTORS OF ABSTINENCE AT ONE-YEAR FOLLOW UP IN A MULTIDISCIPLINARY ALCOHOL-ASSOCIATED LIVER DISEASE CLINIC

Andrew Turunen[1] Patrick Kittredge[1] Bikrum Chahal[1] Fauzia Hollnagel[1] Jessica Musto[1] Margarita German[1], [1]University of Wisconsin

Background: Alcohol-associated liver disease (ALD) is a leading cause of liver-related mortality in the US. Alcohol abstinence is the strongest predictor of survival in ALD. Multidisciplinary care models integrating hepatology and addiction medicine improve outcomes; however, predictors of sustained abstinence remain poorly defined. We aimed to compare baseline and treatment-related factors among patients who achieved abstinence at one-year follow up versus those that had ongoing alcohol use in a multidisciplinary ALD clinic. **Methods:** We performed a retrospective cohort study of patients evaluated at a single-center multidisciplinary ALD clinic. Baseline demographic, psychiatric, substance use, liver disease severity, and treatment-related variables were compared between patients who were abstinent versus those who had ongoing alcohol use at 1 year follow up (+/-45 days). Patients meeting criteria for early or sustained remission from AUD

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

were categorized as achieving abstinence. Continuous and categorical variables were compared using chi-squared or Fisher's exact testing. Univariable logistic regression identified variables associated with abstinence and were incorporated into multivariable regression modeling. **Results:** Forty-eight patients met inclusion criteria, 27 (56.3%) were abstinent at follow-up and 21 (43.7%) continued drinking. Abstinent patients had significantly higher baseline MELD-Na scores compared to patients who continued drinking (15.2 ± 4.9 vs. 11.9 ± 4.4, p = 0.02). Emergency department (ED) visits were significantly lower among abstinent patients (2.3 ± 3.3 vs. 5.4 ± 6.5, p = 0.04). In univariable logistic regression, higher MELD-Na score was associated with increased odds of abstinence (OR 1.17, 95% CI 1.02–1.33, p = 0.026). Positive phosphatidylethanol (PEth) testing at follow-up was more common among patients who continued drinking as expected, however, 2 patients who reported abstinence had a positive PEth (12 (70.6%) vs. 2 (11.1%), p < 0.001). Sex, race, marital status, use of medication-assisted therapy for AUD, among other variables were not independent predictors of abstinence. **Conclusion:** In this multidisciplinary ALD clinic cohort, 56% of patients achieved alcohol abstinence at one year follow up. Abstinent patients demonstrated higher baseline MELD-Na scores and lower ED utilization, suggesting sustained abstinence may improve disease stability and reduce healthcare utilization. Although higher MELD-Na scores were associated with abstinence in univariable analyses, this relationship was attenuated after adjustment for behavioral and substance use-related variables. These findings support integrated hepatology-addiction medicine care models for management of patients with ALD.

Table 1. Univariable logistic regression predicting abstinence at follow-up

Variable	OR (95% CI)	*p*-value
DEMOGRAPHICS		
Age	0.98 (0.92–1.05)	0.575

3148 | PROJECTED TRENDS IN ALCOHOL CONSUMPTION AND ALCOHOL USE DISORDER AMONG U.S. ADULTS THROUGH 2050: A MICROSIMULATION ANALYSIS

Ha Tran[1] Michael Rothberg[2] Katharine Bradley[3] Daniel Jonas[4] Olajide Adekunle[2] Phuc Le[2] Srinivasan Dasarathy[2], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic, [3]Kaiser Permanente Washington, [4]The Ohio State University Wexner Medical Center

Background: Alcohol Use Disorder (AUD) affects 29.5 million U.S. adults and contributes substantially to preventable morbidity and mortality. However, long-term national projections of alcohol consumption patterns and AUD burden across demographic subgroups are limited. This study projected alcohol consumption and AUD prevalence among U.S. adults through 2050 to identify subgroups likely to bear a disproportionate future burden. **Methods:** We developed an individual-level state-transition microsimulation model with annual cycles to follow the US adult population through 2050. The model incorporated population turnover using US Census Bureau projections, transitions across drinking states defined by WHO drinking risk levels (abstinence, low, moderate, high, very high), and transitions across AUD severity states (mild, moderate, severe). Transition probabilities were derived from 7 waves of the Population Assessment of Tobacco and Health and waves 1-2 of the National Epidemiologic Survey on Alcohol and Related Conditions. The model was also calibrated to 2002-2009 National Survey on Drug Use and Health and validated against 2010-2023 NSDUH. COVID-19 disruptions were incorporated using year-specific adjustments to 2020-2021 drinking transitions. **Results:** Model projections showed good agreement with observed 2010-2023 NSDUH estimates for drinking levels and AUD prevalence. The model projected that the number of adult drinkers would increase from 111.3 million in 2024 to 125.6 million in 2050, driven by growth in low-risk drinking which accounted for 90% of net new drinkers. At the same time, the number of adults with AUD was projected to reach 33.1 million (11.3%) by 2050, increasing from 28.2 million (10.8%) in 2024. Severe AUD increased by 60.8% from 4.5 million to 7.2 million. AUD prevalence was projected to decrease among adults aged 18-25 years, from 22.3% to 14.1%, but to more than double among those ≥ 50 years, from 4.2% to 10.4%. AUD prevalence also increased faster among males than females, widening the sex gap from 2.6 to 6.8 percentage points. By 2050, males accounted for 64.7% of the total AUD burden. **Conclusion:** AUD burden is projected to rise through 2050, driven by a growth in severe AUD and a shift toward adults aged ≥ 50 years.

3149 | PETH-DEFINED HEAVY ALCOHOL USE AND OBESITY: A DUAL-HIT STEATOTIC PHENOTYPE IN ALCOHOL USE DISORDER

Omar Albhaisi[1] Monica Melmer[1] Anna Peyton[1] Hannah Kissel-Smith[1] Brandon Wills[1] Matthew Way[1] Megan Lemay[1] Andy Pinson[1] Crystal Watts[1] Chareece Williams[1] Tara Kilman[1] Brian Singh[1] James White[1] Gerry Moeller[1] Juan Pablo Arab[1], [1]Virginia Commonwealth University

Background: Alcohol-associated liver disease (ALD) frequently overlaps with metabolic risk, but the combined relationship of objective alcohol exposure and adiposity with VCTE CAP-defined steatosis is not well defined. We evaluated whether PEth-defined heavy alcohol use and obesity identify a high-steatosis phenotype in patients with alcohol use disorder (AUD). **Methods:** We analyzed patients enrolled in the MOTIVATE Clinic, an outpatient substance use treatment program providing addiction medicine, behavioral health, peer recovery, and care coordination services. All patients underwent VCTE with CAP measurement and BMI assessment. PEth was categorized per local laboratory reference ranges as <20 ng/mL, 20–200 ng/mL, and >200 ng/mL, with >200 indicating heavy or chronic alcohol use. Obesity was defined as BMI ≥ 30 kg/m². The primary steatosis threshold was CAP ≥ 248 dB/m; CAP ≥ 263 and ≥ 275 dB/m were evaluated as sensitivity thresholds. **Results:** We included 94 patients with AUD and available VCTE CAP and BMI; PEth was available in 89 patients. Among patients with PEth, 37 had PEth <20, 17 had PEth 20–200, and 35 had PEth >200 ng/mL. CAP-defined steatosis (≥ 248 dB/m) increased stepwise across PEth categories: 21.6%, 23.5%, and 62.9%, respectively; median CAP also differed across PEth categories (Kruskal-Wallis $p = 0.002$). A stepwise gradient was also observed across combined PEth-obesity phenotypes: 18.4% (PEth ≤ 200 + BMI <30, $n = 38$), 31.2% (PEth ≤ 200 + BMI ≥ 30, $n = 16$), 52.4% (PEth >200 + BMI <30, $n = 21$), and 78.6% (PEth >200 + BMI ≥ 30, $n = 14$). The dual-hit group had the highest median CAP compared with the reference group (285 vs 202 dB/m). Findings were directionally consistent at CAP ≥ 263 and ≥ 275 dB/m. **Conclusion:** In patients with AUD, PEth-defined heavy alcohol use and obesity identify a dual-hit steatotic phenotype with markedly higher CAP-defined steatosis burden. These findings support systematic combined PEth and BMI assessment for steatosis risk stratification in integrated hepatology-addiction care.

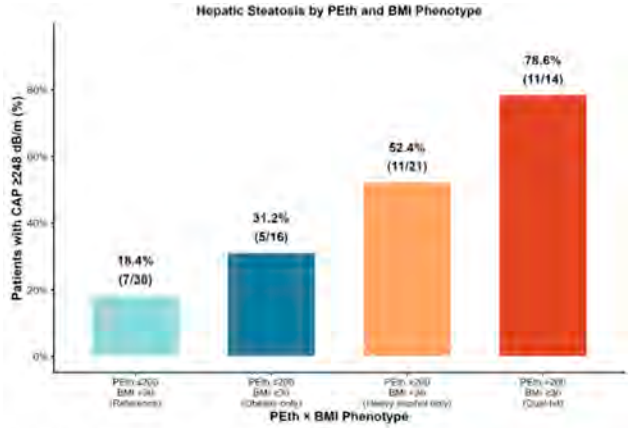

Figure 2. CAP-defined steatosis by PEth and BMI phenotype.
Proportion of patients with hepatic steatosis, defined as CAP ≥248 dB/m, across combined PEth and BMI phenotypes. CAP-defined steatosis increased stepwise from PEth ≤200/BMI <30 to PEth >200/BMI ≥30, reaching 78.6% in the dual-hit group.

3150 | PHOSPHATIDYLETHANOL-BASED VALIDATION OF SELF-REPORTED ALCOHOL MEASURES AND CHARACTERIZATION OF UNDERREPORTING IN EARLY ALCOHOL-ASSOCIATED LIVER DISEASE

Elias Rady[1] Thomas Cotter[1] Ahmad Anouti[1] Thomas Kerr[1] Samer Gawrieh[2] Amit Singal[1] Mack Mitchell[1], [1]University of Texas Southwestern Medical Center, [2]Indiana University School of Medicine

Background: Underreporting of alcohol intake is common in steatotic liver disease (SLD) and contributes to misclassification of SLD subtypes. Phosphatidylethanol (PEth), a biomarker of recent alcohol use,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

has emerged as an objective tool to complement self-report, but the clinicodemographic and psychosocial factors associated with underreporting remain poorly characterized. **Methods:** We performed a cross-sectional analysis of the Dallas Dionysus Study, a prospective early ALD/MetALD cohort at UT Southwestern Medical Center and Parkland Health. Eligible participants had hepatic steatosis, ALT > 33 U/L in men or > 25 U/L in women, and alcohol intake > 210 g/week in men or > 140 g/week in women within the prior 2 years; those with hepatic decompensation were excluded. At the research visit, participants completed standardized alcohol-use questionnaires, including AUDIT-C, Timeline Followback (TLFB), beverage-specific quantity-frequency (BSQF), and Lifetime Drinking History (LDH), and underwent same-day PEth testing. Alcohol use disorder (AUD) severity was assessed via SCID-5. Psychosocial questionaires included B-IPQ (illness perception), PHQ-8 (depression), GAD-7 (anxiety), ISI (insomnia), UCLA Loneliness Scale, and GBMMS (medical mistrust). Underreporting was defined as a TLFB drinking category (no/light < 2, moderate 2–< 4, heavy ≥ 4 drinks/day) below the corresponding PEth category (< 20, 20–199, ≥ 200 ng/mL). Clinicodemographic correlates of underreporting were identified using multivariable logistic regression. Correlation between PEth and each self-report measure were assessed by Spearman correlation. Psychosocial scores were compared between underreporters and accurate reporters using Mann-Whitney U. **Results:** Among 93 participants, 82.8% were men, median age was 46 years (IQR 36–57). PEth correlated moderately with AUDIT-C ($\rho = 0.66$), BSQF ($\rho = 0.62$), and TLFB ($\rho = 0.60$), and weakly with physician-documented intake ($\rho = 0.54$) and LDH ($\rho = 0.44$). AUDIT-C had the highest accuracy for detecting PEth ≥ 20 ng/mL at a cutoff ≥ 3 (sensitivity 92%, specificity 83%) and PEth ≥ 200 ng/mL at a cutoff ≥ 8 (sensitivity 76%, specificity 83%). Concordance between PEth and TLFB was 63.4%; 31 participants (33.3%) underreported, whereas overreporting was uncommon (3.2%). PEth reclassified 17 participants with MASLD and 6 with MetALD as ALD. Underreporting was associated with female sex (aOR 5.78 CI 1.61–20.72) and inversely associated with severe AUD (aOR 0.30 CI 0.09–0.95) (Table 1). Underreporters had lower perceived illness threat (B-IPQ; $p < 0.01$), depression (PHQ-8; $p = 0.05$), and insomnia (ISI; $p = 0.04$) scores than accurate reporters. **Conclusion:** Underreporting is prevalent in early ALD and MetALD, particularly among patients with less severe AUD, lower illness awareness, and lower psychosocial burden. Identifying this profile can facilitate targeted alcohol assessment and timely engagement with AUD-directed care.

3151 | RECEIPT OF MEDICATIONS FOR ALCOHOL USE DISORDER IS INDEPENDENTLY ASSOCIATED WITH REDUCED 30 AND 90-DAY READMISSIONS FOR ALCOHOL-ASSOCIATED HEPATITIS

Krishan Patel[1] Vinay Jahagirdar[2] Omar Albhaisi[2] Husam Mikati[3] Shaanit Sen[4] Butros Fakhoury[1] Na Bo[5] Hannah Kissel-Smith[2] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]VCU Medical Center,

Background: Alcohol-associated hepatitis (AH) is a severe manifestation of alcohol related liver disease that is growing in incidence and associated with a high readmission rate and mortality. Growing evidence demonstrates that medications for alcohol use disorder (MAUD) may mitigate future alcohol related liver injury and decompensation. Thus the goal of this study was to assess the impact of receipt of MAUD on short term readmissions after index AH hospitalization. **Methods:** We performed a retrospective chart review at a single transplant center for patients ≥ 18 years with index admission for AH between March 2023 and March 2025. Clinical and demographic characteristics, substance use, psychiatric diagnoses, receipt of MAUD (naltrexone, acamprosate, gabapentin, baclofen, disulfiram) at discharge, addiction medicine consultation, readmission date and reason, phosphatidylethanol (PEth) (ng/ml), drinks per day, receipt of liver transplant were abstracted. Patients who died or received liver transplant during index were excluded. Primary outcomes were 30 and 90-day unplanned readmission. Multivariate logistic regression was performed. **Results:** A total of 230 patients with AH were included for analysis. Mean age was 44.7 ± 11.3 years, 40.4% were female, 75% white, and median MELD 3.0 score 25 (IQR 22-29). In total, 79 patients (34%) received MAUD, of which were primarily acamprosate (68%) and/or gabapentin (45%) or naltrexone (7.5%). Addiction medicine was consulted in 68% of cases, which was similar for those who were and were not readmitted (p = 0.775). Overall readmission rates at 30 and 90 days were 32% and 43%, respectively. Overall reasons for first readmission were ascites/volume overload (29%), infection (27%), and alcohol-related (15%). In multivariate models, patients with receipt of any MAUD had a lower risk of readmission at both 30 days (aOR 0.30, 95% CI 0.12-0.71) and 90 days (aOR 0.44, 95% CI 0.20-0.93). Additional predictors of 30-day readmission included male sex, presence of HE, receipt of antibiotics, and higher MELD 3.0 score, and receipt of antibiotics and higher MELD 3.0 score for 90-day readmission (Table 1). **Conclusion:** In patients hospitalized for index AH, the receipt of MAUD at discharge was independently associated with reduced odds of 30 and 90-day unplanned readmissions. Other predictors included receipt of antibiotics, higher discharge MELD 3.0, and presence of HE. Notably, ascites and infection were leading causes of readmission, with a lesser contribution from alcohol-related conditions, supporting the idea that MAUD may be hepatoprotective by mitigating harmful alcohol use. Systems level efforts to optimize MAUD prescriptions are necessary to improve outcomes in AH and ALD.

Table 1. Multivariate logistic regression model for predictors of unplanned 30 and 90-day readmission in patients with index alcohol-associated hepatitis hospitalization

	30-day Readmission		90-day Readmission	
Variable	aOR (95% CI)	P value	aOR (95% CI)	P value

3152 | ETHANOL RESHAPES FFC-DRIVEN STEATOHEPATITIS THROUGH TIME-DEPENDENT FIBROSIS AND LIPID-DROPLET REMODELING

Jasmin Weninger[1] Amani Lee[2] George Marek[3] Naomi Lange[4] Amy Mauer[3] Gyanendra Puri[5] Vijay Shah[3] Harmeet Malhi[3], [1]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, 55905, [2]University of Minnesota Medical School, Minneapolis, MN, 55455, [3]Mayo Clinic Rochester, [4]Department of Visceral Surgery and Medicine, Inselspital, Bern University Hospital, Switzerland, [5]Department of Medicine, St. Francis Medical Center, Monroe, LA, 71201

Background: Metabolic dysfunction and alcohol exposure commonly coexist in steatotic liver disease, yet whether alcohol uniformly worsens MASH or selectively modifies disease biology remains unclear. We developed an iterative murine model to define how chronic ethanol alters high-fat, high-fructose, high-cholesterol (FFC)-driven liver injury and to identify MetALD-relevant features beyond routine injury markers. **Methods:** A pilot study in male and female C57BL/6J mice compared chow diet (CD), FFC, CD+ethanol (E), and FFC+E on a high-sugar-water background, with sacrifice at 6, 16, or 24 weeks. A subsequent redesigned study used lower sugar exposure, modified ethanol acclimation and five male cohorts: CD, CD+sugar-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

water (SW), FFC+SW, CD+SW+E, and FFC+SW+E, analyzed at 16 and 24 weeks (n = 4/group/timepoint). Outcomes included body/liver mass, ALT/AST, H&E histology, Sirius Red fibrosis, BODIPY lipid-droplet morphometry, qPCR, *aSMA* immunohistochemistry, and NanoString immune profiling. Statistical analysis was performed in R, GraphPad Prism and NanoString nSolver. **Results:** In the pilot study, FFC induced hepatomegaly, aminotransferase elevation, steatosis, chemokine induction, and fibrosis, but ethanol did not additively increase ALT/AST, or fibrosis, indicating a dominant effect of FFC/high-sugar. Female cohorts showed greater variability and no reproducible ethanol-dependent separation, supporting the redesign in male mice. In the redesigned model, FFC remained the dominant driver of weight gain, hepatomegaly, steatosis, aminotransferase elevation, and *Ccl2/Timp1*-associated fibroinflammatory remodeling. However, ethanol selectively modulated this phenotype. At 16 weeks, FFC+SW+E mice had greater Sirius Red-positive area than FFC+SW despite lower body/liver mass and no broad additive aminotransferase response. BODIPY morphometry showed enlarged lipid droplets in both FFC groups, but combined FFC/ethanol reduced lipid-positive area and the lipid droplet-to-nucleus ratio compared with FFC alone, indicating altered lipid-storage architecture rather than greater steatosis. *Cxcl1* emerged as an ethanol-responsive signal in chow-fed mice but was not uniformly amplified by ethanol on the FFC background. By 24 weeks fibrosis, qPCR markers, *aSMA* staining, and NanoString immune profiles largely converged between FFC+SW and FFC+SW+E. **Conclusion:** In a mouse model of MetALD chronic ethanol does not uniformly intensify FFC-induced liver injury. Instead, it modifies selected aspects of disease progression to early fibrosis, altered lipid-droplet architecture, and context dependent *Cxcl1*-skewed inflammatory signaling, while FFC drives dominant *Ccl2/Timp1*-associated remodeling and later convergence. This refined model supports MetALD as a timing- and pathway-dependent modification of metabolic steatohepatitis.

3153 | ADDICTION MEDICINE CONSULTATION SIGNIFICANTLY IMPROVES PRESCRIPTION OF MEDICATIONS FOR ALCOHOL USE DISORDER IN PATIENTS HOSPITALIZED WITH ALCOHOL-ASSOCIATED HEPATITIS

Krishan Patel[1] Vinay Jahagirdar[2] Omar Albhaisi[2] Husam Mikati[3] Shaanit Sen[4] Na Bo[5] Butros Fakhoury[1] Hannah Kissel-Smith[2] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]VCU Medical Center, [3]Virginia Commonwealth University Health System, [4]VCU School of Medicine, [5]VCU

Background: Alcohol-associated hepatitis (AH) is a severe inflammatory manifestation of alcohol induced liver injury associated with high mortality, and increasing alcohol consumption has led to a growing incidence of AH. Continued alcohol intake is a key driver of hepatic decompensation after AH, and alcohol cessation remains a mainstay of treatment. Despite growing evidence supporting the use of MAUD in patients with alcohol related liver disease (ALD), multiple barriers exist that lead to suboptimal prescriptions for MAUD in practice. Therefore, the aim of this study was to examine factors associated with MAUD presciprtions at discharge in patients with AH. **Methods:** We performed a retrospective chart review in a single transplant center for patients ≥ 18 years with first known admission for AH from March 2023 to March 2025. Clinical characteristics, substance use, psychiatric diagnoses, receipt of MAUD (naltrexone, acamprosate, gabapentin, baclofen, disulfiram) at discharge, hepatology and addiction medicine consultation, phosphatidylethanol (PEth) (ng/ml), drinks per day, and receipt of liver transplant were abstracted. Primary outcome was receipt of prescription for any MAUD at discharge. Multivariate Cox regression was performed. Patients who died, were discharged to hospice, or received liver transplant during admission were excluded. **Results:** A total of 230 patients with AH were included for analysis. The mean age was 44.7 ± 11.3 years, with 40% female, 72% white, and median MELD 3.0 score of 25 (IQR 21-29). In total, 79 patients (34%) received MAUD, with nearly all receiving either acamprosate (68%) and/or gabapentin (45%). Addiction medicine was consulted for 68% of patients, and was higher in those with vs without MAUD at discharge (91% vs 56%, $p < 0.001$). Furthermore, those with MAUD had higher mean PEth (663 vs 464, $p = 0.19$) and daily drinks (10.1 vs 7.4, $p = 0.009$). In multivariate models, receipt of MAUD prescription at discharge was independently associated with addiction medicine consult (aOR 7.44, 2.77-24.3), increasing daily drinks (aOR 1.07,1.01-1.15), PEth >200 ng/ml (aOR 2.70,1.22-6.29), ICU admission (aOR 3.18, 1.11-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

9.66), and younger age (aOR 0.96, 0.93-0.99) (Table 1). **Conclusion:** Addiction medicine consultation was a strong independent predictor of receipt of MAUD at discharge in patients with AH. Interestingly, patients with PEth >200 ng/ml, greater drinks per day, and ICU stay were more likely to receive MAUD, suggesting that those with more severe drinking or illness may be more willing to receive, or were more likely offered, these medications from inpatient teams. Future studies should focus on strategies to improve MAUD prescription, such as integrating electronic decision support to facilitate addiction medicine consultation, increasing addiction education, and empowering both patients and primary teams to engage in conversations regarding MAUD and overall health.

Table 4: Multivariate regression model for predictors of receipt of MAUD prescription at discharge for patients at index alcohol-associated hepatitis hospitalization

Variable	aOR (95% CI)	P value

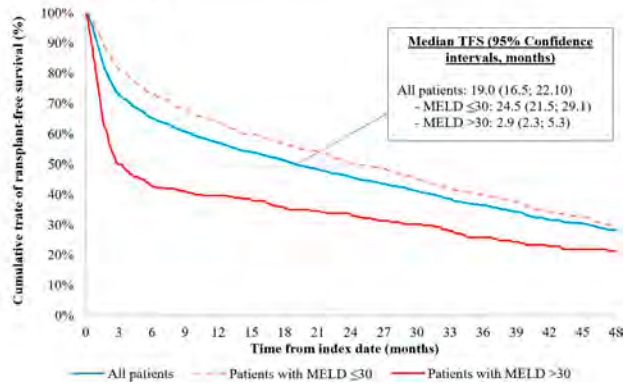
3154 | CLINICAL BURDEN AND OUTCOMES IN A LARGE REAL-WORLD COHORT OF PATIENTS HOSPITALIZED WITH SEVERE ALCOHOL-ASSOCIATED HEPATITIS



Arun Jesudian[1] Arthur Voegel[2] Patrick Gagnon-Sanschagrin[2] Debbie Goldschmidt[2] Kana Yokoji[2] Annie Guerin[2] Olamide Olujohungbe[3] Aarth Sheth[3] Leonardo Passos Chaves[3], [1]Weill Cornell Medicine, [2]Analysis Group, [3]Bausch Health

Background: Alcohol-associated hepatitis (AH) is characterized by high short-term mortality and limited treatment options. Real-world evidence on outcomes is limited, particularly in severe disease. This study evaluated a large real-world US cohort of patients hospitalized with severe AH. **Methods:** This retrospective study used insurance claims and laboratory data from the Komodo Research Database (01/01/2016–07/31/2025). Adults (≥18 years) with an AH-related hospitalization and a Model for End-Stage Liver Disease score (MELD) >20 or Maddrey's discriminant function ≥32 during hospitalization were included. The index date was the admission date of the first qualifying hospitalization. Prior to index, patients had ≥6 months of continuous insurance enrollment and no history of liver transplant. Clinical characteristics were assessed during the 6-month baseline period and index hospitalization. Overall survival (OS), transplant-free survival (TFS), and time to liver transplant were assessed from index date, and time to all-cause rehospitalization from discharge date, using Kaplan-Meier methods. Analyses were conducted overall and stratified by maximum MELD (≤30 vs >30) during the index hospitalization. **Results:** 1,630 patients with severe AH were included (mean age 48.7 years; 56.5% male; 62.9% White). Common baseline liver-related complications included cirrhosis (82.3%), ascites (81.4%), and hepatic encephalopathy (59.0%). Maximum MELD during the index hospitalization was 27.2 on average (median 26.0), and median index hospitalization duration was 11.0 days (IQR: 6.0-23.0). At 3 and 12 months, OS was 76.6% and 62.0%, and TFS was 72.9% and 57.0% (**Figure 1**), respectively. Liver transplant rates were 5.0% and 8.5% and rehospitalization rates were 48.1% and 69.1%.Among 1,303 patients with available MELD, 934 had MELD ≤30 and 369 had MELD >30. At 3 months, OS was 83.3% for MELD ≤30 and 57.5% for MELD >30, and TFS was 81.2% and 49.9%, respectively. At 12 months, OS was 67.5% and 48.0%, TFS was 63.7% and 39.7%, and transplant rates were 6.4% and 17.0% for the MELD ≤30 and >30 subgroups, respectively. Rehospitalization rates were similar across groups. **Conclusion:** In this large real-world cohort of patients hospitalized with severe AH, mortality was high and rehospitalization was frequent. While outcomes were worse among patients with higher MELD, the clinical burden remained substantial across both subgroups, highlighting a pressing unmet therapeutic need.

3155 | PRACTICE PATTERNS ACROSS MULTIDISCIPLINARY ALCOHOL-ASSOCIATED LIVER DISEASE CLINICS IN THE UNITED STATES: A NATIONAL SURVEY

Sasha Deutsch-Link[1] Rebecca Roediger[2] Robin Casey[3] Nader Dbouk[3] Ryan Ford[3] Lamia Haque[4] Kandi Schmidt[5] Isabelle Byers[6] Hersh Shroff[1], [1]UNC Chapel Hill, [2]Weill Cornell Medicine, [3]Emory University School of Medicine, [4]Yale School of Medicine, [5]Loyola University School of Medicine, [6]Univeristy of North Carolina School of Medicine

Background: Optimal management of alcohol-associated liver disease (ALD) involves coordinated ALD and alcohol use disorder (AUD) care. Multidisciplinary clinics (MDCs) integrating ALD and AUD treatment have emerged across the U.S., however clinic prevalence, structure, and practice patterns remain poorly characterized. We conducted a national survey to evaluate structure and practice patterns across MDCs. **Methods:** 119 active U.S. liver transplant centers were contacted between October 2025 and March 2026. Responses were received from 86 institutions (72.3%). Of all contacted centers, 30 (25.2%) confirmed an active MDC and 56 (47.1%) reported no MDC. Among centers with confirmed MDCs, 23 (76.7%) completed the survey. Survey domains assessed clinic structure, staffing, patient population, biomarker use, and provision of AUD medications (MAUD) and behavioral interventions. Data were summarized descriptively and stratified by clinic type (transplant versus general hepatology). **Results:** Among the 23 MDCs that completed the survey, 10 (43.5%) were transplant clinics and 13 (56.5%) were general hepatology clinics, with the majority of clinics established within the past two years (median 26.8 months, IQR 13.9-43.4). Staffing included hepatologists (100%), psychiatrists (52.5%), psychologists (43.5%), social workers (60.9%), and licensed addiction counselors (43.5%). (Figure 1) Most clinics had co-located multidisciplinary services at initial (87.0%) and return visits (72.7%). 17.6% included patients with early stages of ALD and 60.9% required alcohol use within the past 12 months. Nearly all clinics prescribed MAUD (95.7%), most commonly naltrexone (63.6%) or acamprosate (22.7%) as first-line agents. Only 42.9% prescribed oral naltrexone regardless of liver disease severity. All clinics used phosphatidylethanol for biomarker testing. Behavioral therapy was offered in 73.9% of clinics, delivered primarily by psychologists (47.1%) or master's-level therapists (41.2%). **Conclusion:** This national survey demonstrated that MDCs are present in at least one quarter of U.S. transplant centers and are relatively new. While some elements such as hepatologist involvement and biomarker use are nearly universal, significant heterogeneity exists across staffing, patient inclusion criteria, and MAUD prescribing. Overall, survey results indicate a need for evidence-based frameworks to guide multidisciplinary ALD clinic development and implementation.

3156 | EARLY OUTCOMES OF A MULTIDISCIPLINARY ALD CLINIC FOR HIGH-RISK LIVER TRANSPLANT RECIPIENTS

Nishita Sunkara[1] Jarah Whitehead[2] Dominique Mosley[1] Tabitha Casey[3] Ryan Ford[4] Kandi Schmidt[5] Nader Dbouk[4], [1]Department of Internal Medicine, Emory University School of Medicine, [2]Department of Internal Medicine, Emory Univwersity School of Medicine, [3]Department of Psychiatry and Behavioral Sciences, Emory University School of Medicine, [4]Division of Digestive Diseases, Emory University School of Medicine, [5]Psychiatry and Psychology Services, Rush Medical Group

Background: Alcohol-associated liver disease (ALD) is the leading indication for liver transplantation (LT), with a growing burden among young patients and women. Recidivism is a key concern, with at least 10-20% of high-risk patients returning to harmful drinking post LT. Multidisciplinary care models may improve outcomes, but supporting data is limited. We aimed to evaluate the impact of a dedicated multidisciplinary ALD clinic on outcomes in high-risk LT recipients. **Methods:** We conducted a mixed retrospective-prospective study of LT recipients (n = 66) with ALD considered high risk for recidivism (based on SALT and ARRA scores), who were enrolled in a multidisciplinary ALD clinic at Emory University between 11/2024 and 3/2026. The clinic integrates hepatology, transplant behavioral health, and addiction psychology to provide longitudinal care for patients with ALD. Outcomes included alcohol recidivism, follow-up adherence, and patient and graft survival. ChatGPT (OpenAI) was used solely to assist with language refinement and improve readability of the abstract. **Results:** Key baseline characteristics are summarized in Table 1. Follow-up compliance was 81.8%. Fourteen patients (21.2%) experienced post-LT alcohol use and 9 (13.6%) met criteria for sustained or harmful drinking. Pre-transplant participation in mutual support groups was associated with recidivism (OR 5.75, p = 0.012) and sustained drinking (OR 4.90, P = 0.039), likely reflecting greater underlying alcohol use disorder (AUD) severity. Higher pre-transplant PEth levels were associated with increased recidivism. PTSD was a significant predictor of sustained harmful drinking (OR 5.71, p = 0.026). Illicit drug and cannabis use showed non-significant trends toward increased recidivism, while tobacco use demonstrated a non-significant association with sustained drinking. A diagnosis of depression was significantly associated with better follow-up compliance (OR 5.80, p = 0.032). Longer duration of pre-transplant sobriety was also associated with higher follow-up compliance (median 193 days for compliant vs. 72.5 days for non-compliant patients; p = 0.044) as was longer duration from last positive PEth to LT (median 118 days for compliant vs 23 days for non-compliant patients; p = 0.038). Two patients who relapsed experienced graft rejection, but there were no graft losses or patient deaths during follow-up. **Conclusion:** High-risk LT recipients in a multidisciplinary ALD clinic demonstrated excellent follow-up compliance and survival rates. Compliance was particularly high among patients with depression, reflecting greater engagement with integrated mental health services. Recidivism rates were comparable to published data. Pre-transplant group therapy, illicit drug or cannabis use, and tobacco use were associated with higher rates of recidivism and sustained drinking.

Disclosures: Nishita Sunkara:Nothing to Disclose, Jarah Whitehead:Nothing to Disclose, Dominique Mosley:Nothing to Disclose, Tabitha Casey:Nothing to Disclose, Ryan Ford:Nothing to Disclose, Kandi Schmidt:Nothing to Disclose, Nader Dbouk:Nothing to Disclose.

3157 | BILIRUBIN-DRIVEN PHENOTYPE IDENTIFIES HIGHER MORTALITY RISK IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS

Tewodros Ayele[1] Tomohiro Tanaka[1], [1]University of Iowa

Background: Among patients with severe alcohol-associated hepatitis (AH), the prognostic relevance of

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

the dominant component of Maddrey's Discriminant Function (MDF) is unclear. **Methods:** We conducted a retrospective cohort study of adults with AH treated with corticosteroids at a US academic center (January 2016 - December 2024). Using K-means clustering of the bilirubin and prothrombin time (PT) components of MDF, patients were classified into "PT-driven" vs. "bilirubin-driven" phenotypes. The primary outcome was 90-day all-cause mortality. Inverse probability of treatment weighting (IPTW)-weighted Cox proportional hazards (PH) models were performed under an intention-to-treat framework, in which patients were not censored at liver transplantation (LT). Secondary analyses used Fine-Gray competing risk models with LT as a competing event. **Results:** Among 212 patients, 56 (26.4%) died within 90 days. Despite similar Model for End-Stage Liver Disease (MELD), the bilirubin-driven group (n = 100) had significantly lower MDF scores, and less hepatic encephalopathy compared to the PT-driven group (n = 112). Nevertheless, in IPTW-weighted Cox PH model, the bilirubin-driven phenotype was associated with higher 90-day mortality (HR 2.06; 95% CI, 1.05-4.04). Findings were consistent in the Fine-Gray competing risks model (sHR 2.11; 95% CI, 1.03-4.35). **Conclusion:** A bilirubin-dominant phenotype in severe alcohol-associated hepatitis was associated with significantly higher 90-day mortality, highlighting disease heterogeneity and suggesting potential value for risk stratification and for guiding future research on individualized care and optimal timing of liver transplant evaluation.

3158 | ALCOHOL SUPPRESSES KC MATURATION IN A MODEL OF STEATOTIC LIVER DISEASE

Kyle Yuquimpo[1] Sheetalnath Rooge[1] Isabel Aranzazu Pulido Ruiz[2] Lucas Tian[1] Ann Wozniak[1] Steven Weinman[1], [1]University of Kansas Medical Center, [2]The University of Kansas Medical Center

Background: Alcohol consumption is a strong determinant of the severity of liver disease in patients with Met-ALD. The exact mechanisms for how alcohol accelerates disease progression are not well understood. We have previously shown that chronic depletion of mature Kupffer Cells (KCs) in a model of ALD leads to a liver failure phenotype with similar characteristics as alcohol-associated hepatitis, highlighting a critical role of macrophages in maintaining liver function. The replacement of embryonic-derived KCs by monocyte-derived KCs (moKCs) is known to occur in all forms of SLD but whether alcohol alters this process is unknown. The aim of this study was to determine whether the presence of alcohol in SLD alters KC replacement and maturation thus contributing to a more severe disease phenotype. **Methods:** Adult male mice were fed a high fat western diet (WD), or western diet with alcohol (WDA) for 16 weeks. Ms4a3-TdT mice were used to distinguish moKCs expressing TdT from embryonic KCs (emKCs). Clec4f-DTR mice were used to ablate KCs. They were injected with a single dose of DT at the end of feeding and followed 1-2 weeks after ablation to assess the rate of macrophage replacement. Livers were processed for histology and whole tissue analyses or underwent perfusion for isolation of non-parenchymal cells for analytical flow cytometry or separation by FACS. mRNA from FACS-sorted cells was analyzed by qPCR. **Results:** During steady state conditions, BM-derived sinusoidal KCs were present in both WDA and WD mice, but CD163+ TdT+ moKCs were more abundant in WD compared with WDA mice. Using the ClecDTR model to ablate mature KCs, we were able to determine the kinetics of new KC formation from monocyte precursors. After KC ablation, infiltrating macrophages were readily able to take on the mature VSIG4+ moKC phenotype in WD fed mice but this was diminished in the WDA-fed animals. In WDA, recovery from KC ablation led to a paucity of VSIG4+ moKCs and a marked accumulation of macrophages representing intermediate forms along the maturation pathway toward KCs. These represented LAMs and LAM-like KCs. These intermediate forms accumulated in crown-like structures (CLS) which, after KC ablation, were greatly expanded in WDA compared to WD. We isolated mRNA from 2-wk replacement macrophages to assess differences in transcription factor expression between WD and WDA. Egr2, an M2-identify forming macrophage transcription factor, was markedly elevated in the WD but not the WDA condition. **Conclusion:** The addition of alcohol to high fat diet suppresses the maturation of KCs from monocyte precursors. This results in the accumulation of KC intermediate forms, and a paucity of mature KCs. Transcription factors related to macrophage differentiation are suppressed by alcohol and may account for the effects. Impaired KC replacement may contribute to accelerated pathogenesis caused by alcohol consumption in steatotic liver disease.

3159 | RED CELL DISTRIBUTION WIDTH-TO-PLATELET RATIO PREDICTS SHORT-TERM ACUTE DECOMPENSATION IN PATIENTS WITH ALCOHOL-RELATED DECOMPENSATED ADVANCED CHRONIC LIVER DISEASE AND ONGOING NON-ACUTE DECOMPENSATION: A MULTICENTER STUDY WITH EXTERNAL VALIDATION

Mario Romeo[1] Viktor Domislovic[2] Marcello Dallio[1] Fiammetta Di Nardo[1] Carmine Napolitano[1] Paolo Vaia[1] Claudio Basile[1] Luigi Maria Vitale[1] Borna Curtic[2] Anna Mrzljak[2] Alessandro Federico[1], [1]University Hospital Luigi Vanvitelli, Piazza Miraglia 2, 80138, Naples, Italy, [2]University Hospital Centre Zagreb, Zagreb 10000, Croatia

Background: Alcohol-related decompensated advanced chronic liver disease (ALD-dACLD) evolves through non-acute decompensation (NAD) or acute decompensation (AD) (**Figure**). Nearly 30% of patients with ongoing NAD develop AD within 3 months, yet tools for short-term risk stratification remain limited.The red cell distribution width (RDW)-to-platelet (PLT) ratio (RPR) is an index derived from routine hematological parameters. Elevated RDW reflects systemic inflammation, oxidative stress, impaired erythropoiesis, and nutritional deficiencies. In ALD, chronic alcohol exposure further contributes to anisocytosis through bone marrow toxicity and folate deficiency, leading to increased RDW values. Reduced PLT reflects portal hypertension and is exacerbated by alcohol-induced bone marrow suppression (**Figure**). By integrating these mechanisms, RPR is a promising noninvasive tool (NIT) for adverse liver outcomes, particularly in ALD-dACLD.We evaluated the performance of RPR and its consistency across established NITs for predicting 3-month AD in patients with ALD-dACLD and ongoing NAD. **Methods:** Patients with ALD-dACLD and ongoing NAD (n: 122) were enrolled at the University Hospital “Vanvitelli”, Naples, Italy. An independent external validation cohort included 57 patients from another tertiary European center (Hepatology, University Hospital, Zagreb, Croatia). At baseline, clinical and biochemical data were collected, and NITs [RPR, APRI, FIB-4, ALBI-FIB-4, Child-Pugh, MELD, MELD-Na, and liver stiffness measurement (LSM)] were determined. Patients were prospectively followed for 3 months for AD occurrence. Predictive accuracy was assessed by ROC and multivariate analysis; the optimal cut-off was identified using the Youden index and externally validated. **Results:** Baseline RPR was significantly higher in patients who developed AD (n = 53) (0.23 ± 0.07 vs 0.13 ± 0.05, p < 0.0001). In the derivation cohort, RPR had the highest AUC (0.785), followed by LSM (0.713), FIB-4 (0.699), and Child-Pugh (0.689). The optimal cut-off was >0.224 (78.6% sensitivity, 87.8% specificity, 68.8% PPV, 92.3% NPV, and LR+ 6.44). Patients with RPR >0.224 had a higher 3-month cumulative incidence of AD (HR 2.77, 95%CI 1.61–3.76; p = 0.0004). In multivariate analysis, RPR remained independently associated with the outcome after proper adjustment. In the external validation cohort, RPR maintained good performance (AUC 0.758; using the predefined cut-off, sensitivity: 75.0%, specificity: 84.1%, PPV: 60.0%, NPV:91.1%, and LR+ 4.72), confirming reproducibility across independent cohorts. **Conclusion:** RPR is a practical bedside tool for short-term risk stratification in ALD-dACLD with ongoing NAD, enabling personalized monitoring and timely intervention. To our knowledge, this is the first prospective multicenter study demonstrating the ability of RPR to predict 3-month AD in this setting.

Federal University of Rio de Janeiro, Rio de Janeiro, RJ, Brazil, [3]Faculty of Medicine, Chiang Mai University, Chiang Mai, Thailand, [4]University of Texas Southwestern, [5]Rutgers/Newark Beth Israel Medical Center, [6]Griffin Hospital, [7]Mayo Clinic, [8]Stanford University Medical Center, [9]Indiana University School of Medicine, Roudebush Veterans' Administration Medical Center

Background: Sex disparities in steatotic liver disease (SLD) are well recognized, yet sex-specific differences in clinical outcomes among patients with alcohol-associated liver disease (ALD) and concurrent cardiometabolic risk factors (CMRF) remain poorly characterized. **Methods:** We conducted a population-based retrospective cohort study using the TriNetX platform, a federated research network aggregating de-identified electronic health record data from healthcare organizations across the United States. Adults with ALD and CMRF were identified using the updated fatty liver disease nomenclature and stratified by biological sex. Female and male cohorts were balanced using 1:1 propensity score matching, and outcomes were assessed over a 5-year follow-up period using Cox proportional hazards models. **Results:** After propensity score matching, female and male patients with ALD and CMRF had comparable all-cause mortality [hazard ratio (HR) 0.96, 95% confidence interval (CI) 0.91–1.01]. Female patients had higher risks of major adverse liver outcomes [HR 1.13, 95% CI 1.09–1.18] and alcohol-associated hepatitis [HR 1.11, 95% CI 1.05–1.18], but lower risks of major adverse cardiovascular events [HR 0.86, 95% CI 0.81–0.90], arrhythmia [HR 0.87, 95% CI 0.83–0.91], and heart failure [HR 0.81, 95% CI 0.76–0.88]. Female patients also had a substantially higher risk of urinary tract infection [HR 2.66, 95% CI 2.46–2.88] and modestly higher sepsis risk [HR 1.08, 95% CI 1.01–1.17], while pneumonia risk was similar between sexes [HR 0.99, 95% CI 0.91–1.07]. **Conclusion:** In this large, propensity score-matched cohort, female sex was associated with a distinct clinical risk profile among patients with ALD and CMRF, higher liver-related and infection-related morbidity, but lower cardiovascular risk, despite equivalent all-cause mortality. These findings reveal that aggregate mortality metrics can obscure clinically meaningful sex-based differences in organ-specific morbidity, underscoring the need for sex-specific risk stratification and tailored surveillance in this high-risk population.

Table 1: Clinical outcomes post-propensity score matching

Outcome	Female with ALD with CMRF Events N (%)	Male ALD with CMRF Events N (%)	Hazard Ratio (95% CI)	p-value
Death	2,429 (16.6%)	2,492 (17.0%)	0.96 (0.91 - 1.01)	0.137
Liver Outcomes				
Major adverse liver outcome	4,539 (28.5%)	4,052 (25.4%)	1.13 (1.09 - 1.18)	<0.001
Alcohol-associated hepatitis	2,177 (13.7%)	1,954 (12.3%)	1.11 (1.05 - 1.18)	0.001
Cardiovascular Outcomes				
Major Adverse Cardiovascular Events	2,420 (15.2%)	2,736 (17.2%)	0.86 (0.81 - 0.90)	<0.001
Arrhythmia	3,150 (19.8%)	3,494 (21.9%)	0.87 (0.83 - 0.91)	<0.001
Heart failure	1,291 (8.1%)	1,544 (9.7%)	0.81 (0.76 - 0.88)	<0.001
Infection Outcomes				
Urinary tract infection	2,217 (13.9%)	872 (5.5%)	2.66 (2.46 - 2.88)	<0.001
Sepsis	1,544 (9.7%)	1,408 (8.8%)	1.08 (1.01 - 1.17)	0.029

3161 | EXPLORATORY ANALYSIS OF THRESHOLD OF SIPAT LIFESTYLE AND SUBSTANCE USE DOMAIN FOR PREDICTION OF ALCOHOL RELAPSE AFTER LIVER TRANSPLANTATION AMONG PATIENTS WITH ALCOHOL ASSOCIATED CIRRHOSIS

Chung-Heng Liu[1] Manida Wungjiranirun[2] Dekey Lhewa[1] Arnab Mitra[2], [1]Oregon Health & Science University, [2]Oregon Health And Science University

Background: The Stanford Integrated Psychosocial Assessment for Transplantation (SIPAT) offers a standardized method for psychosocial evaluation for liver transplant. Our group found SIPAT lifestyle & substance use domain, and not overall SIPAT score, is independently associated with phosphatidylethanol (PEth) positivity, an objective marker of alcohol use, at 1-year after liver transplant. The aim of this study is to evaluate whether there is a threshold of SIPAT lifestyle and substance use domain score that predicts PEth positivity within 1-year post liver transplant amongst patients with alcohol-associated cirrhosis (AC). **Methods:** This was a retrospective analysis of liver transplant performed at a large transplant center from 2015-2024. All patients with alcohol-associated cirrhosis (AC) who underwent pre-transplant evaluation and transplant with PEth within 1-year post-liver transplant were included. PEth positivity is defined as more than 20ng/mL from 2 or more consecutive follow-ups, within 1-year after liver transplant. Receiver operating characteristic (ROC) analysis was performed to evaluate discriminatory performance of the SIPAT lifestyle and substance use domain for predicting 1-year post-transplant PEth positivity. Youden index optimization was then used to identify a cutoff value. Chi-square and logistic regression were subsequently performed to evaluate associations between SIPAT substance use domain score and post-transplant 1-year PEth positivity. **Results:** A total of 187 patients with alcohol-associated cirrhosis who underwent liver transplant were included. 62% were male, 72% white and 12% Latinx, median age 52 (IQR 45-59), median MELD 29 (IQR 25-34), and 15% had positive PEth within 1 year of liver transplant. ROC analysis demonstrated modest discriminatory performance of the SIPAT substance use domain for predicting 1-year PEth positivity (AUC 0.64), compared to that of the total SIPAT score (AUC 0.58). Exploratory threshold analysis demonstrated cutoff of SIPAT substance use domain of $\geq$ 10. Patients with substance use domain score $\geq$ 10 demonstrated significantly higher post-transplant PETH positivity ($p = 0.029$), and it is independently associated with PEth positivity (OR 3.31, $p = 0.034$). **Conclusion:** SIPAT lifestyle and substance domain may outperform the total SIPAT score. In addition, among patients with alcohol related cirrhosis, SIPAT substance use domain score $\geq$ 10 was associated with increased odds of PEth positivity at 1-year post-liver transplant. These findings suggest SIPAT substance domain threshold may be better at identifying alcohol relapses. External validation in large multicenter studies is needed.

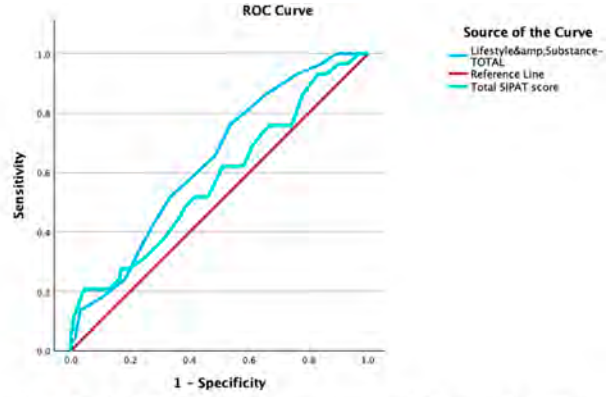

Figure 1: SIPAT lifestyle & substance domain demonstrates modestly improved discriminatory performance for 1-year post-transplant PEth positivity compared to total SIPAT score (AUC 0.64 vs 0.58).

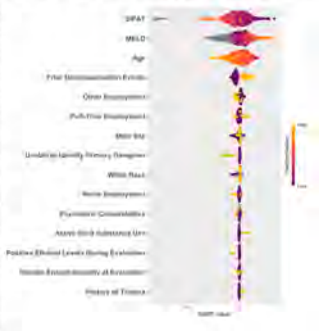
3162 | EVIDENCE FROM AN XGBOOST FEATURE IMPORTANCE ANALYSIS: HOW ARE RISK FACTORS OF POST-TRANSPLANT ALCOHOL RELAPSE APPLIED IN PRACTICE?

Sue Hyon Kim[1] Ethan Weinberg[1] Jonathan Nahas[1] Renee Maggiaro[1] Kimberley Johnson[1] Emily Patrick[1] Christina Cerra[1] Robert Weinrieb[1] Arpita Goswami Banerjee[1] Marina Serper[2], [1]University of Pennsylvania, [2]University of Pennsylvania Health System

Background: Alcohol consumption is reported in over 30% of liver transplant (LT) recipients with alcohol-associated liver disease (ALD) and may compromise post-transplant outcomes. Despite growing evidence on risk factors of alcohol relapse, how they translate into practice is unknown, especially because key factors are not readily captured within structured EHR data. **Methods:** This retrospective cohort study included patients with ALD who underwent LT evaluation at our transplant center. Based on a review of existing literature, we outlined risk factors of post-LT alcohol relapse. We then identified these risk factors from 3373 clinical notes for 829 patients using large language models hosted on Microsoft Azure Databricks, a secure HIPAA-compliant environment. Notes documented by physicians, nurses, social workers, and psychiatrists during the evaluation period up to the selection

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient



© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

committee's decision were included. Multivariable logistic regression was used to evaluate associations between the risk factors and waitlist outcome (listed vs. denied). Variables with high multicollinearity were excluded. We additionally employed XGBoost, a machine learning algorithm robust to missing data and multicollinearity, to validate logistic regression findings and to incorporate 184 patients who had been excluded due to missing data. A subsequent multivariable logistic regression was performed to examine alcohol relapse (reported PEth values >10ng/mL) among 237 LT recipients, using the same variables as the primary model. **Results:** Our sample was predominantly White (80%) and male (67%), with a mean age of 55 ± 10 years. Nearly a quarter were employed full-time (23%) and 21% were retired. Mean MELD score was 19 ± 7 and mean SIPAT score was 23 ± 11. 56% of patients were denied listing and alcohol relapse occurred in 11% of LT recipients.Of the outlined risk factors, logistic regression found prior decompensation events and a positive ethanol lab result during evaluation to be associated with waitlist outcomes (Figure 1A). The XGBoost model achieved good discrimination (AUC = 0.765, accuracy 70.7%), with composite scores and sociodemographic variables emerging as the strongest contributors (Figure 1B). Consistent with logistic regression findings, higher SIPAT scores were associated with reduced odds of listing and higher MELD scores were associated with greater odds of listing. Of the outlined risk factors, prior decompensation events were the most influential feature for predicting waitlist outcomes. In the post-LT logistic regression model, continued drinking after liver disease diagnosis was the only significant factor associated with alcohol relapse (OR = 5.404). **Conclusion:** Differences between the logistic regression and XGBoost models imply nonlinear relationships between sociodemographic characteristics and established risk factors of alcohol relapse, suggesting gaps in risk assessment and management.

A. Multivariable Logistic Regression for Waitlist Outcome

Predictors	OR (95% CI)	p-value
Age	0.991 (0.971 – 1.011)	0.385
Sex (Male)	1.250 (0.864 – 1.812)	0.237
Race (White)	1.166 (0.745 – 1.823)	0.498
Employment (full-time)	0.919 (0.505 – 1.686)	0.781
Employment (retired)	0.631 (0.338 – 1.175)	0.147
Employment (other)	0.637 (0.367 – 1.094)	0.102
MELD	1.055 (1.028 – 1.084)	<0.001***
SIPAT	0.951 (0.934 – 0.968)	<0.001***
Prior decompensation events	1.934 (1.228 – 3.072)	0.004**
Hepatic encephalopathy at evaluation	1.247 (0.704 – 2.236)	0.451
Lack insight into alcohol use disorder	0.711 (0.242 – 2.068)	0.529
Unable to identify primary caregiver	0.625 (0.278 – 1.439)	0.265
Active illicit substance use	1.957 (0.840 – 4.753)	0.121
Psychiatric comorbidities	1.190 (0.674 – 2.112)	0.549
Legal consequences due to alcohol	0.565 (0.174 – 1.906)	0.348
Alcohol-related hospital admissions	1.029 (0.394 – 2.856)	0.954
Positive ethanol levels during evaluation	0.235 (0.070 – 0.693)	0.008**
Drinking after liver disease diagnosis	0.958 (0.468 – 2.003)	0.902
History of trauma	1.015 (0.431 – 2.434)	0.973

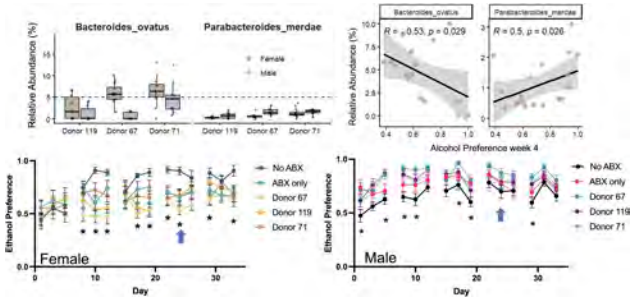
3163 | WAITLIST OUTCOMES AND POST-TRANSPLANT SURVIVAL AMONG CANDIDATES WITH ALCOHOL-ASSOCIATED LIVER DISEASE WITH AND WITHOUT METABOLIC DYSFUNCTION: A UNOS/OPTN ANALYSIS (2012–2024)

Jobin Chandi[1] Tiffany Sahadeo[1] James Park[1] Nabil Dagher[1] Lau Lawrence[1] Nishi Joshi[2] Sanjaya Satapathy[1], [1]Northshore University Hospital/Northwell Health, [2]Northshore University Hospital/Northwell

Background: Alcohol-associated liver disease (ALD) has become the leading indication for liver transplantation in the United States. The increasing prevalence of metabolic dysfunction among liver transplant candidates with ALD has led to the emergence of metabolic–alcohol-associated liver disease (MetALD), but its impact on waitlist and post-transplant outcomes remains unclear. **Methods:** We retrospectively analyzed first-time liver transplant candidates with alcohol-associated liver disease listed in the UNOS/OPTN database from 2012 to 2024. Candidates were classified as ALD-only or MetALD based on the presence of obesity (body mass index ≥ 30 kg/m²) and/or diabetes mellitus. Waitlist outcomes were evaluated using cumulative incidence functions and Fine–Gray competing risks regression. Post-transplant patient and graft survival were assessed using Kaplan–Meier methods and multivariable Cox proportional hazards models. Temporal trends in listing proportions were examined using logistic regression. **Results:** Among 51,325 eligible candidates, 27,953 (54.5%) were classified as ALD-only and 23,372 (45.5%) as MetALD. MetALD candidates were older and had greater metabolic comorbidity burden (all $p < 0.001$). While on the waitlist, MetALD candidates experienced a higher cumulative incidence of transplantation and a lower incidence of death or clinical deterioration compared with ALD-only candidates (Gray's test $p < 0.001$). Median waitlist time was shorter for MetALD candidates (72 vs. 81 days, $p < 0.001$). Among transplanted recipients (ALD: n = 15,796; MetALD: n = 14,159), unadjusted patient survival differed between groups (log-rank $p < 0.001$), but MetALD was not independently associated with post-transplant mortality after multivariable adjustment (adjusted hazard ratio 1.07, 95% CI 0.97–1.18;

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



p = 0.16). Graft survival did not differ between groups (log-rank p = 0.13). The proportion of MetALD listings remained relatively stable from 2012 to 2024, with a small but statistically significant downward trend over time (p for trend = 0.0001). **Conclusion:** Metabolic dysfunction is common among liver transplant candidates with alcohol-associated liver disease and is associated with distinct waitlist outcomes; specifically, higher transplant rates and lower waitlist mortality. However, MetALD is not independently associated with worse post-transplant patient or graft survival. These findings underscore the importance of incorporating metabolic risk factors into the evaluation of transplant candidates with ALD.

3164 | SEX-SPECIFIC REDUCTIONS IN ETHANOL CONSUMPTION FOLLOWING HUMAN FECAL MICROBIOTA TRANSPLANT CORRELATE WITH MICROBIOME CHANGES IN MICE

Jennifer Wolstenholme[1] Jasmohan Bajaj[1] Lauren May[1] Alexander Khoruts[2] Andrew Sommer[2], [1]Virginia Commonwealth University, [2]University of Minnesota

Background: Alcohol use disorder (AUD) remains a significant burden of health worldwide, but treatment options continue to remain limited. Chronic alcohol use leads to changes in the gastrointestinal tract, including changes in the diversity and function of the gut microbiome which can result in the depletion of beneficial taxa and the expansion of potentially harmful taxa. These changes have far-reaching effects, therefore, manipulating the gut microbiome is a potential therapeutic approach for treating AUD. Previous work has shown that a fecal microbiota transplant (FMT) can alter AUD-related behaviors in patients and can improve short-chain fatty acid (SCFA) levels, which were correlated with reduced craving for alcohol and a reported improved quality of life. However, the mechanisms behind why FMT is able to induce these changes is not well understood. Therefore, the goal of this study is to use stools from healthy human donors in a mouse model of alcohol consumption to determine what donor stool characteristics lead to reductions in alcohol consumption. **Methods:** Male and female C57BL/6J mice were treated with a course of antibiotics prior to FMT administration to remove the endogenous mouse microbiome and encourage cross-species engraftment. Three donor stools from healthy donors were used. Following FMT administration, mice began five weeks of drinking in an intermittent two-bottle choice paradigm with intermittent stool collection for metagenomic sequencing. **Results:** In female mice, receiving a FMT significantly decreased ethanol intake and preference with two of the three donor samples. In male mice, the opposite effect was observed: receiving a FMT resulted in an increase in ethanol intake and preference. Alpha and beta diversity changes were greater in female mice than males and female biomes clustered closer to the donor samples suggesting more successful engraftment in female mice. Species-specific changes were also found where *Bacteroides ovatus, a* commensal bacterium with anti-inflammatory properties which produces *GABA,* was significantly increased after donor 67 FMT and remained elevated and negatively correlated to alcohol preference during the 4 week course of drinking. In contrast, *Parabacteroides merdae,* associated with gut dysbiosis, was positively correlated to alcohol preference and higher in males. **Conclusion:** Together, these data show that a cross-species in FMT results in sex-specific changes in ethanol consumption and preference. These changes are further correlated with sex-specific differences in engraftment and in the abundance of specific taxa.

3165 | EFFECT OF DIET, EXERCISE, AND ALCOHOL ABSTINENCE IN A PRE-CLINICAL MODEL OF METALD

Josiah Hardesty[1] Anjali kumari[1] Rui Treves[1] Craig McClain[1] Banrida Wahlang[1] Oluwanifemi Bolatimi[1] Yuan Hua[1] Nicolli Butzke-Souza[1], [1]University of Louisville

Background: Metabolic dysfunction- and alcohol-associated liver disease (MetALD) is a growing health concern due to rising rates of poor metabolic health and over-consumption of alcohol. Diet, exercise, and alcohol abstinence are the most effective and clinician recommended options to improve health outcomes for MetALD patients. However, we know very little about what these lifestyle intervention strategies do in the context of regressing MetALD pathology. This study aimed to identify signatures that are impacted by these lifestyle interventions in a mouse model of MetALD. **Methods:** Male (n = 10 per group) and female (n = 10 per group) mice were fed a high fat diet (HFD, 60% kcal from fat) and given 10% ethanol (EtOH) for 12 weeks (MetALD group) or for 6 weeks followed by the respective intervention including diet (HFD replaced with chow diet), exercise (3 days a week of 30 minute treadmill exercise), alcohol abstinence (10% EtOH replaced with water) or all interventions together. In addition, there was a control group that received all interventions for 12 weeks. Liver and plasma proteins were measured via ELISA and hepatic RNASeq was performed. Data were statistically compared via a one-way ANOVA with a Tukey's multiple comparison test and $p < 0.05$ was considered statistically significant. **Results:** MetALD induction with high-fat diet and EtOH resulted in marked hepatic steatosis, elevated AST/ALT, hyperglycemia, hyperinsulinemia, and increased inflammatory cytokines compared to controls. Lifestyle interventions produced differential improvements. Dietary intervention significantly reduced steatosis and blood transaminases, whereas exercise and alcohol abstinence yielded more modest effects. In contrast, combined intervention produced the most robust recovery, with significant reductions in steatosis and AST/ALT activity, approaching control levels. Glucose and insulin levels were also decreased across intervention groups, with the greatest normalization observed in the combined group. Inflammatory markers, including TNF-α and KC/GRO were elevated in MetALD and attenuated following intervention, most prominently with combined treatment. Exercise induced the greatest change in hepatic differentially expressed genes (DEGs) (3,116 DEGs) followed by dietary intervention (2,682 DEGs), all interventions (2,593 DEGs) and alcohol abstinence (1,857 DEGs). Overall, integrated lifestyle intervention produced the most consistent improvement across hepatic, metabolic, inflammatory, and hepatic gene expression endpoints. **Conclusion:** Integrated lifestyle modification is associated with consistent improvement in hepatic, metabolic, and inflammatory features of MetALD, supporting a multi-component approach for disease reversal.

3166 | ANTI-INFLAMMATORY ACTION OF 18:2 CARDIOLIPIN TREATMENT IN AN *EX VIVO* MODEL OF ALCOHOL-ASSOCIATED LIVER DISEASE

Josiah Hardesty[1] Nicolli Butzke-Souza[1] Rui Treves[1], [1]University of Louisville

Background: Alcohol-associated liver disease (ALD) is characterized by unresolved chronic inflammation that drives chronic liver injury. Previous studies have demonstrated that unsaturated cardiolipin (CL) species can inhibit lipopolysaccharide (LPS)-mediated TLR4 activation, thereby limiting inflammatory signaling. However, this has not been evaluated in models of ALD where both ethanol (EtOH) and LPS are present. We hypothesized that 18:2 CL reduces inflammatory responses in mouse and human whole blood *ex vivo* models. **Methods:** Whole blood was extracted from naïve male (n = 10) and female (n = 9) C57Bl6/J mice (8-12 weeks) and stimulated for 2 hours with vehicle control, EtOH (40 mM), LPS (1 ng/mL), and 18:2 CL (1 -1000 nM). Whole blood from male (n = 10) and female (n = 10) human donors were treated in the same

experimental paradigm. Cell supernatants were collected and cytokines were measured via a multiplex ELISA (MSD). Data were statistically compared by Kruskal-Wallis test followed by Dunn's post hoc analysis, and $p < 0.05$ was considered statistically significant. **Results:** In mouse samples, 18:2 CL reduced IL-2, IL-6, IL-10, and TNFα across all concentrations. IL-2 showed modest reductions (-1.46 -fold). IL-6 was markedly reduced by CL (-12.63-fold). IL-10 levels were also decreased following CL treatment (-2.79-fold). TNFα showed the most pronounced reductions with CL (-139.32-fold). In human samples, the same overall pattern was observed. 18:2 CL reduced IL-2, IL-6, IL-10, and TNFα across all concentrations. IL-2 showed modest reductions (-3.10-fold). Surprisingly, IL-6 showed the strongest response, with great reductions induced by CL (-48.27-fold). IL-10 was decreased following native CL treatment (-2.01-fold). TNFα was markedly reduced with CL (-26.30-fold). **Conclusion:** 18:2 CL attenuated inflammatory cytokine responses under combined EtOH and LPS exposure. This effect was consistent across both mouse and human *ex vivo* whole blood models. These findings suggest that cardiolipin composition influences inflammatory signaling, potentially through modulation of TLR4-dependent pathways and downstream cytokine production. Collectively, our results support 18:2 CL as a potential regulator of inflammation in ALD and highlight lipid peroxidation as a key determinant of its immunoregulatory function.

3167 | IMPACT OF TIME-TO-TERTIARY CARE ON PHOSPHATIDYLETHANOL LEVELS IN HOSPITALIZED PATIENTS WITH ADVANCED CHRONIC LIVER DISEASE: INSIGHTS FROM THE PROSPECTIVE RH7 REGISTRY

Svetlana Adamcova Selcanova[1] Daniela Zilincanova[2] Lubomir Skladany[3] Jana Ciefova[2] Daniel Jan Havaj[4] Karolina Kristina Sulejova[5] Martin Janicko[6] Lukas Laffers[7] Luis Díaz[8] Juan Pablo Arab[9], [1]Div.Hepatology, Gastroenterology, Liver Transplantation, [2]Div. Hepatology, Gastroenterology and Liver transplantation, [3]Faculty Hospital FD Roosevelt, [4]University Hospital of F. D. Roosevelt, [5]Dic. Hepatology, Gastroenterology and Liver Transplantation, [6]2nd Department of Internal Medicine, Medical school of PJS University, Kosice, [7]Department of Mathematics, Faculty of Natural Sciences, Matej Bel University, Banska Bystrica, [8]Division of Gastroenterology, Hepatology, and Nutrition, Department of Internal Medicine, Virginia, [9]Virginia Commonwealth University

Background: In hospitalized patients with advanced chronic liver disease (ACLD), objective assessment of alcohol consumption is essential. Phosphatidylethanol (PEth) is a promising biomarker for evaluating recent alcohol intake; however, its interpretation may be influenced by clinical factors, including hospitalization prior to tertiary admission. We aimed to evaluate the impact of time-to-tertiary care (TTT) on PEth concentrations and to examine whether TTT modifies the association between PEth and self-reported alcohol use estimated by the Alcohol Use Disorders Identification Test (AUDIT). **Methods:** This prospective cohort study included consecutive patients hospitalized with ACLD enrolled in the RH7 cirrhosis registry (NCT04767945). AUDIT and PEth have been included in RH7 since 2019 and 2020, respectively. TTT was treated as a binary variable (TTT = 0: direct admission; TTT > 0: prior secondary-care stay). The PEth–AUDIT association was examined separately in each TTT group using linear regression. **Results:** Of 387 patients, 287 (74%) were admitted directly to our tertiary liver and transplant unit (TTT = 0) and 100 (26%) were transferred from secondary hospitals (TTT > 0). Mean PEth did not differ significantly between groups (0.28 ± 0.53 vs. 0.16 ± 0.26 µmol/L; p = 0.91). However, when PEth was interpreted relative to AUDIT scores, a clinically meaningful discrepancy emerged: transferred patients reported significantly higher alcohol use by AUDIT (13.1 ± 9.9 vs. 8.6 ± 8.4; p < 0.001), had higher MELD scores (p < 0.001) and greater SAH prevalence (51% vs. 29%; p < 0.001), yet their PEth was numerically lower. This pattern — high self-reported alcohol exposure alongside attenuated PEth — is consistent with time-dependent biomarker washout during enforced abstinence prior to tertiary referral. The PEth–AUDIT association differed significantly between groups (Figure), identifying TTT as a relevant temporal confounder of PEth interpretation in hospitalized ACLD patients. **Conclusion:** TTT significantly influences PEth interpretation in hospitalized patients with ACLD. By attenuating PEth during enforced pre-referral abstinence, TTT may lead to underestimation of recent alcohol exposure despite high AUDIT scores.

3168 | LIVER-SPECIFIC BHMT DEFICIENCY RECAPITULATES ALCOHOL-ASSOCIATED LIVER DISEASE PROGRESSION AND HEPATOCARCINOGENESIS DURING AGING

Ramachandran Rajamanickam[1] Sathish kumar Perumal[1] Karuna Rasineni[1] Kurt Fisher[1] Kusum Kharbanda[2]; [1]University of Nebraska Medical Center, [2]Omaha VA Medical Center and University of Nebraska Medical Center

Background: Betaine-homocysteine methyltransferase (BHMT) maintains hepatic methylation potential by regulating intracellular SAH levels and sustaining the SAM:SAH ratio. Chronic alcohol exposure disrupts this pathway, driving steatosis, inflammation, fibrosis, and hepatocellular carcinoma (HCC). To determine whether BHMT loss alone is sufficient to drive a similar disease trajectory, we evaluated aging-associated liver injury in liver-specific BHMT knockout (BHMT LKO) mice maintained on standard chow. **Methods:** BHMT floxed and BHMT LKO mice were aged to 6 months, 1 year, and 2 years. Endpoints included biochemical indices of liver injury, histopathology, fibrosis, lipid peroxidation, inflammation, and expression of canonical HCC markers and oncogenic signaling mediators. **Results:** BHMT LKO mice exhibited progressive, age-dependent liver injury mirroring alcohol-associated liver disease. By 2 years, LKO livers demonstrated marked steatosis, inflammation and fibrosis. Histological evaluation of hematoxylin-eosin and reticulin stained slides demonstrated markedly expanded hepatocyte plates, nuclear atypia, necrotic foci, central tumors, and architectural collapse, collectively consistent with malignant transformation and HCC development.Molecular profiling revealed a pronounced increase in HCC-associated markers, including the cellular myelocytomatosis oncogene (c-myc), golgi phosphoprotein 73, neutrophil gelatinase-associated lipocalin, glypican 3, and cyclin D2. This upregulation was accompanied by activation of multiple oncogenic and stress-responsive signaling pathways involving protein kinase B, nuclear factor kappa-light-chain enhancer of activated B cells, c-jun N-terminal kinase, extracellular signal-regulated kinase, p38 mitogen-activated protein kinase, and signal transducer and activator of transcription 3. Collectively, these molecular alterations mirror those typically induced by chronic alcohol exposure, underscoring that disrupted BHMT-dependent methylation control is a powerful driver of tumor-prone hepatic remodeling during aging. **Conclusion:** These findings establish that hepatic BHMT deficiency alone, even under basal nutritional conditions, is sufficient to trigger a progressive liver disease continuum culminating in HCC. The results highlight the BHMT-betaine metabolic axis as a critical endogenous defense against age-related hepatic injury and tumorigenesis and underscore the potential clinical relevance of BHMT loss-of-function variants in human liver disease risk.

3169 | ENDOCRINE–METABOLIC REPROGRAMMING DRIVES A DISTINCT ONCOGENIC TRANSITION IN METALD

Sundararajan Mahalingam[1] Ramesh Bellamkonda[1] Ojeshvi Ethiraj[1] Carol Casey[1] Kusum Kharbanda[1] Karuna Rasineni[1]; [1]University of Nebraska Medical Center

Background: Steatotic liver disease (SLD) affects over 35% of the global population and is driven by metabolic dysfunction, alcohol use, or their combination. While metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-associated liver disease (ALD) are well characterized, metabolic dysfunction and alcohol-associated liver disease (MetALD) has

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

emerged as a highly aggressive and clinically distinct entity with increased risk of cirrhosis and mortality. The molecular mechanisms underlying this synergistic pathology remain poorly understood. **Methods:** We established experimental mouse models for MetALD (Western diet (ResearchDiets D12079B) + 15% alcohol in drinking water), ALD (chow diet + 15% alcohol in drinking water), and MASLD (Western diet + regular water). This feeding regimen was maintained for 18 weeks. **Results:** MetALD showed greater insulin resistance, hepatic steatosis, apoptosis, inflammation and fibrosis than either MASLD or ALD. Despite severe metabolic dysfunction, GLP-1 levels were paradoxically elevated alongside hyperghrelinemia that suppressed GLP-1 function through direct GHSR-GLP-1R interaction. This hormonal dysregulation was accompanied by amplified pro-fibrotic serotonin signaling, increased peripheral serotonin, and markedly reduced thyroid hormone receptor-β (THRB) signaling, exceeding the suppression observed in MASLD.These endocrine disruptions induce massive lipid accumulation and exacerbate a pathological nuclear lipid shunt via marked upregulation of fatty acid binding protein 5. Consequently, MetALD undergoes a unique and aggressive "metabolic oncogenic transition," linking metabolic dysfunction to early oncogenic reprogramming and accelerated fibrosis. Central to this transition is activation of the hepatocyte nuclear factor 4α (HNF4A), wherein it shifts from a homeostatic regulator to a co-activator of pro-proliferative forkhead box M1 and oncogenic MYC signaling, thereby promoting proliferation and fibrogenesis. **Conclusion:** MetALD is not merely an additive phenotype of MASLD and ALD, but a distinct endocrine-metabolic disorder driven by the ghrelin–serotonin-THRB axis. This axis precipitates metabolic dysfunction and reprograms hepatic signaling toward an oncogenic state. Targeting these converging pathways may provide novel therapeutic strategies to halt disease progression and prevent malignancy in MetALD.

3170 | LONG-TERM BENEFITS OF ALCOHOL REHABILITATION IN PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE: A CALL FOR ACTION

Ahmed Ibrahim[1] Mohamed Eldesouki[2] Eisha Saadat[3] Sajid Jalil[4] Ashwani Singal[5], [1]San Joquin General Hospital, [2]New York Medical College at Saint Michael Medical Center, [3]Agha Khan University, [4]Stanford University, [5]University of Louisville

Background: Alcohol-associated liver disease (ALD) is associated with a high morbidity and mortality. Currently, there are no liver-directed therapies for ALD, with control of alcohol use disorder (AUD) as the sole determinant to improve long-term outcomes. Data on the impact of alcohol rehabilitation on long-term outcomes is limited. **Methods:** We used the TriNetX Research Network (2010-2023), to examine adult patients with alcohol use disorder (AUD) and ALD. The study cohort was extracted using ICD codes. The cohort was stratified based on alcohol rehabilitation within 90 days, defined as ≥ 1 of: (1) enrollment in alcohol/substance use counseling, or (2) initiation of FDA-approved medications for AUD (acamprosate or naltrexone). The primary outcome was all-cause mortality at 3, 6, 12, and 36 months. Secondary outcomes included hospital readmission and liver-related decompensation (ascites, hepatic encephalopathy, variceal bleeding) at the same time. Propensity score matching (PSM) was used to balance baseline characteristics. **Results:** A total of 19,572 patients with AUD and ALD were identified; 1,035 (5.3%) engaged in alcohol rehabilitation within 90 days of discharge from the hospital. After PSM, 1,026 well-balanced pairs were analyzed. Alcohol rehabilitation was associated with lower all-cause mortality at 3 months (HR 0.55; 95%CI 0.50–0.58; $p = 0.02$), 6 months (HR 0.51; 95%CI 0.32–0.82; $p = 0.004$), 12 months (HR 0.67; 95%CI 0.49–0.92; $p = 0.01$), and 36 months (HR 0.63; 95%CI0.56–0.80; $p = 0.004$). Similarly, hospital readmission was consistently lower among patients receiving alcohol rehabilitation at 3 months (HR 0.87; 95%CI 0.76–0.98; $p = 0.02$), 6 months (HR 0.89; 95%CI 0.78–0.97; $p = 0.04$), 12 months (HR 0.93; 95%CI 0.82–0.99; $p = 0.04$), and 36 months (HR 0.80; 95% CI 0.70–0.95; $p = 0.03$). In addition, alcohol rehabilitation was associated with lower rates of liver-related decompensation, including ascites, hepatic encephalopathy, and variceal hemorrhage at 3, 6, 12, and 36 months (Table). **Conclusion:** In this real-world study, engagement with alcohol treatment was low. Alcohol rehabilitation appeared to improve patient survival, with reduced odds for readmission and decompensation. These findings underscore the clinical unmet need to adapt an integrated model with a focus on liver-targeted management combined with treatment for alcohol use, as a basis for providing comprehensive, holistic care to patients with ALD.

3171 | TREATMENT OF AUD IN LIVER TRANSPLANT PATIENTS: A SURVEY OF TRANSPLANT CENTER POLICIES

Sheila Eswaran[1] Megan Saucke[2] Brian Fisher[2] Esra Alagoz[2] Sue Hyon Kim[3] Brian Lee[4] Marina Serper[5] Ethan Weinberg[3] Keren Ladin[6] John Rice[2] George Therapondos[7] Mohamed Shoreibah[8] R. Mark Ghobrial[9] Neha Jakhete[10] Kirti Shetty[11] Christine Hsu[12] Amol Rangnekar[13] Norah Terrault[14] Michael Lucey[2], [1]Northwestern Medicine, [2]University of Wisconsin, [3]University of Pennsylvania, [4]Keck School of Medicine, [5]University of Pennsylvania Health System, [6]Tufts Medical Center, [7]Ochsner Medical Center, [8]University of Alabama at Birmingham, [9]Houston Methodist JC Walter Transplant Center, [10]University of Maryland, [11]University of Maryland, Baltimore, [12]National Institute of Diabetes, Digestive, [13]Georgetown University Hospital, [14]University of Southern California

Background: Alcohol-associated liver disease (ALD) is the leading indication for liver transplantation (LT) in the United States, and while strategies to support long-term abstinence are endorsed by experts, relevant components of management of alcohol use disorder (AUD) in the pre- or post-LT setting are not established. This study characterizes institutional policies related to AUD management across 10 centers with dedicated focus of LT for ALD to gain insights into agreement and variation in practice. **Methods:** ACCELERATE consortium LT centers (geographically distributed across US) provided internal program policies related to AUD treatment before and after LT. All protocols were developed or revised between 2019 and 2025. We conducted a comparative analysis of internal institutional protocols based on the principles of qualitative document analysis using inductive thematic analysis. Documents were independently reviewed systematically and themes were developed inductively to capture emergent patterns. For higher level analysis, we constructed data matrices to facilitate comparison of policies across institutions. **Results:** All centers required patients to remain abstinent from alcohol before and after LT (10/10, 100%). Eight centers outlined an AUD treatment policy in both pre- and post-LT periods (8/10, 80%). Five centers explicitly stated that a transplant psychiatrist was available within the program to assess pre-LT AUD (5/10, 50%). Eight centers recommended post-LT AUD treatment for patients at high risk for return to drinking, as determined by pre-LT characteristics such as early LT (ie recent drinking) or being too ill to engage in pre-LT AUD treatment (8/10, 80%). Only one center specified treatment for patients with documented post-LT return to drinking, in addition to those at high risk (1/10, 10%). None of the policies specified whether AUD treatment was delivered by the LT program, the broader LT center, or external providers (0/10, 0%). No centers had a policy for MAUD pre-LT (0/10, 0%), and one center had a policy for MAUD post-LT (1/10, 10%). **Conclusion:** There is substantial center-level heterogeneity in specialist resources and in pre- and post-LT approaches to AUD treatment, including MAUD. Treatment policies tended to be vague about where and by whom treatment should be delivered. Typically, policies recommending MAUD were absent. Treatment of AUD in the post-LT period represents a key opportunity to intervene before returning to drinking becomes clinically harmful. Centers should strengthen internal resources, standardize their approach to AUD, and integrate MAUD to promote consistent, patient-centered care.

3172 | OUTCOMES FOLLOWING INDEX PRESENTATION WITH DECOMPENSATED ALCOHOL RELATED LIVER DISEASE PRE AND POST COVID: A RETROSPECTIVE COHORT STUDY

Sofia Baldelli[1] Yazan Haddadin[1] Sumita Verma[2], [1]University Hospitals Sussex, [2]Brighton and Sussex Medical School

Background: Liver deaths in England have increased by more than 60% in the past 20 years, largely due to increased prevalence of alcohol-related liver disease (ARLD). National surveys have shown a change in the pattern of alcohol consumption amongst high-risk drinkers following the COVID-19 lockdowns. The aim of this study was to assess the impact of the pandemic on the severity of local hospital admissions with ARLD.
Methods: A retrospective cohort study was conducted in a large teaching hospital in England across two three-year periods: pre-COVID19 (PrC19) and post-COVID19 (PoC19), 1st Jan 2017-31st Dec 2019 and 1st Jan 2021-31st Dec 2023 respectively. Patients who had an unplanned index admission with a decompensation event secondary to ARLD were screened. Eligibility criteria were a coded diagnosis of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

ARLD and a Child-Pugh Score (CPS) ≥8 and/or MELD ≥ 15. Demographic, socialand clinical data relating to the admission were collected from electronic hospital records. Outcomes included alcohol drinking patterns, prevalence of liver related complications, length of stay (LoS), and inpatient mortality. **Results:** A total of 210 patients met our eligibility criteria, 99 in the PrC19 period and 111 in the PoC19 period. Across our cohort mean age was 53 years and 66.2% were male. There were no differences in baseline demographics between the two groups. Alcohol consumption was significantly higher in the PoC19 cohort compared to the PrC19 group (200 vs 130 units/week, p = 0.004). During their index admission, the PrC19 cohort had significantly higher MELD (26 vs 22, p = 0.008),and UKELD scores (62.2 vs 59.7, p = 0.03), higher rates of admission to ITU (23.4% vs 11.1%, p = 0.019) and longer LoS (18 vs 12 days, p < 0.001) compared to the PoC19 cohort. Inpatient mortality rates were higher in PrC19 but did not reach statistical significance (25.2% vs 16.1%, p = 107). There were no differences in the prevalence of spontaneous bacterial peritonitis, ascites, hepatic encephalopathy, sepsis or variceal bleeding between the two groups. On multivariate analysis predictors of inpatient mortality were an admission to ITU (OR 12.7 [95%CI 3.0-54.1], p < 0.001), a higher UKELD score on admission (OR 1.15 [95%CI 1.05-1.26], p = 0.003) and older age (OR 1.08 [95%CI 1.02-1.14], p-0.013). **Conclusion:** This study highlights a concerning trend in the alcohol drinking habits of high-risk users in the years following the COVID-19 pandemic. This was associated with increasing severity of hospital admissions as well as resource utilisation. Our results are consistent with reported national trends and highlight the need for continued support in the community for patients with alcohol use disorder who might have been impacted by the social restrictions relating to the pandemic.

3173 | PATTERNS AND OUTCOMES OF INPATIENT NUTRITION CONSULTATION IN HOSPITALIZED PATIENTS WITH CIRRHOSIS

Jazmin Mexia Cabrales[1] Hassan Sinan[1] Marcin Drzal[1] Joy Kim[1] Frances Lee[2], [1]Department of Medicine, NYC Health + Hospitals/Elmhurst, Icahn School of Medicine At Mt. Sinai, [2]Division of Liver Diseases, Icahn School of Medicine At Mount Sinai, New York, NY

Background: Malnutrition is highly prevalent in patients with cirrhosis and is independently associated with increased morbidity and mortality.[1,2] Both EASL and AASLD guidelines recommend nutrition consultation for hospitalized patients with cirrhosis, with AASLD suggesting evaluation within 24 hours of admission.[3,4] However, data evaluating the association between inpatient nutrition consultation and short-term clinical outcomes in this population remain limited. We aimed to evaluate the association between inpatient nutrition consultation and clinical outcomes in this high-risk population. **Methods:** We conducted a single-center retrospective cohort study of adult patients hospitalized with cirrhosis. Patients were stratified by receipt of inpatient nutrition consultation. Baseline demographics, comorbidities, laboratory values, MELD-Na score, and markers of hepatic decompensation were collected. The primary outcome was 90-day all-cause mortality. Secondary outcomes included ICU admission and 30-day readmission. Baseline characteristics and outcomes were compared between groups using chi-square and Mann–Whitney U tests, as appropriate. Multivariable logistic regression identified independent predictors of nutrition consultation and 90-day mortality. **Results:** Among 1151 patients, 198 (17.2%) received an inpatient nutrition consult. Patients receiving a consult were more frequently male, and demonstrated significantly greater liver disease severity, including lower BMI and albumin levels, higher MELD-Na, and greater prevalence of ascites. 30-day readmission did not differ between groups (26.5% vs 29.3%, p = 0.481). However, patients receiving a consult had higher ICU admission rates (7.1% vs 11.6%, p = 0.047) and 90-day mortality (7.1% vs 15.2%, p < 0.001). On multivariable regression, lower BMI, lower albumin, higher bilirubin, and higher creatinine were independently associated with receiving a consult. Although consultation was associated with higher 90-day mortality in unadjusted analysis, this was no longer significant after adjustment (OR 1.37, 95% CI 0.87–2.13, p = 0.166). Independent predictors of 90-day mortality included higher MELD-Na (OR 1.12, 95% CI 1.09-1.15) and lower albumin levels (OR 0.57, 95% CI 0.41-0.79). **Conclusion:** Despite guideline recommendations for nutrition assessment in all hospitalized patients with cirrhosis, a nutrition consult was obtained in fewer than one in five patients. Consults were directed toward patients with advanced liver disease, reflecting selective rather than systematic utilization. The association between nutrition consult and higher 90-day mortality was explained by disease severity rather than the consults themselves. These findings underscore the need for standardized nutrition screening protocols and prospective studies evaluating whether early, routine nutrition intervention improves outcomes in this population.

3174 | CANNABIS USE IS ASSOCIATED WITH LOWER STEATOSIS SEVERITY AMONG BINGE DRINKERS: A NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (NHANES) TRANSIENT ELASTOGRAPHY ANALYSIS

Calvin Tan[1] Rachan Narala[2] Brian Lee[3], [1]University of Southern California, [2]Stanford University, [3]Keck School of Medicine

Background: Alcohol-associated liver disease (ALD) causes liver-related morbidity and mortality. Prior studies suggest an inverse association between cannabis use and liver disease severity, particularly with heavy alcohol exposure, potentially mediated by cannabinoid receptor anti-inflammatory and anti-fibrogenic signaling. Whether this varies by alcohol-use pattern remains unclear. Binge drinking may provoke inflammatory cascades amenable to cannabinoid modulation. We assessed whether cannabis use is associated with steatosis severity across mutually exclusive drinking groups in a nationally representative cohort. **Methods:** We performed a cross-sectional analysis of National Health and Nutrition Examination Survey participants with transient elastography, a cohort with clinically suspected liver disease. Steatosis was assessed by controlled attenuation parameter (CAP) and staged S0-S3; fibrosis was assessed by liver stiffness measurement (LSM) and staged F0-F4. Participants were categorized as non-drinkers, non-heavy drinkers, binge drinkers, or heavy non-binge drinkers. Cannabis exposure was ever-use. Ordinal logistic regression was used for severity stages; linear regression was used for CAP and LSM. All models adjusted for age, race, sex, and BMI; variance inflation factors assessed multicollinearity. **Results:** Among 5,429 participants, median age was 48.0 years [IQR 32.0-62.0], 48.5% were male, 32.1% were non-Hispanic White, and median BMI was 28.6 kg/m² [IQR 24.6-33.7]. Most were non-heavy drinkers (63.9%), followed by non-drinkers (21.3%), binge drinkers (10.7%), and heavy non-binge drinkers (4.1%). Median CAP was 264.0 dB/m [IQR 218.0-309.0] and median LSM was 5.0 kPa [IQR 4.1-6.2]; severe steatosis and advanced fibrosis were present in 40.3% and 3.9% of participants, respectively. Among binge drinkers (N = 438), cannabis use was associated with 44% lower odds of more severe steatosis after covariate adjustment (OR = 0.56, 95%CI = 0.35-0.92; p = 0.022). A consistent but non-significant association was observed for CAP (β = -7.4 dB/m, 95%CI = -18.0 to 3.2; p = 0.17). Cannabis use was not associated with steatosis severity among non-drinkers (OR = 1.23; p = 0.43), non-heavy drinkers (OR = 0.94; p = 0.59), or heavy non-binge drinkers (OR = 0.86; p = 0.71). In the full sample (N = 4,779), cannabis use was not associated with steatosis severity after adjustment (OR = 0.91; p = 0.29). No associations were identified for fibrosis outcomes. **Conclusion:** Cannabis use was associated with lower hepatic steatosis severity exclusively among binge drinkers, who are most exposed to episodic alcohol-mediated inflammatory injury. The absence of a similar signal in other drinking groups or the pooled sample suggests the association may depend on alcohol-use behavior or exposure intensity. The biologic and behavioral mechanisms underlying this finding remain to be defined and should be explored in future studies.

3175 | CONTRACEPTIVE CARE ACROSS THE SPECTRUM OF LIVER DISEASE SEVERITY IN WOMEN WITH ALCOHOL-RELATED LIVER DISEASE

Rachael Mahle[1] Katherine Cooper[1] Haemi Lee[2] Jay Luther[1] Deepika Devuni[3], [1]Massachusetts General Hospital, [2]Ascension Columbia St Mary's, [3]UMass Memorial Health

Background: As alcohol-related liver disease (ALD) increasingly affects younger women, reproductive counseling and contraceptive care have growing importance. For the last decade, CDC guidance has supported broad contraceptive eligibility for women with liver disease, with no liver-specific contraindications in the absence of overt hepatic decompensation. However, real-world contraception use in reproductive-aged women with ALD remains poorly characterized. We aimed to evaluate contraceptive utilization across the spectrum of ALD severity. **Methods:** We performed a retrospective cohort study using the TriNetX US Collaborative Network of women aged <55 years (2019-2023) diagnosed with ALD or who underwent liver transplant (LT) for ALD. Patients were categorized as ALD without advanced liver disease, alcohol-related hepatitis (AH) without cirrhosis (K70.1 and bilirubin >3mg/dL), alcohol-related cirrhosis (ALC), or post-liver transplant (post-LT). Cohorts were mutually exclusive. The primary outcome was documented contraception use within 2 years of ALD diagnosis; the secondary outcome was incident pregnancy. Exploratory analyses evaluated contraception types, including intrauterine devices (IUD), combined hormonal contraceptives (CHCs), depot medroxyprogesterone acetate (DMPA), and sterilization. Group comparisons were performed using chi-square testing for overall contraception and for pairwise comparisons of contraception subtypes. **Results:** Among 32,176 women identified, 15,637 had ALD without documented ALC/AH, 3,092 had AH without ALC, 12,572 had ALC with or without AH, and 875 had ALD after LT. Documented contraception use differed significantly across ALD phenotypes, with the lowest rates observed among women with AH (11.3%) and ALC (11.6%) compared with women with ALD without ALC/AH (17.6%). Contraception was significantly higher in the post-LT cohort (27.5%) than in all three non-transplant ALD groups. Among women with any documented contraception, method of contraception differed across ALD phenotypes. CHC represented 20.1% of contraception use in ALD without AH/ALC, compared with 10.6% in AH without ALC and 6.1% in ALC. IUD utilization was similar in ALC and AH without ALC, while sterilization was more common in ALC than AH without ALC. Incident pregnancy was most common in women with ALD without AH or ALC. **Conclusion:** Contraception utilization declined with increasing ALD severity, with a marked increase in use after liver transplant. Notably, women with AH but no cirrhosis had contraception rates similar to women with ALC, though this did not apply to CHC. These results suggest that AH represents a clinical "gray zone" that may be approached cautiously due to diagnostic uncertainty or lack of clear management guidance. Future research is needed to understand contraception use in women with AH and to inform recommendations in this high-risk cohort.

	ALD (n=15,637)	AH no ALC (n=3,092)	ALC (n=12,572)	ALD + LT (n=875)	p-value
Age, median (IQR)	38 (13)	37 (11)	41 (10)	41 (7)	—
Any contraception	17.4% (n=2,721)	11.3% (n=349)	11.6% (n=1,452)	27.5% (n=241)	<0.001

3176 | ENVIRONMENTAL FOREVER CHEMICAL EXPOSURES ALTER SEVERITY AND METABOLIC SIGNATURES OF ALCOHOL-ASSOCIATED STEATOHEPATITIS VIA PPARA

Frederick Ekuban[1] Adrian Centers[1] Matthew Smith[2] Vatsalya Vatsalya[1] Kushal Biswas[3] Dhimiter Bello[3] Jennifer Schlezinger[4] Hao Zheng[1] Wanyu Zhang[1] Jasey McNabb[1] Addison Wiggam[1] Maiying Kong[1] Dean Jones[5] Craig McClain[1] Matthew Cave[1], [1]University of Louisville, [2]Emory University, Atlanta, [3]University of Massachusetts Lowell, [4]Boston University, [5]Emory University, Children's Healthcare of Atlanta

Background: Although alcohol use is widespread, only a subset develop advanced liver injury, implicating modifiers beyond ethanol. Per- and polyfluoroalkyl substances (PFAS) are persistent chemicals linked to MASLD and recently detected in US beers above EPA limits (PMID: 40272161), creating exposure pathways for drinkers. Their role in alcohol-associated steatohepatitis (ASH) warrants investigation. We hypothesized that perfluorooctanoic acid (PFOA) disrupts hepatic metabolism and modifies ASH severity via PPARα-dependent mechanisms. **Methods:** Exposomics and metabolomics (LC-MS² & GC-MS²) were performed in archived plasmas from subjects with ASH (severe = 96, moderate = 28) and non-drinking controls (n = 11). Associations between biomarkers of PFOA exposure, ASH severity, and metabolome were determined using linear regression models. Male C57BL/6J mice on chronic-binge ethanol (EtOH) feeding were co-exposed to PFOA (2 mg/kg) or vehicle for 10 days, followed by a 5 g/kg EtOH binge. Liver disease phenotyping, including plasma/hepatic biochemistry, histology, qPCR, and Western blotting were performed. **Results:** Plasma PFOA was elevated in ASH versus controls ($P = 0.02$; 100% detection). MWAS vs PFOA identified 3,318 metabolic features ($P < 0.05$) enriching 32 pathways (fatty acid β-oxidation, glycerophospholipid, alanine/aspartate, urea cycle, glutathione, CYP450); 19 overlapped with the ASH disease-group MWAS, suggesting PFOA contributes to the ASH metabolomic signature. In mice, PFOA worsened EtOH-induced steatosis, hepatic triglycerides, and lipid peroxidation, and activated PPARα targets (*Cyp4a10, Acox1, Cpt1a, Cpt2, Fabp4, Scd2*) and CYP4A10 protein in both pair-fed and EtOH-fed mice, with upregulation of *Pxr, Cyp3a11, Cyp2b10, Pparγ, Cd36*. Interestingly, plasma ALT and AST were paradoxically reduced in EtOH+PFOA despite intensified tissue injury induction of *CHOP* (~50-fold), *Hmox1, Nqo1, Sod1/2; Tnf-α, Il-1β, Il-6*). Notably, this dissociation occurred alongside PFOA-driven induction of ethanol-metabolizing enzymes (*Adh1, Adh5, Aldh1a1, Aldh2, catalase*), CYP2E1 and ALDH1A1 protein, and markedly lowered blood alcohol ($P < 0.0001$). Cross-species pathway overlap spanned fatty acid β-oxidation, glycerophospholipid, transaminase substrates, glutathione, and CYP450. **Conclusion:** PFOA is elevated in ASH and broadly disrupts the plasma metabolome. In mice, PFOA exacerbates ALD severity through PPARα-driven hepatic lipid reprogramming and accelerated ethanol metabolism, producing a complex dissociation between reduced plasma injury biomarkers and intensified tissue injury. These findings identify PFOA as a candidate disease-modifying environmental factor in ASH and have implications for biomarker interpretation in environmentally exposed alcohol consumers. More data are required to establish clarity on the complex interactions between PFAS and alcohol and their role in liver disease.

3177 | GLOBAL PATTERNS OF ALCOHOL-RELATED CARDIOMYOPATHY AND ALCOHOL CONSUMPTION: AN ECOLOGICAL STUDY FROM 2017–2023

Denisse Rubio Cruz[1] Ximena Parraga[1] Kriti Soni[1] Tulio Correa[2] Rylyn Reyes[1] Hyundam (Dami) Gu[1] Joshua Chen[1] Adelina Horhat[1] Vinay Jahagirdar[1] Kavin Parmar[1] Krishan Patel[1] S. Fisher Rhoads[1] Stephen Hoang[1] Luis Antonio Diaz[1] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]University of Pittsburgh

Background: Alcohol-related cardiomyopathy (ACM) is a severe complication of chronic alcohol exposure. Emerging evidence suggests that ACM may represent a more complex disease process than the sole consequence of end-organ ethanol toxicity. Nonetheless, ecological studies characterizing the global burden and geographic heterogeneity of ACM remain limited. **Methods:** We conducted a global ecological analysis including 184 countries across World Health Organization (WHO) regions. Country-level ACM prevalence and alcohol exposure metrics from 2017–2023 were analyzed to characterize geographic and temporal patterns of disease burden. Additionally, a multivariable linear regression was performed to illustrate the association between ACM prevalence and average daily alcohol intake (grams/day), adjusting for gross domestic product (GDP) per capita. To explore distributional differences, sex-specific analyses of alcohol exposure were also included. **Results:** An evident regional heterogeneity in ACM prevalence was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

observed, with the highest burden in the region of the Americas, and a relative stability throughout the available years. Higher daily alcohol intake by nations demonstrated a modest positive association with ACM, with slightly stronger effects on men compared to women; however, none of these models reached statistical significance ($p = 0.16$). The substantial disparities across regions may align with prior observations that cardiac susceptibility to alcohol is highly variable and potentially influenced by other determinants. Given the relatively short study period, delayed clinical manifestations of ACM might not be totally captured. **Conclusion:** Global ACM exhibits a wide geographic dispersion, where country-level alcohol consumption alone may not fully explain the observed trend. These findings may support the multifactorial nature of the ethanol-associated myocardial injury and highlight the need for further studies exploring environmental, socioeconomic, and biologic factors.

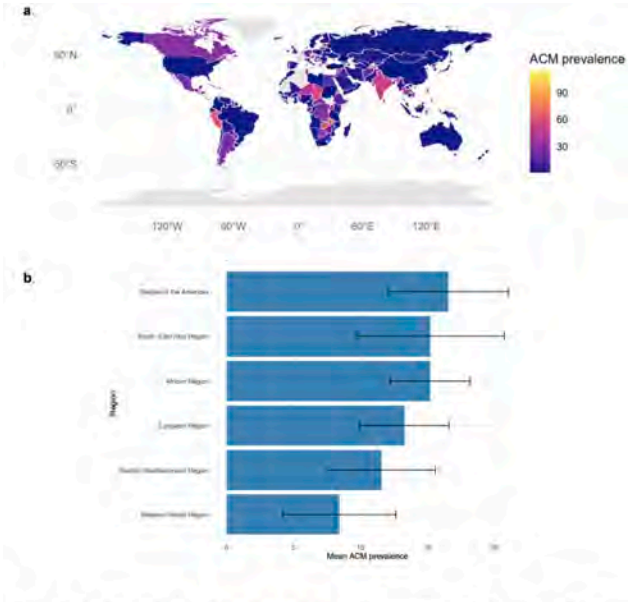

Figure 1a. Global prevalence of Alcoholic Cardiomyopathy by countries. **b.** Regional distribution according to the definitions of the World Health Organization (WHO); variability between nations is shown as standard error bars.

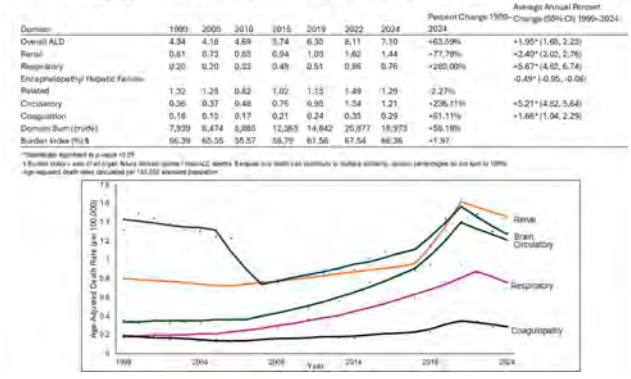
3178 | TRENDS IN EXTRAHEPATIC ORGAN FAILURE CONTRIBUTING TO ALCOHOL-ASSOCIATED LIVER DISEASE MORTALITY IN THE UNITED STATES, 1999-2024: A NATIONAL DEATH CERTIFICATE ANALYSIS

Gabriel Lupu[1] A. Sidney Barritt[1] Isabelle Byers[1] Oren Fix[1] Andrew Moon[1] Anne Peery[1] Neil Shah[1] Hersh Shroff[1] Sasha Deutsch-Link[1], [1]University of North Carolina, Chapel Hill



Background: Alcohol-associated liver disease (ALD) mortality has nearly doubled from 1999 to 2024, a trend further accelerated by increased alcohol consumption during the COVID-19 pandemic. Alcohol contributed to half of all cases of hepatic decompensation globally. In the US, ALD-related hospitalizations were rising among younger populations prior to the pandemic. Hospitalization in ALD is often complicated by acute-on-chronic liver failure (ACLF), a multiorgan failure syndrome triggered by hepatic injury in chronic liver disease and is associated with poor prognosis. We aimed to characterize temporal trends in extrahepatic organ failure domains contributing to ALD mortality across the United States. **Methods:** Data were extracted from the CDC WONDER Multiple Cause of Death (MCOD) publicly available database from 1999-2024 using ICD-10 codes to identify relevant cases. ALD (K70) was selected as the underlying cause of death. Contributing causes were grouped into organ dysfunction domains: renal (N17.0, N17.9, N19, K76.7), respiratory (J96.0, J96.9), circulatory (R57.1, R57.8, R57.9, A41.8, A41.9), encephalopathy/hepatic failure-related (G93.4, K72.0, K72.1, K72.9), and coagulopathy (D65, D68.4, D68.9). We calculated age-adjusted mortality rates and performed a Joinpoint regression to estimate annual percent change (APC) and overall average annual percentage change (AAPC) from 1999 to 2024. A yearly composite organ dysfunction burden index was also constructed. **Results:** Age-adjusted ALD-associated mortality nearly doubled from 1999 (4.34) to 2024 (7.10), with an AAPC of 1.95 (95% CI: 1.65, 2.25). Four of five organ failure domains contributing to ALD mortality increased: respiratory (AAPC: 5.67; 95% CI: 4.62, 6.74), circulatory (AAPC: 5.21; 95% CI: 4.82, 5.64), renal (AAPC: 2.40; 95% CI: 2.02, 2.76), and coagulopathy (AAPC: 2.40; 95% CI: 2.02, 2.76). The encephalopathy/hepatic failure-related domain slightly declined (-0.49; 95% CI: -0.95, -0.06). After 2021, ALD mortality and all organ domain trends declined. The composite organ dysfunction burden index increased from 66.4% to 68.4%. **Conclusion:** ALD mortality has increased substantially in the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

United States since 1999, with parallel increases of contributing extrahepatic organ dysfunction domains. We observed a parallel rise in multiorgan system failures among ALD deaths, most pronounced within circulatory and respiratory domains, and an increase in the composite organ dysfunction index. The absolute burden of systemic critical illness accompanying ALD mortality increased markedly, highlighting significant and persistent contribution of extrahepatic organ dysfunction to ALD mortality in the United States. The burden of ALD-associated mortality is accompanied by a greater severity of illness indicating a growing need for critical care interventions including circulatory and respiratory support.

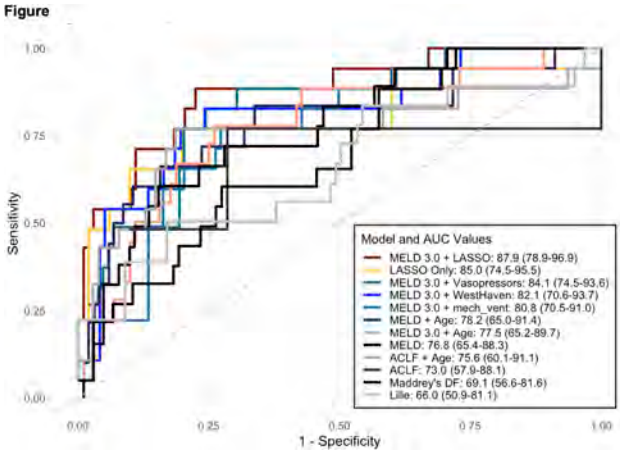
3179 | BEYOND MELD: ORGAN FAILURE MARKERS IMPROVE PREDICTION OF TRANSPLANT-FREE SURVIVAL IN SEVERE ALCOHOL-ASSOCIATED HEPATITIS

Elina Stoffel[1] Jacky Choi[2] Olivia Blocker[2] Himel Mallick[2] Gene Im[3] Elizabeth Verna[1] Stephanie Rutledge[2], [1]Columbia University Medical Center, [2]Weill Cornell Medicine, [3]Center for Liver Disease and Transplantation, Division of Digestive and Liver Diseases Columbia Univ



Background: Severe alcohol-associated hepatitis (sAH) carries high short-term mortality, particularly in the setting of acute-on-chronic liver failure (ACLF). Early liver transplantation (eLT) is lifesaving for selected patients, yet existing prognostic scores have limited discriminative ability in this population. We aimed to develop a prognostic model for transplant-free survival in patients with sAH undergoing eLT evaluation. **Methods:** This retrospective cohort study included adults hospitalized with sAH (NIAAA criteria; MELD >20) evaluated for eLT at two transplant centers (2012–2025). The primary outcome was death without LT at 90 days, with LT treated as a competing risk. LASSO stability selection (100 iterations, 80% subsamples) identified predictors beyond MELD 3.0 components. Four cause-specific Cox regression models were compared: (1) LASSO-selected variables only; (2) MELD 3.0 alone; (3) MELD 3.0 + all LASSO-selected variables; and (4) MELD 3.0 + individual LASSO variables. Discriminative performance was assessed using time-dependent AUC at 30, 90, and 180 days and benchmarked against established scores (Lille, Maddrey, ACLF grade, MELD-Age, MELD 3.0-Age, ACLF-Age). Optimal binary cutoffs were derived via stability-based subsampling. **Results:** Among 135 patients (median age 43; 62% male; 71% with ACLF), 21/135 (16%) died without LT, 67/135 (50%) underwent LT, and 47/135 (35%) survived without transplant. LASSO stability selection identified vasopressor use (100%), West -Haven encephalopathy grade (96%), and mechanical ventilation (53%) as stable predictors. The combined MELD 3.0 + LASSO model achieved the highest 90-day AUC (87.9%, 95% CI 78.9–96.9), substantially outperforming MELD 3.0 alone (76.8%, 95% CI 65.4–88.3) and all established scores, including Lille (66.0%), Maddrey (69.1%), and ACLF-Age (75.1%). Among individual additions to MELD 3.0, vasopressor use provided the greatest incremental improvement (AUC 84.1%). Optimal binary thresholds of MELD 3.0 ≥35 and West Haven grade ≥2 preserved discriminative performance (AUC 73.8%) There was no statistically significant difference in MELD 3.0 or ACLF grade between transplant-accepted and transplant-declined candidates. Results were consistent at 30 and 180 days. **Conclusion:** Incorporating markers of multiorgan dysfunction including vasopressor use, hepatic encephalopathy grade, and mechanical ventilation with MELD 3.0 substantially improves prediction of transplant-free mortality in patients with sAH undergoing eLT evaluation, demonstrating its clinical utility and practical applicability as a mortality risk tool for this population. Given the scarcity of donor organs and the potential for spontaneous recovery in a subset of patients with sAH, accurate risk

3180 | FGF21 ORCHESTRATES HEPATIC PHOSPHOLIPID REMODELING TO MITIGATE ALCOHOL-INDUCED LIVER INJURY IN AGED MICE

Fangfang Zeng[1] Alday Alejandro[1] Qinggong Ping[1] Mengwei Zang[1], [1]University of Texas Health Science Center at San Antonio

Background: Alcohol-associated liver disease (ALD) is a leading cause of liver-related morbidity and mortality worldwide, yet targeted clinical interventions are absent. Although aged individuals exhibit susceptibility to severe liver injury and mortality, the underlying molecular mechanisms remain largely elusive. Our previous studies established fibroblast growth factor 21 (FGF21) as a critical metabolic hepatokine, which has recently emerged as a novel longevity factor. Here, we investigated how aging shapes the hepatic lipidome and phospholipid landscape to influence ALD pathogenesis. **Methods:** Young and aged mice were subjected to the NIAAA chronic-plus-binge ethanol feeding model. FGF21 knockout mice were utilized, and pharmacological recombinant FGF21 (1 mg/kg/day) was administered. **Results:** Lipidomic analysis revealed age-associated remodeling of the hepatic phospholipid landscape. Specifically, phosphatidylethanolamine (PE), a critical structural phospholipid required for membrane integrity, exhibited a selective depletion and a reduction of docosahexaenoic acid (DHA)-containing PE species in aged livers, suggesting disrupted membrane lipid homeostasis. Coinciding with this PE depletion, aged livers displayed a significant decrease in PCYT2, the rate-limiting enzyme in the Kennedy pathway for PE biosynthesis. Following chronic-binge ethanol feeding, aged mice displayed impaired PCYT2 signaling and developed severe ALD, suggesting that aged mice exhibited amplified hepatocellular phospholipid remodeling. Furthermore, ethanol consumption resulted in an accumulation of senescent hepatocytes and a robust pro-inflammatory SASP signature in aged mice, which accelerates alcohol-induced liver fibrosis. Interestingly, genetic FGF21 deficiency further aggravated ALD in aged mice, which was accompanied by downregulation of PCYT2 and activation of SASP signaling. Therapeutically, pharmacological administration of FGF21, which is currently in clinical trials, protected against age-related ALD by restoring PCYT2 expression and repressing hepatocyte senescence. **Conclusion:** The aging liver undergoes selective PE depletion and distinct phospholipid remodeling that promotes hepatocyte senescence and shapes a pro-inflammatory microenvironment. FGF21 functions as a previously unrecognized upstream regulator of the PCYT2-driven Kennedy pathway to control ALD progression, offering a potential therapeutic avenue specifically for ALD in the aged population.

3181 | TRANSPLANT TIMING IN ALCOHOL-RELATED LIVER DISEASE: A META-ANALYSIS OF EARLY VERSUS STANDARD LIVER TRANSPLANTATION

Solonas Symeou[1] Eitan Dines[2] Ricardo Andre Rios Esparza[3] Georgios Tsoulfas[4], [1]University of Ioannina, [2]Carmel Medical Center, [3]Universidad Autonoma De Ciudad Juarez, [4]Aristotle University of Thessaloniki

Background: The 6-month abstinence period before listing patients with alcohol-associated liver disease (ARLD) for liver transplantation (LT) is the current standard practice, followed by most transplant centers worldwide. However, its prognostic validity is still debated for two main reasons: (a) it has not been prospectively validated; (b) patients with ARLD may not survive long enough to make it onto the waitlist. **Methods:** A systematic literature search across three

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

databases (Medline, Scopus, Cochrane Library) was conducted to identify relevant studies comparing early LT (eLT; <6 months of alcohol abstinence) and standard LT (sLT; >6 months of alcohol abstinence). The primary outcomes were overall mortality and any alcohol relapse. Secondary outcomes were risk of graft loss, acute graft rejection, post-operative infection rate, and length of hospital stay. A random-effects model was used for all statistical inferences. **Results:** Twelve studies comparing eLT and sLT for ARLD were included in the quantitative synthesis. Although the trend for overall mortality (RR = 0.94, 95% CI: 0.73–1.22) and any alcohol relapse (RR = 1.37, 95% CI: 0.95–2.00) favored the sLT group, neither was statistically significant. Interestingly, even though the risk of acute graft rejection was higher for eLT patients (RR = 1.22, 95% CI: 0.98–1.52), the risk of graft loss was lower in the same group (RR = 0.97, 95% CI: 0.75–1.25), but none statistically significant. Post-operative infection was higher for eLT patients (RR = 1.19, 95% CI: 0.80–1.77) and, although not significant, it might be associated with the significantly higher length of hospitalization (MD = 5.24 days, 95% CI: 0.15–10.33). **Conclusion:** In appropriately selected ARLD patients, eLT appears to be a comparable approach to sLT. Although length of hospitalization may be higher with eLT, the available data do not suggest it is inferior to sLT. Therefore, eLT should be encouraged as an alternative treatment for ARLD when medical therapy fails.

3182 | CLINICAL APPLICATION OF PHOSPHATIDYLETHANOL IN ALCOHOL-ASSOCIATED LIVER DISEASE IN TAIWAN

Chun-Ming Hong[1] Ching-Hua Lee[2] Ching-Hua Kuo[1] Tung-Hung Su[1] Shih-Jer Hsu[1] Tai-Chung Tseng[1] Hung-Chih Yang[1] Shang-Chin Huang[3] Jia-Horng Kao[1] Chun Jen Liu[1] Pei-Jer Chen[1], [1]National Taiwan University Hospital, [2]School of Pharmacy, College of Medicine, National Taiwan University, [3]National Taiwan University Hospital Bei-Hu Branch

Background: Alcohol-associated liver disease (ALD) has become a serious issue worldwide in recent years and the most common cause of advanced liver disease and leading indication for liver transplantation. It is essential to recognize ALD patients. Acquiring the information of alcohol intake is essential though challenging. Under-reporting may happen and some patients may not be able to report the accurate amount of alcohol intake or cannot be interviewed due to encephalopathy or alcohol intoxication. Therefore, a biomarker with the ability to detect recent alcohol intake is helpful. Phosphatidylethanol (PEth), an ethanol metabolite, can be used as a biomarker for alcohol use in recent 1-4 weeks. There is a consensus that a cut-off value for PEth (16:0/18:1) over 20ng/mL indicates excessive alcohol use. However, usage of PEth is limited in most countries. Our study tried to investigate clinical application of PEth in ALD patients in Taiwan. **Methods:** We conducted a prospective study in National Taiwan University Hospital from May 2025 to March 2026. Upon recruitment, clinical information, AUDIT (Alcohol Use Disorders Identification Test) questionnaire, laboratory tests, and blood were obtained. PEth (16:0/18:1) was measured by liquid chromatography-tandem mass spectrometry from whole blood samples. Testing for PEth was conducted with an Agilent (Santa Clara, USA) 1290 UHPLC system coupled with an Agilent 6460 triple quadrupole LC/MS system. **Results:** Forty-one patients were recruited. Thirty-seven (90.2%) were male. Average age was 58 years old. 22 patients (53.7%) had HBV infection and one had positive anti-HCV Ab. Nine patients (22%) were cirrhotic. Average total bilirubin was 1.2 mg/dL, average AST was 41.5 U/L, average ALT was 36 U/L, and average GGT was 184.9 U/L. 21 patients (51.2%) had AUDIT scores more than 8 points. Average PEth (16:0/18:1) was 256.6 ng/mL. Pearson correlation coefficient between AUDIT score and PEth (16:0/18:1) concentration was 0.692. **Conclusion:** PEth proves to be a reliable biomarker for recent alcohol exposure and its levels correlate with AUDIT scores. Despite its cost and limited accessibility, measurement of PEth should be implemented in the workup of ALD in Taiwan.

3183 | THERMONEUTRAL HOUSING ALTERS ETHANOL METABOLISM AND EXACERBATES GUT PERMEABILITY IN A MOUSE MODEL OF ALCOHOL-ASSOCIATED LIVER DISEASE

Monica Barrios López[1] Laura Fàbrega[1] Susana Nuñez[1] Nayra Rico[2] Carmen Garcia-Ruiz[1] Jose Fernandez-Checa[1], [1]Institute of Biomedical Research of Barcelona (IIBB-CSIC), [2]Biochemistry and Molecular Genetics Department-CDB, Hospital Clínic de Barcelona, 08036 Spain

Background: Current mouse models of alcohol-associated liver disease (ALD) are typically housed at 22°C, which imposes chronic cold stress on rodents whose thermoneutral zone is 30–32°C. This variable may alter disease severity and the mechanisms under study. This study investigates the impact of thermoneutral housing on ALD development, hypothesizing that it elicits distinct metabolic and pathological responses compared to standard housing conditions **Methods:** Male C57BL/6J 8 wks old mice were housed at 22°C or 30°C and subjected to the NIAAA acute-on-chronic ethanol feeding model. Histological and biochemical analysis were assessed in serum and liver tissue. Intestinal barrier integrity was also evaluated. **Results:** Thermoneutral housing attenuated ethanol-induced weight loss and developed exacerbated hepatomegaly with more pronounced histological tissue disorganization, inflammatory infiltration, and ballooning compared to 22°C counterparts. Besides blood ethanol levels were lower in mice housed at 30°C, hepatic acetaldehyde concentration was higher under thermoneutral conditions, what was accompanied by a significant increase in CYP2E1 activity in mice under thermoneutral conditions, suggesting a dissociation between ethanol clearance and toxic metabolite accumulation. Interestingly, serum ALT and AST were elevated by ethanol exposure but not significantly differences were observed between the ethanol-fed groups. Moreover, occludin expression in the gut was lower in mice housed at 30ºC than 22ºC, indicating a temperature-dependent effect on gut barrier homeostasis. These observations paralleled the levels of NO, which were elevated under thermoneutral conditions and further exacerbated by alcohol consumption. **Conclusion:** These data demonstrate that thermoneutral housing elicits distinct metabolic and pathological changes in response to ethanol compared to standard housing, primarily through altered ethanol metabolite dynamics and disrupted gut barrier function. This refined model allows for the study of ALD complexities, potentially offering a more comprehensive understanding of the disease and the influence of environmental factors on its progression and severity.

Background: Alcohol-associated liver disease (ALD) is now the leading indication for liver transplantation (LT) in the United States. Many transplant centers have shifted away from the traditional 6-month abstinence requirement and toward individualized psychosocial risk assessment to allow expedited liver transplant (ELT) for eligible patients. Although intended to expand transplant access, the impact of this policy on alcohol relapse and post-transplant outcomes remains poorly understood relative to pre-policy outcomes at the same center. **:** This study compares outcomes of patients transplanted for ALD after implementation of an early access policy with historical controls under stricter criteria at the same institution. **Methods:** This single-center, retrospective cohort study evaluated adult LT recipients transplanted for ALD. Patients transplanted after implementation of an early access policy without a 6-month abstinence period ("post-policy cohort": 01/01/2023 – 08/31/2024) were compared with a historical cohort transplanted under the 6-month abstinence requirement ("pre-policy cohort": 01/01/2018 – 12/31/2020). Outcomes were collected through May 2026 (minimum 9 months of follow up) in the post-policy cohort, and at least 6 months in the pre-policy cohort. Demographic, clinical, and post-transplant outcomes were extracted from the electronic medical record. Categorical variables were compared using $\chi 2$ and continuous variables using t tests. Median values were compared. **Results:** 141 patients underwent LT during the study period, including 69 patients in the pre-policy cohort and 72 patients in the post-policy cohort. Baseline demographic characteristics were similar between groups. Patients in the post-policy cohort had significantly fewer relapses prior to LT (50.1% vs 25.0%, $p = 0.002$). The post-policy cohort also demonstrated higher median MELD 3.0 scores (21 vs 26, $p = 0.0198$) at the time of LT. Overall relapse rates were similar between groups (26.1% vs 15.3%, $p = 0.112$), with no significant differences in time to relapse, graft dysfunction, or post-transplant mortality. Among patients who relapsed, heavy alcohol use was lower in the post-policy cohort (13.0% vs 0%, $p = 0.005$). **Conclusion:** Despite shorter pre-LT abstinence and greater illness severity, relapse and graft dysfunction rates were similar in patients undergoing LT at the same transplant center with a less strict transplant policy. These findings support expanding transplant access with individualized, evidence-based relapse risk assessment while preserving favorable long-term outcomes.

Table 1. Patient characteristics and relapse outcomes

Characteristic	Pre-policy (N = 69)	Post-policy (N = 72)	Total (N = 141)	p-value
Age, median (IQR)	54 (47-61)	51 (41-59)	53 (43-60)	0.19

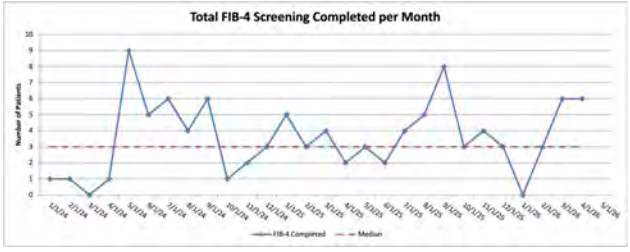
3185 | BRIDGING GAPS IN ALCOHOL-ASSOCIATED LIVER DISEASE SCREENING WITHIN ADDICTION MEDICINE



Michael Carducci[1] Natalie Buslach[2] Vilajet Kovaci[1] Talia Ostrow[1] Jeremy Ziring[1] Sharon Rikin[1] Laila Khalid[1] Rebecca Roediger[3] Alexander Vogel[4] Clara Tow[1], [1]Montefiore Medical Center, [2]Montefiore Medical Center, [3]Weill Cornell Medicine, [4]Montefiore Einstein

Background: The global burden of excessive alcohol consumption constitutes over 3 million deaths, including 25% of global cirrhosis deaths. Early diagnosis of alcohol-associated liver disease is complicated by a long asymptomatic latency period. Identifying high risk patients can provide opportunity to intervene prior to developing cirrhosis. Many at-risk patients are seen outside of specialized hepatology clinics, necessitating screening pathways adapted for primary care and addiction medicine clinics. We aim to (1) identify gaps in screening for alcohol-associated liver disease within

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

an addiction medicine clinic and (2) introduce a standardized pathway to increase screening rates for alcohol related liver disease. **Methods:** We created a screening pathway with addiction and hepatology faculty, adapted from metabolic liver disease guidelines, to risk stratify patients with alcohol use disorder (AUD) at an addiction medicine clinic in a large, urban, academic medical center. It was formatted into an electronic medical record smart phrase and distributed to all providers. An education session was held during grand rounds prior to implementation. New patients with AUD were classified as low, indeterminant, or high-risk with the FIB-4 using labs within 3 months of initial visit. Low-risk patients required no evaluation. Indeterminant-risk patients (FIB-4 1.31-2.67) were referred for vibration-controlled transient elastography (VCTE), while high-risk patients (FIB-4 >2.68) were referred to hepatology. A baseline review of new patients between 1/2024 and 12/2025 was conducted. The intervention was implemented 2/3/2026. **Results:** Baseline review identified 148 patients. Of these, 82 had an initial FIB-4; 43 were low-risk, 19 were indeterminate-risk and 20 were high-risk. Among indeterminate-risk patients, VCTE was ordered for four (two completed) and three were referred to hepatology (two completed visit). Among high-risk patients, one VCTE was ordered (not completed). Five were referred to hepatology (four completed visit). After the implementation of the workflow, there were 24 new patients between 2/3/2026-5/1/2026. FIB-4 was completed for 15 patients. In total, 6 were indeterminant-risk, two of whom were referred for VCTE. Two were high-risk, and both were referred to hepatology. The remainder did not have FIB-4 screening. Two patients who were not high risk were referred to hepatology. **Conclusion:** In our clinic, screening for alcohol-associated liver disease is underutilized in patients with AUD. Referral to hepatology is similarly underutilized, though appointment attendance rates were high. Following the introduction of a screening algorithm implemented through a smart phrase, limited initial data trend towards increased FIB-4 screening and appropriate referral to hepatology, though fibroscan was still underutilized. Though preliminary, this is a promising intervention to improve screening rates.

3186 | VISIUM HD ANALYSIS IDENTIFIES HEPATIC CELL TYPE TRANSCRIPTOME CHANGES DUE TO HEPATOCYTE *PTPMT1*$^{-/-}$ IN ALCOHOL-ASSOCIATED LIVER DISEASE

Josiah Hardesty[1] Rui Treves[1] Nicolli Butzke de Souza[1] Anjali Kumari[1], [1]University of Louisville

Background: Alcohol-associated liver disease (ALD) impacts multiple cell types within the liver contributing to disease pathogenesis. Our group has identified hepatocyte cardiolipin (CL) deficiency as a contributing factor to ALD pathogenesis using a protein tyrosine phosphatase mitochondrial 1 (Ptpmt1, rate limiting enzyme for CL synthesis) hepatocyte specific KO model. In this study we performed Visium HD analysis on liver tissues for WT and *Ptpmt1*$^{-/-}$ mice at 9 and 48 h post ethanol+galactosamine (EtOH-GalN) exposure. Our goal for this study was to identify cell types affected by hepatocyte specific *Ptpmt1* KO in an experimental animal model of ALD. **Methods:** Visium HD analysis was performed on 4 individual liver sections per experimental group. Space ranger was performed to generate count data followed by bin2cell analysis and data visualization in SpatialX software. A two-way ANOVA with a Tukey multiple-comparison test was performed for the transcriptome of each hepatic cell type identified. **Results:** There were 433 differentially expressed genes (DEGs), 243 of which were downregulated with *Ptpmt1*$^{-/-}$. Genes involved in cell cycle progression (*Ccna1*) and mitochondria coded genes (*mt-Co1*) were downregulated in hepatocytes with *Ptpmt1*$^{-/-}$. In the Kupffer cell (KC) population there were 149 DEGs. Among the downregulated KC DEGs in the KO vs WT was *Mki67* which may be indicative of reduced KC repopulation after injury. *Csf3r* was upregulated in KCs which may indicate a novel KC subtype in ALD. In the hepatic neutrophil population there only 16 DEGs when comparing KO vs WT. *Pgm2* was upregulated in neutrophils of KO vs WT mice which can suggest metabolic changes promoting infiltration. *Axl* was reduced in neutrophils in KO vs WT mice which could be a novel neutrophil subtype in ALD. **Conclusion:** A spatial transcriptomic approach and data analysis method was performed to identify hepatic cell type transcriptomic changes in an experimental model of ALD. Future studies are needed to validate novel cell

3187 | CXCL12–CXCR4 AXIS IS ASSOCIATED WITH ENRICHMENT OF CXCR4$^+$ CD8$^+$ T CELLS IN ALCOHOL-ASSOCIATED LIVER DISEASE

Gil Won Lee[1] Pil Soo Sung[2] Ji Won Han[2] Hee Sun Cho[2] Kwon Yong Tak[2], [1]Liver Research Center, [2]Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea

Background: Chemokine-mediated immune cell trafficking contributes to alcohol-associated liver disease (ALD), but mechanisms linking stromal remodeling to CD8$^+$ T-cell recruitment remain unclear. This study aimed to characterize CXCR4$^+$ CD8$^+$ T cells and evaluate the role of the CXCL12–CXCR4 axis in ALD. **Methods:** Peripheral blood mononuclear cells from patients with ALD and healthy controls were analyzed by single-cell RNA sequencing and flow cytometry. Public liver single-cell datasets were integrated to identify CXCR4- and CXCL12-expressing populations. Chemotaxis was assessed using transwell assays, and liver tissues were analyzed by immunohistochemistry. **Results:** Single-cell analysis identified an exhausted/activated CD8$^+$ T-cell subset characterized by PDCD1 (PD-1) and TOX expression, with enriched CXCR4 expression and activation/cytotoxic gene signatures. In peripheral blood, CXCR4$^+$ CD8$^+$ T cells showed increased activation (CD38$^+$HLA-DR$^+$) and cytotoxicity (GrB$^+$Perforin$^+$), associated with disease severity. These cells were detected in both blood and liver, with enrichment in the liver. CXCL12 induced dose-dependent migration of CD8$^+$ T cells, with enrichment of CXCR4$^+$ CD8$^+$ T cells in migrated populations. Liver single-cell analysis identified mesenchymal stromal populations, including stellate-like and perivascular cells, as major sources of CXCL12, with CXCL12–CXCR4 signaling identified as a potential interaction pathway. **Conclusion:** CXCR4$^+$ CD8$^+$ T cells represent a functionally distinct subset with enhanced activation and cytotoxic features in ALD. These findings support a model in which mesenchymal cell–derived CXCL12 contributes to the enrichment and spatial positioning of CXCR4$^+$ CD8$^+$ T cells within fibrotic niches in ALD.

3188 | RELATIONSHIP OF PRESCRIPTION FOR MEDICATIONS FOR ALCOHOL USE DISORDER AND RETURN TO DRINKING AFTER ADMISSION FOR ALCOHOL-ASSOCIATED HEPATITIS

Krishan Patel[1] Vinay Jahagirdar[2] Omar Albhaisi[2] Husam Mikati[3] Shaanit Sen[4] Butros Fakhoury[1] Na Bo[5] Hannah Kissel-Smith[2] Juan Pablo Arab[1], [1]Virginia Commonwealth University, [2]VCU Medical Center, [3]Virginia Commonwealth University Health System, [4]VCU School of Medicine, [5]VCU

Background: Alcohol-associated hepatitis (AH) is a severe inflammatory manifestation of alcohol induced liver injury associated with high mortality, and increasing alcohol consumption has led to a growing incidence of AH. Continued alcohol intake is a primary driver of poor outcomes after AH, and alcohol cessation remains a mainstay of treatment. Unfortunately, patients with AH are known to be at an increased risk of return to drinking. Growing evidence demonstrates that medical therapy for alcohol use disorder (MAUD) may mitigate this risk in patients with alcohol related liver disease (ALD) and may improve clinical outcomes. The aim of this study was to assess the impact of receipt of MAUD on 30 and 90-day return to drinking after AH hospitalization. **Methods:** We performed a retrospective single center chart review for patients age $\geq$ 18 years with index admission for AH from March 2023 to March 2025. Patient characteristics, receipt of MAUD (naltrexone, acamprosate, gabapentin, baclofen, disulfiram) at discharge, addiction medicine consult, readmission date and reason, phosphatidylethanol (PEth) (ng/ml), drinks per day, receipt of liver transplant, and date and reason for first unplanned readmission were abstracted. Primary outcomes were return to any drinking within 30 and 90 days as noted in subsequent clinic or inpatient documentation. Multivariate regression was performed. Patients who died, were readmitted due to non-alcohol related reasons, or had liver transplant during admission were excluded. **Results:** A total of 230 patients with AH were included. Mean age was 44.7 ± 11.3 years, with 40% female, 72% white, and median MELD 3.0 of 25 (IQR 21-29). Addiction medicine was consulted for 68% of patients. In total 79 patients (34%) received MAUD, of which were primarily acamprosate (68%) and/or gabapentin (45%). Mean PEth was 575ng/ml. Return to drinking occured in 23% and 34% of patients at 30 and 90 days, respectively. In multivariate models, patients who received MAUD trended toward higher odds of return to drinking at 30 days (aOR 3.05, 95% CI 0.97-10.8) but no difference at 90 days (aOR 1.35, 0.50-3.84) (Table 1). Predictors of return to drinking at 30 days were outside hospital transfer (aOR 4.78, 1.46-17.9) and age (aOR

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

1.07,1.01-1.14) and at 90 days were ascites (2.87,1.08-7.91), higher MELD (aOR 1.10,1.02-1.20), and less likely PEth >200ng/ml (aOR 0.30, 0.09-0.87). **Conclusion:** In patients hospitalized for AH, the receipt of MAUD at discharge did not mitigate return to drinking at 30 and 90 days; however, the retrospective nature of this analysis limits standardized alcohol reporting in patients who did not have interval clinic follow up or hospitalization. Prospective studies are needed to assess differences in time-to-drinking and impact of MAUD on return to harmful drinking specifically, impact of comorbid psychiatric conditions, and differential efficacy of certain MAUD agents over others.

Table 1. Multivariate regression model for predictors of return to any drinking at 30 and 90-days in patients with index alcohol-associated hepatitis hospitalization

	30 day return to drinking		90 day return to drinking

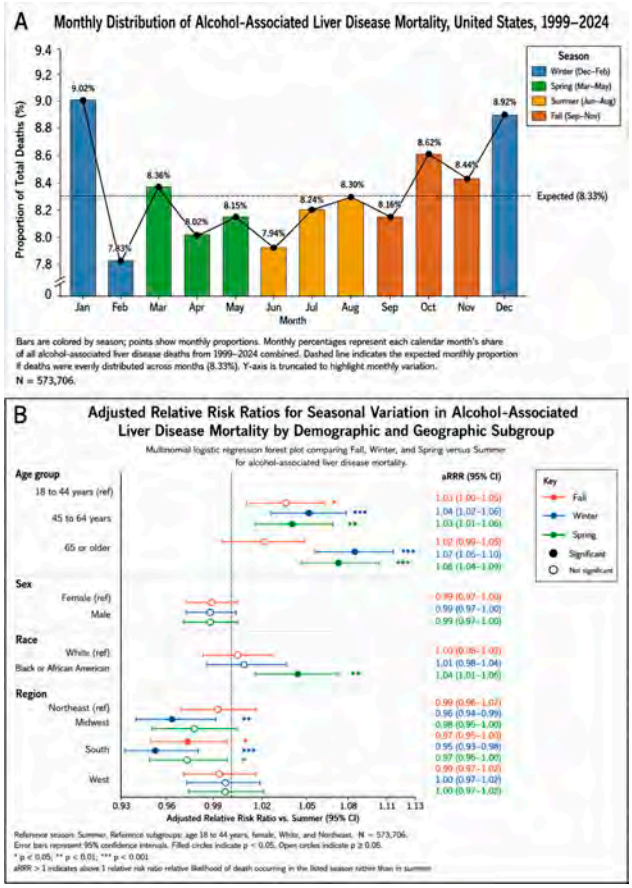
3189 | SEASONAL PATTERNS IN ALCOHOL-ASSOCIATED LIVER DISEASE MORTALITY IN THE UNITED STATES: A NATIONWIDE ANALYSIS FROM 1999-2024



EzzElDien A. Ibrahim[1] Mohammad Alkhateeb[1] Akram Alnounou[2] Nourhan Saleh[1] Mahmoud Majed Mansour[1] Islam Mohamed[1] Jeremy Louissaint[3] Juan Pablo Arab[4] Karn Wijarnpreecha[5] Nikki Duong[6], [1]University of Missouri, Columbia, MO, USA, [2]Western Michigan University Homer Stryker M.D. School of Medicine, USA, [3]University of Texas Southwestern, Dallas, TX, USA, [4]Virginia Commonwealth University School of Medicine, Richmond, VA,USA, [5]Mayo Clinic, Jacksonville, FL, USA, [6]Stanford University, Palo Alto, CA, USA

Background: Alcohol-associated liver disease (ALD) is the leading cause of liver-related mortality in the United States (U.S.). However, seasonal variation in ALD-related mortality and its interaction with demographic and geographic factors remain poorly characterized. We aimed to evaluate potential patterns in seasonal variation in ALD mortality. **Methods:** This is a retrospective cross-sectional analysis of U.S. death certificate data from the CDC WONDER multiple cause of death database from 1999 to 2024. Adults aged ≥18 years with ALD-related mortality were identified using the ICD-10 code K70. Deaths were categorized by meteorological season (Winter: December–February; Spring: March–May; Summer: June–August; Fall: September–November), age group (18–44, 45–64, ≥65 years), sex, race (White, Black), and U.S. Census region. Multinomial logistic regression with summer as the reference season was used to estimate adjusted relative risk ratios (aRRR) with 95% confidence intervals (CIs), adjusting for age, sex, race, and region. **Results:** Among 573,706 ALD-related deaths, the seasonal distribution was winter 25.8%, fall 25.2%, spring 24.5%, and summer 24.5%. January (9.02%) and December (8.92%) accounted for the greatest monthly proportions of deaths, while February had the lowest (7.83%). Compared with summer, adults aged ≥65 had significantly higher relative risk of death during winter (aRRR 1.07, 95% CI 1.05–1.10, p < 0.001) and spring (aRRR 1.06, 95% CI 1.04–1.09, p < 0.001). Adults aged 45–64 years demonstrated increased winter (aRRR 1.04, 95% CI 1.02–1.06, p < 0.001) and spring (aRRR 1.03, 95% CI 1.01–1.06, p = 0.004) mortality, whereas adults aged 18–44 (reference) showed a relative summer excess. Compared with White individuals, Black individuals demonstrated increased mortality in spring (aRRR 1.04, 95% CI 1.01–1.06, p = 0.006). Compared with the Northeast, the South had significantly lower relative risk of mortality in fall (aRRR 0.97, 95% CI 0.95–1.00, p = 0.031) and winter (aRRR 0.95, 95% CI 0.93–0.98, p < 0.001), while the Midwest had lower mortality in winter (aRRR 0.96, 95% CI 0.94–0.99, p = 0.005). **Conclusion:** ALD mortality in the United States demonstrates significant seasonal variation, with differential patterns across age, race, and geographic regions. Older adults (≥45 years) showed increased winter–spring mortality, while younger adults (18–44) showed a relative summer excess. Though effect sizes were modest, the consistency of these findings across a large national cohort suggests that seasonally targeted hepatology outreach and alcohol cessation programs

3190 | PREDICTORS OF ALCOHOL RELAPSE AFTER LIVER TRANSPLANTATION FOR ALCOHOL-RELATED LIVER DISEASE: A RETROSPECTIVE COHORT ANALYSIS

Christina Leyson[1] Bipneet Singh[1] Mustafa Alzubaidi[1] Fady Salama[1] Venkata Rajesh Konjeti[1] Nimish Thakral[1], [1]University of Kentucky

Background: Alcohol relapse after liver transplantation (LT) for alcohol-related liver disease (ALD) threatens graft survival. Identifying modifiable predictors including pharmacotherapy type, timing, transplant indication, and pre-LT abstinence is critical. **Methods:** Retrospective analysis of patients transplanted for ALD at a single center. AUD-specific pharmacotherapy included naltrexone, acamprosate, disulfiram, and topiramate. Gabapentin (neuropathy), baclofen (cramps), and varenicline (smoking) were analyzed separately. Early initiation was defined as prescription at first post-LT visit. Relapse was classified as slip or sustained relapse. **Results:** Sixty-eight patients were included (75% male; mean age 50 ± 11; mean BMI 30 ± 7). Most were transplanted for alcoholic cirrhosis (AC, 84%) versus alcoholic hepatitis (AH, 10%). At median 4-year follow-up, 19 patients (28%) relapsed: 7 slips, 12 sustained relapses. Relapse rates were similar between AH (29%) and AC (26%). Mean pre-LT abstinence was shorter among relapsers (5 vs. 10 months). Only 22 patients (32%) received AUD-specific pharmacotherapy; 9 (41%) relapsed, versus 22% of untreated patients — likely reflecting reactive prescribing after relapse. Early AUD pharmacotherapy (n = 6, 9%) was associated with 17% relapse versus 50% with late initiation. Gabapentin users had lower relapse (23%, 10/43) than non-users (36%, 9/25). Baclofen (27%, 3/11) and varenicline (17%, 1/6) showed similar trends. Two patients on GLP-1 RAs had no relapse. Non-pharmacological interventions were used in only 12%. **Conclusion:** In this cohort of patients transplanted for ALD, the overall alcohol relapse rate was 28%, with no significant difference between AH and AC indications. Shorter pre-LT abstinence was associated with higher relapse risk. AUD-specific pharmacotherapy was prescribed in only one-third of patients and was predominantly initiated late, likely as a reactive measure after relapse. Early proactive AUD pharmacotherapy at the first post-LT visit was rare (9%) but was associated with a numerically lower relapse rate (17% vs. 50% for late initiation. Gabapentin, though prescribed for neuropathy/pain, was associated with a lower relapse rate (23%) compared to non-users (36%), hinting that known anti-craving properties may confer incidental benefit even when prescribed for other indications. Both AUD-specific pharmacotherapy and non-pharmacological interventions were markedly underutilized, suggesting a need to shift focus from reactive to proactive AUD management.

3191 | INTEGRATING AI-DRIVEN HISTOPATHOLOGY AND SPATIAL TRANSCRIPTOMICS IDENTIFIES CELLULAR FUNCTIONAL STATES OF DUCTULAR REACTION IN ALCOHOL ASSOCIATED LIVER FAILURE

Ankita Srivastava[1] Madison Shoraka[2] Rajanikanth Vadigepalli[2], [1]Thomas Jefferson University, [2]University of New Mexico School of Medicine

Background: Alcohol-associated Hepatitis (AH) is a severe inflammatory manifestation of ALD characterized by acute-onset jaundice and liver enzyme abnormalities in the setting of long-term heavy alcohol use with high short-term mortality and limited therapies. AH is a frequent complication of alcohol-associated liver disease (ALD) that accounts for ~40% of liver transplantations. AH is characterized by hepatocellular dysfunction, immune activation, and aberrant proliferation of biliary phenotypic cells, referred to as the ductular reaction (DR). We hypothesize that morphological and molecular features within the liver tissue microenvironment can identify cellular functional states associated with the metabolic dysfunction in AH. **Methods:** High-resolution spatial transcriptomics (Visium HD) and histopathology data were obtained from human liver FFPE tissue from non-ALD (n = 1), AH (n = 6), and alcohol associated cirrhosis (n = 1). The spatial molecular data was analyzed at 16um resolution to identify hepatocyte- and cholangiocyte-like cell subtypes and their functional states. These molecularly defined cell states were positioned along a transcriptional continuum spanning fully hepatocyte-like to fully cholangiocyte-like gene expression profiles. We used AI-driven histopathology to segment the morphology associated with transitioning cells and progressive DR, and mapped the associated spatial molecular profiles with the DR morphologies. **Results:** We found multiple cholangiocyte-like cell states associated with proliferation, inflammation, progenitor cells, secretory cells, and ductular reaction in AH. The distribution of cells partitioned along the transcriptional continuum from fully hepatocyte-like to fully cholangiocyte-like gene expression profiles revealed transitioning states that correlated with the cholangiocyte subgroups. The differential gene expression analysis along the continuum identified metabolic processes with altered expression based on the proportion of hepatocyte versus cholangiocyte archetype. **Conclusion:** Our results point to a spectrum of metabolic, inflammatory, and proliferative cellular states across hepatocytes and cholangiocytes as underlying the progressive ductular reaction in AH.

3192 | UNRAVELING THE PROGRESSIVE REMODELING AND FUNCTIONAL EXHAUSTION OF PERIPHERAL NK CELLS IN ALCOHOL-ASSOCIATED LIVER DISEASE PROGRESSION

Young-Sun Lee[1] Ji Hoon Kim[2] Yang Jae Yoo[2] Jong eun Yeon[2] Eunho Choi[2] Yeon Seok Seo[3] Hyung Joon Yim[3] Young Kul Jung[3] Seong Hee Kang[4] Taehyung Kim[3] Sungjun Jang[2], [1]Korea University College of Medicine, [2]Korea university Guro Hospital, [3]Korea university, [4]4 Seasons Granwell Corp.

Background: Alcohol-associated liver disease (ALD) remains a leading cause of liver-related mortality worldwide, yet the immunological mechanisms driving its progression from steatosis to cirrhosis remain incompletely defined. Although natural killer (NK) cells are central mediators of anti-fibrotic surveillance, their progressive functional impairment is a hallmark of chronic liver injury. We aimed to delineate the high-resolution transcriptomic and functional landscape of peripheral $CD56^{dim}$ NK cells—the principal cytotoxic subset—across the clinical spectrum of ALD. **Methods:** We integrated single-cell RNA sequencing (scRNA-seq) with flow cytometry to profile peripheral blood mononuclear cells (PBMCs) from healthy controls (n = 4), patients with alcoholic fatty liver (AFL, n = 6), and patients with alcoholic cirrhosis (n = 3). A dedicated computational pipeline was applied to resolve subset heterogeneity, functional states, and molecular programs within the $CD56^{dim}$ NK compartment. **Results:** Analysis of 7,354 high-quality $CD56^{dim}$ NK cells revealed four transcriptionally distinct subsets, including a terminally exhausted population that expanded markedly with disease progression and dominated the cirrhotic compartment. Functional trajectory analysis uncovered a biphasic course: transient hyperactivation at the AFL stage was followed by collapse into terminal dysfunction in cirrhosis. Mechanistically, exhausted NK cells in cirrhosis exhibited a fixed molecular program defined by co-upregulation of canonical checkpoints (*TIGIT*, *LAG3*) together with previously unappreciated regulators, including the post-transcriptional repressor *ZFP36* and the GPCR-desensitizing β-arrestin *ARRB2*. **Conclusion:** ALD progression is driven by the systematic expansion and molecular "lockdown" of exhausted peripheral $CD56^{dim}$ NK cells, reflecting a stepwise failure of anti-fibrotic immune surveillance. This

3193 | HEPATIC SIRT7 MODULATES BILE ACID HOMEOSTASIS PROMOTES PMN-MDSC DIFFERENTIATION AND AGGRAVATES ALCOHOL-ASSOCIATED LIVER INJURY

Yicheng Teng[1] Gaoshuang Liang[1] Qin Jiang[2] Qikun Fan[1] Zhuan Li[1], [1]Hunan Normal University, [2]the Second Xiangya Hospital of Central South University

Background: Polymorphonuclear myeloid-derived suppressor cells (PMN-MDSCs), a pathologically activated subset of neutrophils, implicated in the progression of alcohol-associated liver disease (ALD). However, the mechanisms by which injured hepatocytes shape the hepatic immune microenvironment and influence PMN-MDSC differentiation remain unveil. **Methods:** Hepatocyte-specific *SIRT7*-deficient mice (*Alb-Cre SIRT7*$^{-/-}$) and wild-type littermates were subjected to a Lieber-DeCarli ethanol diet to model ALD. Hepatic immune cell populations were characterized using flow cytometry and single-cell transcriptomic analysis. Targeted metabolomic analyses were performed to assess alterations in bile acid composition. PMN-MDSC differentiation was comprehensively tracked using a panel of canonical markers, including *CD300ld*, *Arg1*, and *S100A8/A9 both in vivo* and *in vitro*. **Results:** Analysis of clinical samples and experimental ALD models indicated an enrichment of *CD300ld*$^{+}$ PMN-MDSCs in the diseased liver. Hepatocyte-specific deletion of *SIRT7* was associated with attenuated alcohol-induced liver injury and a reduction in hepatic PMN-MDSC accumulation. Mechanistic investigations revealed that the loss of hepatocyte *SIRT7* resulted in a profoundly altered bile acid spectrum, identifying deoxycholic acid (DCA). *In vitro* studies demonstrated that DCA acts as a potent metabolic signal to drive the differentiation of induced neutrophils toward a PMN-MDSC-like phenotype in a strictly dose- and time-dependent manner, an effect precisely mediated through the activation of *TGR5* receptors on neutrophils. **Conclusion:** Our findings unveil previously unrecognized involvement of hepatocyte SIRT7 orchestrates ALD progression by modulating bile acid homeostasis which in turn promotes PMN-MDSC differentiation. Elucidating this novel *SIRT7-DCA-TGR5* axis provides mechanistic framework for decoding hepatocyte-immune cell crosstalk and uncovers promising therapeutic targets for ALD intervention.

3194 | A NOVEL PERSPECTIVE ON THE ROLE OF CHOLINERGIC ANTI-INFLAMMATION IN ALCOHOLIC STEATOHEPATITIS: THE SPLEEN–LIVER AXIS

Nan Zhang[1] Lin Jia[1], [1]UT Dallas

Background: Alcohol-associated liver disease (ALD) is a leading cause of chronic liver disease worldwide. Alcoholic steatohepatitis, a severe form of ALD, is characterized by hepatic steatosis and inflammation, partially driven by macrophage-mediated immune responses. The α7 nicotinic acetylcholine receptor (α7-nAChR), encoded by the *Chrna7* gene, plays an important role in the cholinergic anti-inflammatory pathway. ALD progression is closely associated with activation of hepatic resident Kupffer cells and infiltrating macrophages. However, the contributions of these two Chrna7-expressing macrophage populations to alcoholic steatohepatitis remain unclear. The spleen is recognized as a reservoir of macrophages that infiltrate target organs and contribute to various inflammatory diseases. However, the potential role of spleen-liver immune crosstalk in ALD remains unknown. **Methods:** Myeloid cell-specific and Kupffer cell–specific Chrna7 knockout mice were generated and subjected to acute-on-chronic (NIAAA) alcohol feeding model. To determine the contribution of spleen-derived macrophages to ALD, splenectomy was performed in C57BL/6J mice prior to alcohol exposure. In addition, *in vivo* splenic macrophage tracking was also used to explore alcohol-induced remodeling of hepatic macrophage populations and spleen-liver immune interactions. **Results:** Myeloid-specific deletion of *Chrna7* exacerbated alcoholic steatohepatitis, with increased plasma ALT, hepatic triglyceride accumulation, and elevated inflammatory cytokines, such as TNF-α and IL-1β. In contrast, Kupffer cell–specific *Chrna7* deletion unexpectedly attenuated liver injury, showing reduced ALT and a modest reduction in pro-inflammatory gene expression. Splenectomized mice displayed significantly reduced ALT and hepatic IL-1β after alcohol feeding. Excessive alcohol intake significantly increased the recruitment of spleen-derived macrophages into the liver in mice. **Conclusion:** Our findings demonstrate that myeloid cell α7-nAChR exerts anti-inflammatory and hepatoprotective effects, whereas its deletion in Kupffer cells

attenuates ALD, suggesting that macrophage heterogeneity differentially regulates ALD progression. This paradoxical effect may be related to altered spleen-derived macrophage recruitment, indicating spleen-liver immune crosstalk as an underappreciated mechanism in ALD.

3195 | ◆ ENTRY INHIBITOR HEPALATIDE AT 4.2 MG ACHIEVED SUBSTANTIAL HDV RNA UNDETECTABILITY AT WEEK 48: FINAL RESULTS FROM A PHASE IIB MULTICENTER RANDOMIZED CONTROLLED TRIAL IN HYPERENDEMIC MONGOLIAN PATIENTS WITH CHRONIC HEPATITIS D

Janchiv Oyunbileg[1] Xiaolu Tang[2] Shirnin Tamir[3] Otgonjargal Nomingerel[3] Batzorig Orgil[3] Batjargal Azjargal[4] Chogsom Munkhzaya[5] Xian Gao[2] Fei Cai[2] Wenhui Liu[2] Hanzhi Fang[6] Hongli Liu[2], [1]National Center for Public Health, Ulaanbaatar, Mongolia, [2]Shanghai HEP Pharma Co., Ltd., [3]SFCS Site Management LLC, Ulaanbaatar, Mongolia, [4]National Center for Communicable Diseases, Ulaanbaatar, Mongolia, [5]National Cancer Center of Mongolia, Ulaanbaatar, Mongolia, [6]Shanghai HEP Pharma Co., Ltd

Background: Chronic hepatitis Delta (CHD) is the most aggressive form of viral hepatitis. The recent FDA approval of bulevirtide has further validated HBV/HDV entry inhibitor monotherapy in CHD treatment; however, post-treatment relapse remains a central challenge. Achievement of undetectable HDV RNA is considered a prerequisite for discontinuing entry inhibitors with a low risk of relapse. Yet in MYR301, Week 48 HDV RNA undetectability with bulevirtide at an 8.5 mg/day delivered dose remained limited (20%). Here, we report the Week 48 results from a phase IIb trial of the entry inhibitor hepalatide in Mongolian patients with CHD, in which hepalatide 4.2 mg achieved a substantial rate of HDV RNA undetectability. **Methods:** This multicenter, randomized, open-label, delayed-treatment–controlled trial enrolled adults aged 18–65 years with compensated CHD and quantifiable HDV RNA in Mongolia (NCT06505928). Participants were randomized 1:1:1 to once-daily subcutaneous hepalatide 2.1 mg, hepalatide 4.2 mg, or delayed treatment for 48 weeks, followed by a 96-week extension with hepalatide. Virological response was defined as undetectable HDV RNA (10 decline from baseline, biochemical response as ALT normalization, and combined response as both. Combined response and safety were assessed at Week 48. **Results:** Ninety participants were randomized to hepalatide 2.1 mg, hepalatide 4.2 mg, or delayed treatment (n = 31, 29, and 30), and 87 completed Week 48. Hepalatide was generally well tolerated, with no grade ≥ 3 treatment-related adverse events. At Week 48, virological response was achieved in 52%, 79%, and 0% of subjects in the 2.1 mg, 4.2 mg, and delayed-treatment groups; mean HDV RNA changes from baseline were −2.2, −3.4, and +0.2 $\log_{10}$ IU/mL. Biochemical response occurred in 65%, 76%, and 7%, and combined response in 45%, 59%, and 0%. Both hepalatide groups showed significantly higher virological, biochemical, and combined response rates than delayed treatment ($P < 0.001$ for each comparison). HDV RNA was undetectable in 16% (5/31) of subjects in the 2.1 mg group and 41% (12/29) in the 4.2 mg group, compared with none in delayed treatment. The 4.2 mg dose yielded a higher virological response rate than 2.1 mg ($P = 0.03$) and more than doubled the HDV RNA undetectability rate ($P = 0.04$). **Conclusion:** Hepalatide demonstrated significant virological, biochemical, and combined responses with good tolerability through Week 48 in Mongolian patients with CHD. Building on MYR301 data showing broadly comparable responses across bulevirtide dose groups, the higher response and HDV RNA undetectability rates observed with hepalatide 4.2 mg versus 2.1 mg add a dose-related signal to the clinical evidence for HBV/HDV entry inhibition. These findings suggest the potential for sustainable post-treatment virological suppression with entry inhibitors in this highly endemic Mongolian population.

Cotugno - AO dei Colli – Napoli, [44]Unit of Infectious Diseases, ASST della Valle Olona, Busto Arsizio, Italy., [45]Niguarda Ca Granda

Background: Bulevirtide (BLV) was licensed in Italy in May 2023 for patients with chronic hepatitis delta (CHD), but no real-life studies have addressed differences in responses rates among patients with and without cirrhosis. **Methods:** CHD patients starting BLV 2 mg/day monotherapy were included in a multicenter prospective real-life Italian study (D-SHIELD). Patients' features and treatment responses were assessed at baseline and trimonthly afterwards. Virological response (VR) ($\geq$2 LogIU/mL HDV-RNA decline *vs.* baseline or HDV RNA undetectable), biochemical and combined responses (BR and CR), incidence of virological breakthroughs (VBK; >1 Log HDV RNA increase *vs.* previous timepoint), biochemical breakthroughs (BKK, >x1.5 ALT increase >1.5× from nadir in patients without BR, or loss of BR with ALT >1.5×ULN in patients previously achieving BR), and

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

safety were assessed comparing patients with and without cirrhosis. **Results:** 501 patients treated with BLV monotherapy up to 96 weeks from 46 centers were enrolled, 358 (72%) with cirrhosis and 142 without cirrhosis. Patients without cirrhosis were younger (54 *vs.* 49, $p < 0.001$), were less commonly treated with NA (98% *vs.* 91%, $p < 0.001$), had lower LSM values (15.8 *vs.* 8.2 kPa, $p < 0.001$) and higher HDV RNA levels (5.2 *vs.* 5.3 Log IU/L $p = 0.02$), PLTs (99 *vs.* 189 $\times 10^9$/L $p < 0.001$), and HBsAg (3.71 *vs.* 3.85 Log IU/mL, $p = 0.03$). ALT did not significantly differ at baseline (75 *vs.* 71 U/L, $p = 0.25$). VR, BR and CR rates increased progressively throughout treatment and did not significantly differ between patients with and without cirrhosis at any timepoint. At week 96, BR rates were 70% *vs.* 69% ($p = 1.00$), VR 75% *vs.* 83% ($p = 0.72$), and CR 61% *vs.* 58% ($p = 0.85$), respectively. Only HDV RNA undetectability rates (HDV RNA vs. 12% $p = 0.005$, p = ns for other timepoints). Overall, 46 patients (9.2%) experienced VBK,[1] most commonly between weeks 48 and 72 (37, 80%). VBK incidence did not differ between patients with and without cirrhosis (9.2% vs. 9.1%, $p = 1.00$). Among patients with available data, VBK was persistent up to week 96 in 44% of cases. 14 patients (2.8%) experienced BKK, [2] [3] again without differences according to cirrhosis status (3.5% vs. 2.5%, $p = 0.55$). Most BKK events (75%) occurred between weeks 48 and 72. Among patients with available data, BKK was persistent up to week 96 in 25% of cases. 8 patients both had a VBK and a BKK. No significant differences were observed in the incidence of adverse events among patients with and without cirrhosis, (15% *vs.* 15%, $p = 1.00$), with mild and transient pruritus and injection site reaction being the most common. Patients with cirrhosis showed higher baseline and on-therapy bile acids levels ($p < 0.001$ at all time-points). **Conclusion:** The effectiveness and safety profile of BLV monotherapy did not differ in patients with or without compensated cirrhosis in this large prospective multicenter Italian study.

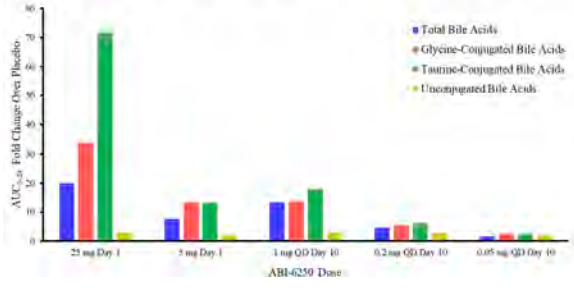
3197 | ◆ ORAL NTCP INHIBITOR ABI-6250 ELEVATES BILE ACIDS IN A RANDOMIZED, BLINDED, PHASE 1A STUDY IN HEALTHY SUBJECTS

Edward Gane[1] Christian Schwabe[2] Katie Zomorodi[3] Jinghu Carl Li[3] Sam Kim[3] Lewyn Li[3] Grace Wang[3] Anuj Gaggar[3] Mathias Haag[4] Matthias Schwab[5], [1]University of Auckland, [2]New Zealand Clinical Research, [3]Assembly Biosciences, Inc., [4]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology, [5]Dr. Margarete Fischer-Bosch Institute of Clinical Pharmacology and University of Tuebingen



Background: ABI-6250 (6250) is an orally bioavailable, small molecule inhibitor of the sodium taurocholate cotransporting polypeptide (NTCP), a bile acid (BA) transporter that both the hepatitis B and D viruses utilize as an entry receptor into hepatocytes. ABI-6250-101 (NCT06740474) was a randomized, blinded study assessing the safety, pharmacokinetics (PK), and pharmacodynamics (PD) of 6250 in healthy

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

participants. PD was assessed by evaluating total BA (tBA) and fractional BA (fBA) levels. **Methods:** Two single-dose (SD) cohorts of 5mg and 25mg, and 3 multiple-dose cohorts of 0.05mg, 0.2mg and 1mg 6250 once-daily (QD) for 10 days were evaluated. In each cohort, 8 participants were randomized 3:1 to 6250 or placebo (PBO). Plasma tBA levels were measured by enzymatic colorimetric assay. Plasma fBAs including unconjugated (UCBA), Glycine-Conjugated (GCBA), and Taurine-Conjugated (TCBA) were measured by Liquid Chromatography Mass Spectrometry (LCMS). Area under plasma concentration curve over 24 hours (AUC_{0-24}) values for each BA were calculated using non-compartmental methods. **Results:** The AUC_{0-24} values for tBA increased by approximately 20-fold, 8-fold, 13-fold, 5-fold, and 2-fold for the 25 mg SD, 5 mg SD, 1 mg QD, 0.2 mg QD, and 0.05 mg QD doses compared with PBO (Figure 1). UCBA levels did not increase significantly after 6250 administrations, and AUC_{0-24} values were generally $\leq$3-fold higher across all doses compared with PBO. GCBA and TCBA levels increased in a dose dependent manner. At the 25 mg SD dose, AUC_{0-24} values increased by approximately 34-fold for GCBA and 72-fold for TCBA compared with PBO. On Day 10 at the 1 mg QD dose, AUC_{0-24} values increased by approximately 14-fold for GCBA and 18-fold for TCBA compared with PBO. **Conclusion:** Elevations in tBAs and fBAs observed with 6250 are consistent with those reported for bulevirtide, a specific inhibitor of NTCP, and indicate potent target engagement of 6250. fBA analysis showed GCBA and TCBA levels, considered measures of on-target NTCP engagement, increased in a dose-dependent and reversible manner, whereas there were no considerable increases in UCBA levels.

Figure 1. Comparative Analysis of tBA, GCBA, TCBA, and UCBA AUCs Relative to Placebo Across ABI-6250 Dose Levels in Study ABI-6250-101

Background: Bulevirtide (BLV) is approved by EMA for treatment of chronic hepatitis Delta (CHD), however data about long-term outcomes in patients with cirrhosis are limited. **Methods:** CHD patients with cirrhosis treated with BLV 2 mg/day in the SAVE-D study (51 centers) were included. Virological (HDV RNA undetectable or ≥ 2 Log_{10} decline *vs.* baseline), biochemical (ALT < 40 U/L), combined response, viral breakthroughs (VBK: 1 Log_{10} HDV RNA increase *vs.* previous timepoint) and liver-related events (LREs) were assessed. Clinically significant portal hypertension (CSPH) was defined according to Baveno VII criteria. **Results:** 424 patients treated with BLV up to 192 weeks (W) were included: age 50 (IQR 40-58) years, 61% men, ALT 78 (51-128) U/L, liver stiffness measurement (LSM) 16.5 (12.6-25.3) kPa, platelets 101 (68-149) x10^9 /L, 96% CPT score A, 51% with varices, 9% with previous decompensation, 90% on NUC. Baseline HDV-RNA was 5.4 (4.2-6.3) Log_{10}IU/mL and qHBsAg 3.7 (3.2-4.1) Log_{10}IU/mL. After W144 of BLV, 73%, 69%, 54% and 35% of patients achieved virological, biochemical, combined response, and HDV RNA undetectability, respectively. In 59 patients with available W192 data, the corresponding figures were 79%, 71%, 59% and 41%. Patients with < 1 Log_{10} HDV RNA decline *vs.* baseline decreased from 20% (W48) to 14% (W144). VBK occurred in 7% between W48-W96 (77% normal ALT) and 9% between W96-W144 (70% normal ALT). Clinically significant portal hypertension according to Baveno VII non-invasive definitions improved in up to 40% of patients. 29 patients developed a LRE, 9 decompensation and 20 HCC: the 3-year cumulative incidences were 2.3% (95% CI 1-4%) and 6.8% (95% CI 3-9%), respectively. Lower baseline albumin independently predicted decompensation, whereas age, BMI and albumin predicted HCC occurrence. 29 patients underwent LT (22 HCC, 7 decompensation) and 14 patients died, 9 of LREs. Persistence on-treatment was maintained by 93%

of patients, 30 discontinued BLV monotherapy (7 add-on IFN, 2 skin allergy, 2 decompensation, 3 undetectable HDV RNA, 3 non-compliance, 2 non-response, 2 clinical trial entry, 1 HBsAg loss), 8 were lost to follow-up. **Conclusion:** In CHD patients with cirrhosis, BLV monotherapy 2 mg/day up to 192 weeks was safe and effective. Virological and clinical responses increased over-time. Rates of de-novo liver-related events remained low, especially liver decompensation.

Background: Chronic hepatitis delta (CHD) carries the highest risk of cirrhosis progression and hepatocellular carcinoma (HCC) among viral hepatitis. However, disease-specific models to guide HCC risk stratification and surveillance in CHD remain undefined. **Methods:** CHD patients with cirrhosis from the retrospective multicenter real-world European SAVE-D study were included. PAGE-B and AMAP scores were calculated at BLV start as previously described. PAGE-B was defined as low (<10) *vs.* intermediate (10-17) *vs.* high (≥ 18) risk profile. AMAP was defined as low (<50) vs. medium (50–59) vs. high (≥ 60) risk profile. HCC incidence rates in the different PAGE-B and AMAP groups during Bulevirtide (BLV) monotherapy were assessed. Patients with previous HCC were excluded. **Results:** 391 patients with cirrhosis treated with BLV monotherapy up to 240 weeks were included: age 49 (IQR 40-57) years, 60% men, median platelet (PLT) count 102 (69-148) x 10^9 /L. At BLV start, 117 (30%) patients had low risk PAGE B score, 255 intermediate risk (65%), and 19 (5%) had high-risk PAGE B score. Median PLT count in the PAGE B high risk score was 75 (60-90), median age 64 (62-67). AMAP score could be calculated in 387 patients: 10 patients (3%) had low risk AMAP score (3%), 84 (22%) intermediate, and 293 (76%) high risk AMAP score. During 240 weeks of BLV monotherapy, 17 de-novo HCC occurred. When analyzing incidence of de novo HCC according to HCC risk scores, 2 (12%) HCC developed in the PAGE-B low-risk group, 11 (65%) in the intermediate-risk group, and 4 (24%) in the high-risk group. The corresponding 240-week cumulative incidence in the 3 groups was 2.2%, 5.7%, and 30.9%, respectively. Concerning AMAP score, no HCC developed in the low-risk group, 1 (6%) in the intermediate risk score, and the remaining 16 (94%) in the high-risk score. No HCC occurred in the 4 patients for whom AMAP could not be calculated due to missing data. The corresponding 240-week cumulative incidence of HCC in the 3 AMAP groups was: 0%, 1.3% and 7.7%, respectively. Median time to HCC was 11 (10-25) months. At baseline lower albumin levels (HR 0.22, 95% CI 0.09-0.56, $p=0.001$), higher bilirubin (HR 2.02; 95% CI 1.12-3.65, $p<0.001$), and higher LSM (HR 1.05; 95% CI 1.02-1.08, $p=0.003$) independently predicted HCC development. **Conclusion:** PAGE-B and AMAP scores retained clinical utility for HCC risk stratification in CHD patients receiving long-term BLV monotherapy, although HDV-specific risk models are still needed for an HDV-tailored HCC surveillance strategy.

3200 | ◆ CHARACTERISTICS AND OUTCOMES OF ON-TREATMENT ALT FLARES IN PATIENTS WITH HEPATITIS DELTA VIRUS RECEIVING BULEVIRTIDE AND PEGYLATED INTERFERON

Fabien Zoulim[1] Soo Aleman[2] Tarik Asselah[3] Pavel Bogomolov[4] Maurizia Brunetto[5] Vladimir Chulanov[6] George Gherlan[7] Pietro Lampertico[8] Viacheslav Morozov[9] Olga Sagalova[10] Tatiana Stepanova[11] Adrian Streinu-Cercel[12] Amos Lichtman[13] Mingyang Li[13] Danielle Shing[14] Shane Kelly[14] Steve Tseng[13] Dmitry Manuilov[13] Heiner Wedemeyer[15], [1]INSERM Unité Mixte de Recherche 1350, PaThLiv IHU EVEREST, Université Claude-Bernard Lyon 1, [2]Department of Infectious Diseases, Karolinska University Hospital/Karolinska Institutet, [3]Hôpital Beaujon APHP, Université de Paris-Cité, INSERM UMR1149, Clichy, France, [4]M.F. Vladimirsky Moscow Regional Research and Clinical Institute, Moscow, Russian Federation, [5]University of Pisa; University Hospital of Pisa, [6]Sechenov University, Moscow, Russian Federation, [7]Dr. Victor Babes Foundation; University of Medicine and Pharmacy Bucharest, [8]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico; University of Milan, [9]LLC Medical Company Hepatolog, Samara, Russian Federation, [10]South Ural State Medical University, Chelyabinsk, Russian Federation, [11]LLC Clinic of Modern Medicine, Moscow, Russian Federation, [12]National Institute of Infectious Diseases Bucharest; University of Medicine and Pharmacy Bucharest, [13]Gilead Sciences, Inc., Foster City, CA, USA, [14]Gilead Sciences International, Ltd., Cambridge, United Kingdom, [15]Hannover Medical School, Hannover, Germany

Background: Bulevirtide (BLV) monotherapy is approved to treat chronic hepatitis delta virus (HDV) in the US, Europe, and other regions, and has demonstrated virologic response (VR) and alanine aminotransferase (ALT) normalization in clinical trials alone and with pegylated interferon alfa-2a (PegIFN). ALT flares can occur during PegIFN therapy and may be beneficial in inducing a VR. This study evaluated on-treatment (on-tx) ALT flares occurring with BLV +PegIFN vs PegIFN monotherapy. **Methods:** A pooled analysis evaluated characteristics and outcomes of on-tx ALT flares in the phase 2 MYR203 (NCT02888106) and MYR204 (NCT03852433) studies in participants (pts) who received PegIFN alone or with BLV 2, 5, or 10 mg, for 48 weeks (wks). On-tx ALT flares were defined as ALT > 10× upper limit of normal (ULN) and > 1× baseline (BL); ALT > 2.5× BL; or ALT > 2.5× previous on-tx nadir and > 2.5× ULN. Beneficial flares were defined as HDV RNA newly undetectable or decline of > 1 $\log_{10}$ IU/mL; or hepatitis B surface antigen (HBsAg) loss or decline of > 0.5 $\log_{10}$ IU/mL; simultaneously or within 8 wks of flare onset. **Results:** Of 184 pts, 56 (30%) had an on-tx ALT flare by Week (W) 48: 28% (40/145) BLV+PegIFN; 41% (16/39) PegIFN (**Table**). Median flare onset for BLV+PegIFN was 8 wks and 78% (31/40) resolved by W48, vs 14 wks and 69% (11/16), respectively, for PegIFN. BLV+PegIFN and PegIFN groups had the same rate (13%) of bilirubin elevation > 2 mg/dL (5/40 and 2/16, respectively); no pts had an international normalized ratio > 1.5. In the BLV+PegIFN group with on-tx ALT flares, 10% (4/40) had a PegIFN dose reduction; 8% (3/40) discontinued PegIFN due to hepatic adverse events (AEs) associated with the flares; 48% (19/40) had on-tx hepatic AEs,

with 1 on-tx liver-related event of hepatic cirrhosis with no decompensation events. Overall, similar safety outcomes of on-tx ALT flares were observed for PegIFN (**Table**). For the 40 pts receiving BLV+PegIFN with on-tx ALT flares, mean change (SD) from pre-flare in HDV RNA was –2.1 (1.1) log_{10} IU/mL and HBsAg was –0.5 (0.8) log_{10} IU/mL within 8 wks of flare onset; 85% (34/40) had a beneficial flare, with all 34 having undetectable or a decline in HDV RNA and 38% (13/34) having a loss or decline in HBsAg within 8 wks of flare onset. Only 38% (6/16) of pts receiving PegIFN with on-tx ALT flares had beneficial flares. HDV RNA undetectability and HBsAg loss rates at W48 were higher in pts receiving BLV+PegIFN with on-tx ALT flares (n = 40; 73% and 10%) vs pts without flares (n = 105, 54% and 4%). **Conclusion:** Rates of on-tx ALT flares were lower with BLV+PegIFN than PegIFN alone (28% vs 41%), but a higher proportion (85% vs 38%) were beneficial and accompanied by declines in viral markers. As safety outcomes observed with the flares were similar between groups this suggests BLV may have positively mediated ALT flares caused by PegIFN. ALT flares during BLV+PegIFN treatment generally self-resolved before end of treatment and were accompanied by a positive treatment response.

Table. Characteristics of On-treatment ALT Flares by Week 48 with Bulevirtide and Pegylated Interferon alfa-2a

n (%), unless otherwise specified	Participants with on-tx ALT flare by Week 48	
	BLV (2 mg, 5 mg, or 10 mg) + PegIFN (n=40)	PegIFN (n=16)
ALT >10× ULN and >1× baseline	9 (23)	5 (31)
ALT >2.5× baseline	25 (63)	11 (69)
ALT >2.5× nadir and >2.5× ULN[c]	29 (73)	12 (75)
Time to flare onset, median (Q1, Q3), weeks	8 (4, 18)	14 (8, 20)
Flare resolved on-tx by Week 48	31 (78)	11 (69)
PegIFN dose reduction due to hepatic AEs[a]	4 (10)	2 (13)
Hepatic AEs leading to PegIFN discontinuation[a,d]	3 (8)	1 (6)
Bilirubin elevation >2 mg/dL[e]	5 (13)	2 (13)
International normalized ratio >1.5[e]	0	0
Hepatic AEs[a,d]	19 (48)	9 (56)
Liver-related events[d,f]	1 (3)	0
Beneficial flare[f]	34 (85)	6 (38)
Decline >1 log_{10} IU/mL or undetectability of HDV RNA[g]	34 (85)	5 (31)
Undetectability of HDV RNA at Week 48	29 (73)	2 (13)
Loss or decline >0.5 log_{10} IU/mL in HBsAg[g]	13 (33)	2 (13)
HBsAg loss at Week 48	4 (10)	0

On-treatment period ends at PegIFN last dose +7 days for BLV+PegIFN and PegIFN groups.
[c]Nadir is the lowest on-treatment ALT value previously. [d]Defined as AEs suggestive of hepatitis flares. [a]Also includes discontinuation due to drug-induced liver injury. [e]Safety outcomes are from on-treatment ALT flare onset up to Week 48 in the on-treatment period. [d]Defined as liver-related clinical events such as cirrhosis development; liver decompensation including development or worsening jaundice, coagulopathy, ascites, hepatic encephalopathy, bleeding from varices, and liver failure; HCC development; liver transplantation and liver related death. [f]Beneficial flares were defined as an HDV RNA newly undetectable or decline of >1 log_{10} IU/mL or HBsAg loss or decline of >0.5 log_{10} IU/mL simultaneously or within subsequent 8 weeks of flare onset in the on-treatment period by Week 48. [g]HDV RNA decline of >1 log_{10} IU/mL or newly undetectable simultaneously or within subsequent 8 weeks of flare onset in the on-treatment period by Week 48. [h]HBsAg loss or decline of >0.5 log_{10} IU/mL simultaneously or within 8 weeks following flare onset in the on-treatment period by Week 48.
AEs, adverse events; ALT, alanine aminotransferase; BLV, bulevirtide; HBsAg, hepatitis B surface antigen; HCC, hepatocellular carcinoma; HDV, hepatitis delta virus; on-tx, on-treatment; PegIFN, pegylated interferon alfa-2a; ULN, upper limit of normal.

3201 | COMPARATIVE EFFICACY AND SAFETY OF TREATMENTS FOR HEPATITIS DELTA VIRUS INFECTION: A BAYESIAN DOSE-POOLED NETWORK META-ANALYSIS

Rahul Falodia[1] Ehsanullah Alokozay[2] Muhammad Junaid Azhar[3] Taha Alam[4] Hamza Sajid[5] Farhan Murtaza[6] Muhammad Zawar Asif[7] Ali Chand[8] Syed Asjad Tauheed Zaidi[8] Miriam Michael[8] Delilah Easom[9] Anand Deonarine[8], [1]All India Institute of Medical Sciences, Jodhpur, [2]Faculty of Medicine, Kandahar University, Kandahar, Afghanistan, [3]Howard University Hospital, Washington DC, [4]Dow University of Health Sciences, Karachi Pakistan, [5]Allama Iqbal Medical College, Lahore, Pakistan, [6]HCA Houston Healthcare/ University of Houston Program, [7]Mercy Hospital Fort Smith, Arkansas/ Arkansas College of Osteopathic Medicine, [8]Howard University Hospital, [9]Mercy Hospital Fort Smith Arkansas College of Ostepathic Medicine

Background: Chronic hepatitis delta virus (HDV) infection is the most severe form of viral hepatitis, frequently leading to liver cirrhosis and hepatocellular carcinoma. Recently, several pharmacological interventions, including entry inhibitors and prenylation inhibitors, have emerged as potential therapeutic options. We conducted a comprehensive Bayesian dose-pooled network meta-analysis (NMA) to evaluate the relative efficacy and safety of current pharmacological treatments for chronic HDV infection. **Methods:** Pubmed, Cochrane, Embase and Scopus were systematically searched for relevant RCTs. Efficacy outcomes included virological response (VR; $\geq$2 log10 HDV RNA decline or undetectable), undetectable HDV RNA (UR), ALT normalization (ALT-N), and a combined response (CR). Safety outcome included Grade $\geq$3 adverse events (AEs). A Bayesian random-effects model was implemented using the gemtc package in R, and odds ratios (OR) with 95% credible intervals (CrIs) was calculated. Treatments were ranked using the Surface Under the Cumulative Ranking curve (SUCRA). **Results:** Thirteen direct comparison edges across eight treatment nodes were analyzed. Bulevirtide plus peginterferon (BLV + Peg-IFN) demonstrated the highest efficacy across all virological and biochemical outcomes, ranking first for VR (OR 393.49; SUCRA 99%), UR (SUCRA 99%), ALT-N (SUCRA 85%), and CR (SUCRA 96%). Bulevirtide monotherapy was consistently identified as the second most effective treatment, showing significant superiority over control for VR (OR 35.88; SUCRA 72%) and CR (SUCRA 76%). Peginterferon-based regimens and Lonafarnib plus ritonavir showed intermediate efficacy while adefovir monotherapy was ineffective (SUCRA 1%). Safety analysis revealed that peginterferon plus adefovir was the safest treatment regarding Grade $\geq$3 AEs (OR 2.26; SUCRA 79%), followed by peginterferon monotherapy (OR 2.11; SUCRA 60%). BLV + Peg-IFN showed a higher AE burden (OR 7.63; SUCRA 29%), likely reflecting the additive toxicity of the interferon component. Disconnected evidence from one study indicated that tobevibart plus elebsiran had a numerically higher VR rate than tobevibart alone (OR 5.94), though this didn't reach statistical significance. **Conclusion:** Bulevirtide in combination with peginterferon is the most effective therapeutic strategy though it carries a higher risk of adverse events. Bulevirtide monotherapy presents as an effective alternative with better-tolerated long-term maintenance strategy While peginterferon-based regimens offer intermediate efficacy with a favorable safety profile, adefovir monotherapy lacks clinical benefit. These findings establish a comprehensive hierarchy of treatments, while transitioning HDV management toward optimized, patient-specific strategies that balance treatment intensity with long-term safety.

Instituto Carlos III, Madrid, Spain, [3]Gilead Sciences, Inc., Stockley Park, United Kingdom, [4]Pharmacoevidence, Mohali, India, [5]Gilead Sciences, Inc., Foster City, CA, USA, [6]Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico and University of Milan, Milan, Italy

Background: Hepatitis delta virus (HDV) infection is associated with substantial liver-related morbidity and mortality. Evaluation of treatment response through reliable surrogate endpoints is critical for timely treatment decisions. This systematic literature review (SLR) and meta-analysis aim to evaluate the association between post-treatment HDV RNA–based surrogate endpoints and long-term clinical outcomes in adults with HDV infection. **Methods:** Embase, PubMed, and Cochrane were searched from inception to August 2025 for studies evaluating associations between HDV RNA–based surrogate endpoints and any clinical outcomes. The review followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. Reported hazard ratios (HRs) and odds ratios (ORs) were extracted directly, where available. In some cases, ORs were calculated from categorical data, and HRs were derived from digitized Kaplan–Meier (KM) curves. Meta-analysis was performed in Stata 19 using the DerSimonian-Laird random-effects model. A separate pooled KM curve analysis was also conducted using metaSurvival package. **Results:** Seventeen studies (15 full-text studies; 2 abstracts) evaluated the association between post-treatment HDV RNA undetectability and any liver-related event, including hepatic decompensation, hepatocellular carcinoma, liver transplantation, and liver-related death. Most studies were retrospective (n = 14) and conducted in Europe (n = 10). In most studies (n = 16), patients were treated with interferon ± nucleotide analogues (IFN ± NAs) while 1 study used NAs only. The HR-based meta-analysis showed that post-treatment undetectable HDV RNA, most often defined as off-treatment sustained response, was significantly associated with a reduced risk of any liver-related event compared to patients with detectable HDV RNA (HR: 0.34; 95% CI: 0.24–0.47, **Figure**). Findings were consistent in the OR-based analysis (OR, 0.47; 95% CI, 0.30–0.75, **Figure**). Overall, the meta-analysis findings were concordant with results reported across individual studies included in the SLR. Pooled KM curve analysis further supported these findings, demonstrating the robustness and reliability of the observed associations; (HR: 0.10; 95% CI: 0.05-0.18). **Conclusion:** Achieving undetectable HDV RNA, most often as off-treatment sustained response after IFN ± NAs therapy, was strongly associated with a reduced risk of liver disease progression and complications. HDV RNA undetectability should be interpreted by treatment context: off-treatment sustained undetectability reflects durable disease control, while the effects of on-treatment suppression depend on mechanism of action. These findings highlight the importance of improved HDV screening among HBV infected patients to support earlier diagnosis and timely treatment.

Background: Based on its efficacy and safety profile in multiple clinical trials, bulevirtide (BLV), a first-in-class entry inhibitor, is approved in the US, the European Economic Area, and other regions **:** for the treatment of patients (pts) with chronic hepatitis delta. To further evaluate the efficacy of BLV 10 mg, an integrated analysis was conducted up to week (W) 96. **Methods:** Data from pts receiving BLV 10 mg/day (d) or 48W of delayed treatment (control group) in the Phase 3 MYR301 (NCT03852719) and Phase 2 MYR204 (NCT03852433) studies were analyzed. Analyses at W48 and W96 included efficacy assessments of virologic response (VR; undetectable hepatitis delta virus [HDV] RNA or ≥ 2 $\log_{10}$ IU/mL decline from baseline), alanine aminotransferase (ALT) normalization, combined response (CR; VR + ALT normalization), and liver stiffness (LS). Partial VR (PR) was defined as ≥ 1 to < 2 $\log_{10}$ IU/mL decline in HDV RNA from baseline, and nonresponse (NR) was defined as < 1 $\log_{10}$ IU/mL decline from baseline; pts with undetectable HDV RNA were not considered to have PR or NR. Subgroup analyses by ALT normalization and suboptimal VR responses at week 96 included pts with observed data at this time point. **Results:** Overall, 150 pts receiving BLV 10 mg and 51 control pts were included. Baseline mean (SD) age in the BLV 10 mg group was 41 (8.2) years; 63% of patients were male, 84% were White, 43% had compensated cirrhosis, and 55% received nucleos(t)ide analogues; and mean (SD) ALT, HDV RNA, and LS were 108 (85) U/L, 5.2 (1.4) $\log_{10}$ IU/mL, and 14.5 (9.5) kPa. Baseline characteristics were similar for pts in the control group. Most pts completed treatment through the end of treatment (EOT; BLV 10 mg: n = 143, 95%; controls, n = 50, 98%). A higher proportion of pts had undetectable HDV RNA and higher mean decreases in HDV RNA at W48 with BLV 10 mg vs control (18% vs 0%; −3.3 vs −0.1 $\log_{10}$ IU/mL; **Table**). CR, VR, and ALT normalization rates and mean (SD) change from baseline in LS at W48 and W96 among pts treated with BLV 10 mg were higher than those of pts in the control group (**Table**). Pts receiving BLV 10 mg with and without a VR at W96 (NR, n = 6 [4%]; PR, n = 11 [7%]; VR, n = 124 [83%]; no data, n = 9 [6%]) had improvements in mean (SD) change from baseline to W96 for ALT and LS (ALT, U/L: VR, −64 [63]; PR, −80 [84]; NR, −168 [280]; and LS, kPa: VR, −4.5 [5.6]; PR, −3.3 [6.0]; NR, −1.2 [4.6]). Pts without ALT normalization at W96 also had improvements in ALT and LS at W96 (ALT normalized [n = 91, 61%]: ALT, −74 [89]; LS, −4.5 [5.9]; ALT not normalized [n = 50, 33%]: ALT, −61 [78]; LS, −4.0 [4.9]; no data, n = 9 [6%]). Of pts without ALT normalization, 30/50 (60%) had ALT ≤ 1.5 × the upper limit of normal (ULN) at W96, and only 1 pt had ALT > 3 × ULN. **Conclusion:** Long-term treatment with BLV 10 mg monotherapy was associated with greater HDV RNA decline and improvements in ALT levels and LS vs the control group at W48, which improved through W96. Reductions in ALT levels and LS were observed in pts both with and without VR and/ or ALT normalization.

Table. Efficacy Outcomes for Integrated Analysis of Bulevirtide Treatment Groups at Weeks 48 and 96

	Control Group (n = 51)	Bulevirtide 10 mg (n = 150)	
	Week 48	Week 48	Week 96
Combined response, n (%)	1 (2)	69 (46)	80 (53)
Virologic response, n (%)	2 (4)	122 (81)	124 (83)
Undetectable HDV RNA, n (%)[a]	0	27 (18)	55 (37)
Change from baseline in HDV RNA, $\log_{10}$ IU/mL, mean (SD)	−0.1 (1.0)	−3.3 (1.4)	−3.8 (1.5)
ALT normalization, n (%)	6 (12)	81 (54)	91 (61)
Change from baseline in liver stiffness, kPa, mean (SD)	0.7 (7.4)	−3.4 (4.6)	−4.3 (5.6)

[a]Defined as <LLOQ (50 IU/mL), target not detected.
For combined response, virologic response, undetectable HDV RNA, and ALT normalization, the missing-equals-failure approach was used; for change from baseline in HDV RNA and liver stiffness, the missing values remained missing.
ALT, alanine aminotransferase; HDV, hepatitis delta virus; LLOQ, lower limit of quantitation.

3204 | THE SAFETY AND TOLERABILITY OF ABI-6250, AN ORALLY ADMINISTERED NTCP INHIBITOR IN HEALTHY PARTICIPANTS

Edward Gane[1] Christian Schwabe[2] Grace Wang[3] Jieming Liu[3] Nuruddin Unchwaniwala[3] Lewyn Li[3] Steven Knox[3] Anuj Gaggar[3] Katie Zomorodi[3], [1]University of Auckland, [2]New Zealand Clinical Research, [3]Assembly Biosciences, Inc.

Background: Chronic hepatitis D virus (HDV) infection (cHDV), the most severe form of viral hepatitis, is estimated to affect 12-72 million patients worldwide. Patients with cHDV are at high risk of developing advanced liver disease and treatment options are limited. HDV utilizes the sodium taurocholate cotransporting polypeptide (NTCP), a transmembrane bile acid transporter on hepatocytes, as an entry receptor into the liver. Bulevirtide (BLV), an NTCP inhibitor administered once-daily (QD) by subcutaneous injection, reduces HDV RNA and ALT and leads to dose-dependent and reversible elevations in total bile acids in patients with cHDV. Orally administered HDV entry inhibitors may provide improved dosing convenience compared to daily subcutaneous BLV injections. ABI-6250-101 (NCT06740474) was a randomized, blinded Phase 1a study assessing the safety and tolerability of a potentially first in class, oral NTCP inhibitor ABI-6250 (6250) in healthy participants. **Methods:** Two single-dose cohorts of 5mg and 25mg, and 3 multiple-dose cohorts of 0.05mg, 0.2mg and 1mg 6250 QD for 10 days were evaluated. In each cohort, 8 subjects were randomized in a 3:1 ratio to receive 6250 or placebo (PBO). Safety was assessed by physical examination, adverse events (AEs), and lab parameters. Genomic DNA from participant peripheral whole blood underwent whole exome sequencing (WES) to characterize variants associated with potential safety observations. **Results:** Overall, treatment-emergent (TE)AEs were reported in 67% (20/30) and 40% (4/10) of 6250 and PBO recipients respectively; all were Grade 1 or 2. No serious AEs were reported. Lab abnormalities were observed in 60% (18/30) and 70% (7/10) of 6250 and PBO recipients respectively; all were Grade 1 or 2 except for a Grade 4 unrelated, self-limited creatine kinase increase in a 5mg recipient. Self-limited, asymptomatic ALT elevations were observed at all dose levels including PBO, with the exception of the 0.05mg dose level; 5 Grade 1, 1 Grade 2. Grade 1 ALT elevations were observed in similar proportions across the multiple-dose groups; 16.7% (1/6) at 1mg, 0.2mg, and PBO, and 0% at 0.05mg. One subject in the 1mg dose group discontinued 6250 due to a treatment-related, Grade 1 ALT elevation (64 U/L); resolved post discontinuation. Dose dependent and reversible

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

increases in total bile acids, a marker of NTCP engagement, were observed without any associated pruritus. WES revealed no association between observed ALT elevations and polymorphisms in NTCP, CYP enzymes, HLA alleles, UGT enzymes, or other bile acid transporter genes. Safety and tolerability will be further described by subgroup analyses. **Conclusion:** Overall, 6250 was well tolerated when administered as single doses up to 25 mg, and up to 1mg QD for 10 days. Total bile acids increased in a dose-dependent and reversible manner without any associated pruritus. Phase 2 studies in participants with chronic HDV infection are planned to start by year end.

3205 | PROTECTIVE ISGYLATION OF HIV PROTEINS IN HEPATOCYTES IS COMPROMISED BY ETHANOL EXPOSURE: CONTRIBUTION TO LIVER FIBROSIS DEVELOPMENT

Natalia Osna[1] Anup Singh Pathania[1] Lyla Hurt[1] Isa Jaskot[1] Grace Bybee[1] Yichen Zhou[2] Ype De Jong[3], [1]University of Nebraska Medical Center, [2]Weill Cornell Medicine, [3]Weill Cornell Medicine

Background: Liver fibrosis is diagnosed in 33.9% People Living with HIV (PLWH), making liver disease one of the leading comorbidities. Alcohol consumption for more than 50g/day increases fibrosis risk, and the mechanisms behind this are multifactorial. Ethanol-induced accumulation of HIV proteins in hepatocytes causes hepatotoxicity and is associated with extracellular vesicle (EV) release. Post-translational modification of these proteins makes them more susceptible to degradation. Ubiquitin-like modifier, ISG15, covalently attaches to metabolically active viral proteins, and ISGylated proteins become a preferable substrate for the lysosome, which regulates EV release. Protein ISGylation is interferon (IFN)-type 1- activated process and is also controlled by de-ISGylase, USP18. We hypothesize that ethanol metabolism increases the release of non-IGylated HIV proteins with hepatocyte-derived EVs, and that engulfment of these EVs by Hepatic Stellate Cells (HSCs) promotes their activation, thereby initiating liver fibrosis. **Methods:** The study was performed on Huh7.5-CYP cells treated with an acetaldehyde-generating system (AGS, for ethanol non- or weak metabolizers) and HIV_{ADA}. Cells differentially overexpressing Nef, Tat, and p24 have also been used. The results were confirmed on primary human hepatocytes (PHH) treated with HIV_{ADA} and 50 mM ethanol. ISG15, USP18, and protein ISGylation were induced by IFNα exposure and visualized by Western Blot and immunoprecipitation (IP). mRNAs were quantified by RT-PCR. **Results:** Ethanol or AGS exposure to cells suppressed protein ISGylation and enhanced EV release. Mechanistically, this happened due to suppression of IFNα signaling at the level of STAT1 phosphorylation, diminishing IFNα-triggered ISG15 induction. Conjugation of HIV proteins with ISG15 was also impaired at the level of the E3 ISGylation enzyme, HERC5, whereas the E1 and E2 enzymes were minimally affected. Additionally, upregulation of USP18 by ethanol metabolites and ROS led to protein de-ISGylation and the accumulation of free, unconjugated ISG15. Finally, non-ISGylated HIV proteins were selected for EVs. Treatment of HSC (LX2) with Nef, Tat, and P24 in hepatocyte EVs induced the expression of Col1A1, SMA, and TIMP1 genes in these cells. **Conclusion:** Ethanol metabolism-induced suppression of HIV protein ISGylation in HIV-accumulating hepatocytes promotes the sorting of non-ISGylated proteins into EV to activate HSC and liver fibrosis.

Ford Health System, Providence, [3]Cleveland Clinic Foundation

Background: Pyogenic liver abscess (PLA) causes substantial inpatient morbidity, and contemporary U.S. national trends after 2010 are limited. We evaluated PLA hospitalization burden, procedure utilization, and factors associated with in-hospital mortality. **Methods:** Adult hospitalizations with a PLA diagnosis were identified in the Nationwide/National Inpatient Sample, 1993–2020, excluding 2015, using ICD-9-CM 572.0 or ICD-10-CM K75.0. Amebic abscess and candidiasis were excluded. Survey-weighted analyses accounted for the NIS sampling design. Temporal trends were assessed with the Cochran-Armitage test, and survey-weighted logistic regression estimated odds ratios (ORs) for factors associated with inpatient mortality. **Results:** Weighted analyses identified approximately 344,000 adult PLA hospitalizations across 27 study years. PLA hospitalizations rose from 5,486 (1993) to 26,390 (2020), and the rate increased from 19 to 98 per 100,000 hospitalizations. In-hospital mortality declined from 7.8% to 4.5%. A total of 132,557 procedures were performed: percutaneous aspiration (92,381; 70%), cholecystectomy (16,366; 12%), hepatotomy (14,622; 11%), other cholangiogram (8,343; 6.3%), and ERCP (845; 0.6%). Procedure receipt was associated with lower odds of inpatient mortality (OR, 0.67; 95% CI, 0.62–0.73; $P < .001$). Higher mortality was associated with severe sepsis (OR, 3.6; 95% CI, 3.4–3.97), dialysis dependence (OR, 2.78; 95% CI, 2.4–3.3), acute kidney failure (OR, 2.7; 95% CI, 2.5–2.9), chronic liver disease (OR, 2.3; 95% CI, 2.04–2.5), and gastrointestinal malignancy (OR, 2.1; 95% CI, 1.9–2.3; all $P < .001$). **Conclusion:** PLA hospitalizations and hospitalization rate increased from 1993 to 2020 while in-hospital mortality declined. Procedure receipt was associated with lower inpatient mortality, and severe sepsis, dialysis dependence, acute kidney failure, chronic liver disease, and gastrointestinal malignancy were associated with higher mortality.

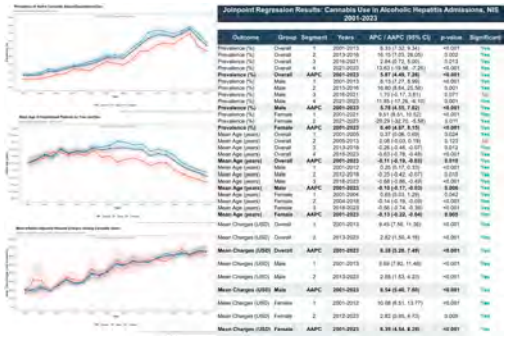
3207 | CANNABIS USE IN ALCOHOL ASSOCIATED HEPATITIS ADMISSIONS: A TWENTY-THREE-YEAR REVIEW OF PREVALENCE, DEMOGRAPHICS, AND HOSPITAL CHARGES



Renuka Verma[1] Ezzeldien Ibrahim[2] Maria Ortega Abad[3] Kamleshun Ramphul[4] Karn Wijarnpreecha[5] Nikki Duong[6], [1]Kirk Kerkorian School of Medicine at the University of Nevad, [2]University of Missouri – Columbia, [3]Cleveland clinic, [4]Independent researcher, [5]University of Arizona College of Medicine-Phoenix, [6]Stanford University

Background: The burden of alcohol associated hepatitis (AAH) in the United States has risen markedly over the past two decades, with recent studies estimating nearly a doubling in admissions between 2009 and 2019. Cannabis use has also increased substantially, with expanding state-level legalization since 2012. At present, there are no national analyses investigating active cannabis use among patients admitted with AAH. We sought to evaluate these trends from 2001 to 2023. **Methods:** Data were collected from the National Inpatient Sample (2001–2023) for admissions for AAH. The mean ages of these patients using cannabis were also explored, along with inflation-adjusted hospital charges. The trends were also stratified for males and females. Appropriate adjustments were made to the database to ensure proper national estimation, as per HCUP's guidelines. Joinpoint regression was used to estimate Annual Percent Changes (APCs) and Average Annual Percent Changes (AAPCs). **Results:** The prevalence of active cannabis use among AAH admissions rose from 1.52% in 2002 to a peak of 7.49% in 2021, before declining to 5.37% in 2023 (AAPC 5.87%; 95% CI 4.49–7.28), driven by a rise of 8.33%/year through 2013, 16.15%/year between 2013–2016, 2.84%/year between 2016–2021, and a sharp reversal of −13.63%/year thereafter. Both males (lowest 1.70% in 2002, peak 7.78% in 2021; AAPC 5.78%) and females (lowest 1.03% in 2002, peak 6.89% in 2021; AAPC 6.40%) showed similar reversals beginning in 2021 (males −11.85%/year, females −20.29%/year). The mean age of cannabis-using AAH patients was highest in 2009 (48.56 years) and lowest in 2023 (46.58 years), with an overall AAPC of −0.11% (95% CI −0.19 to −0.03); the decline accelerated after 2018 (APC −0.63%/year, compared to −0.26%/year from 2013–2018). Inflation-adjusted mean hospital charges rose more than three-fold, from $19,234 in 2004 to $65,828 in 2022 (AAPC 6.38%; 5.28–7.49), with the steepest rise before 2013 (APC 9.45%/year) and slower growth thereafter (APC 2.82%/year). All trends were statistically significant. **Conclusion:** Active cannabis use among AAH

admissions in the United States rose substantially from 2001 to 2021 in both sexes before declining in the final two years. These patients have become progressively younger and incur markedly higher inflation-adjusted hospital charges. These findings highlight an evolving demographic and economic burden of cannabis use among AAH hospitalizations and warrant further investigation into its clinical implications.

3208 | BULEVIRTIDE IMPROVES QUALITY OF LIFE AND MAINTAINS HIGH TREATMENT ADHERENCE AT 12 MONTHS IN CHRONIC HDV INFECTION: DATA FROM THE ENHANCE COHORT

Liliana-Simona Gheorghe[1] Mihaela Ghioca[2] Mirela Onica[2] Daria-Ana-Arina Gheorghe[2] Anca Trifan[3] Laura Huiban[3] Larisa Sandulesscu[4] Dan Gheonea[4] Corina Radu[5] Bogdan Procopet[6] Roxana Sirli[7] Corina Pop[8] Nicoleta Tiuca[8] Bogdan-Silviu Ungureanu[4] Adina Turcu-Stiolica[4] Speranta Iacob[1], [1]Carol Davila University of Medicine and Pharmacy; Fundeni Clinical Institute, Bucharest, [2]Fundeni Clinical Institute, Bucharest, [3]"Grigore T Popa" University of Medicine and Pharmacy Iasi, [4]University of Medicine and Pharmacy Craiova, [5]„Iuliu Haţieganu" University of Medicine and Pharmacy Cluj-Napoca, [6]"Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, [7]Victor Babes University of Medicine and Pharmacy Timisoara, [8]Carol Davila University of Medicine and Pharmacy; SUUB, Bucharest

Background: Bulevirtide (BLV) is the first approved entry inhibitor for chronic HDV infection. Its impact on treatment adherence and quality of life (QoL) across specific domains, and their relationship with virological response and baseline viremia, remain poorly characterized. **Aim:** To evaluate treatment adherence (MMAS-8) and QoL (HQLQ) at 12 months of BLV therapy and to identify associations with virological response category and baseline HDV viremia. **Methods:** Treatment adherence was assessed using MMAS-8 (score 0–10; high ≥ 8, medium 6–7, low < 6) and QoL using the HQLQ (12 subscales, 0–100) at baseline and W48 (12 months) in a prospective cohort of 124 HDV/HBV patients initiated on BLV 2 mg/day s.c. Virological response at W48: complete (CVR, $> 2\log_{10}$ HDV RNA reduction), partial (PVR, 1–$2\log_{10}$), no response (NR, $< 1\log_{10}$). Wilcoxon signed-rank, Kruskal–Wallis tests and Spearman correlations were applied. **Results:** Virological evaluation at W48 revealed: CVR 64%, PVR 18.6%, NR 17.4%; ALT normalisation at 12 months was present in 76% of patients. ***Treatment adherence:*** Mean MMAS-8 score was 7.48 ± 1.05 (median 8). High adherence (score = 8) was present in 62.3% of patients, medium adherence (6–7) in 32.1%, and low adherence (< 6) in only 5.7%. Adherence remained stable from 6 to 12 months (7.67 vs 7.53, $p = 0.403$). MMAS scores did not differ across virological response groups (CVR: 7.46 ± 1.08; PVR: 7.34 ± 1.28; NR: 7.75 ± 0.46; $p = 0.736$) and did not correlate with baseline HDV RNA ($r = 0.02$, $p = 0.89$). ***Quality of life*****:** Of 12 HQLQ subscales, Hepatitis-specific Distress improved significantly from baseline to 12 months (+14.5 points, $p = 0.012$), with a trend in Daily Activities/Well-being (+6.3 points, $p = 0.074$). No subscale differed significantly across virological response groups (CVR vs PVR vs NR; all $p > 0.60$), indicating that QoL benefit is independent of viral suppression depth. Higher baseline HDV RNA correlated with better Physical Functioning ($r = +0.28$, $p = 0.049$) and fewer Hepatitis-related Physical Limitations ($r = +0.29$, $p = 0.037$) at 12 months; improvement in Bodily Pain also correlated positively with baseline viremia ($r = +0.37$, $p = 0.042$). **Conclusion:** BLV treatment sustains high adherence at 12 months, independent of virological outcome. Hepatitis-specific QoL improves significantly at 12 months, particularly Hepatitis Distress, regardless of virological response category. Higher baseline viremia predicts better functional QoL outcomes at one year. These findings support a broad QoL benefit of BLV therapy that is dissociated from the degree of viral suppression.

3209 | BRELOVITUG DEMONSTRATES BIOCHEMICAL AND VIROLOGICAL IMPROVEMENTS IN PATIENTS WITH CHRONIC HEPATITIS D AND CIRRHOSIS: RESULTS FROM A PHASE 2 EXTENSION STUDY

Alina Jucov[1] Kaushik Agarwal[2] Patrick Kennedy[3] Douglas Mogul[4] Susanna Tan[4] Will Garner[4] Paul Eckburg[4] Nancy Schulman[4] Marta Dobryanska[5], [1]Arensia Exploratory Medicine GmbH and Nicolae Testemitanu State University, Chişinău, Moldova, [2]Kings College Hospital, London, UK, [3]Queen Mary University of London, London, UK, [4]Mirum Pharmaceuticals, Inc., Foster City, CA, [5]Arensia Exploratory Medicine Limited Liability Company, Medical Center, Kyiv, Ukraine

Background: Chronic hepatitis D (CHD) represents the most aggressive type of viral hepatitis with increased complications of cirrhosis such as hepatocellular carcinoma and death. Brelovitug (BJT-778) is a fully human monoclonal antibody targeting HBsAg, a protein required for viral entry into hepatocytes, and is being evaluated for the treatment of CHD including patients with cirrhosis. Here we describe the response for up to 84 weeks of brelovitug in cirrhotic patients with CHD from BJT-778-001. **Methods:** In BJT-778-001, a phase 1/2, international, open-label, adaptive trial, adults with CHD received 1 of 3 regimens of brelovitug for 48 weeks. After 48 weeks of treatment, participants with cirrhosis (n = 15) defined as a liver stiffness ≥ 12 kPa at any time during the study, were offered up to an additional 3 years of treatment with brelovitug 900 mg Q4W. Key endpoints included virologic response (HDV RNA ≥ 2 $\log_{10}$ IU/mL reduction from baseline or < LLOQ, target not detected [TND]), ALT normalization, combined virologic and ALT response, and safety/tolerability. Analyses were descriptive. **Results:** All 15 participants have reached at least 24 weeks in the extension period. At Baseline, participants had a median (min, max) age of 47 (37, 68) years, HDV RNA 5.66 (1.34, 7.36) $\log_{10}$ IU/ml and ALT 67 (15, 202) IU/ml; Baseline transient elastography (TE) was 14.2 (9.5, 46.4) kPa. and max TE was 15.3 (12.0, 46.4) kPa. During initial treatment phase, brelovitug dosing included 5 (33%) who received 300 mg once weekly, 1 (7%) who received 600 mg QW from Baseline to Week 12 and then every 2 weeks, and 9 (60%) who received 900 mg every 4 weeks with a loading dose at Week 2. At the end of the first 48 weeks of treatment, all 15 (100%) participants had a virologic response including 10 (67%) who achieved < LLOQ (< 10 IU/ml HDV RNA) and 4 (27%) who achieved TND; ALT normalization and a combined response occurred in 10 (67%) participants. Eight participants had a dose interruption between Week 48 and start of the extension ranging from 44 to 284 days. Data on additional treatment were available for all 15 participants at 24 Weeks (72 weeks total) and for 13 participants at 36 Weeks (86 weeks total). At last follow-up, all 15 (100%) participants had a virologic response, including 11 (73%) who achieved < LLOQ including 9 (60%) who achieved TND; ALT normalization and combined response occurred in 14 (93%). There were no serious AEs, AEs ≥ Grade 3, or AEs that led to study or treatment discontinuation, and the most common treatment-related AEs were mild/moderate injection site reactions and flu-like symptoms, both occurring in 2 (13%) individuals. **Conclusion:** Brelovitug continued to demonstrate efficacy and was well-tolerated in patients with CHD and cirrhosis with up to 86 weeks of treatment. The response was durable; HDV RNA suppression generally deepened, and frequency of ALT normalization increased with longer treatment. Phase 3 registrational trials of brelovitug for CHD are ongoing.

Background: Patients with cirrhosis and high-risk varices (HRV) are at substantial risk of variceal bleeding, a major cause of liver-related morbidity and mortality. The Baveno consensus and AASLD 2024 guidance endorse non-invasive tests (NITs) to identify patients who may safely avoid screening endoscopy for HRV, but data in chronic hepatitis delta (CHD) are lacking. We evaluated the performance of Baveno and AASLD 2024 criteria in untreated patients with HDV-related cirrhosis and derived disease-specific criteria (Baveno-HDV). **Methods:** Untreated patients with HDV-related compensated cirrhosis and available liver stiffness measurement (LSM) and esophagogastroduodenoscopy (EGD) enrolled in the multicenter SAVE-D and D-SHIELD studies were included. Baveno VI and AASLD criteria were applied to identify patients in whom screening endoscopy could have been avoided (LSM <20 kPa + platelets [PLT] count $>150x10^9$ /L). Disease-specific LSM and PLT cut-offs for an "avoid endoscopy" rule applicable to CHD patients was identified. Internal validation of our findings was performed using nonparametric bootstrap resampling. **Results:** 347 patients were included in this analysis (median age 54, 56% males, median LSM 16.7 (11.8-25.2) kPa, PLT 95 (65-147) $x10^9$ /L; spleen size 14 (12-17) cm). 156 (45%) patients showed gastroesophageal varices, of whom 93 (27%) HRV. Avoiding screening endoscopy by Baveno VI/AASLD 2024 criteria resulted in 4 (6.2%) missed HRV (Sn 95.7%, NPV 93.8%). Bootstrap internal validation showed substantial uncertainty around the estimated false negative rate, with a bias-corrected 95% confidence interval (BC-CI) of 1.15%-13.88%. Since only 2 patients had PLT count exactly equal to 150 $x10^9$ /L PLT, and both had LSM 20kPa, no patient was differently classified according to AASLD 2024 criteria. Therefore, the Baveno VI and AASLD criteria were equivalent in our cohort. New cut-offs, "Baveno-HDV", defined by grid search derived combination of LSM ≤ 19 kPa and PLT $\geq 110 \times 10^9$/L, showed improved performances with only 3.6% missed HRV (Sn 95.7% NPV 96.4%) and an increased number of patients avoiding endoscopy (32% *vs.* 19%). Bootstrap validation demonstrated narrower variability estimates, with a 95% BC-CI for the false negative rate of 0.87%-7.76% **Conclusion:** In untreated patients with HDV-related cirrhosis, the Baveno and AASLD 2024 "avoid endoscopy" criteria showed suboptimal performance, with misclassification of patients harboring HRV

and at risk of variceal bleeding. The newly developed disease-specific Baveno-HDV criteria significantly reduced missed HRV while increasing the number of safely spared screening endoscopies.

Background: Chronic hepatitis Delta is the most severe form of viral hepatitis, with accelerated progression to cirrhosis and increased hepatocellular carcinoma (HCC) risk. While cardiometabolic risk factors influence outcomes in other chronic liver diseases, their prevalence and clinical relevance in CHD remain poorly defined. **Methods:** CHD patients included in the retrospective multicenter real-world European SAVE-D study and in the prospective multicenter Italian D-SHIELD study were included. The prevalence of cardiometabolic risk factors (arterial hypertension, type 2 diabetes, overweight/obesity) were evaluated at BLV start. **Results:** 828 patients treated with BLV 2 mg/day subcutaneous monotherapy up to 144 weeks were included in this analysis: age 52 (IQR 42-60) years, 57% men, 698 (84%) with cirrhosis, median BMI was 24.8 (22.7-27.4). 39 (5%) patients had type 2 diabetes (T2DM), and 126 (15%) patients had arterial hypertension (AHTN), 85 (10%) patients had obesity (defined as BMI $\geq$30), of whom 13 (15%) grade II obesity (BMI 35-39) and 2 (2%) grade III obesity (BMI $\geq$40). Controlled Attenuation Parameter (CAP) on Fibroscan ®**:** was available in 484 (59%) patients: median CAP values were 209 (181-238) dB/m. 50 (5%) patients showed hepatic steatosis (by CAP >275 dB/m): median BMI in these patients was 28.4, 6 (12%) patients had T2DM, 11 (22%) AHTN. Overall, median alanine aminotransferase (ALT) levels were 79 (50-129) U/L and 62 (47-94) in patients without and with T2DM, respectively (p=0.04). Median gamma glutamyl transferase (gGT) were 58 (35-97) and 44 (27-74) U/L in patients without and with T2DM, respectively (p=0.03). When analyzing the impact of cardiometabolic risk factors (AHTN, T2DM), BMI and CAP values on responses rates to BLV, only CAP values predicted the achievement of a biochemical response at on-treatment week 48 (OR 1.01 95% CI 1.00-1.02, p=0.02). Conversely, none of the baseline features predicted the achievement of a virological response, combined response, and of HDV RNA undetectability at week 48 of BLV monotherapy. **Conclusion:** European patients with CHD exhibited an unexpectedly low prevalence of cardiometabolic risk factors (MetHDV), compared to other viral hepatitis, with no measurable effect on BLV treatment responses during the first year of therapy.

3213 | BULEVIRTIDE MONOTHERAPY IMPROVES VALIDATED CSPH CRITERIA (BAVENO AND ANTICIPATE) IN HDV PATIENTS WITH ACLD

Marlene Hintersteininger[1] Lisa Sandmann[2] Elisabetta Degasperi[3] Maria Paola Anolli[3] Riccardo Perbellini[3] Adriana Palom[4] Maria Buti[5] Anna Pocurull[6] Sabela Lens[6] Corina Radu[7] Bogdan Procopet[7] Heinz Zoller[8] Michael Gschwantler[9] Tarik Asselah[10] Katja Deterding[2] Heiner Wedemeyer[2] Mattias Mandorfer[1] Thomas Reiberger[1] Mathias Jachs[1] Pietro Lampertico[3] Benjamin Maasoumy[2], [1]Medical University of Vienna, [2]Hannover Medical School, [3]University of Milan, [4]Hospital Vall d'Hebron, [5]Hospital Valle Hebron, [6]University of Barcelona, [7]University of Medicine and Pharmacy, Cluj-Napoca, [8]Medical University of Innsbruck, [9]Sigmund Freud Private University, [10]Hôpital Beaujon

Background: Patients with chronic hepatitis delta (CHD) are at high risk of clinically significant portal hypertension (CSPH) and liver-related complications. Treatment with bulevirtide (BLV) is approved for CHD and is accompanied by a reduction in hepatic venous pressure gradient. In clinical practice, however, liver stiffness (LSM) and platelet count (PLT) are used for non-invasive CSPH assessment. The primary endpoint was to assess improvement of CSPH risk using validated non-invasive CSPH criteria. **Methods:** CHD patients receiving BLV monotherapy at 2mg/day for ≥48 weeks at 7 European centres were included. LSM and PLT data at baseline (BL) and week (W) 48 were recorded. CSPH risk was assessed by Baveno-VII criteria: rule-out (LSM ≤15kPa plus normal PLT ≥150G/L), rule-in LSM >25kPa. Within the grey zone (GZ), we identified probable CSPH [probCSPH] by either LSM >20kPa plus PLT <150G/L or LSM >15 plus PLT <110G/L. The ANTICIPATE model reflecting CSPH risk [%] was calculated, with ≥75% and <60% indicating high and low risk of CSPH, respectively. Improvement was defined as a reduction in estimated CSPH risk and/or regression to a lower CSPH category. **Results:** In total, 188 patients were included: 54.8% male; median for age: 50 years, BMI: 25kg/m2, LSM: 16kPa, PLT: 117G/L and ALT: 79IU/L. At BL, Baveno-VII CSPH criteria classified n=44 (23.4%) as rule-in, n=43 (22.9%) as rule-out, and n=101 as GZ, including n=37 (19.7%) with probCSPH. The ANTICIPATE model at BL yielded a median CSPH risk of 49.1% - identifying n=68 (36.2%) and n=109 (58.0%) as high and low CSPH risk patients, respectively. N=180 (95.7%) had longitudinal data on LSM/PLT at W48 available: 66.6%, 68.9% and 51.1% achieved virologic response (VR), ALT normalization, and complete response (CR) respectively. At W48, median LSM significantly decreased (16.0 vs. 12.6kPa; p<0.001) and PLT significantly increased (117 vs. 132G/L; p<0.001) compared to BL. Baveno-VII CSPH criteria re-classified n=27 (15.0%) as rule-in, n=56 (31.1%) as rule-out, and n=97 as GZ, including 13.9% with probCSPH (Figure-1). The ANTICIPATE CSPH risk decreased to 27.0% at W48 - identifying n=46 (25.6%) and n=119 (66.1%) as high and low CSPH risk patients; respectively. The median relative change in ANTICIPATE CSPH risk was similar for patients with vs. without VR (-21.1% vs. -24.1%, p=0.899) and CR (-21.1% vs. -24.1%, p=0.549), respectively.Overall, improvements in Baveno-VII at W48 (rule-in to GZ/rule-out or GZ to rule-out) and ANTICIPATE CSPH risk categories (negative relative change) were found in 19.4% and 75.0% of CHD patients, respectively. **Conclusion:** After one year of BLV monotherapy, many CHD patients showed improvements in validated non-invasive CSPH tests, i.e. the Baveno-VII criteria and the ANTICIPATE models. While the lack of an untreated control group needs to be acknowledged, the positive signals suggest beneficial effects of BLV monotherapy on the risk of CSPH-driven clinical events.

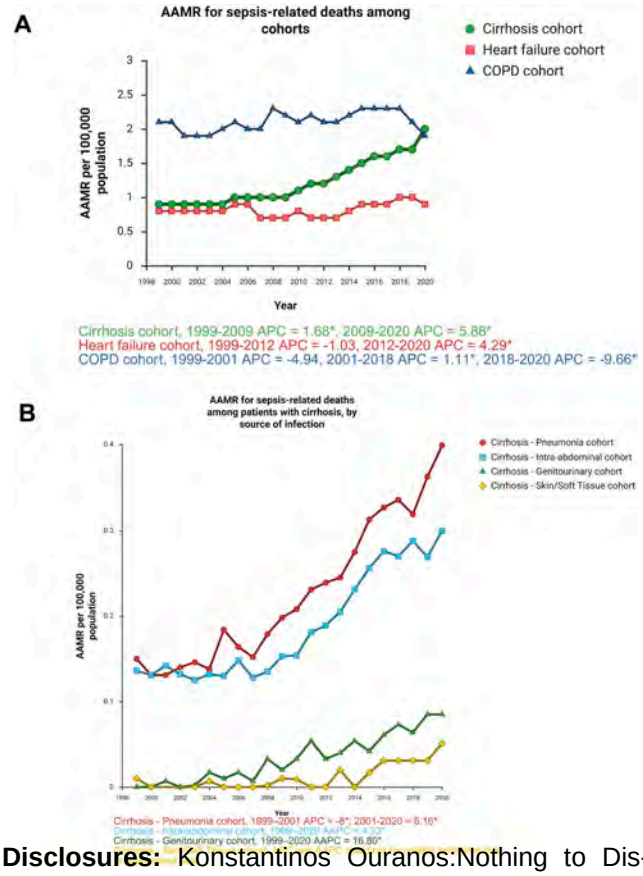
3214 | SEPSIS-RELATED MORTALITY IS RISING DISPROPORTIONATELY IN CIRRHOSIS COMPARED WITH OTHER CHRONIC DISEASE POPULATIONS: A US-BASED POPULATION STUDY, 1999-2020



Konstantinos Ouranos[1] Chanyanuch Nakapakorn[2] Mark Michael[1] Sudha Kodali[1] David Victor[1] Mazen Noureddin[1] Douglas Simonetto[3] Jody Olson[4] Sumeet Arsani[2] Constance Mobley[1] Mark Ghobrial[1] Eleftherios Mylonakis[5] Kavish Patidar[1], [1]Houston Methodist Hospital, [2]Baylor University Medical Center, Dallas, TX, USA, [3]Mayo Clinic Rochester, [4]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, USA, [5]Houston Methodist

Background: Patients with cirrhosis are highly susceptible to sepsis due to immune dysregulation and bacterial translocation, but temporal trends in sepsis-related mortality compared with other chronic diseases remain unclear. We evaluated national

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

trends in sepsis-related mortality among patients with cirrhosis versus congestive heart failure (CHF) and chronic obstructive pulmonary disease (COPD), and characterized the major infection types associated with sepsis in cirrhosis. **Methods:** We performed a cross-sectional analysis of the CDC WONDER Multiple Cause of Death database (1999–2020). Adults with cirrhosis, CHF, and COPD were identified from death certificates using mutually exclusive cohorts. Sepsis-related mortality was determined from listed causes of death. Age-adjusted mortality rates were calculated, and Joinpoint regression was used to estimate annual percent change (APC) and average annual percent change (AAPC). Prespecified subgroup analyses were conducted by sex, age, race, and ethnicity. **Results:** From 1999 to 2020, sepsis-related mortality increased substantially among patients with cirrhosis, with significantly greater rise compared to CHF and COPD. Patients with cirrhosis demonstrated an AAPC of 3.86%, compared to 0.96% among patients with CHF and –0.56% among patients with COPD (**Figure 1A**). Among patients with cirrhosis, rate of increase of annual sepsis-related mortality was highest for genitourinary infections (AAPC 16.8%), followed by pneumonia (AAPC 4.73%) and intra-abdominal infections (AAPC 4.33%) (**Figure 1B**) **.** Across demographic subgroups, cirrhosis consistently demonstrated the steepest increases in sepsis-related mortality. Among adults ≥65 years, sepsis-related mortality increased in cirrhosis (AAPC 3.74%) but declined in CHF and COPD (both AAPC –0.19%). Similarly, among adults <65 years, mortality increased in cirrhosis (AAPC 3.7%) and CHF (AAPC 3.93%), and to a lower extent in COPD (AAPC 0.93%). Hispanic patients with cirrhosis experienced particularly marked increases in sepsis-related mortality (AAPC 2.21%) than those with CHF (–0.77%) or COPD (–2.14%), with similar patterns in non-Hispanic individuals. Female patients with cirrhosis also experienced greater increases in sepsis-related mortality (AAPC 4.4%) compared to males (AAPC 3.45%), while CHF and COPD showed only modest sex-specific changes. **Conclusion:** Sepsis-related mortality has increased among patients with cirrhosis and has outpaced trends in CHF and COPD over past two decades. Genitourinary infections, pneumonia, and intra-abdominal infections represent contributors to sepsis-related mortality in cirrhosis. These findings identify cirrhosis as a uniquely vulnerable population and support development of cirrhosis-specific strategies focused on infection prevention, early sepsis recognition, vaccination, antimicrobial stewardship, and optimized management of high-risk infections.

Sciences, Inc., Foster City, CA, USA, [15]Hannover Medical School, Hannover, Germany

Background: Bulevirtide (BLV) is approved to treat chronic hepatitis delta (CHD) in the United States, European Economic Area, and other regions. Long-term therapy with BLV has demonstrated improvements in liver disease burden test results, including in patients with suboptimal virologic response. To further evaluate responses with BLV monotherapy, an integrated analysis was conducted. **Methods:** Data from patients receiving BLV 10 mg or 2 mg in the Phase 3 MYR301 (NCT03852719) and Phase 2 MYR204 (NCT03852433) studies were pooled and analyzed on treatment up to 96 weeks and posttreatment (PT) through 48 weeks of follow-up (FU48). Alanine aminotransferase (ALT) levels and non-invasive tests (NITs) including the aspartate aminotransferase to platelet ratio index (APRI), Fibrosis-4 Index (FIB-4), and liver stiffness (LS) were evaluated. Subgroups based on end-of-treatment (EOT) outcomes included virological responders (VR) excluding undetectable hepatitis delta virus (HDV) RNA (VRnU; ≥ 2 $\log_{10}$ IU/mL decline in HDV RNA from baseline [BL]), partial VR (PR, ≥ 1 to < 2 $\log_{10}$ IU/mL decline), and nonresponders (NR, < 1 $\log_{10}$ IU/mL decline). Patients with undetectable HDV RNA at EOT were divided based on PT viral status into the following categories: sustained PT undetectable (Und-S), low viremic relapse (Und-LV; detectable PT HDV RNA < 50 IU/mL), and high viremic relapse (Und-HV; PT HDV RNA ≥ 50 IU/mL). **Results:** Overall, 183 patients were included, of whom 76 had undetectable HDV RNA at EOT; 81 were VRnU; 13, PR; and 13, NR. Of patients with undetectable HDV RNA at EOT, during FU, 26 were Und-S; 10, Und-LV; and 39, Und-HV; 1 had no FU data. Improvements in NITs from BL to week 96 were seen in all virologic response subgroups (**Table**), with median LS decreases of −3.1, −3.9, −3.7, −3.6, −1.3, and −2.5 kPa in the Und-S, Und-LV, Und-HV, VRnU, PR, and NR groups, respectively. In the PT period, only patients with Und-S sustained improvements in median LS and ALT and patients with Und-LV sustained median ALT improvements from BL through FU48. Results were not as consistent for FIB-4 and APRI, possibly due to low subgroup sample sizes. **Conclusion:** Long-term therapy with BLV over 96 weeks improved NITs regardless of virologic response; however, these improvements decreased after treatment cessation through FU48 in all patients except the subsets with sustained undetectability or only low-level PT viremia. Most patients with CHD benefit from ongoing long-term BLV treatment, and treatment discontinuation should be considered only in those with a low likelihood of relapse.

Table. On-Treatment and Posttreatment Burden of Liver Disease Tests Stratified by Virologic Response and Relapse Status

	Bulevirtide Monotherapy (N=183)											
	Liver Stiffness, kPa Median (Q1, Q3)			ALT, U/L Median (Q1, Q3)			APRI Median (Q1, Q3)			FIB-4 Median (Q1, Q3)		
	BL	W96	FU48	BL	W96	FU48	BL	W96	FU48	BL	W96	FU48
Und-S (n=26)	13.6 (9.7, 19.1)	8.9 (6.4, 17.2)	8.6 (6.8, 12.9)	93 (64, 117)	35 (26, 62)	30 (22, 48)	1.1 (0.8, 1.5)	0.5 (0.3, 1.1)	0.5 (0.3, 0.7)	1.9 (1.3, 2.4)	1.6 (1.1, 2.8)	1.8 (1.4, 2.7)
Und-LV (n=10)	11.6 (8.9, 20.3)	7.7 (5.7, 9.6)	9.0 (6.9, 9.4)	103 (50, 166)	37 (32, 58)	30 (22, 47)	0.8 (0.7, 1.4)	0.5 (0.3, 1.0)	0.6 (0.4, 0.6)	1.6 (1.2, 2.8)	1.8 (0.8, 2.8)	2.1 (1.1, 3.3)
Und-HV (n=39)	11.4 (8.8, 16.7)	7.7 (6.1, 11.7)	8.9 (6.5, 12.8)	73 (57, 104)	31 (21, 44)	48 (38, 75)	0.8 (0.7, 1.4)	0.4 (0.3, 0.7)	0.7 (0.4, 1.0)	1.7 (1.3, 2.1)	1.3 (1.0, 1.8)	1.5 (1.1, 2.2)
VRnU (n=81)	11.9 (8.8, 17.3)	8.2 (5.8, 12.0)	11.7 (7.6, 16.5)	80 (57, 127)	34 (28, 43)	92 (48, 163)	1.0 (0.6, 1.6)	0.5 (0.4, 0.7)	1.2 (0.5, 2.1)	1.8 (1.1, 2.8)	1.4 (1.0, 2.0)	2.0 (1.1, 3.0)
PR (n=13)	8.5 (7.8, 13.8)	7.6 (6.7, 10.7)	7.5 (6.6, 10.4)	96 (80, 145)	38 (33, 48)	68 (48, 108)	1.1 (0.7, 1.2)	0.5 (0.3, 0.6)	0.7 (0.7, 0.8)	1.3 (1.1, 1.4)	1.0 (0.8, 1.8)	1.4 (1.1, 1.8)
NR (n=13)	12.0 (9.9, 14.8)	8.2 (7.8, 12.3)	10.7 (8.0, 11.7)	138 (105, 189)	64 (23, 76)	95 (76, 121)	1.3 (0.8, 2.2)	0.8 (0.3, 0.8)	0.8 (0.7, 1.1)	2.0 (1.3, 2.5)	1.2 (0.8, 1.6)	1.3 (1.1, 2.0)

Undetectable HDV RNA was defined as HDV RNA less than the lower limit of quantification, target not detected; patients with undetectable HDV RNA were excluded from NR and PR.
ALT, alanine aminotransferase; APRI, aspartate aminotransferase to platelet ratio index; BL, baseline; EOT, end of treatment; FIB-4, Fibrosis-4 Index; FU48, follow-up at 48 weeks posttreatment; HDV, hepatitis delta virus; NR, nonresponders (defined as having <1 $\log_{10}$ IU/mL decline in HDV RNA from BL at EOT); PR, partial responders (defined as having ≥1 to <2 $\log_{10}$ IU/mL decline in HDV RNA from BL at EOT); Q, quartile; Und-HV, high viremic relapse (defined as posttreatment HDV RNA ≥50 IU/mL) after undetectable HDV RNA at EOT; Und-LV, low viremic relapse (defined as detectable posttreatment HDV RNA <50 IU/mL) after undetectable HDV RNA at EOT; Und-S, sustained posttreatment undetectable HDV RNA after undetectable HDV RNA at EOT; VRnU, virological responders excluding undetectable HDV RNA (and defined as ≥2 $\log_{10}$ IU/mL decline in HDV RNA from BL at EOT); W, week.

3216 | DISEASE PROGRESSION AMONG A NATIONALLY REPRESENTATIVE COHORT OF COMMERCIALLY INSURED PATIENTS WITH HEPATITIS DELTA VIRUS IN THE UNITED STATES

Robert Wong[1] Robert Gish[2] Chong Kim[3] Samina Dhuliawala[4] Gary Leung[5] Ira Jacobson[6] Joseph Lim[7] Marvin Rock[3], [1]Division of Gastroenterology and Hepatology, Stanford University, Palo Alto, CA, USA, [2]Hepatitis B Foundation, Doylestown, PA, USA, [3]HEOR—Global Value & Access, Gilead Sciences, Inc., Foster City, CA, USA, [4]IQVIA, San Francisco, CA, USA, [5]RWE—Epidemiology, Gilead Sciences, Inc., Foster City, CA, USA, [6]NYU Grossman School of Medicine, New York, NY, USA, [7]Yale University School of Medicine, New Haven, CT, USA

Background: Coinfection with hepatitis delta virus (HDV) and hepatitis B virus (HBV) is associated with significantly greater risks of progression to cirrhosis, hepatocellular carcinoma (HCC), liver transplant (LT), and liver-related mortality compared with HBV monoinfection. However, it is unclear how the magnitude of increased risk of disease progression varies by baseline liver disease severity. We evaluated the risk of liver disease complications and how this risk varies by severity of baseline liver disease state among adults with HDV infection. **Methods:** A retrospective cohort study using the PharMetrics database searched from 1/1/2006 to 8/31/2022 identified commercially insured adults aged ≥18 years with an HDV diagnosis using *ICD-9/10-CM* codes. Patients were required to have ≥12 months of continuous enrollment pre-index (ie, diagnosis date) and 1 day post-index. Disease progression from baseline to the next disease state was assessed using Kaplan-Meier curves and multivariable Cox proportional-hazards regression models adjusting for patient characteristics. Disease states included noncirrhotic disease (NCD), compensated cirrhosis (CC), decompensated cirrhosis (DC), HCC, and LT. **Results:** Of the 272,148,753 patients identified within the database, 2,317 with HDV met the enrollment criteria, and 2,268 were analyzed after exclusion of patients with LT at baseline. Overall, patients had a mean (SD) age of 48 (11.4) years, and 59% were male. At baseline, liver disease severity was NCD in 70% (1,577/2,268) of patients, CC in 6% (125/2,268), DC in 19% (441/2,268), and HCC in 6% (125/2,268). Patients with more severe disease at baseline had significantly greater risks of further disease progression. Compared to patients with NCD at baseline, those with baseline CC demonstrated a higher rate of progression to DC (log rank $P < .0001$), HCC (log rank $P = .029$), and LT (log rank $P = .003$); those with baseline DC demonstrated a higher rate of progression to HCC and LT (log rank $P < .0001$ for both); and those with baseline HCC demonstrated a higher rate of progression to LT (log rank $P < .0001$). Mean (SD) months to the next disease state were as follows: NCD to CC, 46 (37.2); CC to DC, 37 (32.4); DC to HCC, 37 (40.7); and HCC to LT, 35 (35.7). Using a multivariable Cox regression model, compared to patients with baseline NCD, those with baseline CC had a significantly higher risk of transitioning to DC (hazard ratio, 2.43; 95% CI, 1.70–3.48; $P < .001$). Similar findings were observed for those with baseline DC or HCC (**Figure**). **Conclusion:** Among a large, nationally representative cohort of US adults, more advanced baseline liver disease severity at the time of HDV diagnosis was associated with significantly greater risks of further disease progression. These results highlight the importance of early HDV identification and subsequent linkage to care to prevent further disease progression and reduce the overall burden of disease.

Figure. Risk of Transitioning to More Severe Liver Disease States

Bold values indicate statistical significance. Results were estimated using Cox proportional-hazards regression models.

CC, compensated cirrhosis; DC, decompensated cirrhosis; HCC, hepatocellular carcinoma; HR, hazard ratio; LT, liver transplantation; NCD, noncirrhotic disease.

3217 | CLOSING THE CLINICAL GAP IN HEPATITIS E IN EUROPE: ONWARD, A PAN-EUROPEAN ONE HEALTH NETWORK ADDRESSING THE RISING BURDEN OF ACUTE AND CHRONIC HEV INFECTION

Imran Hasanoglu[1] Adriana Anita[2] Florence Abravanel[3] Gábor Reuter[4] Susanne Dudman[5] Nassim Kamar[6] Lorena Jemeršić[7] Ilaria Di Bartolo[8] Nigel Cook[9] Simona Ruta[10] Inne Nauwelaers[11] Lazar Milojević[12] Elena Todorovska[13] Sandra Mojsova[14] Arjana Zerja[15] Ana Avellon[16] Renate Hakze[17] Branko Velebit[12] Reimar Johne[18] João Mesquita[19] Antonio Rivero-Juarez[20], [1]Ankara Yildirim Beyazit University Bilkent City Hospital, [2]University of Life Sciences Ion Ionescu de la Brad, [3]Toulouse University Hospital, [4]Pecsi Tudomanyegyetem - University Of Pecs, [5]University of Oslo, [6]Centre Hospitalier Universitaire De Toulouse, [7]Hrvatski Veterinarski Institut, [8]Istituto Superiore Di Sanita, [9]Jorvik Food and Environmental Virology Ltd., [10]Universitatea De Medicina Si Farmacie Carol Davila Din Bucuresti, [11]Sciensano Belgium, [12]Institute of Meat Hygiene and Technology, [13]Agrobioinstitute Bulgaria, [14]Ss. Cyril and Methodius University in Skopje, [15]University of Medicine Tirana, [16]Instituto De Salud Carlos III, [17]Wageningen University, [18]German Federal Institute for Risk Assessment, [19]Universidade Do Porto, [20]Instituto Maimonides de Investigación Biomédica de Córdoba (IMIBIC)

Background: Hepatitis E virus (HEV) causes an estimated 20 million infections worldwide each year and is now the leading cause of acute viral hepatitis in Europe, yet most clinicians have rarely diagnosed a case. Chronic HEV has emerged as a serious complication in a rapidly expanding population of immunocompromised hosts: solid-organ transplant recipients, patients on biologic or cytotoxic therapy, and those with hematological malignancies. Extrahepatic and neurological manifestations are increasingly recognized. Yet across European centers, testing remains inconsistent, no antiviral or vaccine is licensed, ribavirin remains off-label, and immunosuppression reduction is not standardized. The emergence of *Rocahepevirus ratti* (ratHEV) as a cause of acute and chronic hepatitis further complicates routine diagnostics. Europe has lacked a coordinated clinical response. **Methods:** ONWARD (One Health Zoonotic Hepevirus Network; COST Action CA24140; 2025–2029) is the first dedicated pan-European platform for zoonotic hepeviruses. It unites 34 countries and more than 160 experts across hepatology, transplant medicine, virology, microbiology, veterinary science, food safety and public health. Five integrated Working Groups cover diagnostics and surveillance, clinical management and therapeutics, prevention and control, dissemination, and policy synergies. ONWARD engages European scientific societies, regulatory bodies and public health organizations to turn scientific consensus into harmonized clinical practice. **Results:** ONWARD's clinical focus translates into a concrete delivery agenda for hepatologists. Within its first year, the network has built an operational structure aligned with the SAPEA criteria for One Health Governance in the European Union, to develop harmonized diagnostic protocols for HEV and rat HEV; a shared framework for clinical trial design, outcome measures and biomarkers in chronic HEV; consensus on antiviral candidates and treatment strategies for immunocompromised hosts; targeted training for early-career hepatology and infectious disease clinicians; and active engagement to position HEV within the European hepatitis elimination agenda. Short-Term Scientific Missions, conference grants and the network's communication platform (hev-onward.eu) are already accelerating cross-border clinical collaboration. **Conclusion:** ONWARD delivers the first

coordinated European response to the rising clinical burden of HEV and rat HEV, directly relevant to hepatologists managing acute hepatitis of unknown origin and chronic infection in immunocompromised patients. Its outputs will support harmonized diagnostic and treatment pathways, inform future ECDC and EFSA guidance, and strengthen preparedness for emerging hepeviruses across Europe and beyond.

3218 | COAGULOPATHY AND SEVERE MORBIDITY IN U.S. HOSPITALIZATIONS FOR AMEBIC LIVER ABSCESS, 2002-2023

Akram Alnounou[1] Brian Nohomovich[2] Mohammad Alabbas[3] Eric Sieloff[1] Syed-Mohammed Jafri[4] Serge Sorser[2] Thomas Melgar[1], [1]Western Michigan University Homer Stryker MD SOM, [2]Henry Ford Health System, Providence, [3]Cleveland Clinic Foundation, [4]Henry Ford Health System

Background: U.S. population-based data on amebic liver abscess (ALA) are limited in the ICD-10 era. We evaluated national trends, inpatient outcomes, and markers of severe morbidity among adult ALA hospitalizations. **Methods:** Adult hospitalizations in the 2002–2023 National Inpatient Sample (NIS), excluding 2015, were analyzed. ALA was identified by ICD-9-CM 006.3 or ICD-10-CM A06.4. The primary outcome was a severe ALA composite (severe sepsis, acute kidney injury, liver-related decompensation, gram-negative septicemia, or unspecified septicemia). Analyses incorporated discharge weights, strata, and clustering. Markers of the composite were assessed with survey-weighted multivariable logistic regression, using general adult NIS hospitalizations as a benchmark. **Results:** We identified 688 ALA hospitalizations, representing 3,314 weighted national hospitalizations (95% CI, 2,982–3,646). The annual proportion of ALA hospitalizations declined (Cochran-Armitage P < .001). ALA hospitalizations were younger than general adult hospitalizations (mean age, 46.8 vs 57.5 years), predominantly male (77.6%), and frequently Hispanic (51.7%) or in the West (45.6%). Drainage was performed in 57.2% (percutaneous, 55.5%; surgical, 2.7%). The severe ALA composite occurred in 25.1% vs 15.1% of general hospitalizations (P < .001); SIRS/sepsis (13.7% vs 3.9%), severe sepsis (4.1% vs 1.4%), and liver-related decompensation (5.5% vs 1.4%) were also more frequent (all P < .001). In-hospital mortality was not reportable (HCUP small-cell suppression). Mean length of stay was longer (8.64 vs 4.83 days) and mean 2023-adjusted charges higher ($82,964 vs $55,508; both P < .001). Within ALA hospitalizations, coagulopathy was the only independent marker of the severe composite (adjusted OR, 3.82; 95% CI, 1.49–9.77; P = .006). **Conclusion:** ALA is rare in U.S. inpatient practice but is associated with severe morbidity, frequent drainage, longer stays, and higher charges. Coded coagulopathy identifies ALA hospitalizations with higher odds of severe in-hospital events, while administrative data remain insufficient for individual-level risk stratification.

3219 | HDV STRAIN-SPECIFIC FITNESS AND HBSAG PAIRING REFINE THE GENOTYPE-BASED PARADIGM OF HDV PATHOBIOLOGY

Takeshi Saito[1] Daniel Pinski[2] Masashi Okawa[2] Shiuan-Chi Wang[2] Meng Li[1] Garnik Arustamyan[2], [1]University of Southern California, [2]Keck School of Medicine, University of Southern California

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Hepatitis delta virus (HDV) accelerates HBV-associated liver disease and exhibits marked genetic diversity across eight genotypes. Certain HDV genotypes have been clinically linked to aggressive necroinflammation, fibrosis progression, and hepatocellular carcinoma; however, these associations are confounded by strain diversity, co-infecting HBV, host genetics, and regional comorbidities. Building on our prior cross-genotype HDV platform, this study tested whether clinically recognized genotype differences reflect intrinsic HDV genotype properties, strain-specific hepatocyte fitness, or functional compatibility between HDV genomes and HBV surface antigen (HBsAg). **Methods:** We analyzed 25 full-length HDV strains spanning all eight genotypes, including strains from genotypes clinically associated with aggressive disease. Using our established cross-genotype HDV-HBsAg platform, each HDV construct was evaluated with HBsAg expression systems representing distinct HBV envelope backgrounds. Producer-cell readouts included intracellular HDV RNA replication, S-HDAg/L-HDAg production, extracellular HDV RNA release, and particle-associated HDV output. The resulting HDV preparations were then assessed in optimized PHH cultures under HDV-alone and HBV-HDV coinfection conditions. PHH-based analyses quantified HDV entry/propagation, intracellular and extracellular HDV RNA, HBV-HDV interactions, and HBV-envelope–supported HDV particle production. **Results:** Across 25 HDV strains, we observed marked strain-to-strain variability in intracellular HDV RNA replication and S-HDAg/L-HDAg production. These phenotypes were not consistently predicted by HDV genotype as strains within the same genotype differed in replication efficiency and antigen production. HBsAg pairing further modified HDV propagation in a bidirectional and combination-specific manner. For a given HDV strain, selected HBsAg backgrounds enhanced intracellular HDV RNA replication and increased extracellular virion production, whereas others suppressed both intracellular and extracellular HDV readouts. Conversely, the same HBsAg background supported different levels of intracellular replication and virion production depending on the paired HDV strain. In most combinations, intracellular HDV replication and virion output changed in parallel, although select pairings showed partial dissociation between genome replication and envelope-supported particle production. **Conclusion:** This cross-sectional analysis of HDV strains and HBsAg pairings refines the genotype-based view of HDV pathobiology. HDV replication, HDAg production, and virion formation were determined by strain-specific fitness and HBsAg compatibility rather than genotype alone, suggesting that aggressive disease may reflect high-fitness HDV-HBsAg pairings.

3220 | HBCRAG LEVELS IN PATIENTS WITH HDV-RELATED CIRRHOSIS TREATED WITH BULEVIRTIDE MONOTHERAPY FOR 3 YEARS: A SINGLE-CENTER REAL-WORLD STUDY

Elisabetta Degasperi[1] Floriana Facchetti[1] Dana Sambarino[1] Caroline Scholtes[2] Barbara Testoni[3] Sara Uceda Renteria[4] Maria Paola Anolli[1] Caroline Charre[5] Marie-Laure Plissonnier[6] Riccardo Perbellini[1] Annapaola Callegaro[4] Massimo Levrero[7] Fabien Zoulim[8], [1]Division of Gastroenterology Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, [2]Virology Department, Hospices Civils de Lyon (HCL) and Université Claude Bernard Lyon 1, Lyon, [3]CRCL - INSERM U1052, [4]Microbiology and Virology Unit, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, [5]INSERM U1016, CNRS, UMR8104, Paris, [6]INSERM U1052, CNRS UMR-5286, Cancer Research Center of Lyon (CRCL), Lyon, [7]University Claude Bernard Lyon 1 - INSERM U1350, [8]Lyon 1 University

Background: Serum HBcrAg is a useful biomarker in the management of HBV patients, however its role in patients with chronic hepatitis Delta (CHD) under treatment with Bulevirtide (BLV) is currently unknown. Aim of the study was to investigate HBcrAg levels in CHD patients treated with BLV monotherapy. **Methods:** CHD patients treated with BLV 2 mg/day monotherapy in a single Center from the multicenter retrospective SAVE-D study were enrolled. Serum HBcrAg levels were quantified by LUMIPULSE® G HBcrAg assay (Fujirebio Europe, LLOQ 3 Log_{10} U/mL). Virological (HDV-RNA undetectable or ≥ 2 Log_{10} decline *vs.* baseline), biochemical (ALT < 40 U/L) and combined response (biochemical+virological) were assessed. **Results:** 405 serum samples were collected from 79 patients treated with BLV up to W144. At BLV start, median age was 55 (IQR 37-43) years, 53% males, 100% with cirrhosis (CPT-A score A in 87%), 100% NUC-treated, median ALT 97 (52-151) U/L, HBsAg 3.7 (3.4-3.9) Log_{10}IU/mL, 92% HBeAg-negative, 90% HBV DNA undetectable, median HDV RNA 5.5 (4.2-6.2) Log_{10}IU/mL. HBcrAg tested positive in 63 (80%) patients [4.0 (3.5-4.8) Log_{10} U/mL]. HBcrAg

levels positively correlated with HBsAg ($r = 0.37$, $p = 0.002$) and HDV RNA levels ($r = 0.30$, $p = 0.01$), but not with ALT or HBV DNA. After 144 weeks of BLV monotherapy, rates of virological, biochemical, combined response and HDV RNA undetectability were 70%, 64%, 52% and 33%, respectively. HBcrAg levels significantly declined during therapy: -0.31 Log_{10} at week 48 ($p = 0.02$), -0.63 Log_{10} at week 96 ($p = 0.003$), and -0.62 Log_{10} at week 144 ($p = 0.01$). During treatment, HBcrAg levels did not correlate with HDV RNA levels at single on-treatment timepoints but maintained a positive correlation with HBsAg levels over-time at all on-treatment timepoints (W48: $r = 0.35$, $p = 0.007$; W96: $r = 0.45$, $p = 0.006$; W144: $r = 0.50$, $p = 0.01$). Neither baseline nor on-treatment HBcrAg levels were associated with virological response or HDV RNA undetectability rates. Overall, HBcrAg levels became negative in 10 patients (week 48 in $n = 5$, week 96 in $n = 3$; week 144 in $n = 2$): at the time of HBcrAg negativity, 7 had achieved a virological response (HDV RNA undetectable in 3), while 3 patients were suboptimal responders (< 2 Log_{10} HDV RNA decline). Conversely, HBcrAg levels became positive during treatment in 5 patients who tested negative at baseline (< 3.5 Log_{10} U/mL in all cases; $n = 4$ at week 48, $n = 1$ at week 144): at the time of HBcrAg positivity, 3 had achieved a virological response (HDV RNA undetectable in $n = 2$), while 2 patients were suboptimal responders. During BLV monotherapy, no significant changes of HBsAg levels were observed. **Conclusion:** In CHD patients with cirrhosis treated with BLV monotherapy up to W144, HBcrAg levels were detectable in most patients at baseline and correlated with HBsAg and HDV RNA levels. During BLV, HBcrAg declined and correlated with HBsAg levels, but not with HDV virological responses.

3221 | NATIONAL TRENDS AND OUTCOMES OF HERPES SIMPLEX VIRUS HEPATITIS IN THE UNITED STATES

Lindsey Martens[1] Spencer Goble[1] Thomas Leventhal[1], [1]University of Minnesota

Background: Herpes simplex virus (HSV) is a rare cause of viral hepatitis. Severe cases of HSV hepatitis including acute liver failure have been reported, but large-scale analysis of HSV hepatitis hospitalizations and outcomes is lacking. We aimed to describe cases of HSV hepatitis using a generalizable, national database. **Methods:** Adult hospitalizations for HSV hepatitis, defined by the ICD-10 code B00.81, were assessed using the National Inpatient Sample from 2016-2023. Outcomes assessed included: the rate of HSV hepatitis hospitalizations in the US, in-hospital mortality, and index admission liver transplantation. Annual and overall hospitalization and inpatient mortality rates were calculated. Logistic regression was used to assess factors associated with the composite outcome of liver transplantation or inpatient death. An immunocompromised state was defined using ICD-10 codes for primary immunodeficiency disorders, neutropenia, aplastic anemia, chronic corticosteroid use, antineoplastic immunotherapy, and other immunosuppressive drug therapy. **Results:** A total of 995 hospitalizations for HSV hepatitis were identified. The median age was 39 years (IQR 27-57 years). Most patients were female (n = 605, 60.8%), and 125 (20.7%) of the included females were pregnant at the time of admission. An immunocompromised state was documented in 36.2% (n = 360). The overall rate of HSV hepatitis hospitalizations was 3.78 per 10,000,000 and peaked in 2017 at 5.24 (Figure 1). Overall mortality was 10.6% (n = 105), and 20 patients underwent liver transplantation (2.0%). Age (OR per 10 years = 1.40, 95% CI: 1.15-1.71, p = 0.001) and immunocompromised state (OR = 4.25, 95% CI: 1.71-10.55, p = 0.002) were associated with the composite outcome of liver transplantation or death. No deaths or liver transplantations were reported in pregnant patients. **Conclusion:** In the largest to date assessment of HSV hepatitis, we found largely stable rates of HSV hepatitis hospitalizations from 2016-2023. Mortality was high in the cohort, particularly in patients with an immunocompromised state, underscoring the importance of prompt recognition and antiviral therapy.

3222 | "LIVER" MORTIS: A CASE OF ACUTE ADENOVIRUS HEPATITIS, FROM ANTEMORTEM BIOPSY TO POSTMORTEM EXAMINATION

David Jumes[1] Jamie Kallan[1] Adnan Said[1] Megan Campbell[1] Jefree Schulte[1] Anna Fox[2] Heidi Stingley[2] Carla Zuniga[2] Charles Rohrer[1], [1]University of Wisconsin School of Medicine and Public Health, [2]William S. Middleton Memorial Veterans Hospital and Clinics

Background: Human Adenovirus is a common non-enveloped, double-stranded DNA virus that infects the upper respiratory, ocular, or gastrointestinal systems, and often has a mild, self-limited course in immunocompetent patients. Immunosuppressed patients experience more severe infections including pneumonia, enterocolitis, hepatitis, meningoencephalitis, hemorrhagic cystitis, and disseminated disease. Adenovirus viremia is detectable via polymerase chain reaction (PCR). Adenovirus hepatitis has no proven effective treatment and often results in liver failure and death. Histopathologic diagnosis of acute adenovirus hepatitis is made nearly as frequently during liver biopsy (49%) as it is during autopsy (51%). Our report illustrates this aggressive disease in a fatal case that was initially seen on antemortem liver biopsy and more thoroughly documented during autopsy. **Methods:** A 62-year-old woman with multiple myeloma status-post autologous stem cell transplant and CAR-T therapy was seen as an outpatient for presumed sinusitis and treated with azithromycin; a respiratory viral panel at the time was positive for Adenovirus. Two days later she presented to the hospital with several days of fever (100-101°F) and malaise. She was found to have an acute liver injury (AST 7,423 U/L; ALT 4,072 U/L; ALKP 258 U/L; total bilirubin 2.5 mg/dL, normal INR). Labs were also remarkable for pancytopenia, low fibrinogen (137 mg/dL), elevated triglycerides (287 mg/dL), and markedly elevated ferritin (182,289 ng/mL). Hepatology was consulted. There was concern for hemophagocytic lymphohistiocytosis (HLH) with a differential diagnosis including viral infection, autoimmune hepatitis, and drug induced liver injury. An ultrasound guided percutaneous liver biopsy was obtained. Later that day she was found pulseless and died despite resuscitative efforts. Shortly after her death, quantitative Adenovirus PCR resulted with >2 million copies/mL. An autopsy was requested by the patient's family. **Results:** Antemortem liver biopsy showed acute hepatitis with lobular disarray, numerous hepatocytes with viral cytopathic effect and degenerative changes with frequent apoptosis and relatively scant inflammatory infiltrate (Figure 1A). Features of HLH were not observed. Adenovirus immunohistochemistry (IHC) stain showed strong nuclear and cytoplasmic positivity (Figure 1B). Autopsy showed 1,350 mL of hemoperitoneum and widespread hepatic necrosis (Figure 1C). Electron microscopy confirmed virion ultrastructure (Figure 1D). **Conclusion:** Adenovirus hepatitis is often fatal in immunocompromised patients and presents with distinct pathologic findings as demonstrated in this case. Due to the patient's strong adenovirus IHC staining, over 600 blocks of liver tissue from autopsy were retained at our institution to develop new IHC control slides, now used by our laboratory and distributed to other laboratories.

3223 | REGIONAL DISPARITIES IN HEPATITIS D SCREENING AND PREVALENCE ACROSS TURKEY:A MULTICENTER COHORT STUDY

Müge Özarı Gülnar[1] Çiğdem Mermutluoğlu[2] Özgür Aktaş[3] İlker Şen[4] Mehmet Akif Yağlı[5] Erman Mercan[6] Furkan Çakmak[7] Zeynep Melekoglu Ellik[8] Derya Arı[9] Onur Keskin[7] Meral Akdogan Kayhan[9] Canan Alkim[6] Ramazan İdilman[10] Kendal Yalçın[2] Olga Metin[11] Sabahattin Kaymakoğlu[5] Mustafa Kemal Çelen[2] Cihan Yurdaydın[1], [1]Koç University Hospital, [2]Dicle University Hospital, [3]Koç University School of Medicine, [4]Prof. Dr. Cemil Taşcıoğlu City Hospital, [5]İstanbul University Hospital, [6]Şişli Hamidiye Etfal Training and Research Hospital, [7]Hacettepe University Hospital, [8]Ankara University Hospital, [9]Ankara Bilkent City Hospital, [10]Ankara University Hospit, [11]Prof. Dr. Cemil Taşcıoğlu City Hospital

Background: Hepatitis D virus (HDV) continues to be underdiagnosed worldwide. In this study, we aimed to describe (1) the referral patterns between HDV screening practices and hospital departments and regions of Turkey, and (2) the clinical characteristics associated with HDV positivity in patients under specialist follow-up. **Methods:** This multicenter cohort study, consisting of two parts, evaluated 31,657 HBsAg-positive patients covering a total of 20 hospitals within 6 participating centers: four single-hospital academic centers in Istanbul, one single-hospital academic center in Diyarbakir (endemic Southeast Turkey [SET]), and one 15-hospital private health network in Western Turkey [WT]. During the pre-COVID (2016-18) and post-COVID (2022-24) periods, independent predictors of anti-HDV status and HDV positivity were identified by multivariable logistic regression in a total of 11,515 patients followed by Gastroenterology (GE) and Infectious Diseases (ID) departments in three centers. **Results:** Of 31,657 HBsAg-positive patients, only **39.8%** of those diagnosed outside specialist departments were referred to GE/ID; **60.2% never reached specialist care**. Post-COVID anti-HDV testing reached **68.9%** in specialist versus only **15.3%** in non-specialist settings (4.5-fold difference, $p < 0.001$), with marked regional disparity (SET 37.2% vs WT 9.5%, $p < 0.001$). Anti-HDV testing declined post-COVID in GE (84.1→67.6%) and non-specialist departments (24.5→15.3%, $p < 0.001$). **HDV prevalence was higher in SET than WT (7.0% vs 4.9%, $p = 0.001$).** In the GE/ID cohort, independent predictors of anti-HDV testing included younger age (aOR 0.98), post-COVID period (aOR 2.20), GE setting (aOR 1.17), and higher ALT (aOR 1.07). Among tested patients, the strongest predictor of HDV positivity was **lower platelet count** (aOR 0.26 per log unit, 95% CI 0.19–0.35), followed by post-COVID period (aOR 5.45), **female sex** (aOR 1.92), and GE setting (aOR 1.91). **Lifetime cirrhosis was 8-fold more common in HDV-positive patients** (36.7% vs 6.7%, OR 8.06, 95% CI 6.54–9.95). **Conclusion:** Significant gaps in HDV screening remain: 60% of HBsAg-positive patients detected in non-specific departments never reach GE/ID and their screening rates remain extremely low. Clinicians make ALT-based selection, but HDV-positive patients are best differentiated by thrombocytopenia; this mismatch supports a reflex universal screening approach rather than symptom-triggered testing.

3224 | POTENT INHIBITION OF HEPATITIS DELTA VIRUS REPLICATION BY THE ANTISENSE OLIGONUCLEOTIDE ALG-215007

Yannick Debing[1] Caroline Pons[2] Jin Hong[3] Lars Degrauwe[1] Isabel Heremans[1] Kellan Passow[3] Lawrence Blatt[3] Julian Symons[4] Vivek Rajwanshi[3] David Smith[3] Eloi Verrier[2] David Durantel[5] Julie Lucifora[2], [1]Aligos Belgium BV, [2]Centre International de Recherche en Infectiologie (CIRI), INSERM, U1111, CNRS, UMR-5308, Univ. Lyon, [3]Aligos Therapeutics, Inc., [4]Aligos Therapeutics, [5]INSERM U1052

Background: Chronic hepatitis delta virus (HDV) infection is a severe form of viral hepatitis and often accelerates the progression to liver cirrhosis and hepatocellular carcinoma. Currently approved treatments rarely cure patients. Direct inhibition of viral replication has been underexplored as a therapeutic strategy. Since HDV replicates its RNA genome in the nucleus via rolling-circle amplification, it may efficiently be targeted by antisense oligonucleotides (ASOs). In addition, unconjugated ASOs such as the HBV-directed

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

bepirovirsen could distribute significantly to Kupffer cells and potentially stimulate Toll-like receptor 8 (TLR8) and contribute to the antiviral effects. From our initial screening, we identified ALG-215007 as a lead candidate for further exploration. Here, we describe its in vitro antiviral activity. **Methods:** Antiviral activity was assessed in HDV mono-infected HepG2-NTCP and differentiated Huh7-NTCP cells by RT-qPCR, hepatitis delta antigen immunofluorescent staining and Western blotting. Time-resolved effects on HDV genome, antigenome and mRNA levels were investigated through an RNA species-specific droplet digital PCR protocol. Induction of TLR activity was assessed in HEK-Blue hTLR3, 7, 8 and 9 cells. The HBV-directed ASO bepirovirsen was used as a non-targeting ASO control. **Results:** ALG-215007 showed potent inhibition of HDV replication in multiple cellular systems and all read-outs with calculated EC_{50} values around or below 1 nM. This is considerably more potent than other ASOs, which typically require higher concentrations to reach a similar level of efficacy. As expected, it was less efficacious when combined with ASOs carrying a complementary sequence. In an in vitro system that supports bona fide HDV spread under cell culture conditions, ALG-215007 demonstrated strong impairment of HDV propagation, slightly faster than a presS1 peptide equivalent to bulevirtide. Finally, ALG-215007 also stimulated hTLR8 activation, but not hTLR3, hTLR7 and hTLR9, with a profile similar to bepirovirsen. **Conclusion:** ALG-215007 is a highly potent ASO directly targeting HDV replication in the hepatocyte and possibly also inducing antiviral cytokines, making it a promising candidate for further explorations.

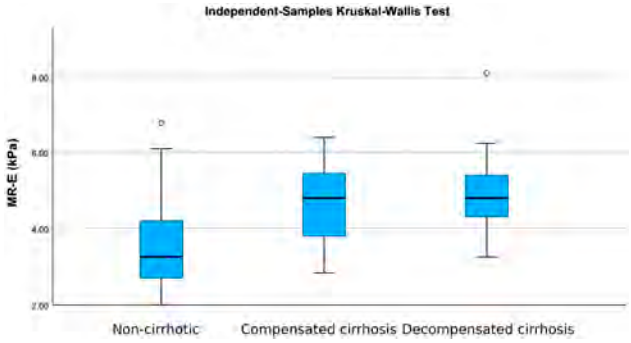
3225 | LIVER STIFFNESS MEASUREMENT WITH MAGNETIC RESONANCE ELASTOGRAPHY ACROSS THE SPECTRUM OF CHRONIC HEPATITIS DELTA: FROM NON-CIRRHOTIC TO DECOMPENSATED CIRRHOSIS



Özge Koç[1] Diğdem Kuru Öz[1] Emin Bodakci[2] Fatih Karakaya[3] Zeynep Ellik[1] Volkan Yilmaz[1] Mesut Gumussoy[4] Ramazan Erdem Er[1] Atilla Halil Elhan[1] Hale Gokcan[1] Gul Ayse Erden[1] Ramazan Idilman[1],

[1]Ankara University School of Medicine, [2]Gaziantep City State Hospital, [3]Medicana International Ankara, [4]Ankara University

Background: Non-invasive assessment of liver stiffness has good diagnostic accuracy for advanced fibrosis. Magnetic resonance elastography (MRE) is a non-invasive technique used to detect and stage hepatic fibrosis in patients with chronic liver disease. However, there are no data on the application of MRE in patients with chronic hepatitis delta (CHD). This study aimed to evaluate the diagnostic accuracy of MRE for assessing liver fibrosis in patients diagnosed with CHD. **Methods:** A total of 59 patients with CHD were included in the study. Magnetic resonance imaging was performed using a 1.5-T MR system (Magnetom Aera, Siemens Healthcare), including magnetic resonance elastography (MRE) for liver stiffness measurement (LSM). FIB-4 and APRI scores were calculated using laboratory parameters obtained on the day of the MRE examination. As demonstrated in previous studies, the MEFIB index, defined by the combination of MRE-LSM $\geq$ 3.3 kPa and FIB-4 $\geq$ 1.6, can identify patients with stage $\geq$2 fibrosis and has a high positive predictive value; therefore, it was also evaluated in the present study. **Results:** All 59 patients were Caucasian (male/female ratio: 26/33), with a median age of 56 years (interquartile range [IQR]: 14 years). Twenty-five patients were non-cirrhotic, whereas 25 had compensated cirrhosis and nine had decompensated cirrhosis. The median MELD score was 8.0. The mean FIB-4 and APRI scores were 3.78 ± 3.52 (median: 2.97, IQR: 3.07) and 1.15 ± 1.13 (median: 0.74, IQR: 1.08), respectively. Overall, the mean MRE-LSM was 4.30 ± 1.27 kPa (median: 4.30 kPa, IQR: 2.14 kPa).The mean MRE-LSM values in non-cirrhotic patients, patients with compensated cirrhosis, and patients with decompensated cirrhosis were 3.58 ± 1.22 kPa (median: 3.26 kPa, IQR: 1.62 kPa), 4.71 ± 0.96 kPa (median: 4.80 kPa, IQR: 1.75 kPa), and 5.02 ± 1.17 kPa (median: 4.80 kPa, IQR: 1.13 kPa), respectively ($p < 0.001$) (Figure 1). MRE demonstrated good diagnostic performance for detecting cirrhosis, with an area under the receiver operating characteristic curve (AUROC) of 0.809 ± 0.065 (95% CI: 0.681–0.937) and a cutoff value of 4.2 kPa (sensitivity: 72%; specificity: 72.3%). Logistic regression analysis revealed that MRE-LSM was a significant predictor of cirrhosis (odds ratio [OR]: 5.789; 95% CI: 1.452–23.087; $p = 0.013$).The MEFIB index was positive in 36.4% of non-cirrhotic patients, 71.4% of patients with compensated cirrhosis, and 76.9% of patients with decompensated cirrhosis ($p = 0.018$). **Conclusion:** MRE demonstrated good diagnostic performance for detecting cirrhosis and decompensated cirrhosis in patients with CHD, with a cutoff value of 4.2 kPa and acceptable sensitivity and specificity. In addition, combining MRE-LSM with other non-invasive fibrosis markers may improve diagnostic accuracy in patients with CHD.

3226 | EXTREMELY LOW PREVALENCE OF ANTI-HDV IN PATIENTS WITH HBV-RELATED FIBROSIS: A LARGE NATIONAL MULTICENTER COHORT STUDY IN MAINLAND CHINA

Xiaoning Wu[1] Bingqiong Wang[1] Jialing Zhou[1] Tongtong Meng[1] Shuyan Chen[1] Yameng Sun[1] Luqi Tang[1] Qiushuang Guan[1] Tongtong Wang[1] Shuai Xia[1] Zhiying He[2] Wentao Tan[1] Xiaojuan Ou[1] Jidong Jia[2] Hong You[2], [1]Beijing Friendship Hospital , Capital Medical University, [2]Beijing Friendship Hospital, Capital Medical University

Background: China is the world's largest potential reservoir for HDV infection. However, the overall prevalence of anti-HDV among patients with HBV-related liver fibrosis remains unknown. **Methods:** We retrospectively enrolled patients with HBV-related liver fibrosis from five national cohorts. Serum samples were tested for anti-HDV, with reflex testing for HDV RNA in anti-HDV-positive cases. Clinical data were collected at enrollment and every six months thereafter until October 2025. **Results:** A total of 2,661 patients from 55 centers across mainland China were screened and 2,085 were enrolled. Of these, 74.4% were male, with a median age of 46.0 years. There were 751 patients had biopsy-proven liver fibrosis, and 1,334 (64.8%) had cirrhosis diagnosed by biopsy or clinically. Samples from 1,709 patients were collected before antiviral treatment, and 376 samples were from patients on treatment. Anti-HDV was positive in 23 patients (1.10%; 95% CI 0.73%–1.65%). Only one patient was HDV RNA positive (4.3% in anti-HDV-positive patients; 0.05% in all patients). Among patients with ALT $\leq$40 U/L, the anti-HDV positive rate was higher in cirrhosis group than non-cirrhosis group (1.89% vs 0.43%; P = 0.034). In patients with histological activity index $\geq$9, the positive rate was higher in treated group than in un-treated group (10.0% vs 0, P = 0.042). No significant differences were observed in virological response, biochemical response, liver stiffness, or HBsAg change between anti-HDV-positive or not. During 4 to 10 years of follow-up, 264 patients developed liver-related events, including two who were anti-HDV positive (P = 0.929). **Conclusion:** The overall seroprevalence of anti-HDV in patients with HBV-induced fibrosis/cirrhosis was extremely low at 1.10% in mainland China.

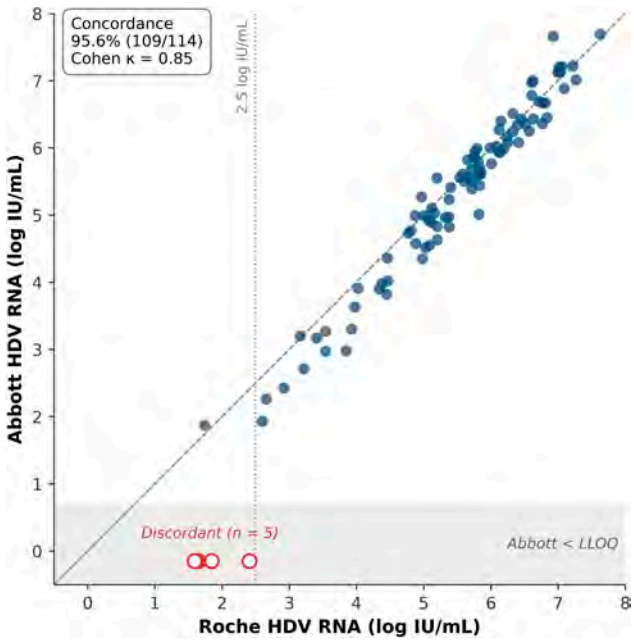
3227 | DISCORDANCE BETWEEN TWO HDV RNA ASSAYS IS LIMITED TO LOW-LEVEL VIREMIA IN CHRONIC HEPATITIS D



Wesam Aleyadeh[1] Jenny Oh[2] Gian Rodriguez Franco[3] Lezlie Kelzenberg[4] Laura Spina[5] Tiffany Fortney[6] Christian Voitenleitner[7] Mark Anderson[6] Gavin Cloherty[8] Ashli Rode[4] Marc Ghany[9], [1]National Institute of Diabetes and Digestive and Kidney Diseases; National Institutes of Health, [2]NIDDK, NIH, [3]Texas Tech University Health Science Center El Paso, [4]Diasorin Inc, [5]Diasorin SPA, [6]Abbott Diagnostics, [7]Roche Diagnostics International AG, [8]Abbott, [9]NIH/NIDDK

Background: Anti-HDV indicates exposure, whereas active infection requires HDV RNA confirmation. Several non-FDA-authorized HDV RNA assays are available in the U.S., but comparative performance data are limited. We compared 2 quantitative HDV RNA assays and 5 anti-HDV serologic assays in patients with presumed chronic hepatitis D (CHD). **Methods:** Among 896 HBsAg-positive persons evaluated at a tertiary liver clinic, anti-HDV testing was performed using the FDA-authorized LIAISON XL MUREX (DiaSorin), 3 laboratory-developed tests (Quest, Eurofins Viracor, Mayo Clinic Laboratories), and a research-use-only (RUO) Abbott assay. CHD was classified as confirmed (delta antigen staining on liver biopsy) or probable (compatible risk factors, elevated ALT, and low HBV DNA). Equivocal anti-HDV results were considered positive.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Samples with sufficient volume underwent quantitative HDV RNA testing using Roche and Abbott RUO assays; the Abbott assay was performed at 1:10 dilution. Results below the lower limit of quantification were considered negative. **Results:** Of 896 HBsAg-positive persons, 146 (16%) were anti-HDV positive by at least one assay (63 confirmed, 83 probable). The cohort was 62% male, 42% Asian, 30% White, 24% Black, and 70% foreign-born. Of 146 anti-HDV-positive persons, 114 had evaluable results from both HDV RNA assays (51 biopsy-proven, 63 probable). Anti-HDV positivity was 100% by LIAISON XL and Abbott (114/114), 93.9% (107/114) by LDT1, 99.1% (113/114) by LDT2, and 98.1% (104/106) by LDT3. HDV RNA was detected in 97/114 (85.1%) by Roche and 92/114 (80.7%) by Abbott, with median viral loads of 5.66 and 5.58 log10 IU/mL, respectively. Seventeen samples (15%) were negative by both HDV RNA assays. Among these, anti-HDV was positive by all 5 assays in 4 cases, 4 assays in 10 cases, and 3 assays in 3 cases. Concordance between assays was 95.6% (109/114; 95% CI, 90.1–98.1%; $\kappa = 0.85$). All 5 discordant samples were positive only by Roche at low viral loads (1.6–2.4 log10 IU/mL) and likely reflect sample dilution in the Abbott assay; no discordance occurred above 2.5 log10 IU/mL. The 5 discordant cases comprised 1 confirmed and 4 probable and occurred in both sexes and across all races. **Conclusion:** Approximately 15% of CHD cases likely represented resolved HDV infection. Agreement between HDV RNA assays was excellent overall (96%); however, differences at low-level viremia may affect treatment eligibility, highlighting the need for standardized HDV RNA testing.

3228 | CLINICAL OUTCOMES IN UNTREATED AND BULEVIRTIDE-TREATED PATIENTS WITH CHRONIC HEPATITIS DELTA COULD BE PREDICTED BY ARTIFICIAL INTELLEGENCE (AI) ASSISTED SYNTHETIC DATA GENERATION

Saverio D'Amico[1] Elisabetta Degasperi[2] Stella De Nicola[3] Nicola Pugliese[3] Maria Paola Anolli[2] Marta Borghi[2] Sara Baccino[1] Ivan Ferrari[1] Dominique Roulot[4] Matteo Della Porta[1] Alessio Aghemo[3], [1]IRCCS Humanitas Research Hospital, Rozzano, Milan, Italy, [2]Division Gastroenterology and Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, [3]Division of Internal Medicine and Hepatology, IRCCS Humanitas Research Hospital, [4]Liver Unit, Avicenne Hospital, AP-HP, Sorbonne Paris Nord University, Bobigny, France

Background: Bulevirtide (BLV) monotherapy induces virological and biochemical responses in patients with CHD, but the possibility to evaluate its impact on clinical outcomes is currently limited by unavailability of comparable untreated controls. Synthetic data (SD) mimic real-patient statistical and clinical properties, potentially overcoming limitations. We aimed to generate and validate high-fidelity SD evaluating disease outcomes in BLV-treated versus untreated CHD patients with cirrhosis. **Methods:** Clinical data from 344 CHD patients with cirrhosis treated with BLV in the SAVE-D study and two historical BLV-untreated cohorts from Italy and France (n = 298) were used to train models. Two settings were defined: A) 1:1 generation of both cohorts assessing clinical fidelity and privacy standards; B) generation of balanced, augmented cohorts (n = 3000/group), reproducing clinical endpoints and addressing matching challenges. SD were evaluated using SAFE framework (PMID: 41197110) against a real data pool excluded from the training phase. Fidelity and privacy were evaluated by Clinical Synthetic Fidelity (CSF) score (average of statistical metrics) and Nearest Neighbour Distance Ration (NNDR) (optimal 0.65-0.85).

Propensity score matching (logistic regression) aligned clinical and demographic covariates (SMD < 0.1). Primary endpoint compared three-year incidences of liver-related events (hepatocellular carcinoma [HCC] and decompensation). **Results:** In setting A, synthetic cohorts of BLV-treated and untreated patients showed high fidelity and privacy (CSF 90%/94%, NNDR 0.71/0.85). In setting B, propensity score matching identified 624 pairs from 3,000 SD samples per group with consistent SAFE metrics. 3-year cumulative incidences of decompensation and HCC were similar across real *vs.* synthetic BLV-treated and untreated patients: decompensation 2.7% *vs.* 4.2% (BLV-treated) and 11.3% *vs.* 10.0% (untreated), HCC 6.6% *vs.* 8.5% (BLV-treated) and 3.6% *vs.* 4.8% (untreated), respectively. Compared to real patients, the synthetic cohort significantly improved statistical robustness, due to the larger pool of matched individuals with perfectly comparable characteristics (real: $p = 0.054$ and $p = 0.378$ *vs.* synthetic: $p = 0.039$ and $p = 0.546$). **Conclusion:** High-fidelity synthetic patient-level data accurately reproduce clinical outcomes in untreated and BLV-treated CHD patients with cirrhosis. This strategy may overcome some of the challenges in rare diseases.

3229 | REAL-WORLD EPIDEMIOLOGY, DISEASE BURDEN, AND BULEVIRTIDE TREATMENT EXPERIENCE IN A MULTICENTRE COHORT WITH HEPATITIS DELTA VIRUS INFECTION IN CANADA

Roshawn Jamasi[1] Sébastien Poulin[2] Julian Hercun[3] Jordyn Vienneau[1] Matthew Sadler[1] Stephen Congly[1] Mayur Brahmania[1] Laura Stinton[1] Karen Doucette[4] Vanessa Meier-Stephenson[4] Conar O'Neil[4] Tianyan Chen[5] Giada Sebastiani[5] Philip Wong[5] Curtis Cooper[6] Alnoor Ramji[7] Hin Hin Ko[7] Edward Tam[8] Sergio Borgia[9] Scott Fung[10] Jordan Feld[11] David Wong[12] Nabiha Faisal[13] Mang Ma[4] Alexander Wong[14] Keith Tsoi[15] Carmine Nudo[16] Emma Lee[17] Carla Coffin[1], [1]University of Calgary, [2]CISSS des Laurentides, [3]Centre hospitalier de l'Universite de Montreal, [4]University of Alberta, [5]McGill University Health Centre, [6]University of Ottawa, [7]University of British Columbia, [8]St. Paul's Hospital, [9]William Osler Health System, [10]University Health Network, [11]Toronto General Hospital, [12]University of Toronto, [13]University of Manitoba, [14]University of Saskatchewan, [15]McMaster University, [16]Hôpital de la Cité de la Santé, [17]Public Health Agency of Canada

Background: Hepatitis D virus (HDV) infection is the most severe form of chronic viral hepatitis, characterized by accelerated fibrosis progression, cirrhosis, and increased liver-related mortality. Despite its clinical burden, treatment options remain limited, and real-world data in emerging therapies such as bulevirtide (BLV) are scarce. We aimed to characterize the epidemiology, clinical burden, and treatment outcomes of HDV infection within a Canadian cohort. **Methods:** We conducted a retrospective multicentre cohort study of HBsAg+/anti-HDV+ patients enrolled in the Canadian Hepatitis B Network registry, followed from 2004-2026 (8.7yrs [3.6-11.1] since initial visit). Demographic characteristics, genotypes, antiviral treatment, and clinical outcomes were summarized. A secondary analysis compared BLV-treated patients with untreated HDV RNA+ patients using the most recent available clinical data. Median (IQR) values were reported and continuous variables were compared using the Wilcoxon rank-sum test. **Results:** The most common countries of birth ($N = 225$) were Canada (8.9%; $n = 20$), Mongolia (8.4%; $n = 19$), Cameroon (8%; $n = 18$), and Sudan (6.7%; $n = 15$). 28 (12.4%) had HIV or HCV and 5 had triple HDV/HIV/HCV infection. Of patients with HBV genotype data ($n = 44/225$), 26 (59%) were HBV-D, 11 (25%) HBV-E and 4 (9%) HBV-A. Of those with HDV genotype data ($n = 107/225$), HDV genotype 1 was most prevalent ($n = 86$, 80%), followed by genotype 5 ($n = 14$, 13%). 160/225 patients received anti-HBV nucleos(t)ide analog and/or interferon-based therapy. During follow-up, 22 patients (9.8%) underwent liver transplant or died. Over follow-up of 4.9yrs (2.4-7.5), 27/51 (52.9%) HDV RNA+, non-BLV-treated patients had increased median liver stiffness measurements (LSM) from 7.4 to 11.3kPa, with a median patient-level increase of 2.7kPa. At baseline, 12/51 (23.5%) had evidence of cirrhosis. At follow-up, this had increased to 24/51 (47.1%), including 12/39 (30.8%) who had developed new cirrhosis evidence during follow-up based on LSM and/or clinical criteria. Compared to untreated HDV RNA+ ($n = 127$), BLV-treated patients ($n = 17$) had lower ALT levels (Table 1, $p = 0.003$) and lower HDV RNA levels (Table 1, $p = 0.024$). HDV RNA became undetectable in 31.3% (5/16) of BLV-treated patients, with no decompensating events occurring in this cohort. **Conclusion:** In this Canadian HDV cohort, HDV genotype 1 and HBV genotype D predominated. A

significant proportion of patients were HDV RNA+ and had advanced liver disease at initial presentation. A subset of BLV-treated patients showed improved biochemical and virological response. HDV RNA+ patients not on BLV showed progressive liver disease during follow-up. These findings highlight the aggressive natural history of HDV infection and support the urgent need for expanded access to effective antiviral therapies and longitudinal monitoring strategies.

Table 1. *Comparison of Clinical, Biochemical, and Fibrosis Parameters Between Bulevirtide-Treated and Bulevirtide-Untreated HDV RNA-Positive Patients at last available follow-up*

Parameter	BLV-Treated (n=17*)	HDV RNA-Positive, No BLV (n=128*)
Treatment Duration		
Weeks since BLV initiation, median (IQR) or since initial assessment	139.1 (90.3–139.3)	463.7 (193.0–710.8)
Virology		
HDV RNA detected, n/N (%)	11/16 (68.8%)	128/128 (100.0%)
HDV RNA, IU/mL — median (IQR)†	325 (159–1,770)	90,100 (2,750–1,390,000)
qHBsAg, IU/mL — median (IQR)	6,429 (3,777–10,061)	4,057 (1,461–11,450)
Liver Biochemistry		
ALT, U/L — median (IQR)	29 (23–40)	50 (30–109.5)
ALT above ULN, %	47.1%	70.9%
AFP, ng/mL — median (IQR)	3.5 (2.5–5.0)	3.5 (2.9–5.4)
Fibrosis Assessment		
Liver stiffness, kPa — median (IQR)	12.3 (7.8–17.6)	9.0 (6.4–14.1)
FIB-4 — median (IQR)	2.61 (2.01–4.07)	1.77 (1.24–3.15)

All continuous variables expressed as median (IQR). BLV = bulevirtide; ULN = upper limit of normal; qHBsAg = quantitative hepatitis B surface antigen; IQR = interquartile range; AFP = alpha-fetoprotein.

** Sample sizes vary by parameter: time since initial assessment n=17 (BLV, n=127 (no BLV); liver stiffness n=10 (BLV), n=104 (no BLV); FIB-4 n=17 (BLV), n=123 (no BLV); AFP n=13 (BLV), n=84 (no BLV); qHBsAg n=11 (BLV), n=56 (no BLV); HDV RNA n=9 (BLV, detected only), n=58 (no BLV); ALT n=17 (BLV), n=127 (no BLV).*

† HDV RNA reported among patients with detectable viral load only.

3230 | PREVALENCE OF HEPATITIS D VIRUS INFECTION AMONG IN CHINESE INDIVIDUALS AGED 1–69 YEARS

Qiudong Su[1] Guomin Zhang[1] Xiaoning Wu[2] Shuang Zhang[1] Feng Qiu[1] Fuzhen Wang[1] Hui Zheng[1] Bingqiong Wang[2] Luqing Tang[2] Zhiying He[2] Yu Wang[1] Feng Wang[1] Hong You[2] Jidong Jia[2] Zundong Yin[1],
[1]Chinese Center for Disease Control and Prevention, [2]Beijing Friendship Hospital, Capital Medical University

Background: Nationwide data on hepatitis D virus (HDV) prevalence in China are scarce. This study aimed to determine the seroprevalence and correlates of HDV infection among HBsAg-positive individuals in a national, population-based cohort. **Methods:** A

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

stratified, three-stage cluster study was conducted within the 2020 national HBV sero-survey (91,896 participants aged 1–69 years). Among 4,321 HBsAg-positive participants, anti-HDV antibodies were screened using chemiluminescent immunoassay. HDV RNA was quantified and genotyped in positive samples. Demographic, virological, and clinical correlates were analyzed. **Results:** The overall anti-HDV seroprevalence among HBsAg-positive individuals was 1.32% (95%CI: 1.09–1.55%), implying approximately 990,000 HDV-infected individuals among China's estimated 75 million CHB carriers. Age-specific analysis revealed parallel epidemiological curves for HBsAg and anti-HDV prevalence, with both peaking in middle-aged and older adults (40–69 years). Prevalence was significantly higher in males (1.90% vs. 0.78%; OR = 2.48, 95%CI: 1.41–4.36) and in Tibetans (2.71% vs. 1.11% in Han). Virologically, anti-HDV positivity was associated with HBeAg seropositivity (OR = 2.07), higher HBV viral load (≥ 1,000 IU/mL), and HBV genotype CD. Clinically, it was linked to active liver disease (elevated ALT: OR = 3.19; chronic hepatitis diagnosis: OR = 3.20). The HDV RNA positivity rate among anti-HDV-positive individuals was 1.89% (1/53). **Conclusion:** The nationwide survey reveals a lower HDV seroprevalence in China (1.32%) than clinic-based estimates, but indicates a substantial absolute burden. The epidemiology is characterized by specific demographic and virological correlates. The extremely low HDV RNA detection rate highlights challenges in population-level assessment of active infection.

3231 | SUPPRESSION OF FIBROGENESIS DURING BULEVIRTIDE THERAPY IN HEPATITIS D: A LONGITUDINAL ANALYSIS USING PRO-C3 DYNAMICS

Giuseppe Rusignuolo[1] Philipp Mathe[2] Thomas Wiggers Møller[3] Morten Karsdal[3] Diana Leeming[4] Christoph Neumann-Haefelin[5] Robert Thimme[6] Tobias Boettler[6], [1]Department of Medicine II, University Hospital Freiburg, Ge, [2]University Hospital Freiburg, Germany, [3]Nordic Bioscience, [4]Nordic Bioscience A/S, [5]University Hospital Freiburg, [6]University of Freiburg

Background: Chronic hepatitis D virus (HDV) infection is associated with rapid fibrosis progression and poor clinical outcomes. While bulevirtide effectively suppresses viral replication, its impact on fibrogenesis is insufficiently characterized. We aimed to assess dynamic changes in fibrogenesis using PRO-C3 and to define temporal patterns and determinants of treatment response using a proportional log-ratio framework. **Methods:** In this longitudinal monocentric cohort study, 13 patients with chronic HDV infection undergoing bulevirtide therapy were analyzed (45 observations). Serial measurements of HDV RNA, PRO-C3, PRO-C6, and ALT were collected. Liver stiffness measurement at baseline was used for stratification. The primary endpoint was proportional change in PRO-C3 from baseline to furthest follow-up, expressed as log(follow-up/baseline). Linear regression models adjusted for follow-up duration were used. Secondary analyses included associations with viral-load log-ratio, temporal modeling, baseline fibrosis burden, and relationships with ALT. **Results:** Virological response was independently associated with a greater proportional reduction in PRO-C3 ($\beta = -0.60$, $p = 0.008$). Responders showed a mean PRO-C3 reduction of −30.9% compared to no meaningful change in non-responders. Continuous viral decline, expressed as viralload log-ratio, was associated with PRO-C3 reduction ($\beta = 0.071$, $p = 0.040$; Spearman $\rho = 0.63$, $p = 0.021$), whereas no significant associations were observed for PRO-C6. Longitudinal analysis revealed a marked latency effect, with no early change (0–3 months: $p = 0.93$) but significant PROC3 reduction emerging after 6–12 months ($p = 0.0077$) and persisting beyond 12 months ($p = 0.0034$). Baseline liver stiffness was associated with treatment response, with higher baseline values predicting attenuated PRO-C3 decline ($\beta = 0.021$, $p = 0.032$). Additionally, proportional changes in ALT were significantly associated with PRO-C3 dynamics ($\beta = 0.31$, $p = 0.012$; Spearman $\rho = 0.58$, $p = 0.037$), indicating that biochemical activity closely reflects fibrogenesis suppression. **Conclusion:** Bulevirtide therapy is associated with delayed but significant suppression of fibrogenesis in virological responders. The observed latency suggests that extracellular matrix remodeling requires sustained viral suppression. The association with baseline fibrosis burden supports early treatment initiation before advanced structural damage occurs

3232 | PREVALENCE AND INCIDENCE OF HEPATITIS D VIRUS INFECTION AMONG PATIENTS WITH HEPATITIS B: A REAL-WORLD ANALYSIS OF 4,966,701 PATIENTS FROM THE TRINETX GLOBAL NETWORK

Mhd Kutaiba Albuni[1] Mohamad Hijazi[2] Elias Battikh[3] Christina Leyson[4], [1]TriHealth- Good Samaritan Hosptial, [2]Internal Medicine Department TriHealth, [3]Internal Medicine Department Stroger Hospital Of Cook County, [4]University of Kentucky Medical Center

Background: Hepatitis D virus (HDV) is the most severe form of viral hepatitis. It infects individuals with concurrent or prior hepatitis B virus (HBV) infection, as it requires the HBV surface antigen (HBsAg) for virion assembly. HDV co-infection with HBV is associated with accelerated progression to cirrhosis, hepatic decompensation, and hepatocellular carcinoma compared to HBV mono-infection. Despite this significance, HDV testing remains underperformed in routine practice, and the prevalence of HDV among HBV-infected patients in the United States—stratified by demographic characteristics—has not been well characterized using large-scale electronic health record data. **Methods:** We conducted an incidence and prevalence analysis using the TriNetX Global Collaborative Network, involving 173 healthcare organizations. Our study cohort included all patients with documented hepatitis B, identified through ICD-10 codes (B18.1, B19.10, B16.1, Z22.51), serologic tests (LOINC 55275-2), HBV-related medications (RxNorm: 1427211, 26744), and SNOMED procedure codes. We analyzed data from 4,966,701 patients from May 2000 to May 2026, focusing on HDV-related events defined by relevant diagnosis codes (ICD-10: B17.0, B17.8, B16.1, B18.0), serologic tests, and HDV RNA quantification. Results were stratified by age, sex, race, and ethnicity. **Results:** Among 4,966,701 patients with documented HBV infection, the documented prevalence of HDV co-infection was **0.86%** (incidence proportion 0.86%; incidence rate 2.45 × 10^{-6} cases/person-day). HDV prevalence increased with age from childhood, peaking in the **25–29 year age group (1.26%)**, followed by a progressive decline in older adults, reflecting the predominance of HDV acquisition through parenteral and sexual routes in young adulthood.Marked racial and ethnic differences in HDV prevalence were observed. **Native Hawaiian or Pacific Islander patients had the highest HDV prevalence (4.39%)**, followed by Asian patients (3.05%) — both substantially exceeding the overall rate. Black or African American patients had a prevalence of 1.12%, while White patients had the lowest documented rate (0.52%). Male patients had nearly 1.5-fold higher prevalence than female patients (**1.04% vs. 0.70%**). By ethnicity, non-Hispanic or Latino patients had higher HDV prevalence than Hispanic or Latino patients (**1.09% vs. 0.55%**), likely reflecting the demographic composition of HBV-endemic immigrant populations. **Conclusion:** Disparities were noted among racial groups, with Asian and Native Hawaiian or Pacific Islander patients most affected, reflecting global HDV trends. These results underscore the need for universal HDV testing in all HBV-positive patients, highlighting a critical gap in clinical practice for minority and immigrant populations.

KEY STATISTICS

Stratum	Group	Prevalence (%)	Incidence Rate (/person-day)
Overall	All HBV patients	0.86%	2.45×10^{-6}
Age (peak)	25–29 years	1.26%	3.49×10^{-6}
Age (lowest)	75–79 years	0.23%	9.02×10^{-7}
Sex	Male	1.04%	3.16×10^{-6}
Sex	Female	0.70%	1.87×10^{-6}
Race (highest)	Native Hawaiian/Pacific Islander	4.39%	1.02×10^{-5}
Race (highest)	Asian	3.05%	8.39×10^{-6}
Race	Black/African American	1.12%	2.49×10^{-6}
Race (lowest)	White	0.52%	1.20×10^{-6}

3233 | EVALUATION OF HIV-REPROGRAMMED LIVER MACROPHAGES USING A NOVEL *EX VIVO* HUMAN LIVER MODEL

Yongtao Wang[1] Xia Xiao[1] Tanvi Patel[1] Shadi Salloum[1] Zeinab Heidariyan[1] Wenyu Lin[1] Ibrahim Eissa[1] Ben Leaker[1] Thien Nguyen[1] Olivia Mezzetti[1] Swastika Tripathi[1] Zhu Zhang[1] Nadia Alatrakchi[1] Kenneth Tanabe[1] Raymond Chung[1], [1]Massachusetts General Hospital and Harvard Medical School

Background: Current animal models, including non-human primates, fail to effectively recapitulate the complex interplay of human HIV infection and associated hepatic pathology. Consequently, physiologically relevant and tractable models for HIV-related liver

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

research are urgently required. The *ex vivo* precision-cut liver slice (PCLS) platform preserves the native, three-dimensional architecture of the human liver, allowing for the precise modeling of cell-to-cell signaling pathways. This includes the responses of resident tissue macrophages, which drive hepatic damage through localized cytokine production. **Methods:** Bioinformatic profiles of *in vitro* Kupffer cells (resident liver macrophages) exposed to HIV were analyzed. Concurrently, human PCLS were prepared, infected with HIV *ex vivo*, and subjected to further molecular and phenotypic assessments. **Results:** Bioinformatic analysis revealed that HIV infection drives a robust immune activation program in cultured Kupffer cells, characterized by the marked upregulation of TNFA signaling, IL-6 signaling, and interferon responsive genes. Notably, gene sets responding to interferon-gamma, the prototypical driver of classical macrophage activation, were significantly positively enriched. Signatures of interferon gamma-stimulated macrophage were also positively enriched, indicating that Kupffer cells undergo functional reprogramming upon HIV exposure. In the *ex vivo* human PCLS model, viral entry and active transcription were confirmed via detectable mRNA expression of the HIV *Gag* gene alongside the host co-receptors *CCR5* and *CXCR4*. Flow cytometric analysis revealed an expansion of $CD45^+$ intrahepatic leukocytes in HIV-infected slices, indicating elevated immune activation within the tissue microenvironment. Furthermore, HIV infection prompted a distinct reprogramming of resident macrophage phenotypes toward a hybrid activation state. Specifically, the expression of pro-inflammatory M1-associated gene (e.g., *TNFA*) increased significantly, and pro-fibrotic M2-associated markers (including *ARG1*, *LY75*/CD205, and *TGFB*) were concurrently elevated. Driven by this macrophage reprogramming, downstream hepatic inflammatory and profibrogenic gene expression were significantly upregulated in the infected PCLS tissue. **Conclusion:** These findings demonstrate that human PCLS represents a robust *ex vivo* platform to investigate HIV-mediated macrophage reprogramming. This tractable human-tissue model offers a powerful alternative to accelerate the study of HIV-associated liver disease and therapeutic intervention.

3234 | CLINICAL CORRELATES OF BULEVIRTIDE PLASMA LEVELS IN PATIENTS WITH CHRONIC HEPATITIS DELTA DURING THERAPEUTIC DRUG MONITORING: A CROSS-SECTIONAL ANALYSIS

Elisabetta Degasperi[1] Amedeo De Nicolo[2] Dana Sambarino[1] Alice Palermiti[2] Alessandra Manca[2] Maria Paola Anolli[1] Marta Borghi[1] Riccardo Perbellini[1] Roberta Soffredini[1] Sara Monico[1] Floriana Facchetti[1] Antonio D'Avolio[2], [1]Division of Gastroenterology Hepatology, Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, [2]Laboratory of Clinical Pharmacology and Pharmacogenetics, University of Turin

Background: Bulevirtide (BLV) monotherapy achieves efficient responses in patients with chronic hepatitis Delta (CHD), however little is known about plasma drug concentrations. Aim of the study was to evaluate BLV levels in CHD patients treated in a real-world setting. **Methods:** Consecutive CHD patients treated with BLV in an Italian center underwent single timepoint plasma sampling for BLV quantification between November 2024 and April 2025. BLV plasma levels were assessed through a validated ultra-high performance liquid chromatography coupled with tandem-mass spectrometry method (UHPLC-MS/MS). **Results:** 72 CHD patients were enrolled: at sampling, median age was 56 (IQR 43-61) years, 53% males, BMI 25 (23-27), 81% with cirrhosis (100% CPT-A; CPT A6 in 28%), ALT 32 (26-43) U/L, bile acids 20 (9-36) µmol/L, vitamin D 16 (11-20) ng/mL, HBsAg 3.7 (3.1-3.9) Log_{10}IU/mL, HDV RNA 2.3 (0.7-3.3) Log_{10}IU/mL. Patients had been under BLV treatment for a median of 84 (72-138) weeks; 78% had achieved virological response, 24% target not detected. At sampling, 70/72 (97%) of the patients had detectable BLV plasma levels, overall median values were 1.8 (0.6-7.8) ng/mL. BLV levels did not correlate with age ($p = 0.17$), sex ($p = 0.78$), BMI ($p = 0.22$), and presence of cirrhosis ($p = 0.44$). Among the 56 patients with cirrhosis, BLV levels were similar across CPT subclasses [A5 vs A6: 1.5 (0.6-7.2) ng/mL *vs.* 4.5 (1.1-9.5) ng/mL, $p = 0.27$]. When analyzing biochemical and virological features at sampling, BLV levels did not correlate with ALT ($p = 0.44$), bile acids ($p = 0.67$), vitamin D ($p = 0.20$), and HDV RNA ($p = 0.74$), while there was a trend towards an inverse correlation with HBsAg levels ($r = 0.23$; $p = 0.06$). BLV levels did not differ according to time interval between BLV injection and sampling (≤ 12 *vs.* > 12 hours, $p = 0.13$), and duration of BLV treatment: concentrations were 1.5 (0.8-2.9) ng/mL in patients treated with BLV for ≤ 48 weeks *vs.* 2.9 (1.5-8.6) ng/mL for 49-96 weeks *vs.* 1.7 (0.6-9.3) ng/mL for 97-144 weeks *vs.* 0.6 (0.4-2.5) ng/mL for > 144 weeks, respectively ($p = 0.13$). BLV levels were also independent of virological response ($p = 0.67$). **Conclusion:** In a preliminary cross-sectional therapeutic drug monitoring of BLV performed in a single-center cohort of CHD patients,

BLV levels was quantifiable in 97% of patients 12-24 hours after the last administration but did not significantly correlate with patient features and/or virological outcomes.

3235 | REAL-WORLD ADHERENCE TO BULEVIRTIDE IN CHRONIC HEPATITIS D: A MULTICENTER PROSPECTIVE STUDY USING TWO VALIDATED INSTRUMENTS

Amanda Beatriz Cohn Vaya[1] Elena Vargas Accarino[1] Carles Aracil Blanch[2] Adrià Rodríguez Castellano[3] Patricia Huelin Alvarez[2] Judit Romero[1] Adriana Palom[1] Juan Carlos Ruiz Cobo[1] Maria Buti Ferret[1], [1]Research group of liver diseases, Vall Hebron Research Institute, Barcelona, Spain. [2]Department of Gastroenterology and Hepatology, University Hospital Arnau de Vilanova, IRBLleida, Lle, [3]Gastroenterology Department, Joan XXIII University Hospital, Tarragona

Background: Chronic hepatitis D virus (HDV) infection is the most severe form of viral hepatitis, with rapid progression to cirrhosis and limited therapeutic options. Bulevirtide (BLV) has recently changed the treatment landscape, but real-world data on adherence remain scarce. We aimed to assess adherence to BLV in routine clinical practice and identify associated factors. **Methods:** Prospective multicenter study including patients with chronic HDV infection receiving BLV at three tertiary hospitals. Adherence was evaluated using the Morisky–Green Test and the Simplified Medication Adherence Questionnaire (SMAQ). Demographic and clinical variables were analyzed. **Results:** Thirty patients were included (40% male, mean age 46.6 years, 33% born in Spain, 43% with cirrhosis, and mean time since diagnosis was 17.3 years). Most patients (83%) had been on BLV for >6 months. According to the Morisky–Green scale, 57% showed high adherence, 20% intermediate, and 23% low adherence. SMAQ classified 67% as adherent. Both tools showed good overall agreement in adherence classification. No differences in adherence were observed by sex, origin, treatment duration, or fibrosis stage. Longer time since diagnosis was significantly associated with higher adherence ($p = 0.005$). Patients with high adherence had longer disease duration than those with intermediate adherence (22.06 vs. 5.67 years). **Conclusion:** In this real-world cohort, adherence to BLV was remarkably high despite its daily injectable administration, particularly among patients with a long disease duration. Both validated tools provided consistent adherence classifications. Given that a shorter time since diagnosis significantly correlates with lower adherence, early clinical support and targeted education strategies are crucial for newly diagnosed patients initiating BLV therapy.

Background: Liver stiffness measurement (LSM) by transient elastography has shown good diagnostic performance as an indirect noninvasive test (NIT) for hepatic fibrosis, but limited data are available in patients (pts) with chronic hepatitis delta (CHD). Integrated clinical trial data on bulevirtide (BLV) evaluated the relationship of LSM and other NITs with necroinflammation and fibrosis by biopsy. **Methods:** Pts with CHD, with or without compensated cirrhosis, with baseline (BL) biopsy data were included from the MYR202, MYR203, MYR204, and MYR301 trials. On/post-treatment (Tx) biopsy data from pts receiving BLV +/− pegylated interferon alfa-2a (PegIFN) at weeks 24 and 48, and post-Tx week 24 were analyzed. Only on-Tx biopsies (1/pt) were selected from pts with both on- and post-Tx samples. Biopsies were scored with METAVIR for fibrosis stage (F0–F4) and necroinflammation grade (Histological Activity Index [HAI]/A0–A3). NITs included LSM, aspartate aminotransferase to platelet ratio index (APRI), and Fibrosis-4 (FIB-4). Diagnostic accuracy for advanced fibrosis ($\geq$F3) and cirrhosis (F4) was assessed using area under the receiver operating characteristic curves (AUROC). **Results:** Of 308 pts with BL biopsies, 263 had LSM, 279 had FIB-4, and 279 had APRI within 3 months of biopsy. BL fibrosis stages were 43% F0–F1, 34% F2, 17% F3, and 6% F4; HAI scores were 7% A0, 37% A1, 30% A2, and 25% A3. Of this cohort, 73 (24%) with BL classification by investigator assessment had cirrhosis; 56% (10/18) F4 vs 22% (63/290) $\leq$F3 (30 pts missing status). At BL, LSM had good diagnostic accuracy (AUROC) for detecting cirrhosis (F4; 0.82 [95% CI 0.69–0.94]), similar to FIB-4 and higher vs APRI (**Table**); for advanced fibrosis ($\geq$F3), LSM, FIB-4, and APRI AUROCs were 0.72, 0.67, and 0.63, respectively. For diagnosing cirrhosis at BL, an LSM cutoff of $\geq$15.2 kPa had 56% sensitivity and 84% specificity (positive predictive value [PPV] 18%, negative PV [NPV] 97%). For excluding advanced fibrosis at BL, a <10.2 kPa LSM cutoff had 57% sensitivity and 72% specificity (PPV 86%, NPV 35%). In the on/post-Tx group, fibrosis stages (n=166) were 52% F0–F1, 34% F2, 13% F3, and 1% F4; HAI scores (n=167) were 23% A0, 46% A1, 21% A2, and 10% A3. The LSM AUROC of 0.74 for advanced fibrosis was similar to BL but had a wide CI. A <10.2 kPa LSM cutoff had similar specificity for excluding advanced fibrosis in the on/post-Tx group (LSM cirrhosis cutoff not evaluated due to limited pts). **Conclusion:** In pts with CHD, LSM identified advanced fibrosis and cirrhosis at BL and on/post BLV Tx with good diagnostic specificity. A limitation is that a mixed on/post-BLV cohort was used for Tx status and type (with or without PegIFN). Interestingly, the LSM cutoff to exclude advanced fibrosis on/post-Tx had similar specificity to that seen at BL, despite the reduction in necroinflammation seen with BLV.

Table. Diagnostic Performance of LSM, FIB-4, and APRI for Advanced Fibrosis and Cirrhosis at Baseline, on BLV Treatment, and Post BLV Treatment

Liver Fibrosis Stage	Time Point	NIT	Events, n/N (%)	AUROC (95% CI)	LSM Cutoff, kPa	Sensitivity, %	Specificity, %	PPV, %	NPV, %
Advanced fibrosis (≥F3)	Baseline	LSM	64/263 (24)	0.72 (0.64–0.79)	<10.2	57	72	66	35
		FIB-4	65/279 (23)	0.67 (0.59–0.75)	—	—	—	—	—
		APRI	65/279 (23)	0.63 (0.55–0.71)	—	—	—	—	—
	On/post BLV treatment	LSM	18/143 (13)	0.74 (0.61–0.87)	<10.2	72	72	95	27
		FIB-4	23/165 (14)	0.73 (0.60–0.85)	—	—	—	—	—
		APRI	23/165 (14)	0.65 (0.53–0.77)	—	—	—	—	—
Cirrhosis (F4)	Baseline	LSM	10/283 (6)	0.82 (0.69–0.94)	≥15.2	56	84	18	97
		FIB-4	15/279 (5)	0.82 (0.70–0.95)	—	—	—	—	—
		APRI	15/279 (5)	0.76 (0.62–0.90)	—	—	—	—	—

The AUROC was estimated using a logistic regression model of METAVIR stages of liver fibrosis (evaluated at thresholds of ≥F3 and F4) by LSM, FIB-4, and APRI. Patients with LSM/laboratory data and biopsy dates more than 90 days apart were excluded from analysis. An LSM cutoff of <10.2 kPa was used to exclude advanced fibrosis (≥F3). An LSM cutoff of ≥15.2 kPa was used for diagnosis of cirrhosis (F4).
APRI, aspartate aminotransferase to platelet ratio index; AUROC, area under the receiver operating characteristic curve; BLV, bulevirtide; FIB-4, Fibrosis-4; LSM, liver stiffness measurement; NIT, noninvasive test; NPV, negative predictive value; PPV, positive predictive value.

3237 | LOW ADHERENCE TO GUIDELINE-RECOMMENDED HDV-RNA RETESTING IN ANTI-HDV POSITIVE INDIVIDUALS: A MULTICENTER REAL-WORLD STUDY FROM CATALONIA

Ariadna Rando-Segura[1] Adriana Palom[1] Laura Calatayud-Samper[2] Gema Fernández-Rivas[3] Alicia Sellés-Sanchez[4] Saray Mormeneo-Bayo[5] Dúnia Pérez del Campo[6] Eva del Corral[7] Tomàs Balari Balari[2] Rosa Maria Morillas[3] Adrià Rodríguez-Castellano[4] Patricia Huelin[5] Carmen López[6] Darly Salazar[7] Joana Villaverde[8] Indiana Abdo[9] José Castellote[2] Joan Carles Quer[4] Carlos Aracil Blanch[6] Andrés Marco[9] Maria Buti[1], [1]Hospital Universitari Vall d'Hebron, [2]Hospital Universitari De Bellvitge, [3]Hospital Universitari Germans Trias I Pujol, [4]Hospital Universitari Joan XXIII De Tarragona, [5]Hospital Universitari Arnau De Vilanova, [6]Hospital Universitari Doctor Josep Trueta, [7]Hospital Universitari Verge De La Cinta, [8]Hospital de Viladecans, [9]Penitentiary Health Program, Catalan Institute of Health

Background: Hepatitis D virus (HDV) infection is associated with accelerated liver disease progression. Current EASL guidelines recommend repeat HDV-RNA testing in anti-HDV positive individuals with initially undetectable viremia because viral replication may fluctuate over time. However, real-world data on implementation and yield of this strategy remain limited. We aimed to evaluate the rate of HDV-RNA positivity upon repeat testing in anti-HDV positive individuals with initially undetectable HDV-RNA. **Methods:** OPTI-HEP-D is a prospective intervention study implementing universal anti-HDV reflex testing in all HBsAg-positive individuals across seven hospital centers covering > 95% of the adult population in Catalonia, Spain. Anti-HDV positive individuals with initially undetectable HDV-RNA who underwent repeat testing during follow-up were included in this analysis. Timing of repeat testing was not protocolised and performed opportunistically at the discretion of treating physicians or triggered by laboratory follow-up processes cohort. **Results:** Among 107 newly identified anti-HDV positive individuals with initially undetectable HDV-RNA, 28 (26.2%) underwent repeat HDV-RNA testing during follow-up. Median time to retesting was 5.3 months (range, 0.2–15.7 months). One patient (3.6%) had detectable HDV-RNA upon retesting, identifying an active infection that would have been missed on initial assessment. **Conclusion:** Although EASL guidelines recommend repeat HDV-RNA testing at 3–6 month intervals, implementation in real-world clinical practice remains limited, with only one quarter of eligible patients undergoing repeat testing and heterogeneous follow-up timing. These findings highlight gaps in the cascade of care beyond initial reflex screening. Despite these limitations, repeat testing identified one additional case of active HDV infection that would have been missed on initial assessment.

3238 | LIVER INJURY IS ASSOCIATED WITH LONG-TERM MORTALITY IN PATIENTS WITH COVID-19 – A 6-YEAR ANALYSIS

Grace Wong[1] Vincent Wong[1] Jimmy Che-To Lai[1] Grace Lui[1] Terry Cheuk-Fung Yip[1], [1]The Chinese University of Hong Kong

Background: We previously demonstrated the impact of liver injury on short-term adverse clinical outcomes, including intensive care unit (ICU) admission, use of invasive mechanical ventilation and/or death, in patients with COVID-19. We aimed to evaluate the 6-year outcome of patients with liver injury during COVID-19. **Methods:** This was a real-world cohort study with data retrospectively collected in May 2020, followed by long-term prospective follow-up from May 2020 to May 2026 of patients with COVID-19 recruited in 2020 during the early days of the pandemic. Liver injury was defined as elevation of plasma alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) to $\geq 2 \times$ upper limit of normal (i.e., 80 U/L). The primary endpoint was all-cause mortality. **Results:** Among the 1,040 patients with COVID-19 (mean age 38 years, 54% men, 4.1% chronic hepatitis B, 0.3% chronic hepatitis C), liver injury occurred in 192 (18.5%) patients, which was comparable in patients with and without chronic hepatitis B or C. Seventeen patients died during a median (interquartile range) follow-up of 74.2 (73.7-74.6) months. Four patients died during the acute episode of COVID-19, another four patients died within the first six months, and the remaining nine patients died from 21 to 68 months after COVID-19. The 6-year mortality rate was higher in patients with liver injury during COVID-19 (4.7% vs. 0.9%, $p < 0.001$ by log-rank test; Figure 1). Liver injury remained the independent risk factor of all cause-mortality after adjusted for older age, presence of diabetes mellitus, low platelet and albumin, and high creatinine. **Conclusion:** Liver injury is associated with higher risk of all-cause mortality in patients with COVID-19; the excess risk concentrated in the early post-COVID period within the first six months. Whereas the absolute long-term mortality remains low. The impact of liver injury is the greatest in short term. Further evaluation to understand the factors contributing to these deaths would provide important information to mitigate the mortality in the post-COVID-19 era.

3239 | OCULAR HSV-1 INFECTION DRIVES HEPATIC SYMPATHETIC NEUROPATHY RESULTING IN THE DISRUPTION OF ENERGY METABOLISM HOMEOSTASIS IN THE LIVER

Jonathan Toriumi[1] Hemant Borase[1] Ipsita Volety[1] Chandrashekhar Patil[1] Deepak Shukla[1], [1]University of Illinois Chicago

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Herpes Simplex Virus Type 1 (HSV-1) is a DNA virus in the human Herpesviridae family. As of 2025, 3.8 billion individuals under age 50 are seropositive worldwide. Mucosal tissues like the cornea are common infection sites and can result in Herpes simplex keratitis (HSK). As a neurotropic virus, its role in the central nervous system (CNS) has been widely studied in the context of herpes simplex encephalitis, but its impact on the sympathetic nervous system is less defined. Metabolic stress drives sympathetic dysregulation in the liver, and ocular HSV-1 infection significantly alters host metabolism. We hypothesized that ocular infection disrupts catecholaminergic signaling and alters hepatic homeostasis. **Methods:** Wildtype (WT) C57/BL6 Mice were ocularly infected with the neurovirulent McKrae HSV-1 strain with a titer of 10^6 PFU via corneal scarification. Mice were then sacrificed at 4, 8 and 18 days post infection (dpi) and the livers were collected. Eye washes were collected on 1, 2, and 4dpi to quantify HSV-1 replication using plaque assays and animal body weights are measured throughout the duration of infection. Protein expression and transcript levels were measured through western blot and RT-qPCR respectively. Liver pathology was scored blindly using immunohistochemistry. Data was analyzed by one-way ANOVA and t-test. **Results:** We found that key sympathetic markers like Tyrosine Hydroxylase (TH), Dopa decarboxylase (DDC), and Dopamine B-hydroxylase (DBH) showed significant reduction in protein expression at 4, 8, and 18dpi. To measure hepatic neuropathy, we measured PGP9.5 levels and found a significant loss of expression at 18dpi. To understand the downstream effects of the loss of sympathetic nerve markers, we measured the expression of key glycogen homeostasis markers; Glycogen synthase 2 (GYS2) and Liver glycogen phosphorylase (PYGL) and found that both were significantly reduced at all three 3 timepoints. With glycogen input and output both being halted, we wanted to see if there was an energy switch towards fatty acid oxidation. We measured Carnitine palmitoyltransferase 1a (CPT1a), the rate limiting enzyme for fatty acid oxidation and found that expression levels at 4 and 8dpi were downregulated. With both glycogen homeostasis and fatty acid oxidation being significantly inhibited, we wanted to measure PGC-1a, which is the master regulator of energy metabolism and beta-oxidation and lies downstream of this pathway. We found that PGC-1a is significantly reduced at 4, 8 and 18dpi. **Conclusion:** Overall, our findings show that ocular HSV-1 infection is able to induce sympathetic neuropathy in the liver at 18dpi which may be due to acute metabolic stress. This leads to the inhibition of catecholaminergic signaling, resulting in the disruption of glycogen and fatty acid oxidation homeostasis due to the loss of PGC-1a expression.

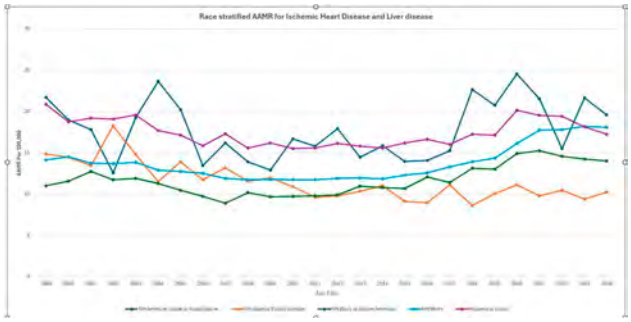
3240 | TEMPORAL TRENDS & DEMOGRAPHIC DISPARITIES IN LIVER DISEASE & ISCHEMIC HEART DISEASE MORTALITY AMONG OLDER ADULTS IN THE UNITED STATES, 1999–2024



Manish KC[1] Sujata Lamichhane[1] Sae-Jong Oum[1] Anam Farrukh[1] Neha Singh[1], [1]North Alabama Medical Center

Background: This study analyzes the temporal trends in sex & race-stratified age-adjusted mortality rates (AAMR) for concurrent liver disease & IHD among the aging population in the US over the period of 25 years (1999-2024). **Methods:** We performed a retrospective national level mortality analysis with the help of CDC WONDER cause of Death Database from 1999-2024 among patients aged 65-85 & above for IHD (I20–I25) & Liver Disease (B15–B19, C22, K70–K76). Data were stratified by Race, sex & age groups. We calculated AAMR per 100,000 population based on the 2000 US standard population. Temporal trends were assessed using Joinpoint regression to calculate annual percent change (APC), with statistical significance defined by $p < 0.05$. **Results:** AAMR with liver & IHD showed marked temporal fluctuation in all groups (1999-2024). In females AAMR decreased from 1999-2013 (APC = -2.45%, $p < 0.05$), showed non-significant increase in 2013-2018 (APC = 2.23%), rapid rise in 2018-2021 (APC = 9.93%, $p < 0.05$) & plateau in 2021-2024 (APC = -0.39%). In males, AAMRs decreased during 1999-2008 (APC = -2.59%, $p < 0.05$), remained stable in 2008-2016 (APC = 0.95%) & increased during 2016-2021(APC = 6.65%, $p < 0.05$) & plateau thereafter (APC = 0.79%).By race, Non-Hispanic [NH] whites decreased during 1999-2009 (APC = -2.17%, $p < 0.05$), increased during 2014-2018 (APC = 3.36%, $p < 0.05$) & 2018-2021 (APC = 9.05%, $p < 0.05$), and ultimately reached stabilization from 2021-2024 (APC = 1.06%). AAMRs for NH Blacks decreased from 2001-2007 (APC = -5.02%, $p < 0.05$), increased from 2015-2021 (APC = 5.75%, $p < 0.05$) with a subsequent plateau from 2021-2024 (APC = -2.91%). Hispanics decreased during 1999-2009 (APC = -2.61%, $p < 0.05$) increased from 2017-2021 (APC = 5.56%, $p < 0.05$) & decreased in 2021 to 2024 (APC = -4.92%, $p < 0.05$). NH American Indian/Alaska Native populations showed a non-significant decline from 1999-2009 (APC = -3.31%) followed by increase during 2009-2024 (APC = 2.56%, $p < 0.05$). Asian/Pacific Islanders

decreased till 2020 (APC = -2.18%, p < 0.05) & later stabilized from 2021-2024 (APC = 0.34%). **Conclusion:** After ten years of improving death rate, deaths from comorbid liver disease and ischemic heart disease among older US individuals have been on the rise over the last decade, with a prominent rise during 2018-2021 across all demographic groups. For Hispanic populations, mortality rates have stabilised or are trending downward, while NH American Indian or Alaskan Native populations face an ongoing rise in mortality from 2009-2024. These findings present a concerning setback in health progress and highlight growing disparities between different populations.

3241 | FROM USABILITY TO UPTAKE: REAL-WORLD EXPERIENCE WITH A DIGITAL HEALTH TOOL IN CHRONIC HEPATITIS D

Judit Romero[1] Belen Duarte[2] Elena Vargas-Accarino[3] Adriana Palom[3] Nuria Fabrellas[4] Maria Buti[5], [1]Vall Hebron Research Institute, [2]Departament de Medicina, Universitat Autònoma de Barcelona, [3]Vall D'hebron Research Institute, [4]Departament d'Infermeria i Salut, Universitat de Barcelona, [5]Hospital Universitario Vall d'Hebron

Background: Hepatitis D virus (HDV) is the most severe form of chronic viral hepatitis and is associated with rapid progression to cirrhosis and increased risk of hepatocellular carcinoma. Digital health tools may support long-term follow-up and patient engagement in this complex condition. We aimed to evaluate the usability, user experience, and perceived usefulness of the NORA mobile application in patients with chronic HDV infection, and to identify barriers to non-use. **Methods:** We conducted a cross-sectional observational study in patients with chronic hepatitis D. Participants were classified as users and non-users of the NORA app (1). The application provided a secure chat for communication with healthcare staff, quality of life and knowledge questionnaires, and medication reminders. Usability and user experience were assessed using the Mobile App Usability Questionnaire (MAUQ). Sociodemographic, clinical, and app-related variables were collected.(1) Romero-Vico J, Feliu A, Vargas-Accarino E, Sánchez-Gavilán E, Ribó M, Palom A, Ruiz-Cobo JC, Riveiro M, Fabrellas N, Buti M. Enhancing Chronic Hepatitis B and D Management Through a Tailored Mobile Health Application: Real-World Outcomes From the Adaptation of the NORA App. J Viral Hepat. 2026 Apr;33(4):e70160. **Results:** Fifty-two patients were included: 19 users and 33 non-users (22 newly enrolled). Overall usability was high (MAUQ 5.07 ± 1.43). Quality-of-life monitoring and educational modules were the most used features, while biometric tracking showed low engagement. Patients prioritized expanded educational content (57.9%), improved data visualization (31.6%), and better communication with clinicians (21.1%). Lack of motivation was the leading barrier to adoption among non-users (72.7%). Perceived usefulness exceeded actual use across most functions, indicating a clear engagement gap. App uptake was higher in patients with detectable HDV RNA and recent diagnosis, suggesting greater engagement in those perceiving higher disease burden. **Conclusion:** NORA was well accepted among patients with chronic hepatitis D and may represent a useful tool for patient monitoring.. Engagement was driven by perceived need; motivation was the main barrier. These findings highlight that successful digital health implementation in HDV requires not only technical design but also behavioural and educational strategies. Tailoring content, strengthening clinician–patient communication, and aligning app functions with patient-perceived need may substantially improve engagement and long-term utility in real-world care.

3242 | INCONSISTENT HDV-1 SUBGENOTYPE CLASSIFICATION LIMITS EPIDEMIOLOGICAL COMPARABILITY

Ana Alberola[1] Lorenzo Piermatteo[2] Adolfo de Salazar[1] Romina Salpini[2] María José Pena[3] Stefano D'anna[2] Antonio Aguilera[4] Alessia Magnapera[2] Jorge García García[5] Lavinia Fabeni[6] María Asunción Iborra[7] Francesca Ceccherini-Silberstein[8] Valentina Svicher[2] Federico Garcia[9], [1]Hospital Universitario Clínico San Cecilio, Instituto de Investigación Ibs.Granada, CIBERINFEC, [2]Department of Biology, University of Rome "Tor Vergata", Rome, Italy, [3]Hospital Universitario de Gran Canaria Dr. Negrín, [4]Complexo Hospitalario Universitario de Santiago de Compostela, [5]Hospital Universitario Clínico San Cecilio, Instituto de Investigación Ibs.Granada, [6]National Institute for Infectious Diseases Lazzaro Spallanzani-IRCCS, [7]Hospital Clínico Universitario Virgen de la Arrixaca, [8]Department of Experimental Medicine, University of Rome "Tor Vergata", Rome, Italy, [9]Hospital Universitario Clínico San Cecilio

Background: Hepatitis delta virus (HDV) genotype assignment is well established; however, HDV-1 subgenotype classification remains inconsistent across phylogenetic frameworks. Different reference sequence sets and clustering criteria generate non-equivalent subtype definitions, limiting comparability between studies and potentially affecting epidemiological interpretation and genotype–phenotype analyses. We therefore evaluated the level of agreement between two published HDV-1 subgenotype classification systems and assessed how reference selection influences subgenotype assignment in clinical isolates. **Methods:** A comparative phylogenetic analysis was performed using 357 near full-length HDV genome sequences obtained from individuals with detectable HDV-RNA. Sequences were aligned using MAFFT v7 and phylogenetic trees were generated in MEGA v6 using the Neighbor-Joining method under the Tamura 92 + gamma model with 1,000 bootstrap replicates. Subgenotype assignment was independently performed according to the reference frameworks proposed by Le Gal et al. (HDV-1a–1d) and Karimzadeh et al. (HDV-1a–1e). Potential recombination events were screened using sliding-window similarity analysis and will be further validated using RDP. **Results:** Genotype-level classification showed complete concordance across both systems. HDV genotype 1 predominated (329/357, 92.2%), followed by genotype 5 (23/357, 6.4%), while genotypes 3, 6 and 7 were infrequent. Among genotype 5 isolates, subgenotypes 5a (n = 7) and 5b (n = 16) were identified. Thirty potential HDV-1 recombinant strains were initially detected.After excluding putative recombinant sequences, 299 genotype 1 isolates were retained for subtype comparison. Marked discrepancies were observed between classification systems. Only 10/299 sequences (3.3%) showed concordant subtype assignment using both frameworks. Using the Le Gal classification, subgenotype 1d predominated (245/299, 81.9%), whereas 1a, 1b and 1c accounted for smaller proportions (8%, 6.4% and 3.7%, respectively). When the Karimzadeh references were applied, the distribution shifted markedly: subgenotype 1e became predominant (172/299, 57.5%), followed by 1c (90/299, 30.1%), while 1a, 1b and 1d were infrequent (5.7%, 6.4% and 0.3%, respectively). **Conclusion:** HDV genotype determination appears robust across classification systems; however, HDV-1 subgenotype assignment is highly dependent on the selected phylogenetic references. These findings highlight the need for a harmonized consensus-based classification framework to improve epidemiological comparability and support future clinical and translational HDV research.

University of Milan, Italy, [3]University of Milan, Italy; Foundation IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [4]University of Barcelona, IDIBAPS, Barcelona, Spain; Instituto de Salud Carlos III, Madrid, Spain, [5]Hannover Medical School, Hannover, Germany, [6]Gilead Sciences, Inc., Foster City, CA, USA

Background: Patients (pts) with chronic hepatitis delta (CHD) often show rapid fibrosis progression and may develop clinically significant portal hypertension (CSPH), which increases the risk of liver-related events. Models based on liver stiffness measurement (LSM) and platelet count (PLT) enable noninvasive CSPH assessment in pts with CHD. Bulevirtide (BLV) is approved in the US, EU, and other countries for CHD. This analysis evaluated CSPH prevalence and impact of BLV monotherapy on noninvasive CSPH criteria in pts with CHD. **Methods:** LSM and PLT data at BL and week (W) 48 of pts with CHD treated with BLV 10 or 2 mg monotherapy in the MYR301 (NCT03852719), MYR204 (NCT03852433) and MYR203 (NCT02888106) studies were analyzed. Outcomes were compared to pts with delayed treatment (control) for 48W in MYR301. CSPH risk was assessed using Baveno-VII (LSM/PLT) criteria: rule-out (LSM $\leq$15 kPa + PLT $\geq$150 109/L), rule-in (LSM >25kPa), and gray zone (GZ; all other pts, including probable CSPH [probCSPH]: LSM >20 to $\leq$25 kPa + PLT <150 109/L or LSM >15 to $\leq$20 kPa + PLT <110 109/L). The ANTICIPATE model (reflecting CSPH risk [%]) was calculated based on LSM and PLT, with $\geq$75% and <60% indicating high and low CSPH risk, respectively. **Results:** At BL, of 206 BLV pts, 51.5% (n=106) and 10.7% (22) met Baveno-VII CSPH rule-out and rule-in criteria, respectively, while 37.9% (78) were in GZ (including 7.3% [15] with probCSPH) (Table). By ANTICIPATE, 13.6% (28/206) were $\geq$75%, 3.9% (8/206) were $\geq$60% to <75%, and 82.5% (170/206) were <60% CSPH risk at BL. Distribution was similar for control pts (n=45). At W48, 59.1% (13/22) of BLV pts with Baveno-VII rule-in criteria improved to GZ or rule-out vs 25.0% (1/4) of control pts. Of the 13 improving BLV pts, 69.2% (n=9) had virologic response (VR; $\geq$2 log10 IU/mL decline in HDV RNA or undetectable), 46.2% (6) had alanine aminotransferase (ALT) normalization and 30.8% (4) had a combined response (CR; VR+ALT normalization) at W48. Of 28 BLV pts with BL ANTICIPATE $\geq$75%, 18 (64.3%) improved to <75% at W48; of these 18 pts, 66.7% (n=12) had VR, 44.4% (8) had ALT normalization, and 33.3% (6) had CR at W48. Of 8 BLV pts with BL ANTICIPATE $\geq$60% to <75%, 75.0% (6) improved to <60% at W48.Overall, for BLV pts, 41.0% (41/100) without rule-out CSPH at BL improved in CSPH category by Baveno-VII vs 23.1% (6/26) of control pts; 66.7% (24/36) of BLV pts without <60% ANTICIPATE risk at BL had improvement in ANTICIPATE vs 45.5% (5/11) of control pts. Worsening of CSPH category in pts without rule-in CSPH or $\geq$75% ANTICIPATE risk at BL occurred in 8.2% (15/184) and 2.8% (5/178) for BLV pts vs 14.6% (6/41) and 7.9% (3/38) for control pts. **Conclusion:** BLV may improve or prevent progression of CSPH in select pts with CHD, even in those without VR or ALT normalization; pts receiving BLV were over twice as likely to improve from rule-in CSPH at BL to GZ or rule-out by Baveno-VII criteria by W48 vs control. Results were consistent across CSPH diagnostic models.

Table. Changes in Clinically Significant Portal Hypertension Risk Characteristics With Bulevirtide Treatment

	Control		Bulevirtide 2 mg and 10 mg	
n (%)	Baseline (N=45)	Week 48 (N=45)	Baseline (N=206)	Week 48 (N=206)
Baveno-VII criteria[a]				
Rule-in CSPH	4 (9)	5 (11)	22 (11)	9 (4)
Gray zone	22 (49)	22 (49)	78 (38)	77 (37)
Gray zone – probable CSPH	7 (16)	4 (9)	15 (7)	18 (9)
Rule-out CSPH	19 (42)	18 (40)	106 (51)	120 (58)
ANTICIPATE CSPH (%) ≥75%[b]	7 (16)	6 (13)	28 (14)	13 (6)
ANTICIPATE CSPH (%) ≥60 to <75%[b]	4 (9)	2 (4)	8 (4)	11 (5)
ANTICIPATE CSPH (%) <60%[b]	34 (76)	37 (82)	170 (83)	182 (88)

Patients with detectable baseline HDV RNA, and LS and PLT values at baseline and week 48 were included in the analysis.

[a] Baveno-VII (LSM/PLT) criteria: rule-out (LSM ≤15kPa plus PLT ≥150 10^9/L), rule-in (LSM >25kPa), gray zone (all other pts) with probable CSPH (LSM >20 to ≤25 kPa + PLT <150 10^9/L *or* LSM >15 to ≤20 kPa + PLT <110 10^9/L).

[b] ANTICIPATE model (Abraldes JG, et al, 2016): Logit = −6.3320165 + 3.1001014 × ln(LSM) − 0.0204815 45 × PLT (PLT >150 set to 150). ANTICIPATE-predicted CSPH probability (%) = 1 / (1 + exp(−Logit)) × 100. LSM units: kPa. PLT units: 10^9/L. ANTICIPATE ≥75% indicates high-risk of CSPH, ≥60% to <75% is intermediate risk of CSPH, and <60% indicates low risk of CSPH.

CSPH, clinically significant portal hypertension; HDV, hepatitis delta virus; LSM, liver stiffness measurement; PLT, platelets.

3244 | HEPATITIS D VIRUS SCREENING AND TESTING AT A COMMUNITY HEALTH CENTER IN THE SAN FRANCISCO BAY AREA

Morgan Manter[1] Zinnia Dong[1] Amy Tang[1], [1]North East Medical Services

Background: Hepatitis D virus (HDV) infection causes severe liver disease and occurs in 1-5% of individuals with hepatitis B virus (HBV) infection. Federally-funded community health centers (CHCs) provide care for many vulnerable patients with chronic HBV infection, yet HBV and HDV care in these settings remains understudied. North East Medical Services (NEMS) is a CHC in the San Francisco Bay Area serving a large Asian immigrant population and uses an electronic health record (EHR)-based HBV registry with a universal HDV screening prompt for all patients with chronic HBV. We aimed to describe the demographic and clinical care characteristics of patients receiving primary care-based HDV screening at NEMS. **Methods:** We conducted a retrospective analysis of HBV registry patients with at least one primary care medical visit at NEMS between 10/3/2023 and 4/14/2026 and their HDV testing status. Demographic and clinical data were extracted from NEMS' EHR-based HBV registry report, including HDV antibody total (HDV Ab) and HDV RNA testing. **Results:** Of the 3,544 HBV registry patients who met study criteria, 59% (2,086/3,544) were screened for HDV Ab, with 1.6% (34/2,086) HDV Ab test positivity. Of the 34 HDV Ab+ patients, 76% (26/34) had follow-up HDV RNA testing, with 19% (5/26) HDV RNA detected. Of the 5 total patients diagnosed with active HDV co-infection based on detectable HDV RNA, all were male with a median age of 49 (range: 40-61) and were born in China (60%, 3/5) or Mongolia (40%, 2/5), 80% (4/5) were on antiviral treatment, and 60% (3/5) had a cirrhosis diagnosis. **Conclusion:** At this large CHC, we found HDV testing was completed in over 2,000 patients with chronic HBV. This finding suggests that implementation of universal HDV screening prompt in the EHR for patients with chronic HBV patients can improve HBV and HDV care delivery in the primary care setting. Further expansion of HDV testing among patients with HBV would allow for more timely diagnosis and treatment of liver complications associated with HBV-HDV coinfection.

Table 1. Demographics of NEMS HBV Registry Patients with HDV Screening

Characteristic	HDV Ab Negative N = 2,052 n (column%)	HDV Ab Positive and HDV RNA Negative or Unknown N = 29 n (column%)	HDV Ab Positive and HDV RNA Positive N = 5 n (column%)	Total N=2,086

3245 | ACUTE LIVER FAILURE FROM DISSEMINATED HSV-2 IN AN IMMUNOCOMPETENT PATIENT: THE DIAGNOSTIC VALUE OF MUCOCUTANEOUS LESIONS

Keeranmayee Mishra[1] Chirag Doshi[2] Apurba Mishra[3] Geetha Krishnamoorthy[1] Mihaela Batke[1], [1]Trinity Health Oakland/Wayne State University, [2]Banas

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Medical College, Gujarat, India, [3]Nootan Medical College, Gujarat, India.

Background: Herpes simplex virus (HSV) hepatitis is an exceedingly rare but often fatal cause of acute liver failure (ALF), representing less than 1% of ALF cases. Mortality remains as high as nearly 90 % due to delayed recognition, as presentation is frequently anicteric with disproportionate aminotransferase elevation. Although classically associated with pregnancy and immunosuppression, disseminated HSV infection can occur in immunocompetent patients and should not be excluded based on immune status alone. Early diagnosis is essential, as prompt antiviral therapy can be life-saving. **Methods:** A 43-year-old immunocompetent man with type 2 diabetes and recent thoracolumbar surgery for an epidural abscess presented with fever, chills, and right upper-quadrant pain. Initial labs revealed severe hepatocellular injury with AST and ALT exceeding 5,000 IU/L, while total bilirubin and INR were near normal, consistent with anicteric ALF. Mental status progressively declined. He denied alcohol, illicit drugs, high-risk sexual behavior, and hepatotoxic exposures. Serologies for hepatitis A, B, C, and E were negative. Autoimmune markers were unremarkable. Abdominal ultrasound demonstrated diffuse hepatic hypoechogenicity with patent vasculature consistent with acute hepatic injury.As encephalopathy worsened with ammonia >100 µmol/L and MELD-Na of 26, N-acetylcysteine and lactulose were initiated and transplant referral was pursued. Careful examination revealed painful oral ulcerations involving the lips, buccal mucosa, and tongue, and healed vesicular lesions on the right index finger consistent with herpetic whitlow. Mucocutaneous swabs and serum HSV PCR both returned positive for HSV-2 DNA, confirming disseminated infection. Intravenous acyclovir was started promptly. Liver enzymes declined dramatically within 48 hours. On hospital day four, stage 3 acute kidney injury developed (creatinine rising from 1.19 to 3.30 mg/dL), attributed to acyclovir crystal nephropathy compounded by vancomycin tubular toxicity. Vancomycin was replaced with daptomycin, and aggressive hydration was administered. Renal function recovered, encephalopathy resolved, and liver enzymes normalized prior to discharge. **Results:** Covered in methods section. **Conclusion:** Disseminated HSV must be considered in any patient with severe anicteric acute liver failure, regardless of immune status. A meticulous skin and mucosal examination may reveal subtle but decisive diagnostic clues, allowing early diagnosis without invasive liver biopsy. Serum HSV PCR is a rapid test that confirms viremia and supports the diagnosis of disseminated disease. Early empiric acyclovir with renal monitoring can ensure recovery of both hepatic and renal function.

3246 | RISK FACTORS FOR LIVER FAILURE IN PATIENTS WITH HEPATITIS E VIRUS INFECTION: A SYSTEMATIC REVIEW AND NARRATIVE SYNTHESIS

Shuiweizhi Dai[1] Chengxuan Yao[1] Huaibin Zou[1], [1]Fourth Department of Liver Disease, Beijing You'an Hospital, Capital Medical University

Background: Hepatitis E virus (HEV) infection is an important etiology of liver failure, but risk factors for liver failure among patients with acute hepatitis E remain inconsistently reported. This study aimed to identify candidate risk factors and assess whether quantitative synthesis was appropriate. **Methods:** PubMed, Web of Science, Embase, the Cochrane Library, CNKI, and WanFang databases were systematically searched from database inception to May 17, 2026. Studies were eligible if they included HEV-infected patients, reported liver failure or severe hepatitis, and compared patients with and without liver failure. Study characteristics, definitions of liver failure, adjusted effect estimates, candidate risk factors, and study quality assessed using the Newcastle-Ottawa Scale were extracted. Variables overlapping with liver failure definitions, including bilirubin, INR, hepatic encephalopathy, and ascites, were not considered antecedent risk factors. Meta-analysis was considered only when comparable adjusted estimates were reported for the same factor and outcome. **Results:** Out of 5206 records identified, 12 studies met inclusion criteria and were included in the review. Six evaluated liver failure, ALF, or ACLF; three evaluated severe hepatitis; and three focused on biomarker or prediction profiles. Most studies were retrospective and hospital-based, with substantial variation in outcome definitions, exposure cutoffs, covariate adjustment, and effect measures. In studies with stricter liver failure definitions, older age (adjusted odds ratios [aORs] 2.08-2.50), HBV-related status including HBsAg positive or HBV coinfection (aORs 3.70-5.62), and cirrhosis (aORs 2.10-6.05) were repeatedly reported as independent risk factors. Thrombocytopenia was associated with liver failure in one large cohort (aOR 5.90). Other predictors included respiratory infection, hydrothorax, neutrophil-to-lymphocyte-related indices, lipid profiles, and fibrosis markers. However, these were generally single-study findings or prediction-marker studies and were not suitable for primary pooling. Because no factor was supported by at least three directly comparable adjusted estimates, a formal primary meta-analysis was not performed. **Conclusion:** Older age, HBV-related

infection status, and cirrhosis were repeatedly reported as candidate risk factors, while thrombocytopenia was identified in one large cohort. Heterogeneity in liver failure definitions, exposure definitions, and adjustment strategies limits quantitative synthesis. Standardized prospective studies are needed to clarify independent risk factors of HEV-related liver failure.

3247 | SERIAL ORAL CHOLATE CHALLENGE (HEPQUANT DUO®) TESTING ENHANCES PREDICTION OF CLINICAL OUTCOME IN COMPENSATED CHRONIC LIVER DISEASE

Mitchell Shiffman[1] Michael McRae[2] Joanne Imperial[3] Gregory Everson[4], [1]Bon Secours Mercy Health, [2]Custom DX Solutions LLC, [3]HepQuant LLC, [4]HepQuant

Background: Identifying patients with compensated advanced chronic liver disease at risk for decompensation remains a central clinical goal. In the HALT-C quantitative liver function ancillary study (hepatitis C), 215 subjects with advanced fibrosis (n = 124) or compensated cirrhosis (n = 91) had serial Disease Severity Index (DSI) assessments by the oral cholate challenge test (OCCT) and were followed for up to 7.9 years (Everson et al. 2012). We evaluated whether repeated DSI measurements added prognostic value beyond baseline assessment alone. **Methods:** The OCCT was performed at baseline and approximately 2 years and 4 years. The composite outcome included liver-related death, Child-Pugh progression, variceal hemorrhage, ascites, and/or encephalopathy. Subject-level 5-fold cross-validated landmark Cox models with a fixed 2-year prediction horizon were fit for each visit (baseline, 2-year, and 4-year) using DSI as the only predictor. At each visit, three models were compared: (1) baseline DSI, (2) most recent DSI, and (3) serial DSI (DSI values from current visit and the previous visit). Model performance was assessed by cross-validated AUROC, Brier score, and calibration intercept and slope. A fixed 4-year prediction horizon was additionally evaluated and compared to the 2-year prediction results. **Results:** The cohort had mean age 50 ± 7 years, 75% were male, and 50 of 215 subjects experienced a clinical progression event during overall follow-up. At baseline, 215 subjects were available with 23 events observed within the subsequent 2 years. The baseline model had an AUC of 0.79, Brier score of 0.08, calibration intercept of -0.17, and calibration slope of 0.90. At 2 years, 160 subjects were available with 11 events observed within the subsequent 2 years. The updated model improved discrimination compared with the baseline-only model (AUC 0.91 vs 0.84), reduced prediction error (Brier 0.05 vs 0.06), and improved calibration (intercept -0.11 vs -0.59; slope 0.93 vs 0.73). At 4 years, 108 subjects were available with 10 events observed within the subsequent 2 years. The updated model again outperformed the baseline-only model (AUC 0.81 vs 0.61; Brier score 0.095 vs 0.102; calibration intercept -0.54 vs -1.50; slope 0.72 vs 0.30). When the period of follow-up was extended to 4 years, although more outcomes were encompassed, the prognostic performance decreased (AUC range 0.82-0.91 for 2-year horizon versus 0.79-0.82 for 4-year horizon). **Conclusion:** Repeated DSI measurements provided incremental prognostic value beyond baseline assessment, with the largest gain in discrimination observed at later follow-up. These findings support dynamic risk updating with serial liver function testing rather than reliance on a single baseline measurement alone. Based on the comparison of prognosing outcomes over 2 years vs 4 years, the recommended time interval for repeat testing is 2 years.

Comparison of models for predicting 2-year clinical outcomes

	Baseline DSI	Most recent DSI	Serial DSI
AUROC (95% CI)

3248 | HCV CARE CASCADE AFTER IMPLEMENTATION OF POC RNA TESTING IN AN URBAN MOBILE HCV CARE UNIT

Bharathi Selvan[1] Katie Burk[2] Sara Duran[2] Shelley Facente[2] Cecilia Rivas Alfaro[1] May Myat Mon[1] Srilakshmi Seetharaman[1] Yesenia Laguardia[1] Pauli Gray[1] Rosaura Camberos[1] Jennifer Price[1], [1]University of California San Francisco, [2]Facente Consulting

Background: Traditional hepatitis C virus (HCV) testing paradigms are insufficient to overcome the barriers faced by marginalized communities. Point-of-care (POC) RNA testing may improve HCV diagnosis and care linkage by removing need for venipuncture and providing same-day confirmation of viremia. We aimed to evaluate the initial impact of using POC RNA testing on an urban mobile HCV testing and treatment van. **Methods:** The UCSF DeLIVER van is a mobile liver care unit with two outreach shifts per week, offering free HCV screening and on-site treatment via telehealth. Prior to July 2025, all screening was performed using POC HCV antibody tests, followed by on-site venipuncture for laboratory-based confirmatory RNA testing. Starting in July 2025, we offered the Cepheid Xpert HCV POC RNA testing on the mobile van in place of laboratory-based confirmatory testing. Individuals who reported a history of hepatitis C or recent high-risk exposure underwent viral-first RNA testing rather than HCV antibody testing. We compared HCV care cascade data from 8 months pre-(11/2024-6/2025) and post-(7/2025-2/2026) POC RNA implementation. We also interviewed 8 patients using a semi-structured guide to elicit their experience with the POC RNA test. **Results:** HCV testing on the van increased from 378 people pre-implementation to 767 people post-implementation (Figure). Pre-implementation, 142 (38%) had reactive HCV antibody and thus were eligible for RNA testing. Post-implementation, 510 (67%) underwent antibody-first testing and 55 (11%) had reactive HCV antibody. Combined with those triaged to RNA-first testing, 312 individuals were eligible for RNA testing, and 295 RNA tests were completed (96% with Xpert, per patient preference over traditional venipuncture). Pre-implementation, 36 cases of active HCV were identified, and 9 (25%) started treatment. Post-implementation, 86 cases of active HCV were identified, and 20 (23%) started treatment. All interviewees endorsed positive experiences with the POC RNA test, sharing that it felt comfortable, painless, and quick. Participants stated feeling ready to start treatment, even same day, if offered. **Conclusion:** After offering HCV POC RNA on a mobile HCV van, overall screening volume doubled, identification of individuals with HCV viremia increased 2.4-fold, and treatment initiation increased 2.2-fold. However, despite diagnosing more people and using a testing modality preferred over venipuncture, only one-quarter started treatment, similar to pre-implementation. Our findings underscore that improving HCV diagnosis is necessary, but not sufficient, to achieve HCV elimination and that focused efforts are needed to support patients in starting treatment after RNA positivity. Same-day treatment initiation may help overcome barriers and is an acceptable option to patients but will require further investment and resources.

Medical Center, [3]University at Buffalo Jacobs School of Medicine, [4]University of Rochester Medical Center

Background: The World Health Organization (WHO) aims to eliminate hepatitis C virus (HCV) by 2030; however, the United States (US) is unlikely to meet this target. Screening, linkage to care, and treatment initiation rates remain suboptimal, hindering progress toward elimination targets. HCV point-of-care testing has been shown to shorten the time from diagnosis to treatment initiation and increase treatment uptake. The recent FDA approval of the Point-of-Care (POC) HCV RNA test (Xpert® HCV) enables viral-first testing, potentially shortening time to diagnosis and overall treatment uptake, particularly in priority settings such as addiction medicine clinics, incarceration settings, and among unhoused individuals. **Methods:** La Bodega, a co-localized hepatology and addiction medicine program in Buffalo, New York (NY), specializes in HCV management among active People Who Use Drugs (PWUD). HCV medications are kept on the shelf in an on-site pharmacy, facilitating same-day treatment initiation. Between January and December 2025, POC HCV RNA testing was utilized on-site among PWUD being seen for evaluation of substance use disorder. Patients with a positive HCV RNA were initiated on HCV therapy at the time of the initial visit. POC HCV RNA testing was also used in conjunction with lab-based RNA testing on serum to evaluate SVR4 when indicated. **Results:** 100 people were screened with POC HCV RNA testing, of whom 66 had a prior HCV antibody test. 38 had previously received treatment.19 individuals were found to be HCV RNA positive, all of whom were linked to care. Among RNA-positive individuals, 1 was linked to their primary care clinic based on the patient's preference, and 18 initiated therapy and received the full 8- or 12-week course, depending on the chosen regimen. 12 individuals achieved SVR, one of whom was pregnant and treated with sofosbuvir/velpatasvir, and 6 were lost to follow-up. Of the 12 individuals achieving SVR, all had both undetectable serum HCV RNA and negative POC HCV RNA results. There were 11 invalid tests, 7 due to insufficient sample, 2 due to air bubbles, and 2 due to loss of electrical power. **Conclusion:** POC HCV RNA testing is advantageous in shortening the HCV care cascade, resulting in rapid identification and initiation of therapy. POC HCV RNA testing enables a true test-and-treat model of care for HCV, particularly in decentralized settings such as addiction medicine clinics. Data regarding the use of Xpert HCV for SVR assessment is encouraging, and further evaluation is warranted.

3250 | CHARACTERIZATION OF THE CIRCULATING SMALL NON-CODING RNA PROFILE IN PATIENTS WITH CHRONIC HEPATITIS C VIRUS INFECTION BEFORE AND AFTER SUSTAINED VIROLOGICAL RESPONSE TO DIRECT ACTING ANTIVIRAL AGENTS

Samantha Muccilli[1] Jordan Pardoe[1] Amanda Henning[1] Marc Ghany[2] Valeria De Giorgi[1], [1]NIH Clinical Center, [2]NIDDK

Background: Chronic hepatitis C virus (HCV) infection is known to modulate the expression of small non-coding RNAs (sRNAs). These sRNAs are promising noninvasive biomarkers of disease severity and progression. Since the discovery of direct acting antivirals (DAAs), over 12 million people have been cured of HCV. While some studies have examined the expression of miRNAs following DAA treatment, very little is known about how the full sRNA repertoire changes following sustained virological response (SVR). We sought to characterize the sRNA profiles of patients before and longitudinally after DAA treatment to gain new insights into how viral clearance modulates the sRNA repertoire following HCV cure. **Methods:** As part of a large, ongoing prospective clinical study (18DK0091), serum samples were collected from 105 chronic HCV-infected patients prior to DAA treatment, immediately following SVR, and every 48 weeks for up to ten years post-treatment. In this pilot study, we analyzed the longitudinal changes to the sRNA profiles of 34 HCV patients at 8 timepoints (pretreatment, 12-, 36-, 84-, 132-, 180-, 228-, and 276-weeks post-treatment) and compared them to 15 healthy donors using next generation sequencing. **Results:** We characterized the distribution of sRNA species present in each sample. The most highly expressed sRNA class in both HCV patients and healthy donors was miRNAs (60%) followed by piRNAs (7%), miscRNAs (5%), and snoRNAs (4%). Following DAA treatment, the distribution pattern did not significantly change. While the overall expression pattern did not change, initial analyses indicate that some sRNAs were uniquely differentially expressed at each timepoint while others were common among post-treatment timepoints. Indeed, 5 differentially expressed miRNAs were common between 12- and 276-weeks post-treatment and four of those genes (miR-122, miR-205, miR-885, and miR-4662a) have known functions in either HCV

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

infection or immune modulation. Further, there were no differentially expressed snoRNAs at 12-weeks post-treatment but there were 5 differentially expressed snoRNAs at 276-weeks post-treatment. Interestingly, two of the snoRNAs that were downregulated at 276-weeks post-treatment (SNORD15B and SNORD3A) were also downregulated in healthy donors indicating that snoRNA regulation may take longer to equilibrate following SVR. **Conclusion:** In all, our early results indicate that while the overall distribution of sRNAs does not change over time, individual sRNA species can be tracked longitudinally and are differentially regulated at different timepoints post cure. In the future, we hope to correlate these sRNA profiles to the clinical characteristics of our unique cohort to identify biomarkers of complications following SVR and reveal novel insights into the role sRNAs play in recovery from chronic HCV infection.

3251 | REFINING BIDIRECTIONAL DISCORDANCE BETWEEN FIB-4 AND ELASTOGRAPHY USING LIVER FUNCTION BIOMARKERS IN HCV PATIENTS RECEIVING OPIOID SUBSTITUTION THERAPY

Nikolaos Papadopoulos[1] Eleni Myrto Trifylli[2] Charikleia Kranidioti[3] Nikolaos Tsiaberas[3] Dimitrios Papanikolaou[3] Pinelopi Antonakaki[1] Thalia Lehmann[1] Melanie Deutsch[3] Spilios Manolakopoulos[3], [1]National Organization for the Prevention and Treatment of Addictions (EOPAE), Athens, Greece, [2]GI-Liver Unit, 2d Academic Dpt Internal Medicine, NKUA,, [3]GI-Liver Unit, 2nd Department of Internal Medicine, General Hospital of Athens "Hippocratio", Nation

Background: Discordance between serum fibrosis scores and transient elastography is frequently encountered in chronic hepatitis C (HCV). We aimed to evaluate bidirectional discordance between FIB-4 and Baveno VII–defined compensated advanced chronic liver disease (cACLD) in compensated HCV patients receiving opioid substitution therapy (OST), and to assess whether liver function biomarkers could refine discordant phenotypes. **Methods:** We retrospectively analyzed baseline pre-treatment data from compensated HCV-infected patients receiving OST. Liver stiffness measurement (LSM) was assessed by vibration-controlled transient elastography (VCTE). According to Baveno VII–informed thresholds, LSM <10 kPa was considered cACLD unlikely, 10–14.9 kPa possible cACLD, and ≥ 15 kPa highly suggestive cACLD. Low FIB-4 was defined as <1.45 and high FIB-4 as >3.25. Bidirectional discordance was defined as either low FIB-4 despite LSM ≥ 10 kPa or high FIB-4 despite LSM <10 kPa. ROC analyses and exploratory multivariable models were used to evaluate the contribution of liver function biomarkers. **Results:** A total of 459 were included, 52/459 (11.3%) had LSM 10–14.9 kPa, and 48/459 (10.5%) had LSM ≥ 15 kPa. Among patients with low FIB-4 (<1.45), 28/267 (10.5%) had LSM ≥ 10 kPa. Conversely, among patients with high FIB-4 (>3.25), 16/49 (32.7%) had LSM <10 kPa. Compared with concordant low-risk patients, the low FIB-4 + high LSM phenotype demonstrated significantly higher AST (median 78 vs 42 U/L), ALT (96 vs 51 U/L), bilirubin (1.1 vs 0.7 mg/dL), and GGT levels (132 vs 48 U/L). Exploratory ROC analysis identified albumin ≤ 4.2 g/dL and bilirubin ≥ 0.61 mg/dL as optimal phenotype-associated thresholds. Adding albumin and bilirubin to FIB-4 improved discrimination for LSM ≥ 10 kPa (AUC 0.787 vs 0.733 for FIB-4 alone). Compared with concordant high-risk patients, the high FIB-4 + low LSM phenotype demonstrated higher AST (112 vs 74 U/L) but lower bilirubin levels (0.8 vs 1.4 mg/dL). In exploratory ROC analysis within the high FIB-4 subgroup, albumin ≥ 4.3 g/dL and bilirubin ≤ 0.41 mg/dL were associated with the discordant low-LSM phenotype. **Conclusion:** Distinct discordance phenotypes between FIB-4 and elastography demonstrate different biochemical profiles, while routine liver function biomarkers may improve phenotype characterization beyond isolated interpretation of FIB-4 or elastography alone.

3252 | DE NOVO MASLD AND METABOLIC OUTCOMES FOLLOWING DAA-MEDIATED HCV ERADICATION: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Jashanveer Johal[1] Bianca Patel[1] Mahmoud Al-Bataineh[1] Archana Salek[1] Brandon Cunha[1] Abdallah Hussein[1] Yecheskel Schneider[1] Jason Hyman[2], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Patients achieving sustained virologic response (SVR) following direct-acting antiviral (DAA) therapy for hepatitis C represent a growing post-cure cohort at theorized risk for de novo metabolic dysfunction–associated steatotic liver disease (MASLD). Viral clearance removes HCV's suppressive effect on hepatic lipid metabolism, potentially unmasking underlying metabolic dysfunction. Whether SVR12 is associated with incident MASLD or paradoxically confers protection through reduced hepatic inflammation remains poorly characterized. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised adults with HCV who received DAA therapy and achieved SVR12 (HCV RNA $\leq$10 IU/mL within 12 months). Cohort 2 comprised DAA-treated patients with persistent viremia (HCV RNA $\geq$10,000 IU/mL), representing treatment non-responders. Both cohorts excluded prior MASLD, cirrhosis, HCC, and liver transplant. 1:1 PSM yielded 3,133 patients per arm over a 6–60 month follow-up. Outcomes included incident MASLD, new cirrhosis, incident HCC, new-onset T2DM, incident hyperlipidemia, AST/ALT normalization, all-cause mortality, and inpatient encounters. **Results:** Post-PSM cohorts were well-balanced. Contrary to the pre-specified hypothesis, incident MASLD was equivalent between arms (5.1% vs. 5.4%; HR 0.99, 95% CI 0.78–1.25; p = 0.92). SVR12 was associated with lower rates of new cirrhosis on MOA analysis (4.2% vs. 5.5%; RR 0.78; p = 0.049), though KM analysis trended non-significant (HR 0.80; p = 0.084). Incident T2DM was significantly lower in the SVR arm (4.2% vs. 5.6%; HR 0.78, 95% CI 0.60–1.00; p = 0.050). Incident HCC trended lower with SVR (1.3% vs. 1.8%; RR 0.72; p = 0.108). All-cause mortality was lower on MOA analysis (6.6% vs. 8.2%; RR 0.80; p = 0.014) and trended lower on KM analysis (HR 0.83; p = 0.052). Inpatient burden trended lower with SVR (28.5% vs. 33.2%; mean 8.4 vs. 10.0 encounters; p = 0.10). **Conclusion:** DAA-mediated SVR12 was not associated with increased de novo MASLD incidence, arguing against the "metabolic unmasking" hypothesis in the short-to-medium term. SVR was associated with lower incident T2DM, a trend toward reduced cirrhosis and all-cause mortality, and numerically lower HCC incidence. These findings support viral eradication as metabolically protective and suggest post-SVR MASLD surveillance should be guided by underlying cardiometabolic risk burden rather than SVR status alone.

3253 | DETECTION OF ADVANCED FIBROSIS USING GLAS IN HCV PATIENTS IN TAIWAN

Jenna Bedrava[1] Claire Chen[1] Susan Gawel[1] Randal Schneider[1] Chen-Hua Liu[2], [1]Abbott Laboratories, [2]National Taiwan University Hospital

Background: The Asia-Pacific region bears a disproportional burden of liver disease mortality. This burden is largely attributable to complications of cirrhosis and hepatocellular carcinoma (HCC), both of which are highly associated with Hepatitis C infection (HCV), underscoring the necessity of liver disease surveillance in HCV populations. Biomarker-based classification models such as GLAS (GP73, LG2m, age, and sex) have become an area of increased interest, as they potentiate earlier identification of advanced liver fibrosis and a reduction in the risk of progression to malignancy. In this study, we evaluate the performance of GLAS in the detection of advanced fibrosis in a cohort of HCV positive patients in Taiwan. **Methods:** We retrospectively enrolled 960 patients with HCV, for whom samples collected both prior to direct-acting antiviral (DAA) treatment and after achieving sustained virological response (SVR) were available. Fibrosis stages were diagnosed pre-DAA using vibration-controlled transient elastography (VCTE) with cutoff values of $\leq$ 7.0, 7.1-9.4, 9.5-12.4, and $\geq$ 12.5 kPa corresponding to F0-F1, F2, F3, and F4. Serum GP73 and LG2m levels were measured on both samples using Abbott Alinity assays. The diagnostic performance of the GLAS model in pre-DAA samples in the discrimination of early-stage fibrosis (defined as F0-F2) and advanced fibrosis (defined as F3-F4) was compared to that of other models, including FIB-4, APRI, and NFS using receiver operating (ROC) curves and area under the curve (AUC) values. Optimal cutoffs for each model were determined by Youden's Index. **Results:** Our sample was comprised of 56.6% males with a median age of 57 years. Of the 960 patients, 284 (29.6%) were determined to have advanced fibrosis. GLAS had the highest AUC value in the discrimination of early and advanced fibrosis compared to FIB-4, APRI, and NFS. GLAS yielded an AUC of 0.89 (95% CI: 0.87, 0.91), significantly higher than that of APRI (p-value < 0.001) and NFS (p-value = 0.003). At the validated cutoff of 0.50, GLAS had a sensitivity of 100.0%, but a specificity of 10.9%. The optimal GLAS cutoff for this discrimination was determined to be 0.98. Changes in GLAS scores from pre-DAA to post-SVR were significant (p-value < 0.001). On average, patients with early-stage fibrosis saw a decrease of 0.064 in GLAS score from pre-DAA to post-SVR, a significantly larger decrease than those with advanced fibrosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(p-value < 0.001). **Conclusion:** GLAS had the highest AUC in the discrimination of early and advanced fibrosis compared to other risk models in pre-DAA HCV patients. The suboptimal specificity observed with the validated cutoff of 0.50 and the high optimal cutoff of 0.98 prompts the need for future evaluations to determine a more optimal cutoff. The significant decrease in GLAS scores from pre-DAA to post-SVR underscores the importance of early HCV diagnosis and treatment and early fibrosis detection.

3254 | EMERGENCY DEPARTMENT–BASED OPT-OUT VIRAL HEPATITIS SCREENING WITHIN AN INTEGRATED SYNDEMIC CARE MODEL

Sarah Merchant[1] James d'Etienne[1] Nanda Reamy[2] Sally Spann[1] Suzana Limones[2], [1]Integrative Emergency Services, JPS Health Network, [2]JPS Health Network

Background: Emergency departments (EDs) are critical access points for identifying viral hepatitis among underserved populations with limited engagement in longitudinal care. JPS Health Network, the safety-net health system for Tarrant County, Texas, expanded an existing opt-out HIV screening program into an integrated ED-based syndemic screening initiative incorporating hepatitis C virus (HCV), hepatitis B virus (HBV), syphilis, and HIV testing within routine workflows. The program aimed to normalize blood-borne virus screening, improve equitable access to testing, and strengthen linkage to hepatology and prevention services. **Methods:** A systems-based screening and linkage model was implemented using automated electronic medical record eligibility triggers, reflex laboratory testing, and closed-loop referral pathways. Opt-out age-based screening protocols reduced reliance on disclosure of sexual behaviors or substance use histories. Integrated workflows aligned ED screening with outpatient hepatology, infectious disease, and prevention services. Patients with negative screening results were evaluated using EMR-supported prevention eligibility logic incorporating historical laboratory data and syndemic vulnerability indicators. Eligible individuals received culturally responsive prevention navigation, behavioral risk-reduction education, vaccination support, and referrals for biomedical prevention services. ED clinicians and nursing staff received standardized training on trauma-informed communication, stigma-free screening, and coordinated linkage strategies. **Results:** From June 2025 through February 2026, 3,688 HCV antibody tests identified 259 positive results (7.0%). Among these, 74 individuals were HCV RNA-positive and referred for treatment coordination. HBV screening included 2,378 HBsAg tests identifying 19 positive results (0.8%). Integrated screening additionally identified 312 HIV-positive results among 34,288 tests and 408 positive syphilis results among 4,098 tests. Implementation demonstrated the feasibility of embedding high-volume viral hepatitis screening and coordinated linkage pathways into routine ED practice using automated EMR decision support and reflex testing protocols. The opt-out framework facilitated identification of new diagnoses, late diagnoses, and previously diagnosed individuals out of care who may not have engaged in traditional risk-based screening models. **Conclusion:** ED-based opt-out viral hepatitis screening integrated within syndemic prevention workflows is feasible and may improve identification of HBV and HCV infection among underserved populations disproportionately impacted by liver disease. Automated EMR decision support, prevention navigation, and coordinated referral systems can strengthen linkage to hepatology care while reducing barriers associated with stigma and risk-based screening approaches.

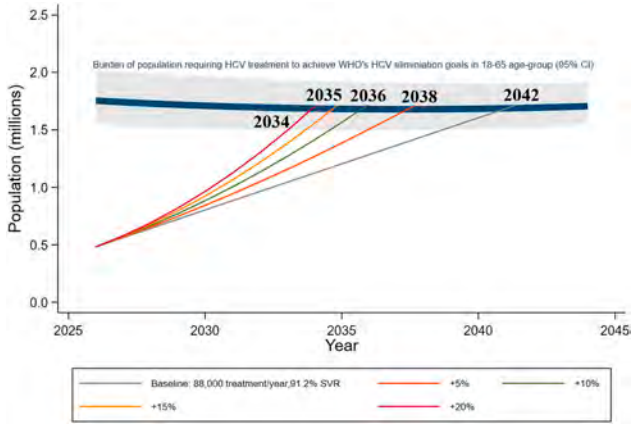
3255 | ◆ ROADMAP TO ACHIEVE HEPATITIS C ELIMINATION AMONG LOW-RISK POPULATION IN INDIA: A MODELLING STUDY USING 67 MILLION BLOOD DONOR DATA COLLECTED OVER A DECADE



Amit Goel[1] Ashish Awasthi[2] Manisha Dubey[1] Ajay Kumar Mishra[1] Surender Singh[1] Radha Dhiman[3], [1]Sanjay Gandhi Postgraduate Institute of Medical Sciences (SGPGI), [2]CSIR-Central Drug Research Institute, Lucknow, India, [3]Sanjay Gandhi Postgraduate Institute of Medical Sciences

Background: Hepatitis C virus (HCV) claims ~240,000 lives globally and target is to eliminate HCV by 2030. Countries need a well-articulated and realistic roadmap to achieve the elimination. We modelled the HCV elimination framework for India based on granular seroprevalence data and estimated the HCV burden, mortality, and elimination trajectories through 2050. **Methods:** Administratively, India is divided into state followed by districts. District level blood-donors HCV screening data, gathered from blood-units donated

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

between 2011-2020, were used to estimate the district level anti-HCV seroprevalence, treatment eligible HCV population, and HCV-related deaths. Weighted pooled estimates were generated for the states and the country. Age- and fibrosis-stage specific transition probabilities were applied to estimate progression, mortality, and hepatocellular carcinoma. We applied standard demographic methods, on country's census 2011 data, to project 18-65 years population from 2012 to 2050. Data on annual HCV treatment capacity and treatment success were collected from published reports. Developed a compartment model at base year 2025, assuming 88,000 being treated annually with 0.44 million already treatment so far since the inception of the national program, 91.2% treatment response rate, no-reinfection, and 110 new infections per million of population at risk. The Rogan–Gladen estimator was used for prevalence correction. Probabilistic sensitivity analysis and 95% confidence interval (CI), was performed using 10,000 Monte Carlo simulations. **Results:** Anti-HCV seroprevalence (95% CI) in 666,875,796 blood-units, donated between 2011-2020 in 609/640 districts, was 0.32% (0.28-0.36). At base-year 2025, estimated anti-HCV reactive burden among 18-65 year at base-year 2025 was 2.72 million (95%CI 2.39-3.14). Of them, 1.77 million (95%CI 1.55-2.04) require treatment to achieve HCV elimination goal (90% of anti-HCV reactive identified, 80% are viremic, and 80% of viremic are started on treatment). Estimated annual HCV-related deaths were 36,945 (95%CI 32,460-42-622). With current efforts, India can achieve HCV elimination among low-risk population aged 18-65 by the year 2042. By enhancing the existing treatment capacity by 5%, 10%, 15%, and 20%, HCV elimination goal could be achieved by the year 2038, 2036, 2035, and 2034 respectively (Figure 1). **Conclusion:** At the current pace of treatment, India is unlikely to achieve HCV elimination target by the year 2030. Scaling-up the existing treatment capacity by 20% could help to achieve the elimination by 2034.

3256 | ◆ SCALING UP HEPATITIS C SCREENING IN LOW-ENDEMIC AREA: EXPLORATION OF STRATEGIES INTEGRATING BIG DATA RISK CONCENTRATION AND LOW-COST ONE-SAMPLE SCREENING IN CHINA

Qiran Zhang[1] Feng Sun[2] Hongrang Zhou[3] Zhe Zhou[3] Yiqi Yu[2] Guifu Li[3] Sen Wang[2] Wenhong Zhang[2], [1]Huashan Hospital, Fidan University, [2]Huashan Hospital, Fudan University, [3]Center for Disease Control and Prevention of Qingpu District

Background: Low-endemic areas face a critical dilemma in hepatitis C elimination, where universal screening is costly,while screening only high-risk groups misses a substantial number of infections. One-sample testing and big data-driven risk concentration may be useful to address this dilemma, yet real-world public health practice is lacking to confirm their feasibility and benefits. **Methods:** This study employed a real-world evidence-driven modeling approach. In phase I, we took real-world public health practice to investigate the feasibility of low-cost one-sample testing and big data-driven risk concentration in large-scale HCV screening, and derived empirical parameters. In this phase, firstly a universal screening was conducted in the general population across four provinces in China,implementing low-cost POCT antibody screening, and diagnosis with one-sample reflex HCV RNA testing or two-step process. Secondly, A big data risk concentration model was developed and field-validated inShanghai for HCV screening. In phase II, we conducted health economic modeling to compare HCV screening strategies. All empirically derived parameters were input into a Marko model to compare the cost-effectiveness of eight strategies (defined by screening pools and testing methods). **Results:** In phase I, 21598 individuals were screened and the anti-HCV prevalence in the general population was0.088%. Linkage rate between screening and diagnostic was 100% in one-sample reflex testing and 46%in two-step process. Then in Shanghai, 4349 individuals from concentrated pool were screened, and the anti-HCV positivity rate was 1.17% in this group. In phase II, screening big data-concentrated population using low-cost one-sample testing achieved the most favorable

cost-effectiveness profile. Universal screening with one-sample testing was also cost-effective over the long term, and threshold analysis showed that when the test cost falls below 6.9 RMB, universal screening becomes cost-effective within a10-year horizon. To achieve WHO's target of a 65% reduction in mortality, either the rate of confirmatory testing completion or the linkage-to-care must be increased from the current site-measured rate of 80%to above 87.4%. **Conclusion:** The strategy using low-cost one-sample testing with big data risk concentration is the optimal pathway for large-scale HCV screening in low-endemic areas. In conditions where big-data are not available,universal screening using low-cost one-sample testing is also cost-effective in long term.

3257 | ◆ NATIONAL TRENDS AND HEALTHCARE UTILIZATION OF CHRONIC HEPATITIS C AMONG HOMELESS HOSPITALIZATIONS: A NATIONWIDE ANALYSIS, 2016–2023

Renuka Verma[1] Maria Ortega Abad[2] Ezzeldien n Ibrahim[3] Kamleshun Ramphul[4] Karn Wijarnpreecha[5] Nikki Duong[6], [1]Kirk Kerkorian School of Medicine at the University of Nevad, [2]Cleveland clinic, [3]University of Missouri – Columbia, [4]Independent reseacher, [5]University of Arizona College of Medicine-Phoenix, [6]Stanford University

Background: An estimated 2.7 to 3.9 million Americans live with chronic hepatitis C (HCV), with approximately 17,000 new cases reported each year. Homeless populations bear a high burden of HCV due to higher rates of intravenous drug use and systemic barriers to healthcare. We aim to explore the prevalence and predictors of HCV among homeless hospitalizations in the United States, along with its healthcare burden. **Methods:** The National Inpatient Sample (NIS), the largest inpatient database in the United States, was queried for hospitalizations of homeless patients between 2016 and 2023. The prevalence of HCV was examined over the study period. Baseline demographics, comorbidities, and independent predictors of HCV were analyzed, along with mean length of stay (LOS) and inflation-adjusted hospital charges. **Results:** A total of 3,334,534 weighted hospitalizations among homeless patients were analyzed, of whom 4.4% had HCV, with the prevalence declining significantly from 4.71% in 2016 to 3.40% in 2023 (p- trend <0.001). Affected patients were predominantly male (75.66%; aOR 1.10, 95% CI 1.07 to 1.14, $p<0.001$), older (49.4 vs. 46.6 years), and carried a greater comorbidity burden (Charlson index 2.61 vs. 1.22). Most were admitted to urban teaching hospitals (83.65%; aOR 1.46, 95% CI 1.32 to 1.61, $p<0.001$), and both Medicaid (63.09%; aOR 1.53, 95% CI 1.47 to 1.59, $p<0.001$) and uninsured status (9.76%; aOR 1.09, 95% CI 1.02 to 1.17, $p=0.017$) were independently associated with higher odds compared to Medicare. Compared to those without HCV, affected patients had a higher prevalence of drug abuse (72.91%; aOR 3.08, 95% CI 2.98 to 3.17, $p<0.001$), alcohol use disorder (37.64%; aOR 1.22, 95% CI 1.18 to 1.25, $p<0.001$), HIV/AIDS (7.66%; aOR 2.40, 95% CI 2.26 to 2.56, $p<0.001$), and cachexia (2.64%; aOR 1.74, 95% CI 1.61 to 1.89, $p<0.001$). Weekend admission was independently associated with higher odds of HCV (aOR 1.06, 95% CI 1.04–1.09, $p<0.001$).. Mean LOS increased significantly from 8.12 to 8.43 days (p-trend = 0.009), peaking at 8.92 days in 2022, while inflation-adjusted total charges showed no significant differences (p-trend = 0.241), ranging from $72,371 to $79,529. **Conclusion:** Despite a significant decline in HCV prevalence among homeless hospitalizations over time, affected patients continue to experience a disproportionately high burden of comorbid illness and healthcare utilization. Substance use, HIV/AIDS, and inadequate insurance coverage remained strong independent predictors, reflecting persistent structural barriers to HCV care. Expanded harm reduction strategies, improved linkage to treatment, and integrated care models are needed to reduce ongoing disparities in this vulnerable population.

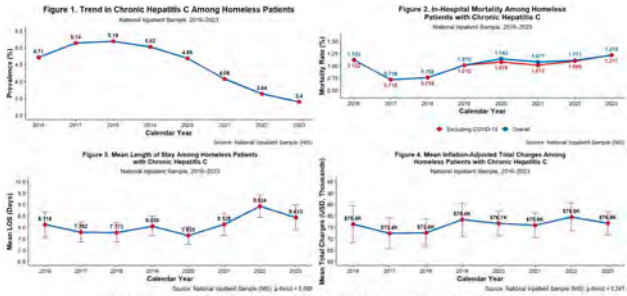

Table. Temporal Trends in Chronic Hepatitis C Among Homeless Patients National Inpatient Sample, 2016–2023

Year	Prevalence (Figure 1)	Mortality - Overall (Figure 2)	Mortality - No COVID (Figure 2)	Mean LOS, days (Figure 3)	Mean Total Charges (Figure 4)
2016	4.712%	1.122%	1.122%	8.118	$76,391.74
2017	5.142%	0.718%	0.718%	7.792	$72,371.12
2018	5.187%	0.758%	0.758%	7.773	$72,633.40
2019	5.025%	1.010%	1.010%	8.055	$78,401.31
2020	4.688%	1.143%	1.078%	7.635	$76,722.05
2021	4.076%	1.077%	1.013%	8.128	$75,862.53
2022	3.640%	1.111%	1.099%	8.924	$79,529.18
2023	3.398%	1.218%	1.217%	8.433	$76,786.92
p-trend	<0.001	0.293	0.355	0.009	0.241

3258 | ◆ FIVE-YEAR MORTALITY, OVERDOSE, AND HEPATIC OUTCOMES ASSOCIATED WITH PROMPT DIRECT-ACTING ANTIVIRAL THERAPY IN ADULTS WITH OPIOID USE DISORDER AND CHRONIC HEPATITIS C: A PROPENSITY-MATCHED COHORT STUDY

EzzElDien A. Ibrahim[1] Mahmoud Majed Mansour[1] Nourhan Saleh[1] Mohamed Omar[1] Mostafa Adel T. Mahmoud[2] Akram Alnounou[3] Nour Aldin T. Ahmed[4] Youssef Hafez[5] Mohammad Alabbas[6] Nathan Tofteland[7], [1]University of Missouri, Columbia, MO, USA, [2]Beni Suef university, Beni Suef, Egypt, [3]Western Michigan University Homer Stryker M.D. School of Medicine, [4]Beni-Suef university, Beni-Suef, Egypt, [5]St. Louis University School of Medicine, [6]Cleveland Clinic Foundation, Cleveland, Ohio, USA, [7]University of Kansas Medical Center

Background: Adults with opioid use disorder (OUD) carry the largest pool of new and prevalent hepatitis C virus (HCV) infection in the United States, yet have the lowest direct-acting antiviral (DAA) treatment uptake. Guidelines endorse universal DAA therapy regardless of substance use, but the recommendation rests largely on viral cure as a surrogate. Real-world long-term clinical outcomes after prompt DAA initiation in OUD populations remain limited. **Methods:** Retrospective propensity-matched cohort study on TriNetX Research USA (147M patients, 113 HCOs). Adults ≥18 with chronic HCV (B18.2, B19.2, B17.1, Z22.52, or HCV RNA ≥15 IU/mL) and OUD identified by the Wakeman 2020 composite definition (inpatient F11.x, repeated outpatient F11.x, or F11.x with overdose, injection-drug-use-related infection, or methadone/buprenorphine prescription) were included; pre-index HCC, liver transplant, HIV, or chronic HBV excluded. The index date was the first qualifying HCV anchor. A 180-day landmark required survival and observability through day 180. Cohort 1 had ≥1 DAA RxNorm fill in days 0–180; Cohort 2 had none. 1:1 propensity matching used 25+ covariates (demographics, era, prior methadone/buprenorphine, prior overdose, IDU-proxy infections, psychiatric comorbidity, baseline labs, liver-disease context; all post-match SMDs <0.05). Primary outcomes (days 181–1825, 5 years): all-cause mortality, opioid overdose, hepatic decompensation, and confirmed virologic clearance. Cox proportional hazards models estimated hazard ratios (HR). **Results:** 10,142 matched pairs were analyzed. Over 5 years, prompt DAA initiation was associated with lower all-cause mortality (5-year survival 94.3% vs 88.8%; HR 0.48, 95% CI 0.43–0.54; p<0.001), lower opioid overdose (HR 0.74, 95% CI 0.65–0.84; p<0.001), and higher confirmed virologic clearance (HR 4.14, 95% CI 3.46–4.95). Coded hepatic decompensation was higher among DAA-treated patients (HR 1.35, 95% CI 1.21–1.50) but attenuated from the 3-year HR of 1.43 — a pattern more consistent with competing-risks bias than with treatment harm, as untreated patients died before accumulating decompensation diagnoses. Findings were similar at 3-year follow-up (mortality HR 0.42; overdose HR 0.76; decompensation HR 1.43). Absolute 5-year differences in the DAA arm: 5.5 percentage-point lower mortality and 2.3 percentage-point higher coded decompensation, for a net 3.2 fewer adverse events per 100 patients. **Conclusion:** In adults with OUD and chronic HCV, prompt DAA initiation within 180 days was associated with lower 5-year mortality and overdose, and higher virologic clearance. The decompensation excess attenuated with longer follow-up, a pattern more consistent with competing-risks bias than with treatment harm. Findings are consistent with the case for universal, prompt DAA delivery in OUD populations regardless of perceived cascade barriers.

3259 | ◆ URGEN-C: EARLY OUTCOMES FROM A NOVEL TELEHEALTH HCV TREATMENT PROGRAM FOR GEORGIANS WITH SUBSTANCE USE DISORDERS

Jake MacDonald[1] Kirsten Dodson[1] Marie Sutton[2] Patrick Reilly[2] Lesley Miller[1], [1]Emory University School of Medicine, [2]Imagine Hope, Inc.

Background: Hepatitis C virus (HCV) disproportionately affects people with substance use disorders (SUD), yet access to curative direct-acting antiviral (DAA) therapy remains limited, even for those with health insurance. Multiple telehealth models have demonstrated high sustained virologic response (SVR) rates in vulnerable populations, but few have targeted patients identified through publicly-funded substance use disorder (SUD) treatment programs. Urgen-C partners Imagine Hope, Inc. (IH) with the Grady Memorial Hospital Liver Clinic (GLC), using publicly-funded SUD treatment sites as HCV screening access points. We report early outcomes. **Methods:** Retrospective chart review of all patients referred to GLC from IH through May 2026. Primary outcome: per-protocol SVR12 (undetectable HCV RNA $\geq$12 weeks post-DAA). Secondary outcomes included care cascade metrics. **Results:** Of 78 patients referred (June 2025–May 2026), 80.8% were White, with a mean age of 45.4 years, and 51.3% were male. Most had a history of intravenous drug use (IVDU) (78.2%), 91.0% were insured, 9.0% were experiencing homelessness, and 24.4% had mental health comorbidities; no patients had HIV co-infection. Of the 78 referred, 76 (97.4%) attended an initial telehealth appointment and 61 (78.2%) started DAAs (86.4% sofosbuvir/velpatasvir). Median time from referral to treatment start was 54 days (IQR 36–82). HCV genotype 1a was most common (n = 30, 38.5%), followed by genotype 2 (n = 11, 14.1%) and genotype 3 (n = 10, 12.8%), with genotype unknown or not reported in 24 patients (30.8%). Fibrosis staging by FIB-4, APRI, and/or previous imaging was available in 74 patients (94.9%), the majority of whom had early-stage disease (F0–F1, 67.6%), while advanced fibrosis or cirrhosis (F3–F4) was present in only 2 patients (2.8%), and imaging evidence of portal hypertension was identified in 5 patients (6.4%). Forty-one patients (52.6%) completed treatment, 10 (12.8%) were lost to follow-up during treatment, and 10 (12.8%) remain on treatment as of May 2026. Among the 51 patients who had completed treatment at the time of analysis (excluding 10 currently on treatment), 41 (80.4%) completed a full course of DAA therapy; confirmed SVR was achieved in 17 patients (33.3%), while 24 patients (47.1%) completed treatment but did not have confirmatory SVR labs drawn. Of 41 completers with SVR testing, all achieved undetectable HCV RNA (per-protocol SVR 100%; 17/17). **Conclusion:** Urgen-C achieved high appointment attendance and treatment initiation rates comparable to prior telehealth HCV interventions, with a 100% per-protocol cure rate among those with confirmatory testing. SVR12 follow-up failure (58.5% of completers) was the primary gap, underscoring the need for community-based testing strategies. Urgen-C is a scalable model for advancing HCV elimination among people with SUD.

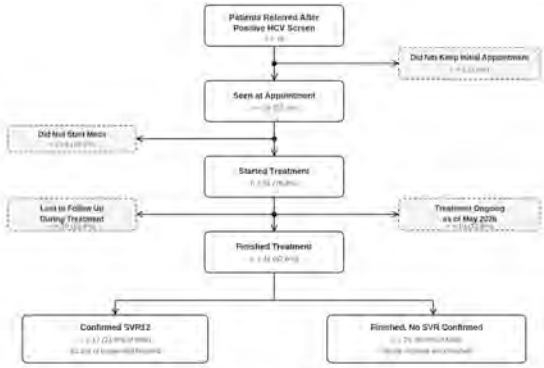

Figure 1. Care cascade of patients referred to Urgen-C.

HCV=hepatitis C virus; SVR12=sustained virologic response at 12 weeks; Finished, No SVR Confirmed = patients who completed medication course, but no confirmatory lab result was obtained.

3260 | PROGRESS TOWARD WHO 2030 TARGETS: 46-MONTH RESULTS OF THE NATIONAL HEPATITIS C SCREENING AND ELIMINATION PROGRAM IN LITHUANIA

Limas Kupcinskas[1] Janina Petkeviciene[1] Artur Kozlov[2] Jurate Sabaliene[2] Alexis Voeller[3] Devin Razavi-Shearer[3] John Ward[4] Juozas Kupcinskas[5], [1]Lithuanian University of Health Sciences, Kaunas, Lithuania, [2]National Health Insurance Fund under the Ministry of Health, Vilnius, Lithuania, [3]Center for Disease Analysis Foundation, Lafayette, United States, [4]Coalition for Global Hepatitis Elimination, Decatur, United States, [5]Lithuanian University of Health Sciences, Kaunas, Lithuania

Background: The Lithuanian National HCV screening and elimination program was launched in May 2022. General practitioners (GPs) received special promoting fee for serological HCV antibody testing: (1) a one-time test for individuals born between 1945 and 1994, and (2) annual testing for people who inject drugs (PWID) and people with HIV. This initiative is the first of its kind in Central and Eastern Europe. The aim of this study

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

was to assess the results of the first 46 months of the program and the different scenarios for achieving the WHO 2030 targets. **Methods:** GPs invited people to perform a serum blood test for HCV antibodies. Anti-HCV+ patients were referred to a specialist (gastroenterologist or infectologist) for HCV RNA testing, and if result was positive, direct-acting antiviral (DAA) therapy was prescribed. Information about patients was obtained from the National Health Insurance Fund. The Markov disease progression model elaborated by the CDA Foundation was used to assess HCV elimination progress. The data from the 2022-2023 screening were used as inputs. Three scenarios were developed: the 'Base' scenario - return to pre-screening level and 2 scenarios with different extents of treatment. **Results:** At the beginning of 2022, about 1.8 million people born in 1945-1994 lived in Lithuania. Between May 5, 2022, and Feb 28, 2026, from this population 1494093 people (83.7%) were tested for HCV antibodies. Positive test results were found in 1.32% of cases. In the risk group, 13019 PWID and/or HIV+ people were screened, of whom 28.2 % were seropositive. Specialists consulted 62% anti-HCV+ persons, but only 29% from risk group ($p < 0.001$). Viremia was detected in 51.2 %. During the 46-month of the program (May 2022- Feb 2026) 2.4 times more HCV patients were treated by specialists with DAA in comparison to the same period before starting of the program (9256 vs 3890). The Markov disease progression model to assess HCV elimination progress showed the following scenarios: Scenario 1: if the same number of patients are treated as before the screening, the WHO targets will not be reached. Scenario 2: treating 70% of infected patients will meet most but not all WHO targets. Scenario 3: by treating all infected patients by 2030, the WHO target will be met by saving 150 lives and preventing 90 new cases of decompensated cirrhosis and 120 cases of hepatocellular carcinoma. **Conclusion:** Our data show that promotion fee effectively motivated family physicians to perform anti-HCV antibodies screening and more than 83 % (approximately 1.5 million) of the target population was tested. However, 38% of people with positive HCV antibodies in the general population and 71% in high-risk groups still need to be examined by specialists. Therefore, additional measures to increase GP's motivation for rapid referral of anti-HCV+ persons to specialists and enhance compliance of risk group participants to program logistic are necessary to achieve WHO 2030 targets in Lithuania.

3261 | INFECTION CONTROL APPROACH TO HEPATITIS C VIRUS SCREENING AT A TERTIARY CARE CANCER CENTER IN THE UNITED STATES

Harrys Torres[1] Khalis Mustafayev[1] Bruno Granwehr[1] Adina Feldman[1] Amy Spallone[1] Eduardo Yepez Guevara[1], [1]The University of Texas MD Anderson Cancer Center

Background: Universal hepatitis C virus (HCV) screening is recommended nationwide. Acute HCV is a reportable condition in the United States. In many healthcare centers, infection prevention and control (IPC) teams collect reactive HCV antibody (anti-HCV) test results for public health reporting purposes, while also obtaining additional information to differentiate between acute and chronic HCV infections. Herein, we describe the 14-year experience leveraging HCV as a reportable infection to optimize screening and linkage to care at a tertiary care cancer center in the United States. **Methods:** All patients screened at MD Anderson Cancer Center for HCV from May 2012 to May 2026 were analyzed retrospectively. During that period, Infection Preventionists sent weekly reports of reactive anti-HCV results to a physician screening champion. Afterward, the champion contacted ordering providers and educated them about the need for confirmatory testing to reduce HCV-associated morbidity and mortality. Reflex HCV RNA testing was excluded from the testing sequence to prevent gaps in the discussion of anti-HCV results with patients. Descriptive statistics were used to state the prevalence of reactive anti-HCV and the patient's progression through the HCV care cascade. **Results:** Of 133,222 patients screened, 4,889 (3.7%) had reactive anti-HCV results. After excluding 1,107 patients initially referred to HCV specialists, ordering providers were contacted for 2,063 patients (Figure 1). Only five patients had acute HCV, and their cases were reported to the local health department. When providers were contacted, 876/2,063 (42.5%) of patients were linked to care. Most of the patients not linked to care came to our institution for a second opinion about cancer treatment and were asked to address their HCV locally. Of the patients linked to HCV care at our center, 556 (63.5%) had proven HCV (detectable HCV RNA or history of treated HCV). The majority of patients with proven HCV (341/556 [61.3%]) received direct-acting antivirals and had sustained virologic responses (SVRs; 340/341 [99.7%]) (Figure 1). **Conclusion:** HCV screening can be successfully performed in cancer hospitals using existing IPC platforms combined with HCV screening champions. This approach enabled high-volume screening, systemic reporting to health departments, provider education, care coordination, and excellent SVR. These results underscore that although treatment

is highly effective, enhanced outreach and navigation strategies are needed to close care cascade gaps and achieve HCV elimination targets.

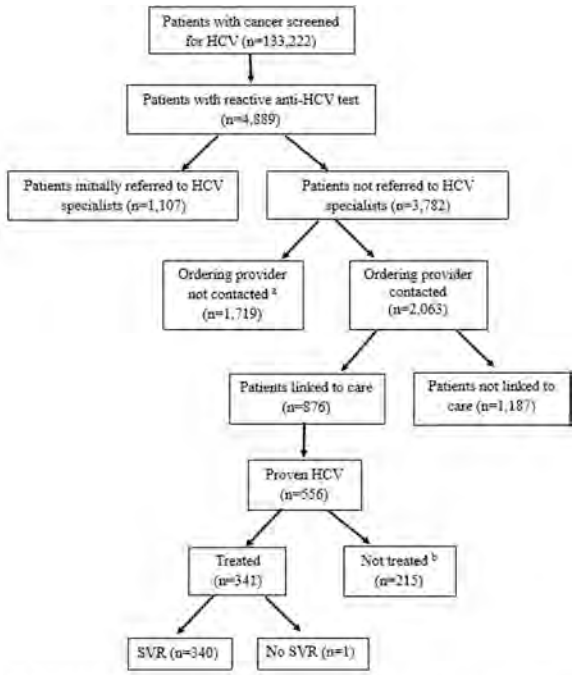

Figure 1. Study flow diagram.
[a] The main reasons for not contacting providers were: 1) HCV management was addressed by the oncology team (n=745) and 2) HCV treatment was contraindicated (n=583).
[b] Of the 215 patients not treated, 85 were lost to follow-up, 62 had advanced cancer, 38 died, 16 did not receive treatment due to potential drug-drug interactions with cancer treatment, 10 had decompensated cirrhosis, 2 had no insurance, and 2 refused treatment.

3262 | GUT MICROBIOME–ASSOCIATED PERSISTENCE OF PORTAL VEIN SUCCINATE ACCUMULATION AFTER HEPATITIS C VIRUS ERADICATION

Nivedha Vaidy[1] Mary Winnicki[1] Moumita Chakraborty[1] Kareen Akiva[2] Grace Zhang[3] Gabriella Quinn[1] Elizabeth Townsend[4] Lisa Scheuing[1] Elliott Levy[5] David Kleiner[6] Christopher Koh[1] Ohad Etzion[1] Anjali Rai[7] Rownock Afruza[1] Rabab Ali[8] Theo Heller[7], [1]NIDDK, [2]University of Maryland Medical System, [3]University of California, San Francisco, [4]NewYork-Presbyterian/ Columbia University Irving Medical Center, [5]NIH, [6]National Cancer Institute, Bethesda, [7]NIH/NIDDK, [8]McGaw Medical Center at Northwestern University

Background: Despite effective direct-acting antiviral therapy for Hepatitis C Virus (HCV), many patients remain cirrhotic and at risk for hepatocellular carcinoma after sustained virologic response (SVR), suggesting persistent disease mechanisms after viral clearance. Cirrhosis is characterized by dysregulation of the gut–liver axis, in which microbiome-derived metabolites are delivered via the portal circulation to regulate hepatic inflammatory and fibrotic signaling. Among these, succinate is a gut-derived metabolite that can bind and activate SUCNR1 signaling in the liver, promoting inflammation and fibrosis. However, whether portal succinate is an upstream driver of this pathway in cirrhosis remains unclear. Thus, we investigated portal succinate dynamics during and after HCV eradication and their association with gut microbial and hepatic transcriptional changes. **Methods:** We studied paired samples from patients (n = 22) during active HCV infection (HCVi) and 6 months post-SVR. We analyzed liver biopsy, portal and peripheral blood, and stool samples using liver transcriptomics, metabolomics, and 16S rRNA sequencing. Patients were classified as non-cirrhotic (n = 14) or cirrhotic (n = 8). **Results:** In non-cirrhotic patients, portal succinate significantly decreased following SVR, consistent with metabolic recovery after viral clearance. In contrast, cirrhotic patients exhibited persistent elevation of portal succinate post-SVR, indicating sustained gut–liver axis dysregulation despite viral clearance. In cirrhotic patients, succinate showed state-dependent microbial associations, including a strong negative correlation with the succinate-consuming *Dialister pneumosintes* during HCVi (r = −0.86) and a strong positive correlation with the succinate-producing *Odoribacter splanchnicus* after SVR (r = 0.83). During active infection, portal succinate correlated with hepatic inflammatory and fibrotic gene programs, but these associations were lost after SVR. **Conclusion:** Collectively, these findings suggest that in cirrhosis, portal succinate remains elevated after HCV eradication and reflects persistent gut metabolic input, but decouples from hepatic transcriptional programs. This work highlights succinate as a candidate biomarker of persistent metabolic dysfunction after HCV clearance that may play a role in persistent metabolic dysregulation in cirrhosis and warrants further mechanistic investigation.

3263 | TARGETED HEPATITIS C PREVENTION, TESTING, AND LINKAGE TO CARE THROUGH CLINIC AND MOBILE OUTREACH IN SOUTHERN NEVADA

Darya Fridman[1], [1]The LGBTQ+ Center of Southern Nevada

Background: Hepatitis C virus (HCV) disproportionately affects underserved populations, including people who inject drugs, unhoused individuals, rural communities, and adults born between 1945–1965. In 2025, The LGBTQ+ Center of Southern Nevada expanded HCV prevention, testing, and linkage-to-care services through fixed-site and mobile outreach programs emphasizing culturally competent care and wraparound services. **Methods:** The Center operates a Sexually Transmitted Infection (STI) Clinic, Primary Care Clinic, and Mobile Health Clinic. All patients were offered free HIV and HCV testing and received biomedical and behavioral prevention interventions with individualized assessments. Care delivery was guided by culturally competent, trauma-informed approaches and integrated wraparound services, including syringe services, substance use recovery linkage, peer navigation, bilingual support, housing and social service referrals, and prevention supplies. Community-based HCV education and testing were conducted across substance use treatment facilities, Native American Reservations, libraries, shelters, and outreach events throughout Southern Nevada. Patients with reactive HCV antibody (HCV Ab) tests were referred for confirmatory HCV RNA testing and linkage to treatment coordinated by a dedicated Hepatitis C Manager. Pharmacy services at both clinic locations provide medication delivery to support timely initiation and adherence to HCV therapy. **Results:** In 2025, 2,062 individuals were tested for HCV Ab; 67 (3.2%) tested positive. Of those, 63 (94%) completed confirmatory HCV RNA testing. 31 of 63 (49.2%) had detectable HCV RNA indicating active infection. All 31 initiated treatment and achieved subsequent HCV RNA negativity following therapy. Four patients pending confirmatory testing remain engaged in follow-up care coordination.Among the 67 HCV Ab-positive individuals, 10 (15%) were unhoused, 1 (1.5%) resided in a rural community, 3 (5%) were identified through a substance use rehabilitation center (Crossroads), 19 (28%) reported injection drug use, and 10 (15%) were born between 1945–1965.The Mobile Health Clinic, launched in 2025, tested 71 individuals, identifying 3 (4.2%) HCV Ab-positive cases; all 3 were linked to care and initiated treatment (100%). Mobile outreach expanded testing access among rural and high-risk populations, including individuals with substance use disorder and housing instability. **Conclusion:** Integrated clinic and mobile outreach achieved high rates of HCV confirmatory testing, linkage to care, treatment initiation, and cure among underserved populations in Southern Nevada. A model combining culturally competent care, wraparound services, and mobile delivery reduced structural barriers to HCV care and supported progress toward HCV elimination in high-risk communities.

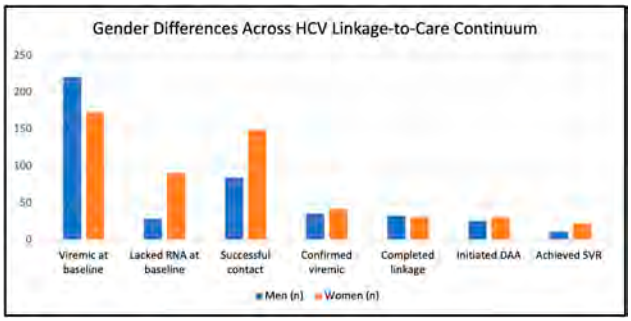
3264 | GENDER DIFFERENCES IN STAGES OF LINKAGE-TO-CARE AMONG PERSONS WITH UNTREATED OR INCOMPLETELY DIAGNOSED HEPATITIS C VIRUS INFECTION IN SAN FRANCISCO



Rena Fox[1] Matthew Caliz[1] Jennifer Price[2] Mai Sedki[3] Jeffrey McKinney[3] Katrina Alcantara[3] Tasha Toliver[3] Michael Helle[3], [1]Division of General Internal Medicine, UCSF, [2]Division of Gastroenterology and Hepatology, UCSF, [3]University of California, San Francisco

Background: Prior studies of the hepatitis C virus (HCV) care cascade have reported gender differences, but findings vary across settings and treatment eras. Women spontaneously clear HCV more often but face access barriers related to caregiver responsibilities and had lower treatment uptake during the interferon era, while men engage with healthcare less regularly. We evaluated gender differences at each stage of the cascade in a large HCV outreach program in the direct-acting antiviral (DAA) era in San Francisco. **Methods:** Using the electronic medical record (EMR), we identified adults seen in an urban healthcare system from 2020–2024 who either had 1) detectable or quantified HCV RNA at most recent testing or 2) HCV antibody reactive without RNA testing. Manual review then incorporated unstructured external laboratory data. Two patient navigators attempted a minimum of three outreach calls per patient and offered laboratory testing at the site of the patient's choice and linkage visits by telephone, video, mobile van, or in person. No incentives were provided. **Results:** EMR query followed by manual review identified 514 living patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

with current HCV viremia or incomplete diagnostic testing. Men had higher rates of viremia (88% vs. 65%), while more women (34% vs. 12%) lacked RNA testing. Navigators reached 234 patients, with higher success rates among women (56% vs 34%). Of these, 159 agreed to confirmatory RNA testing and linkage visits. At confirmatory testing, 45 were undetected, of whom 36 completed linkage visits, and 78 were viremic. Among the viremic, more than half were women. Overall, 82% of viremic patients completed linkage visits and 89% initiated DAA (100% of women vs 79% of men). To date, 67% achieved documented sustained virologic response (SVR) (73% of women vs 58% of men). Overall linkage was achieved in 100/159 patients (63%). **Conclusion:** Important gender differences persist in the HCV care cascade in the DAA era. We found at baseline, substantially more women lacked confirmatory RNA testing while more men had untreated viremia. However, once they were reached and completed testing, women had equivalent rates of viremia, linkage, and DAA initiation, and ultimately higher rates of documented SVR. These data suggest that upstream differences in the cascade, such as completed diagnosis and entry into care, are the key barriers for women. This pattern raises the possibility that gender disparities in HCV care may be driven in part by missed opportunities for early diagnosis rather than unwillingness to participate in care, and that navigator-based outreach programs that offer flexible testing and multiple care modalities may be particularly effective in achieving HCV elimination for women.

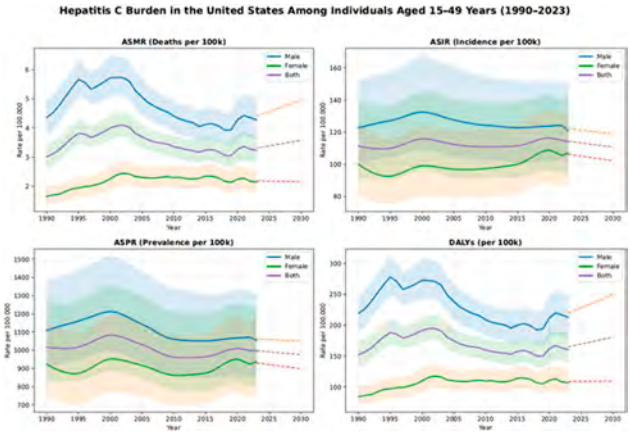
3265 | EVOLVING EPIDEMIOLOGY AND DISEASE BURDEN OF HEPATITIS C AMONG US ADULTS AGED 15–49 YEARS, 1990–2023



Mohammed Y. Youssef[1] Kylie Dunn[2] Mohamed Eldesouki[3] Crisy Abraham[2] Spencer klatt[4] Hazem Abosheaishaa[5] Ehab Faheid[1] Sherif Elhanafi[2], [1]Hunt Regional Medical Center, [2]The University of Texas at Tyler School of Medicine, [3]New York Medical College at Saint Michael Medical Center, [4]The University of Texas at Tyler School of Medicine], [5]hazemabosheaishaa@gmail.com

Background: Hepatitis C virus (HCV) infection remains a significant contributor to chronic liver disease, cirrhosis, and hepatocellular carcinoma in the United States. This study aimed to evaluate epidemiologic trends and disease burden of HCV among individuals aged 15–49 years in the United States from 1990 to 2023 using Global Burden of Disease (GBD) data. **Methods:** In this retrospective epidemiologic analysis, we assessed GBD 2023 estimates for the United States from 1990–2023. Age-standardized mortality rates (ASMR), age-standardized incidence rates (ASIR), prevalence rates (ASPR), and disability-adjusted life year (DALY) rates per 100,000 population were analyzed by sex. Corresponding 95% uncertainty intervals (UIs) were obtained directly from the GBD database. **Results:** From 1990 to 2023, the ASMR for HCV among individuals aged 15–49 years increased from 3.01 per 100,000 population (95% UI, 2.60–3.44) to 3.23 per 100,000 (2.78–3.71). In males, ASMR remained relatively stable, changing from 4.36 (3.75–4.99) to 4.28 (3.63–5.04) per 100,000, whereas in females it increased from 1.65 (1.39–2.00) to 2.15 (1.78–2.59) per 100,000. ASIR rose slightly overall from 111.38 (91.35–138.03) to 114.02 (94.12–142.46) per 100,000 population. Male incidence rates decreased modestly from 122.74 (99.97–152.09) to 120.90 (100.69–150.45), while female incidence rates increased from 99.97 (82.23–125.49) to 106.96 (87.39–133.54) per 100,000. ASPR remained relatively stable overall, decreasing slightly from 1017.31 (830.51–1270.07) to 996.67 (805.57–1249.52) per 100,000 population. DALY rates increased from 151.98 (131.87–174.10) to 160.58 (138.14–185.09) per 100,000 population overall. Among females, DALY rates rose substantially from 84.34 (71.33–101.46) to 106.87 (88.33–128.39), whereas rates in males remained relatively unchanged. **Conclusion:** Despite major therapeutic advances in HCV management, the burden of hepatitis C among Americans aged 15–49 years has remained substantial over the past three decades. Mortality and DALY rates increased modestly overall, with particularly notable increases among females. Stable prevalence and incidence rates

may reflect ongoing transmission alongside improved survival due to effective antiviral therapies. These findings highlight the continued need for expanded screening, prevention initiatives, linkage to care, and equitable access to curative treatment in younger populations at risk for HCV infection.

3266 | DERIVATION AND EXTERNAL VALIDATION OF THE BILIRUBIN-ALBUMIN-DIABETES-SCORE FOR PREDICTION OF TRANSPLANT-FREE SURVIVAL AFTER SVR IN PATIENTS WITH DECOMPENSATED HCV CIRRHOSIS

Lisa van Velsen[1] Javier Ampuero Herrojo[2] Yolanda Sánchez-Torrijos[3] Lisette Krassenburg[4] Grishma Hirode[5] Kosh Agarwal[6] Graham Foster[7] Zillah Cargill[6] Raoel Maan[1] Heiner Wedemeyer[8] Markus Cornberg[8] Rob De Knegt[9] Gonzalo Crespo[10] Jose Calleja[11] Alnoor Ramji[12] Giuseppina Brancaccio[13] Maria Cristina Morelli[14] Ilaria Lenci[15] Monica Cucco[16] Raffaella Viganò[17] Jose Miguel Rosales-Zabal[18] Isabel Carmona[19] Manuel Rodriquez-Peralvarez[20] Carlota Jimeno[21] Angeles Lopez-Garrido[22] Marta Casado[23] Gema Romero[24] Miren Garcia-Cortes[25] Paolo Angeli[26] Patrizia Burra[27] Maria Donato[27] Paola Carrai[28] Silvia Martini[29] Paolo Caraceni[30] Francesco Paolo Russo[26] Harry Janssen[31] Bettina Hansen[9] Adriaan Van der Meer[9] Jordan Feld[32] Milan Sonneveld[1], [1]Erasmus University Medical Center, [2]Hospital Universitario Virgen del Rocío, [3]Hospital Universitario Virgen del Rocío, Sevilla, Spain, [4]University Medical Center Rotterdam, [5]Toronto Centre for Liver Disease, [6]King's College Hospital, [7]Queen Mary University of London, [8]Hannover Medical School, [9]Erasmus MC University Medical Center Rotterdam, [10]University of Barcelona, [11]Universidad Autonoma de Madrid and CIBERehd, [12]University of British Columbia, [13]Link University of Rome, [14]IRCCS Azienda Ospedaliero-Universitaria di Bologna, [15]Tor Vergata University Rome, [16]ASST Ospedale Niguarda, Milan, Italy, [17]ASST Ospedale Niguarda Milan, [18]Hospital Universitario Costal del Sol, Marbella, Spain, [19]Hospital Universitario Virgen Macarena, Sevilla, Spain, [20]Hospital Universitario Reina Sofía, [21]Hospital Universitario Virgen de Valme, Sevilla, Spain, [22]Hospital Universitario Virgen de las Nieves, [23]Hospital Universitario Torrecárdenas, Almería, Spain, [24]Hospital Universitario Juan Ramón Jiménez, Huelva, Sevilla, Spain, [25]CIBEREHD, Madrid, Spain; Hospital Universitario Virgen de la Victoria, Málaga, Spain, [26]University of Padova, [27]University Hospital Padua, [28]Academic Medical Center, [29]Liver Sub-intensive Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy, [30]IRCCS Azienda Ospedaliera-Universitaria di Bologna, [31]Erasmus MC, [32]Toronto General Hospital

Background: High rates of sustained virological response (SVR) can be achieved with direct acting antivirals (DAAs) in patients with decompensated hepatitis C virus (HCV) cirrhosis. However, despite SVR, these patients remain at risk for liver-related events (LREs). We aimed to derive and externally validate a risk score that predicts transplant-free survival in patients with decompensated HCV cirrhosis who have achieved SVR. **Methods:** We included patients with decompensated HCV cirrhosis (Child-Turcotte-Pugh (CTP) ≥ 7 and/or history of decompensating events) who achieved SVR after DDA therapy from 16 centers in Europe, and Canada (derivation cohort) and 9 centers in Spain (validation cohort). Predictive factors for transplant-free survival, were assessed in the derivation cohort using multivariable Cox regression, and a risk score was constructed based on the obtained hazard ratios. The performance of the score was subsequently assessed in the external validation cohort. **Results:** A total of 561 patients were included in the derivation cohort. Median age was 54.3 (IQR 48.7-59.1) years, 70% was male, 23% had DM, and the median MELD score at the time of SVR was 11.2 (IQR 9.2-13). Median follow-up time after SVR was 24 (IQR 9-33) months. In the derivation cohort, the 1-, and 3-year transplant-free survival was 86% and 62%. Presence of DM (aHR: 1.5, $p = 0.026$), lower albumin (aHR 28-35g/L: 2.2, aHR $<$ 28g/L: 3.8, $p < 0.001$), and higher bilirubin (aHR 34.2-51.3 umol/L: 1.7, aHR $>$ 51.3 umol/L: 2.2, $p < 0.001$) were associated with an increased risk of LT and death. Patients were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

allocated to a low risk (no risk factors [31%]), intermediate risk (1-3 risk points [53%]) and high risk group (≥ 4 risk points [16%]). Amongst patients with no risk factors, the 1-year and 3-year transplant-free survival was 93% and 82%, compared to 87% and 58% in the intermediate group, and 71% and 41% in the high risk group ($p < 0.001$) (Figure 1A). Similar findings were observed when HCC, orfurther decompensation were added as outcomes. In the validation cohort, 131 patients were included; median age was 55 (IQR 49-65) years, 68% was male, 28% had DM, and the median MELD score at the time of SVR was 10 (IQR 9-13). Median follow-up time after SVR was 54 (IQR 26-87) months. In the validation cohort, 47% of patients were at low predicted risk, 45% at intermediate risk and 8.4% at high risk. Amongst patients at low predicted risk, the 3-year transplant-free survival was 81%, compared to 68% in the intermediate group and 54% in the high risk group ($p = 0.027$) (Figure 1B). **Conclusion:** Patients with decompensated HCV cirrhosis remain at high risk of LREs despite SVR. The externally validated bilirubin-albumin-DM (BAD) score, effectively predicts transplant-free survival and can be used to guide management.

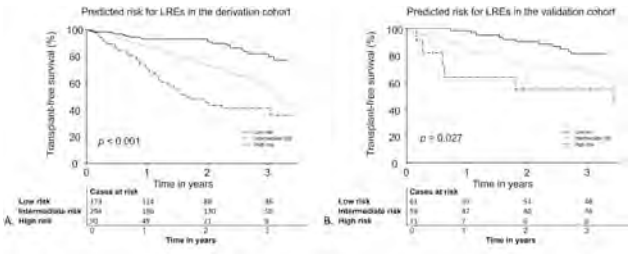

Figure 1. Transplant-free survival after SVR in patients with decompensated HCV cirrhosis stratified for a predicted high, intermediate and low risk in A) the derivation cohort, and B) the external validation cohort.

3267 | PERSISTENT RISKY ALCOHOL USE AMONG U.S. ADULTS WITH CHRONIC VIRAL HEPATITIS DESPITE ADVANCES IN HEPATITIS CARE: NHANES 1988-2023 NEW SUBMISSION

Haemi Lee[1] Hyunseok Kim[2] Yun Wang[3] Aarshi Vipani[3] Ju Dong Yang[3] Walid Ayoub[3] Alexander Kuo[3] Paul Martin[3], [1]Ascension Columbia St Mary's, [2]Cedars Sinai Medical Center, [3]Cedars-Sinai Medical Center

Background: Risky alcohol use accelerates fibrosis progression and hepatocellular carcinoma risk in chronic viral hepatitis. Despite advances in antiviral therapy, screening, and public awareness, nationally representative data on temporal trends in alcohol use among HBV- and HCV-infected adults remain limited. We evaluated the prevalence, temporal trends, and predictors of risky alcohol use among U.S. adults with viral hepatitis using NHANES 1988-2023. **Methods:** We identified 1,303 adults with serologically confirmed HBV or HCV infection from NHANES 1988–2023. Risky alcohol use was defined as binge drinking (≥ 5 drinks/occasion for men, ≥ 4 for women) or heavy weekly consumption (>14 drinks/week for men, >7 for women). Survey-weighted logistic regression examined predictors of risky alcohol use across three eras (1988-1994, 1999-2010, 2011-2023), adjusting for sociodemographic characteristics, smoking, and fibrosis severity (FIB-4). **Results:** The weighted prevalence of risky alcohol use was 46.0% (95% CI 36.8-55.3), 39.4% (33.1-45.6), and 41.3% (31.7-50.9) across the three eras, with no significant decline over more than three decades ($p=0.267$). Older age (OR 0.95 95% CI 0.92–0.98 per year) and female sex (OR 0.34 95% CI 0.19–0.59) were independently associated with lower odds of risky drinking, whereas current (OR 3.02 95% CI 1.52–5.98) and former smoking (OR 3.31 95% CI 1.49–7.34) were associated with higher odds. Compared with Hispanic participants, non-Hispanic Black (OR 0.43 95% CI 0.21–0.88) and non-Hispanic White participants (OR 0.42 95% CI 0.20–0.91) had lower odds of risky use. Self-reported awareness of underlying liver disease was associated with lower odds of risky drinking (OR 0.58, 95% CI 0.36-0.94, $p=0.028$). In advanced fibrosis (FIB-4 >2.67), odds of risky drinking were higher in 2011-2023 versus 1999-2010 (OR 6.83, 95% CI 1.54-30.26, $p=0.017$), though subgroup size was limited. Hepatitis type was not associated with risky drinking (HCV vs HBV: OR 0.88, $p=0.740$). **Conclusion:** Risky alcohol use remained persistently high (39-46%) among US adults with chronic viral hepatitis over more than three decades, with no significant decline despite advances in antiviral therapy and hepatitis screening. Liver disease awareness was modestly protective, yet individuals with advanced fibrosis continued to show signals of risky alcohol use. These findings highlight persistent gaps in alcohol-related risk reduction, support routine alcohol screening and behavioral intervention in viral hepatitis care.

3268 | IMPACT OF CHRONIC HEPATITIS C VIRUS INFECTION AND ANTIVIRAL TREATMENT ON COMPOSITE CARDIOVASCULAR DISEASE RISK: A NATIONWIDE COHORT STUDY

Min Kyung Park[1] Hwa Young Choi[2] Hyung Jun An[1] Chang Wook Park[1] Gwang Hyun Choi[1] Eun Sun Jang[1] Moran Ki[2] Kyung-Ah Kim[3] Sook-Hyang Jeong[1], [1]Department of Internal Medicine, Seoul National University Bundang Hospital, [2]Department of Cancer Control and Policy, National Cancer Center, [3]Department of Internal Medicine, Inje University Ilsan Paik Hospital

Background: Chronic hepatitis C virus (HCV) infection triggers systemic inflammation, potentially elevating cardiovascular risk. We evaluated the independent association between HCV infection and composite cardiovascular disease (CVD) risk, alongside the impact of antiviral treatment completion on this risk. **Methods:** Utilizing the South Korean National Health Insurance Service (NHIS) database, we analyzed 40,724 HCV patients and 610,860 age- and sex-matched controls (1:10 ratio). Individuals with prior liver transplantation, decompensated cirrhosis, or pre-existing CVD were excluded. The composite CVD outcome comprised ischemic heart disease, stroke, or peripheral artery disease. Multivariable Cox models and competing risk regressions adjusted for socio-economic status, lifestyle factors, and comorbidities. **Results:** The mean age was 46.0 ± 12.8 years in both groups. During follow-up, 30,348 patients developed composite CVD outcomes (incidence rate: 4.7 per 1,000 person-years). At baseline, the HCV group exhibited a higher prevalence of diabetes (17.6% vs. 13.1%, P < 0.001) and hypertension (24.2% vs. 20.1%, P < 0.001) than the control group. Despite these unfavorable baseline profiles, HCV infection remained an independent predictor of CVD. After adjusting for all covariates and accounting for competing risks of death, the HCV group showed a significantly higher composite CVD risk (adjusted hazard ratio [aHR], 1.17; 95% confidence interval [CI], 1.12–1.22). Within the HCV cohort (treatment completion rate: 33.4%), the risk was markedly lower among those who completed therapy; the untreated group carried a substantially higher CVD risk compared to the treated group (aHR, 1.67; 95% CI, 1.51–1.85). **Conclusion:** Chronic HCV infection is an independent risk factor for composite CVD in this nationwide cohort. Crucially, successful antiviral therapy significantly mitigates this risk, underscoring that HCV eradication confers systemic benefits extending well beyond hepatic outcomes and serving as a vital strategy for cardiovascular prevention.

3269 | CASE ASCERTAINMENT RATES FOR CHILDREN INFECTED WITH HEPATITIS C IN FLORIDA: EPIDEMIOLOGIC EVIDENCE OVER ONE DECADE

Madison Machado[1] Palack Agrawal[2] Aymin Delgado-Borrego[3], [1]Kidz Medical Research Trainee from the University of Central Florida, [2]Ssm Cardinal Glennon Children's Hospital/ St. Louis University, [3]KIDZ Medical Multispecialty Group

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Hepatitis C virus (HCV) infection remains the most common chronic bloodborne infection in the U.S. and a major cause of liver-related morbidity and mortality worldwide (*JAMA.* 2020;323:970-975). Despite effective curative therapies, HCV incidence in the U.S. increased 106% between 2015 and 2021 (*JAMA.* 2023;330:2200-2208). A prior epidemiologic survey demonstrated that only 12% of expected pediatric HCV cases in Florida and 4.9% nationwide were identified between 2000 - 2009 (*J Pediatr.* 2012;161:915-21). The objective of this study was to evaluate the current rate of pediatric HCV case ascertainment relative to the estimated number of actual cases. **Methods:** All HCV antibody-positive cases reported to the FL Department of Health among individuals aged 0–19 years between May 10, 2016 and May 9, 2026 were analyzed using the statewide MERLIN surveillance database which excludes duplicate reports. Pediatric cases were analyzed by year of diagnosis and age group. Florida population estimates per age group were obtained (Florida EDR and U.S. Census). Expected pediatric HCV cases were calculated using estimated pediatric prevalences of 0.3% based on published literature (*J Pediatr.* 2012;161:915–921; *Am J Gastroenterol.* 2021;116:2068–2078). The primary outcome was the percentage of expected cases identified within the surveillance system. (identified cases ÷ expected cases) × 100. **Results:** Between 2016 and 2026, a total of 1,198 pediatric chronic HCV cases were identified in Florida. Adolescents aged 15–19 years accounted for 949 cases (79.2%) of the entire pediatric cohort. In comparison, only 118 cases (9.8%) were identified among children aged 0–4 years, 70 cases (5.8%) among children aged 5–9 years, and 61 cases (5.1%) among children aged 10–14 years. Annual reported pediatric HCV cases declined from 267 in 2016 to 58 in 2025. Adolescents aged 15-19 years represented the largest age group, with cases decreasing from 222 to 35 over the same timeframe. Using an expected pediatric chronic HCV prevalence estimate of 0.3%, observed-to-expected (O/E) ratios remained low throughout the study period. Overall O/E ratios declined from 0.0192 (1.92%) in 2016 to 0.0038 (0.38%) in 2025. **Conclusion:** Pediatric HCV case identification in Florida, despite one of the nation's strongest surveillance systems, has declined precipitously which likely reflects a national trend. Pediatric case ascertainment in Florida decreased from 12% of expected cases in 2000–2009 to 1.92%–0.38% in 2016–2026 despite curative therapies and universal screening recommendations, highlighting an urgent public health gap.Urgent strategies are needed for the implemenation of effective surveilance and linkage to care among pediatric patients at risk of HCV infection.

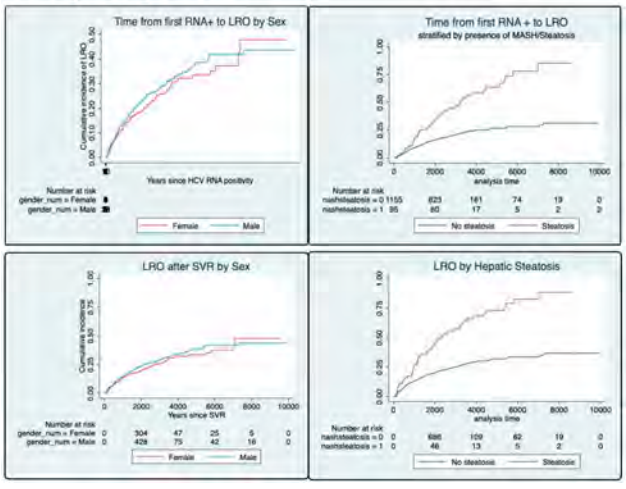
3270 | RISK FACTORS FOR LIVER-RELATED OUTCOMES AFTER HEPATITIS C VIRUS TREATMENT WITH SUSTAINED VIROLOGICAL RESPONSE IN THE DIRECT-ACTING ANTIVIRAL ERA

Mai Sedki[1] Jennifer Price[1] Matthew Caliz[1] Rena Fox[1],
[1]University of California, San Francisco



Background: Sustained virological response (SVR) after chronic hepatitis C virus (HCV) treatment reduces, but does not eliminate, the risk of liver-related outcomes (LRO), including hepatocellular carcinoma (HCC). As time into the direct-acting antiviral (DAA) era lengthens, predictors of post-SVR outcomes may be evolving. Although prior studies have identified independent risk factors for LRO after SVR, few have evaluated interactions among these factors in time-to-event analyses. **Methods:** We conducted a retrospective cohort study using electronic medical record data from a large urban medical center from 2016–2024. Adults with detectable HCV RNA at any time were included. SVR was defined as detectable HCV RNA followed by undetectable HCV RNA. LRO was defined by ICD codes for cirrhosis, HCC, or liver transplantation. The primary analysis evaluated time from first detectable HCV RNA to first LRO using Cox proportional hazards models. A secondary analysis evaluated time from SVR to LRO among patients achieving SVR. Models included sex, HbA1c, BMI, hepatic steatosis, and alcohol use disorder (AUD) with time-updated metabolic covariates. Interaction terms assessed effect modification by sex. Robust standard errors accounted for clustering. **Results:** Among 4,916 patients with detectable HCV RNA, 2,146 LRO events occurred over a median follow-up

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

of 7.43 years. In the primary analysis, higher HbA1c was independently associated with increased LRO risk (hazard ratio [HR] 1.15 per 1% increase, 95% confidence interval [CI] 1.03–1.28, p = 0.01). Hepatic steatosis was also associated with increased risk (HR 1.72, p≈0.001). Sex, BMI, and AUD were not independently associated with LRO. No significant sex interactions were observed for HbA1c or BMI. Interactions between sex and hepatic steatosis (p = 0.06) and sex and alcohol abuse (p = 0.05) approached significance, although confidence intervals were wide. In the SVR-restricted analysis, higher HbA1c remained independently associated with increased LRO risk, whereas sex, BMI, and AUD were not associated with outcomes. No major violations of proportional hazards assumptions were identified. **Conclusion:** Metabolic health remains a major determinant of liver-related outcomes in patients with HCV, including after SVR. The persistent association between elevated HbA1c and LRO, together with the effect of hepatic steatosis, underscores the importance of routine metabolic risk assessment and management in patients with HCV both before and after cure. As many patients achieving SVR are transitioned out of specialty care, greater attention to long-term metabolic monitoring in primary care settings may be critical to reducing ongoing liver-related risk. Although definitive sex-based differences were not identified, potential interactions involving hepatic steatosis and alcohol use warrant further investigation.

Figure 1. Time-to-Liver-Related Outcomes from initial HCV RNA detection and from SVR, stratified by sex and hepatic steatosis

3271 | IMPACT OF DEFAULT REFLEX HCV RNA TESTING ON TIMELY DIAGNOSTIC COMPLETION AND DOWNSTREAM CARE

Jacqueline Henson[1] Andrew Muir[1], [1]Duke University

Background: Incomplete confirmatory RNA testing after a positive hepatitis C virus (HCV) antibody test remains a critical gap in the HCV care cascade and a barrier to elimination efforts. We evaluated the impact of implementing default reflex HCV RNA testing on timely diagnostic completion and downstream care. **Methods:** We conducted a quasi-experimental pre-post study of patients with positive HCV antibody tests from January 2023 to December 2025 across a large academic health system. Default reflex RNA testing for positive antibody results was implemented in July 2024. The primary outcome was the proportion of patients with positive antibody testing without RNA testing within 90 days. Secondary analyses evaluated outcomes by care setting (emergency department [ED], inpatient, outpatient). Among patients with detectable HCV RNA and ≥6 months of follow-up, we assessed hepatology or infectious disease clinic visits and HCV treatment initiation within 6 months of positive antibody test. **Results:** Among 3,599 patients with positive antibody tests, the proportion without RNA testing within 90 days decreased from 14.9% pre-intervention (254/1,699) to 2.2% post-intervention (41/1,900) (p < 0.001). This corresponded to a reduction in the median number of patients per quarter without RNA testing from 42 (IQR 39-47) to 6 (IQR 4-11), with sustained improvement over 12 months (**Figure**). Reductions were observed across care settings and were most pronounced in the ED (61.9% vs 9.1%), followed by inpatient (14.6% vs 2.4%) and outpatient settings (13.4% vs. 1.7%). Among patients with detectable HCV RNA and ≥6 months follow-up (n = 872; 444 pre, 428 post), the proportion with a hepatology or infectious diseases clinic visit (27.3% vs. 27.6%) or treatment initiation within 6 months (29.0% vs. 30.7%) was similar pre- and post-intervention. **Conclusion:** Default reflex HCV RNA testing was associated with a large, sustained improvement in timely diagnostic completion across care settings, particularly in the ED. However, improved diagnostic completion did not translate into improved specialty linkage or treatment initiation, highlighting persistent downstream barriers in the HCV care cascade.

3272 | UNIVERSAL INTEGRATED HBV AND HCV SCREENING IN PRIMARY CARE REVEALS A SUBSTANTIAL HIDDEN BURDEN AND ACHIEVES EXCELLENT LINKAGE TO CARE: A WHO-ALIGNED DECENTRALIZED MODEL

Imma Valls Figueras[1] Maria Santos[1] Montse Mullol[1] Ariadna Rando-Segura[2] Elena Vargas-Accarino[3] Maria Buti[4], [1]CAP Sant Rafael, Primary Care Department, Barcelona, Spain, [2]Microbiology Department, Vall d'Hebron University Hospital, Barcelona, Spain, [3]Vall Hebron Research Institute, [4]Hospital Valle Hebron

Background: Risk-based screening for hepatitis B virus (HBV) and hepatitis C virus (HCV) misses many infected individuals, particularly those without recognized risk factors or elevated liver enzymes. Decentralized screening integrated into primary care may improve diagnosis and linkage to treatment. We evaluated the feasibility and effectiveness of a universal HBV/HCV screening program embedded in routine primary care and linked to hepatology referral pathways. **Methods:** We conducted a prospective interventional study including adults attending a primary care center for routine blood testing between February 2023 and February 2025. Universal screening for HBsAg and anti-HCV was incorporated into standard laboratory panels. Positive serologies automatically triggered reflex HBV-DNA and HCV-RNA testing. Liver fibrosis was assessed using non-invasive markers (FIB-4 and APRI), and participants completed a structured risk factor questionnaire. Positive cases were referred directly to hepatology through an integrated electronic pathway designed to facilitate rapid linkage to care. **Results:** A total of 3,103 individuals were screened; 41% were male, mean age was 51 years, 69% were Caucasian, and 64% were born in Spain.Anti-HCV prevalence was 2%, while active HCV infection (HCV-RNA positive) was identified in 0.35% of participants. Among viremic individuals, 82% were successfully linked to hepatology care and initiated antiviral therapy. HBsAg prevalence was 0.8%, and 92% of newly identified or previously unlinked HBV-positive individuals were connected to specialist care. Among patients evaluated by hepatologists, 25% initiated HBV treatment. Non-invasive fibrosis assessment identified advanced fibrosis in two anti-HCV-positive patients (FIB-4 >3.25 and APRI >1.5), highlighting the potential clinical impact of missed diagnoses.In multivariable analysis, recognized risk factors (OR 2.52, $p<0.001$) and elevated ALT levels (OR 1.007, $p=0.002$) were independently associated with anti-HCV positivity. Elevated ALT was also associated with detectable HCV-RNA (OR 1.007, $p=0.015$). No significant predictors were identified for HBsAg positivity.Importantly, 45% of individuals with active HCV infection and 44% of HBsAg-positive patients had neither recognized risk factors nor elevated ALT levels and therefore would likely have remained undiagnosed under current risk-based screening approaches. **Conclusion:** Universal HBV/HCV screening integrated into primary care identified a substantial hidden burden of viral hepatitis missed by conventional risk-based approaches. Reflex testing and automated referral pathways achieved high linkage-to-care and treatment rates, supporting universal primary care-based screening as a pragmatic strategy to advance viral hepatitis elimination goals.

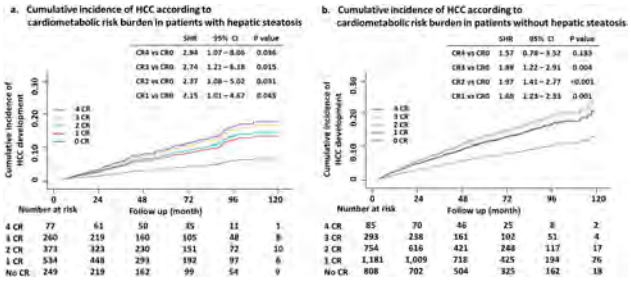
3273 | IMPACT OF CARDIOMETABOLIC RISK ON RESIDUAL HCC RISK AFTER HCV CURE DIFFERS BY HEPATIC STEATOSIS STATUS: A REAL-C STUDY



Haruki Uojima[1] Hidenori Toyoda[2] Rui Huang[3] Takanori Suzuki[4] Chung-Feng Huang[5] Eiichi Ogawa[6] Dae Won Jun[7] Akito Nozaki[8] Manabu Morimoto[8] Treta Purohit[9] Huy Trinh[10] Takashi Honda[11] Cheng-Hao Tseng[12] Yao-Chun Hsu[13] Masanori Atsukawa[14] Tsunamasa Watanabe[15] Hiroshi Abe[16] Fanpu Ji[17] Carmen Preda[18] Masaru Enomoto[19] Philip Vutien[20] Toru Ishikawa[21] Carla Lam[22] Koichi i Takaguch[23] Hiroaki Haga[24] Norio Itokawa[14] Motoyuki Kohjima[25] Hideyuki Nomura[26] Eiji Kajiwara[27] Koichi Azuma[28] Kazufumi Dohmen[29] Akira Kawano[30] Toshimasa Koyanagi[31] Aritsune Ooho[32] Takeaki Satoh[33] Kazuhiro Takahashi[34] Eileen Yoon[35] Sang Bong Ahn[36] Do Seon Song[37] Hyun Jin Cho[38] Jang Han Jeong[39] Seung Ha Bak[40] Satoshi Yasuda[41] Yunyu Zhao[17] Yishan Liu[17] Ritsuzo Kozuka[42] Mayumi Maeda[43] Yoshiyuki Ueno[24] Wan Long Chuang[44] Jee-Fu Huang[44] Chia-Yen Dai[44] Ramsey Cheung[45] Ming-Lun Yeh[46] Pei-Chien Tsai[44] Man-Fung Yuen[47] Norihiro Furusyo[48] Chao Wu[49] Jun Hayashi[50] Ming-Lung Yu[51] Yasuhito Tanaka[1] Mindie Nguyen[43], [1]Kumamoto University, [2]Department of Gastroenterology, Ogaki Municipal Hospital, Gifu, Japan, [3]Nanjing Drum Tower Hospital, [4]Nagoya City University Graduate School of Medical Sciences, [5]Kaohsiung Medical University Hospital, [6]Kyushu University Hospital, [7]Hanyang University, [8]Yokohama City University Medical Center, [9]San Jose Gastroenterology, [10]Gastroenterology & Hepatology, [11]Nagoya University Graduate School of Medicine, [12]E-Da Cancer Hospital/I-Shou University, [13]E-Da Hospital/I-Shou University, [14]Division of Gastroenterology and Hepatology, Nippon Medical School, [15]Division of Gastroenterology and Hepatology, St. Marianna University School of Medicine, [16]Division of Gastroenterology and Hepatology, Shinmatsudo Central General Hospital, [17]The Second Affiliated Hospital of Xi'an Jiaotong University, [18]Gastroenterology&Hepatology Department, Clinic Fundeni Institute, [19]Osaka Metropolitan University, [20]Division of Gastroenterology and Hepatology, University of Washington, [21]Department of Gastroenterology, Saiseikai Niigata Hospital, [22]Department of Medicine, The University of Hong Kong, [23]Department of Hepatology, Kagawa Prefectural Central Hospital, [24]Department of Gastroenterology, Yamagata University of Medicine, [25]Department of Gastroenterology, NHO Kyushu Medical Center, [26]Department of Internal Medicine, Haradoi Hospital, [27]Kajiwara Clinic, [28]Department of Hepatology, Kyushu Central Hospital, [29]Department of Internal Medicine, Chihaya Hospital, [30]Department of Hepatology, Kitakyushu Municipal Medical Center, [31]Department of Hepatology, Fukuoka City Hospital, [32]Department of Hepatology, Steel Memorial Yawata Hospital, [33]Center for Liver Disease, NHO Kokura Medical Center, [34]Department of Internal Medicine, Hamanomachi Hospital, [35]Department of Internal Medicine, Hanyang University, College of Medicine, [36]Department of Internal Medicine, Eulji University Seoul hospital, [37]The Catholic University of Korea, [38]Departments of Internal Medicine, Gyeongsang National University Hospital, [39]Departments of Internal Medicine, Hallym University Dongtan Scared Heart Medical center, [40]Departments of Internal Medicine, Inje University Haeundae Paik Hospital, [41]Ogaki Municipal Hospital, [42]Graduate School of Medicine Department of Clinical Medical Science, Osaka Metropolitan Universit, [43]Stanford University Medical Center, [44]Kaohsiung Medical University Hospital, Kaohsiung Medical University, [45]Division of Gastroenterology and Hepatology, Veterans Affairs Palo Alto Health Care System, [46]Kaohsiung Medical University, [47]The University of Hong Kong, [48]Taihaku Avenue Clinic, [49]Affiliated Hospital of Medical School, Nanjing Universit, [50]Kyushu University, [51]Kaohsiung Medical University/ Kaohsiung Medical University Hospital

Background: Cardiometabolic risk (CMR) is increasingly recognized as a contributor to hepatocarcinogenesis after HCV cure. However, hepatic steatosis may diminish with aging and fibrosis progression, potentially modifying the association between cardiometabolic risk and HCC risk after HCV cure. We aimed to evaluate the impact of CMR on residual HCC risk according to HS status after HCV cure. **Methods:** We conducted a multinational retrospective cohort study using data from the REAL-C consortium, including 4,614 patients with HCV infection who achieved HCV cure (sustained virologic response, SVR) following direct-acting antiviral therapy across 23 centers in six countries/regions. Patients were stratified according to the presence or absence of hepatic steatosis at baseline. CMR burden was defined according to the number of CMR factors, including obesity, diabetes mellitus, dyslipidemia, and hypertension. The primary endpoint was incident HCC after SVR, evaluated according to CMR burden stratified by the presence of hepatic steatosis. Fine–Gray competing-risk regression models were applied, with non-HCC death treated as a competing event. **Results:** This study evaluated 4,614 patients with HCV cure, including 1,493 patients with hepatic steatosis and 3,121 patients without hepatic steatosis. Patients with hepatic steatosis were younger and exhibited lower fibrosis burden. During follow-up, HCC occurred in 108 patients with hepatic steatosis and 326 patients without hepatic steatosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(P < 0.001). In patients with hepatic steatosis, cumulative HCC incidence demonstrated a graded increase according to increasing CMR burden, with progressively higher subdistribution hazard ratios across risk categories (Figure 1a). In contrast, among patients without hepatic steatosis, although CMR burden was also associated with HCC risk, the incremental increase in cumulative HCC incidence across categories appeared less distinct (Figure 1b). In multivariable analysis, increasing CMR burden remained independently associated with HCC development in patients with hepatic steatosis (adjusted SHR 2.42, 95% CI 1.03–5.67, P = 0.038), together with cirrhosis (adjusted SHR 3.61, 95% CI 2.18–5.98, P < 0.001). In contrast, among patients without hepatic steatosis, the association between CMR burden and HCC risk was attenuated after adjustment (adjusted SHR 1.37, 95% CI 0.97–1.94, P = 0.073), whereas cirrhosis remained the predominant determinant of HCC development (adjusted SHR 3.93, 95% CI 2.91–5.31, P < 0.001). **Conclusion:** The impact of CMR on residual HCC risk after HCV cure differed according to hepatic steatosis status. A graded increase in HCC risk with increasing CMR burden was observed in patients with hepatic steatosis, but not among those without hepatic steatosis.

3274 | A CASE SERIES ON OUTCOMES OF HEPATITIS C INFECTED PATIENTS WHO RECEIVED FULL COURSE OF 84 TABLETS OF SOFOSBUVIR/ VELPATASVIR AT THE BEGINNING OF THERAPY

Farrah Black[1] Stacey Scherbakovsky[1] Amy Seale[2], [1]Gilead Sciences, [2]Gastro Group

Background: There are limited data around prescribing and dispensing 84 tablets of SOF/VEL at the onset of treatment. A phase 4, open-label, single-arm trial (MINMON) was published evaluating the safety and efficacy of prescribing and dispensing all 84 tablets at the onset of treatment with no scheduled in person follow-up visits. The study included 399 patients and resulted in an overall 95% sustained virologic response rate (SVR) with no treatment related serious adverse events and no treatment discontinuations.(1) Despite these findings, the standard of care continues to rely on monthly prescription refills and frequent in-person follow-up visits. This approach is not patient-centered and poses significant barriers to access, particularly for individuals in rural settings. This case series addresses this by providing data on dispensing all 84 tablets at once with minimal monitoring during therapy. **Methods:** This case series includes patients from a single center in rural Louisiana. A retrospective chart review was conducted from January 1, 2022, through March 1, 2025. Patients with an HCV viral load (VL) who were then prescribed 84 tablets of SOF/VEL were included. Data collected included: age, sex, genotype, HBV and/or HIV co-infection, housing stability, history of and/or active IV drug use, specific medications, follow-up contact at treatment completion week 12 and 12 weeks post treatment, reported adverse events, self-reported adherence and SVR (drawn between 4-24 weeks post treatment). **Results:** 55 patients were included in the analysis. The mean age was 49.5 years (range 25-78), and 42% were female. The SVR12 per-protocol analysis was 100%, and the intention to treat analysis was 78.8%. 43 patients achieved SVR and 12 patients were lost to follow up and did not have SVR labs drawn. 41 patients had a history of IV drug use and 3 were actively using. 14 patients were on Medication Assisted Treatment: 11 buprenorphine, 1 methadone and 2 naltrexone. There were no reported treatment discontinuations. **Conclusion:** This case series of 55 patients in the real world support the implementation of the updated simplified treatment algorithm recommended by AASLD and demonstrates patients can be safely and effectively treated and cured with 84 tablets dispensation and minimal monitoring.

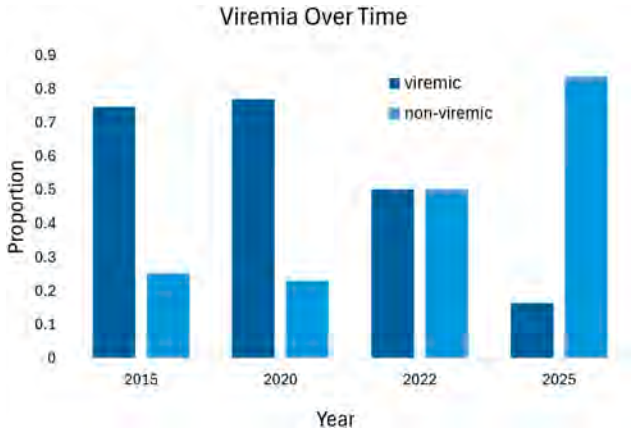
3275 | TRACKING OF HCV VIREMIA RATES IN VANCOUVER, CANADA'S INNER-CITY REVEALS CONSISTENT AND SUSTAINED DECREASES OVER TIME



Christina Wiesmann[1] Shana Yi[2] David Truong[2] Brian Conway[2], [1]Simon Fraser University, [2]Vancouver Infectious Diseases Centre

Background: Vancouver, Canada's downtown east side (DTES) neighbourhood is known for high rates of poverty, drug use, and Hepatitis C (HCV) infection, with up to 40% of individuals having HCV exposure. The Vancouver Infectious Diseases (VIDC) has been providing accessible point-of-care HCV testing and treatment (as allowed by treatment restrictions), to individuals living in this neighborhood for more than 10 years. **Methods:** VIDC has provided and continues to provide regular point-of-care antibody testing, follow-up confirmation of viremia, and HCV treatment to individuals encountered at various inner-city locations including community centers, shelters, and single room occupancy buildings for more than 10 years. In addition, the physicians at the clinic receive a large number of referrals for providing HCV treatment to individuals who are part of Vancouver's inner-city population. **Results:** The proportion of individuals tested who are positive for HCV antibodies each year from 2015 to 2025 revealed no clear differences or trends, with similar rates of antibody positivity across all 10 years. In 2015, more than 70% of individuals we encountered at our

community pop-up clinics were viremic for HCV. In 2020, the proportion of viremic individuals encountered was similar (~70%); however, in 2022 the proportion was reduced to around 50% and in 2025 the proportion was less than 20% (Figure 1). From 2015 until 2018 (inclusive), VIDC treated an average of 20-40 individuals actively using drugs per year. From 2019 until 2024, this number increased to around 100 individuals or more per year, and in 2025 was around 40 individuals. **Conclusion:** Through universal access to highly effective curative DAA treatments and high rates of treatment, we are well on our way to achieving HCV elimination in Vancouver's DTES neighbourhood. Follow-up work will determine if the rates of antibody positivity and viremia continue to decrease in the population over time. This work will ultimately help to inform and provide evidence-based support for micro-elimination efforts in similar communities around the world.

3276 | AN INNOVATIVE MULTICENTER COLLABORATIVE RE-LINK MODEL SIGNIFICANTLY IMPROVES RE-ENGAGEMENT AND TREATMENT IN DIAGNOSED BUT UNTREATED CHRONIC HEPATITIS C PATIENTS

Aiqi Lu[1] Jinfeng Liu[2] Guangda Tang[3] Yuqian Du[1] Shuxin Mo[1] Zhijiao Xiong[4] Mingya Xiao[5] Wenli Li[5] Long Xu[6] Runqi Luo[6] Hong Li[7] Lingjie Wu[7] Fengdi Chen[8] Xi He[8] Simin Lai[9] Xiaocong Wu[10] Zeng Pang[10] Jianping Li[1] Yinjiao Cai[3] Honglian Bai[2] Yujuan Guan[11], [1]Guangzhou Eighth People's Hospital , Guangzhou Medical University, [2]The First People's Hospital of Foshan, [3]Luoding People's Hospital, [4]Guangdong North Second People's Hospital, [5]Guangdong Second Provincial General Hospital, [6]The Second Affiliated Hospital of Guangzhou Medical University, [7]Shantou Central Hospital, [8]Qingyuan People's Hospital, [9]The Fourth Affiliated Hospital of Guangzhou Medical University, [10]Central People's Hospital of Zhanjiang, [11]Guangzhou Eighth People's Hospital, Guangzhou Medical Univ.

Background: Chronic hepatitis C patients who are diagnosed but untreated (DBU) frequently fail to re-engage in care, representing a major barrier to hepatitis C virus (HCV) elimination. We developed a multicenter, cross-regional re-link (re-engagement to care) model led by a specialized hospital and evaluated its effectiveness and determinants of successful re-link. **Methods:** We conducted a prospective multicenter interventional study in Guangdong Province, China. From 2022 to 2023, 24,664 HCV RNA–positive patients without records of direct-acting antiviral (DAA) therapy were identified through the Center for Disease Control and Prevention surveillance system in Guangdong. Adult DBU patients ($\geq$18 years) were eligible; exclusions included invalid contact information or death prior to outreach. Dedicated hepatitis C re-link teams across 10 hospitals in 7 cities implemented standardized telephone outreach. The teams are responsible for the hepatitis C patient re-link program in partial areas of Guangdong Province.The primary outcome was the re-link rate, defined as the proportion of successfully contacted patients who returned to hospital for follow-up. Secondary outcomes included DAA treatment initiation among re-linked patients and independent predictors of re-link success, assessed by multivariable logistic regression. HCV knowledge was measured using a structured questionnaire (score 0–8; $\geq$6 defined as high knowledge). **Results:** Among 5,254 eligible patients, 3,343 (63.6%) were successfully contacted. Of those contacted, 2,052 returned for follow-up, yielding a re-link rate of 61.4%, substantially higher than the historical baseline (<20%). Among re-linked patients, 2,027 completed questionnaires (98.8%). The mean age was 51.6 ± 12.4 years; 27.0% were $\geq$60 years, 62.8% were male, 20.8% had at least a college education, 44.7% had urban employee medical insurance, and 60.2% demonstrated high HCV knowledge. Higher education, urban employee insurance, and high HCV knowledge were independently associated with successful re-link (all $P < 0.001$), whereas age $\geq$60 years, perceived absence of symptoms or treatment need, and concerns about treatment cost were associated with unsuccessful re-link (all $P < 0.01$). Among re-linked patients, 1,691 initiated DAA therapy (treatment initiation rate 82.4%). Re-link and treatment rates were comparable across different city tiers (table 1). **Conclusion:** This multicenter collaborative re-link model substantially improved re-engagement of DBU hepatitis C patients, achieving a 61.4% re-link rate and high treatment rate (>80%) across diverse hospital settings. The establishment of a dedicated, well-trained re-link team operating under a clear and standardized process was central to its

success. This scalable model provides a practical strategy to strengthen linkage to care and supports progress toward HCV elimination.

Table 1. City Tier–Stratified Analysis of Re-link Outcomes Among DBU Hepatitis C Patients

Distribution of Medical Institutions by City Tier	Number of centers	Patients eligible for re-link	Patients successfully contacted by phone	Patients who returned for follow-up	Re-link rate (%)	Difference from overall mean (%)	Patients initiating treatment	Treatment rate (%)	Difference from overall mean (%)
First-tier / New first-tier cities	5	3058	1832	1155	63.0	+1.6	923	79.9	-2.5
Third-tier / Fourth-tier cities	4	1676	1120	629	56.2	-5.2	539	85.7	+3.3
County-level cities	1	520	391	268	68.5	+7.1	229	85.4	+3.0
Total	10	5254	3343	2052	61.4	NA	1691	82.4	NA

Note: City tiers were defined according to the "2023 City Business Attractiveness Ranking" by the Yicai (First Financial) New First-tier Cities Research Institute. First-tier/New first-tier city centers include Guangzhou Eighth People's Hospital Guangzhou Medical University, The Fourth Affiliated Hospital of Guangzhou Medical University, The Second Affiliated Hospital of Guangzhou Medical University, Guangdong Second Provincial General Hospital, and The First People's Hospital of Foshan; third-/fourth-tier city centers include Shaoxing Central Hospital, Central People's Hospital of Zhanjiang, Guangdong North Second People's Hospital, and Qingyuan People's Hospital; the county-level city center is Laoding People's Hospital.

3277 | EVALUATING EHR-BASED PATIENT IDENTIFICATION STRATEGIES FOR HEPATITIS C LINKAGE TO CARE IN NORTH CAROLINA

Lauryn Ursery[1] Corinne Spencer[2], [1]Gillings School of Global Public Health, University of North Carolina, Chapel Hill, USA, [2]School of Medicine, University of North Carolina, Chapel Hill, USA

Background: Hepatitis C (HCV) remains a leading contributor to liver cancer and liver disease in the United States. Creating accurate registries of diagnosed but untreated (DBU) patients is vital for hepatitis elimination, but methods used to generate registries vary in effectiveness, cost, and time. To evaluate the effectiveness of new tools, we compared three methods to generate registries of DBU HCV-positive individuals. **Methods:** We utilized three patient extraction methods to generate registries of DBU HCV-positive individuals living in North Carolina between May 1, 2024 and May 7, 2025. First, we used EPIC's SlicerDicer, a self-service reporting tool, to identify HCV-positive individuals. We excluded individuals with visits to infectious diseases (ID) or gastroenterology (GI) specialists, with this criterion intended to serve as a proxy for excluding those who were likely to have already received HCV care. The second approach involved partnering with a programmer from UNC's Perinatal Research Service Center (PRSC), who queried patient data to identify HCV-positive individuals and include indicators for whether patients had already seen a specialist or been prescribed HCV medications. Finally, we used SideKick, an AI tool embedded into EPIC, to identify HCV-positive individuals while excluding those who had seen a specialist or were prescribed HCV medication. All data were collected in REDCap and aggregate statistics were computed in R. **Results:** The SlicerDicer registry identified 724 HCV-positive individuals. After screening out patients who were deceased (n = 61), did not live in North Carolina (n = 19), or did not have true HCV RNA+ test results (n = 24), 624 individuals remained. The majority (63.9%, n = 399) of these individuals were confirmed to be DBU via chart review, while 36.1% (n = 225) were found to have already been linked to care (Table 1). Approximately 66.7% of those previously linked received hepatitis care via a GI or ID specialist, while one quarter (25.1%) received care via a generalist. The PRSC registry identified 1,236 HCV-positive individuals, almost half (51.1%, n = 632) of whom also appeared in the SlicerDicer registry. Among the 605 individuals captured by both registries and eligible for chart review, 64.0% (n = 389) were confirmed to be DBU (Table 1). The EPIC SideKick AI tool identified 508 DBU HCV patients, 71.1% (n = 361) of whom were also captured in the SlicerDicer registry. Among the 336 individuals appearing in both registries and eligible for chart review, 65.8% (n = 221) were confirmed to be DBU (Table 1). **Conclusion:** Each patient registry method showed flaws in identifying DBU individuals. Using visits with specialists as a proxy for HCV care failed to capture the growing number of patients receiving treatment through generalists. New AI-based tools show promise, but refining search criteria to reflect how HCV care is delivered is essential to building accurate DBU registries.

Table 1. Comparison of Search Criteria and Effectiveness Across Three Generation Methods for HCV Patient Registries.

Search Criteria	Slicer Dicer	Programmer-Defined Query	SideKick
HCV RNA Positivity	√	√	√
Excluded Patients with ID/GI Visits	√	√	√
Excluded Patients with HCV Treatment Prescription	–	√	√
Effectiveness	*N* (%)	*N* (%)	*N* (%)
Total Identified	724	1,236	508
Overlap with Slicer Dicer	–	632 (51.1)	361 (71.1)
Number eligible for chart review[a]	624 (86.2)	608 (49.2)	336 (66.1)
Confirmed DBU by chart review[b]	399 (63.9)	389 (64.0)	221 (65.8)
Chart review showed ID visit[c]	50 (8.01)	49 (8.10)	27 (8.04)
Chart review showed GI visit[c]	100 (16.0)	93 (16.1)	48 (14.2)
Chart review showed generalist visit[c]	57 (9.13)	56 (9.21)	31 (9.22)

[a] Eligibility for chart review was defined as individuals who were alive, resided in North Carolina, had a positive HCV RNA test result.
[b] Confirmed DBU by chart review was defined as patients who had not already received HCV treatment per manual review of their electronic health records.
[c] Chart review showed ID/GI/generalist visit was defined as individuals who were found to have already been connected to HCV care via an ID or GI specialist or generalist, respectively, via manual review of their electronic health records.

3278 | INCENTIVIZING ADHERENCE TO IMPROVE OUTCOMES IN A HEPATITIS C VIRUS (HCV) TREATMENT TRIAL: RESULTS FROM THE KENTUCKY VIRAL HEPATITIS TREATMENT (KEY TREAT) STUDY

Jennifer Havens[1] Takako Schaninger[2] Michelle Lofwall[1] Sharon Walsh[1], [1]University of Kentucky College of Medicine, [2]University of Kentucky

Background: As we march towards worldwide elimination of the hepatitis C virus (HCV), critical gaps still exist in treatment access for those at greatest risk for HCV transmission; namely those who use and inject drugs. The purpose of this analysis is to examine the role of incentives to improve adherence to direct acting antiviral (DAA) treatment and HCV cure among rural HCV+ individuals with a history of drug use. **Methods:** KeY Treat was conducted between 2019-2025 in Appalachian Kentucky, enrolling 380 rural residents. Point-of-care (POC) RNA testing was conducted with most RNA-positive participants initiating same day treatment with sofosbuvir/velpatasvir (sof/vel). Incentivized daily medication reminders (tailored to the individuals' chosen time) were provided via text or Facebook (for those without a phone/stable phone number). A response to daily reminders (any acknowledgement was considered a response – text, emojis, pictures) earned participants $1, and they could earn up to $84 for responding to each daily reminder during the treatment regimen. Sustained virologic response was established using POC RNA testing at least 12-weeks after treatment completion (SVR-12). Generalized linear modeling was used to estimate the impact of medication reminders on SVR-12. **Results:** Most participants preferred SMS reminders (53.9%), followed by Facebook (33.7%). The median proportion of response to reminders, calculated as the total number of responses divided by 84 days, was 74.4% (interquartile range: 42.3%, 92.8%). Response rates were significantly lower among people who continued to inject drugs (54.3% vs. 71.7%, $p < 0.001$), men, and those reporting unstable housing. Intent-to-treat analyses revealed that for each additional percentage point increase in incentive response rate, the odds of SVR-12 increased by 1.22 (95% confidence interval [CI]: 1.02, 1.48). **Conclusion:** Incentivizing adherence to DAAs using medication reminders shows promise in improving cure rates. Compared to the significant costs associated with not treating and/or not achieving SVR due to suboptimal adherence, incentivizing at $1/day is likely highly cost-effective, with or without insurance reimbursement. Limitations of the study include greater likelihood that response to reminders was a proxy for greater overall stability and that response was not a guarantee that participants took the medication. Even with these potential limitations, results from this study indicate that minimal investment via incentivized medication reminders may improve treatment outcomes.

3279 | INCIDENCE AND PREVALENCE OF DECOMPENSATED CIRRHOSIS AMONG PATIENTS WITH HEPATITIS C VIRUS INFECTION: POOLED ESTIMATES ACROSS US CLAIMS DATABASES, 2011 TO 2023

Patrick Horne[1] Kevin Leyden[2] Joseph Guilfoyle[3] Julie Zhao[3] Lisa Johnson[3] Anthony Martinez[4], [1]University of Florida, [2]NJCRI (North Jersey Community Research Initiative), [3]AbbVie Inc, [4]University at Buffalo Jacobs School of Medicine

Background: Decompensated cirrhosis is a serious complication in adults with chronic hepatitis C virus (HCV) infection, leading to increased morbidity and health care utilization. There is limited data on incidence and prevalence of HCV-related decompensated cirrhosis in the United States. This study aimed to estimate annual incidence and prevalence of HCV-associated decompensated cirrhosis in insured US populations with HCV, but without other chronic liver disease. **Methods:** MarketScan commercial, Medicare, and Medicaid claim databases were analyzed for adults aged 18 years or older with at least one claims diagnosis of chronic HCV (ICD-9: 070.44, 070.54, V02.62; ICD-10: B18.2) from 2011 to 2023. Individuals with hepatitis B, metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction-associated steatohepatitis (MASH), alcohol-associated liver disease, autoimmune or drug-induced hepatitis, hepatocellular carcinoma, or liver transplantation were excluded. Decompensated cirrhosis was identified using validated diagnosis algorithms based on clinical complications such as variceal bleeding,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

hepatic encephalopathy, ascites, or jaundice.[1] Annual incidence rates were calculated for 2011–2023 in patients with ≥1 year continuous prior enrollment. Prevalence was calculated for 2020–2023, accruing cases from 2018 onward. All rates were age- and sex-standardized to the 2020 US census population. **Results:** Overall, 616,137 patients with HCV and without other diseases were included, of whom 19,125 had decompensated cirrhosis and >1 year enrollment prior to index. Annual incidence rates of HCV-associated decompensated cirrhosis in adults ranged from 0.7% to 1.3% during 2011–2023. Incidence has decreased by 44% from its peak in 2016 to 2023. Annual prevalence of HCV-related decompensated cirrhosis ranged from 2.5% to 2.9% for 2020–2023. Stratified analyses showed higher incidence and prevalence among older age groups (over 4% for age 75 and older) and among males compared to females. Prevalence was elevated in Medicare and Medicaid populations versus commercial insurance ranging from 1.3-2.8%, 1.7-3.0%, and 0.9-2.1% respectively. **Conclusion:** HCV-related decompensated cirrhosis prevalence among insured US adults has remained stable over eight years. These findings highlight the ongoing need for targeted interventions, particularly for at-risk populations such as older adults, males, and those covered by Medicare or Medicaid, as well as the necessity for further research into uninsured groups to fully understand the national impact.Reference: 1. 3280 | EVALUATING DETECTION AND OUTCOMES BEFORE AND AFTER UNIVERSAL HEPATITIS C SCREENING IN PREGNANCY RECOMMENDATION

Priyanka Gaur[1] Daniel Chang[2] Suzy Newton[2] Keira Hall[2] Talia Pindyck[2] Lindsey Sizemore[2] Kate Woodworth[2] Jason Hsi[2] Lorraine Yeung[2] Moeun Son[1] Van Tong[2], [1]Weill Cornell Medicine, [2]Centers for Disease Control and Prevention

Background: To evaluate detection and outcomes among women with preconception and prenatal hepatitis C virus (HCV) infection before and after universal HCV screening recommendation in 2020, using the U.S. Centers for Disease Control and Prevention (CDC) Surveillance for Emerging Threats to Mothers and Babies Network (SET-NET). **Methods:** Pregnancies among women with a laboratory-confirmed HCV infection during or up to 1 year prior to pregnancy ("in pregnancy") with a singleton, live birth between 2018-2023 were reported from Massachusetts, New York City, New York State, Los Angeles County, Pennsylvania, Tennessee, and Washington. We calculated rates of HCV detection in pregnancy per 100,000 live births and examined outcomes pre- (January 2018-December 2019) and post-implementation (July 2020-December 2023) of the universal screening recommendation. January-June 2020 was a washout period for the COVID-19 pandemic peak and guideline dissemination. HCV rates and obstetric outcomes were compared using t-tests or chi-square tests. **Results:** 3,694 pregnancies were included: 1,446 pre-implementation, 1,896 post-implementation, and 352 in the washout period. HCV detection increased from 172.6 to 210.0 cases per 100,000 live births post-implementation (i.e., approximately 37 additionally detected HCV-affected pregnancies per 100,000 births) ($p < 0.001$). Post-implementation, there was a shift toward earlier detection of HCV in the first trimester ($p = 0.001$, Table 1). There were similar proportions of cesarean and breastfeeding. Only 4.3% and 5.8% of women had a prior history of HCV treatment pre- and post-implementation, respectively ($p = 0.16$). **Conclusion:** These preliminary findings suggest a modest increase in the HCV detection rate and earlier detection of HCV in pregnancy after the universal screening recommendation. Aligned with no contraindications to vaginal delivery or breastfeeding related to HCV, there are no observed changes in cesarean or breastfeeding frequency. There are opportunities for antiviral treatment to attain HCV elimination goals, particularly for women who do not breastfeed and may be considered for expedited antiviral treatment.

3281 | DYNAMIC EVOLUTION OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE, STEATOTIC LIVER DISEASE, AND CARDIOMETABOLIC RISK FACTORS AFTER DIRECT-ACTING ANTIVIRAL-INDUCED HEPATITIS C CURE

Chen-Hua Liu[1] Yun-Chu Chen[1] Yu-Ping Chang[2] Pin-Nan Cheng[3] Yu-Jen Fang[4] Chi-Yi Chen[5] Wei-Yu Kao[6] Chih-Lin Lin[7] Sheng-Shun Yang[8] Yu-Lueng Shih[9] Cheng Yuan Peng[10] Fu-Jen Lee[11] Ming-Chang Tsai[12] Chih-Horng Wu[13] Shang-Chin Huang[14] Tung-Hung Su[1] Tai-Chung Tseng[1] Chun Jen Liu[1] Pei-Jer Chen[1] Jia-Horng Kao[1], [1]National Taiwan University Hospital, [2]National Taiwan University Biomedical Park Hospital, [3]National Cheng Kung University Hospital, [4]National Taiwan University Hospital, Yun-Lin Branch, [5]Chia-Yi Christian Hospital, [6]Taipei Medical University Hospital, [7]Taipei City Hospital, Ren-Ai Branch, [8]Kuan Tien General Hospital, [9]Tri-Service General Hospital, [10]China Medical University Hospital, [11]Fu Jen Catholic University Hospital, [12]Chung Shan Medical University Hospital, [13]Shuang Ho Hospital, [14]National Taiwan University

Background: Data on dynamic changes in determinants of metabolic dysfunction–associated steatotic liver disease (MASLD) following direct-acting antiviral (DAA)-induced hepatitis C virus (HCV) cure remain limited. **Methods:** We enrolled 1,661 patients achieving sustained virologic response after DAAs. MASLD was defined as presence of steatotic liver disease (SLD), identified by controlled attenuation parameter (CAP) $\geq$248 dB/m, along with $\geq$1 cardiometabolic risk factor (CMRF). Distributions of MASLD, SLD, and CMRFs before and after viral cure were compared. Akaike information criterion (AIC)-based multivariable regression models were used to identify factors associated with MASLD, SLD, and CMRF changes. **Results:** The prevalence of MASLD (44.2% vs. 35.8%, $p<0.001$), SLD (44.5% vs. 35.9%, $p<0.001$), and CMRF burden ($p=0.047$) decreased after HCV cure. Glycemic (45.2% vs. 42.5%, $p=0.012$) and triglyceride (15.3% vs. 23.9%, $p<0.001$) criteria changed significantly. Age >50 years (aOR: 1.60, 95% CI: 1.07–2.43), absence of glycemic criterion (aOR: 1.37, 95% CI: 1.04–1.97), and absence of high-density lipoprotein-cholesterol (HDL-C) criterion (aOR: 1.58, 95% CI: 1.10–2.27) predicted SLD regression. Age $\leq$50 years (aOR: 1.73, 95% CI: 1.18–2.52), absence of SLD (aOR: 1.45, 95% CI: 1.01–2.07), and absence of hypertension (aOR 1.72, 95% CI 1.15–2.60) predicted glycemic criterion regression. Age $\leq$50 years (aOR: 1.48, 95% CI: 1.07–2.04), absence of SLD (aOR: 1.41, 95% CI: 1.07–1.93), and absence of HDL-C criterion (aOR: 2.31, 95% CI: 1.68–3.19) predicted triglyceride criterion emergence. **Conclusion:** Following HCV cure, MASLD, SLD, and glycemic abnormalities decreased, whereas triglyceride abnormalities increased, indicating heterogeneous metabolic trajectories after viral eradication.

3282 | HCV TREATMENT TIMING AND HEPATOCELLULAR CARCINOMA RISK AMONG PEOPLE WHO INJECT DRUGS IN TAIWAN AFTER NATIONWIDE HCV ELIMINATION

Yen-Fang Huang[1] Ta-Chien Chan[2] Yu-Ching Huang[3] Hsiu-Ju Lin[4] Emily Ai-hua Wang[5] Chun Jen Liu[6] Chen Hua Liu[7] Ming-Tsan Liu[1] Jyh-Yuan Yang[1] Chin-hui Yang[8] Chien-Ching Hung[9] Yu-Hsin Liao[1] Ching-Han Liu[3], [1]Centers for Disease Control, Taiwan, [2]National Academy of Taiwan, [3]National Research Institute of Chinese Medicine, Taiwan, [4]University of Connecticut, [5]Yale University School of Medicine, [6]National Taiwan Univeristy, [7]National Taiwan University, [8]Centers for Disease Control.Taiwan, [9]National Taiwan Univerity

Background: People who inject drugs (PWID) are at high risk for chronic hepatitis C virus (HCV) infection and hepatocellular carcinoma (HCC). Taiwan launched a nationwide HCV elimination program in 2018, but its impact on high-risk populations remains unclear. We evaluated the association between HCV treatment timing, cirrhosis, and HCC risk among PWID with incarceration history in Taiwan. **Methods:** We conducted a retrospective cohort study using linked incarceration and National Health Insurance databases in Taiwan. Chronic HCV infection was identified using repeated HCV diagnoses, HCV RNA testing, or antiviral treatment records. Participants were followed until HCC diagnosis, death, or December 31, 2022. HCC incidence rates were calculated across three periods: 2008–2012, 2013–2017, and 2018–2022.In the primary analysis, HCV treatment was modeled as a time-varying exposure in multivariable Cox proportional hazards models adjusting for age, sex, HBV, HIV, and cirrhosis. Secondary analyses classified participants into three groups: untreated, treated without pre-existing cirrhosis, and treated with pre-existing cirrhosis. Untreated individuals were not further stratified by cirrhosis because untreated cirrhosis accounted for only 1.5% of the cohort. **Results:** A total of 29,189 PWID with chronic HCV infection were included; 67.9% received HCV treatment. Overall, 87.5% were male, 16.7% had HBV coinfection, 17.3% had HIV infection, and 12.1% had cirrhosis.HCC incidence increased from 1.28 per 1,000 person-years in 2008–2012 to 2.15 in 2013–2017 and 2.91 in 2018–2022. The relative increase was 67.7% before 2018 and 35.3% after implementation of the nationwide HCV elimination program.In the primary time-varying Cox model, HCV treatment was independently associated with reduced HCC risk (adjusted hazard ratio [aHR] 0.81, 95% confidence interval [CI]: 0.66–0.99, p = 0.045). Male sex, older age, HBV coinfection, and cirrhosis were independently associated with increased HCC risk. Cirrhosis was the strongest predictor of HCC (aHR 23.65, 95% CI: 18.44–30.33, p < 0.001).In secondary analyses, individuals treated without pre-existing cirrhosis had substantially lower HCC risk than untreated individuals (aHR 0.25, 95% CI: 0.20–0.32, p < 0.001). In contrast, individuals treated with pre-existing cirrhosis had higher HCC risk than untreated individuals (aHR 2.37, 95% CI: 1.91–2.94, p < 0.001) and markedly higher risk than treated individuals without pre-existing cirrhosis (aHR 9.41, 95% CI: 7.25–12.22, p < 0.001). **Conclusion:** HCC incidence remained high among PWID despite nationwide HCV elimination efforts in Taiwan. HCV treatment was associated with reduced HCC risk, particularly when initiated before cirrhosis development. Cirrhosis remained the dominant predictor of HCC, highlighting the importance of early HCV diagnosis and timely antiviral treatment in marginalized populations.

3283 | ENHANCING HEPATITIS C SCREENING AND MANAGEMENT THROUGH A HOSPITAL-COMMUNITY BIDIRECTIONAL-DRIVEN HCV CARE INTEGRATION MODEL

Panpan Zhai[1] Xueting Ou[1] Liyang Zhou[1] Jiayi Chen[2] Shiyun Wu[1] Yinxing Lin[3] Yi Gao[4] Jing Hu[1] Xing-Fei Pan[1], [1]The Third Affiliated Hospital, Guangzhou Medical University, [2]The Third Affiliated Hospital, [3]he Third Affiliated Hospital, Guangzhou Medical University, [4]Department of Infectious Diseases

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: There are about 50 million people who globally have chronic hepatitis C virus infection. Direct-acting antivirals (DAAs) can cure over 95% of people with HCV infection. However, insufficient screening remains the major barrier to HCV elimination. We developed a hospital-community bidirectional-driven HCV care integration model. This model can enhance hepatitis C screening and management to meet and exceed the WHO's expectations. **Methods:** We developed the in-hospital and community bidirectional-driven HCV care integration model. Hospital management mainly included Department of Infectious Disease, Department of Hospital Infection Control, Laboratory Department, Information Department. Community management included public education, community-wide screening, accurate identification high-risk groups, peer education, targeted referrals, and following-up. We calculated the change of HCV RNA testing volumes, the number of treated and cured patients, and community outreach events. We designed a questionnaire to understand the view of hospital physicians/community physicians, and a random sampling telephone survey questionnaire for patients to understand the impact of community peer education. **Results:** During the implementation period from 2021 to 2024, HCV RNA testing volumes were strategically increased for four consecutive years. The annual HCV RNA testing volume raised from 169 tests in 2020 to 2,201 tests in 2024. The cumulative growth rate of HCV RNA testing volume ranged from 13% to 362%. Since the initiation of the program, 3,219 individuals were diagnosed as HCV infection, and were timely treated with antiviral drugs. During the four-year implementation period, 1,995 individuals had received antiviral treatment, 1,895 achieved sustained HCV cure (Table 1a). 86.6% (13/15) of hospital-based physicians and 90% (72/80) of community physicians indicated that the model had strengthened the hospital-community collaboration. 93.3% (14/15) of hospital physicians and 62.5% (50/80) of community physicians indicated that the model substantially made a progress towards elimination of HCV(Table 1b,c). 35.8% (114/318) and 25.8% (82/318)were referred to our hospital by Community referrals and HCV-cured relatives or friends, respectively(Table 1d). The total number of community outreach events had increased by 3.2-fold (from 5 in 2021 to 16 in 2022), with sustained engagement thereafter (n = 20 in 2023 and 2024). Collectively, these 61 outreach activities doubled the number of communities participating in this activity (from 5 to 10), reaching over 1800 attendees, and 920 patients who sought treatment(Table 1e). **Conclusion:** The volumes of viral testing, diagnosis, treatment, cure for HCV patients were substantially improved following implementation of the hospital-community bidirectional-drive HCV care integration model.

Table 1a. Annual patient numbers across the HCV care cascade, 2020–2024*

Year	HCV RNA testing (n)	HCV RNA positive (n)	Treatment (n)	Cure (n)	Cure (%)
2020 (pre implementation period)	169	39	33	33	93.94%
2021	781	115	118	112	94.92%
2022	1650	722	688	654	95.06%
2023	1860	1046	515	489	95.00%
2024	2201	1336	674	640	95.00%
2021-2024 (during implementation period)	6492	3219	1995	1895	94.99%

*This project was implemented across four components: screening, diagnosis, treatment, and cure. (follow-up) . At each stage, there was a dynamic bidirectional flow of patients—some were referred to our hospital after being screened or diagnosed at external institutions, while others were screened or diagnosed at our hospital and sought care elsewhere. This reflects the dynamic nature of patient movement across institutions. The year-on-year increase in the number of diagnosed and treated patients suggests the effectiveness of the project.

Table 1b. Community physicians' perceptions of barriers and benefits of the HCV elimination program (n=80)

Items / Options	Major barrier	Some barrier	No impact	Some benefit	Major benefit	Not sure / Not familiar with this program
Yourself	0(0%)	2(2.5%)	6(7.5%)	28(35.0%)	41(51.3%)	3(3.8%)
Your patients	0(0%)	2(2.5%)	4(5%)	25(31.25%)	45(56.25%)	4(5%)
Progress of hepatitis C elimination efforts	0(0%)	1(1.25%)	3(3.75%)	22(27.5%)	50(62.5%)	4(5%)
Healthcare network relationships (e.g., collaboration between hospitals and community clinics)	0(0%)	0(0%)	4(5%)	26(32.5%)	46(57.5%)	4(5%)

Table 1c. Hospital physicians' perceptions of barriers and benefits of the HCV elimination program (n=15)

Items / Options	Major barrier	Some barrier	No impact	Some benefit	Major benefit	Not sure / Not familiar with this program
Yourself	0(0%)	0(0%)	0(0%)	1(6.7%)	13(86.7%)	1(6.7%)
Your patients	0(0%)	0(0%)	0(0%)	4(26.7%)	11(73.3%)	0(0%)
Progress of hepatitis C elimination efforts	0(0%)	0(0%)	0(0%)	1(6.7%)	14 (93.3%)	0(0%)
Healthcare network relationships (e.g., collaboration between hospitals and community clinics)	0(0%)	0(0%)	0(0%)	2 (13.3%)	11(73.3%)	2 (13.3%)

Table 1d. Telephone survey results: patient contact outcomes, drivers of re-engagement, and willingness to refer (2021–2024)*

Year	Sampled patients (n)	Successfully contacted patients (n)	Drivers of re-engagement with hospital care				Willingness to refer family/friends with hepatitis C for treatment
			Community referrals	Family/friends referrals	Self-initiated visit after HCV antibody-positive screening	Symptom-driven visit	
2021	21	19	6	7	4	2	11
2022	124	109	41	24	33	11	30
2023	93	83	24	24	30	5	46
2024	122	107	43	27	33	4	80
2021-2024	360	318	114	82	100	22	147

*A total of 360 patients treated between 2021 and 2024 were randomly selected via telephone sampling; 318 were successfully contacted, while 42 did not respond. Among contacted patients, care-seeking was driven by community referral, recommendations from relatives or friends, positive anti-HCV screening results, or physical discomfort. Notably, 147 patients expressed willingness to recommend our hospital to relatives or friends diagnosed with hepatitis C.

Table 1e. Community-based health education activities and patient participation (2021–2024)

	Covered Communities (n)	Education sessions (n)	Education participants (n)	Treated patients who participated in community education (n)
2021	5	5	163	37
2022	8	16	600	299
2023	10	20	496	223
2024	10	20	602	361
Total	10	61	1861	920

3284 | INTEGRATING SOCIAL DETERMINANTS OF HEALTH INTO MACHINE LEARNING MODELS TO PREDICT HEPATITIS C TREATMENT INITIATION AMONG MEDICAID BENEFICIARIES

Suk-Chan Jang[1] Wei-Hsuan Lo-Ciganic[2] Chanakan Jenjai[1] Pilar Hernandez-Con[1] Khoa Nguyen[1] Robert Cook[1] Christine Gage[1] David Nelson[1] Haesuk Park[1], [1]University of Florida, [2]University of Pittsburgh

Background: Despite high cure rates with direct acting antivirals, treatment initiation remains suboptimal among Medicaid beneficiaries with HCV, a population disproportionately affected by adverse social determinants of health (SDoH). We developed and validated machine learning prediction models to identify Medicaid beneficiaries with HCV who were unlikely to initiate treatment and compared model performance with and without regional-level SDoH predictors. **Methods:** We conducted a prognostic modeling using the 2016–2023 OneFlorida+ database for Florida Medicaid beneficiaries aged 18–79 years with laboratory-confirmed HCV infection. Least Absolute Shrinkage and Selection Operator (LASSO) regression models were used to predict treatment initiation. Model 1 included 42 individual-level predictors, encompassing sociodemographic characteristics and clinical characteristics (e.g., cirrhosis, substance use disorders, HIV) during the 6 months prior to the HCV diagnosis date. Model 2 extended Model 1 by adding 57 regional-level predictors based on beneficiaries' residential zip codes, including measures from the Agency for Healthcare Research and Quality SDoH data, Area Deprivation Index, Social Vulnerability Index, and Rural-Urban Commuting Area codes. Model performances were assessed using C-statistics (based on the DeLong test), sensitivity, and specificity. **Results:** Among 4,032 Medicaid beneficiaries with HCV, 8.73% initiated treatment within one year. Training (75%) and validation (25%) samples had similar characteristics (age [SD], 46 [15] years; 52% female; 33% Black). Model 2 achieved a C-statistic of 0.793 (95% CI 0.754–0.833), significantly outperforming Model 1 (0.754 [95% CI 0.715–0.795]; p=0.027). Using the Youden index, Model 2 achieved 66% sensitivity and 80% specificity, with a number needed to screen of 4. Key risk predictors for remaining untreated included HIV infection, opioid injection drug use, pregnancy, and homelessness at the individual level, and residence in areas with higher proportions of Hispanic residents, higher uninsured rates or poverty, and greater area deprivation at the regional level. **Conclusion:** Incorporating regional-level SDoH predictors in addition to individual-level predictors significantly improved the prediction of HCV treatment initiation. These findings underscore the importance of contextual SDoH barriers among Medicaid beneficiaries at risk of remaining untreated or delayed treatment initiation.

3285 | RELINKING PATIENTS WITH HEPATITIS C WHO ARE DIAGNOSED BUT UNTREATED TO CARE IN THE BRONX, NY

Jared Coe[1] Hannah Manley[2] Nicolette Fitzgibbons[3] Matthew Akiyama[1], [1]Albert Einstein College of Medicine/Montefiore Medical Center, [2]Albert Einstein College of Medicine, [3]Montefiore Medical Center

Background: In New York City (NYC), an estimated 59,400 people have chronic hepatitis C virus infection (HCV), with the Bronx having a higher proportion of newly diagnosed cases compared to the citywide average. While the number of people with chronic infections has been declining, many individuals remain eligible for treatment but have been lost to follow-up. This project evaluated a program to link diagnosed but untreated (DBU) patients to care. **Methods:** We created a retrospective cohort of patients with positive HCV antibody and detectable viral load results between 1/1996 and 10/2023 from inpatient, emergency department, or outpatient encounters at Montefiore Medical Center's 3 hospitals and 31 clinics in the Bronx and Westchester County. We began reviewing Epic patient charts in 12/2024 to determine who remained DBU. We also searched the Bronx Regional Health Information (RHIO) database for records at outside facilities as well as city, state, and federal incarceration databases in case patients were in jail/prison over the course of the outreach period. We attempted to contact patients by telephone and/or mail. We also outreached to emergency contacts if the patient could not be reached. Lastly, we sent patient names to the NYC Department of Health (DoH) to request test results that were not available via Epic and RHIO chart review as well as the Department of Homeless Services (DHS) to identify those currently in an NYC shelter. **Results:** In total, 1798 patient charts were reviewed and addressed as of 5/21/2026 with further outreach ongoing. Of the 1046

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

patients who were cured, 968 (92.5%) cases were closed based on chart review and 48 (4.6%) based on updated test records from DoH. Outreach to DHS did not lead to any linkages or updates to contact information as DHS could only provide information on people who were currently residing in a shelter at the time of our outreach. Most mail outreach did not yield any response, although 164 letters were returned and 13 did prompt the patient to call the navigator. 432/1798 (24%) of patients were eligible for relinkage and 15/432 patients were successfully relinked to care yielding a relinkage rate of 3.5% with an additional 8 patients with upcoming appointments. **Conclusion:** HCV elimination will require improvements in information sharing across health record systems and robust outreach to people who are difficult to reach by traditional means. Direct outreach to patients through phone calls and mail, plus searches of public health databases may help link DBU individuals to care; however, additional outreach methods, including home and shelter visits, are needed to increase relinkage rates.

Table 1 Demographic Data (n=2331)	
% Female	829 (35.5%)
% Male	1502 (64.4%)

3287 | IS THERE A DIFFERENCE IN THE PREVALENCE OF NS5A RESISTANT-ASSOCIATED SUBSTITUTIONS BY EXPOSURE TO DIFFERENT NS5A-CONTAINING REGIMENS?

Murad Qirem[1] Jihad Slim[1] Lina AlQirem[2] Shahd Yaghi[1] Ahmad AlQirem[3] Corey Rosmarin-DeStefano[4] Kevin Leyden[5], [1]New York Medical College, [2]UAMS, [3]Jordan University Of Science and Technology, [4]North Jersey Community Research Initiative, [5]NJCRI (North Jersey Community Research Initiative)

Background: NS5A resistance-associated substitutions (RAS) may persist after prior exposure to NS5A-containing direct-acting antiviral regimens and can complicate retreatment decisions in individuals with hepatitis C virus infection (HCV). The two most commonly used regimens for treatment-naive individuals with HCV are sofosbuvir/velpatasvir (S/V) and glecaprevir/pibrentasvir (G/P), In this study, we are interested in the prevalence of RAS to NS5A comparing a prior exposure to each of those agents. **Methods:** We conducted a retrospective review of prospectively collected data from our telehealth-based HCV treatment model in New Jersey among individuals who underwent NS5A resistance testing. Individuals were classified as treatment-naive (TN) to NS5A-containing regimen or treatment-experienced (TE) using documented treatment history. Among treatment-experienced individuals, prior regimen exposure was categorized as S/V, G/P, or other regimens. The primary outcome was the presence of NS5A RAS. Resistance prevalence was compared between TN and TE and across prior regimen exposure groups using Fisher's exact testing. **Results:** A total of 96 individuals underwent NS5A resistance testing, including 41 TN and 55 TE. Overall, NS5A RAS was detected in 14 individuals (14.6%) (Table 1). Resistance was more frequent among TE compared with TN, although the difference did not reach statistical significance (11/55 [20.0%] vs 3/41 [7.3%]; Fisher's exact p = 0.142).Among TE, prior regimen exposure included S/V in 27 individuals, G/P in 20 individuals, and other regimens in 8 individuals. NS5A RAS was detected in 6/27 individuals (22.2%) previously exposed to S/V, 4/20 (20.0%) previously exposed to G/P, and 1/8 (12.5%) in the other-regimen group. There was no significant difference in resistance prevalence across prior regimen exposure groups (exact p = 1.000).Compared with TN, NS5A resistance was numerically higher among individuals previously exposed to S/V (22.2% vs 7.3%; Fisher's exact p = 0.140) and G/P (20.0% vs 7.3%; Fisher's exact p = 0.203), although neither comparison reached statistical significance. **Conclusion:** In this real-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

world cohort, NS5A RAS was detected in approximately 15% of individuals tested and was numerically more common among TE than TN. Among TE, NS5A RAS rates were similar after prior exposure to S/V and G/P, with no statistically significant difference by prior regimen. These findings support the need for larger real-world studies to better define the burden of NS5A RAS and its implications for retreatment strategies.

Table 1: NS5A RAS detected among individuals

Mutation Group	n (%)
Y93 substitutions (Y93H/Y93C/Y93Y-H/Y93Y-C-N)	7 (50.0%)
M28 substitutions (M28T/M28E/M28M-T/M28M-V)	4 (28.6%)
Q30 substitutions (Q30Q-H/Q30R)	2 (14.3%)

3288 | RE-ENGAGING DIAGNOSED BUT UNTREATED INDIVIDUALS THROUGH A HEPATITIS TREATMENT RELINKAGE PROGRAM

Leigh Brooks[1], [1]Bluestone Health Association Inc

Background: Despite highly effective antiviral therapies, many people diagnosed with viral hepatitis remain untreated because of loss to follow-up, fragmented records, and barriers to navigating care. Closing this gap is essential to hepatitis elimination. This relinkage initiative was implemented within a primary care program that also provides substance use disorder services, enabling hepatitis evaluation and treatment to be delivered in the same clinical setting. **Methods:** A centralized relinkage registry was created by integrating data from the electronic health record (EHR), laboratory reporting, public health/ surveillance line lists, and referral logs. Records were deduplicated and treatment status was verified. Outreach staff conducted structured re-engagement using phone calls, text messages, mailed letters, and coordination with care teams and community partners. Patients who were reached were navigated to appointments, laboratory workup, and clinical evaluation within primary care, with care coordinated alongside substance use disorder visits when applicable to facilitate treatment initiation. **Results:** A total of 697 individuals with diagnosed viral hepatitis and no documented treatment initiation were identified. Outreach was initiated for all 697 individuals; 697 (100.0%) were successfully contacted and 680 (97.6%) were linked to hepatitis care with a documented linkage date indicating successful connection to treatment services (e.g., referral or appointment coordination completed). Embedding hepatitis care within primary care that manages substance use disorder improved care navigation and strengthened documentation of treatment status across systems. **Conclusion:** A structured, data-driven relinkage model embedded in primary care with substance use disorder services can rapidly reconnect diagnosed but untreated individuals to hepatitis care. Combining robust data reconciliation with multimodal outreach and coordinated navigation supports closing treatment gaps and advancing hepatitis elimination efforts in rural, high-burden settings.

3289 | HEPATITIS C ELIMINATION IN HIGH-RISK PSYCHIATRIC AND ADDICTION POPULATIONS: PREVALENCE AND TREATMENT OUTCOMES

Cristina del Rio Cubilledo[1] Luis Enrique Morano Amado[2] Denise Montserrat Arroyo Jarrin[3] Miriam Soriano Garcia[3] Catalina Fernandez Mendez[3] Maria Jose Alvarez Alonso[4] Francisco Otero Lamas[4] Jesus Cancelo[5] Sandra Cortizo Vidal[3] Isabel Coejo[6] Begoña Chapela Broullon[7] Laura Labajo Leal[8] Antonio Ocampo Hermida[8] Antonio Ocampo Hermida[8] Jose Manuel Olivares Diez[9] Aitana Morano Vazquez[10], [1]University of La Rioja, La Rioja, Spain, [2]Universitiy Hospital Alvaro Cunqueiro, Vigo, Spain, [3]University Hospital Alvaro Cunqueiro, Vigo, Spain, [4]Addictions Unit CEDRO, Vigo, Spain, [5]Addictions Unit Alborada, Vigo, Spain, [6]Addictions Unit Alborada Vigo. Spain., [7]Addictions Unit Cangas. Spain. [8]University Hospital Alvaro Cunqueiro. Vigo. Spain., [9]Hospital Alvaro Cunqueiro. Vigo. Spain., [10]University Hospital Gregorio Marañon. Madrid. Spain.

Background: Hepatitis C virus (HCV) affects an estimated 50 million people chronically worldwide (2022). In Spain, HCV antibody prevalence is 0.85%, with active infection in 0.14–0.22%. Prevalence is higher among people with substance use disorders (SUD), severe mental illness (SMI), and dual disorder (DD). Despite efficacy of direct-acting antivirals (DAA), individuals with SUD and DD remain under-prioritized for screening. We analysed HCV prevalence in SMI and DD patients attending a Psychiatry Unit and SUD patients attending four Substance Abuse Units (SAU) in Vigo, Spain. **Methods:** Retrospective study (January 2019 – December 2025) including 2,693 SAU users and 2,026 Psychiatry Unit patients (339 DD). Users were classified as anti-HCV status (positive, negative,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

unknown). Covariates: Age, sex, and type of user or patient. **Results:** In the Psychiatry Unit (2,206; mean age 48), 1,494 (67.7%) were tested and 134 (9.0%) were anti-HCV positive. 131 were tested for RNA, of these 122 (93.2%) had undetectable RNA: 88 (72.1%) achieved sustained virological response (SVR) after treatment and the rest spontaneous clearance (SVC). Schizophrenia (24.6%) and other psychotic disorders (19.4%) were most frequent. Positives were older than negatives (51.7 ± 8.4 vs. 47.0 ± 16.6 years; $p < 0.001$). Prevalence was higher in men (13.2% vs. 4.7%; OR 3.09; $p < 0.001$). In DD patients (339; mean age 42.3), 289 (85.2%) were tested and 71 (24.6%) were anti-HCV positive. Of these 100% were tested for RNA, 68 (95.7%) had undetectable RNA: 52 (76.5%) SVR and 16 SVC. Substance use was multiple in 63%, single in 30%, and alcohol in 7%. Higher prevalence occurred in psychotic disorders (22.5%), schizophrenia (19.7%), and personality disorders (18.3%). Positives were older (50.3 ± 7.7 vs. 39.6 ± 12.7; $p < 0.001$). Male prevalence was higher but not significant (27.8% vs. 18.1%; OR 1.75; $p = 0.098$). In SAU users (2,693; mean age 46), 22.3% had alcohol use disorder, 44.7% single drug use, and 33% multiple drug use. Testing coverage was 81.3%, with 52.2% anti-HCV positive. Of these 1057 were tested for RNA, 86.2% had undetectable RNA (77.2% SVR, 22.8% SVC). Prevalence was higher in men (52.9% vs. 47.9%; OR 1.22; $p = 0.063$). Positives were older (50.1 vs. 43.4 years; $p < 0.001$). **Conclusion:** HCV prevalence was 52.3-fold higher in SAU, 10.5-fold in SMI, and 28.9-fold in DD patients. SVR after DAA was comparable to the general population. Systematic test-and-treat strategies in psychiatric units and SAU are essential to improve care and support WHO 2030 elimination goals.

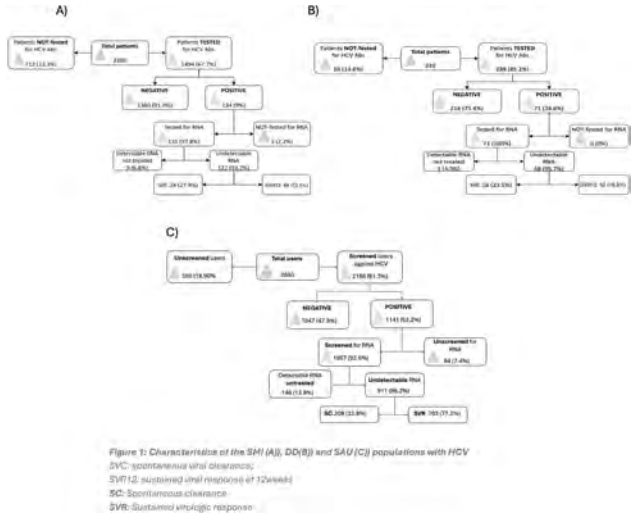

Figure 1: Characteristics of the SMI (A)), DD(B)) and SAU (C)) populations with HCV

3290 | LIVER DISEASE SEVERITY, COMORBIDITY BURDEN, AND SUSTAINED VIROLOGIC RESPONSE AMONG ADULTS WITH HCV VIREMIA

Hannah Fry[1] Leah Harvey[2] Mark Rosenberg[1] Filipe Monteiro[2], [1]Warren Alpert Medical School of Brown University, [2]Brown University Health

Background: Hepatitis C (HCV) remains a significant public health challenge due to persistent gaps along the care cascade. Understanding predictors of failure to achieve sustained virologic response (SVR) is essential for targeting interventions to medically complex populations. This study evaluated (1) the proportion of adults with active HCV viremia who achieved SVR within a large regional health system and (2) clinical factors associated with incomplete progression through the care cascade. **Methods:** We conducted a retrospective cohort study of 1,039 patients diagnosed with HCV viremia within an academic medical center in New England between 1/1/2018 - 12/31/2018. Treatment completion and SVR were measured by repeat HCV RNA testing within 40 weeks of treatment initiation, accounting for real-world delays. Demographic, clinical, and social variables, including liver disease severity (MELD and cirrhosis status) and comorbidity burden (Charlson Comorbidity Index [CCI]) were extracted from the electronic health record. Group differences were assessed using chi-square, Fisher's exact, and t-tests. Logistic regression models generated adjusted odds ratios (aOR) for SVR and clinical severity predictors. **Results:** Among 1,039 adults with HCV viremia, the mean age was 49.4 ± 12.8 years, 61.6% were male, 72.1% White, and 15.4% Hispanic. Mild liver disease (MELD 6-10) was present in 56.9% of the cohort, while 5.1% had severe liver disease. Most patients had low comorbidity burden (CCI 0–1 in 54.6%). Overall, 771 patients (74.2%) achieved SVR and 268 (25.8%) did not. Higher MELD scores were predictive of not achieving SVR: MELD 20–29 (aOR 4.01, 95% CI 1.77–9.08) and MELD >39 (unadjusted OR 7.31, 1.41–37.9). Fibrosis severity was not independently associated with SVR when controlling for other variables. Higher CCI scores significantly

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

increased the likelihood of severe liver disease (aORs 3.91–10.71), and CCI remained an independent predictor of not achieving SVR even after adjusting for demographic and social factors. **Conclusion** Clinical complexity, described by MELD score, fibrosis markers, and comorbidity burden, is associated with decreased likelihood of achieving SVR. These findings highlight the need for multidisciplinary coordination and closer monitoring for medically complex patients with HCV. Integrating social supports, early cirrhosis evaluation, and comorbidity-focused care pathways may improve treatment completion and optimize cure rates in high-risk clinical subgroups.

3291 | CHARACTERISTICS OF INDIVIDUALS WITH HIV EXPOSURE: INSIGHTS FROM 10 YEARS OF HEPATITIS C TESTING IN VANCOUVER, CANADA'S INNER-CITY

Christina Wiesmann[1] Shana Yi[2] David Truong[2] Brian Conway[2], [1]Simon Fraser University, [2]Vancouver Infectious Diseases Centre

Background: Vancouver, Canada's inner-city, or downtown east side (DTES) neighborhood is known for high rates of poverty and drug use. The Vancouver Infectious Diseases Centre (VIDC) has been carrying out point-of-care testing at DTES community locations, and providing HCV treatment to viremic individuals for more than 10 years. We chose to evaluate both characteristics associated with HCV exposure, and proportions of HCV exposure and viremia over time. **Methods:** VIDC provides regular point-of-care antibody testing in various inner-city locations including community centers, shelters, and single room occupancy buildings. We collect data about HCV antibody and viremia status, as well as a range of other demographic and social variables. We used odds ratios to determine characteristics significantly associated with HCV exposure from 2015 until September of 2025. **Results:** A range of characteristics were found to be significantly associated with individuals with HCV exposure (Table 1). The most strongly associated characteristic was having a history of injection drug use. Smoking, poorer health status, being unemployed, having no post-secondary education, and having an HIV infection were also significantly associated with having been exposed to HCV.We saw that in 2025, individuals testing positive for HCV exposure were significantly older than individuals with no exposure (44.5 YO vs. 48.6 YO; p = 3.16E-07).We saw no clear trend in the proportion of individuals testing positive for HCV antibodies over time, but saw that a much lower proportion of individuals were viremic in 2025 (~15%) compared to 2015 (~70%). **Conclusion** We identified many factors associated with HCV exposure, most of which are consistent with variables previously identified by other research groups. The observation that individuals without HCV exposure were significantly younger in 2025 is a novel finding that may indicate that sustained treatment of HCV in this population is reducing the risk of HCV acquisition by individuals new to drug use. Follow-up analyses will further investigate this intriguing finding. This work will ultimately help to inform and provide evidence-based support for micro-elimination efforts in Vancouver's inner-city community, as well as similar communities around the world.

Characteristic		Unadjusted OR (95% CI); HCV+ vs. HCV-
Gender	Male vs. Not Male	1.06 (0.78 - 1.44)
HIV result	HIV+ vs. HIV-	**3.74** (1.37 - 10.18)
Ethnicity	Indigenous vs. Non-Indigenous	1.31 (0.90 - 1.90)
Relationship Status	Single vs. Married/Common Law	1.39 (0.89 - 2.18)
Education Level	<= High school vs. > High School	**1.78** (1.23 - 2.60)
Employment Status	Not Working vs. Working/Studying	**1.77** (1.12 - 2.79)
Incarceration History	Yes vs. No	0.93 (0.65 - 1.33)
Health Status	Poor/Fair vs. Good/VG/Excellent	**1.71** (1.18 - 2.47)
Alcohol Consumption	>1 drink/day vs <1 drink/day	0.83 (0.50 - 1.40)
Smoking	Yes vs. No	**2.23** (1.33 - 1.74)
Injection Drug Use History	Yes vs. No	**13.98** (8.62 - 13.98)

3292 | EVALUATING POSTPARTUM LINKAGE TO HEPATITIS C CARE: RESULTS OF A PATIENT OUTREACH STUDY

Megan Betancourt[1] Jasmine Gamez[2] Jennifer Price[1] Annie Leutkemeyer[1] Dominika Seidman[1] Monika Sarkar[2], [1]University of California San Francisco, [2]University of California, San Francisco

Background: Recommendations to universally screen for hepatitis C virus (HCV) during pregnancy have increased HCV diagnosis in this population. However, peripartum linkage to care remains a major challenge. In our prior retrospective study, most pregnant patients with HCV viremia were lost to follow-up. Our current study investigates patient-reported barriers and facilitators to postpartum linkage of care. **Methods:** We identified patients with HCV viremia in pregnancy who delivered at an urban tertiary academic center and affiliated county hospital from 1/1/2014 – 12/31/2024. We designed a structured telephone survey to determine whether patients and their offspring received follow-up HCV care and to solicit barriers and facilitators to access. Initial patient contact was conducted by phone call and text. **Results:** Between 2014-2024 we identified 110 qualifying pregnancies. Of these, 11 patients (10%) could be reached at a median of 9 years after pregnancy (IQR 6.5 – 10.5), 10 of whom responded to text outreach but not to initial phone. All respondents consented to and completed the telephone survey. Regarding psychosocial stressors, 9 patients (82%) experienced housing instability, and 10 (91%) reported substance use prior to pregnancy (opiates 70%, methamphetamine 30%) with all 10 having prior injecting drug use. Two respondents noted active substance use during pregnancy, and all 7 with opiate use reported being managed with methadone intrapartum. Notably, 6 (55%) reported no healthcare provider discussed their HCV during their pregnancy and therefore did not think postpartum HCV follow-up was needed. 5 (45%) reported a clear follow-up plan after delivery. Despite this, 9 patients (82%) received antiviral therapy initiated ~6-8 months postpartum with one receiving treatment 3 years postpartum. Six of these 9 (67%) received HCV treatment at their methadone clinic, even if lost to follow-up through their hospital system. Most (82%) felt comfortable discussing HCV with providers and only 1 reported feeling judged or stigmatized due to HCV. Regarding infant follow-up, 10 of the 11 respondents (91%) reported their infant received HCV testing. One patient reported her infant was diagnosed with HCV at 48 months and received antiviral therapy. **Conclusion:** Postpartum follow-up after HCV diagnosis in pregnancy remains challenging with low successful outreach, underscoring the need for routine and structured models of postpartum linkage to care. Integration of addiction medicine and HCV treatment programs, patient outreach through text messaging, and enhanced counseling regarding HCV treatment in pregnancy may be additional strategies to optimize peripartum HCV management.

3293 | RELINK ANGH, FINDING PATIENTS WITH LOST-TO-FOLLOW-UP VIRAL HEPATITIS: A NATIONAL MULTICENTRE STUDY IN NON-UNIVERSITY HOSPITALS

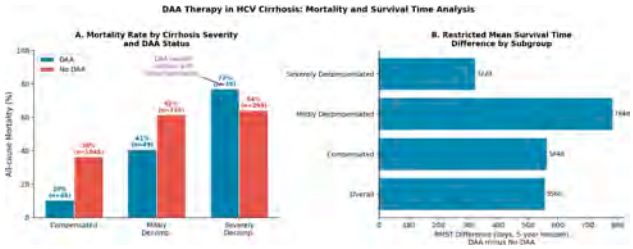
Andre Jean Remy[1] Edoardo Poli[2], [1]Centre Hospitalier De Perpignan, [2]Centre Hospitalier Nord Essonne

Background: The recall of patients diagnosed with HCV+ but lost to follow-up or untreated has been shown to be effective in some countries, including France. The first Relink-C program was set up at the Annecy hospital and successfully replicated in 3 other general hospitals (Perpignan, Créteil and Avignon). Systematic screening for all pregnant women is mandatory for HBV and strongly recommended for HCV in France. No recent data are available on the rates of screening for these two viruses in pregnant women. In the patients who were screened, HBsAg was globally positive in 0.8%, but this rate ranged from 0.3% in women born in France to 6.7% in those born in Africa. The French Describe study finds a HDV screening rate in pregnant women with positive Ag HBS of less than 10%. No data on the care pathway and access to treatment is available. **Methods:** For RELINK generalist to find untreated and lost-to-follow-up HCV (+/- HDV) patients diagnosed with HCV and for RELINK pregnant women to find lost-to-follow-up HCV (+/- HDV) patients whose diagnosis has been made or confirmed during pregnancy monitoring. Each center used its internal, virological or hepatological databases. For HBV patients found, a HDV serology was systematically performed. **Results:** As of May 12, 2026, 197 patients (23% women) had been included in the general RELINK observatory and 38 patients in the pregnant RELINK observatory. Sixteen centers included at least one patient. The average response rate

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

was 79%. The table below details the main characteristics of the two groups: **Conclusion** All patients diagnosed with chronic viral hepatitis B and C who have been lost to follow-up may return to a care pathway after being contacted again. Direct contact is the preferred way to find these patients, followed by referral to a general practitioner or midwife. The diagnosis was known for 8 to 7 years on average. HBV is predominant in women followed in obstetrics. In the random access patients, there was equality between HBV and HCV and 23% had an F3F4 fibrosis.



RELINK	number	average age	HCV	HBV	HDV	diagnotic	contact method	F0-F1	F3-F4	HCV treatment	HBV treatment	HDV treatment

3294 | ABSOLUTE SURVIVAL BENEFIT OF DAA THERAPY IN HOSPITALIZED PATIENTS WITH HCV-RELATED CIRRHOSIS: A RESTRICTED MEAN SURVIVAL TIME ANALYSIS

Innocent Lutaya[1] Brian Xu[1] Vicki Oladoyin[1] Shanelle Brodeur[1] Christopher Fay[1] Shahena Polynice[1] Chioma Nwabuoku[1] Tsering Shola[1] Chima Amadi[1] Shaikhoon Mohammed[1] Nicolas Bakinde[1], [1]Morehouse School of Medicine

Background: Direct-acting antiviral (DAA) therapy achieves sustained virologic response (SVR) >95% in hepatitis C (HCV), but data regarding absolute survival benefit in hospitalized patients with advanced cirrhosis remains unquantified. Most studies report hazard ratios, which quantify relative risk reduction, but do not convey the absolute survival gain, which is most meaningful to patients and clinicians. We used restricted mean survival time (RMST) to address this gap, by providing a direct estimate of life-months gained with DAA therapy. **Methods:** We conducted a retrospective cohort study of 2,205 adults hospitalized with HCV-related cirrhosis at a major academic medical center (Beth Israel Deaconess Medical Center, 2008–2019). Rather than reporting relative risk alone, our primary outcome was survival benefit measured in life-months gained; specifically, the restricted mean survival time (RMST) difference at 12 and 36 months between DAA-treated and untreated patients. Secondary outcomes included Kaplan-Meier survival curves to visually compare how patients did based on whether they had liver cancer (HCC) and how advanced their cirrhosis was, with multivariable Cox regression confirming that DAA treatment independently predicted better survival after accounting for differences between groups. **Results:** Of 2,205 patients (mean age 56.3 years, 29.3% female), 136 (6.2%) received DAA therapy. At 36 months, DAA was associated with 10.3 additional life-months (RMST 32.4 vs 22.1 months; 95% CI 8.5-12.0). Benefit was greatest in mildly decompensated cirrhosis (+13.9 months) and patients with HCC (+11.9 months). In severely decompensated patients, RMST gain was +6.3 months (95% CI 2.9-9.5; p=0.275). DAA therapy independently reduced mortality based on our adjusted hazard ratio after accounting for other factors that could influence survival, like cirrhosis severity (aHR 0.45, 95% CI 0.34-0.59; p<0.001). **Conclusion** DAA therapy added nearly 10 months of life at 3 years, even in hospitalized patients with advanced cirrhosis. The survival benefit was largest in those with liver cancer (+11.9 months) and mild decompensation (+13.9 months), while gains in severely decompensated patients were smaller and did not reach statistical significance. Our data is meant to highlight a window of opportunity where treatment makes the greatest difference.

University, [3]Loyola University Chicago, [4]Food and Drug Administration, [5]University of Illinois at Chicago

Background: Persons who inject drugs (PWID) are at high risk for acquiring and transmitting hepatitis C virus (HCV). Direct-acting antiviral (DAA) therapy can not only cure HCV but can also protect PWID from repeat infections by suppressing viral replication while on treatment. Currently approved DAA regimens have an 8 or 12 week treatment duration and similar efficacy. We aimed to study the effect and cost of DAA treatment duration for PWID in the context of efforts to achieve HCV micro-elimination in metropolitan Chicago, IL, USA. **Methods:** We used our advanced Hepatitis C Elimination in PWID (HepCEP) agent-based model [10.1093/ofid/ofag297] in which HCV transmission probability is determined using a mathematical model that includes HCV RNA titers among needle/syringe-sharing donors [Sci Transl Med 2018; 10(449): eaao4496], to identify and optimize DAA therapy scale-up and treatment strategies. DAA treatment adherence was fixed at 90% and assumed a conservative estimate for cure rates of 90%. DAA treatment enrollment is modelled as (unbiased) random sampling of infected PWID using an annual target enrollment rate of 7.5% of the total PWID population in Chicago and surrounding area (32,000 individuals). Access to DAAs was simulated for 10 years. We compared the mean frequencies (using stochastic model replicates) of repeat infections, and number of unique treatment courses for DAA treatment duration lengths of 8 and 12 weeks. **Results:** The model predicts that during a 10-year period, a 12-week treatment duration results in fewer total infections (4,567, 95%CI: 4,376-4,758) compared to an 8-week treatment duration (5,214, 95%CI: 5,023-5404), many of which consist of repeat infections (12-week: 2,042, 95%CI: 1,917-2,166; 8-week: 2,581, 95%CI: 2,448-2,715). The need for DAA re-treatments for re-infected individuals and the total number of treatments was smaller in the 12-week group compared to the 8-week group. Specifically, use of a 12-week regimen (17,437 treatments) was projected to result in the need for 715 fewer treatments compared to an 8-week regimen (18,152 treatments) (Table 1). The total DAA cost to reach elimination for 8-week and 12-week treatment duration were estimated at ~$200 and ~192 million, respectively. **Conclusion** Our modeling results indicate that a 12-week DAA treatment would result in a smaller number of repeat infections and an estimated mean DAA cost reduction of about $8 million compared to 8-week DAA treatment over a 10-year effort to reach HCV micro-elimination in metropolitan Chicago due to a longer period of protection from infections during the DAA treatment window.

	8-week DAA Treatment Duration				12-week DAA Treatment Duration				Diff vs 12wk total treatment counts/cost difference

3296 | HEPATITIS C RETREATMENT DURING THE DIRECT-ACTING ANTIVIRAL ERA, UNITED STATES, 2014-2025

Eyasu Teshale[1] Yuna Zhong[1] Brooke Hoots[1] Hasan Symum[1] Julian Grass[1], [1]Center for Disease Control and Prevention

Background: Despite the effectiveness of direct-acting antiviral (DAA) drugs for hepatitis C treatment, a subset of persons require retreatment for various reasons. Because DAA regimens are costly, retreatment adds substantial burden to patients and health care systems. In this large population of DAA-treated persons, we aimed to quantify retreatment and describe characteristics associated with retreatment. **Methods:** Using IQVIA's Longitudinal Prescription Claims data, we identified persons who received more than one DAA treatment course during 2014—2025. Retreatment was defined as initiation of a new DAA treatment $\geq$6 months after the last date of the prior treatment. We described persons who were retreated and compared demographics, payer type, and prescriber specialty corresponding to the first retreatment with the characteristics of those who were treated only once. We used logistic regression to determine factors associated with retreatment. **Results:** 1,119,896 persons were treated with DAAs, of whom 36,089 (3.2%) were retreated. Most (93.7%) had only one retreatment. Among those retreated, 66.2% were male and 55.8% were aged $\geq$ 60 years; 35.9% had private insurance, 31.0% had Medicaid, and 27.6% had Medicare. Over half (52.5%) received prescriptions from specialists. Retreatment was higher during 2014–2016 (4.4%), at the start of the DAA era compared to 2023–2025 (1.6%), and among persons initially treated with earlier generation DAAs (8.4%) than with pangenotypic drugs (2.5%). Younger age, male sex, treatment with earlier generation DAAs, and non-

private insurance were significantly associated with retreatment compared to being treated once. Those who were prescribed treatment by nurse practitioners or primary care physicians were more likely to be retreated than those prescribed treatment by specialists. **Conclusion:** During 2014–2025, 3.2% of persons treated with DAAs underwent retreatment. Better understanding of factors associated with retreatment—including age, sex, insurance type, and prescriber characteristics—is essential for optimizing clinical management and reducing the long-term health and economic impacts of hepatitis C.

3297 | LEAVING MONEY ON THE TABLE: THE COST OF MISSED HEPATITIS C TREATMENT OPPORTUNITIES AMONG PREGNANT AND POSTPARTUM WOMEN

Audrey Lloyd[1] Van Thi Ha Nghiem[2] Robert Johnson[1] Greer Burkholder[1] Akila Subramaniam[1] Emma Kay[1] Karen Cropsey[1], [1]University of Alabama at Birmingham, [2]University of Alabama at Birmingham School of Public Health

Background: With the injection drug use (IDU) epidemic, hepatitis C virus (HCV) has emerged as a public health threat to pregnant women and their infants, increasing the risk of adverse pregnancy outcomes including perinatal HCV transmission. Despite availability of curative treatment (direct-acting antivirals [DAA]), poor treatment uptake is a prevalent issue depreciating the value of universal HCV screening mandate from 2019. 340B funding offers a path to recover administrative costs associated with DAA prescription, but perceived low numbers of eligible (privately insured) patients in this population disincentivizes institutional investment. We examined the HCV care utilization and cost of untreated maternal HCV in a large academic health system in Alabama, a non-Medicaid expansion state. **Methods:** We abstracted electronic medical records using the International Classification of Diseases (10th Revision) clinical and procedural codes, clinic notes, pharmacy records, and laboratory results to elucidate the care cascade of pregnant women with HCV who delivered at our institution's health system between 2018-2024. We derived the rates of healthcare utilization of these women and private insurance coverage rates. Accounting for the 35% discount rate and the local staffing model and care therapies, we estimated the financial advantage (2026 USD) of treating all pregnant women with HCV and capturing all who were eligible to generate 340B savings in comparison to status quo. Sensitivity analyses were conducted to explore the robustness of the result. **Results:** There were 28,616 pregnancies among 23,268 women aged 18-51 years old. HCV screening was performed in 21,502 women and 492 (1.7%) pregnancies had positive HCV antibody. Positive HCV RNA was detected in 316 (1.4%) of pregnant women - averaging to 45 women per year. Of the 316 HCV RNA positive women, only 52 (16.3%) were prescribed DAA during pregnancy or within 12 months of delivery. Pregnant women with HCV viremia were less likely to be enrolled in private insurance (7% vs 40%) than pregnant women without HCV. Despite this cohort of pregnant women with HCV only including 22 women (7%) who were eligible to generate 340B cost-savings, had all been treated, the financial gain still would have been $215,000 in comparison to status quo. **Conclusion:** Despite universal HCV screening at our institution since 2017, DAA uptake among pregnant and postpartum women remains unacceptably low. **:** Our data demonstrates potential direct and immediate financial gain to investing in improved DAA uptake among pregnant and postpartum women with HCV, despite the small percentage eligible to generate 340B cost savings.

Table 1. Staffing model to provide Hepatitis C treatment in Status quo vs. Treat All

Staff	Percentage of FTE* for 52 patients** (Status quo)	Percentage of FTE* for 316 patients** (Treat All)
Pharmacist	4.16%	25.28%
Pharmacy technician	4.16%	25.28%
Case manager	2.60%	15.80%
Clinical research nurse practitioner	1.25%	7.58%
Gastroenterologist	1.25%	7.58%
Infectious disease physician	1.25%	7.58%
Radiologist	0.22%	1.36%
Ultrasound technician	1.08%	6.59%
Fibroscan technician	0.57%	3.45%

*FTE, one year of full time equivalent; **each patient is treated only once

3298 | HEPATOCELLULAR CARCINOMA RISK AFTER DIRECT-ACTING ANTIVIRAL-INDUCED SUSTAINED VIROLOGIC RESPONSE ACCORDING TO BIOPSY-PROVEN FIBROSIS STAGE AND CLINICAL RISK FACTORS IN CHRONIC HEPATITIS C

Yuki Tahata[1] Hayato Hikita[2] Yasutoshi Nozaki[3] Nobuyuki Tatsumi[4] Atsushi Hosui[5] Fumihiko Nakanishi[6] Naruyasu Kakita[7] Hisashi Ishida[8] Ryotaro Sakamori[9] Takayuki Yakushijin[10] Kazuho Imanaka[11] Yuichi Yoshida[12] Sadaharu Iio[13] Takatoshi Nawa[14] Kazuyoshi Ohkawa[15] Masanori Miyazaki[16] Mitsuru Sakakibara[17] Kazuhiro Murai[18] Yuki Makino[18] Yoshinobu Saito[2] Takahiro Kodama[19], [1]The University of Osaka, [2]Osaka University Graduate School of Medicine, [3]Kansai Rosai Hospital, [4]Japan Community Healthcare Organization Osaka Hospital, [5]Osaka Rosai Hospital, [6]National Hospital Organization Osaka Minami Medical Center, [7]Kaizuka City Hospital, [8]Ikeda Municipal Hospital, [9]National Hospital Organization Osaka National Hospital, [10]Osaka General Medical Center, [11]Itami City Hospital, [12]Suita Municipal Hospital, [13]Hyogo Prefectural Nishinomiya Hospital, [14]Higashiosaka City Medical Center, [15]Osaka International Cancer Institute, [16]Osaka Police Hospital, [17]Yao Municipal Hospital, [18]The University of Osaka, Graduate School of Medicine, [19]Osaka University

Background: Although direct-acting antiviral (DAA) therapy markedly reduces the risk of hepatocellular carcinoma (HCC) in patients with chronic hepatitis C, HCC continues to occur after sustained virologic response (SVR). Current surveillance strategies differ across regions, particularly for patients without cirrhosis. We aimed to clarify HCC incidence after SVR according to biopsy-proven fibrosis stage and to identify risk factors for HCC among patients with non-advanced fibrosis. **Methods:** We analyzed patients with chronic hepatitis C who initiated DAA therapy between September 2014 and July 2022 and achieved SVR. Patients with prior HCC, coinfection with HBV or HIV, autoimmune liver disease, primary biliary cholangitis, prior liver transplantation, or unavailable post-SVR HCC assessment were excluded. SVR was defined as serum HCV-RNA negativity at 24 weeks after the end of therapy. Among 3,369 SVR patients without prior HCC, 1,096 who underwent liver biopsy within 1 year before DAA initiation and had adequate histological assessment were included. Fibrosis stage was assessed using the METAVIR score and categorized as F0–2, F3, or F4. Follow-up started at SVR24. The cumulative incidence of HCC was evaluated using a competing-risk model, and risk factors were analyzed using Fine–Gray hazard regression. **Results:** The study cohort included 904 patients with F0–2, 103 with F3, and 89 with F4 fibrosis. During a median follow-up of 58.8 months from SVR24, 53 patients developed de novo HCC. The 5-year cumulative incidence of HCC increased with fibrosis stage: 3.6% in F0–2, 6.8% in F3, and 11.3% in F4. Annual HCC incidence remained below 1.5%, a commonly cited threshold for cost-effective for HCC surveillance, throughout follow-up in F0–2 patients, whereas it exceeded or approached this threshold in several post-SVR periods among patients with F3 or F4 fibrosis. Among F0–2 patients, multivariable Fine–Gray analysis identified age $\geq$75 years, diabetes mellitus, AST levels $\geq$30 U/L at SVR24, albumin levels $<$4.0 g/dL at SVR24, and AFP levels $\geq$5.0 ng/mL at SVR24 as independent risk factors for HCC. **Conclusion:** In patients with chronic hepatitis C who achieved DAA-induced SVR, biopsy-proven advanced fibrosis, particularly F4 fibrosis, was associated with a higher cumulative incidence of HCC, supporting continued long-term surveillance. Although most patients with F0–2 fibrosis had low annual HCC incidence, older age, diabetes, higher AST, lower albumin, and higher AFP levels were associated with HCC occurrence. These findings may help refine post-SVR HCC surveillance strategies beyond fibrosis stage alone.

3299 | A SIMPLIFIED APPROACH TO CURE CONFIRMATION USING SVR4 TO REPLACE SVR12 FOR PATIENTS WITH HCV WITH LEDIPASVIR/SOFOSBUVIR OR SOFOSBUVIR/VELPATASVIR WITH OR WITHOUT RIBAVIRIN TREATMENT (LEAP STUDY)

Li Liu[1] Xiaobo Lu[2] Zhu Chen[3] Junmin Huang[4] Xiaoyun Peng[5] Caixia Yang[6] Chunfang You[7] Jie Wang[8] Cunliang Deng[9] Peng Hu[10] Li Zhang[10], [1]Kunming Third People's Hospital, Yunnan, China, [2]The First Affiliated Hospital of Xinjiang Medical University, Xinjiang, China, [3]Public Health Clinical Centre of Chengdu, Sichuan, China, [4]Zhaotong Hospital of Traditional Chinese Medicine, Yunnan, China, [5]Baoshan People's Hospital, Yunnan, China, [6]Dali Prefecture People's Hospital, Yunnan, China, [7]The First People's Hospital of Zigong City, Sichuan, China, [8]Linshui County People's Hospital, Sichuan, China, [9]The Affiliated Hospital of Southwest Medical University, Sichuan, China, [10]The Second Affiliated Hospital of Chongqing Medical University, Chongqing, China

Background: In western China, hepatitis C virus (HCV) exhibits substantial genotype diversity. Although sustained virologic response at post-treatment week 12 (SVR12) remains the standard endpoint for cure confirmation, loss to follow-up can be frequent in routine practice, limiting the feasibility of SVR12-based monitoring. In line with WHO-recommended simplified care models for HCV care, we evaluated whether sustained virologic response at post-treatment week 4 (SVR4) can reliably replace SVR12 after Ledipasvir/Sofosbuvir (LDV/SOF) or Sofosbuvir/Velpatasvir (SOF/VEL) with or without ribavirin (RBV) treatment. **Methods:** We performed a multicenter retrospective study across 10 hospitals (May 2018–February 2026). We assessed the concordance between SVR4 and SVR12 among patients with available results at both time points. **Results:** A total of 3676 patients with both SVR4 and SVR12 were included. Of these, 2029 were males, with a median age of 51 years (range 12-98). The HCV genotype was undetected for 1628 patients. Among the remaining 2048 patients, the proportions of genotype 1/2/3/6 and mixed genotypes were 25.39%, 38.38%, 31.15%, 4.98% and 0.10%, respectively. In the entire population, 97.77% (3594/3676) achieved SVR4 and 97.42% (3581/3676) achieved SVR12. Among SVR4 achievers, 13 failed to maintain SVR12, while all patients (82/82) who did not achieve SVR4 also failed SVR12. The positive predictive value (PPV) and negative predictive value (NPV) of SVR4 to predict SVR12 were 99.64% (95% confidence interval: 99.44-99.84) and 100%. **Conclusion:** Post-treatment week 4 HCV RNA testing provides excellent replacement of SVR12 and may serve as an earlier endpoint for cure confirmation in patients treated with LDV/SOF or SOF/VEL ± RBV. Shifting SVR assessment from week 12 to week 4 post-treatment may simplify cure confirmation and reduce loss to follow-up, particularly in regions with complex genotype distributions.

Concordance between SVR4 and SVR12

	Achieved SVR12	Failed SVR12	Total
Achieved SVR4	99.64% (3581/3594)	0.36% (13/3594)	3594
Failed SVR4	0	100% (82/82)	82
Total	3581	95	3676

3300 | DIRECT-ACTING ANTIVIRAL THERAPY IS ASSOCIATED WITH REDUCED CARDIOVASCULAR, PSYCHIATRIC, AND MORTALITY OUTCOMES IN CHRONIC HEPATITIS C: A PROPENSITY SCORE-MATCHED ANALYSIS

Muhammad Hassaan Arif Maan[1] Anand Shah[1] Rohan Karkra[2] Muhammad Mursaleen Ahmad[3] Sunnia Khan[4] Ethan Shamsian[1] Kaveh Hajifathalian[1] Ahmed Al-Khazraji[1], [1]Rutgers NJMS, [2]Rutgers New Jersey Medical School, [3]Hennepin County Medical Center, [4]Baptist Hospitals of Southeast Texas

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Chronic HCV infection drives extrahepatic morbidity across cardiovascular, metabolic, and psychiatric systems. DAA therapy achieves SVR in >95% of patients, yet US treatment uptake remains ~30%. Quantifying the full spectrum of extrahepatic benefits is critical to reframing DAAs as a multisystem intervention and strengthening the case for universal treatment. **Methods:** This retrospective propensity score-matched cohort study utilized the TriNetX federated network (111 healthcare organizations). Adults (≥18 years) with chronic HCV (ICD-10: B18.2) diagnosed ≥2014 were stratified by DAA exposure. Patients with HIV, hepatitis B, liver transplant, HCC, chronic hepatic failure, variceal bleeding, or ascites were excluded. 1:1 propensity score matching balanced demographics, comorbidities (fibrosis, cirrhosis, diabetes, obesity, hypertension, dyslipidemia, CKD, ischemic heart disease, substance use disorders, mood/anxiety disorders, nicotine dependence), and platelet count. Primary outcomes were assessed 180–1,825 days post-index; a sensitivity analysis used unlimited follow-up. Kaplan-Meier analyses with hazard ratios (HR) were calculated. **Results:** After matching, 75,758 patients per cohort were analyzed (mean age ~52; ~58% male; ~61% White; ~21% Black; all standardized differences <0.1). DAA treatment was associated with significantly lower risk of MACE (HR 0.730, 95% CI 0.700–0.761), heart failure (HR 0.838, 0.791–0.888), type 2 diabetes (HR 0.830, 0.787–0.875), major depressive disorder (HR 0.859, 0.824–0.895), anxiety disorders (HR 0.876, 0.843–0.911), and all-cause mortality (HR 0.576, 0.547–0.606; all $p < 0.001$). Atrial fibrillation trended toward benefit (HR 0.909, $p = 0.009$). CKD, PAD, and liver cancer were not significant. Sensitivity analysis with unlimited follow-up confirmed all significant associations. **Conclusion:** DAA therapy was associated with significant reductions in MACE (27%), heart failure (16%), diabetes (17%), depression (14%), anxiety (12%), and mortality (42%) across >150,000 chronic HCV patients. These benefits demonstrate that DAAs function as a multisystem intervention beyond viral eradication. Current cost-effectiveness models focusing on liver outcomes likely underestimate treatment value. These findings support prioritizing DAA uptake toward HCV elimination.

3301 | PREGNANCY OUTCOMES FOLLOWING GLECAPREVIR/PIBRENTASVIR EXPOSURE IN PREGNANT WOMEN WITH HEPATITIS C: A PHARMACOVIGILANCE ANALYSIS

Tatyana Kushner[1] Barbra Cave[2] John Marcinak[2] Catherine Chappell[3] Laura Marks[4] Madeline McCrary[4] Ahizechuwu Eke[5] Alexandru Iacob[2] Josephine Kwong[2] Rinal Patel[2] Ravi Jhaveri[6], [1]Weill Cornell Medicine, [2]AbbVie Inc, [3]University of Pittsburgh Medical Center, [4]Washington University School of Medicine, St. Louis, [5]Johns Hopkins University, [6]Northwestern University Feinberg School of Medicine

Background: Despite highly effective direct-acting antivirals (DAAs) for hepatitis C virus (HCV), safety data during pregnancy remain limited. As HCV rates increase among women of childbearing age, clinicians increasingly encounter inadvertent early pregnancy exposure to DAAs or would like to offer antenatal treatment, including the pangenotypic regimen glecaprevir/pibrentasvir (GLE/PIB). There is a lack of treatment recommendation for HCV during pregnancy, but AASLD/IDSA guidance states treatment can be considered during pregnancy on an individual basis after patient-physician discussion about the potential risks and benefits. **Methods:** We conducted a cumulative and descriptive analysis of pregnancy cases reported to AbbVie's global pharmacovigilance database (July 2017 to March 2026) from clinical trials, spontaneous reports, solicited sources and literature. Pregnancy cases with reported exposure were identified, and duplicate reports were reconciled. Maternal and fetal safety data, together with pregnancy outcomes, evidence of vertical transmission, and sustained virologic response at post-treatment week 12 (SVR12) following GLE/PIB exposure, were reviewed and analyzed. **Results:** A total of 328 pregnancies with reported GLE/PIB exposure were identified (**Table 1**); data were reported for 4 mother–neonate pairs. Most cases were spontaneous reports (N = 202); others were from solicited sources (N = 109), clinical trials (N = 10), and literature (N = 7). Of the 87 cases (26.5%) with documented pregnancy outcomes, 45 (51.7%) were live births, 17 (19.5%) were elective abortions, and 25 (28.7%) were spontaneous abortions. Among live births, 3 (6.7%) were preterm and 2 had reported congenital anomalies, including one case of patent ductus arteriosus/ventricular septal defect (PDA/VSD) after second-trimester exposure in a mother with comorbid substance use, and one case of early infantile epileptic encephalopathy with unknown timing of exposure. Treatment status was available for 223 cases: 58 ongoing at the time of reporting, 19 completed and 146 discontinued. No cases of vertical transmission were reported. 17 cases contained information consistent with achieving SVR. **Conclusion:** In this pharmacovigilance database analysis, reporting rates of spontaneous abortion and preterm birth in pregnancies with known outcomes were lower than rates reported in pregnant people with HCV without DAA exposure. Congenital anomalies were rarely reported, limiting detection of a pattern or trend. Interpretation is limited by missing outcome data and potential reporting bias inherent in real-world sources. The high rate of discontinuation may reflect a lack of shared decision making between patients and providers. These findings add to the collection of evidence of GLE/PIB in pregnancy and underscore the need for prospective studies to better define the safety of GLE/PIB exposure in pregnancy.

Table. Maternal characteristics of mothers with reported GLE/PIB exposure

Characteristic	Value
Region (n, %)	
United States	194 (59.1)
Germany	20 (6.1)
Japan	17 (5.2)
United Kingdom	13 (4.0)
Others	84 (25.6)
Ethnicity (n, %)	
Unknown	303 (92.4)
Caucasian	21 (6.4)
Asian	2 (0.6)
African American	1 (0.3)
Hispanic	1 (0.3)
Median age (years, IQR; n=147)	31 (26–35)
Age range (years)	17-52
Timing of GLE/PIB exposure (n, %)	
Unknown	190 (57.9)
Preconception	52 (15.9)
1st trimester	70 (21.3)
2nd trimester	11 (3.4)
3rd trimester	5 (1.5)

Note: Due to the nature of data collection in the pharmacovigilance database, some cases were reported as preconception exposures without clarifying if the exposure carried into the 1st trimester. In cases where continuation of treatment into the 1st trimester were clearly reported, they were counted as 1st trimester exposures.

3302 | PERSISTENT NS5A RESISTANCE AFTER DIRECT-ACTING ANTIVIRAL FAILURE IN GENOTYPE 3 HEPATITIS C: IMPLICATIONS FOR RETREATMENT IN RESOURCE-LIMITED ELIMINATION PROGRAMS

Saima Mushtaq[1] Amjad Khan[1] Aaron Lim[2] Yu Fang[3] Tayyab Saeed Akhter[4], [1]The First Affiliated Hospital of Xi'an Jiaotong University, [2]University Of Bristol, [3]Xi'an Jiaotong University, [4]Center for Liver and Digestive Diseases, Holy Family Hospital, Rawalpindi Medical University, Pak

Background: Hepatitis C virus genotype 3 (HCV GT3) remains difficult to cure in patients with cirrhosis and prior direct-acting antiviral (DAA) exposure, particularly in low- and middle-income countries where access to high-barrier salvage regimens is limited. Pakistan has one of the world's largest HCV burdens, with GT3 predominance, yet real-world data on post-failure NS5A resistance and its persistence are scarce. We evaluated treatment failure, NS5A resistance-associated substitutions (RASs), and RAS persistence in a multicenter GT3 cohort from Pakistan. **Methods:** Adults with chronic HCV GT3 receiving DAA therapy through tertiary centers linked to hepatitis control programs in Pakistan were enrolled and followed for SVR12. Treatment-naïve patients received sofosbuvir/daclatasvir, while treatment-experienced patients received sofosbuvir/velpatasvir; patients with compensated cirrhosis received extended therapy with ribavirin according to local practice. Among patients with virological failure, NS5A RASs were assessed by Sanger sequencing. Longitudinal post-failure samples were evaluated up to 24 months to assess RAS persistence. Outcomes were stratified by prior treatment status and compensated cirrhosis. **Results:** Of 2,000 enrolled patients, 1,390 had evaluable SVR12 outcomes, including 972 treatment-naïve and 418 treatment-experienced patients. Overall SVR12 was 93.3% but was substantially lower in treatment-experienced than treatment-naïve patients. Treatment failure occurred in 93 patients and was strongly concentrated among those with compensated cirrhosis: 64 of 127 cirrhotic patients failed treatment compared with 29 of 1,263 non-cirrhotic patients. The risk of failure was approximately 22-fold higher in patients with cirrhosis than in those without cirrhosis. Among treatment failures, NS5A RASs were common, with Y93H detected more frequently in treatment-experienced than treatment-naïve patients. Multi-site RAS patterns were especially enriched in treatment-experienced patients with cirrhosis, suggesting accumulation of resistance after sequential NS5A-containing regimens. In the longitudinal subset, NS5A RASs persisted for up to 24 months, with the slowest clearance observed in treatment-experienced patients with compensated cirrhosis and faster decline among treatment-naïve non-cirrhotic patients. **Conclusion:** In this real-world HCV GT3 cohort from Pakistan, virological failure was concentrated in patients with compensated cirrhosis and prior DAA exposure, who also showed frequent and persistent NS5A resistance. These findings support risk-stratified retreatment pathways, avoidance of regimen recycling after NS5A failure, and prioritization of resistance-informed salvage strategies in resource-limited HCV elimination programs.

3303 | COMPARATIVE EFFICACY AND SAFETY OF GLECAPREVIR/PIBRENTASVIR VERSUS SOFOSBUVIR/VELPATASVIR IN PATIENTS WITH HEPATITIS C: A MULTICENTER PROSPECTIVE STUDY

Aryoung Kim[1], [1]Ilsan Paik Hospital

Background: Direct-acting antivirals, including glecaprevir/pibrentasvir (GLE/PIB) and sofosbuvir/velpatasvir (SOF/VEL), have revolutionized hepatitis C virus (HCV) treatment. However, comparative data regarding their clinical outcomes and long-term risk of hepatocellular carcinoma (HCC) after sustained virologic response at 12 weeks (SVR12) remain limited. This study aimed to compare the clinical outcomes of these two regimens and identify predictors of post-SVR12 HCC development. **Methods:** A total of 478 patients with chronic HCV infection treated with GLE/PIB or SOF/VEL were prospectively enrolled in a multicenter cohort between January 2016 and June 2025. Changes in liver enzymes, renal function, hepatic function, and fibrosis markers, including fibrosis-4 (FIB-4) index and aspartate aminotransferase-to-platelet ratio index (APRI), were assessed from baseline to end of treatment (EOT) and SVR12. Logistic regression analysis was performed to identify independent predictors of post-SVR12 HCC. **Results:** The mean age was 60.5 ± 11.8 years, 46.8% were male, and the mean follow-up duration was 26.5 ± 19.9 months. Overall, 474 patients (99.2%) achieved SVR12, while the 4 patients who failed to achieve SVR12 had all received GLE/PIB

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

therapy. Both regimens significantly improved liver enzymes and fibrosis markers from baseline to EOT and SVR12 (all $P < 0.001$). At EOT, alanine aminotransferase reduction was greater in the GLE/PIB group than in the SOF/VEL group (-45.9 ± 63.6 vs. -21.4 ± 41.9, $P < 0.001$). Estimated glomerular filtration rate (eGFR) significantly decreased in the SOF/VEL group, but not in the GLE/PIB group, with a significant between-group difference ($P = 0.009$). At SVR12, eGFR decreased in both groups, with a greater decline in the SOF/VEL group (P-between = 0.02). During follow-up after SVR12, 9 patients developed de novo HCC. Multivariable analysis identified EOT ALBI > -2.6 (adjusted odds ratio [aOR] 5.98, 95% confidence interval [CI] 1.06–33.68), FIB-4 > 3.25 (aOR 6.74, 95% CI 0.97–46.95), and APRI > 1.0 (aOR 15.26, 95% CI 2.18–106.55), as well as SVR12 APRI > 1.0 (aOR 16.36, 95% CI 2.38–112.51), as predictors of HCC development. **Conclusion:** Both GLE/PIB and SOF/VEL achieved excellent antiviral efficacy and improved hepatic inflammation and fibrosis markers. GLE/PIB showed greater improvement in liver enzymes, whereas SOF/VEL was associated with greater renal function decline. Residual fibrosis and liver dysfunction after SVR12 remained associated with de novo HCC development.

3304 | SHORTER, FASTER: PATIENT CHARACTERISTICS ASSOCIATED WITH 12- VERSUS 8-WEEK SOFOSBUVIR/VELPATASVIR IN AN INCARCERATED HCV COHORT

Christine Wong[1] Victoria Galustian[1] Juneho Jang[1] Grace Ruhnke[1] Mahesh Patel[2] Scott Borgetti[2] Juliana Chan[3], [1]University of Illinois Chicago Retzky College of Pharmacy, [2]University of Illinois Chicago, [3]University of Illinois at Chicago

Background: Chronic hepatitis C virus (HCV) infection is disproportionately prevalent in incarcerated populations. Sofosbuvir/velpatasvir (SOF/VEL) is an effective, well-tolerated therapy with a standard 12-week duration. Available data suggest that an 8-week course may achieve comparable sustained virologic response (SVR) in treatment-naïve, non-cirrhotic patients. Shorter regimens may offer logistical advantages in correctional settings, where treatment continuity is challenged by transfers and variable release dates. Real-world data describing patient characteristics by SOF/VEL treatment duration in carceral systems remain limited. This study compared patient characteristics by treatment duration and evaluated SVR outcomes. **Methods:** We conducted an IRB-approved retrospective chart review of incarcerated adults treated with SOF/VEL in the Illinois Department of Corrections from 1/29/2016 to 11/25/2025. Patients without documented fibrosis stage or HCV genotype were excluded. Variables included age, race/ethnicity, HCV genotype, and fibrosis stage (F0-F1, F2, F3, F4). Patient characteristics were compared by treatment duration (12 versus 8 weeks). Mean age differences were assessed using Welch's t-test and chi-square tests were used for categorical variables. SVR was defined as undetectable HCV RNA ≥ 12 weeks post-treatment. Ribavirin use was evaluated descriptively. **Results:** Among 1065 incarcerated adults, 873 (81.9%) received 12-weeks and 192 (18%) received 8-week therapy. SVR was similar between regimens (12-week: 96.4%; 8-week: 95.8%). Mean age differed by treatment duration, with older patients receiving 12-week versus 8-week (48.2 ± 12.9 versus 36.5 ± 8.9 years; $p < 0.0001$). Fibrosis stage differed by duration ($p < 0.001$): 26.7% of F0-F1, 11.5% of F2, 8.8% of F3, and 1.4% of F4 patients received 8-week therapy. HCV genotype distribution differed by duration in unadjusted analysis ($p = 0.001$). Race/ethnicity differed by duration ($p < 0.001$): 23% White, 4.6% Black, and 7.5% Hispanic patients received 8-week therapy. Ribavirin use differed between regimens, with greater use in the 8-week group (53.6% versus 43.8%; $p = 0.014$). **Conclusion:** In this incarcerated cohort, age, fibrosis stage, genotype, and race/ethnicity differed between patients receiving 12- versus 8-week SOF/VEL in unadjusted analyses, while SVR remained high across all treatment groups. These findings support real-world treatment selection practices and suggest that individualized use of shortened SOF/VEL therapy may improve treatment efficiency and offer potential cost savings in correctional health systems.

Stroger Jr. Hospital of Cook County, [7]Brookdale University Hospital and Medical Center, [8]Nnamdi Azikiwe University Teaching Hospital, [0]Dept of Internal medicine Cape fear valley North Carolina , [10]Montefire Medical Center, Bronx NY, [11]Universidad Icesi, [12]Department of General Practice, Bradford Teaching Hospitals , NHS Foundation Trust, UK, [13]University of Lancashire School of medicine and dentistry

Background: Metabolic dysfunction may worsen liver disease progression in chronic hepatitis B (CHB), yet whether antiviral choice is associated with differential hepatic outcomes in patients with concurrent type 2 diabetes mellitus (T2DM) and MASLD/MASH remains unclear. We compared incident cirrhosis and hepatic decompensation among adults with CHB, T2DM, and MASLD/MASH treated with tenofovir versus entecavir. **Methods:** We performed a retrospective propensity score–matched cohort study using a federated electronic health record network. Adults with CHB, T2DM, and MASLD/MASH were grouped by tenofovir-based therapy or entecavir. Patients with chronic hepatitis C, alcohol-associated liver disease, autoimmune liver disease, cholestatic liver disease, or inherited liver disease were excluded. Outcomes were assessed from 1 day after index through available follow-up. The primary outcome was incident cirrhosis; the secondary outcome was hepatic decompensation, defined by ascites, hepatic encephalopathy, variceal bleeding, hepatorenal syndrome, hepatic failure, or spontaneous bacterial peritonitis. Patients with the outcome before the time window were excluded. Matching yielded 255 patients per cohort **Results:** After matching, median follow-up was 1,233 days in the tenofovir cohort and 1,195 days in the entecavir cohort. For incident cirrhosis, 89 tenofovir-treated and 94 entecavir-treated patients were excluded for prior cirrhosis, leaving 166 and 161 patients, respectively. Incident cirrhosis occurred in 25 tenofovir-treated patients versus 24 entecavir-treated patients, with similar risk between groups (15.1% vs 14.9%; risk difference [RD] 0.002, 95% CI -0.076 to 0.079, p = 0.969; risk ratio [RR] 1.010, 95% CI 0.603–1.693). Kaplan-Meier analysis showed no significant difference in time-to-cirrhosis (HR 0.816, 95% CI 0.460–1.446; log-rank p = 0.484). For hepatic decompensation, 47 tenofovir-treated and 61 entecavir-treated patients were excluded for prior decompensation, leaving 208 and 194 patients, respectively. Decompensation occurred in 17 tenofovir-treated patients versus 18 entecavir-treated patients (8.2% vs 9.3%; RD -0.011, 95% CI -0.066 to 0.044, p = 0.694; RR 0.881, 95% CI 0.468–1.659). Time-to-decompensation was not significantly different between groups (HR 0.739, 95% CI 0.377–1.448; log-rank p = 0.377). **Conclusion:** In this propensity-matched real-world cohort of adults with CHB, T2DM, and MASLD/MASH, tenofovir-based therapy and entecavir were associated with similar risks of incident cirrhosis and hepatic decompensation. These findings suggest comparable hepatic effectiveness between antiviral strategies in a metabolically high-risk CHB population, although residual confounding, coding-based ascertainment, and lack of granular liver disease severity measures limit causal interpretation.

3306 | REDEFINING THRESHOLDS FOR APRI AND FIB-4 SCORES IN DIAGNOSING CIRRHOSIS: EVIDENCE FROM A HIGH-PREVALENCE DISTRICT IN KARACHI, PAKISTAN

Ursala Adil[1], [1]Rutgers Health Trinitas Regional Medical Center

Background: Chronic infection with hepatitis C virus (HCV) is a major public health problem. Simplified and cost-effective diagnostic algorithms and decentralized care can improve access to treatment and reduce delays between testing and treatment initiation. APRI and FIB-4 scores are widely used scoring systems for liver fibrosis and have been validated against transient elastography. A cut-off of 1.5 and 3.25 for APRI and FIB-4 respectively is highly specific but not sensitive enough for diagnosing cirrhosis. **Methods:** This study was conducted in rural communities of district Malir of Karachi which is a high burden area for Hepatitis C. As part of micro elimination efforts in this area from Oct 2019 to June 2022, door-to-door screening was performed using RDTs, those with a positive HCV Ab result were reflex tested for HCV RNA, CBC, and liver enzymes (AST and ALT). Patients with APRI $\geq$ 1.5 and/or FIB-4 $\geq$ 3.25 were categorized as having cirrhosis and prescribed a 24-week DAA regimen of Sofosbuvir and Daclatasvir. Those with APRI < 1.5 and FIB-4 < 3.25 were considered to be non-cirrhotics and received a 12-week treatment. SVR 12 testing was done to assess treatment outcomes, and ROC curves were used to determine APRI and FIB-4 cutoffs based on SVR 12 results. Chi-square test was applied to determine any significant association between

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

treatment outcome (SVR 12 result) and duration of treatment using the new threshold for APRI and FIB-4. **Results:** The study included 1,424 individuals with chronic HCV (average age: 47), with 64% females and 36% males who completed treatment with DAAs and SVR 12 testing. Of these, 87% received a 12-week treatment, and 13% received a 24-week treatment. The overall SVR 12 rate was 88%. Based on the ROC analysis, we determined a cutoff value of 0.639 as the predicted threshold for APRI and 1.351 as the predicted threshold for FIB-4 requiring a 24-week treatment duration.With the existing cut-off for APRI, 11.3% of individuals who received 12 weeks of treatment did not achieve SVR 12. However, upon categorizing using a new threshold ($\leq$0.639), there was a reduction in treatment failures in those who received 12 weeks of treatment to 9.7%. Similarly, applying the established FIB-4 cutoff of 3.25 showed 11.4% treatment failures in individuals on a 12-week treatment, however categorizing with a new threshold ($\leq$1.351) reduced treatment failures to 9.4%. **Conclusion:** Lowering the threshold for APRI to 0.639 and FIB-4 to 1.35 for determining cirrhosis in patients with chronic HCV can improve SVR 12 results after treatment with Sofosbuvir and Daclatasvir.

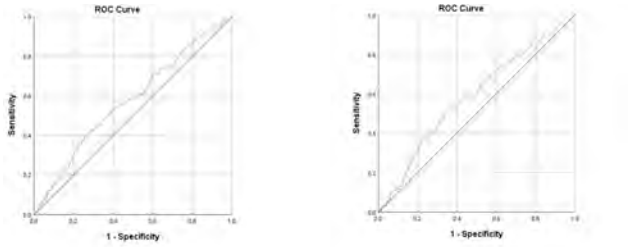

Figure: Receiver-operating characteristic (ROC) curve for APRI (left) and FIB-4 (right) scores in predicting optimal cirrhosis cutoff threshold to determine appropriate treatment duration to achieve SVR12

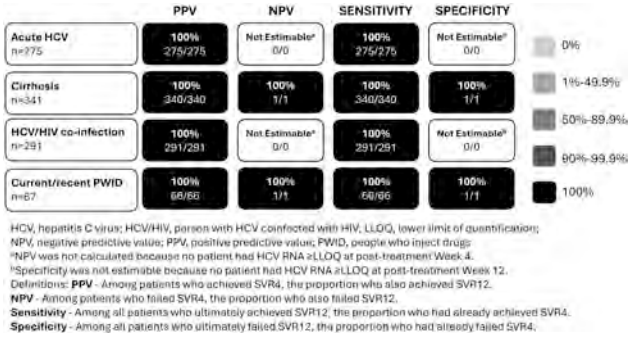
Disclosures: Ursala Adil:Nothing to Disclose.



3307 | PREDICTIVE VALUE OF SVR4 WITH GLECAPREVIR/PIBRENTASVIR IN PATIENTS WITH CIRRHOSIS, HCV/HIV COINFECTION, RECENT INJECTION DRUG USE, OR ACUTE INFECTION

Mark Sulkowski[1] Marina Klein[2] Chris Fraser[3] Barbra Cave[4] Rinal Patel[5] Yanna Song[4] Dimitri Semizarov[4] Karine Lacombe[6] Julio Gutierrez[7], [1]Johns Hopkins Medicine, [2]McGill University Health Centre, Montreal, QC, Canada, [3]Cool Aid Community Health Centre, Victoria, BC, Canada, [4]AbbVie Inc, [5]rinal.patel@abbvie.com, [6]Sorbonne Université, Paris, France, [7]Scripps Center for Organ and Cell Transplantation, La Jolla, CA

Background: Capturing sustained virologic response at post-treatment week 12 (SVR12) can be challenging in real-world clinical practice. Concordance between SVR4 and SVR12 is well established in chronic HCV, and guidelines have introduced SVR4 as a potential endpoint for some populations. However, the predictive value of SVR4 is incompletely understood in acute HCV cases and in special populations, such as those with compensated cirrhosis, HIV coinfection (HCV/HIV), or people who inject drugs (PWID). **Methods:** SVR data were pooled from 14 Phase 2/3 studies of patients with chronic or acute HCV treated for 8 weeks with glecaprevir/pibrentasvir (G/P). To determine the concordance of SVR4 with SVR12, we measured positive predictive value (PPV), negative predictive value (NPV), sensitivity, and specificity of SVR4 in 4 cohorts: cirrhosis, HCV/HIV, current/recent (within the last 12 m) PWID, and acute HCV infection. Missing HCV RNA values in the SVR window were imputed backward, where possible, first using the nearest post-window central lab HCV RNA result and then using a local lab HCV RNA result (if central lab results were unavailable). In the primary analysis, patients with missing HCV RNA data within the SVR4 and/or SVR12 window after imputations were excluded; also excluded were those with adjudicated reinfection (new infection) at SVR12. In the sensitivity analysis, patients with missing SVR4 and/or SVR12 after backward imputation were deemed as failures. **Results:** Among 2824 patients with HCV, 12.3% (n = 348) had cirrhosis, 10.5% (n = 296) had HCV/HIV, 2.7% (n = 75) were current/recent PWID, and 10.1% (n = 286) had acute HCV infection. In the primary analysis, PPV of SVR4 was 100% across all cohorts; NPV and specificity were 100% for the cirrhosis and PWID cohorts; they were not estimable for HCV/HIV or acute infection. Sensitivity was 100% across all cohorts. The small sample sizes in the nonresponder categories limited the assessment of specificity and NPV in some cohorts. In the sensitivity analysis, when missing values after imputation, relapses, and reinfections were treated as failures, PPV was 100% in cirrhosis (340/340), 99.3% in HCV/HIV (291/293), 97.1% in PWID (66/68), 97.9% in acute HCV (275/281); NPV and sensitivity were 100% throughout. Specificity was 100% in cirrhosis, 60.0% in HCV/HIV, 77.8% in PWID, and 45.5% in acute HCV. **Conclusion:** In patients with cirrhosis, HCV/HIV coinfection, current/recent illicit drug use or acute HCV, treated with 8-week G/P for HCV in clinical trials, SVR4 and SVR12 were concordant, with high PPV and NPV. These data support SVR4 as a potential surrogate for HCV cure in clinical practice when SVR12 may later be unavailable. Although the clinical trial results may not be fully generalizable to real-world patient behavior and visit adherence, confirmation of SVR12 remains important for patients with HCV who may be at risk for early reinfection or relapse.

3308 | COMPARISON OF EFFICACY BETWEEN 12-WEEK SOFOSBUVIR/VELPATASVIR (SOF/VEL) REGIMEN COMBINED WITH PRE-USE TENOFOVIR ALAFENAMIDE (TAF) FOR HCV/HBV COINFECTION AND SOF/VEL ALONE FOR HCV MONOINFECTION

Ning Lin[1] Yifan Han[1] Qingya Wang[1] Haiyang Zhou[2] Ying Liu[2] Mengqi Li[3] Yanyan Yu[1] Xiaoyuan Xu[1], [1]Peking University First Hospital, [2]Beijing iGandan Foundation, [3]Beijing Ditan Hospital, Capital Medical University

Background: Compare and evaluate the efficacy and safety of the 12-week sofosbuvir/velpatasvir (SOF/VEL) regimen combined with pre-use tenofovir alafenamide (TAF) for 4 weeks in the treatment of hepatitis C virus (HCV)/hepatitis B virus (HBV) coinfection, and SOF/VEL alone for 12 weeks in the treatment of HCV monoinfection, in treatment-naive adult patients with genotype 1–6 HCV, with or without compensated cirrhosis in China. **Methods:** This was a multi-center, prospective, single-arm, open-label clinical trial (ChiCTR2000033390). Eligible treatment-naive adult patients were enrolled and divided into the HCV/HBV coinfection group and the HCV monoinfection group according to the infection type. The coinfection group was treated with the 12-week SOF/VEL regimen combined with pre-use TAF for 4 weeks, while the monoinfection group was treated with the 12-week SOF/VEL regimen alone. The primary endpoint was the sustained virological response (SVR12) for HCV at 12 weeks after the discontinuation of SOF/VEL treatment. The secondary endpoints included HBV virological response in the coinfection group, changes in ALT, AST and liver stiffness in both groups, incidence of adverse reactions, and comparisons of the above indicators between the two groups. **Results:** A total of 144 eligible patients were enrolled, including 96 patients in the HCV/HBV coinfection group (Group 1) and 48 patients in the HCV monoinfection group (Group 2). There were no statistically significant differences in baseline data (age, gender, distribution of HCV genotypes, proportion of cirrhosis, etc.) between the two groups ($P > 0.05$). After treatment, the overall SVR12 rates were 97.9% in the coinfection group and 100% in the monoinfection group, with no significant difference ($P > 0.05$). HCV RNA levels were dramatically decreased in all patients. In the co-infection group, the HBV DNA level was significantly decreased compared with the baseline, and one patient experienced HBV reactivation. Liver stiffness measurements (LSM), ALT, and AST were all significantly improved in both groups, with no between-group differences ($P > 0.05$). During the entire treatment process, the incidence of adverse reactions in both groups was low (5.2% vs 4.1%), most of which were mild to moderate (such as fatigue and nausea), and there were no serious adverse reactions or treatment-related withdrawal events. **Conclusion:** The 12-week SOF/VEL regimen combined with pre-use TAF for 4 weeks for HCV/HBV coinfection and SOF/VEL alone for HCV monoinfection both achieve excellent efficacy and favorable safety, with no significant difference between regimens. Pre-use TAF effectively prevents HBV reactivation in patients with coinfection, providing a reliable basis for the individualized treatment of patients with different HCV-related infection types in clinical practice.

3309 | REAL-WORLD IMPACT OF DRUG-DRUG INTERACTIONS (DDI): WHY COMPLEX HCV PATIENTS ARE PREFERENTIALLY TREATED WITH SOFOSBUVIR/VELPATASVIR (SOF/VEL) OVER GLECAPREVIR/PIBRENTASVIR (GLE/PIB)

Juan Macias[1] Francisco Tellez[2] Angela Camacho[3] Pilar Rincon[4] Antonio Rivero[3] Dolores Arenga-Barrios[2] Juan Pineda[5], [1]Departamento de Medicina. Universidad e Sevilla, [2]Hospital Universitario Puerto Real, Cadiz, Spain, [3]Hospital Universitario Reina Sofía, Cordoba, Spain, [4]Hospital Universitario Virgen de Valme, Seville, Spain, [5]Departamento de Medicina. Universidad de Sevilla, Spain

Background: Direct-acting antivirals (DAAs) share pharmacokinetic pathways with comedications, posing a risk for DDIs. Despite this, there is limited information on whether these DDIs translate into changes in toxicity or efficacy in clinical practice. We aimed to compare the impact of DDIs on safety and efficacy of GLE/PIB vs SOF/VEL, as well as the clinical actions (comedication switches, withdrawals, or dose reductions) required to address DDIs with either regimen in real-world conditions of use. **Methods:** This multicenter, retrospective, observational study included HCV treatment-naive patients from the GEHEP 001/HEPAVIR cohort taking ≥ 1 comedication or recreational drug. Data from patients treated with SOF/VEL or GLE/PIB in clinical practice between January 2018 and December 2023 were analyzed. **Results:** 542 patients were evaluated (SOF/VEL: 354; GLE/PIB: 188). Baseline patient characteristics for SOF/VEL vs GLE/PIB were: Age, 53.7 vs 51 ($p = 0.002$); HIV, 151 (42.7%) vs 50 (26.6%), ($p < 0.001$); cirrhosis 107 (31.0%) vs 15 (8.2%), ($p < 0.001$); comorbidities, 303 (86%) vs 128 (68%), $p < 0.001$. Before treatment, clinical actions were observed in 101 (31%) SOF/VEL and 44 (23%) GLE/PIB patients ($p = 0.199$). GLE/PIB required more drug discontinuations [35 (80%) vs 44 (44%); $p < 0.001$]. More dose/schedule changes were recorded for SOF/VEL [38 (35%) vs 7 (16%); $p = 0.009$]. During treatment, there were 54 (15.3%) clinical actions in SOF/VEL and 30 (16.0%) in GLE/PIB groups ($p = 0.830$). Discontinuations were more frequent with GLE/PIB [14 (46.7%) vs 4 (7.4%); $p < 0.001$]. Adverse events (AE) were recorded in 93 (26%) SOF/VEL and 36 (19%) GLE/PIB patients ($p = 0.064$). Out of those AE, 20 (22%) SOF/VEL vs 17 (47%) GLE/PIB patients suffered AE attributable to comedication ($p = 0.007$). AE's related with DDIs were identified in 3 (8.3%) patients on GLE/PIB vs none on SOF/VEL ($p = 0.021$). Virological response to SOF/VEL and GLE/PIB was similar. **Conclusion:** In clinical practice, because of the different DDI profile, SOF/VEL may be suitable in a broader spectrum of patients than GLE/PIB, including those with more comorbidities and comedications. Permanent comedication discontinuations are more frequent with GLE/PIB, before and during treatment. Conversely, SOF/VEL was associated with more dose/schedule modifications pre-treatment. Patients on GLE/PIB show a higher frequency of adverse effects related to comedications and with DDIs, but no differences in the rate of SVR.

3310 | DOES THE PRESENCE OF NS5A RESISTANCE-ASSOCIATED SUBSTITUTION SIGNIFICANTLY AFFECT THE SVR RATE?

Murad Qirem[1] Jihad Slim[1] Lina AlQirem[2] Shahd Yaghi[1] Ahmad AlQirem[3] Kevin Leyden[4] Corey Rosmarin-DeStefano[5], [1]New York Medical College, [2]UAMS, [3]Jordan University Of Science and Technology, [4]NJCRI (North Jersey Community Research Initiative), [5]North Jersey Community Research Initiative

Background: NS5A resistance-associated substitutions (RAS) may be an important predictor of treatment response among individuals infected with chronic hepatitis C virus (HCV), particularly among genotype 1a and genotype 3. However, real-world data evaluating sustained virologic response (SVR) in individuals harbouring clinically significant NS5A mutations remain limited. **Methods:** We conducted a retrospective review of prospectively collected data through our telehealth model of HCV treatment in New Jersey among individuals with HCV infection who underwent NS5A resistance testing. Individuals with genotype 1a and genotype 3 infection harbouring significant NS5A RAS were included. Demographic, laboratory, fibrosis, treatment, and virologic outcome data were collected. The primary outcome was achievement of SVR following direct-acting antiviral therapy. **Results:** A total of 14 HCV-infected individuals with significant NS5A RAS were identified. The mean age was 49.3 ± 12.3 years, and 78.6% were males. Race included 42.9% African American, 35.7% White, and 14.3% Hispanic or Latin American. Genotype 1a was present in 57.1% of individuals, while 42.9% had genotype 3 infection. Mean baseline HCV viral load was 2.52 ± 2.73 million IU/mL. Fibrosis staging demonstrated predominantly minimal fibrosis, with 57.1% of patients classified as F0/F1 fibrosis (Table 1).Treatment regimens included sofosbuvir/velpatasvir (S/V) (n = 6), glecaprevir/

pibrentasvir (G/P) (n = 4), and sofosbuvir/velpatasvir/voxilaprevir (S/V/V) (n = 4). Overall, SVR was achieved in 11 out of 14 (78.6%). Individuals treated with S/V/V achieved the highest SVR rate at 100% (4/4), followed by S/V at 83.3% (5/6). Patients treated with G/P demonstrated a lower SVR rate of 50% (2/4). Three patients failed to achieve SVR, including two treated with G/P and one treated with S/V. **Conclusion:** In this real-world cohort of HCV patients with clinically significant NS5A RAS mutations, high SVR rates remained achievable with direct-acting antiviral therapy, particularly with salvage therapy using S/V/V. Lower response rates observed with G/P may highlight the importance of resistance profiling when selecting antiviral regimens. Larger studies are needed to further define optimal treatment strategies for patients with NS5A RAS.

Table 1. Baseline Characteristics of Patients With Significant NS5A Mutations (n=14)

Characteristic	Value
Age, mean ± SD (years)	49.3 ± 12.3
Sex, n (%)	Male: 11 (78.6%); Female: 3 (21.4%)
Race, n (%)	White: 5 (35.7%)
	Black or African American: 6 (50%)
	Hispanic or Latin American: 2 (14.3%)
Genotype, n (%)	Genotype 1a: 8 (57.1%)
	Genotype 3: 6 (42.9%)
Baseline HCV Viral Load, mean ± SD (IU/mL)	2,519,704 ± 2,726,167
Fibrosis Stage, n (%)	F0/F1: 8 (57.1%)
	F2/F3: 4 (28.6%)
	F4: 2 (14.3%)

3311 | ◆ PRE-TREATMENT HCV VIRAL LOAD IS ASSOCIATED WITH BLUNTED ISG RESPONSES IN POST-CURE PBMCS

Olivia Mezzetti[1] Jasneet Aneja[1] Min Xu[1] Thien Trang Nguyen[1] Yongtao Wang[1] Shadi Salloum[1] Swastika Tripathi[1] Zeinab Heidariyan[1] Raymond Chung[1] Wenyu Lin[1], [1]Massachusetts General Hospital, Harvard Medical School

Background: Despite successful cure with direct-acting antiviral (DAA) therapy, chronic Hepatitis C virus (HCV) infection may induce persistent alterations in innate immune function. Previous transcriptomic analyses demonstrated lower post-cure interferon-stimulated gene (ISG) expression in patients with high pre-treatment viral load (VL) compared to those with low VL. Because type I interferons play a central role in antiviral immunity through induction of ISGs, we investigated whether immune cell responsiveness to exogenous type I IFN remains altered after cure and whether the magnitude of these responses is associated with pre-treatment viral load. **Methods:** Preliminary tests of uninfected PBMCs treated with 2, 10, and 30 IU/mL IFN-α for 4, 6, 8, 12, and 24 hours were used to determine optimal IFN dosage and time course for ISG responses. Patients cured of HCV within the past 4 years, defined by sustained virologic response 12 weeks after treatment completion (SVR12), were then identified from our extensive repository. All patients were treatment naïve. Pre-treatment and post-SVR PBMC samples were obtained from 15 patients who harbored high VL (>500K) and 15 patients who harbored low VL (<500K) prior to treatment. PBMC samples were also obtained from 15 uninfected control patients. PBMCs from each time point (pre-treatment or post-cure) were treated with 10 IU IFN-α for 4 hours, and expression of a panel of 20 ISGs was assessed by qPCR. Post-cure ISG expression at baseline and in response to IFN stimulation was compared between VL groups and as a continuous function of pre-treatment VL. **Results:** Preliminary findings in healthy PBMCs showed that 10 IU/mL IFN-α treatment for 4 hours showed the most significant increase in expression of 15 of the 20 target ISGs. Prior to IFN stimulation, baseline ISG expression in post-cure PBMC samples was found to be lower in patients who had a high VL prior to DAA therapy compared to those who had a low VL, supporting previous findings. In response to IFN stimulation, post-cure PBMCs from the high VL group exhibited a lower fold change in ISG expression than the low VL group on average. Further, pre-treatment VL exhibited a significant negative linear correlation with IFN-stimulated ISG fold change. All post-cure PBMCs, regardless of viral load, exhibited a lower fold change in expression compared to the healthy controls. **Conclusion:** Post-cure PBMC interferon responsiveness was altered in a viral load–dependent manner. Specifically, individuals with higher pre-treatment viral load exhibited persistently reduced baseline ISG expression and diminished ISG induction in response to exogenous type I IFN compared to low viral load individuals and healthy controls, suggesting that chronic infection persistently impairs innate immune signaling pathways and may durably alter host immune responses even after cure. These findings have potential implications for immune function in cured HCV patients.

3312 | ◆ MULTISTEP AND DE NOVO-LIKE HEPATOCARCINOGENESIS AFTER SUSTAINED VIROLOGIC RESPONSE FOR CHRONIC HEPATITIS C: AN EOB-MRI-BASED ANALYSIS

Tomoko Tanaka[1] Takuto Nosaka[1] Shouichi Namikawa[1] Arisa Saito[1] Yosuke Murata[1] Yu Akazawa[1] Kazuto Takahashi[1] Tatsushi Naito[1] Yasunari Nakamoto[2], [1]University of Fukui, [2]University of Fukui

Background: Although sustained virologic response (SVR) after antiviral therapy reduces hepatocellular carcinoma (HCC) incidence in chronic hepatitis C virus (HCV) patients, hepatocarcinogenesis can still occur post-SVR. Hepatobiliary phase (HBP)-hypointense nodules on Gd-EOB-DTPA-enhanced magnetic resonance imaging (EOB-MRI) are considered precursors of multistep hepatocarcinogenesis; however, hypervascular HCC may also develop without detectable antecedent lesions. This study aimed to characterize imaging progression patterns of HCC post-SVR and investigate their associated clinicobiological features. **Methods:** We retrospectively analyzed 134 patients with chronic HCV infection who achieved SVR and underwent serial follow-up EOB-MRI examinations between January 2015 and December 2022. Newly developed hypervascular HCCs were classified into a multistep group, showing progression from preceding HBP-hypointense nodules, or a de novo-like group, developing without detectable precursor lesions. Clinical characteristics, metabolic factors, and serum cytokine profiles were compared between the two groups. **Results:** A total of 50 hypervascular HCC nodules were identified in 33 patients and classified into multistep (25 nodules in 17 patients) or de novo-like groups (25 nodules in 16 patients). Serial EOB-MRI demonstrated stepwise hypervascular transformation from HBP-hypointense nodules in the multistep group, whereas hypervascular HCC newly appeared without antecedent lesions in the de novo-like group. Compared with the multistep group, the de novo-like group showed significantly larger tumor sizes. An increase in HbA1c from SVR to HCC diagnosis was observed more frequently in the de novo-like group, suggesting the involvement of metabolic abnormalities after SVR. Serum cytokine analysis revealed significantly higher TNF-α levels and lower MIG levels in the de novo-like group, suggesting distinct inflammatory and metabolic backgrounds associated with imaging progression patterns. **Conclusion:** HCC developing after HCV-related SVR may exhibit heterogeneous imaging progression patterns, including multistep hepatocarcinogenesis and de novo-like tumor development. These radiologic patterns may reflect different inflammatory and metabolic backgrounds associated with hepatocarcinogenesis after SVR. Longitudinal EOB-MRI assessment may provide clinically relevant insight into the heterogeneity of post-SVR hepatocarcinogenesis.

3313 | LEVERAGING HUMANIZED LIVER CHIMERIC MOUSE MODELS TO CHARACTERIZE HCV INFECTIVITY AND STANDARDIZE CHALLENGE INOCULA FOR CONTROLLED HUMAN INFECTION MODELS (CHIM)

Seung Bum Park[1] Justin Shields[2] Laura Collignon[3] Kenn Holmbeck[3] Atif Zahoor[4] Lorne Tyrrell[2] Jens Bukh[3] Jordan Feld[4] T. Jake Liang[1], [1]National Institutes of Health, [2]University of Alberta, [3]University of Copenhagen, [4]University of Toronto

Background: A major obstacle in hepatitis C virus (HCV) vaccine development is the lack of standardized, high-titer challenge inocula suitable for Controlled Human Infection Models (CHIM). Humanized liver chimeric mouse models, including Fah−/−/Rag2 −/−/Il2rg−/− (FRG) and urokinase-type plasminogen activator–severe combined immunodeficiency (uPA-SCID) mice, support robust HCV infection and provide a potential platform for evaluating clinically relevant infectious materials. However, their utility in characterizing qualitative and quantitative determinants of HCV infectivity in human-derived serum remains incompletely defined. **Methods:** Primary human hepatocytes were engrafted into FRG and uPA-SCID mice, followed by infection with HCV derived from human serum or lipid nanoparticle (LNP)-encapsulated full-length HCV RNA. Viral replication kinetics and infectivity were evaluated across multiple HCV genotypes. Human donor sera were further analyzed to determine the relationship between antibody-free HCV RNA fractions and *in vivo* infectivity. In selected experiments, infected

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

mice were treated with direct-acting antiviral (DAA) regimens to assess virologic response. **Results:** Humanized liver chimeric mice supported sustained HCV viremia reaching up to 10^8 copies/mL across multiple genotypes. Analysis of human donor serum demonstrated that higher proportions of antibody-free HCV RNA correlated with increased *in vivo* infectivity, identifying a potential metric for selecting optimal donor serum for CHIM applications. In addition, LNP-mediated delivery of full-length HCV RNA established productive infection in chimeric mice with infection kinetics comparable to serum-derived HCV infection, supporting the feasibility of RNA-based generation of infectious challenge inocula. Infected mice also responded to DAA treatment with sustained virologic response. **Conclusion:** Humanized liver chimeric mouse models provide a robust platform not only for antiviral studies but also for characterization and quality control of clinically relevant HCV infectious materials. These findings support the use of chimeric mouse systems to evaluate donor serum infectivity and develop standardized challenge inocula for future HCV controlled human infection models.

3314 | EFFECT OF DIRECT-ACTING ANTIVIRALS (DAA'S) ON HEPATIC STEATOSIS AND INSULIN RESISTANCE IN TREATMENT-NAIVE HEPATITIS C PATIENTS IN INDIA

Mayank Agarwal[1] Sumit Rungta[2] Kothalkar Srikanth[3], [1]King George Medical University, Lucknow, India, [2]KGMU, [3]KGMU, Lucknow, India

Background: Chronic Hepatitis C virus (HCV) infection is closely associated with insulin resistance (IR) and hepatic steatosis, both of which contribute to accelerated fibrosis progression, cirrhosis, and hepatocellular carcinoma. Genotype 3, the predominant genotype in India, is particularly associated with severe metabolic derangements. Although direct-acting antivirals (DAAs) achieve high sustained virologic response (SVR) rates, their impact on insulin resistance and hepatic steatosis in treatment-naïve non-diabetic Indian patients remains inadequately studied. The present study was conducted to evaluate the effect of DAA therapy on insulin resistance, insulin sensitivity, and hepatic steatosis in chronic HCV-infected non-diabetic patients. **Methods:** This prospective analytical study was conducted at the Department of Medical Gastroenterology, King George's Medical University, Lucknow, among 200 treatment-naïve non-diabetic chronic HCV-infected patients. Baseline demographic, clinical, biochemical, and radiological parameters were recorded. Insulin resistance and insulin sensitivity were assessed using Homeostasis Model Assessment for Insulin Resistance (HOMA-IR) and Quantitative Insulin Sensitivity Check Index (QUICKI), respectively. Hepatic steatosis and liver stiffness were evaluated using FibroScan-controlled attenuation parameter (CAP) and liver stiffness measurement (LSM). Patients received DAA therapy according to national guidelines and were reassessed 12 weeks after completion of treatment (SVR12). Statistical analysis was performed using SPSS version 25.0. **Results:** The mean age of participants was 42.49 ± 13.05 years, and 43.5% were males. Before treatment, insulin resistance was present in 58.5% patients by HOMA-IR and in 77% by QUICKI criteria. Mean HOMA-IR significantly decreased from 3.09 ± 2.11 to 1.65 ± 1.17, while QUICKI significantly increased from 0.336 ± 0.037 to 0.367 ± 0.035 following DAA therapy ($p < 0.001$). The proportion of insulin-resistant patients declined markedly after treatment. Mean CAP values significantly decreased from 265.03 ± 35.32 dB/m to 225.44 ± 34.28 dB/m, indicating substantial improvement in hepatic steatosis. Severe steatosis decreased from 21.5% to 2.0%. Liver stiffness also improved significantly. All patients achieved SVR. Hepatic steatosis emerged as an independent predictor of insulin resistance. **Conclusion:** DAA therapy significantly improves insulin resistance, insulin sensitivity, hepatic steatosis, and liver stiffness in treatment-naïve non-diabetic chronic HCV patients. Viral eradication not only achieves virological cure but also favorably modifies important metabolic abnormalities associated with HCV infection. These findings support early diagnosis and prompt DAA treatment to reduce long-term hepatic and metabolic complications in chronic HCV infection.

3315 | ◆ EFFICACY OF PLASMAPHERESIS VERSUS STANDARD MEDICAL THERAPY IN PATIENTS WITH SEVERE DRUG-INDUCED LIVER INJURY (DILI) AND UNDERLYING CHRONIC LIVER DISEASE: INTERIM ANALYSIS OF AN OPEN-LABEL RANDOMISED CONTROLLED TRIAL

Khushboo Yadav[1] Shiv Kumar Sarin[2] Saggere Muralikrishna Shasthry[2] Ankur Jindal[2] Rajan Vijayaraghavan[2] Satender Pal Singh[1] Harsh Tevethia[3] Vinod Arora[4] Manoj Sharma[2] Ashok Kumar Choudhury[5], [1]institute of liver and biliary science, [2]Institute of Liver and Biliary Sciences, [3]Institute Of Liver And Biliary Sciences(ILBS), New Delhi, [4]institiute of liver and biliary sciences, [5]institute of liver and bilary sciences

Background: Drug-induced liver injury (DILI) superimposed on chronic liver disease (CLD) poses a distinct and under recognised clinical challenge. In this setting, DILI presents with greater severity, and carries a higher mortality risk. Therapeutic plasma exchange (PLEX) can remove albumin-bound toxins, damage-associated molecular patterns (DAMPs), bile acids, cytokines, and inflammatory mediators, and may offer benefit through immunomodulatory and haemodynamic mechanisms. We undertook a randomised controlled trial to evaluate SMT with SMT plus PLEX therapy in CLD patients with DILI **Methods:** This prospective, randomised, active-controlled, open-label trial (NCT06797011) conducted at ILBS, New Delhi, enrolled adults (18–75 years) with CLD and severe DILI (bilirubin >12 mg/dL or INR >2, confirmed by RECAM score), excluding those with active infection, PLEX contraindications, creatinine >2 mg/dL, or HCC. Patients were randomised 1:1 to PLEX (≥3 alternate-day sessions) plus SMT (Gr. A) or SMT alone (Gr. B), with transplant-free survival at 30 days as the primary endpoint. **Results:** Of 151 patients assessed for eligibility, 96 were randomised (48 per arm). The two groups were well-matched at baseline: mean age 47.2 vs 44.7 years, male sex 79.2% vs 85.4%, mean MELD score 26.9 vs 26.8, and CTP score 11.4 vs 11.0 (all p>0.05). ACLF with DILI was present in 64.6% of the SMT group and 66.7% of the PLEX group (p=ns). The predominant aetiology of CLD was metabolic (MASLD/MASH: 45.8% vs 52.1%), followed by alcohol-related liver disease. The most frequent implicating agent was complementary and alternative medicine (CAM/Ayurvedic preparations: 52.6%), followed by anti-tubercular therapy (9.5%).The primary endpoint of 30-day transplant-free survival was significantly higher in the PLEX+SMT group compared with SMT alone (81.0% vs 59.5%; p=0.038). This survival advantage was sustained at 90 days (69.0% vs 47.6%; p=0.076). The most common PLEX-related adverse events were shivering (25.3%), dyselectrolytaemia (13.7%), tingling (13.7%), fever (11.6%), and post-PLEX sepsis (10.5%). Among patients who died, sepsis/septic shock was the leading cause in both arms (27.3% SMT vs 61.5% PLEX; p=0.075). Of 96 patients, all 96 completed 1-month follow-up and 80 have completed 3-month follow-up **Conclusion:** This interim analysis from an ongoing RCT demonstrates that the addition of PLEX to SMT improves 30-day transplant-free survival in patients with severe DILI presenting as ACLF and acute decompensation PLEX is feasible and tolerable, though post-procedure complications and sepsis require vigilant monitoring.

3316 | ◆ STATIN HEPATOTOXICITY PATIENTS WITH PROLONGED LATENCY (> 1 YEAR) HAVE MORE AUTOIMMUNE FEATURES AND GREATER RATE OF CHRONIC LIVER INJURY: RESULTS FROM THE US DRUG INDUCED LIVER INJURY NETWORK (DILIN)

Alisa Likhitsup[1] Naga Chalasani[2] Ronald Kamusiime[3] Huiman Barnhart[3] David Kleiner[4] Robert Fontana[5], [1]University of Michigan, [2]Indiana University Medical Center, [3]Duke Clinical Research Institute, [4]National Cancer Institute, Bethesda, [5]University of Michigan Hospitals and Health Centers

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Statins are widely used with an estimated 100 million prescriptions per year in the US. However, rare instances of clinically significant statin hepatoxicity have been reported. The aim of this study was to describe the presenting laboratory and histological features and 6-month outcomes amongst 88 high confidence cases enrolled in the Drug Induced Liver Injury Network (DILIN) prospective registry study. **Methods:** Adjudicated cases of statin-DILI with a causality score of definite/highly likely/probable DILI enrolled between Sept 2004 and Jan 2026 were included. Analyses were stratified by drug latency: standard (< 365 days) vs prolonged (> 365 days). 28 of the 42 patients had their liver biopsies centrally reviewed by an experienced hepatopathologist (DEK) and 14 others were retrieved from local records. Simplified autoimmune hepatitis (AIH) scores were calculated to identify cases with probable/definite AIH (score >/=6). Chronic DILI was defined as laboratory evidence of ongoing injury at 6 months after DILI onset. **Results:** 88 cases of definite (5), high-likely (49), or probable (34) statin-DILI are included. Atorvastatin (67%) was most frequently implicated followed by rosuvastatin (11.4%). 7 (8%) developed DILI after a dose increase and another 7 (8%) after switching statins. Median age was 64 years, 74% female, 75% White. The liver injury was hepatitic in 48 (55%) and mixed-cholestatic in 40 (45%). Median drug latency was 132 (67.5, 367.5) days with 66 (75%) having standard latency (365 days). Prolonged latency cases were less likely White (55% vs 82%), but more likely had hepatocellular injury (63.6% vs 51.5%), ANA positivity (62% vs 38%), and were more likely to develop chronic DILI (36.8% vs 14.3%). Of 42 liver biopsies, 10 were typical for and 12 were compatible with AIH. 20 (23%) cases were scored as probable/definite AIH based on simplified AIH score (>/=6) and this was more common in the prolonged latency group (40.9% vs 16.7%). Regarding severity, 33 (37.4%) were hospitalized, 2 (2.3%) underwent liver transplant, and 4 (5%) died with 2 (2.6%) liver-related deaths. The prolonged latency group were more likely to develop chronic DILI (37 vs 14%) but use of corticosteroids was similar. **Conclusion:** Statin-DILI most commonly develops within 12 months after drug initiation, but 25% had prolonged drug latency exceeding 12 months. Over 20% of statin-DILI patients met clinical criteria for autoimmune hepatitis. The prolonged latency patients were more likely to have autoimmune- features and evolve into chronic DILI. HLA data will be presented at the meeting.

Table 1: Clinical Characteristics of 88 statin-DILI patients stratified by drug latency (drug start to DILI onset).

Clinical features	Latency </=365 days (n=66)	Latency >365 days (n=22)	p-value
Age (years)	64 (53, 70)	68 (59, 74)	0.11
Female	48 (73%)	17 (77%)	0.67
White	53 (82%)	12 (55%)	**0.006**
BMI (kg/m^2)	27 (23, 34)	26 (25, 31)	0.66
Statin			0.70
Atorvastatin	43 (65.1%)	16 (72.7%)	
Rosuvastatin	7 (10.6%)	3 (13.6%)	
Simvastatin	9 (13.6%)	0	
Pravastatin	4 (6.1%)	1 (4.5%)	
Lovastatin	2 (3%)	1 (4.5%)	
Fluvastatin	1 (1.5%)	1 (4.5%)	
Statin dose changes	10 (15.2%)	4 (18.2%)	
Latency (days)	94.5 (51, 155)	955 (728, 2238)	**<0.001**
Hepatocellular/ Mix-chol (%)	34 (51.5%)/ 32 (48.5%)	14 (63.6%)/ 8 (36.4%)	0.07
Initial ALT (U/L)	525 (307, 1119)	842 (371, 1181)	0.23
Initial ALk P (U/L)	299 (194, 575)	253 (145, 425)	0.21
Initial INR	1.2 (1, 1.9)	1.2 (1, 1.2)	0.41
Initial bilirubin (mg/dL)	2.7 (1, 6.7)	1.2 (0.8, 2.8)	0.21
R-value	5.1 (1.5, 12.2)	8.6 (3.5, 15.5)	0.09
Peak bilirubin (mg/dL)	4 (1.2, 11.8)	1.7 (0.9, 10.4)	0.24
Peak INR	1.1 (1, 1.4)	1.1 (1, 1.3)	0.66
ANA (1:40)	24 (38%)	13 (62%)	0.06
ASMA (1:40)	26 (42%)	12 (57%)	0.23
IgG (mg/dL)	1150 (861, 1410)	1565 (1155, 1967)	0.06
Liver biopsy performed	28 (42.4%)	14 (63.6%)	0.09
Simplified AIH score >/=6	11 (16.7%)	9 (40.9%)	**0.02**
Treated with corticosteroids	13 (19.7%)	5 (22.7%)	0.77
DILIN Severity score			0.27
Mild (1+)	25 (37.9%)	14 (63.6%)	
Moderate (2+)	14 (21.2%)	2 (9.1%)	
Moderate Hospitalized (3+)	15 (22.7%)	5 (22.7%)	
Severe (4+)	8 (12.1%)	1 (4.5%)	
Fatal (5+)	4 (6.1%)	0	
Chronic liver injury	8 (14.3%)	7 (36.8%)	**0.048**
Liver transplant	2 (3%)	0	>0.99
Death	3 (5.2%)	1 (5%)	>0.99

3317 | ◆ COMPARATIVE EVALUATION OF SMALL MOLECULE GLP-1RA-INDUCED HEPATOTOXICITY IN IPSC-DERIVED HUMAN LIVER ORGANOIDS

Samantha Boisvert[1] Max Garcia[1] Jonathan Sexton[2] Jacob Calka[1] Joel Yates[1] Robert Fontana[3], [1]University of Michigan, [2]University of Michigan Medical Center, [3]University of Michigan Hospitals and Health Centers

Background: Orforglipron, the first FDA-approved, orally bioavailable small molecule glucagon-like peptide-1 receptor agonist (GLP-1RA), has rapidly emerged as an important treatment for obesity/metabolic disease. Adverse events were observed in clinical studies for lotiglipron and danuglipron that ultimately halted their development, including drug-induced liver injury (DILI) and adverse gastrointestinal effects. The mechanisms underlying the divergent outcomes for the gliprons remain poorly understood. Here, we evaluated the effects of three gliprons in human liver organoid (HLO) models to investigate early signatures associated with hepatotoxicity risk. **Methods:** iPSC-derived HLOs were treated with orforglipron, danuglipron, and lotiglipron for 24 or 72 hours. High-content imaging was performed using a multiplexed dye panel to assess effects on viability, cellular perturbations, lipid accumulation, and mitochondrial stress. Segmentation and feature extraction was performed with CellPose/CellProfiler, and per-cell features were aggregated to the well level for morphological analysis. Mahalanobis distance scores were tabulated relative to DMSO controls and unsupervised dimensionality reduction and clustering analyses were performed. BMDExpress3 was used to assess the concentration of the phenotypic "point-of-departure" (PoD) to estimate the toxicity threshold for each compound. Bulk RNA sequencing was done with paired samples for transcriptomic analysis to inform the mechanism of toxicity. **Results:** Preliminary analyses demonstrate compound and concentration-dependent phenotypic perturbations across gliprons. Unsupervised analyses supported the sensitivity of the HLO phenotypic platform in detecting differential responses at clinically meaningful concentrations. Orforglipron exhibited the most potent in vitro toxicity with a phenotypic PoD of 15 uM, followed by danuglipron (45 uM) and lotiglipron (62 uM). To contextualize these thresholds against clinical exposure, both peak (Cmax) and time-averaged steady-state (Css,avg = AUC24/24 h) plasma concentrations were derived from published Phase 1 PK studies. The computed safety margins (PoD/Css,avg): orforglipron 139x, danuglipron 52x, and lotiglipron 1.8x, exhibit a wide safety margin for orforglipron, and indicate a narrow safety margin for lotiglipron, consistent with its observed transaminase elevations. **Conclusion:** These findings demonstrate the utility of phenotypic profiling in HLOs for detecting cytotoxicity and hepatocellular perturbations induced by gliprons and demonstrate orforglipron has the largest safety margin. Ongoing transcriptomic and image-based analyses aim to identify pathways and cellular phenotypes associated with differential hepatotoxic liability among the compounds.

Compound	Raw BMD50	Cmax Adjusted BMD50	Css avg Adjusted BMD50
Danuglipron	45.5616	40.0084	40.23908046
Lotiglipron	62.8544	1.464736842	2.162776389
Orforglipron	15.53645	31.76270588	39.98436364

Compound	Raw IC50	Cmax Adjusted IC50	Css avg Adjusted IC50
Danuglipron	82	65.6	94.26
Orforglipron	10.32	60.7	93.81
Lotiglipron	56.62	1.064	1.573

patients with statin DILI are not well described. In this study, we report the histological features in 28 patients with statin hepatotoxicity enrolled in the US Drug Induced Liver Injury Network (DILIN) whose biopsies were centrally reviewed. **Methods:** Adjudicated high causality cases of statin-DILI with an evaluable liver biopsy enrolled between September 2004 to January 2026 were included. Liver biopsies were interpreted using a standardized scoring system and scored as unlikely, compatible with, or typical of autoimmune hepatitis (AIH) by an expert hepatopathologist (DEK). **Results:** 28 statin-DILI cases adjudicated as definite (2), highly-likely (16), or probable (10) were included. The suspect drugs were atorvastatin (68%), simvastatin (14%), rosuvastatin (7%) and others (11%). Median age was 65 years, 64% female, 89% White, and the median latency to DILI onset was 125 (range 11 - 3572) days. The median time from DILI onset to liver biopsy was 11 (range 1 to 46) days, and 6 (21.4%) were receiving corticosteroids at the time of biopsy. Histological pattern of liver injury was hepatitic in 15 (54%) and mixed/cholestatic in 13 (46%). With respect to features of AIH, 8 (29%) were typical, 7(25%) were compatible, and 13 (46%) were unlikely AIH. Simplified AIH scores were higher among typical/possible vs unlikely (5 vs 3.2, $p = 0.007$. When compared with unlikely AIH, histologically compatible/typical for AIH had higher onset ALT levels [1383 vs 338 U/L, $p < 0.001$], higher R-values [14 vs 1.8, $p < 0.001$], and a trend towards higher IgG levels [1230 vs 1070, $p = 0.12$]. Although ANA/ASMA positivity were similar, the compatible/typical AIH patients were more likely to receive corticosteroids. Histologically compatible/typical of AIH demonstrated more severe interface hepatitis (73 vs 15%), lobular hepatitis (87% vs 46%), and portal inflammation (27% vs 0), increased plasma cells (67% vs 0), coagulative necrosis (37.5% vs 0), bridging necrosis (47% vs 0), central vein endophlebitis (21% vs 0), and hemorrhage (38% vs 0), compared to unlikely AIH (**Table 1**) Ductal paucity and advanced fibrosis were more prevalent among the unlikely AIH cases. Overall, 50% were hospitalized, 2 (7.1%) underwent liver transplantation, and 2 deaths occurred amongst the unlikely AIH while 6 (22%) developed chronic DILI. **Conclusion:** Over 50% of high confidence causality statin DILI cases showed histological findings which were compatible with or typical of sporadic AIH. Clinically, these patients have markedly higher serum aminotransferase levels at presentation, a higher simplified AIH score, and are more likely to receive corticosteroids. These findings raise the possibility that statins may be a precipitant of an autoimmune-like hepatitis in susceptible white patients.

Table 1: Clinical and Histologic Findings of selected statin-DILI cases enrolled in the Drug Induced Liver Injury Network (DILIN)

Histological findings of AIH	Typical/compatible (n=15)	Unlikely (n=13)	p-value
Age (years)	65 (59, 74)	64 (55, 73)	0.70

3319 | CHARACTERIZATION OF IBUPROFEN-INDUCED LIVER INJURY: A GLOBAL MULTI-REGISTRY STUDY

Ismael Alvarez-Alvarez[1] Fernando Bessone[2] Guruprasad Aithal[3] Harshad Devarbhavi[4] Einar Bjornsson[5] Hao Niu[1] M Lucena[1] Raul Andrade[1] Nelia

Hernandez[6] Paul Hayashi[7] Jay Hoofnagle[8] Naga Chalasani[9] Marwan Ghabril[9], [1]University of Malaga, [2]University of Rosario School of Medicine, [3]University of Nottingham, [4]St Johns Medical College Hospital, [5]University of Iceland, [6]Universidad de la República, [7]FDA, [8]NIH, NIDDK, [9]Indiana University

Background: Idiosyncratic drug-induced liver injury (DILI) due to non-steroidal anti-inflammatory agents is responsible for 3 to 10% of cases in different registries. Ibuprofen use is widespread both by prescription and over the counter. While generally safe, ibuprofen can rarely cause severe liver injury but has not been frequently implicated in many registries. We aimed to describe the frequency and clinical features of ibuprofen DILI using globally diverse registries. **Methods:** We reviewed 50 high confidence (probable, highly likely and definite) cases of ibuprofen DILI from multiple prospective and globally diverse registries including; European [Spanish (n = 23), iDILIC (n = 5), Eudragene (n = 4) and ProEuroDILI (n = 1)], Latin American [LatinDILI (n = 13)], North American [US DILIN (n = 3)], and Indian [Bangalore (n = 1)]. Demographics, clinical characteristics, and outcomes were analyzed. **Results:** The majority (72%) of patients with high confidence ibuprofen DILI were reported from Spain and Latin America, 20% from Northern Europe, and only 8% from North America and India. The median age was 46 (range 18 to 83) years and 52% were women. Ibuprofen was used for analgesia in 84%. The injury pattern was hepatocellular in 56%, mixed in 27% and cholestatic in 17% of patients, with similar proportions in the Spanish and LatinDILI vs other registries. Demographic and clinical variables in 38 patients with complete data are described in **Table 1** . The median daily dose of ibuprofen was 1,200 (range 400 to 3600) mg, median duration of use 15 (range 1 to 980) days. 3 patients developed severe skin reactions (DRESS in 2 and Steven-Johnson Syndrome in 1). Among 9 patients undergoing liver biopsy, all featured hepatitis, 2 had cholestasis, and 1 had bile duct loss at 3 weeks after onset. Overall, 3 patients died from liver failure, and 8 patients had abnormal liver chemistries at 6 months or more after onset. There were no sex-based differences in baseline characteristics, liver injury phenotype, or outcome. Ibuprofen treatment continued for 4 days or more (median 11, range 4 to 95 days) after onset in 9 (24%) patients including 2 of the 3 fatal cases. **Conclusion:** Global reporting rates of ibuprofen DILI vary significantly, suggesting an impact of biological or genetic risk factors. However, phenotypic similarities of DILI in Spanish/Latin vs. other registries suggest that this variability may be related to non-biological factors as well, such as prescription policies and dose regimen. Ibuprofen DILI can present with variable patterns of injury, and a low threshold of suspicion to implicate it is needed to avoid misdiagnosis. Delays in withdrawal of ibuprofen suggest lack of recognition of its potential to cause liver injury or overlooking an ibuprofen history due to its over-the-counter use and perceived safety.

Table 1: Selected Characteristics of Ibuprofen DILI Among 38 Cases With Detailed Data

Variable	Number (percentage) or median (range)
Age (yr)	45 (18-83)
Female sex	19 (50%)
Race	
White	36 (95%)
Black	1 (2.6%)
South Asian	1 (2.6%)
BMI (kg/m^2)	26 (21-36)

3320 | FREQUENCY, CAUSES, AND CONSEQUENCES OF LIVER INJURY IN PATIENTS WITH DRUG REACTION WITH EOSINOPHILIA AND SYSTEMIC SYMPTOMS (DRESS)

Divya Minnaganti[1] Craig Lammert[2] Marwan Ghabril[3] Elizabeth Phillips[4] Naga Chalasani[5] Sahand Rahnama-Moghadam[2], [1]Indiana University School of Medicine/ Indiana University Health, [2]Indiana University School of Medicine, [3]Indiana University, [4]Vanderbilt University Medical Center, [5]Indiana University Medical Center

Background: Drug reaction with eosinophilia and systemic symptoms (DRESS) is a severe adverse drug reaction to a medication. Liver injury can occur in DRESS, but its characteristics remain unclear. We describe the frequency, causative agents, and outcomes of liver injury in a large cohort of patients with DRESS. **Methods:** We manually examined the records of patients with DRESS at a tertiary care dermatology practice from 2014–2024. Cases meeting Registry of Severe Cutaneous Adverse Reactions criteria ≥ 3 were included. Liver injury was defined as AST or ALT > 3 x ULN or AP > 2 x ULN, or total bilirubin > 2 X ULN during the DRESS episode. Cases with and without liver injury were compared according to clinical data and drug exposures. Beta lactams, sulfa compounds, and antiepileptics were considered as one class for analysis. Finally, multiple agents were considered as "antibiotics of different classes" and "unrelated drugs". **Results:** Liver injury was present in 105 DRESS cases (62.1%). Demographics were not different between DRESS cases with and without liver injury. However, DRESS cases with liver injury had higher rates of fever, peak creatinine, peak AST, peak ALT, peak Alkaline Phosphatase, and peak total bilirubin compared to cases without liver injury (p-value < 0.05 for all, Table1). The most frequent drugs associated with DRESS cases were mixed classes of antibiotics (17%), beta-lactam antibiotics (15%), glycopeptide antibiotics (12%), sulfa compounds (12%) and anti-epileptics (10%). In terms of frequency of liver injury in DRESS, vancomycin-DRESS and lamotrigine-DRESS had highest frequency of liver injury (90% and 89%, respectively) for single agents, followed by trimethoprim sulfamethoxazole (62%), piperacillin/tazobacam (60%), and allopurinol (50%). Among the 105 cases of liver injury, 61% were considered cholestatic, 25% were hepatocellular, 14% were mixed. Patients with DRESS and liver injury had significantly higher 6-month mortality than DRESS patients without liver injury (26.7%, vs 10.9%, OR: 2.96 95% 95% CI: 1.2- 7.3). Among 28 deaths in DRESS cases with liver injury, 2 were directly related to liver injury, while in 3, liver injury was considered contributory. All liver related deaths had underlying liver disease. **Conclusion:** Liver injury was observed in ~ 60% of patients with DRESS and vancomycin and lamotrigine demonstrated high rates of liver injury. Liver injury was associated with significantly higher 6-month mortality in patients with DRESS.

Table 1: Comparison of selected characteristics of patients with DRESS with and without liver injury

Characteristic	Liver injury n=105	No liver injury n=64	P-value
Age (years)	45.92 ± 22.06	49.09 ± 25.07	0.41
Weight (kg)	80.32 ± 33.24	82.07 ± 37.78	0.76
Female sex	53 (50.5%)	39 (60.9%)	0.24
White	88 (83.8%)	55 (85.9%)	0.88
Latency (days)	19.92 ± 12.62	17.89 ± 14.94	0.40

College, Gujarat,India, [3]Medical Student Year 3, [4]Nootan Medical College,Gujarat,India, [5]Andhra Medical College

Background: Tinospora cordifolia (Giloy) is an increasingly recognized cause ofherb-induced liver injury that can closely resemble autoimmune hepatitis, creating a majordiagnostic challenge. Prior systematic evaluations have been limited by inadvertent poolingof look-alike species, particularly T. crispa, and by small-sample rare-event bias. To ourknowledge, this is the first species-restricted meta-analysis of T. cordifolia-induced liverinjury focused on phenotype, autoimmune serology, and outcomes. **Methods:** We systematically identified clinical studies of T. cordifolia-induced liver injury.Reports involving alternative species, unverified polyherbal exposures, or absent botanicalvalidation were excluded. Rare-event outcomes were pooled using generalized linear mixedmodels with random-intercept logistic regression; higher-heterogeneity endpoints wereanalyzed with inverse-variance random-effects models using Paule-Mandel au^2 estimation. **Results:** Eight studies comprising 94 species-verified patients met inclusion criteria. Pooledmortality was 4.26% (95% CI, 1.62–10.79%; $I^2 = 0.0\%$), representing 4 deaths across theliterature. The pooled transplantation rate was 3.19% (95% CI, 1.03–9.43%). Among 92evaluable cases, a hepatocellular phenotype predominated in 80.43% (95% CI, 71.07–87.31%). ANA positivity was present in 44.20% of tested patients and SMA positivity in14.60%. Corticosteroids were administered in 33.33% of cases with available therapeutic data(n = 78). Complete recovery occurred in 73.10% of the cohort. **Conclusion:** Tinospora cordifolia hepatotoxicity is an important and underrecognized cause of herb-induced liver injury that often mimics autoimmune hepatitis. In this species-restricted synthesis, the injury pattern was predominantly hepatocellular, and autoimmune serologies were frequently positive, especially ANA, supporting the clinical challenge of distinguishing toxic injury from true autoimmune disease. The observed corticosteroid use likely reflects diagnostic uncertainty rather than evidence that steroids are routinely needed. Most patients recovered after exposure cessation, reinforcing that the mainstay of management is prompt withdrawal of the offending herb and supportive care. Rare outcomes such as liver transplantation and death highlight that this entity is not always benign. Clinicians should specifically ask about herbal supplements, particularly T. cordifolia, before diagnosing autoimmune hepatitis or starting immunosuppression.Figure legend- Pooled All-Cause Mortality in Species-Restricted Tinospora cordifolia-Induced-Liver Injury. The common effect model indicates an estimated pooled mortality of 4.26% (95% CI: 1.62%–10.79%)

3322 | COMPARATIVE EVALUATION OF ROENIGK, METAVIR, AND SAF SCORING SYSTEMS IN METHOTREXATE-INDUCED LIVER INJURY: CLINICAL IMPLICATIONS FOR FIBROSIS ASSESSMENT

Melina Almeida Dias Torres[1] Maria Chiara Chindamo[1] Cristiane Villela-Nogueira[1] Renata Perez[1] Vera Lucia Nunes Pannain[1], [1]Federal University of Rio de Janeiro

Background: Long-term methotrexate (MTX) therapy has historically been associated with concerns regarding liver fibrosis, leading to the development of the Roenigk classification for histological monitoring. As liver biopsy has become less frequent with the widespread adoption of non-invasive fibrosis assessment, familiarity with MTX-specific histological classifications has declined. We aimed to evaluate the agreement between the Roenigk classification and contemporary fibrosis staging systems (METAVIR and SAF) and to assess the reproducibility of Roenigk scoring among pathologists with different levels of expertise. **Methods:** We performed a retrospective cross-sectional study of 61 liver biopsies obtained from 43 patients receiving chronic MTX therapy between 2000 and 2019. Biopsies originally evaluated by general pathologists were independently re-reviewed by an experienced hepatopathologist using the Roenigk, METAVIR, and SAF classifications. Agreement for significant fibrosis (Roenigk $\geq$ IIIa, METAVIR $\geq$ F2, and SAF $\geq$ F2) was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

assessed using Cohen's kappa coefficient (κ). **Results:** Agreement for significant fibrosis was substantial between Roenigk and METAVIR (κ = 0.681, p < 0.0001) and moderate between Roenigk and SAF (κ = 0.496, p < 0.0001). The prevalence of significant fibrosis varied according to the scoring system, ranging from 8.2% with Roenigk to 14.7% with METAVIR and 21.3% with SAF. No cases of cirrhosis were identified. Interobserver agreement for Roenigk classification was low between general pathologists and a hepatopathologist (κ = 0.299), but substantial between hepatopathologists (κ = 0.690), highlighting the influence of subspecialty expertise on score interpretation. **Conclusion:** The Roenigk classification demonstrated substantial agreement with METAVIR for identifying clinically significant fibrosis in MTX-treated patients. However, its limited reproducibility among non-specialist pathologists may restrict its applicability in contemporary practice. These findings support the use of more widely adopted fibrosis staging systems, such as METAVIR, and underscore the importance of standardized histological assessment in the evaluation of MTX-associated liver injury.

3323 | USE OF POTENTIALLY HEPATOXIC BOTANICAL PRODUCTS HAS SIGNIFICANTLY INCREASED AMONG US ADULTS; NHANES 2003-2023

Alisa Likhitsup[1] Vincent Chen[1] Robert Fontana[2], [1]University of Michigan, [2]University of Michigan Hospitals and Health Centers

Background: Millions of US adults consume Dietary Supplement (DS) for a variety of perceived health benefits. With an increased number of dietary supplements available online, consumers have shifted from traditional multivitamin/mineral formulations to multi-ingredient botanical and synthetic mixtures products. Some botanicals such as those containing Green tea extract, turmeric, *Garcinia cambogia*, and ashwanganda have been associated with hepatotoxicity. Our study explored trends over time of DS and potentially hepatotoxic botanical products use among US adults. **Methods:** DS use within the past 30 days from 2003-2023 NHANES biannual survey of adults (>/= 18 years) were analyzed. Botanical ingredients were identified using detailed ingredients database. Average biennial percentage change (ABPC) and biennial percentage change (BPC) were reported. Joinpoint regression analysis was performed for trends of DS and potentially hepatotoxic botanical use over time. Data from NHANES Population Totals were used for population size estimates. **Results:** Amongst 59,753 adults surveyed between 2003 to 2023, 28,467 (53.2%) consumed at least one DS and 7,096 (17.2%) consumed botanical products. The most commonly reported potential hepatotoxic botanicals consumed were GTE (1.9%), turmeric (1.7%), ashwagandha (0.26%), and *Garcinia cambogia* (0.16%). Since 2003, DS use increased in all age groups; ABPC 2.63(95%CI 0.33, 4.89) for age 18-39 years, ABPC 1.54(95%CI 0.5, 2.86) for age 40-59 years, and ABPC 2.50(95%CI.98, 3.75) for age >/= 60 years (P < 0.05). Botanical products use also increased since 2010 (BPC 6.22 [95% CI, 5.00 -8.36], p = 0.001), but non-botanical products use remained stable. Botanical use particularly increased since 2003 among females >/= 60 years old (BPC 2.81(95% CI, 1.53- 4.10), p = 0.001) and since 2010 among females age 40-59 years old (BPC 4.10 (95% CI, 1.82- 6.42), p = 0.005), and since 2012 among men 40-59 years old (BPC 10.59(95%CI, 1.95- 19.98), p = 0.03). Since 2003, there was a significant increase in turmeric; ABPC 9.62(95% CI 5.88, 15.83) and ashwagandha use; ABPC 28.9(95% CI 20, 45.7) over time (p < 0.0001), but GTE and *Garcinia cambogia* use remained stable. In 2021-2023, an estimated 155.4 million Americans consumed a DS, an estimated 62.3 million Americans consumed a botanical products and an estimated 30.9 million American adults consumed at least one potentially hepatotoxic botanical. Population-based estimate exposures include 14.3 million turmeric, 8 million ashwagandha, 6.8 million GTE, and 1.8 million *Garcinia cambogia*. **Conclusion:** The prevalence of DS use among US adults has increased over time and primarily driven by a disproportionate increase in a multitude of multi-ingredient botanical products used some of which are potentially hepatotoxic. The trends of botanical products use significantly increased particularly among middle-aged men and women (40-59), and in women >/= 60 years old.

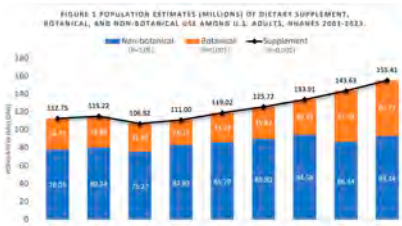

Table 1. Top 15 botanical products used by US adults, NHANES 2017-2023

3324 | HTMP 192: AN IMPROVED HIGH-THROUGHPUT MICROWELL PLATFORM FOR LONGITUDINAL 3D HEPATIC CELL CULTURE AND HEPATOTOXICITY SCREENING

Dominick Hellen[1] Saul Karpen[2], [1]HTMP Inc., [2]VCU Stravitz-Sanyal Institute for Liver Disease and Metabolic Health

Background: Multicellular 3D culture represents an expanding framework of methodologies for physiologically relevant in vitro drug discovery, screening, and disease modeling. Microwell platforms have garnered interest in hepatobiliary research for the development and maintenance of in-suspension size-controlled spheroids and organoids with enhanced transcriptomic and morphologic maturity. These microwell platforms, however, remain constrained in high-throughput settings by longitudinal cell-loss, inter-well variability, and difficult handling, ultimately limiting their broader adoption. **Methods:** To address these limitations, the spacing of a 384-well pitch was modified to engineer a patent pending 192-well High-Throughput Microphysiological Platform (HTMP 192), with each well incorporating a microwell field, an adjacent pipette-access region, and flow-reducing partition wall (Figure). 300 cell spheroids comprised of human hepatocellular carcinoma (HepG2; 95%) and immortalized stellate (LX-2; 5%) cells were seeded in the HTMP 192 and two commercially available high throughput microwell plates. Over 7 days in culture, cells in the 3 platforms were compared for numerous endpoints (spheroid retention, viability [WST-8], albumin [immunofluorescence and ELISA], uniformity, total media exchange) and hepatotoxicity assays following concentration-dependent exposures to diclofenac, tamoxifen, troglitazone, and acetylsalicylic acid. **Results:** Repeated media exchange in the two commercial microwell platforms results in non-circular spheroid formation and significant longitudinal spheroid displacement / loss of 35.4% & 57.8% over 7 days, respectively. In contrast, the HTMP 192 platform maintained longitudinal spheroid and organoid stability (< 5% loss) while enabling > 85% media exchange per well, compared with 50-75% in the commercial platforms. Enabled by this improved retention and media exchange profile, albumin secretion was significantly higher in the HTMP 192 platform compared with both commercial platforms (Figure). Hepatotoxicity screening yielded reproducible dose-response curves in the HTMP 192 platform, supporting compatibility with downstream drug-response assays. **Conclusion:** The HTMP 192 platform provides a longitudinally stable, high-throughput, physiologically relevant microwell culture system with replicability and operational simplicity. These results support consideration of the HTMP 192 platform as an improved infrastructure for reproducible 3D hepatobiliary culture, drug screening, and new approach methodological development. Ongoing studies are extending the platform to additional cell types, molecular exposures, and translational disease models.

3325 | MULTICELLULAR 3D BIOPRINTED LIVER MODELS FOR LIVER TISSUE MODELING, DRUG SCREENING, AND CANCER IMMUNO-ONCOLOGY

Ting-Yu Lu[1], [1]UCSD

Background: Advanced in vitro liver models are needed to improve human-relevant drug screening, toxicology assessment, disease modeling, and NAM-compatible testing. Liver biology is regulated by hepatocytes, endothelial cells, stellate cells, immune cells, extracellular matrix, and tissue architecture. These interactions influence xenobiotic metabolism, inflammation, fibrosis signaling, injury response, and tumor-immune crosstalk. Conventional 2D cultures and many 3D systems do not capture this complexity or allow control of tissue composition, matrix context, geometry, spatial organization, and reproducibility. We developed a 3D bioprinted liver platform for tissue modeling and oncology applications. **Methods:** Printable hydrogel bioinks generated 3D liver constructs with defined cell composition, matrix context, geometry, and spatial organization. For tissue modeling and toxicology studies, constructs incorporated hepatocytes or iPSC-derived hepatocyte-like cells to assess hepatic function, metabolism, and drug-induced injury. For oncology modeling, the hepatic compartment was replaced with hepatocellular carcinoma cells to evaluate tumor behavior and therapeutic response. Both configurations included endothelial, stellate, and immune cells. In the immuno-oncology model, liver cancer cells were combined with myeloid cells under stromal, vascular, and fibrosis-associated cues. **Results:** Our current assay framework focuses on two key performance areas: drug response and CYP-mediated hepatic function. Printed constructs will be evaluated for viability, morphology, albumin secretion, urea production, and CYP450 activity, with emphasis on drug-metabolizing enzymes such as CYP3A4. Drug testing will use benchmark hepatotoxic or metabolism-related compounds to assess dose-dependent changes in viability, ATP activity, LDH release, hepatic function, CYP activity, and inflammatory cytokine secretion. In the multicellular liver cancer model, tumor viability, immune activation, cytokine response, and CYP-related metabolic changes will be assessed to determine how stromal, endothelial, and immune components influence therapeutic response. **Conclusion:** This project positions 3D bioprinting as an engineering-driven approach for modeling liver biology in a controllable, scalable format. By integrating hepatic or liver cancer cells with immune, endothelial, and stellate components, the platform moves beyond simple cultures toward a human-relevant model of liver function, inflammation, fibrosis signaling, and tumor-immune interaction. Its combination of engineering precision, multicellular biology, drug response testing, and CYP readouts supports hepatotoxicity screening, liver cancer modeling, therapeutic development, and NAM-compatible drug testing.

3327 | EX VIVO HUMAN LIVER PLATFORM FOR PHARMACOLOGY AND TOXICOLOGY RESEARCH

Carly Strelez[1] Yumeng (Angela) Sun[1] Virginia Orozco[1] Dan Fower[2] Clare Swift[2] Chris Morris[2] Rachel Perez[1] Cara Sake[1] Desirea Mecenas[1] Brianna Simental[1] Denisse Sibrian[1] Arely Gil[1] Yuyuan Zhou[1] Kruttika Dabke[1] Charlie Ambrose[1] Lily Dara[3] Pratik Mehta[4] Sergei Tatishchev[3] Jonathan Katz[1] Andy Self[2] Shannon Mumenthaler[1], [1]Ellison Medical Institute, [2]OrganOx Ltd, [3]University of Southern California, [4]Procure On-Demand

Background: Preclinical models poorly predict human hepatotoxicity, contributing to drug attrition and safety failures. Advances in ex vivo organ perfusion systems, such as normothermic machine perfusion (NMP), have extended viability for organs prior to transplantation and offer a compelling platform for testing drug metabolism and toxicity. These systems maintain donor organs at physiological body temperature while circulating oxygenated, nutrient-rich blood solutions through the organ. **Methods:** We utilized a modified NMP system (Organox *metra* platform) to perform long-term perfusion on whole, human livers that are unsuitable for transplantation and would otherwise have been discarded. We used APAP as proof of concept to perform toxicological studies. A total of 6 livers were used (n = 3 APAP-dosed, n = 3 controls) in our cohort. During perfusion, viability and function were assessed by lactate clearance, liver enzymes levels, pH maintenance, bile production, and cytokine secretion. Histological assessment of the degree of fibrosis, steatosis, inflammation, injury, and necrosis was performed on pre- and post-perfusion biopsies. Phase I and II metabolites were detected by mass spectrometry. Markers of hepatocellular injury in the perfusate, including GSTα and HMGB1 were measured. **Results:** We demonstrate, in an experimental setting, that successful NMP sustained liver viability for 96-hour in 5/6 donor livers, demonstrating stable performance even in marginal livers, including those with up to 30hrs of cold ischemia times and steatosis levels as high as 40%. Based on H&E, Mason's trichrome, periodic acid-Schiff (PAS), and glutamine synthetase (GS) staining, we showed that the baseline fibrosis and steatosis grade influenced long-term perfusion outcomes. As a case study, three livers were administered

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

acetaminophen (APAP), and metabolism and excretion were monitored in a time- and dose-dependent manner. APAP-treated human livers displayed elevated GSTα and HMGB1 levels, compared with controls in a dose-dependent manner. Histological analysis of pre- and post- perfusion biopsies demonstrated centrilobular necrosis, sinusoidal injury, inflammation, and loss of GS staining in an APAP dose-dependent manner. **Conclusion:** Long-term human liver NMP provides a robust, physiologically relevant platform for real-time assessment of drug metabolism and toxicity, with broad applications in preclinical development, precision therapeutics, and organ-focused research.

3328 | EVALUATING LIVER TOXICOLOGY OF MEDICAL COUNTERMEASURES AGAINST HIGH CONTAINMENT PATHOGENS USING PRIMARY HEPATOCYTES GROWN ON THE PHYSIOMIMIX LC12 MICROPHYSIOLOGICAL SYSTEM

Jennifer Chua[1] Marjorie Torres[1] Jade Spencer[1] Bobby Curry[1] James Meinig[1], [1]US Army Medical Research Institute of Infectious Diseases

Background: The use of animal testing to evaluate pharmacokinetics, pharmacodynamics, and toxicokinetics of therapeutics may be limited in its translatability to humans. Therapeutics developed for pathogens of biodefense concern requiring high biological containment are uniquely exposed to this risk due to reliance on the FDA “Animal Rule” pathway for development. Interspecies differences in liver response and drug induced liver injury (DILI) remain major concerns. New approach methodologies (NAM) such as microphysiological systems (MPS) using human hepatocytes to mimic the structure, function, zonality and compartmentalization of the liver show greater promise in predicting responses to drugs and potential DILI. **Methods:** Here, we have established a NAM to investigate candidates against biodefense pathogens using the perfusable PhysioMimix LC12 microphysiological system. To directly compare risk between human and relevant animal models, primary hepatocytes from four species (human, rat, dog, non-human primate) were cultured and compared for interspecies differences in cell health (LDH, urea, albumin), metabolic activity (CYP3A4), toxicity (AST, ALT) and 3D structural organization (microscopy) in response to rifampin, a test case antibiotic and second-line agent against *Bacillus anthracis*. **Results:** Minimal effects with rifampicin treatment have been shown, which is supported by rifampicin being a low risk of idiosyncratic DILI. Results continue to support study designs and power analysis for future novel therapeutics within the biodefense pipeline. **Conclusion:** Future work will examine the inclusion of feeder cells for supporting hepatocyte health and longevity and Kupffer cells to assess immune responses. Together this work supports transitioning of the NAM system into high biological containment to support mixed toxicological evaluations during infection studies.The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy or position of the Defense Health Agency, Department of War, nor the U.S. Government.

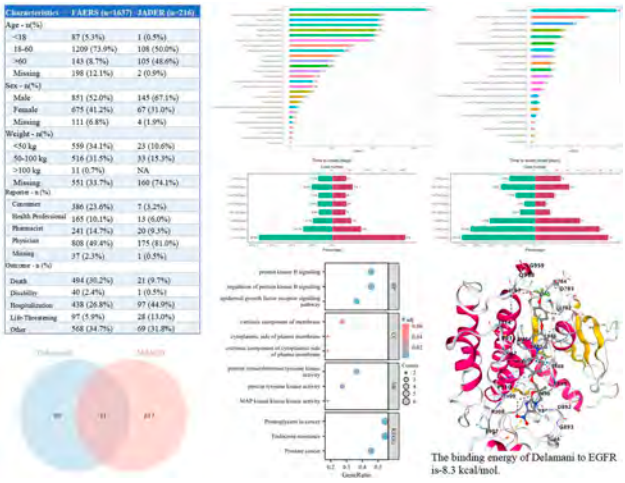
3329 | DELAMANID-ASSOCIATED METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE RISK: A PHARMACOVIGILANCE ANALYSIS COMBINING FAERS AND JADER DATABASES WITH NETWORK TOXICOLOGY STUDY



Ke Mi[1] Wei Tang[1] Zhidan Zuo[2] Qianjun Zhao[3] Sha Lin[1] Zhixiong Fang[1], [1]Xiangtan Central Hospital, Hunan University, [2]Hunan University, [3]Nanhua University

Background: Delamanid is a novel anti-tuberculosis drug used for multidrug-resistant tuberculosis. Previous studies have suggested its potential for metabolic adverse reactions such as hyperlipidemias, but systematic safety studies are lacking. This study aims to systematically evaluate the risk signals and potential mechanisms of delamanid-associated MASLD by jointly analyzing the FDA Adverse Event Reporting System (FAERS) and Japanese Adverse Drug Event

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Report (JADER) pharmacovigilance databases, combintegrated with network toxicology methodanalysis. **Methods:** Based on FAERS (2014-2025) and JADER (2014-2025) data, reports identified as primary suspect were screened. Four disproportionality analysis methods and Bayesian analysis were applied, and resuignalts pdetected consistivently across all methods were considered associated with delamanid. Network toxicology was used to screen delamanib targets, explore key gproteines involved in inducing MASLD, and perform pathway enrichment analysis. **Results:** A total of 1,637 adverse event reports from FAERS and 216 from JADER were analyzed. Metabolic and nutritional disorders showed significant adverse signals associated with delamanid in both databases (FAERS ROR: 3.63 (3.18-4.14); JADER ROR: 1.88 (1.24-2.86)). Subgroup analysis from FAERS indicated that male sex may be negatively associated with delamanid-related metabolic disorders (ROR = 0.72 (0.55-0.95)). The median time to adverse event occurrence was 56 days (IQR: 15-148) in FAERS and 65 days (IQR: 28.5-155.75), respectivelyn JADER. Network toxicology revealed that delamanid may promote MASLD through regulation of protein kinase B signaling pathway, modulation of protein tyrosine kinase activity, and induction of insulin resistance. Molecular docking suggested stable interactions between delamanid and key gproteines such as EGFR, PTK2, and IGF1R. **Conclusion:** Delamanid may increase the risk of MASLD, particularly in female patients. Clinical monitoring of liver function and metabolism should be strengthened in patients receiving delamanid for antituberculosis treatment. Future prospective cohort studies and animal experiments are needed to validate its toxicological mechanisms.

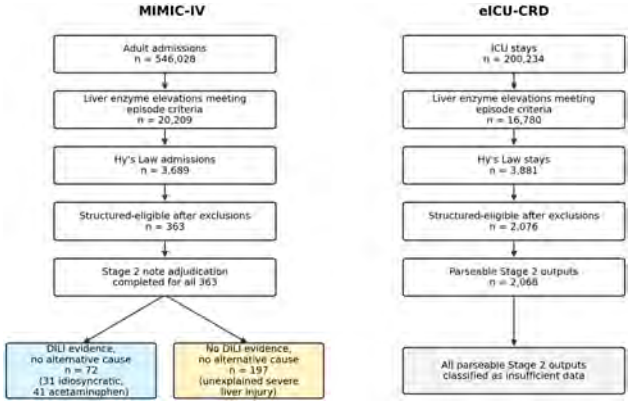
3330 | LLM-AUGMENTED EHR PHENOTYPING IDENTIFIES UNDERRECOGNIZED SEVERE DRUG-RELATED LIVER INJURY IN HOSPITALIZED ADULTS



Thanathip Suenghataiphorn[1] Kochakorn Buasri[2] Narathorn Kulthamrongsri[3] Pojsakorn Danpanichkul[4], [1]Yale/Griffin Hospital, [2]Cincinnati Children's Hospital Medical Center, [3]University of Hawaii, [4]Texas Tech University Health Sciences Center

Background: Drug-induced liver injury (DILI) is diagnostically challenging and may be underrecognized during hospitalization because relevant evidence is often distributed across laboratory data, imaging, medication exposures, and narrative documentation. We developed a two-stage electronic health record phenotyping pipeline combining structured data filters with large language model-assisted chart review to identify severe, potentially underrecognized drug-related liver injury. **Methods:** We performed a retrospective cross-sectional study using the MIMIC-IV and eICU-CRD datasets. Adult admissions were screened for biochemical Hy's Law laboratory thresholds, followed by structured exclusions for common competing etiologies using diagnosis codes and baseline laboratory filters. In MIMIC-IV, an open-source large language model analyzed discharge summaries and radiology reports for evidence of DILI, culprit medications, and alternative explanations. Robustness was assessed using two auxiliary LLMs. A selected subset of adjudicated cases underwent independent dual-reviewer manual validation. **Results:** In MIMIC-IV, 3,689 admissions met biochemical Hy's Law thresholds, of which 363 remained after structured exclusions. LLM-assisted adjudication identified 72 admissions with evidence of drug-related liver injury and no clear alternative explanation, including 31 probable idiosyncratic cases. An additional 197 admissions had severe hepatocellular injury without documented DILI recognition or another clear cause, representing a clinically enriched pool of potentially missed cases requiring focused manual review. Auxiliary LLMs matched the primary model's final binary classification in 88.7% and 89.5% of cases. In the manual validation subset, reviewers agreed on 93 of 100 charts, with substantial interrater agreement (κ = 0.86). Compared with independent reviewer adjudication, the primary model achieved 78.0% and 83.0% accuracy against reviewers A and B, respectively, with higher precision than the auxiliary models. **Conclusion:** A two-stage structured EHR and LLM-assisted phenotyping strategy identified a clinically enriched subgroup of severe, potentially underrecognized drug-related liver injury among hospitalized adults. The pipeline also identified a larger group with severe unexplained hepatocellular

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

injury who may benefit from focused manual review. LLM-augmented EHR phenotyping may support scalable surveillance for severe DILI, but prospective validation and expert adjudication remain necessary before clinical deployment.

3331 | A NOVEL ADJUNCTIVE APPROACH WITH N-ACETYLCYSTEINE AND URSODIOL IN IMMUNOSUPPRESSIVE THERAPY-REFRACTORY IMMUNE CHECKPOINT INHIBITOR-INDUCED HEPATITIS&MDASH;CASE SERIES

Yao (Michelle) Lan[1] Beshoy Yanny[2] Kirellos Mikhail[3] Parsia Vazirnia[2] Trinity Michael[2], [1]UCI Health, [2]University of California, Irvine, [3]University of California, Los Angeles

Background: Immune checkpoint inhibitor (ICI)-induced hepatitis occurs in up to 25% of patients ICIs. Immunosuppressive therapy (IST) is considered first line treatment. When patients have contraindication or fail IST, it becomes a necessity to explore adjunctive therapies. N-acetylcysteine (NAC) and Ursodeoxycholic acid (UDCA) have promising roles in other forms of liver injury but lack data when used together in ICI-induced hepatitis. In this case series, we aim to evaluate the addition of NAC and UDCA in patients with immune suppressive therapy-refractory (ISTR) ICI-induced hepatitis and assess efficacy, safety, and monitoring strategies. **Methods:** Retrospective case series of three patients diagnosed with ISTR-ICI-induced hepatitis who received NAC and UCDA as adjunctive therapy. Diagnosis was via liver biopsy. Liver chemistries were obtained at presentation and monthly. Patients with persistent elevated liver chemistries at week 4 of IST were classified as refractory and received adjunctive ursodiol (12.5 mg/kg/day) and NAC (500 mg PO TID). Percentage change from baseline was calculated for each parameter post-NAC/ursodiol. Data were expressed as mean percentage change ± standard error of the mean (SEM). Paired t-tests were used to compare biochemical responses between the two timepoints, with each patient serving as their own control. A two-tailed p-value of 0.05 was considered significant. We also studied the adverse drug reactions with NAC and ursodiol therapy using the FDA Adverse Event Reporting System (FAERS). **Results:** Addition of NAC and ursodiol, significantly improved AST (Mean decrease from 543 to 44 IU/L) with percent change p-value = 0.016, ALP (Mean decrease from 797 to 130 IU/L) with percent change p-value = 0.008, total bilirubin (Mean decrease from 5.1 to 1.2 mg/dL) with percent change p-value = 0.027, and conjugated bilirubin (Mean decrease from 3.5 to 0.77 mg/dL) with percent change p-value = 0.008. ALT showed a trend toward greater reduction (Mean decrease from 614 to 33 IU/L) with percent change p-value = 0.066. Total protein (p-value for percent change = 0.926) and albumin (p-value for percent change = 0.660) remained stable. No adverse events were reported. IS therapy was fully tapered off by week 28. Adverse drug reactions with NAC and ursodiol therapy using the FDA Adverse Event Reporting System (FAERS) and significant low odds ratio further support the safety profile for these drugs and potential therapeutic benefit in treatment of ICI-induced hepatitis. (ROR 0.136, 95% CI 0.019–0.97; p = 0.0465). **Conclusion:** NAC and UDCA combined use in ISTR-ICI-induced hepatitis was effective, safe and associated with statistically significant improvement in hepatocellular and cholestatic markers beyond what was achieved with corticosteroids and MMF alone. Larger prospective studies are needed to evaluate the efficacy and generalization of this approach.

Figure 1: Longitudinal trends in hepatic biochemistries across the treatment timeline in three patients with steroid-refractory immune checkpoint inhibitor-induced hepatitis.

3332 | STUDY DESIGN AND BASELINE CHARACTERISTICS OF APOLLO: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED CONFIRMATORY TRIAL OF BITOPERTIN IN ADULTS AND ADOLESCENTS WITH ERYTHROPOIETIC PROTOPORPHYRIA OR X-LINKED PROTOPORPHYRIA

Amy Yeung[1] Gayle Ross[2] Mark Amster[3] Karl Anderson[0] Manisha Balwani[5] Herbert Bonkovsky[6] Edward Cordasco[7] Manucher Darani[8] Laurent Gouya[9] Sioban Keel[10] Janneke Langendonk[11] Cynthia Levy[12] Tasneem Mohammad[13] Bruce Wang[14] Will Savage[15], [1]Harvard Medical School and Massachusetts General Hospital, Boston, MA, USA, [2]Royal Melbourne Hospital, Melbourne, Australia, [3]MetroBoston Clinical Partners, Boston, MA, [0]University of Texas Medical Branch, Galveston, TX , [5]Icahn School of Medicine at Mount Sinai, [6]Wake Forest University School of Medicine and Atrium Health Wake Forest Baptist, Winston-Salem, NC, [7]Remington-Davis Clinical Research, Columbus, OH, [8]Marvel Clinical Research, Huntington Beach, CA, [9]University of Paris Diderot, Paris, France, [10]University of Washington/Fred Hutch Cancer Institute, Seattle, WA, [11]Erasmus MC, University Medical Center Rotterdam, Rotterdam, Netherlands, [12]University of Miami, [13]Henry Ford Health System, Detroit, MI, [14]University of California San Francisco Porphyria Center, San Francisco, CA, [15]Disc Medicine

Background: Erythropoietic protoporphyria (EPP) and X-linked protoporphyria (XLP) are characterized by the accumulation of photoreactive protoporphyrin IX (PPIX), causing debilitating cutaneous phototoxic reactions and, in some cases, protoporphyric hepatopathy. Glycine transporter 1 (GlyT1) supplies extracellular glycine for erythroid heme biosynthesis. Bitopertin is an investigational oral GlyT1 inhibitor shown in Phase 2 studies (AURORA [NCT05883748], BEACON [ACTRN12622000799752]) to significantly reduce PPIX and improve light tolerance and quality of life. APOLLO (NCT06910358) was designed to confirm safety, tolerability, and efficacy of bitopertin in adults and adolescents with EPP or XLP. **Methods:** APOLLO is a global randomized, double-blind, placebo-controlled Phase 3 study evaluating once-daily oral bitopertin 60 mg versus placebo over 24 weeks. Eligible participants were $\geq$12 years of age with confirmed EPP or XLP by biochemical and/or genetic testing. Co-primary endpoints are 1) percent change in whole blood metal-free PPIX and 2) average monthly total time in sunlight without pain from a phototoxic reaction between 10:00 and 18:00 after 24 weeks of treatment. Secondary endpoints include occurrence of phototoxic reactions, cumulative sunlight exposure without pain, and change from baseline in time to first prodromal symptoms. Other assessments will evaluate patient-reported quality-of-life measures. Participants completing treatment may continue into the HELIOS open-label extension study. **Results:** Between April 2025 and March 2026, 199 patients were screened at 28 study sites in the US, Canada, Europe, United Kingdom, and Australia; 183 participants were randomized. Mean (SD) age was 37.1 ± 17.1 years; 59% were female and 91% were White. Most participants (93%) had EPP, while 7% had XLP. Diagnostic confirmation was supported by biochemical testing in 52% and genetic testing in 48% of participants. Overall, 60% had not received prior treatment for EPP; 28% and 18% previously received afamelanotide or dersimelagon, respectively. Baseline light tolerance was balanced between participants with $<$30 versus $\geq$30 minutes of tolerance. Adolescents (12 to $<$18 years) represented 19% of enrolled participants, and most adolescents (85%) had not previously received afamelanotide or dersimelagon. Other baseline characteristics were generally similar across adolescent and adult subpopulations. **Conclusion:** APOLLO is designed to evaluate bitopertin as a potential disease-modifying treatment for EPP and XLP. Baseline demographic and disease characteristics were generally consistent with prior EPP/XLP studies and reflective of the broader patient population, supporting the relevance and generalizability of the study results.

★ 3333 | PPARA-MEDIATED SPECIES-SPECIFIC HEPATIC RESPONSES TO PFOS EXPOSURE IN HUMANIZED AND KNOCKOUT MOUSE MODELS OF ALCOHOL-ASSOCIATED LIVER DISEASE

Frederick Ekuban[1] Paxton Ames[1] Abigail Ekuban[1] Oluwanifemi Esther[1] Adrian Centers[1] Yuan Hua[1] Jianzhu Luo[1] Josiah Hardesty[1] Jasey McNabb[1] Addison Wiggam[1] Walter Watson[1] Banrida Wahlang[1] Dhimiter Bello[2] Jennifer Schlezinger[3] Craig McClain[1] Matthew Cave[1], [1]University of Louisville, [2]University of Massachusetts Lowell, [3]Boston University

Background: Perfluorooctane sulfonate (PFOS) is increasingly linked to metabolic dysfunction-associated steatotic liver disease (PMID: 35475652), yet its role in alcohol-associated liver disease (ALD) is understudied. Our prior studies showed that PFOS exacerbates ALD via PPARα (PMID: 40347464), but its mechanistic role and species specificity remain unclear. As PFOS is a strong mouse but weak human PPARα agonist, the human relevance of murine models is uncertain. We investigated species-specific hepatic responses using humanized PPARα (hPPARα) and PPARα-knockout (KO) mice. **Methods:** Male hPPARα and PPARα-KO mice (C57BL/6J) received Lieber-DeCarli diet with 5% ethanol (EtOH) or isocaloric control, with concurrent gavage of 1 mg/kg PFOS or vehicle for 10 days, then a 5 g/kg EtOH binge and euthanasia 5-6h later. Assessments included biochemistry, histology (H&E), gene expression, and high-content imaging of primary hepatocytes. **Results:** PFOS exposure increased EtOH-induced hypertriglyceridemia and elevated VLDL in both genotypes. PFOS decreased EtOH-induced ALT/AST in both genotypes, contrasting prior wild-type findings (PMID:40347464). Blood alcohol levels decreased significantly in KO and trended lower in hPPARα mice with PFOS. Histology revealed genotype-dependent differences: hPPARα mice showed progressive steatosis (mild PFOS, moderate EtOH, severe PFOS +EtOH), whereas KO mice exhibited baseline steatosis with persistent severity across treatments. PFOS+EtOH upregulated *PXR/Cyp3a11* in both genotypes; *CAR/Cyp2b10* remained stable in KO but declined in hPPARα. Lipogenic genes (*PPARγ, Cd36, Fasn*) were upregulated in KO but trended downward in hPPARα. High-content imaging showed enhanced mitochondrial function (4-fold) in hPPARα hepatocytes, versus increased lipid peroxidation (5-fold) in KO. PFOS altered mitochondrial dynamics in a genotype-dependent manner by enhancing ethanol-induced gene expression of *Pink1*, *Park2*, *Drp1*, and *Mfn2* in hPPARα mice while driving a robust, diet-independent upregulation that reflects exaggerated mitochondrial stress in PPARα-KO mice. **Conclusion:** These findings reveal species-specific, PPARα-mediated responses and underscore its central role in modulating hepatic outcomes during PFOS–ethanol co-exposure. Mechanistically, PPARα exhibits dual and context-dependent functions: it preserves lipid homeostasis yet exacerbates hepatocellular injury under combined PFOS and ethanol exposure. Humanized PPARα mice display intermediate phenotypes, underscoring translational differences in receptor activation. Compensatory activation of PXR and CAR pathways in the absence of PPARα suggests cross-regulatory crosstalk. This work provides mechanistic and translational insight into pollutant–alcohol liver interactions and underscores the need for human-relevant models in risk assessment.

3334 | HEPATIC ADAPTATION TO EXPERIMENTAL DRUGS IN CLINICAL TRIALS: RESULTS OF THE IQ DILI INITIATIVE SURVEY OF MULTI-STAKEHOLDER EXPERTS: IMPACT ON DRUG DEVELOPMENT AND IMPLICATIONS FOR DILI DETECTION AND EVALUATION

Melissa Palmer[1] John Caminis[2] Eric Cohen[3] Daniel Seekins[4] Lucy Walker[5] James Philip Esteban[5] James Lewis[6] Don Rockey[7] Nefeteria Coffee[8], [1]CEO Liver Consulting LLC, [2]Gilead, [3]Abbvie, [4]Bristol-Myers Squibb, [5]GSK, [6]Georgetown University Hospital, [7]MUSC, [8]Sanofi

Background: The liver typically adapts after exposure to experimental drugs by modulating cellular and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

metabolic processes, resulting in transient increases in liver tests that return to normal or baseline despite continued dosing. This phenomenon, known as hepatic adaptation, is often observed in clinical trials, but is likely underestimated due to conservative and unnecessary stopping criteria (ALT or AST ≥3×ULN), often leading to premature subject withdrawal, study pause or termination, or discontinuation of drug development altogether. In addtiion the definition of hepatic adaptation has never been clearly and universally defined. To assess how key stakeholders define and manage adaptation, two workstreams of investigation were implemented **Methods:** First, a comprehensive literature search (PubMed, MEDLINE, EMBASE) was conducted using key words "hepatic" and "liver" adaptation or tolerance, alone or combined with: drug-induced liver injury (DILI), hepatotoxicity, liver enzyme elevations, liver adverse events, and liver toxicity. Second, a 14-question survey was administered to DILI academic and regulatory experts and representatives from IQ DILI Industry partners, to assess the current state of practice and its potential impact on drug development and implications for DILI detection/assessment. **Results:** Except for INH-based regimens, the literature review was limited, especially on the topics addressed in the survey. Among 43 respondents (25 industry, 14 academic, 3 regulatory, 1 other), opinions sometimes varied. For example: 68% defined adaptation as liver enzyme elevations returning to baseline or normal despite continued dosing, 22% reported that symptoms were a component of adaptation, 30% reported that a negative rechallenge qualified as adaptation and 11% reported that elevations of liver tests that plateaued defined adaptation. All respondents associated ALT with adaptation, 50% and 42% included ALP and TBIL respectively. To qualify as adaptation, 81% expected liver test elevations to normalize or return to baseline, 30% required them to decrease to <3xULN, 22% felt liver tests can reach a plateau (not elevte further) and 14% proposed liver tests decrease by 50%. Latency was most commonly considered to occur between 1-3 months of exposure (58%), although 20% and 22% of respondents stated that it could occur within the first 72 hours and > 6 months of drug exposure, respectively, to be defined as adaptation. **Conclusion:** There is limited literature on the details of hepatic adaptation and key aspects remain poorly understood. Practices and perspectives among key stakeholders sometimes varied. Improved understanding will impact decision-making in drug development and have implications on identification and evaluation of potential DILI cases. These survey results will be used to develop a multi-stakeholder expert consensus opinion, recommendations, best practices and research priorities.

3335 | GENETIC ARCHITECTURE OF PRURITUS IN IDIOSYNCRATIC DRUG-INDUCED LIVER INJURY (DILI): HLA AND GENE-LEVEL BURDEN TESTING USING WHOLE-EXOME SEQUENCING IN A DEEPLY PHENOTYPED DISCOVERY COHORT

Stuart Astbury[1] Jessica Wong Sun Wai[1] Jane Grove[1] Liou Wei Lun[1] Paola Nicoletti[2] Guruprasad Aithal[1], [1]University of Nottingham, [2]Icahn School of Medicine at Mount Sinai

Background: About 40% of patients with DILI present with itching which reduces quality of life substantially. Despite major advances in the understanding of the genetic susceptibility to DILI, correlations between genotypes and phenotypes are sparse. We investigated genetic factors underlying itching in patients with DILI. **Methods:** In a prospective cohort of 135 patients with DILI evaluated systematically to exclude alternative etiologies and adjudicated following formal causality assessment, genomic DNA of 59 patients with and 76 without itching was sequenced using a whole exome capture panel (Twist Bioscience). STAARpipeline was used to perform both single-variant and gene-based analyses in a model weighted by functional annotation scores (FAVORannotate). Analyses were restricted to the Genomics England Cholestasis v3 panel of 58 candidate genes. In addition, HLA types were imputed using HLA-LA. All analyses were adjusted for population structure and injury pattern (hepatocellular n = 67, cholestatic/mixed n = 64 and unknown n = 4). **Results:** The T allele of ABCC2 rs3740066 (c.3972C > T) was associated with lack of itching (AF 0.23 cases vs 0.42

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

controls; gnomAD NFE 0.37; OR 0.37 (0.20 – 0.67), P = 6.0×10^{-4}). Gene-level STAAR-O analysis indicated that pruritic cases were significantly enriched for missense variants in SMPD1 (4 variants carried by 13% of cases, p = 0.039), NPC1 (3 variants, 4% cases, p = 0.044), and LRP5 (7 variants, 16% cases, p = 0.040). We imputed 66 HLA alleles across 8 loci, and observed a significant association between itching and HLA-C*06:02 (OR 2.93, p = 0.007). **Conclusion:** We present several potential genetic links with pruritus in DILI in a deeply phenotyped cohort. Itching in DILI was associated with genetic factors increasing the level of lysophosphatidylcholine (LPC), its conversion through the autotaxin-lysophosphatidic acid (LPA) axis and subsequent activation of skin C-fibres as well as HLA alleles involved in drug-specific immune reactions. Variants in LRP5, NPC1 and ABCC2 have been linked to pruritus through an upregulation in autotaxin expression observed in cholestasis. Variants in NPC1 and SMPD1 will both alter the amount of substrate available for autotaxin and may also influence pruritus directly through LPC levels.

Gene/Locus	OR (95% CI)	P	AF DILI	AF DILI + pruritus

3336 | ENVIRONMENTAL CO-EXPOSURE TO PFAS AND HEAVY METALS CREATES A CLINICALLY RELEVANT PRO-TUMORIGENIC TRANSCRIPTOMIC SIGNATURE IN A NON-TUMOR MASLD MOUSE MODEL

Haley Arbore[1] Hamda Siddiqui[1] Shannon Heinig[1] Pooja Muddasani[1] Charis-Marie Vanderpuye[1] Jiang Li[1] Natalie Price[1] Zachary Zimmerman[1] Shuai Yuan[1] Sudrishti Chaudhary[1] Noriko Kitano[1] Tyler Yasaka[1] Jia-Jun Liu[1] Silvia Liu[1] Gavin Arteel[1] Junyan Tao[1] Satdarshan (Paul) Monga[1] Alison Sanders[1] Juliane Beier[1], [1]University of Pittsburgh

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the fastest-growing etiology of hepatocellular carcinoma (HCC), yet environmental factors that accelerate MASH-to-HCC progression remain poorly understood. "Rust to Resilience" (R2R) chemical mixtures containing heavy metals (lead, cadmium, arsenic) and PFAS represent environmentally relevant co-exposures common to industrialized regions worldwide. This study investigates the capacity of R2R mixture exposure to promote a pro-tumorigenic hepatic transcriptomic environment in the absence of frank tumor formation, in the context of diet-induced MASLD. **Methods:** C57Bl/6J mice were fed a western diet (WD) or control diet (CD) for 12 weeks with concurrent exposure to vehicle or 1X R2R mixture in drinking water. Bulk RNA-sequencing was performed on liver tissue with DESeq2, KEGG enrichment, and upstream regulatory analysis (IPA/StringDB). Mouse transcriptomic data were cross-referenced against TCGA-LIHC to identify concordantly dysregulated genes, from which a 7-gene prognostic signature was derived via elastic net Cox regression and validated for overall survival and etiology-specific prognostic impact (n = 366). **Results:** R2R exposure worsened WD-induced liver injury. Importantly, none of the animals developed hepatic tumors. Upstream regulatory network analysis revealed dysregulation of HCC-associated upstream regulators including PPARA, FOXO1, CREBBP/EP300, KRAS, MAPK1, and IGF1R, suggesting coordinated suppression of metabolic homeostasis together with oncogenic and epigenetic reprogramming. These findings were further supported by Wnt/β-catenin oncogenic signaling, HCC pathway enrichment (FDR = 5.13×10^{-7}), and suppression of cytotoxic T lymphocyte checkpoints (CTLA4/PD-1). Cross-referencing with TCGA-LIHC identified 90 concordantly dysregulated genes. Elastic net Cox regression derived a 7-gene signature (GAS2L3, SNHG4, CCNB1, ME1, RAPGEF3, SLC22A7, GNA14) predicting worse overall survival (HR = 2.54, 95% CI:1.77-3.65, p < 0.0001), with markedly amplified prognostic impact in MASLD-enriched HCC patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(HR = 3.17, 95% CI:1.70-5.90, p < 0.0001; median OS 20.6 vs. 70.0 months). **Conclusion:** In the absence of frank tumor formation, R2R co-exposure induced a pro-tumorigenic transcriptomic program in MASLD mice, that maps onto human HCC and carries the greatest prognostic impact in metabolic-etiology disease. These data position environmental chemical mixtures as modifiable contributors to MASH-to-HCC progression and underscore the need to account for industrial toxicant co-exposure in at-risk populations globally. Importantly, preliminary evidence of R2R-associated tumorigenesis has been observed in a hepatic tumor induction model, with full histopathological characterization pending.

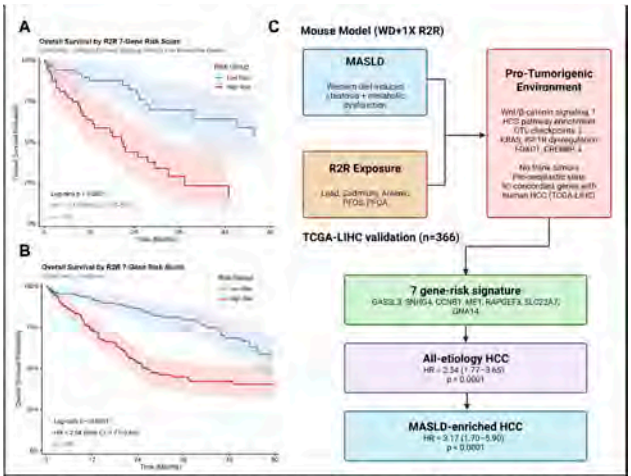

Figure 1. R2R chemical mixture exposure promotes a pro-tumorigenic hepatic transcriptomic environment in MASLD that is clinically validated in human HCC. (A) Kaplan-Meier overall survival in the TCGA-LIHC MASLD-enriched subgroup (n=103), stratified by a 7-gene R2R-derived elastic net risk score (HR=3.17, 95% CI: 1.70–5.90; log-rank p<0.0001). **(B)** Kaplan-Meier overall survival in the full TCGA-LIHC cohort (n=366) stratified by the same signature (HR=2.54, 95% CI: 1.77–3.65; log-rank p<0.0001). Shaded regions represent 95% confidence intervals. **(C)** In a WD+1X R2R mouse model, exposure to R2R chemical mixtures combined with WD-induced MASLD, generating a pro-tumorigenic hepatic environment characterized by Wnt/β-catenin signaling, HCC pathway enrichment, CTL checkpoint suppression, and dysregulation of HCC-associated upstream regulators in the absence of frank tumor formation. Cross-referencing with TCGA-LIHC identified 90 concordantly dysregulated genes, from which a 7-gene prognostic signature was derived and validated in human HCC with greatest prognostic impact in MASLD-enriched patients.

3337 | INVESTIGATING SIRTUIN DEACETYLASE INHIBITION AS A MECHANISM OF PFAS-INDUCED METABOLIC STRESS AND STEATOSIS

Jon Woodward[1] Emily Mitchem[1] Ettayapuram Ramaprasad Azhagiya Singam[2] Martyn Smith[3] Jed Lampe[1] Kristofer Fritz[1] Rebecca McCullough[4], [1]University of Colorado-Anschutz, [2]Molecular Graphics and Computational Facility, UC Berkeley, CA, [3]Division of Environmental Health Sciences, School of Public Health, UC Berkeley, CA, [4]University of Colorado - Anschutz

Background: Per- and polyfluoroalkyl substances (PFAS) are persistent environmental contaminants detected in > 99% of the global population. Their widespread use and resistance to biodegradation contribute to bioaccumulation in the liver. Exposure to the legacy PFAS perfluorooctane sulfonic acid (PFOS) has been associated with an increased risk of metabolic-associated fatty liver disease (MAFLD), but the steatotic potential of next-generation PFAS remains less established. Because sirtuins (SIRTs) regulate hepatocyte lipid metabolism and PFOS has been reported to target sirtuin 1 (SIRT1), we hypothesized that both legacy and next-generation PFAS promote fatty liver via inhibition of SIRTs 1-3. **Methods:** Potential PFAS-SIRT interactions were evaluated using in silico molecular docking (Autodock Vina v1.2; Schrodinger). Predicted binding affinities and interaction profiles were analyzed for SIRT1-3. PFAS-mediated effects on SIRT deacetyl activity were assessed in vitro using a deacetylation-based recombinant protein assay with Superoxide Dismutase 3 (SOD3) and NAD(P)H quinone oxidoreductase 1 (NQO1) as the acetyl targets. To evaluate SIRT inhibition and lipid accumulation in cells, differentiated human hepatocyte-like HepaRG cells were exposed for 72 hrs to 25 µM PFOS or next-generation PFAS: perfluorobutane sulfonic acid (PFBS), perfluorohexane sulfonic acid (PFHxS), perfluorobutane sulfonamide (FBSA), perfluorohexane sulfonamide (FHxSA), or 1,1,2,2 perfluorohexane sulfonic acid (4:2 FTS). Total protein acetylation was quantified via Western Blot, and neutral lipid accumulation was quantified by Nile Red staining. SIRT-selective inhibitors served as positive controls (SIRT1 = EX-527, SIRT2 = AGK2, SIRT3 = 3-TYP), along with the pan-SIRT inhibitor (FK866 and

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

nicotinamide [NAM]). **Results:** Across compounds, PFAS preferentially docked within the NAD+ cofactor site of SIRTs and adopted consistent orientations within the pocket. Docking suggested hydrogen-bond and VDW interactions with residues key for SIRT activation, substrate/partner interactions, and catalytic deacetylation. Predicted binding affinity positively correlated with PFAS backbone length, but not with PFAS subclass. In vitro, PFAS inhibition across SIRT isoforms was SIRT3 > SIRT1 > SIRT2. In HepaRG cells, all PFAS increased total protein acetylation and neutral lipid load, consistent with diminished SIRT-mediated deacetylation and altered hepatocyte metabolic regulation. **Conclusion:** These findings support a model where PFAS interact with SIRTs, disrupting SIRT-mediated deacetylation, providing a plausible mechanistic link to PFAS-driven hepatic steatosis and MAFLD. Future work will define PFAS-associated changes in the hepatic acetylome to identify the most affected SIRT-regulated metabolic pathways. This work was supported in part by NIH/NIEHS grants R21ES032529 to JL/RM and T32ES029074 (JB/JW).

3338 | POST-TREATMENT SYMPTOMS AND HEALTHCARE UTILIZATION ARE COMMON AFTER EXTERNAL BEAM RADIOTHERAPY FOR HEPATOCELLULAR CARCINOMA BUT DO NOT PREDICT LIVER DECOMPENSATION

Patrick Hazelrigg[1] Elizaveta Lavrova[2] Vir Kalaria[3] Panayiotis Mavroidis[2] Allison Jones[2] Chidi Iloabachie[3] Merete Lund[1] Arjun Juneja[3] Parsa Pazooki[3] Sydney Power[4] Gabriel Lupu[4] Joyce Badal[1] Lawrence Marks[2] Shiva Das[2] Theodore Yanagihara[5] Andrew Moon[5], [1]University of North Carolina Department of Medicine, [2]University of North Carolina Department of Radiation Oncology, [3]University of North Carolina School of Medicine, [4]University of North Carolina Division of Gastroenterology/Hepatology, [5]University of North Carolina Lineberger Comprehensive Cancer Center

Background: External beam radiation therapy (EBRT) has been incorporated into treatment guidelines for hepatocellular carcinoma (HCC). Although EBRT is associated with low rates of severe toxicity, the relationship between early toxicity and subsequent hepatic decompensation remains incompletely characterized. We sought to evaluate the incidence of acute symptom burden and healthcare utilization during EBRT and assess whether these factors predict clinically significant deterioration in liver function. **Methods:** We performed a retrospective cohort study of 192 patients with HCC treated with liver-directed EBRT at a single tertiary center. Acute toxicities were recorded, including the rate of new or worsening symptoms during treatment requiring new prescription medication. Healthcare utilization included emergency department visits or hospitalizations within 90 days of treatment completion. The primary outcome was a $\geq$2-point increase in Child-Pugh (CP) score at 6 months. Univariable logistic regression was performed, followed by a prespecified multivariable model adjusting for baseline liver function, age, acute toxicity, and liver dose. **Results:** Fifty-eight percent of patients reported at least one acute symptom during EBRT, and 20% required new prescription medications. Acute healthcare utilization occurred in 12.5% of patients. At 6 months, 14.7% experienced a $\geq$2-point increase in CP score. Acute toxicity measures, including nausea/vomiting requiring medication (OR 1.01, $p = 0.98$) and acute care utilization (OR 1.51, $p = 0.55$), were not associated with CP worsening on univariable analysis. In contrast, higher baseline Albumin-Bilirubin (ALBI) score (OR 3.16 per SD, $p < 0.001$) and liver V15 (OR 1.28 per 100 cc, $p = 0.015$) were associated with increased odds of hepatic decompensation. In mulivariable analysis, ALBI score remained strongly associated with 6-month CP worsening (OR 3.94 per standard deviation increase, $p < 0.001$). Liver V15 was also independently associated with CP worsening (OR 1.54 per 100 cc increase, $p = 0.001$) **Conclusion:** In patients treated with EBRT for HCC, post-treatment hepatic decompensation was associated with baseline liver function and the volume of liver receiving at least 15 Gy, but not acute symptom burden and post-treatment healthcare utilization. These findings inform predictions of post-EBRT hepatic decompensation and suggest that patient-reported acute toxicity may not reflect underlying hepatic reserve.

3339 | CLINDAMYCIN-INDUCED LIVER INJURY: PHENOTYPE, OUTCOMES, AND HLA RISK ALLELES

Wesam Aleyadeh[1] Yi-Ju Li[2] Samuel Broderick[3] Huiman Barnhart[3] Jay Hoofnagle[4], [1]National Institute of Diabetes and Digestive and Kidney Diseases, National Institutes of Health, [2]Duke University School of Medicine, [3]Duke Clinical Research Institute, Duke University, Durham, NC, [4]NIH, NIDDK

Background: Clindamycin is a widely used lincosamide antibiotic but is infrequently reported as a cause of drug-induced liver injury (DILI). HLA associations have been identified for DILI caused by several antibiotics but have not been evaluated for clindamycin. We describe the clinical phenotype, outcomes, and HLA associations of clindamycin DILI in the DILIN prospective registry. **Methods:** We identified DILIN-enrolled cases in which clindamycin was listed as a primary or secondary suspected cause. Causality was adjudicated by expert opinion as definite (1), highly likely (2), probable (3), possible (4) or unlikely (5). Cases were reviewed for latency, R ratio at onset, peak liver biochemistries, drug allergies, comorbidities, and outcomes. HLA class I and II typing was performed on available samples and compared with population controls and with other DILIN cohorts (non-antibiotic drug associated cases). **Results:** Clindamycin was a suspected agent in 33 cases: 6 high-confidence (causality 1 to 3), 22 possible, and 5 unlikely. Twenty-seven cases had complete HLA data. The 6 high-confidence cases comprised 4 scored as highly likely and 2 as probable, with clindamycin the sole implicated drug in 5. In this cohort, median age was 51 years (range 29-73) and 3 (50%) were women. Median latency to symptom onset was 17 days (range 3-36) after a median 10-day course. Injury pattern was predominantly mixed (median R 2.4), with one strongly hepatocellular outlier (R 61, ALT 5625 U/L). Median peak ALT was 886 U/L, alkaline phosphatase 272 U/L, and bilirubin 3.1 mg/dL. A history of beta-lactam allergy was reported in 4 of 6 cases. All 6 cases recovered without evidence of chronic injury. The HLA allele DQA1*03:01 combined with either DQB1*03:01, *03:02, or both) was present in 4 of 5 high-confidence cases with HLA data (carrier frequency 80%) and 9 of 18 possible cases (50%). The single high-confidence case lacking this allele combination was the hepatocellular outlier. Allele frequency was 0.31 across all clindamycin cases versus 0.11 in a DILI control population. **Conclusion:** Clindamycin DILI is typically mild, mixed and self-limited, which makes it more likely to be missed or misattributed. It is strongly associated with an uncommon combination of HLA class II alelles, DQA1*03:01 together with DQB1*03:01 and/or DQB1*03:02, that is shared by DILI from several structurally unrelated antibiotics. This overlap points to a mechanism driven by shared antibacterial activity rather than chemical structure. HLA testing offers insight into the pathogenesis of antibiotic DILI and may inform causality assessment and future approaches to its prevention and treatment.

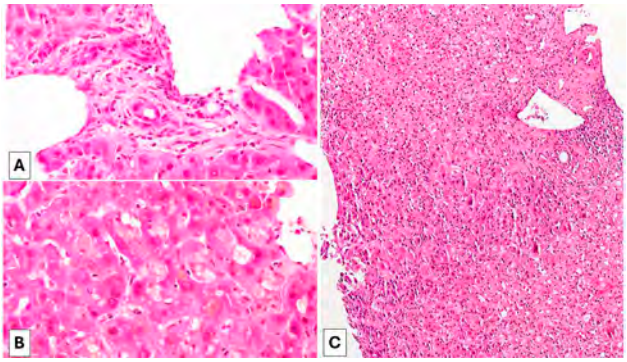
3340 | HISTOLOGICAL ASSOCIATIONS WITH HLA RISK ALLELES IN LIVER INJURY DUE TO AMOXICILLIN-CLAVULANATE



David Kleiner[1] Yi-Ju Li[2] Paola Nicoletti[3] Naga Chalasani[4], [1]National Cancer Institute, Bethesda, [2]Duke University, [3]Icahn School of Medicine at Mount Sinai, [4]Indiana University Medical Center

Background: Drug-induced liver injury (DILI) is a rare but potentially serious adverse event. Genetic factors, especially HLA alleles, have been associated with liver injury in many drugs. In amoxicillin-clavulanate (AC) injury, the HLA alleles A*02:01 and DRB1*15:01 have been identified as risk factors. We hypothesized that the presence of HLA risk alleles may be associated with varied histological injury patterns in AC DILI. **Methods:** Among high causality cases of AC DILI evaluated in the Drug-Induced Liver Injury Network, cases with adequate biopsy material and known HLA haplotypes were identified. Biopsies were evaluated by previously published criteria (PMID: 24037963). Histological features and the overall pattern of injury were analyzed with respect to the presence or absence of the A*02:01 and DRB1*15:01 alleles as well as the total number of risk alleles and the combination of risk alleles. Chi-square and Kruskal-Wallis tests were used to identify possible associations. **Results:** 52 subjects met the inclusion criteria for analysis. At DILI onset, mean age was 60 years (range 13-87) and 18 were female. 23 subjects had only A*02:01 alleles, 6 had only DRB1*15:01 alleles, 16 subjects had at least one allele of each and 7 subjects had neither risk allele. Biopsies in subjects with risk alleles showed more duct injury ($p = 0.03$) (Figure Panel A) and more cholestasis ($p = 0.009$) (Panel B), while cases without risk alleles showed more confluent necrosis ($p = 0.046$) (Panel

C). Increased eosinophils were seen more often in subjects with HLA-A*02:01 risk alleles. **Conclusion:** We are unaware of any systematic histological comparisons of single agent DILI stratified by HLA genotype. Although the number of subjects with biopsy material is low, the data suggests that there could be histological differences between subjects with risk alleles and those without. The immunological injury mechanism may therefore be different when mediated by specific HLA alleles.

3341 | ACUTE EXPOSURE TO AN ENVIRONMENTALLY RELEVANT DIOXIN MIXTURE INDUCES SEX-SPECIFIC HEPATIC METABOLIC DYSREGULATION IN A HUMANIZED AHR MOUSE MODEL

Oluwanifemi Esther Bolatimi[1] Yuan Hua[1] Shikshita Singh[2] Marissa Johns[1] Abigail Ekuban[1] Gavin Philips[1] Frederick Ekuban[1] Banrida Wahlang[1], [1]University of Louisville, [2]Rocky Vista University College of Osteopathic Medicine

Background: Exposure to persistent organic pollutants like ‘dioxins’ has shown causal and correlation effects in metabolic dysfunction-associated steatotic liver disease (MASLD). Dioxins are potent aryl hydrocarbon receptor (AHR) activators and have been reported to induce hepatoxicity via this pathway. However, majority of mechanistic studies utilize murine models expressing murine AHR (mAHR) which has significantly higher ligand affinity and responsiveness than the human AHR for xenobiotics. Thus, this study investigates the translational relevance of acute exposure to an environmentally relevant dioxin mixture in the context of underlying sex differences, using a humanized AHR (hAHR) mouse model. **Methods:** Male and female hAHR-C57BL/6 mice (6-8-week-old) fed a low-fat diet were administered a weekly oral dose of a dioxin mixture: 2,3,7,8-Tetrachlorodibenzo-p-dioxin (10ng/kg) + 2,3,4,7,8 Pentachlorodibenzofuran (80ng/kg) + Polychlorinated biphenyl 126 (140ng/kg) or vehicle control for 2 weeks. At euthanasia, plasma and tissues were collected for downstream analyses. Parallel *in vitro* dioxin exposures were conducted using primary mAHR and hAHR hepatocytes. **Results:** Dioxin exposure induced striking sex-specific metabolic phenotypes. Females exhibited higher hepatic triglyceride and cholesterol levels than males. Plasma glucose and glucose uptake levels were increased in exposed males but decreased in females. Dioxin exposure also reduced insulin resistance and pancreatic insulin production in males, while exposed females displayed increased levels of these measurements. Notably, the dioxin mixture did not significantly activate hepatic hAHR *in vivo* as canonical target genes (*Cyp1a1* and *Cyp1a2*) were not induced in either sex. However, hepatic gene expression of xenobiotic (*Car* and *Pxr*) and nuclear receptors (*Lxr* and *Pparα*) were selectively decreased in exposed females. *In vitro*, exposure of primary hAHR-C57BL/6 hepatocytes to higher concentrations of individual components of the dioxin mixture led to induction of *Cyp1a1* and *Cyp1a2*, with the magnitude of induction differing by sex and chemical. Importantly, induction in males was more robust in wildtype C57BL6 mouse hepatocytes expressing mAHR versus hAHR-C57BL/6 hepatocytes. **Conclusion:** Acute exposure to the dioxin mixture resulted in sex-specific disruptions in glucose and lipid metabolism as well as in hepatic transcriptional machinery independent of canonical hepatic hAHR activation *in vivo*, suggesting off-target effects and mechanisms. The contrast in hepatocyte responsiveness between mAHR and hAHR highlights the necessity of humanized models. Comprehensive evaluation of non-canonical AHR mechanisms, extrahepatic responses, and chronic outcomes in this human-relevant model is critical to accurately assess how current environmental dioxin levels drive sex-specific liver and metabolic toxicity in humans.

3342 | INNATE LYMPHOID CELL 1 IS ASSOCIATED WITH DISEASE SEVERITY AND PROTECTS AGAINST DRUG INDUCED LIVER INJURY

Rongtao Lai[1] Jingjing Jiang[1] Weiwei Lou[1] Mei Huang[1] Qing Li[1] Ziqiang Li[1] Qing Xie[1], [1]Department of Infectious Diseases, Ruijin Hospital, Shanghai Jiao Tong University School of Medicine

Background: Drug nduced liver injury (DILI) is a major cause of acute liver injury, yet the immune mechanisms that govern tissue damage and recovery remain poorly defined. Innate lymphoid cell 1 (ILC1), a liver-enriched innate immune subset, has been implicated in hepatic immune surveillance, but its clinical significance and functional role in DILI are unknown. **Methods:** Peripheral blood ILC subsets were quantified by flow cytometryin patients with DILI and healthy controls, and their associations with biochemical markers of liver injury were assessed. Acetaminophen (APAP)-induced liver injury was established in mice to characterize the dynamic changes of circulating and hepatic ILC1. Functional relevance was tested by Anti-AsGM1-mediated depletion and adoptive transfer of purified hepatic ILC1. Liver injury and repair were assessed by serum aminotransferases, histological necrosis, hepatocyte proliferation, and regeneration-associated signaling proteins. **Results:** Circulating ILC1 frequencies were significantly decreased in patients with DILI, declined with increasing disease severity, and were negatively correlated with total bilirubin levels ($r = -0.4614$, $p = 0.0001$). In APAP-treated mice, circulating ILC1 showed an early decline at 6 h after injury and reached the lowest level at 12 h. In contrast, hepatic ILC1 rapidly accumulated and peaked at 12 h. Anti-AsGM1-mediated depletion aggravated APAP-induced liver injury at 24 h and 48 h, as shown by increased serum ALT and AST levels and enlarged hepatic necrotic areas. ILC1-depleted also impaired reflected reparative responses, with fewer Ki67-positive hepatocytes and reduced expression of PCNA, Cyclin D1, and phosphorylated STAT3. In contrast, adoptive transfer of hepatic ILC1 attenuated liver injury, reduced necrosis, and restored regeneration-associated protein expression. **Conclusion:** Circulating ILC1 are closely associated with DILI severity, while hepatic ILC1 rapidly expand in response to APAP-induced liver injury. In vivo depletion and adoptive transfer experiments identify ILC1 as a previously underappreciated hepatoprotective population that limits liver injury and promotes liver regeneration in DILI.

3343 | TARGETING MITOCHONDRIA TO AMELIORATE MICROCYSTIN-LR-INDUCED LIVER TOXICITY

Neeraja Purandare[1] Apurva Lad[1] Steven Haller[1] David Kennedy[1] Andrew Fribley[1], [1]University of Toledo

Background: Cyanotoxins generated by harmful algal-blooms are increasingly being recognized as important modulators of human disease. One of the most commonly identified toxins in contaminated water is microcystin-LR (MC-LR) which is a potent hepatotoxin. Animal studies have revealed that MC-LR exacerbates liver diseases such as non-alcoholic steatohepatitis. At the intracellular level, MC-LR induces liver damage by activating pro-inflammatory signaling via NF-kappaB, but the upstream signal for this pathway is not well-defined. RNA-sequencing analysis from mouse livers of mice who ingested MC-LR revealed that mitochondrial beta-oxidation (breakdown of fatty acids) is down-regulated with a concomitant upregulation of pro-inflammatory pathways. Mitochondria are important organelles that generate energy by utilizing various substrates such as glucose, glutamine and fatty acids. We hypothesized that MC-LR induces mitochondrial dysfunction activates pro-inflammatory NF-kappaB signaling and induce liver inflammation. **Methods:** This work utilized high-throughput RNA-seq and metabolomic analyses and mitochondria-specific assays (Seahorse bioanalyzer for oxygen consumption, MitoSOX red for reactive oxygen species), NF-kappaB-luciferase reporter assays, luminescence-based ELISAs (cytokines) and qPCR for mitochondrial DNA (mtDNA) measurements. **Results:** We first tested the effect of MC-LR in an in vitro model of human liver cells (Hep3B) and found that MC-LR induces mitochondrial dysfunction by reducing mitochondrial oxygen consumption and increasing ROS. It also reduced mtDNA and protein levels. Mitochondria-specific metabolite and lipid analysis identifed several significantly differentially regulated factors. Of these, carnitine an important precursor involved in mitochondrial beta-oxidation and the fatty acid palmitate were accumulated in liver cells, suppporting the in vivo findings that MC-LR impairs beta-oxidation. To assess the effects on inflammatory signaling, we measured the levels of NF-kappaB phosphorylation, and the levels of TNF-alpha and IFN-gamma, two important pro-inflammatory cytokines which were increased in MC-LR treated hepatocytes. To block these pathogenic effects, we also used an FDA-approved drug nitazoxanide that was identified on a screen of compounds that could activate mitochondria. Nitazoxanide rescued the MC-LR induced oxygen consumption deficit and blocked activation of NF-kappaB. **Conclusion:** Taken together, these findings suggest that mitochondria play a key role in MC-LR-

induced liver damage and therefore, serve as an important mechanistic target to reduce inflammation. This work is particularly significant in the context of preventing effects of this environmental toxin in the pathogenesis and exacerbation of pre-existing liver conditions such as non-alcoholic steatohepatitis and metabolic dysfunction-associated steatotic liver disease.

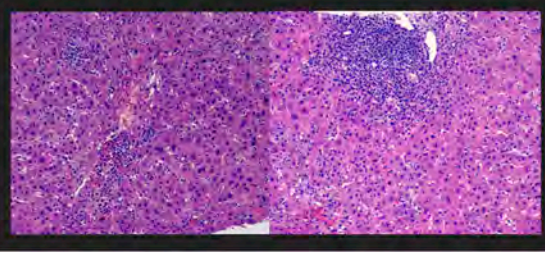
3344 | RIBOCICLIB INDUCED HEPATOTOXICITY: INSIGHTS INTO THE MECHANISM OF LIVER INJURY, CLINICAL COURSE, AND MANAGEMENT



Shelbie Manna[1] Shaun Li[1] Arvind Murali[1],
[1]Orlando Health

Background: Ribociclib, a selective cyclin dependent kinase 4 and 6 (CDK 4/6) inhibitor, has been increasingly used for the treatment of hormone receptor-positive (HR+), human epidermal growth factor receptor-2 negative (HER2-) breast cancer. Ribociclib has been shown to cause acute liver injury. The exact mechanism of hepatotoxicity with ribociclib is unclear. **Methods:** We present a case series of five consecutive patients with ribociclib induced hepatotoxicity. Clinical course, laboratory trends, histopathology, and response to therapy were assessed, and a mechanism of liver injury from ribociclib is discussed. **Results:** Five consecutive patients with ribociclib induced liver injury were studied. Median age was 58 years. The onset of liver injury from the time of initiation of ribociclib ranged from 5 to 12 weeks. All 5 patients developed hepatocellular pattern of injury. Peak alanine aminotransferase (ALT) ranged from 271 to 1125 IU/ml (Table 1). Thorough work up for viral hepatitis (A, B, C, E), EBV, CMV, HSV viral loads, autoimmune markers, ferritin, ceruloplasmin, contrast enhanced imaging were negative in all patients. No alternate medication for drug induced liver injury was noted and no patient had significant alcohol use. All patients had persistent elevation in liver enzymes despite discontinuation of ribociclib. Patients A and B developed grade 4 liver injury while patients C, D, and E had grade 3 liver injury. Patient A developed hyperbilirubinemia. Liver biopsy in patient A revealed acute severe hepatitis with centrilobular hepatocyte dropout, marked lobular and portal lymphocytic inflammation without interface hepatitis, parenchymal collapse and Kupffer cell hyperplasia. Systemic corticosteroid therapy resulted in rapid biochemical improvement and normalization. She was then started on palbociclib, another selective CDK 4/6 inhibitor, resulting in an elevation in AST/ALT, suggesting a class effect of hepatotoxicity. Palbociclib was held and liver enzymes normalized. Prednisone was started in all our patients resulting in rapid improvement and normalization of liver enzymes. Based on our experience with patients A, B, and C, corticosteroid therapy was started early in patients D and E resulting in faster resolution of liver injury and enabling early initiation of alternative breast cancer therapy. **Conclusion:** We believe that ribociclib causes indirect hepatotoxicity, mechanistically like immunotherapy induced hepatitis (ICH) as seen with immune check point inhibitors. Hepatotoxicity from ribociclib, like ICH, is dose-independent with variable latency period. Liver biopsy showed features commonly seen in ICH. While it is possible that liver enzymes may improve eventually without corticosteroid therapy, we recommend considering early initiation of corticosteroids in patients with liver injury grades 3 or 4, to allow for faster resolution and minimize delays in further oncologic treatment.

Table 1: Demographic and Clinical Data of patients with Ribociclib induced hepatotoxicity.

Patient	Age (years)	Onset of liver injury from start of Ribociclib (days)	Peak bilirubin (mg/dl)	Peak ALP (U/L)	Peak AST (U/L)	Peak ALT (U/L)	Start of Prednisone from onset of DILI (days)	Time to normalize liver enzymes from start of prednisone (days)
A	46	55	5.3	230	873	1125	57	78
B	56	83	0.8	67	583	815	61	84
C	68	41	1.3	103	238	417	48	8
D	69	47	0.5	82	215	511	14	27
E	50	41	0.7	97	99	271	21	18

3345 | ◆ IMMUNE CHECKPOINT INHIBITOR THERAPY FOR NON-HEPATIC CANCERS IS ASSOCIATED WITH INCREASED RISK OF LIVER INJURY AMONG PATIENTS WITH COMPENSATED CIRRHOSIS: A MULTICENTER PROPENSITY-MATCHED COHORT STUDY

Nakul Ganju[1] Vinay Jahagirdar[2] Shubham Gupta[3] Abhinav Birda[4] Sahak Hovsepian[5] Farshad Aduli[1], [1]Howard University Hospital, [2]Virginia Commonwealth University Division of Gastroenterology, Hepatology and Nutrition, [3]Virtua Health, [4]Kaiser Permanente Los Angeles Medical Center, [5]Kaiser Permanente Los Angeles

Background: Immune checkpoint inhibitors (ICIs) are increasingly used in patients with chronic liver disease, yet individuals with cirrhosis have been underrepresented in pivotal ICI trials. The hepatic safety of ICIs in compensated cirrhosis for non-hepatic malignancies remains poorly defined. We evaluated this in a multicenter real-world cohort. **Methods:** We performed a propensity score–matched cohort study using the TriNetX Global Collaborative Network of 172 U.S. healthcare organizations (2020–2025). Adults with compensated cirrhosis receiving ICI therapy for non-hepatic cancers were matched 1:1 to ICI-treated adults without liver disease. Patients with prior hepatic decompensation, hepatocellular carcinoma, viral hepatitis, autoimmune hepatitis, or cholestatic liver disease were excluded. Cohorts were matched on demographics, comorbidities, cancer treatment, hepatotoxic medications, and baseline liver-related laboratory values. Primary outcome: diagnosis-coded liver injury within 180 days. Secondary outcomes: hepatotoxicity management proxies, hospitalization, all-cause mortality, hepatic decompensation, and post-ICI transaminases. Hazard ratios were estimated using Kaplan-Meier analysis with log-rank testing. **Results:** Before matching, 1,132 patients with compensated cirrhosis and 118,534 ICI-treated patients without liver disease were identified. After 1:1 propensity matching, 1,132 patients per arm (total N = 2,264). Compensated cirrhosis was associated with significantly higher 180-day liver injury after ICI initiation (5.3% vs 3.3%; HR 1.72, 95% CI 1.11–2.66; p = 0.014). Hepatotoxicity management proxies were similar (35.8% vs 37.6%; HR 1.00, 95% CI 0.64–1.58; p = 0.986). All-cause mortality was similar (20.3% vs 20.5%; HR 1.03, 95% CI 0.86–1.24; p = 0.736). Hospitalization was not significantly increased in cirrhosis patients (18.1% vs 25.9%; HR 0.70, 95% CI 0.49–1.01; p = 0.057). Hepatic decompensation events were uncommon and suppressed due to privacy thresholds. Post-ICI ALT and AST did not significantly differ between cohorts. **Conclusion:** Among ICI-treated patients with non-hepatic cancers, compensated cirrhosis was associated with a higher 180-day hazard of clinically recognized liver injury, without higher mortality or hospitalization. These findings support cirrhosis-specific hepatic risk stratification, closer biochemical monitoring after ICI initiation, and prospective studies to define predictors and management of ICI hepatotoxicity in cirrhosis.

Background: Idiosyncratic drug-induced liver injury (DILI) follows a highly variable clinical course, ranging from spontaneous recovery to liver failure, liver transplantation, or death. Reliable serum biomarkers for early risk stratification remain lacking. We aimed to identify and validate serum proteomic biomarkers associated with adverse outcomes in DILI. **Methods:** Patients with idiosyncratic DILI were prospectively enrolled from 11 Chinese hospitals. In the discovery phase, serum samples from 106 patients enrolled between June 2022 and August 2025 underwent 4D-DIA proteomics and were randomly split into a training set (n = 74) and an internal validation set (n = 32). Adverse outcomes were defined as liver failure, liver transplantation, or death. Machine-learning algorithms were used to identify prognostic biomarkers, whose performance was assessed by ROC analysis and compared with established prognostic scores. Selected biomarkers were validated by ELISA in an independent temporal cohort of 109 patients enrolled between September and December 2025. Functional enrichment, single-cell transcriptomic, and immunohistochemical analyses were performed for biological validation. **Results:** Proteomic profiling and machine-learning screening identified THBS2, SSC5D, and PGK2 as candidate biomarkers associated with adverse outcomes, all of which were significantly elevated in patients with adverse outcomes in both the training and internal validation sets (Figure 1A, B). Because PGK2 has limited established biological relevance to DILI pathobiology, subsequent validation focused on THBS2 and SSC5D. THBS2 and SSC5D showed higher discriminatory performance than nR Hy's law and the Spanish DILI score in both the training set (AUCs: 0.819, 0.732, 0.560, and 0.630, respectively) and internal validation set (AUCs: 0.854, 0.917, 0.396, and 0.750, respectively) (Figure 1C, D). In the independent validation cohort, ELISA confirmed higher serum THBS2 and SSC5D levels in patients with adverse outcomes, with THBS2 showing superior discriminatory performance (Figure 1E, F). THBS2 and SSC5D were correlated with ALB, INR, PLT, and TBIL. Single-cell analysis localized THBS2 upregulation to hepatocytes and mesenchymal cells in DILI-related liver failure, whereas SSC5D upregulation was mainly observed in mesenchymal cells. Immunohistochemistry further confirmed marked hepatic THBS2 upregulation. **Conclusion:** This multicenter proteomic study identified a three-protein serum signature associated with adverse outcomes in idiosyncratic DILI. THBS2 showed robust external validation performance and consistent cellular and tissue-level evidence, supporting its potential as a non-invasive serum biomarker for early risk stratification in DILI.

Background: The Revised Electronic Causality Assessment Method (RECAM) is a computerized causality assessment instrument that was validated against expert opinion for the diagnosis of drug-induced liver injury (DILI) due to a single medication. However, the use of Drug RECAM in assessing the likelihood of liver injury due to herbal and dietary supplements (HDS) indicates a lower level of agreement with expert opinion. Our study aimed to develop a new and improved HDS RECAM for HDS-induced liver injury (HILI) by using clinical data from participants enrolled in the Drug Induced Liver Injury Network (DILIN) Registry study. **Methods:** Data from DILIN patients with suspected single-agent HILI enrolled between 2014-24 were reviewed. Cases attributed to anabolic steroids or those with missing data were excluded. Drug RECAM Domains 1a and 3 were modified to arrive at the new HDS-RECAM to improve agreement in the overall score with expert opinion scores. New domain 1a includes point values of 4, 2 and 0 for HILI latency intervals of 0- 6 months, 6-10 months, and > 10 months, respectively. New domain 3 has point values 3, 1 and 0 based on LiverTox likelihood classification of HDS agent: A /B, C/ D/ E or unknown/not listed, respectively. The resulting HDS-RECAM instrument has values ranging from -6 to 14. **Results:** Amongst the 64 cases of single agent HILI, 54 were definite/high likely/ probable cases and 16 possible/unlikely cases. Median age was 50.9 years, 59.4% female, 70.3% were hepatocellular and 77% required hospitalization. The most commonly implicated HDS were products containing Turmeric (n = 13), Green Tea Extract (n = 8), and Kratom (n = 7). Classification tree analysis found diagnostic cutoffs for overall HDS RECAM scores to be -6 to -2 for 'Unlikely', -1 to 2 for 'Possible', 3 to 5 for 'Probable', and $\geq$ 6 for 'Definite/Highly Likely'. The HDS RECAM outperformed Roussel Uclaf Causality Assessment Method (RUCAM) in identifying at least probable HILI with AUCs of 0.84 vs. 0.59, respectively (p = 0.003). Additionally, the HDS RECAM categories had better overall agreement with expert opinion as compared to RUCAM categories (54.7% vs. 31.3%, p = 0.01) and Drug RECAM categories (54.7% vs. 39.1%, p = 0.052) **(Table 1)** . The HDS RECAM also had better sensitivity than both RUCAM and Drug RECAM to categorize definite/highly likely /probable cases versus possible/ unlikely cases. **Conclusion:** The HDS RECAM is a newly developed causality assessment tool to help adjudicate HILI cases attributed to a single implicated HDS product. It has superior sensitivity and accuracy compared to the RUCAM and Drug-RECAM in high causality HILI cases. HDS RECAM's increased objectivity and ease of use compared to the RUCAM may help improve precision, reliability, and standardization of HILI diagnosis, but additional refinement and validation in other cohorts is needed.

Table 1: Diagnostic Performance of HDS RECAM vs RUCAM and the Drug RECAM in 64 Single HDS Agent Cases Adjudicated By Expert Opinion

Performance Statistic	Causality Score Category	HDS-RECAM	RUCAM	Drug RECAM*	P-value*	P-value**
Percent Agreement with Expert Opinion (95% CI)		54.7 (42.5, 66.9)	31.3 (19.9, 42.6)	39.1 (27.1, 51)	0.01	0.052
AUC (95% CI)	Definite/ Highly likely/Probable	0.84 (0.74, 0.95)	0.59 (0.43, 0.76)	0.82 (0.70, 0.94)	0.003	0.40
Sensitivity (%) (95% CI)	Definite/ Highly likely/Probable	91.5 (83.5, 99.5)	78.7 (67.0, 90.4)	76.6 (64.5, 88.7)	0.048	0.004
Specificity (%) (95% CI)	Definite/ Highly likely/ Probable	58.8 (35.4, 82.2)	35.3 (12.6, 58.0)	76.5 (56.3, 96.6)	0.08	0.056

Background: Acute liver failure (ALF) is an uncommon but fatal outcome of drug-induced liver injury (DILI). Limited data are available comparing the clinical phenotype and outcomes of ALF according to liver injury pattern and causative agent, particularly herbal and dietary supplements (HDS) versus conventional medications. We aimed to characterize the ALF cases from the Spanish DILI Registry and the Latin American DILI Network (LATINDILI) according to liver injury pattern and to compare the clinical characteristics and outcome between HDS- and conventional drug-induced ALF. **Methods:** We performed a retrospective analysis of adjudicated ALF cases identified from the Spanish DILI Registry and LATINDILI Network. Demographic, clinical, biochemical, and outcome variables were analyzed according to liver injury pattern (hepatocellular, cholestatic, or mixed) and causative agent (HDS vs conventional drugs). **Results:** Among 1,546 DILI/HDS cases, 59 (3.8%) ALF cases were identified and analyzed. Hepatocellular injury predominated (90%), whereas cholestatic and mixed patterns each accounted for 5% of cases. Mean age was 51 ± 17 years, and 73% of patients were female. Antituberculosis agents were the most frequently implicated drugs, followed by HDS [*Chelidonium majus*, *Peumus boldus*, *Senecio brasilensis*, *Garcinia cambogia*, *Lipodex and Herbalife Products (reported in 2012)],* amoxicillin-clavulanate, nimesulide, and flutamide.Hepatocellular cases showed significantly higher AST and ALT levels and lower ALP values compared with mixed and cholestatic injury ($p = 0.032$, $p = 0.011$, and $p = 0.002$, respectively). Classical Hy's law and nR-based Hy's criteria were met in 91% of hepatocellular clinical pattern. Fifty-nine of cases died (liver-related death), while 41% underwent liver transplantation. Strikingly, no cases of spontaneous resolution were observed in the present cohort.HDS accounted for 10% (n = 6) of ALF cases and tended to occur in younger individuals (40 ± 13 vs 52 ± 17 years) and more frequently in women (83% vs 72%). Notably, most ALF cases due to conventional drugs were hospitalized (96%) compared with 67% of HDS-induced ALF ($p = 0.048$). Importantly, no significant differences were observed between HDS- and conventional drug-induced ALF regarding liver-related mortality (50% vs 60%, respectively) or liver transplantation rates (50% vs 40%, respectively) (Table). **Conclusion:** In this cohort, ALF developed in 3.8% of DILI/HDS cases and was associated with high liver-related mortality and transplantation rates. HDS accounted for 10% of ALF cases and predominantly affected younger women. Outcomes of HDS-related ALF were comparable to those of conventional drug-induced ALF.

Table. Comparison of demographics, clinical characteristics, and outcome according to causative agent in DILI cases in the Spanish DILI registry and the Latin American DILI (LATINDILI) Network.

	Total registry n=59	HDS induced ALF n=6	Conventional drug-induced ALF n=53	p value

3349 | MASLD AND DRUG-INDUCED LIVER INJURY AFTER AMOXICILLIN-CLAVULANATE EXPOSURE: A LARGE REAL-WORLD COHORT STUDY

Skylar Hargrove[1] Vinay Jahagirdar[2] Butros Fakhoury[3] Vaishali Patel[4] Amon Asgharpour[3] Richard Sterling[3], [1]Department of Internal Medicine, Virginia Commonwealth University, Richmond, VA, United States, [2]Division of Gastroenterology, Hepatology and Nutrition, Virginia Commonwealth University, Richmond,, [3]Virginia Commonwealth University, [4]Division of Gastroenterology, Hepatology and Nutrition, Virginia Commonwealth University, Richmond,

Background: Amoxicillin-clavulanate is a leading cause of drug-induced liver injury (DILI), but whether metabolic dysfunction-associated steatotic liver disease (MASLD) modifies DILI risk or biochemical severity is unclear. We evaluated outcomes after amoxicillin-clavulanate exposure among patients with and without MASLD. **Methods:** We performed a retrospective cohort study using the TriNetX US Collaborative Network. Adults aged ≥18 years who received amoxicillin-clavulanate between 2010 and 2025 were included. MASLD was defined by ICD-10 codes for fatty liver disease or non-alcoholic steatohepatitis, within 3 years of antibiotic exposure. Patients with underlying chronic liver diseases were excluded. The primary comparison evaluated MASLD vs. no liver disease after propensity score matching for demographics, tobacco use, alcohol-related disorders, and BMI. Outcomes from 1 day to 365 days after exposure included new abnormal liver function tests (R94.5) and toxic liver disease/DILI using (K71). Kaplan-Meier analysis was used to estimate hazards. Among patients with DILI, serial ALT, AST, alkaline phosphatase (ALP), and total bilirubin were compared at baseline, 1 week, 1 month, and 1 year. **Results:** Among approximately 6.15 million adults who received amoxicillin-clavulanate, 164 patients with MASLD and 1,236 patients without MASLD had DILI. After matching, 155,478 patients were included in each cohort (Figure). Compared with matched patients without liver disease, MASLD patients had higher 1-year hazards of new diagnoses of abnormal liver function test (HR 3.25, 95% CI 2.90-3.65) and toxic liver disease/DILI (HR 1.86, 1.25 -2.78) after antibiotic exposure. Among patients with DILI, baseline aminotransferases were modestly higher in MASLD versus non-MASLD patients: ALT 38 vs 33 U/L and AST 34 vs 29 U/L. Liver tests peaked within 1 week in both groups, with ALT 96 vs 84 U/L, AST 59 vs 52 U/L, ALP (153 vs 159 U/L, and total bilirubin 0.8 vs 0.6 mg/dL. Values declined by 1 month and approached baseline by 1 year. **Conclusion:** MASLD was associated with higher DILI within 1 year after amoxicillin-clavulanate exposure. However, absolute event rates were low, and MASLD was not clearly associated with greater biochemical severity among patients with DILI. Further studies using peak labs, R-ratio, INR, latency, competing hepatotoxic exposures, and adjudicated DILI definitions are needed.

Figure. Baseline characteristics, 1-year liver-related outcomes, and serial liver biochemistries after amoxicillin-clavulanate exposure stratified by MASLD status. After propensity score matching, baseline demographic, alcohol/tobacco use, and BMI distributions were well balanced between patients with MASLD and those without liver disease. MASLD was associated with higher 1-year hazards of abnormal liver function test diagnosis and ICD-10-coded toxic liver disease/DILI. Among patients with coded DILI, liver tests peaked within 1 week after exposure and declined over time, with broadly similar biochemical trajectories in patients with and without MASLD.

Characteristic after PSM	MASLD + Amoxicillin-clavulanate (n=155,478)	No liver disease + Amoxicillin-clavulanate (n=155,478)
White race	77.9%	78.0%
Female sex	58.0%	58.0%
Male sex	42.0%	42.0%
Not Hispanic or Latino	73.8%	73.9%
Hispanic or Latino	9.9%	9.9%
Black or African American	9.6%	9.5%
Asian	3.3%	3.3%
Tobacco use	4.6%	4.6%
Alcohol-related disorders	4.6%	4.5%
BMI 20–30 kg/m²	29.7%	29.6%
BMI 30–40 kg/m²	44.8%	44.9%
BMI ≥40 kg/m²	21.0%	21.0%

Outcomes in 1 year	Risk % MASLD + Amoxicillin-clavulanate	Risk % No liver disease + Amoxicillin-clavulanate	Hazard ratio (95% CI)	Log-rank p value
Abnormal LFT diagnosis (R94.5)	0.84%	0.25%	3.25 (2.90–3.65)	<0.001
Toxic liver disease / DILI (K71)	0.05%	0.02%	1.86 (1.25–2.78)	0.002

Lab Median (IQR)	Baseline		1 week		1 month		1 year	
Cohort	DILI with MASLD	DILI without MASLD	DILI with MASLD	DILI without MASLD	DILI with MASLD	DILI without MASLD	DILI with MASLD	DILI without MASLD

Cincinnati, [3]Department of Internal Medicine, TriHealth, [4]College of Medicine, University of Illinois, [5]Department of Family Medicine, Ghana Health Service,, [6]University of Michigan Hospitals and Health Centers

Background: The Revised Electronic Causality Assessment Method (RECAM) is an updated, electronic version of the Roussel Uclaf Causality Assessment Method (RUCAM) to diagnose drug-induced liver injury (DILI). A modification of RECAM (RECAM-V3) significantly improved agreement between RECAM and DILIN expert opinion in a retrospective cohort (Am J Gastroenterol 2024;120:1325). However, RECAM-V3 requires validation and refinement. This study compared RECAM-V3 vs. RECAM and RUCAM for patients with suspected idiosyncratic DILI in a community-based cohort. **Methods:** Patient encounters from 10/1/2015 to 9/30/2023, at TriHealth, a large community-based health system, were searched for suspected DILI using ICD-10 K71 codes for toxic liver disease. DILIN expert opinion scores were assigned to each case (1/2/3 = probable-DILI, 4/5 = non-DILI). RECAM-V3 modified scoring of domain 4 of the original RECAM with HCV RNA and anti-HEV testing being optional and a dynamic range of – 6 to +20 points like the original RECAM. RECAM-V3, RECAM, and RUCAM scores were compared with DILIN expert opinion scores. **Results:** After excluding 30 cases of acetaminophen hepatotoxicity, 135 patients with suspected idiosyncratic DILI were analyzed. The average age was 56.9 ± 15.4, 47.4% female, 82.9% Caucasian, and 53.3% hepatocellular injury. Sixty-eight (50.4%) of the 135 cases were adjudicated as probable-DILI, and 67 cases (49.6%) as non-DILI using DILIN expert opinion. The most frequent suspect drugs for probable-DILI were antimicrobial (32.4%), anti-neoplastic (16.2%), statin (13.2%), and herbal supplement (7.4%). The most frequent alternative diagnoses for non-DILI were viral hepatitis (26.9%), decompensated cirrhosis (19.4%), ischemic hepatitis (14.9%), and biliary obstruction (14.9%). RUCAM classified 57 cases (42.2%) as probable-DILI, RECAM classified 28 cases (20.7%) as probable-DILI, while RECAM-V3 classified 59 cases (43.7%) as probable-DILI. RECAM-V3 had better overall agreement with DILIN expert opinion for probable-DILI vs. RUCAM (77.9% vs. 63.2%, $p = 0.09$) or RECAM (77.9% vs. 38.2%, $p < 0.0001$). The overall sensitivity of RECAM-V3 was significantly better than the original RECAM (77.9 % vs 38.2%, $p < 0.0001$) while both instruments had high specificity (Table 1). **Conclusion:** Among 135 suspected idiosyncratic DILI cases, RECAM-V3 had better overall agreement with DILIN expert opinion compared to RECAM or RUCAM. With HCV RNA and anti-HEV IgM testing optional, RECAM-V3 had better sensitivity than the RECAM and RUCAM instruments, suggesting that the proposed modifications improve DILI diagnosis without compromising specificity in this independent validation cohort.

Table 1: Comparison of RECAM-V3, Original RECAM and RUCAM to DILIN Expert Opinion amongst 135 patients with suspected DILI*

Metric	RECAM-V3 Estimate (95% CI)	Original RECAM Estimate (95% CI)	RUCAM Estimate (95% CI)
Sensitivity	77.9 (66.2 – 87.1)	38.2 (26.7 – 50.8)	63.2 (50.7 – 74.6)
Specificity	82.1 (70.8 – 90.4)	97.0 (89.6 – 99.6)	79.1 (67.4 – 88.1)
Positive predictive value	81.6 (72.3 – 88.2)	92.9 (76.3 – 98.1)	75.4 (65.1 – 83.5)
Negative predictive value	78.6 (69.8 – 85.3)	60.7 (56.1 – 65.2)	67.9 (60.3 – 74.8)
Accuracy	80.0 (72.3 – 86.4)	67.4 (58.8 – 75.2)	71.1 (62.7 – 78.6)

3351 | ETIOLOGY, AND RISK FACTORS OF DRUG-INDUCED LIVER INJURY IN AFRICA: A SYSTEMATIC REVIEW

Nkengeh Tazinkeng[1] Bolaji Ayinde[2] Lantum Lydia Dzeenyuy[3] Kenyi Zarrah[3] Sarpong Boateng[4] Mexan Mapouka[5] Albert Owusu-Ansah[1] Basile Njei[6], [1]Rutgers/Newark Beth Israel Medical Center, [2]Northeast Georgia Medical Center, [3]University of Buea, Cameroon, [4]Yale New Haven Health, [5]University of Maryland Capital Region Medical Center, [6]Yale School of Medicine

Background: Drug-induced liver injury (DILI) is a major contributor to acute liver failure worldwide. However, little is known about the population-level epidemiology, causative drug spectrum, and risk factor profile of DILI in Africa, where the use of potentially hepatotoxic antimicrobial therapies and traditional medicine is common. We conducted a systematic review to address these gaps. **Methods:** We performed a systematic search of PubMed, EMBASE, and African Journals Online from inception to February 16, 2026, to identify studies reporting the epidemiology, causative agents, and risk factors of DILI in Africa. We extracted data on study design, population denominators, incidence and prevalence estimates, implicated drug classes, and risk

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

factors including host, demographic, pharmacogenomic, and comorbidity variables. **Results:** After screening for eligibility, we included 63 studies published between 1975 and 2025 across 20 African countries. Geographically, the majority of studies came from South Africa (n = 13 studies), Cameroon (n = 7), Ethiopia (n = 6), and Nigeria (n = 6). All included studies were hospital-based. There were no national DILI registries used in our included studies. Population-level incidence data were largely absent; most studies reported proportions of hepatotoxicity among drug-exposed cohorts rather than true incidence rates, thus preventing reliable continent-wide estimates. Antituberculosis medications (ATT), particularly isoniazid, rifampicin, and pyrazinamide, were the most common implicated causes of DILI, followed by nevirapine- and efavirenz-based antiretroviral therapy (ART). Beyond antimicrobials, NSAIDs (such as diclofenac), acetaminophen overdose, carbamazepine, antineoplastic agents, and herbal or traditional medicines (including Senecio-type plants and khat) were identified as causes of DILI. The most commonly reported risk factors of DILI were concurrent HIV and TB treatment, malnutrition and low BMI, alcohol use, and polypharmacy. **Conclusion:** This study reveals that DILI in Africa is predominantly driven by ATT and ART. The true population-level incidence of DILI remains unknown due to the absence of national registries and reliance on hospital-based cohort designs. Establishing continent-wide pharmacovigilance infrastructure and expanding DILI surveillance beyond tertiary hospital settings are urgent priorities for health systems within Africa.

3352 | ETIOLOGICAL SPECTRUM, HISTOPATHOLOGICAL FEATURES, AND PREDICTORS OF OUTCOME IN SEVERE DRUG-INDUCED LIVER INJURY: A TERTIARY-CENTER EXPERIENCE FROM INDIA

Babu Lal Meena[1] Sunil Taneja[1] Ajay Duseja[2] Arka De[1] Suvradeep Mitra[3] Bijaylaxmi Behera[3] Nipun Verma[3], [1]Postgraduate Institute of Medical Education and Research, Chandigarh. India, [2]Postgraduate Institute of Medical Education & Research, Chandigarh, India, [3]Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: Drug-induced liver injury (DILI) is an important cause of acute liver dysfunction and liver-related mortality. Data regarding the etiological spectrum, histopathological characteristics, treatment practices, and outcomes of severe DILI from India remain limited. We evaluated the clinical profile, histopathological features, management strategies, and outcomes of patients with DILI at a tertiary liver center. **Methods:** Consecutive patients with DILI managed at a tertiary liver center were evaluated. Demographic, clinical, biochemical, histopathological, treatment, and outcome data were collected. Severity was assessed using Drug-Induced Liver Injury Network (DILIN) severity grading. Factors associated with mortality were evaluated using logistic and Cox regression analyses. Multivariable models adjusting for MELD score and lactate were used to account for baseline disease severity. **Results:** A total of 136 patients were included. Complementary and alternative medicines (CAM) were the commonest cause of DILI (52.2%), followed by over-the-counter medications (13.2%), miscellaneous agents (12.5%), anti-tubercular therapy (ATT) (8.8%), antimetabolites (8.8%), and antibiotics (4.4%). Underlying liver disease was present in 45.6% of patients. Most patients had severe liver injury, with DILIN grade 4 observed in 92.6% of cases. Overall mortality was 11.8% (16/136).Histopathological findings included cholestasis (49.3%), necrosis (29.4%), fibrosis (26.5%), steatosis (22.1%), eosinophilic infiltrates (16.2%), granulomas (13.2%), and interface hepatitis (11.0%). Neither DILIN severity grade nor histological features, including necrosis and fibrosis, were associated with mortality.ATT-related DILI was associated with higher crude mortality than non-ATT DILI (33.3% vs 9.7%; OR 4.59, p = 0.036). However, this association was attenuated after adjustment for MELD score and lactate (adjusted OR 2.10, 95% CI 0.18–19.29). Patients receiving combined steroid and plasma exchange (PLEX) therapy had substantially greater baseline disease severity (median MELD 26 vs 15 among untreated patients) but demonstrated

comparable mortality (7.5% vs 6.9%). In adjusted logistic and Cox regression analyses incorporating MELD score and lactate, neither steroid therapy nor plasma exchange independently predicted mortality. **Conclusion:** CAM predominated in severe DILI, whereas ATT-related DILI showed the highest crude mortality. Histological features were not prognostic. Larger multicenter cohorts are needed to identify robust outcome predictors and guide therapeutic interventions in severe DILI.

Table 1. Baseline Disease Severity and Mortality According to Treatment Strategy

Treatment Group	n	Median MELD	Mortality (%)
Neither	29	15	6.9
Steroid	54	22	13.0
Steroid + PLEX	40	26	7.5
PLEX	13	27	30.8

Table 2. Adjusted Predictors of Mortality in Patients with Drug-Induced Liver Injury

Variable	HR	95% CI	p
Steroid only vs Both*	1.83	0.46–7.26	0.388
PLEX only vs Both*	2.51	0.28–22.87	0.414
Neither vs Both*	1.08	0.12–9.70	0.948
MELD	1.05	0.94–1.18	0.385
Lactate	1.33	0.72–2.48	0.364

3353 | ESTABLISHMENT OF BASELINE ALT LEVELS IN CLINICAL TRIALS OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH): RESULTS OF >5200 PATIENTS FROM THE IQ DILI INITIATIVE DATA SHARING PROJECT: IMPLICATIONS FOR DILI DETECTION AND EVALUATION

Melissa Palmer[1] John Marcinak[2] Melvin Munsaka[2] Daniel Seekins[3] Vineet Shastri[4] Alexandru Iacob[2] Gianna Huang[5] James Lewis[6] Don Rockey[7] Adrian Di Bisceglie[8] Maura Fallon[9] Ajit Dash[10] Meenal Patwardhan[2] Shahla Bolbolan[5] Eirum Chaudhri[11] John Vierling[12] Robert Fontana[13] Hans Tillmann[14], [1]CEO Liver Consulting LLC, [2]AbbVie, [3]Bristol-Myers Squibb, [4]Amgen, [5]gilead, [6]Georgetown University Hospital, [7]MUSC, [8]Saint Louis University, [9]DSI, [10]Genentech, [11]merck, [12]Baylor College of Medicine, [13]University of Michigan Hospitals and Health Centers, [14]East Carolina University

Background: Patients with MASH exhibit spontaneous fluctuations in serum ALT levels over time which can complicate identification and evaluation of DILI during clinical trials. This variability has led some experts to recommend obtaining as many as 3 screening ALT measurements to establish a more accurate and reliable baseline level to use for comparison if treatment-emergent ALT elevations occur during the trial. However, this approach has never been evaluated in a systematic manner and is the focus of this data analysis of MASH patients from 12 combined clinical trials. **Methods:** MASH trials listed on clinicaltrials.gov prior to 06/06/22 were identified using search terms: NASH, steatohepatitis and cirrhosis. Included studies were required to have been: completed and unblinded; with or without compensated cirrhosis; placebo-controlled; histologically confirmed; MASH; an IQ DILI member industry company; and have informed consent. By pooling data from numerous clinical trials, we aimed to define the expected range of ALT variability in MASH patients with and without compensated cirrhosis during the pre-treatment period. Differences between screening and baseline ALT values of patients ultimately randomized to either the placebo or active arm were evaluated to determine the degree of variance between screening and baseline ALT values, and establish the adequate number of measurements needed to determine baseline values. Comparisons were also made between patients with and without cirrhosis. **Results:** 12 clinical trials were identified (4 in compensated cirrhosis) that met inclusion criteria and were enrolled. A total of 4860 (93.4%) subjects had 1, 325 (6.3%) had 2 and 16 (0.3%) had $\geq$3 screening ALT assessments. The mean interval between successive screening ALT assessments was 65 days for 1, 24 days for 2, and 16 days for 3 of more assessments. Overall, ALT values did not significantly differ between screening (mean 59 U/L (SD 39); median 48 U/L) and baseline (mean 56 U/L (SD 38); median 46 U/L), independent of the number of screening values obtained. Most subjects (68%) did not have a clinically relevant change (+/- 25%) in ALT from screening to baseline visit, and only 7.5% had a $\geq$50% increase or decrease ALT value difference between screening and baseline visit. A total of 12.6% exhibited $\geq$30% within subject ALT variability. Less variability in ALT was observed in cirrhotic than in noncirrhotic patients. **Conclusion:** Analysis of 12 MASH clinical trials which included 4 trials in cirrhotics, involving 5201 patients revealed that

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

< 7% had > 1 screening ALT value performed. Most patients had minimal variation in ALT levels between screening and baseline visits. Fluctuations in ALT levels were less for cirrhotic than non-cirrhotic patients. These data demonstrate that more than one screening ALT value is uncommonly measured and may not be necessary in MASH clinical trials to establish an accurate and reliable baseline level.

Comparison of ALT Values at Screening and Baseline Between Patients With and Without Cirrhosis *

	Overall		With Cirrhosis		Without Cirrhosis	
Characteristic	N = 5,559	N = 5,098	N = 1,807	N = 1,651	N = 3,752	N = 3,447
ALT (U/L)	Screening	Baseline	Screening	Baseline	Screening	Baseline
N	5,543	5,085	1,807	1,651	3,736	3,434
Mean (SD)	58.7 (38.7)	56.1 (38.0)	50.4 (31.0)	48.0 (28.3)	62.7 (41.3)	59.9 (41.3)
Median	48.0	46.0	42.0	41.0	52.0	49.0
Min	6.0	3.0	6.0	7.0	6.0	3.0
Max	469	506	286	286	469	506

*N= number of assessments. N's at screening are larger compared to the unique subjects' N's due to multiple screening values as below:

Number of Screening Assessments	Number of total patients = 5201
1	4,860 (93.4%)
2	325 (6.3%)
≥3	16 (0.3%)

3354 | ◆ HEPATIC STELLATE CELL–SPECIFIC MFAP-4 ENHANCES LIVER FIBROSIS BY STABILIZING THE EXTRACELLULAR MATRIX AND ACTIVATING INTRACELLULAR RHO-ROCK SIGNALING

Wenyue Wu[1] Wen Zhang[1] Hong Li[1] Haodong Ma[1] Ziyan Pan[1] Caihong Wang[1] Yameng Sun[1] Ning Zhang[1] Xuzhen Yan[1] Aiting Yang[1] Wei Chen[1] Hong You[1],
[1]Beijing Friendship Hospital, Capital Medical University

Background: Microfibril-associated protein 4 (MFAP-4) is a member of the fibrinogen-related protein superfamily and a key component of the extracellular matrix (ECM). However, its role in the pathogenesis of liver fibrosis remains poorly defined. **Methods:** Liver biopsy samples from cirrhotic patients of different etiologies and several mouse models of liver fibrosis were used to examine MFAP-4 expression and cellular localization. To explore its role in hepatic stellate cells (HSCs) in vivo, HSC-specific deletion of *Mfap4* was induced in *Mfap4*$^{fl/fl}$ mice using AAV6-*Lrat-Cre* in the CCl_4 fibrosis model. In vitro, LX-2 cells with MFAP-4 overexpression or knockdown were used to assess HSC activation, while 3D ECM culture, collagen gel contraction, and immunofluorescence were performed to evaluate its functional effects. Potential MFAP-4 interacting proteins and related pathways were identified by IP-MS and further verified using pathway inhibitors. The antifibrotic potential of MFAP-4 inhibition was tested using AAV6-mediated Mfap4 shRNA delivery in CCl_4 and BDL models, together with a small-molecule MFAP-4 inhibitor identified through virtual screening. **Results:** MFAP-4 was predominantly enriched in activated HSCs and significantly upregulated in advanced liver fibrosis in both humans and mice. HSC-specific suppression of *Mfap4* in *Mfap4*$^{\triangle HSC}$ mice markedly attenuated fibrosis and intrahepatic inflammation after CCl_4 treatment. Mechanistically, MFAP-4 promoted Collagen I and Elastin deposition, as well as gel contraction, thereby enhancing ECM stiffness-mediated HSC activation. IP-MS analysis showed that MFAP-4 interacts with multiple

components of the Rho-ROCK pathway; inhibition of this pathway reversed MFAP-4-induced HSCs activation and gel contraction in the 3D ECM. Notably, selective knockdown of *Mfap4* by either AAV6-GFAP-sh*Mfap4* or AAV6-U6-sh*Mfap4* significantly retarded liver fibrosis in CCl_4 and BDL models. BJFSH102, a selective small-molecule MFAP-4 inhibitor, ameliorated liver fibrosis by disrupting MFAP-4 interactions with Elastin and Collagen I in CCl_4 models. **Conclusion:** Our findings indicate that HSC-derived MFAP-4 drives liver fibrogenesis by promoting Elastin and Collagen I deposition and reinforcing ECM stiffness-mediated HSC activation. Selective inhibition of HSC-derived MFAP-4 effectively attenuates fibrosis, representing a promising therapeutic strategy for liver fibrosis.

3355 | ◆ HEPATIC STELLATE CELL–DERIVED CXCL12 PROMOTES LIVER FIBROSIS BY SUPPRESSING T CELL–INDUCED HSC APOPTOSIS

Maria Hernandez Tejero[1] Sofia Jerez[1] Shawna Cooper[1] Usman Yaqoob[1] Soo Mi Kim[1] Luke Doskey[1] Dawood Al Dawood[2] Colin Chen[1] Mobin Ibne Mokbul[1] Kun Cao[1] Zeba Firdaus[1] Le Z Day[3] Papawee Sutthirat[1] Kevin Pavelko[1] Jon Jacobs[3] Moira Hilscher[4] Nidhi Jalan-Sakrikar[1] Sheng Cao[1] Vijay Shah[1], [1]Mayo Clinic Rochester, [2]Mayo Clinic, [3]Pacific Northwest National Laboratory, Richland, WA, [4]Penn Medicine

Background: Liver fibrosis is driven by persistent activation of hepatic stellate cells (HSCs) and their interactions with the immune microenvironment. However, the molecular mechanisms by which HSCs sustain immune-mediated pro-fibrotic circuits remain poorly defined. We investigated whether HSC-derived signals establish a pro-fibrotic immune loop. **Methods:** Spatial proteomics of human cirrhotic liver tissue was performed using laser capture microdissection coupled with nanoPOTS-based sample preparation and liquid chromatography–tandem mass spectrometry (LC–MS/MS) to identify proteins enriched in collagen-rich fibrotic niches. Findings were validated in murine carbon tetrachloride (CCl_4)-induced fibrosis using spatial transcriptomics, RNA in situ hybridization, and single-cell RNA sequencing (scRNA-seq). HSC-specific Cxcl12 knockout mice (Cre^+, CXCL12-deficient) were compared with CXCL12-expressing controls (Cre^-). Fibrosis, immune infiltration, DNA damage, and T-cell phenotypes were evaluated using histology, immunofluorescence, TUNEL assay, and Cytometry by Time-Of-Flight (CyTOF). In vitro assays assessed the effects of CXCL12 on $CD8^+$ T-cell function and CXCR4 signaling. **Results:** Spatial proteomics demonstrated marked enrichment of CXCL12 within collagen-rich fibrotic niches in human cirrhotic liver compared to non-fibrotic regions ($p < 0.0001$). Spatial transcriptomics and RNA in situ hybridization confirmed these findings in murine CCl_4-induced fibrosis **(Fig. 1)** . scRNA-seq identified activated collagen-producing HSCs as the predominant source of Cxcl12, with increased expression during fibrosis. Control mice expressing HSC-derived CXCL12 (Cre^-) developed significantly greater CCl_4-induced fibrosis and intrahepatic immune cell infiltration compared to HSC-specific Cxcl12 knockout mice (Cre^+) ($p < 0.0001$ and $p < 0.05$, respectively). CyTOF revealed expansion of a distinct $CD8^+CXCR6^+$ T-cell population expressing inhibitory receptors including PD-1, TIM3, and TIGIT in Cre^- versus Cre^+ mice (all $p < 0.001$). In vitro, CXCL12 suppressed $CD8^+$ T-cell IFNγ production, an effect reversible with CXCR4 inhibition. TUNEL staining showed increased DNA fragmentation in fibrotic livers from Cre^- mice compared to Cre^+ mice, supporting a role for CXCL12 in regulating immune-mediated HSC apoptosis. **Conclusion:** HSC-derived CXCL12 promotes a pro-fibrotic immune circuit by inducing a hypofunctional, inhibitory receptor–expressing $CD8^+$ T-cell phenotype within the fibrotic niche, thereby limiting immune-mediated HSC apoptosis. The CXCL12–CXCR4 axis represents a key regulator of HSC–immune crosstalk and a potential therapeutic target.

3357 | ◆ HEPATIC STELLATE CELL-SPECIFIC *NTRK3* DELETION ATTENUATES LIVER FIBROGENESIS IN MICE

Bruno Cogliati[1] Aina Anton[1] Dipankar Bhattacharya[1] Li Chen[2] Shuang Wang[1] Scott Friedman[3], [1]Icahn School of Medicine at Mount Sinai, [2]PharmaNest, [3]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Neurotrophic receptor tyrosine kinase 3 (NTRK3) has been discovered as a component of an autocrine signaling network among activated hepatic stellate cells (HSC) in advanced liver fibrosis, implicating NTRK3-dependent pathways in its pathogenesis (DOI: 10.1126/scitranslmed.add3949). To definitely establish NTRK3 as a driver of hepatic fibrosis, we investigated whether inducible, HSC-specific deletion of *Ntrk3* modulates liver fibrogenesis or its resolution in mice. **Methods:** A novel Colec11-Cre^{ERT2} mouse line whose expression is highly restricted to HSCs was crossed with *Ntrk3* floxed mice (Ntrk3$^{fl/fl}$) to generate tamoxifen (TAM)-inducible HSC-specific *Ntrk3* knockout (Ntrk3$^{\Delta HSC}$) and heterozygous deletion (Ntrk3$^{\Delta/+}$) mice. Cre-negative littermates served as controls. To assess fibrosis progression, mice received TAM (75 mg/kg/day, i.p.) for 5 consecutive days, followed by 20% CCl_4 (i.p., 3x per week) for 6 weeks before euthanasia. For fibrosis regression analysis, mice received 20% CCl_4 for 4 weeks, followed by TAM treatment and continued CCl_4 to complete 6 weeks of injury, and then recovered for 2 weeks before euthanasia. Fibrosis and stromal/immune remodeling were assessed by AI-assisted digital pathology, flow cytometry, RT-qPCR, and western blotting. In parallel, primary Ntrk3$^{fl/fl}$ HSCs were transduced with adenoviral Cre to assess the cell-autonomous effects of *Ntrk3* loss *in vitro.* **Results:** In CCl_4-treated male mice, both Ntrk3$^{\Delta HSC}$ and Ntrk3$^{\Delta/+}$ livers developed less fibrosis during disease progression compared with controls. This was associated with lower expression of canonical markers of HSC activation and extracellular matrix remodeling, including *Acta2*, *Col1a1*, *Col1a2*, *Mmp2*, and *Pdgfr*β. Western blot documented reduced protein expression of α-SMA, COL1A1, and COL1A2 in *Ntrk3*-deficient livers. By flow cytometric profiling *Ntrk3* deletion also reshaped the non-parenchymal cell compartment, characterized by decreased natural killer and endothelial cell populations and increased macrophage abundance. In contrast, HSC-specific *Ntrk3* deletion had no effect on fibrosis regression. These findings suggest that *Ntrk3* contributes more to active fibrogenesis than to spontaneous fibrosis resolution. *In vitro*, adenoviral Cre-mediated *Ntrk3* depletion in primary Ntrk3$^{fl/fl}$ HSCs attenuated profibrogenic gene expression, supporting an HSC-intrinsic role for NTRK3 signaling in fibrogenic activation. **Conclusion:** 1) Our newly developed, highly specific, regulable Cre mouse line is a powerful new tool for *in vivo* studies of HSC biology; 2) HSC-specific *Ntrk3* ablation attenuates CCl_4-induced liver fibrogenesis *in vivo*, identifying Ntrk3 as an autocrine regulator of fibrosis progression and a potential antifibrotic target; 3) Mediators of fibrosis resolution likely engage different mediators and signaling loops than those driving progression.

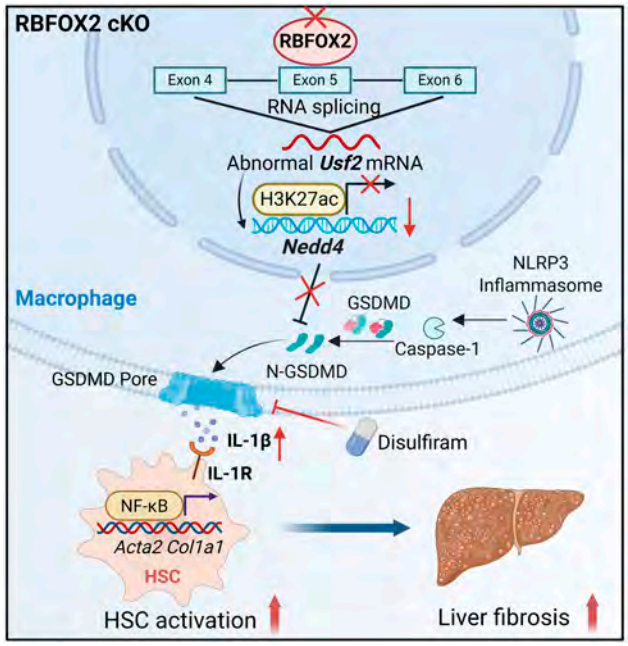
3358 | MYELOID RBFOX2 CONTROLS USF2 SPLICING TO PREVENT MACROPHAGE–HEPATIC STELLATE CELL CROSSTALK AND LIVER FIBROSIS



Xuewen Duan[1], [1]Shanghai Jiao Tong University School of Medicine

Background: Macrophage pyroptosis is a key driver of inflammation and fibrogenesis in liver injury. Increasing evidence implicates alternative splicing in the regulation

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

of inflammatory signaling, yet whether it modulates macrophage pyroptosis remains unclear. Here, we investigated the role of RBFOX2 in macrophage pyroptosis and macrophage–hepatic stellate cell (HSC) crosstalk during liver fibrosis and explored the therapeutic potential of targeting RBFOX2 for fibrosis resolution. **Methods:** Circulating monocytes and liver tissues from healthy controls and patients with liver fibrosis of diverse etiologies were examined for RBFOX2 expression and its clinical relevance. Myeloid-specific Rbfox2 knockout (Rbfox2 cKO) mice were subjected to carbon tetrachloride-, bile duct ligation-, and high-fat high-cholesterol diet-induced fibrosis models to define RBFOX2 function. RNA sequencing, histological analyses, and phenotypic characterization assessed macrophage pyroptosis, HSC activation, and fibrosis progression. Single-cell RNA sequencing profiled immune remodeling. CLIP-seq and epigenetic analyses defined mechanisms regulating inflammasome activation. Rbfox2 cKO; Il1r1$^{-/-}$ mice and disulfiram-mediated GSDMD inhibition tested whether blockade of IL-1R or pyroptosis signaling attenuated fibrosis caused by Rbfox2 deficiency. AAV8-mediated Rbfox2 restoration was evaluated in fibrotic wild-type mice. **Results:** RBFOX2 expression was increased in circulating monocytes and liver tissues from patients with liver fibrosis and was associated with fibrosis severity. Myeloid-specific Rbfox2 knockout mice exhibited exacerbated liver injury and fibrosis, accompanied by increased macrophage pyroptosis, inflammatory cytokine release, and HSC activation. Mechanistically, loss of Rbfox2 promoted *Usf2* exon 5 skipping, impairing USF2 transcriptional activity and reducing H3K27ac enrichment at the NEDD4 promoter, thereby relieving repression of inflammasome activation and enhancing NLRP3 inflammasome-dependent macrophage pyroptosis. In macrophage–HSC co-culture systems and fibrosis models, Rbfox2-deficient macrophages exhibited increased IL-1β secretion, activating IL-1R/NF-κB signaling in HSCs to promote profibrotic gene expression and HSC activation. Genetic deletion of Il1r1 or pharmacological inhibition of GSDMD with disulfiram reversed macrophage pyroptosis and fibrosis induced by Rbfox2 deficiency. AAV8-mediated Rbfox2 restoration alleviated liver fibrosis in wild-type mice, highlighting RBFOX2 as a potential therapeutic target. **Conclusion:** Our findings identify RBFOX2 as a critical suppressor of inflammasome activation and macrophage pyroptosis in liver fibrosis. Loss of RBFOX2 amplifies macrophage–HSC crosstalk, driving HSC activation and fibrosis progression. Targeting the RBFOX2-regulated pyroptosis pathway may provide a therapeutic strategy for liver fibrosis.

3359 | HETEROZYGOUS LOXL1 MUTATION IMPAIRS FIBROSIS REVERSAL AND PRIMES A PRO-TUMORIGENIC NICHE VIA ENHANCED ECM CROSS-LINKING

Wen Zhang[1] Wenyue Wu[1] Hong Li[1] Ning Zhang[1] Ziyan Pan[1] Haodong Ma[1] Caihong Wang[1] Ruoyu Gao[1] Qiushuang Ji[1] Zhi Chen[1] Xuzhen Yan[1] Aiting Yang[1] Wei Chen[1] Hong You[2], [1]Beijing Friendship Hospital, Capital Medical University, [2]Capital Medical University

Background: Lysyl oxidase-like 1 (LOXL1) is a copper-dependent enzyme that plays a critical role in extracellular matrix (ECM) cross-linking, contributing to tissue remodeling and fibrotic processes. Although LOXL1 mutations are known to enhance ECM cross-linking in glaucoma, their involvement in liver fibrosis remains poorly understood. **Methods:** LOXL1 single nucleotide polymorphisms (SNPs) were analyzed in genomic DNA from 168 patients with chronic hepatitis B (CHB)-related liver fibrosis, and their associations with fibrosis progression and regression were examined. Functional validation was performed using heterozygous Loxl1G153D mutant mice in a carbon tetrachrachloride (CCl_4)-induced liver fibrosis model with spontaneous regression. Integrated proteomic, transcriptomic, and metabolomic analyses of decellularized livers were conducted to characterize mutation-associated biological changes. In vitro assays were performed to assess

LOXL1 cleavage, enzymatic activity, and ECM crosslinking capacity. **Results:** Patients harboring the heterozygous LOXL1G153D mutation exhibited a significantly lower rate of fibrosis reversal after 78 weeks of antiviral therapy compared with non mutant patients (26.3% vs. 52.4%, P = 0.025), along with higher post treatment levels of alanine aminotransferase (ALT), gamma glutamyl tansferase (GGT), liver stiffness measurement (LSM), and Ishak fibrosis scores. The G153D mutation resides adjacent to the putative bone morphogenetic protein 1 (BMP1)-binding region of LOXL1, and functional assays demonstrated that it enhances BMP1 mediated LOXL1 cleavage, increases the activity of mature LOXL1, and augments ECM crosslinking capacity. In CCl_4 induced fibrosis models, Loxl1 G153D mice displayed exacerbated perisinusoidal fibrosis, increased ECM deposition, lipid accumulation, and delayed fibrosis regression. Decellularized liver proteomics confirmed enhanced ECM stabilization and crosslinking, and in vivo tumorigenesis experiments showed that the mutation increases susceptibility to hepatocellular carcinoma (HCC) development. Integrated transcriptomic and metabolomic analyses further revealed a hepatic microenvironment characterized by immunosuppression and metabolic activation, supporting the formation of a protumorigenic niche. These findings suggest that LOXL1G153D promotes fibrosis persistence by enhancing LOXL1 cleavage and ECM remodeling, while also shaping a protumorigenic microenvironment. **Conclusion:** The heterozygous LOXL1G153D mutation impairs fibrosis regression by enhancing LOXL1 cleavage, enzymatic activation, and ECM crosslinking, while promoting a metabolically active and immunosuppressive microenvironment that may favor HCC development.

3360 | THE FGF21 ANALOG EFX REGULATES INTERCELLULAR FIBROGENIC SIGNALING BY DISRUPTING HEPATOCYTE TO STELLATE CELL TRANSFER OF DYSFUNCTIONAL MITOCHONDRIA.

Suyavaran Arumguam[1] Xinshou Ouyang[1] Timothy Rolph[2] Erik Tillman[2] Wajahat Mehal[1], [1]Yale School of Medicine, Yale University, [2]Akero Therapeutics, a Novo Nordisk Company, Boston, United States

Background: Mitochondrial dysfunction in steatotic hepatocytes drives MASLD progression, but how organelle-level injury is communicated to hepatic stellate cells (HSCs) to initiate fibrosis remains unresolved. Horizontal mitochondrial transfer is an emerging pathophysiological regulator. We previously showed self-mtDNA leakage activates STING in HSCs under TGF-β stimulation (Arumugam et al., Hepatology 2023), implicating mitochondrial signals as fibrogenic effectors. Efruxifermin (EFX), a long-acting FGF21 analog, has diverse effects on hepatocytes and has demonstrated anti-fibrotic effects in clinical trials. **Aim:** To determine whether lipotoxic hepatocytes transfer mitochondria to HSCs and whether EFX disrupts this fibrogenic axis. **Methods:** Primary human hepatocytes (PHH) and primary human HSCs were co-cultured under palmitate-induced steatosis ± EFX (6hrs pre/16hrs post-EFX exposure to palmitate), and HSC activation was assessed by α-SMA immunofluorescence with intensity quantification. To track mitochondrial transfer, HepG2 (Mito-RFP/TOM20-mPLUM, red) and LX-2 (Mito-GFP, green) reporter co-cultures were imaged by high-resolution confocal microscopy (Leica SP5, 40×; Leica Stellaris 8 DIVE, 100×). MitoSOX (mitochondrial ROS), TMRE (mitochondrial membrane potential [MMP]), MitoPQ (ROS inducer), and MitoTEMPO (antioxidant) dissected ROS causality. **Results:** Palmitate stressed PHH induced robust α-SMA expression in HSCs ($P < 0.0001$ vs control), which was significantly attenuated by EFX treatment ($P < 0.01$ vs PA). In HepG2-LX-2 co-cultures, palmitate increased mitochondrial oxidative stress and impaired MMP in HepG2 cells, (while triggering horizontal transfer of HepG2-derived damaged mitochondria into LX-2 cells. Mitochondrial fragments delivered to LX-2 were selectively enriched for high mitoROS ($P < 0.05$) and low MMP ($P < 0.01$), indicating lipotoxicity-induced active export of ROS-enriched and damaged organelles. MitoPQ was sufficient to drive mito transfer ($P < 0.01$), while the anti-oxidant MitoTEMPO reduced mtROS but failed to abrogate palmitate-induced mitochondrial transfer, establishing mitoROS as sufficient but not necessary to drive hepatocyte-to-HSC mito transfer. EFX abrogated this fibrogenic signal by suppressing MitoROS ($P < 0.05$), preserving MMP ($P < 0.01$), and abrogating hepatocyte-to-HSC mitochondrial transfer ($P < 0.01$). **Conclusion:** Lipotoxicity in hepatocytes selectively segregate and transfer ROS-enriched, depolarized mitochondria to HSCs, driving their activation. EFX restores hepatocyte mitochondrial quality and interrupts this intercellular, organelle-transfer driven profibrogenic signaling, identifying a novel therapeutic node in MASLD and MASH-associated fibrosis.

3361 | AN AGED IMMUNE MICROENVIRONMENT IS SUFFICIENT TO PROMOTE REGENERATIVE FAILURE AND LIVER FIBROSIS

Rahagir Salekeen[1] Elizabeth Schmidt[1] Samuel Peters[1] Laura Niedernhofer[1], [1]University of Minnesota – Twin Cities

Background: Chronic liver disease is projected to impose a global economic burden exceeding $2.8 trillion by 2050. Aging is the strongest risk factor for chronic disease and regenerative failure, with liver-related mortality tripling in patients over 65. While immune cells are essential mediators of liver homeostasis and repair, how age-associated immune dysfunction affects regenerative decline remains unexplored. Using human clinical samples and novel transgenic mouse models, we investigated the impact of immune aging on liver regeneration and fibrotic resolution. **Methods:** Human liver single-cell RNA-seq and spatial transcriptomics datasets were analyzed to define conserved regenerative and immune aging states. To model immune-driven aging, we used Cre-loxP mouse models subjected to chemical liver injury and assessed using histochemistry, RNA-seq and 3D spheroid cultures. **Results:** Human single-cell RNA-seq and spatial transcriptomic profiling across aging and pathological grades revealed progressive disruption of regenerative immune–epithelial coordination, accompanied by expansion of inflammatory states and near complete loss of spatially organized periportal progenitor niches. Cell–cell communication analyses of hepatic niches further implicated aberrant interactions with both infiltrating and resident macrophage compartments as key contributors to age-associated transcriptional remodeling.These signatures were functionally modeled using Vav1-Cre and Cx3cr1-Cre conditional systems, where we selectively accelerated DNA damage and aging signatures in hematopoietic stem and monocyte compartments respectively. Following chemical liver injury, both models exhibited impaired regenerative recovery relative to controls, with significant increases in bridging fibrotic lesions and non-parenchymal infiltration, and prolonged persistence of injury-associated states. Spatial analyses revealed disruption of organized regenerative microenvironments, characterized by sustained pro-inflammatory signaling, skewing toward inflammatory macrophage polarization states, and aberrant recruitment of B-cell populations. Mechanistically, co-culture and conditioned media experiments using hepatic spheroids identified immune-derived signals that suppress mitogenic responses, hepatic identities and organization. **Conclusion:** Aging drives maladaptive immune–epithelial interactions in the liver that disrupts regenerative niche organization and coordinated repair. Immune aging is a previously underappreciated driver of fibrotic progression, revealing a targetable non-autonomous mechanism of liver disease etiology. These insights have immense implications in translational frameworks aiming to improve outcomes in aged patients – including enhancing graft recovery, optimizing transplant resilience, and informing immune-targeted therapies in chronic disease management.

3362 | ISOGENIC HIPSC DERIVED LIVER-ON-CHIP SYSTEM: A VALUABLE TOOL FOR MODELLING FIBROSIS

Kehinde Oluwasegun Aina[1], [1]Friedrich Schiller University Jena

Background: Background and aimsModeling the human liver in vitro is a challenging task. Yet information from such models about the architecture of the liver is important for the development of drugs and the study of different liver diseases. The functional characterization of these components remains difficult owing in part to a scarcity of human model systems. To improve the predictive power of in-vitro models, (HLA-matched) hiPSCs from a healthy and diseased donor were used in this study to generate parenchyma and non- parenchyma liver-like cells, through tissue engineering approaches interfaced with organ- on-chip technology. **Methods:** This system was designed to allow for long-term investigation of tissue-tissue crosstalk without any bias and recapitulation of micro-environmental cues in a 3D culture format.The platform is intended for the culture and co-culture of isogenic cells (hepatocytes, stellate cells, endothelial cells (EC), and macrophages) and its application in the context of disease modeling. Firstly, HLA-matched hiPSC-derived liver cells were generated, functionally characterized, and bio banked. To investigate vascular-immune cellular crosstalk, hiPSC-derived endothelial cells were co- cultured with polarized macrophages, on chip under static and dynamic flow conditions. **Results:** Fibrosis phenotype was validated based on endothelial cell dysfunction, stellate cell activation, and deposition of extracellular matrix. This phenotype was more pronounced in LoC models treated with TGFβ compared to untreated controls. The TGFβ treated models were characterized by the extracellular deposition of collagen, upregulation of fibrosis markers (Alpha- smooth muscle actin, Fibronectin, Glial fibrillary acidic protein, Col1ά1, PDGRFβ), and activation of stellate cells as indicative markers related to fibrosis development. Thus, the data suggest that the dynamic interactions between diMerent liver cell types via soluble mediators and cytokines play an important role in the progression of fibrosis. **Conclusion:** ConclusionThis lays the groundwork for its use in preclinical studies and the investigation of the of new molecules such as short-chain fatty acids and bile acids on disease progression or therapeutics for disease intervention. Therefore, these LoC systems oMer the advantage of the combination of different liver cells with matched donors with individualized study of monogenic diseases.

3363 | HIV COINFECTION EXACERBATES HBV-INDUCED LIVER FIBROGENESIS THROUGH AN EXOSOMAL MIR-103A-3P DEPENDENT PATHWAY

Min Xu[1] Olivia Mezzetti[1] Thien Nguyen[1] Sreya Biswas[2] Cecilie Back-Nielsen[1] Charlotte Warner[1] Xiaoqiong Duan[3] Shasha Li[4] Yongtao Wang[1] Volney Spalding[1] Zeinab Heidariyan[1] Shadi Salloum[1] Chuanlong Zhu[5] Xu Yu[6] Benjamin Burwitz[2] Raymond Chung[1] Wenyu Lin[7], [1]Massachusetts General Hospital, Harvard Medical School, [2]Oregon National Primate Research Center, Oregon Health and Science University, [3]Chinese Academy of Medical Sciences and Peking Union Medical College, [4]The Second People's Hospital of Fuyang City, [5]The First Affiliated Hospital of Nanjing Medical University, [6]The Ragon Institute of Massachusetts General Hospital, MIT, and Harvard University, [7]Massachusetts General Hospital

Background: Approximately 4 million people worldwide are co-infected with HBV and HIV, yet the mechanisms by which HIV accelerates HBV-induced liver fibrosis remain unclear. Pantothenate kinase 2 (PANK2) and PANK3 encode rate-limiting enzymes in coenzyme A synthesis, and each hosts an intronic miRNA (MIR103A2 and MIR103A1, respectively) that produces miR-103a, a potential regulator of fibrotic and metabolic pathways. Here we integrate transcriptomics and functional experiments to explore how HIV-induced dysregulation of the PANK2–MIR103A2 and PANK3–MIR103A1 loci contributes to fibrogenesis. **Methods:** RNA-seq (GSE76246) of PBMCs from HBV mono-infected individuals and rhesus macaques (HBV mono-infection vs. SHIV/HBV co-infection) were examined. Infectious HBV viral particles (HBVvp) were purified from the supernatant (HBVsup) of HepAD38 cells. HIV NL4-3 strain viral particles (HIVvp) and exosomes were isolated from the supernatants of HIV-infected (HIVexo) and uninfected (U937exo) U937 macrophages. NTCP-HepG2 cells, LX-2 cells, primary human hepatocytes, and primary human hepatic stellate cells, as well as 3D co-culture models and precision-cut liver slice (PCLS) models, were directly exposed to HIVsup, HIVvp, HIVexo, or U937exo in both mono- and co-culture settings. These cells and culture systems were also treated with synthetic miR-103a-3p mimics or inhibitors with or without siRNA-mediated knockdown of inhibitor of DNA-binding protein 2 (ID2), which was identified as a potential target of miR-103a-3p by bioinformatic analysis. **Results:** Compared to uninfected PBMCs, HIV infection was associated with upregulated PANK2, PANK3, and miR-103a-3p in human PBMCs and in HBV/SHIV-infected macaque livers, along with profibrotic genes (TGFB1, TIMP1, ACTA2, COL1A1) and collagen deposition. These

changes were only partially reversed by ART. HIV-positive exosomes enhanced HBV-induced fibrogenic responses in our cell culture models. Mechanistically, miR-103a-3p directly suppressed ID2 and was associated with increasing HIF1α and TGF-β1 consequently accelerated HBV-induced liver fibrogenesis. A miR-103a-3p inhibitor attenuated the pro-fibrotic effects in 3D co-culture models with HIV and HBV coinfection, while treatment with ID2 siRNA partially reversed these effects. Notably, because *MIR103A2* and *MIR103-A1*are embedded within PANK2 and PANK3 respectively, coordinated regulation of these loci by HIV infection links metabolic reprogramming to fibrogenesis. **Conclusion:** HIV co-infection exacerbates HBV-induced liver fibrogenesis via upregulation of miR-103a-3p, which suppresses ID2 and hyperactivates HIF1α/TGF-β1 signaling. The embedded location of miR-103a-3p within PANK2/3 suggests a conserved regulatory axis. These results highlight miR-103a-3p as a potential diagnostic and therapeutic target for liver fibrosis in individuals living with HBV and HIV co-infection.

3364 | MATRIX STIFFNESS INDUCES CXCL12 IN HUMAN HEPATIC STELLATE CELLS AND HI-C REVEALS A PRECONFIGURED CHROMATIN DOMAIN AT THE CXCL12 LOCUS

Dawood Al Dawood[1] Luke Doskey[2] Usman Yaqoob[2] Shawna Cooper[2] Sofia Jerez[2] Maria Hernandez Tejero[2] Soo Mi Kim[2] Sheng Cao[2] Vijay Shah[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Liver fibrosis is driven by hepatic stellate cell (HSC) activation, extracellular matrix deposition, and progressive tissue stiffening. CXCL12 is highly expressed by HSCs during fibrosis and mediate fibrotic stromal signaling. However, whether stiffness induces CXCL12 in human HSCs, and whether the CXCL12 locus is organized within a defined 3D chromatin regulatory neighborhood, remain unclear. **Methods:** Primary human HSCs were cultured on soft (0.5 kPa) or stiff (32 kPa) matrices, and CXCL12 was quantified by qPCR. Genome-wide 3D chromatin organization was evaluated by Hi-C from vehicle- and TGF-β-treated human HSC cell line LX-2 cultured on stiff plastic. Results were visualized with the Juicebox web app and analyzed in IGV using genome assembly GRCh38/hg38 and *CXCL12* transcript NM_199168.4 ($n = 3$ each). CRISPRi was used for functional testing with sgRNA designed using the UCSC Genome Browser to target the mouse *Cxcl12* promoter on chromosome 6. Transfection was done on primary fibroblasts expressing dCas9-KRAB and *Cxcl12* expression was measured by qPCR. Candidate *Cxcl12* mechanoenhancer regions centered at chr6:117,300,000 and chr6:117,325,000 were identified by comparing H3K27ac ChIP-seq in activated/quiescent HSCs (GSM4176113) with snATAC-seq peaks from a CCl_4-induced fibrosis model HSCs. sgRNA were designed to target the mechanoenhancer region. **Results:** A stiff matrix increased CXCL12 in primary human HSCs compared to a soft matrix ($FC = 6$, $p < 0.05$). In stiff-cultured LX-2 cells, Hi-C maps revealed a reproducible local interaction domain encompassing the CXCL12 locus on chromosome 10. IGV tracks showed recurrent upstream-to-CXCL12 contacts, consistent with a pre-established regulatory neighborhood, with no major changes following TGF-β treatment. In mouse CRISPRi experiments, promoter-targeting sgRNAs achieved >80% knockdown of *Cxcl12*; the top-performing guide is being packaged for lipid nanoparticle delivery. Mechanoenhancer-targeting sgRNAs are being tested in parallel. **Conclusion:** Fibrotic-like stiffness induces CXCL12 in primary human HSCs. Hi-C/IGV analysis support the presence of a preconfigured CXCL12 chromatin neighborhood in stiff-cultured LX-2 cells, and CRISPRi identifies promoter and candidate mechanoenhancer elements for future in vivo validation.

3365 | PRO-FERROPTOTIC AND ANTI-FIBROTIC FUNCTIONS OF MIR-122-ENRICHED HEPATOCYTE EXTRACELLULAR VESICLES

Xinlei Li[1] Sherri Kemper[1] David Brigstock[1], [1]Nationwide Children's Hospital

Background: Hepatocyte extracellular vesicles (EVs) are anti-fibrotic in toxin- or fatty acid-induced liver fibrosis. While the underlying mechanisms are elusive, we have explored the involvement of miRNAs which efficiently regulate post-transcriptional gene expression by targeting a mRNA 3'UTR. Here we investigate the role of miR-122, which is abundant in hepatocytes and their EVs, in driving ferroptosis in activated hepatic stellate cells (HSC), a novel mechanism which likely contributes to the anti-fibrotic actions of hepatocyte EVs. **Methods:** Mouse hepatocyte AML-12 EVs were purified from 48-hr conditioned medium of cell cultures, and their constituent miRNAs were profiled by small RNA-seq. Human LX2 HSC were incubated with AML-12 EVs for 48 h and with erastin for the last 24 h prior to measuring ferroptosis. Scramble control (LX2-miR-NC) or miR-122 stably expressing LX2 cells (LX2-miR-122) were generated by lentiviral transduction. The cells were treated with erastin, RSL-3, FIN56, or in cystine-depleted medium along with inhibitors of apoptosis, necroptosis, or pyroptosis. Intracellular ferrous levels in cells under normal or serum-free culture condition were measured by FerroOrange. Wildtype or mutant NRF1 3'UTR reporters were used for miR-122 target assays. GPX4, NRF1 knockdown or overexpression was achieved by lentiviral transduction. iPSCs were differentiated into multicellular human liver organoids (HLO) which were treated with 20ng/ml TGFβ for 72 h to induce fibrogenesis. miR-122-enriched lentiviruses or EVs were added 24 h post TGFβ treatment in HLOs. **Results:** MiR-122 was the most abundant of 156 miRs in AML-12 EVs, which exacerbated erastin-induced LX2 cell death. Transient or stable expression of miR-122 in LX2 cells led to drastic ferroptosis induced by erastin, RSL-3, FIN56, or cystine depletion. miR-122-induced cell death was reversed by inhibitors of ferroptosis but not of apoptosis, necroptosis, or pyroptosis. Serum-starved quiescent HSCs but not activated HSC were resistant to miR-122-induced ferroptosis. In HSC, miR-122 enhanced cellular ferrous levels, reduced expression of NRF1 and GPX4, and targeted the NRF1 3'UTR. Knockdown of GPX4 or NRF1 led to enhanced ferroptosis in LX2 cells. NRF1 overexpression partially reversed miR-122-induced ferroptosis. Multicellular HLOs comprising hepatocytes, HSCs, macrophages, endothelial cells, and cholangiocytes demonstrated fibrosis-related changes at protein and transcript levels in response to TGF-β, but this was significantly ameliorated by delivery of miR-122. **Conclusion:** Hepatocyte EVs potentiate ferroptosis in activated HSC by delivering miR-122, which leads to elevated cellular ferrous iron level and reduction of GPX4 expression by directly repressing NRF1 expression. HLOs are a promising platform for investigating miR-122-mediated fibrosis therapy.

3366 | HYDRONIDONE REVERSES GLYCOLYTIC REPROGRAMMING AND LIVER FIBROSIS BY TARGETING THE STAT3/LOXL2-MEDIATED STABILIZATION OF HIF1α IN HEPATIC STELLATE CELL

Qichao Ge[1] Zhangdi Hangjing[1] Yufei Yang[1] Ling Zhang[2] Ying Luo[2] Lungen Lu[1], [1]Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, [2]Continent Pharmaceuticals Co. ,Ltd., Beijing, China

Background: Hepatic stellate cell (HSC) activation is central to liver fibrosis. Hydronidone (HDD) is a clinically advanced anti-fibrotic candidate, but its direct target and mechanism of action remain incompletely defined. We sought to identify the molecular target of HDD and determine how it modulates HSC activation. **Methods:** Fibrotic multilineage human liver organoids (hLOs), murine and human HSC models, multi-omics profiling, target deconvolution, and mouse fibrosis models were combined with HSC-specific genetic manipulation. Human relevance was assessed in HBV-related cirrhosis and paired biopsies from a phase II HDD trial. **Results:** Target discovery and orthogonal validation identified STAT3 as a direct HDD-binding protein. HDD engaged the STAT3 SH2 domain through Pro639/Tyr640, inhibiting STAT3 signal transduction and STAT3–SMAD2/3 crosstalk. Functionally, HDD preferentially blunted glycolysis-associated remodeling during HSC activation and LOXL2 was identified as a direct STAT3 target and a key HDD-reversible effector. Mechanistically, intracellular LOXL2 bound YB1 and promoted YB1 Lys81 deacetylation, enhancing YB1 binding to *Hif1a* mRNA and increasing HIF1α synthesis, thereby driving glycolysis reprogramming. In paired phase II biopsies, HDD reduced αSMA, pSTAT3, and HK2 in fibrotic regions, accompanied by improved fibrosis/inflammation scores, liver stiffness, and transaminases. **Conclusion:** HDD exerts anti-fibrotic activity by directly targeting STAT3 and suppressing a LOXL2-YB1-HIF1α axis that links HSC activation to glycolysis-associated metabolic reprogramming.

3367 | INTEGRIN αVβ3/αVβ5 INHIBITION AMELIORATES LIVER FIBROSIS AND PORTAL HYPERTENSION IN CONGESTIVE HEPATOPATHY

Hayato Hikita[1] Seiya Kato[1] Yasuharu Kawamoto[1] Kenji Fukumoto[1] Yuta Myojin[1] Yuki Makino[1] Yoshinobu Saito[1] Takahiro Kodama[1], [1]The University of Osaka, Graduate School of Medicine

Background: Congestive hepatopathy induces liver fibrosis and portal hypertension despite minimal hepatic inflammation and without marked AST/ALT elevation. Recently, we demonstrated that activation of the integrin αV-YAP-CTGF pathway in liver sinusoidal endothelial cells (LSECs) promotes liver fibrosis, portal hypertension, and hepatocarcinogenesis in congestive hepatopathy. In this study, we investigated the therapeutic potential of integrin inhibitors for congestive hepatopathy. **Methods:** Congestive hepatopathy was induced in mice by partial inferior vena cava ligation (pIVCL). Two weeks after pIVCL, mice were subcutaneously treated with either the pan-integrin αV inhibitor CWHM-12 (100 mg/kg/day) or the integrin αVβ3/αVβ5 inhibitor cilengitide (10 mg/kg/day). Mice were analyzed after 4 weeks of treatment. Liver samples from patients with Fontan-associated liver disease (FALD) were analyzed as clinical specimens of congestive hepatopathy. **Results:** pIVCL induced liver fibrosis and portal hypertension accompanied by YAP pathway activation and CTGF overexpression in LSECs. Administration of the pan-integrin αV inhibitor significantly reduced Sirius Red-positive fibrotic areas and portal pressure. Single-cell RNA-seq (scRNA-seq) analysis of pIVCL livers revealed reduced expression of YAP/TAZ target genes, including CTGF, in LSEC clusters after treatment, indicating suppression of the integrin αV-YAP-CTGF pathway in LSECs. Since integrin αV forms heterodimers with multiple β subunits, we further investigated the involved β subunits to improve therapeutic specificity. In pIVCL livers, expression of *Itgb3* and *Itgb5*, encoding integrin β3 and β5, respectively, was significantly increased. Moreover, scRNA-seq analysis demonstrated increased expression of Itgb3 in the LSEC fraction. Based on these observations, mice were treated with cilengitide, a selective inhibitor of integrin αVβ3 and αVβ5. Cilengitide significantly attenuated liver fibrosis and reduced portal pressure in pIVCL mice, similar to the effects of the pan-integrin αV inhibitor. Furthermore, scRNA-seq analysis of FALD livers revealed expression of ITGAV, ITGB3, and ITGB5 within LSEC clusters, supporting the relevance of integrin αVβ3/αVβ5 signaling in human congestive hepatopathy. **Conclusion:** Integrin αVβ3/αVβ5 signaling contributes to the progression of congestive hepatopathy through activation of the YAP-CTGF pathway and may represent a novel therapeutic target for congestive hepatopathy, including FALD.

3368 | PRIMARY CILIA IN HEPATIC STELLATE CELLS PROMOTE LIVER FIBROSIS

Yang Xiao[1] Zeba Firdaus[1] Alexander Washington[1] Emily Rogers[1] Kai He[1] Jinghua Hu[1] Enis Kostallari[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Hepatic stellate cell (HSC) activation via profibrotic factors, such as platelet-derived growth factor B (PDGF), leads to liver fibrosis. PDGF receptors (PDGFRs) are the first to be identified on primary cilia. However, the role of primary cilia in HSCs remains unclear and is the aim of this study. **Methods:** Primary human HSCs were activated by PDGF treatment. Primary mouse HSCs were activated by culturing them for 5 days on plastic culture dishes. Primary cilia were characterized by public single-cell RNAseq (scRNA-seq) datasets and immunofluorescence. Primary cilia formation was inhibited by intraflagellar transport 88 (*IFT88*) siRNA transfection. HSC proliferation was assessed by 5-Ethynyl-2'-deoxyuridine (EdU) incorporation. *In vivo*, *Ift88* deletion in HSCs was achieved by breeding *Lrat-Cre* mice to *Ift88-flox* mice. Liver fibrosis was induced by intraperitoneal injection of carbon tetrachloride (CCl_4) for 6 weeks and analyzed by immunofluorescence (IF), Sirius Red staining, and Western blot (WB). **Results:** To know whether HSCs can develop primary cilia, we first analyzed several public scRNAseq datasets, where HSCs expressed several primary cilia genes, including *IFT88*, suggesting that HSCs might develop primary cilia. Activated primary mouse HSCs cultured for 5 days developed primary cilia compared to mouse HSCs cultured for 2 days, as assessed by ARL13B and glutaminated tubulin immunofluorescence. Primary human HSCs treated with PDGF increased the development of primary cilia *in vitro* by 1.6-fold ($n = 3$, $p < 0.05$). Primary cilia on HSCs expressed PDGFRs, which are important for HSC proliferation. Thus, we next examined the role of primary cilia on HSC proliferation *in vitro* and found that PDGF increased 5.5-fold EdU incorporation ($p < 0.001$), which was significantly reduced 1.8-fold when *IFT88* was knocked down by siRNA ($n = 3$, $p < 0.05$). Finally, CCl_4 administration increased liver fibrosis 5-fold in *Ift88*-flox control mice (WB, $p < 0.001$), which was significantly reduced 2.8-fold when *Ift88* was selectively deleted in HSCs ($p < 0.05$, $n = 6$-7 mice/group). Altogether, these results suggest that activated HSCs develop primary cilia, leading to HSC proliferation and liver fibrosis in vivo. **Conclusion:** The development of primary cilia in HSCs can be a therapeutic target against the progression of liver fibrosis.

3369 | SINGLE-CELL TRANSCRIPTOMICS IDENTIFIES CCDC80 AS A CONSERVED BIOMARKER OF HEPATIC STELLATE CELL ACTIVATION AND FIBROSIS SEVERITY IN MASLD

Le Thuy[1] Hoang Hai[2] Tuan Anh Pham[2] Duc Pham Minh[2] Bui Tam Chi Nguyen[2] Thi Ha Nguyen[2], [1]Osaka Metropolitan University, [2]Graduate School of Medicine, Osaka Metropolitan University

Background: Liver fibrosis is a complex pathological process driven by the activation of hepatic stellate cells (HSCs), which transition from a quiescent (qHSC) to an activated, myofibroblastic phenotype (aHSC). Identifying specific markers that define these transitions and offer therapeutic targets remains a critical unmet need. In this study, we employed single-cell RNA sequencing (scRNA-seq) to explore HSC heterogeneity and identify novel regulatory factors involved in fibrosis progression and regression. **Methods:** Liver fibrosis was induced in eight-week-old mice by intraperitoneal injection of CCl_4 for 6 weeks, with or without a spontaneous recovery period. Non-parenchymal cells (NPCs) were isolated for scRNA-seq. Bioinformatic analyses included subclustering, trajectory analysis (pseudotime), and Gene Ontology (GO) enrichment. Findings were validated across multiple mouse models (CCl_4, TAA, CDAA) and human MASLD (F1–F4) samples. Mechanistic studies were conducted in vitro using human hepatic stellate cells (HHSteCs). **Results:** scRNA-seq identified three distinct HSC clusters: qHSCs, aHSCs, and inactivated HSCs (iHSCs). Coiled-coil domain-containing protein 80 (CCDC80) emerged as one of the most significantly upregulated genes in aHSCs, with a strong positive correlation with Col1a1 expression (Pearson $R = 0.65$ in human liver data). Trajectory analysis confirmed that CCDC80 expression increases progressively along the HSC activation path. In vivo, CCDC80 protein levels were elevated with advancing fibrosis stage in both mouse and human HSCs across CCl_4, TAA, and CDAA diet-induced models. Notably, CCDC80 expression correlated with fibrosis severity in human MASLD (F3–F4 vs. F1–F2). Mechanistically, silencing CCDC80 in HHSteCs significantly attenuated expression of fibrogenic markers (α-SMA, COL1A1) by inhibiting

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

phosphorylation of the JAK2/STAT3 signaling pathway. **Conclusion:** This study identifies CCDC80 as a novel, evolutionarily conserved marker of activated HSCs. Its dynamic expression across both mouse models and human MASLD highlights its potential as a biomarker for fibrosis severity. Furthermore, our findings demonstrate that CCDC80 promotes fibrogenesis via the JAK2/STAT3 pathway, positioning it as a promising therapeutic target for liver fibrosis.

3370 | QFIBROSIS-BASED COLLAGEN MICROARCHITECTURE PROFILING IDENTIFIES RECURRENCE-ASSOCIATED FIBROTIC SIGNATURES IN HCC BIOPSIES

Kutbuddin Akbary[1] Vlad Ratziu[2] Chia-Jui Yen[3] Chih-Chieh Yen[4] I-Ting Liu[4] Yayun Ren[5] Dean Tai[6], [1]HistoIndex Pte Ltd, [2]Sorbonne Université, Institute for Cardiometabolism and Nutrition, Hospital Pitié-Salpêtrière, Paris, [3]National Cheng Kung University Hospital, College of Medicine, National Cheng, [4]National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, [5]HistoIndex Pte Ltd, Singapore, [6]HistoIndex

Background: Hepatocellular carcinoma (HCC) develops within a complex fibrotic & stromal microenvironment that influences tumor progression, treatment response and recurrence risk. Conventional fibrosis staging systems provide limited spatial and quantitative characterization of collagen remodelling within HCC-associated liver tissue. qFibrosis, an AI-based second harmonic generation/two-photon excitation-based quantitative histopathology platform, enables detailed assessment of collagen features and microarchitectural profiling across anatomically distinct tissue zones within the lobule. This study evaluated whether region-specific qFibrosis parameters are associated with the timing of recurrence post-surgical resection in HCC. **Methods:** Peri-tumoral liver samples from 85 HCC patients surgically resected (National Cheng Kung University Hospital, Taiwan) were analysed for qFibrosis-based collagen morphometry. Patients had either cirrhotic [n = 40; (HBV = n26, HCV = n14)] or non-cirrhotic [n = 45; (HBV = n40, HCV = n5)] backgrounds. Early recurrence was defined as disease-free survival (DFS) < 1 year (n30), and late recurrence as DFS ≥ 1 year (n55). Quantitative fibrosis parameters were assessed and compared across multiple hepatic lobule regions (overall liver tissue, portal tract, peri-portal, zone 2, peri-central, central vein, chicken-wire fibrosis). **Results:** In early recurrence, distinct collagen morphology was seen in patients with vs. without cirrhosis. In the peritumoral region non-cirrhotic biopsies, displayed higher qFibrosis parameters ($p < 0.05$-$p < 0.01$) in zone 2 and chicken-wire fibrosis regions, suggesting localized sinusoidal/pericellular collagen remodelling in absence of cirrhosis (Fig.1). Cirrhotic biopsies with early recurrence had distinct pattern of high pericentral qFibrosis parameters ($p < 0.05$-$p < 0.01$). These findings show recurrence-associated collagen remodelling patterns could differ by underlying cirrhosis status and may be localized to distinct hepatic regions. Comparisons in cirrhotic and non-cirrhotic biopsies within early and late recurrence groups (Fig.1) demonstrated significantly higher qFibrosis parameters across multiple regions in cirrhotic biopsies (portal, peri-portal, zone 2, and chicken-wire fibrosis). **Conclusion:** qFibrosis-based collagen morphometry identifies distinct spatial fibrosis patterns associated with early HCC recurrence in cirrhotic and non-cirrhotic liver backgrounds. These findings suggest that region-specific ECM alterations may reflect biologically distinct tumor-stroma interactions and recurrence mechanisms across different HCC backgrounds. Quantitative spatial fibrosis profiling using qFibrosis may provide clinically relevant prognostic information beyond conventional fibrosis staging and support biomarker-driven patient stratification in HCC clinical trials.

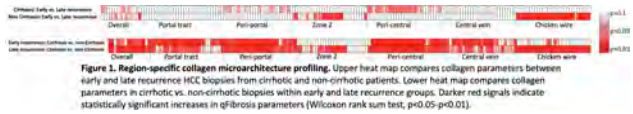

Figure 1. Region-specific collagen microarchitecture profiling. Upper heat map compares collagen parameters between early and late recurrence HCC biopsies from cirrhotic and non-cirrhotic patients. Lower heat map compares collagen parameters in cirrhotic vs. non-cirrhotic biopsies within early and late recurrence groups. Darker red signals indicate statistically significant increases in qFibrosis parameters (Wilcoxon rank sum test, p<0.05-p<0.01).

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Biliary atresia (BA) is an inflammatory fibrosing disease of the biliary tree that is the most common cause of pediatric liver transplant. Previous work demonstrated a correlation between neutrophil extracellular trap (NETs) and worse clinical outcomes; however, the mechanisms remain unclear. Portal fibroblasts (PFs) and hepatic stellate cells (HSCs) are the primary precursors of myofibroblasts in the liver and activation of these cells leads to fibrosis. Hepatic organoids (HOs) present an ex vivo model to study the role of NETs in the pathogenesis of BA. The aim of this study was to develop a HO model that could be used to study the role of NETs in PF and HSC activation. **Methods:** HOs were derived from induced human pluripotent stem cells (iPSC) using a series of media changes containing various growth factors and small molecules. HOs were characterized using RT-qPCR and immunohistochemistry (IHC). HOs were treated with NETs purified from PMA-activated neutrophils or vehicle only (control) and analyzed by single cell RNA sequencing (scRNA seq). **Results:** HO characterization: H&E, IHC and RT-qPCR demonstrated that HOs develop complex structures, including vasculature (CD31+), bile ducts (CD19+), hepatocytes (HNF4a+) and HSC (smooth muscle actin+). scRNA seq confirmed the presence of these major cell types in HOs. HOs exposed to NETs: scRNA seq revealed that NET exposure altered HO gene expression. Differential expression analysis of the PFs cluster identified 1,269 genes whose expression was significantly altered in response to NETs ($p < 0.05$). When Bonferroni correction was applied for multiple comparisons, insulin-like growth factor 2 (*IGF2)*, was found to be significantly increased in PFs in response to NET treatment ($q < 0.05$). Differential expression analysis of HSCs predicted 4,115 quiescent and 2,836 myofibroblast genes whose expression was significantly altered in response to NET treatment. Bonferroni correction revealed 245 quiescent and 42 myofibroblast genes whose expression was significantly altered in response to NETs ($q < 0.05$), including quiescent HSC genes (*NFATC2*, *HSPH1*, *PDLIM5*, *EGR3*) and myofibroblast genes (*HSPA1A*, *MRTFA*, *HSPA1B* and *IGF2)* that were previously shown to be enriched in fibrotic livers. **Conclusion:** iPSC-derived HOs are a functional model of the human liver, containing complex structures, all major liver cell types, and the ability to respond to profibrotic factors such as NETs. HOs exposed to NETs resulted in upregulation of many pro-fibrogenic genes within HSCs and PFs, suggesting that NETs play a role in liver fibrogenesis. Future HO co-culture studies will involve NETs isolated from BA or other liver disease control neutrophils, to determine the role of NETs in BA fibrogenesis.

3372 | CTX-343, A SELECTIVE, POTENT, PERIPHERALLY RESTRICTED LPA RECEPTOR 1 (LPAR1) ANTAGONIST FOR TREATING MASH AND OTHER FIBROTIC LIVER DISEASES

Didier Bagnol[1] James Swaney[1] Dan Lorrain[1] Kym Lorrain[1] Alex Broadhead[1] Chris Baccei[1] Lisa Eide[1] Bryanna Paulson[1] Geraldine Edu[1] John Atkins[1] Karin Stebbins[1] Michael Poon[1] Austin Chen[1], [1]Contineum Therapeutics

Background: Repeated liver injury results in progressive hepatocellular damage and hepatic stellate cell (HSC) differentiation into myfibroblasts, ultimately leading to tissue fibrosis and cirrhosis. The underlying mechanism involves aberrant upregulation of LPA and increased LPAR1 expression on activated HSCs. LPAR1 stimulation is believed to be a key fibrotic driver in liver disease. In support of this, LPAR1 antagonists inhibit HSC proliferation and activation, and reduce liver fibrosis in preclinical models of Metabolic Dysfunction-Associated Steatohepatitis (MASH). Here, we characterized the potency, selectivity, PK/PD profile and efficacy of CTX-343, a peripherally restricted LPAR1 antagonist as a potential treatment for liver fibrosis/MASH. **Methods:** CTX-343 binding kinetics and functional activity were evaluated in B103 cells stably expressing human LPAR1. CTX-343 selectivity for human LPAR1-6 was evaluated using transiently transfected HEK293T cells. CTX-343 inhibition of primary human HSC activation was evaluated by immunocytochemistry. C57Bl6/N female mice (8-10 weeks old) were dosed intraperitoneally twice a week for 6 weeks with 1 mL/kg of CCl_4 dissolved in corn oil to induced liver injury. Cholestatic liver injury was induced in C57Bl6/N male mice (8-10 weeks old) by performing a double ligation of the common bile duct for 11 days. Wistar male rats (7-8 weeks old) were dosed intraperitoneally weekly with 50 mg/Kg of diethylnitrosamine (DEN) dissolved in PBS for 18 weeks to induce severe liver fibrosis and cirrhosis. CTX-343 with doses ranging from 0.003 to 3 mg/kg was formulated as a suspension in vehicle (1%HPMC/0.1%TWEEN80) and administered orally once a day in all models. **Results:** In human LPAR1 overexpressing B103 cells, CTX-343 inhibited LPA-stimulated Ca^{+2} mobilization with an IC_{50} of 44.1 nM. In HEK293T cells overexpressing human LPAR1-6, CTX-343 was >17-fold selective for LPAR1 versus LPAR2, and >82 fold selective for LPAR3-6. CTX-343 exhibited slow binding kinetics in a human LPAR1 membrane binding assay (3 h, K_i = 5.6 nM)

with steady state reached at 12 h, a residence time (1/K_{off}) of 46 h, and a dissociation constant (K_d) of 1.2 nM. *In vitro,* CTX-343 inhibited LPA-induced human HSC activation (IC_{50} = 40 nM). In mice, single oral administration of CTX-343 blocked LPA induced histamine release (3 h, EC_{50} = 110 nM; 24 h EC_{50} = 4.6 nM). In adult male rats, CTX-343 exhibited good overall PK properties and distributed preferentially to the liver. In models of liver fibrosis (mouse CCl_4 and rat DEN), CTX-343 reduced liver total soluble collagen, fibrotic gene expression, proportional fibrosis (up to 50%), and protected against hepatic necrosis in the mouse cholestasis model. **Conclusion:** These data indicate that CTX-343 is a potent and selective LPAR1 antagonist that may serve as a novel treatment for MASH and other fibrotic liver diseases.

3373 | A NOVEL SMALL-MOLECULE GLT25D1 INHIBITOR SUPPRESSES HEPATIC STELLATE CELL ACTIVATION AND FIBROGENESIS

Menggi Li[1] Xiaoyuan Xu[2] Hongshan Wei[1], [1]Department of Gastroenterology, Beijing Ditan Hospital, Capital Medical University, Beijing, China, [2]Department of Gastroenterology, Peking University First Hospital, Beijing, China

Background: Hepatic fibrosis is characterized by excessive extracellular matrix (ECM) deposition and may progress to cirrhosis and hepatocellular carcinoma (HCC). GLT25D1, a key enzyme involved in collagen glycosylation and maturation, has recently emerged as a potential regulator of hepatic fibrogenesis, although its therapeutic targeting remains largely unexplored. We identified a novel GLT25D1 inhibitor, GLT-03, through AlphaFold2-guided virtual screening and investigated its antifibrotic effects and underlying mechanisms in hepatic stellate cells (HSCs). **Methods:** MOE-based virtual screening using an AlphaFold2-predicted GLT25D1 structure identified GLT-03. GLT25D1–GLT-03 interactions were evaluated by CB-Dock2 and surface plasmon resonance (SPR). TGF-β1-activated LX-2 cells were treated with GLT-03 (1 μM). PIIINP and CIV levels were measured by sandwich immunoassay, while GLT25D1, COL1A1, and α-SMA expression was assessed by qPCR and western blotting. Cell migration and apoptosis were evaluated by scratch assay and flow cytometry, respectively. Network pharmacology, GO/KEGG enrichment, PPI-Cytoscape analysis, and RNA-seq were performed to explore the underlying molecular mechanisms. Acute toxicity was evaluated in male C57BL/6 mice after oral GLT-03 administration (50 or 100 mg/kg). **Results:** GLT-03 showed favorable binding to GLT25D1 (MOE S-score: −11.75; CB-Dock2 Vina: −8.5; Fig. 1A). Purified GLT25D1 was >97% pure by SEC-HPLC and predominantly monomeric (Fig. 1B). SPR demonstrated a KD comparable to UDP-α-D-galactose but with slower dissociation, indicating greater binding stability. (Table 1, Fig. 1C). In TGF-β1-activated LX-2 cells, GLT-03 reduced PIIINP secretion without affecting CIV levels, decreased GLT25D1, COL1A1, and α-SMA expression, inhibited migration, and promoted apoptosis (Fig. 1D–H). Network pharmacology identified 246 overlapping targets associated with hepatic fibrosis (Fig. 1I). GO/KEGG analyses revealed enrichment in leukocyte migration, insulin signaling, and MAPK/PI3K-Akt pathways (Fig. 1J). PPI-Cytoscape identified five hub targets: TP53, SRC, EGFR, HSP90AA1, and AKT1 (Fig. 1K). RNA-seq identified 359 DEGs in GLT-03-treated activated LX-2 cells; GO analysis further confirmed enrichment in MAPK/ERK regulation, FGFR binding, and negative regulation of collagen metabolism, consistent with network pharmacology predictions (Fig. 1L). Acute toxicity studies showed no significant changes in ALT, AST, CREA-S, or UREA levels compared with controls (Fig. 1M). **Conclusion:** GLT-03 attenuated HSC activation and fibrogenesis while exhibiting a favorable preliminary safety profile, potentially through modulation of MAPK/ERK and PI3K-Akt signaling pathways. These findings identify GLT25D1-mediated collagen glycosylation as a promising therapeutic target and suggest a novel antifibrotic strategy for hepatic fibrosis.

3374 | BRD4 CONDENSATES REGULATE COL1A1 EXPRESSION IN ACTIVATED HEPATIC STELLATE CELLS

Luke Doskey[1] Dawood Al Dawood[1] Usman Yaqoob[1] Maria Hernandez Tejero[2] Sofia Jerez[1] Sheng Cao[2] Vijay Shah[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Liver fibrosis is characterized by excessive extracellular matrix (ECM) deposition by activated Hepatic Stellate Cells (HSCs). The main component of fibrotic ECM is collagen 1 (COL), encoded by *COL1A1*. Transcriptional condensates are molecular phase-separated assemblies of transcriptional machinery known to regulate the expression of key cell identity genes. They also bind clusters of positive co-regulatory elements known as Super Enhancers (SEs) and influence chromatin interactions. Previously, we showed that BRD4 condensate formation is induced by TGFβ in HSCs in vitro and in a CCl_4-induced fibrosis mouse model in vivo, also, that BRD4 and histone acetylation inhibition, reduces COL expression. However, the epigenetic mechanisms linking TGFβ signaling, super enhancer (SE) formation, and chromatin organization to COL1A1 expression in HSCs remain unclear. **Methods:** To assess BRD4 and H3K27ac occupancy chromatin immunoprecipitation sequencing (ChIP-Seq) was performed on an HSC cell line (LX-2) after TGFβ stimulation, with or without the BRD4 inhibitor I-BET151. H3K27ac signals were analyzed using the LILY algorithm to rank order SEs and identify genes regulated by SEs. Treatment with the condensate inhibitor 1,6-Hexanediol was used to determine the effect of condensate disruption *on COL1A1* expression, measured by qPCR. Finally, the chromatin conformation capture method Hi-C was performed to study the effect of TGFβ on chromatin organization using LX-2 cells. **Results:** ChIP-Seq revealed a regulatory region 10 kb upstream of *COL1A1* locus enriched with H3K27ac and BRD4 following TGFβ stimulation, consistent with the presence of a SE. Ranking of SEs by LILY identified 807 SEs under basal conditions. The putative *COL1A1* SE ranking shifted from 55 to 17 with TGFβ stimulation, and BRD4 inhibition reduced the ranking to 44. Pharmacologic disruption of condensates with 1,6-hexanediol reduced TGFβ-induced *COL1A1* expression by 50%, supporting a role for condensate formation in regulating *COL1A1* expression. Finally, Hi-C demonstrated the presence of contact points between the *COL1A1* promoter and the *TMEM92* promoter, which also interacts with the *PDK2* and *SGCA* loci, suggesting a coordinated co-regulatory gene network in HSCs. **Conclusion:** These findings support a novel model for the regulation of collagen expression, whereby TGFβ induces the formation of BRD4 condensates at the *COL1A1* SE region to regulate the expression of COL1A1 and a coordinated gene network in HSCs. Targeting transcriptional condensates may offer a novel therapeutic approach for the treatment of liver fibrosis.

3375 | C3 COMPLOSOME-DEPENDENT METABOLIC REPROGRAMMING REGULATES HEPATIC STELLATE CELL ACTIVATION AND FIBROGENESIS IN METALD

Lauren N. Rutt[1], Kris Fritz, Rebecca L. Mccullough[2], [1]University of Colorado, Anschutz Medical Campus, [2]University of Colorado - Anschutz

Background: Metabolic alcohol-associated liver disease (MetALD) is a leading cause of liver-related morbidity and mortality, with fibrosis serving as the

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

strongest predictor of clinical outcomes. Despite this burden, therapies targeting fibrogenic mechanisms remain limited, leaving liver transplantation the only viable option for end-stage liver disease. Hepatic stellate cells (HSCs), the primary fibroblast of the liver, transdifferentiate into activated myofibroblasts and undergo metabolic adaptations to support excessive extracellular matrix production in response to injury. Although HSC metabolic reprogramming is a key driver of fibrogenesis, the upstream mechanisms coordinating these adaptations remain poorly understood. Intrinsic Complement C3 is increased in activated fibroblasts in other fibrotic diseases and linked to profibrotic metabolic programs; however, its role in HSC biology remains undefined. Emerging evidence suggests intracellular complement signaling through mitochondrial C3a receptor (C3aR1) regulates mitochondrial function and oxidative stress, identifying the C3 complosome as a potential mediator of metabolic reprogramming during fibrogenesis. We hypothesize that activation of the alternative complement pathway enhances mitochondrial C3aR1 signaling in HSCs, driving metabolic reprogramming that promote HSC activation and fibrogenesis in MetALD. **Methods:** Alcohol-associated hepatitis (AH) explanted and healthy donor liver tissue from the R24 resource at Johns Hopkins University underwent multispectral imaging of C3, C3aR1, VDAC, and aSMA. To determine if the C3 complosome is associated with HSC activation and fibrosis, a murine model of MetALD , eight-week-old male mice were fed a GAN diet (high fat/cholesterol/sugar) for 12 weeks and received weekly oral ethanol gavages thrice weekly on weeks 8-12, and primary human and mouse HSCs were used to evaluate complement activation and glycolytic remodeling during HSC activation. **Results:** C3aR1 expression and colocalization with alpha smooth muscle actin (a-sma)-positive cells was increased in AH liver compared to healthy donor tissue. RNA-sequencing of liver tissue revealed enrichment of genes associated with acute phase/injury response, extracellular matrix reorganization and fibrosis, myofibroblast activation, complement, and glycolysis, which were further increased in GAN+Ethanol treated mice. *In vitro*, ethanol increased colocalization of C3aR1 with the mitochondrial marker Tom20 in primary hHSCs, which was attenuated by pretreatment with the mitochondrial-targeted antioxidant MitoTEMPO. **Conclusion:** These studies identify intrinsic C3 complement as a potential regulator of HSC metabolic reprogramming and fibrogenesis in MetALD. Targeting complement-dependent metabolic dysfunction may represent a novel therapeutic strategy to limit HSC activation and fibrosis progression during liver disease.

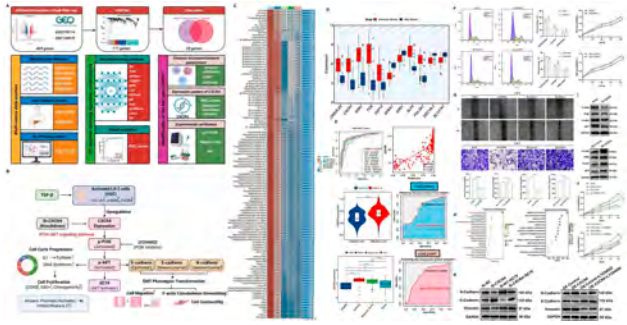
3376 | CXCR4 PROMOTES HEPATIC STELLATE CELL ACTIVATION AND LIVER FIBROSIS THROUGH THE PI3K/AKT SIGNALING PATHWAY



Huiru Liu[1] Yuexi Yu[1] Fengmei Wang[1], [1]Tianjin First Central Hospital

Background: Liver fibrosis is a progressive wound-healing response to chronic liver injury characterized by excessive extracellular matrix deposition and activation of hepatic stellate cells (HSCs). Persistent fibrosis can progress to cirrhosis and hepatocellular carcinoma, yet effective antifibrotic therapies remain limited. The chemokine receptor CXCR4 and its ligand CXCL12 have been implicated in fibrotic diseases in multiple organs. However, the role of CXCR4 in liver fibrosis and its regulatory mechanisms in HSC activation remain incompletely understood. This study aimed to investigate the function and molecular mechanisms of CXCR4 in liver fibrosis. **Methods:** Public liver fibrosis transcriptomic datasets from the Gene Expression Omnibus (GEO) were analyzed to identify fibrosis-related genes using differential expression analysis and weighted gene co-expression network analysis (WGCNA). A diagnostic model was constructed using 127 machine-learning algorithm combinations and evaluated using receiver operating characteristic analysis. Immune cell infiltration was assessed using CIBERSORT and single-sample gene set enrichment analysis (ssGSEA). Single-cell RNA sequencing data were analyzed to construct a cirrhotic liver atlas and evaluate cellular hypoxia using a LightGBM-based cell hypoxia prediction framework. CXCR4 expression was validated in human liver tissues using qRT-PCR, Western blotting, and immunohistochemistry. Functional experiments were performed in TGF-β–stimulated LX-2 cells with CXCR4 knockdown or overexpression. Cell proliferation, migration, epithelial–mesenchymal transition (EMT), and cytoskeletal remodeling were assessed using CCK-8, colony formation, EdU, wound-healing, Transwell, phalloidin staining, and cell cycle analysis. Transcriptomic sequencing and pathway analyses were used to identify downstream signaling pathways. **Results:** Integrated analyses identified 23 fibrosis-associated core genes and established an 11-gene diagnostic model with strong predictive performance. CXCR4 demonstrated the highest diagnostic value and was significantly correlated with fibrosis risk scores. Immune analyses revealed enhanced immune activation in advanced fibrosis. CXCR4 expression was significantly elevated in cirrhotic liver tissues and positively correlated with fibrosis markers COL1A1 and α-SMA. In vitro, CXCR4 knockdown suppressed LX-2 cell proliferation, migration, EMT, and cytoskeletal remodeling,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

whereas CXCR4 overexpression promoted these phenotypes. Mechanistically, CXCR4 regulated HSC activation primarily through activation of the PI3K/AKT signaling pathway. **Conclusion:** CXCR4 plays a critical role in liver fibrosis progression by promoting HSC activation and profibrotic phenotypes via the PI3K/AKT pathway. Targeting CXCR4 may represent a potential therapeutic strategy for liver fibrosis.

3377 | A NOVEL FGFR INHIBITOR IN COMBINATION WITH A PDE4B INHIBITOR SYNERGISTICALLY ATTENUATES LIVER FIBROSIS IN LX-2 CELLS

Dongke Yu[1] Yating Li[2] Liang Qi[3] Hongqiong Yuan[4] Lin Cheng[5] Jianyou Shi[6], [1]Sichuan Provincial People's Hosptial, [2]Chengdu University of Traditional Chinese Medicine, [3]University of Electronic Science and Technology of China, [4]Xihua University, [5]Southwest Jiaotong University, [6]Sichuan Provincial People's Hospital

Background: FGFR is a potential target for liver fibrosis therapy, and PDE4 mediates immunomodulatory and anti-inflammatory effects. This study investigated the therapeutic effects and mechanisms of a novel FGFR inhibitor B102 combined with the PDE4B inhibitor BI1015550 in TGF-β1 induced LX-2 cells, an in vitro model of liver fibrosis. **Methods:** The in vitro kinase inhibitory activity of B102 was determined by Eurofins KinaseProfiler™. CCK-8 assay was used to evaluate B102 toxicity on LX-2 cells, and acute toxicity experiments in mice assessed its safety. An in vitro fibrosis model was established using TGF-β1 induced LX-2 cells. RT-qPCR measured treatment effects on mRNA expression, and the combination index (CI) was calculated via CompuSyn software. **Results:** B102 exhibited potent inhibitory activity against FGFR1, FGFR2, and FGFR3, with IC50 values of 3 nM, 2 nM, and 3 nM, respectively, while showing slightly weaker activity against FGFR4 (IC50 = 33 nM). Additionally, B102 strongly inhibited Fms (CSF1R) with an IC50 of 9 nM, moderately inhibited Flt1, KDR, and Flt4 (IC50 = 42, 51, and 112 nM, respectively), and only weakly suppressed Ret and ALK (IC50 = 295 and 497 nM). To evaluate the in vivo safety of B102, mice received a single dose of 2000 mg/kg. No significant differences in body weight change, organ indices (heart, liver, spleen, lung, and kidney), or plasma biochemical parameters (ALT, ALP, TBIL, BUN, CREA, and CK) were observed between the vehicle and treatment groups ($p > 0.05$), and all biochemical values fell within normal reference ranges. Furthermore, the CCK-8 assay showed that B102 was safe for LX-2 cells at 5 μmol/L within 24 hours. In TGF-β1 induced LX-2 cells, the combination of B102 and the PDE4B inhibitor BI1015550 significantly downregulated the mRNA levels of TGF-β1, COL1A1, and TIMP1. CI was less than 1, indicating a synergistic effect of the two drugs in inhibiting the expression of liver fibrosis-related genes. Western blot analysis revealed that the phosphorylation levels of FGFR1, FGFR2, and FGFR3 were significantly increased in TGF-β1 induced LX-2 cells. Combination treatment markedly suppressed the phosphorylation of these FGFR proteins, showing superior effects compared to either monotherapy. Moreover, the combination treatment also significantly inhibited the phosphorylation of the key FGFR substrates PLCγ1 and FRS2α. STAT3, a downstream target of FGFR, promotes the expression of fibrosis-related genes upon activation; combination treatment significantly downregulated STAT3 phosphorylation. **Conclusion:** B102, a potent and selective FGFR inhibitor with nanomolar activity and a favorable in vivo safety profile, synergistically downregulates fibrosis markers, suppresses FGFR signaling, and reduces inflammation-related proteins when combined with the PDE4B inhibitor BI1015555 in TGF-β1 induced LX-2 cells, providing an in vitro basis for liver fibrosis treatment.

3378 | HEPCIDIN TO FERRITIN RATIO DRIVEN ENHANCED LIVER FIBROSIS INDEX AND FIBROSIS-4 SCORES FOR HEPATIC FIBROGENESIS RISK IN β-THALASSEMIA PATIENTS

Narayan Gautam[1] Mukesh Sharma Paudel[2] Bipin Adhikari[3] Prabodh Risal[4], [1]Universal College of Medical Sciences (UCMS), Bhairahawa and KUSMS, Dhulikhel, Nepal (PhD scholar), [2]National Academy of Medical Sciences (NAMS), Kathmandu, Nepal, [3]Mahidol-Oxford Tropical Medicine Research Unit,

Bangkok, Thailand, [4]Kathmandu University School of Medical Sciences (KUSMS), Dhulikhel, Nepal

Background: β-thalassemia is characterized by ineffective erythropoiesis, chronic anemia, and dysregulated iron homeostasis. Beyond transfusion-related iron overload, suppression of the hepcidin axis promotes increased intestinal iron absorption and macrophage iron release, potentially contributing to hepatic injury and fibrogenesis. This study investigated iron regulatory biomarkers, fibrogenic signaling, and non-invasive fibrosis indices in β-thalassemia and non-β-thalassemia microcytic hypochromic anemia (N-βT McHc) participants and assessed independent risk factors. **Methods:** A cross-sectional study was conducted among the study population (n = 768) for the screening of β-thalassemia by multistage random sampling in four districts of Lumbini Province, Nepal. Suspected β-thalassemia (n = 117) identified through hemogram, peripheral blood smear examination, and high-performance liquid chromatography (HPLC) confirmed 39 β-thalassemia and 78 N-βT McHc cases. Liver fibrosis risk was evaluated using the Enhanced Liver Fibrosis (ELF) score and Fibrosis-4 (FIB-4) index. Iron homeostasis was assessed using serum ferritin and hepcidin concentrations, while fibrogenic activity was evaluated using transforming growth factor-beta 1 (TGF-β1), hyaluronic acid (HA), procollagen III N-terminal peptide (PIII-NP), and tissue inhibitor of matrix metalloproteinase-1 (TIMP-1). Multivariable logistic regression analyses were performed to identify factors associated with advanced fibrosis. **Results:** Although serum hepcidin concentrations were significantly higher in β-thalassemia participants than in N-βT McHc participants (86.51 vs. 58.35 ng/mL), the hepcidin-to-ferritin ratio was substantially lower (0.65 versus 1.41), indicating relative hepcidin insufficiency in relation to iron burden. β-thalassemia participants demonstrated significantly higher ELF scores and circulating TGF-β1 levels, consistent with enhanced fibrogenic activity. In multivariable analysis, increasing age (aOR: 1.15, 95% CI: 1.09–1.22; $p < 0.001$), rural residence (aOR: 4.516, 95% CI: 1.31–14.34; $p = 0.016$), and lower odds of β-thalassemia category (aOR: 0.17, 95% CI: 0.04–0.76; $p = 0.020$) were independently associated with the advanced fibrosis FIB-4 model. In contrast, TGF-β1 was the only independent predictor with higher odds of ELF for the probability of cirrhosis risk (aOR: 1.003, 95% CI: 1.001–1.006; $p = 0.008$). **Conclusion:** β-thalassemia was characterized by evidence of disrupted iron regulation, reflected by a reduced hepcidin-to-ferritin ratio, and increased fibrogenic signaling, reflected by elevated TGF-β1 levels. The independent association between TGF-β1 and ELF score supports a potential link between profibrotic pathways and extracellular matrix remodeling in β-thalassemia in resource-limited settings.

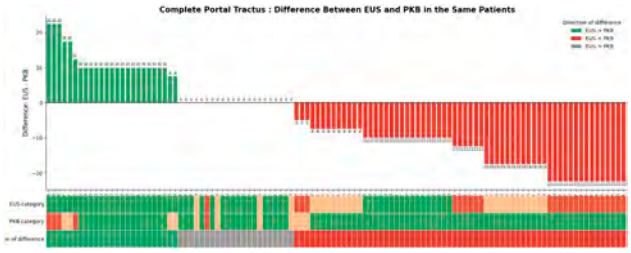
3379 | HISTOPATHOLOGICAL COMPARISON OF ENDOSCOPIC ULTRASOUND-GUIDED FINE-NEEDLE BIOPSY AND PERCUTANEOUS LIVER BIOPSY



Hayri Kagan Goren[1] Burcu Saka[1] Ayse Armutlu[1] Hale Kirimlioglu[2] Genco Gencdal[3] Sidar Copur[1] Murat Akyildiz[4], [1]Koc University, [2]Acibadem University, [3]Liv Hospital, [4]University Of South Caroline, School of Medicine-Greenville, DEPARTMENT OF GASTROENTEROLOGY&HEPATOLO

Background: Liver biopsy is a gold standart procedure for the diagnosis, treatment response and follow up of liver disease. In recent years, endoscopic ultrasound-guided liver biopsy has also gained attention and there have been developed some conflicts about especially adequate sample size and histopathological evaluation perspectives between EUS FNB vs percutaneous liver biopsy.In this study, we aimed to compare the histolopathologic adequacy and interpretation of percutaneous liver biopsy vs endoscopic ultrasound-guided liver biopsy samples from the same patients by two independent, blinded hepatopathologist. **Methods:** A total of 60 different liver biopsy specimens were evaluated in this study. Of these, 30 were obtained by the percutaneous method and 30 by endoscopic ultrasound guidance. After anonymization, all specimens were evaluated in a blinded manner by two different hepatopathologists, with the aim of reducing observer-related bias and assessment bias.The adequacy of the biopsy materials was primarily evaluated based on the number of portal tracts/islands. Portal areas were classified as complete and incomplete portal islands, and the number of complete portal islands was accepted as the primary adequacy criterion. In addition, the evaluability of key histopathological parameters such as fibrosis staging, degree of steatosis, ballooning degeneration, bile duct atrophy, and cholestasis was assessed as secondary adequacy criteria. **Results:** All the biopsy samples had at least 10 portal areas and there were no inadequate sample for the evaluation.The number of complete portal areas, was significantly higher in the percutaneous biopsy group compared with the EUS-guided biopsy group [percutan vs EUS , 20 vs 15, $p < 0.001$]. A significant difference was observed between the two groups in terms of the number of fragments containing more than three portal areas ($p = 0.0006$). In contrast, no significant difference was found in the number of incomplete

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

portal areas (p = 0.7072). When secondary histopathological parameters were evaluated, no statistically significant difference was detected between the two methods in terms of major findings such as fibrosis, steatosis, ballooning degeneration, bile duct atrophy, and cholestasis, except for cholangiolar proliferation (p = 0.0129) and lobular inflammation (p = 0.0347). **Conclusion:** In light of these findings, there was no significant difference between EUS vs percutaneous liver biopsy in terms of adequate sampling and diagnostic criteria and histopathogic evaluation. In conclusion, EUS-guided liver biopsy may be considered a good alternative to percutaneous liver biopsy.

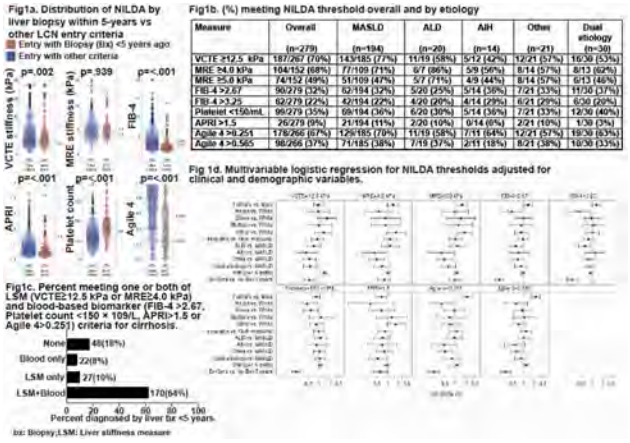
3380 | ◆ PERFORMANCE OF NON-INVASIVE LIVER DISEASE ASSESSMENT (NILDA) MEASURES AND CLINICAL PREDICTORS OF THRESHOLD ATTAINMENT IN COMPENSATED CIRRHOSIS (CC): EXPERIENCE FROM THE LIVER CIRRHOSIS NETWORK (LCN)



Nicole Welch[1] Abigail Smith[2] Bilal Hameed[3] Monica Tincopa[4] Manal Abdelmalek[5] Jasmohan Bajaj[6] Giuseppe Cullaro[7] Amreen Dinani[8] David Goldberg[9] Patricia Jones[10] Ani Kardashian[11] Mandana Khalili[12] Rohit Loomba[4] Neehar Parikh[13] Douglas Simonetto[5] Elliot Tapper[13] Elizabeth Verna[14] Kara Wegermann[15] Norah Terrault[11] Srinivasan Dasarathy[1] Richard Sterling[6], [1]Cleveland Clinic, [2]Northwestern University, [3]University of San Francisco, [4]University of California, San Diego, [5]Mayo Clinic Rochester, [6]Virginia Commonwealth University, [7]Columbia University, [8]Duke University School of Medicine, [9]University of Miami, [10]University of North Carolina at Chapel Hill, [11]University of Southern California, [12]University of California, San Francisco, [13]University of Michigan Medical Center, [14]Columbia University Medical Center, [15]Duke University

Background: NILDA are increasingly used to diagnose cirrhosis, but their performance across etiologies in CC has not been well characterized. We aimed to determine how often NILDA thresholds were met in biopsy-confirmed CC and whether baseline characteristics were associated with meeting thresholds. **Methods:** The LCN Cohort Study is a prospective observational study at 10 US centers. Adults met LCN cirrhosis criteria by liver biopsy < 5 yrs or by > 2 other criteria: biopsy > 5 yrs ago, vibration-controlled transient elastography (VCTE) ≥ 12.5 kPa, magnetic resonance elastography (MRE) ≥ 5.0 kPa, nodular liver and splenomegaly/recanalized umbilical vein < 1 yr on imaging, esophageal varices < 3 yrs, FIB-4 > 2.67, or platelets < 150,000 < 6 months. In this cross-sectional baseline analysis, we summarized VCTE, MRE, FIB-4, platelets, APRI, and Agile 4 in biopsy-confirmed cirrhosis and fit multivariable logistic regression models for meeting NILDA thresholds adjusted for entry criteria, sex, race, ethnicity, etiology, and BMI. **Results:** Among 1199 subjects, 279 entered via biopsy < 5 yrs and 920 by other criteria. In the biopsy < 5 yrs group, median (IQR) NILDA were VCTE 16.6 (11.4, 24.7) kPa, MRE 4.8 (3.7, 6.0) kPa, FIB-4 1.99 (1.48, 2.98), platelets 171 (131, 213) x 10^9 /L, APRI 0.542 (0.359, 0.874), and Agile 4 0.408 (0.163, 0.703). VCTE, FIB-4, APRI, and Agile 4 were higher and platelets lower in the other criteria group, whereas MRE distributions were similar (**Fig 1a**). Despite biopsy-confirmed cirrhosis, only 70% met VCTE ≥ 12.5 kPa, 68% and 49% met MRE ≥ 4.0 and ≥ 5.0 kPa, 32% and 22% met FIB-4 > 2.67 and > 3.25, 35% had platelets < 150 x 10^9 /L, 9% met APRI > 1.5, and 67% and 37% met Agile 4 > 0.251 and > 0.565. Threshold attainment differed by etiology: highest with VCTE in MASLD and MRE in ALD (**Fig 1b**). Combination of VCTE ≥ 12.5 kPa, Agile 4 > 0.251, and platelets < 150 x 10^9 /L increased identification of biopsy-confirmed cirrhosis from 70% (VCTE alone) to 79%, with minimal gain from FIB-4 > 2.67 (80%); 18% met no NILDA criteria (**Fig 1c**). In compensated cirrhosis, each 1-unit increase in BMI was associated with higher odds of meeting VCTE ≥ 12.5 kPa (OR 1.13, 95% CI 1.07-1.20), MRE ≥ 4.0 kPa (OR 1.08, 1.01-1.16), and MRE ≥ 5.0 kPa (OR 1.06, 1.00-1.13). Compared with MASLD, ALD was associated with lower odds of meeting FIB-4 thresholds, while other and dual etiologies were associated with lower odds of meeting VCTE/MRE thresholds (**Fig 1d**). **Conclusion:** Commonly used, non-etiology specific NILDA thresholds were not met uniformly in CC, including biopsy-confirmed disease, suggesting that individual NILDA criteria may lack sensitivity as stand-alone tests in compensated disease. A combined VCTE, Agile 4, and platelet-based strategy improved

identification of cirrhosis beyond VCTE alone. These findings support a combined NILDA panel, rather than any single threshold, to identify suspected CC and future evaluation of lower thresholds in combination.

Measure	Overall (n=279)	MASLD (n=194)	ALD (n=20)	AIH (n=14)	Other (n=21)	Dual etiology (n=30)
VCTE ≥12.5 kPa	187/267 (70%)	143/185 (77%)	11/19 (58%)	5/12 (42%)	12/21 (57%)	16/30 (53%)
MRE ≥4.0 kPa	104/152 (68%)	77/109 (71%)	6/7 (86%)	5/9 (56%)	8/14 (57%)	8/13 (62%)

3381 | PERFORMANCE EVALUATION OF A LARGE LANGUAGE MODEL FOR AUTOMATED FIBROSIS STAGING FROM LIVER BIOPSY REPORTS: A MULTISITE VALIDATION STUDY

Marwan Qasem[1] Kamalpreet Hara[1] Alberto Calleri[1] Hugo Vargas[2] Andrew Keaveny[3] Daniel Penrice[4] Patrick Kamath[1] Vijay Shah[1] Douglas Simonetto[1], [1]Mayo Clinic Rochester, [2]Mayo Clinic Arizona, [3]Mayo Clinic Florida, [4]Mayo Clinic Health System - Eau Claire

Background: Accurate fibrosis staging from liver biopsy reports is essential for cohort construction, real-world evidence generation, and clinical trial recruitment in liver research. Manual review of large pathology datasets is labor-intensive and subject to inter-reviewer variability, representing an unmet need for scalable automated solutions. We assessed whether a locally deployed, HIPAA-compliant large language model (LLM) based on Gemini 2.5 Flash

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

could accurately stage hepatic fibrosis from unstructured liver biopsy reports. **Methods:** This retrospective multisite validation included adult liver biopsy reports (2004–2026) from 3 Mayo Clinic sites (MN, AZ, FL) and Mayo Clinic Health System. Of 67,454 liver biopsy reports, 21,262 (31.5%) parenchymal adult liver biopsy reports were identified via structured-field and free-text filters. An LLM prompt was iteratively refined against a held-out set (n = 100). It was then applied to the full cohort to assign an F0-F4 stage by concordance mapping from established staging systems or by characteristic histological features and to flag reports it deemed unstageable. Two site-stratified samples were drawn: 500 stageable reports (125 per site; 100 per LLM-assigned stage) and 100 unstageable reports. Two blinded hepatology research MD fellows independently staged each report, with discordance resolved by a blinded transplant hepatologist, yielding a composite reference standard. LLM performance was evaluated at the stage level and at significant (≥F2) and advanced (≥F3) fibrosis thresholds. **Results:** Among 500 LLM-staged reports, 492 were judged stageable and 8 (1.6%) uninterpretable by the reference standard. Exact agreement was 91.6% overall and 93.1% in the 492 stageable reports, with 100% within-one-stage agreement and a quadratic-weighted κ of 0.983 (95% CI 0.977–0.989). Per-stage sensitivity ranged from 86.4% (F2) to 98.8% (F1) and specificity from 96.6% (F1) to 99.7% (F0) across all stages. The LLM achieved 97.6% accuracy for ≥F2 (95% CI 95.8–98.6; sensitivity 96.1%, specificity 100%, PPV 100%, NPV 93.9%) and 97.4% accuracy for ≥F3 (95% CI 95.5–98.4; sensitivity 94.6%, specificity 99.3%, PPV 99.0%, NPV 96.3%). On the 492 stageable pairs, exact inter-reviewer agreement was 93.9% with weighted κ 0.973 (95% CI 0.960–0.987). Adjudication for disagreements was needed in 37 reports (7.4%). Inter-reviewer agreement was comparable to LLM and reference agreement. Of 100 unstageable reports, 12 (12.0%) were judged stageable on manual review. Performance was consistent across all sites, time, age, sex, and race. **Conclusion:** This LLM-enabled approach accurately identified and staged liver fibrosis from unstructured biopsy reports, with strong agreement compared to expert staging, including high accuracy at both significant and advanced fibrosis thresholds. Findings support LLM use for scalable identification and characterization of liver fibrosis in research.

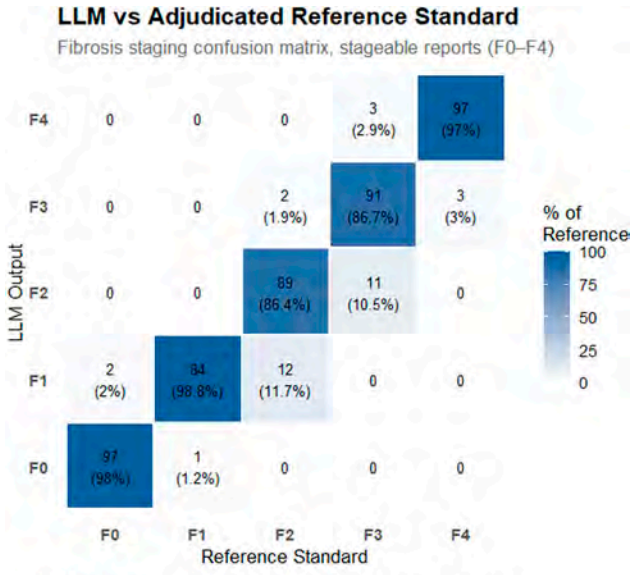

Figure 1. Confusion matrix of LLM-assigned fibrosis stage versus the adjudicated reference standard among 492 stageable reports (F0–F4). Cell values show counts with column percentages (% of each reference standard category). Diagonal cells represent exact agreement; off-diagonal cells represent misclassifications. Colour intensity reflects column percentage.

3382 | HYDRONIDONE ATTENUATES LIVER FIBROSIS PROGRESSION BY AMELIORATING LSEC ENDOTHELIAL DYSFUNCTION

Zhuqiong Lu[1] Guangwen Chen[1] Hanjing Zhangdi[1] Qichao Ge[1] Yufei Yang[1] Jianxiang Wang[1] Yuchen Ding[1] Yuecheng Guo[1] Jie Jian[1] Ying Luo[2] Ling Zhang[2] Hui Dong[1] Lungen Lu[1] Xiaobo Cai[1], [1]Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, [2]Continent Pharmaceuticals Co. ,Ltd., Beijing, China

Background: LSEC capillarization and endothelial dysfunction are early events in liver fibrogenesis and may precede overt fibrosis. Hydronidone (HDD), a novel pirfenidone-related antifibrotic compound, has shown antifibrotic activity in preclinical studies and clinical benefit in chronic hepatitis B-related liver fibrosis. Previous mechanistic studies have suggested that HDD exerts antifibrotic effects mainly by inhibiting hepatic stellate cell activation through modulation of TGF-β/Smad signaling. However, whether HDD directly protects sinusoidal endothelial cells, rather than improving endothelial injury secondarily through fibrosis regression, remains unclear. This study therefore investigated the direct effect of HDD on LSEC capillarization and endothelial dysfunction. **Methods:** A classical CCl_4-induced fibrosis model was used to evaluate the anti-fibrotic and endothelial-protective effects of HDD in vivo.An early one-week CCl_4 model was established to assess whether HDD could reverse LSEC capillarization before overt fibrosis developed. Primary LSECs were isolated for in vitro experiments to determine the direct effect of HDD on capillarization and endothelial dysfunction.Endothelial- and capillarization-related markers were analyzed by qPCR and Western blotting following HDD treatment.LSEC fenestrae were examined by scanning electron microscopy (SEM) to evaluate the effect of HDD on fenestrae. **Results:** In the classical CCl_4-induced fibrosis model, HDD markedly alleviated liver fibrosis and was accompanied by significant improvement in LSEC capillarization and endothelial dysfunction.In the early one-week CCl_4 model, HDD improved capillarization-related changes before obvious fibrosis developed, suggesting a direct protective effect on LSECs.In primary LSECs, HDD directly improved capillarization- and endothelial dysfunction-related phenotypes in vitro.qPCR and Western blot analyses showed restoration of endothelial-associated markers and reduction of capillarization-related markers after HDD treatment.SEM further demonstrated that HDD preserved LSEC fenestrae and attenuated fenestrae loss **Conclusion:** HDD alleviates liver fibrosis by directly improving LSEC capillarization and endothelial dysfunction, suggesting that protection of sinusoidal endothelial homeostasis is an important component of its anti-fibrotic action. Further studies will focus on the underlying eNOS-related mechanisms.

3383 | ASSOCIATION OF DIABETIC NEPHROPATHY WITH LIVER FIBROSIS IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

Sisi Zhou[1] Xinyu Hu[2] Qianqian Chen[3] Fajuan Rui[2] Jie Li[1], [1]Nanjing Drum Tower Hospital Clinical College of Nanjing Medical University, Nanjing, Jiangsu, China, [2]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, [3]Huai'an Hospital of Xuzhou Medical University,Huai'an Jiangsu, China.

Background: To investigate the association between diabetic nephropathy (DN) and liver fibrosis in patients with type 2 diabetes mellitus (T2DM), and to further evaluate whether metabolic associated fatty liver disease (MAFLD) status influences this relationship. **Methods:** Data were obtained from the National Health and Nutrition Examination Survey (NHANES) 2017–2020 cycle. Participants with T2DM who underwent vibration-controlled transient elastography were included. DN was defined based on estimated glomerular filtration rate and urinary albumin-to-creatinine ratio (UACR). Liver fibrosis was defined as liver stiffness measurement ≥ 6 kPa. Multivariable logistic regression models were applied to assess the association between DN and liver fibrosis. Dose–response relationships were examined according to UACR categories. Stratified analyses by MAFLD status and interaction tests were performed. Inverse probability of treatment weighting (IPTW) was used to evaluate the robustness of the findings. **Results:** A total of 1,104 participants with T2DM were included,of whom 449 (40.67%)had DN.DN was independently associated with an increased risk of liver fibrosis(adjusted odds ratio[aOR]1.46, 95% confidence interval [CI] 1.11–1.93, P = 0.006). A dose–response relationship was observed across UACR categories: compared with UACR < 30 mg/g, the risks of liver fibrosis were higher in the 30–300 mg/g and ≥ 300 mg/g groups (aOR 1.47 and 1.70, respectively; both P < 0.05). Stratified analyses showed consistent directions of association across MAFLD subgroups, and no statistically significant interaction was observed (P for interaction = 0.742). IPTW-weighted analyses yielded similar results (aOR 1.44, 95%CI 1.20–1.73, P < 0.001). **Conclusion:** DN is significantly associated with an increased risk of liver fibrosis in patients with T2DM, and this association remains consistent across MAFLD status. Higher UACR levels are positively associated with liver fibrosis risk, suggesting that markers of renal injury may help identify individuals at high risk of liver fibrosis. These findings highlight the importance of considering kidney–liver interactions in the management of T2DM.

Figure 1. Flow Chart

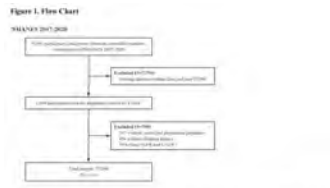

Table 1.Demographics and clinical characteristics of the patients with T2DM according to diabetic nephropathy (DN) in NHANES 2017-2020.

3384 | MACHINE LEARNING ALGORITHMS USING ELECTRONIC HEALTH RECORD DATA OUTPERFORM FIB-4 INDEX IN DETECTION OF CLINICALLY SIGNIFICANT FIBROSIS

Ashley Spann[1] Natalie Vellutini[1] Dameia Brewster[1] Qingxia Chen[1] Jackson Resser[1] Manhal Izzy[1], [1]Vanderbilt University Medical Center

Background: Clinically significant fibrosis (F2+) is a major determinant of liver-related morbidity and mortality, and accurate predictive models of fibrosis staging would have substantial clinical significance in facilitating earlier disease detection and therapeutic opportunities. The FIB-4 index represents a common tool for detecting advanced fibrosis stages (stage F3-F4) and is routinely used in clinical practice for screening for liver disease. However, FIB-4 performs poorly for detection of earlier stages of fibrosis (stage F2), which is a pharmacotherapeutic target/threshold for initiation of anti-fibrotic therapies. Machine learning methodologies that leverage readily available electronic health record data may improve upon the accuracy of earlier detection of moderate fibrosis. We aimed to develop a predictive model to improve the predictive accuracy of detecting clinically significant fibrosis. **Methods:** This single center retrospective cohort study of patients undergoing either transient (TE) or MRI elastography (MRE) study between 01/01/2018 – 12/31/2025 included those with pre-assessment FIB-4 data and excluded liver transplant recipients and those with poor quality elastography studies (IQR >30 or unsatisfactory MRE). Fibrosis was evaluated using normalcy cutoffs for FIB-4 (1.3 for those age < 65; 2.0 for those age ≥ 65), and current society guidelines for TE & MRE cutoffs for F0-F1 versus F2+. Prediction models included logistic regression and random forest (RF) with covariates including FIB-4, sex, BMI, race/ethnicity, diabetes, hypertension, hyperlipidemia, and interaction between FIB-4 and diabetic status. Missing data underwent multiple imputation with the bootstrap method. Performance metrics were calculated for all algorithms, including AUROC, accuracy, precision, recall, and F1-score. SHAP score was constructed to assess RF model feature importance. Delong's test was performed to assess differences in ROC curves between models. **Results:** Of 5045 total patients, 1750 (34.7%) had F2+ fibrosis. The FIB-4 AUC was 0.718 [CI 0.703-0.733], which was not significantly different from the logistic regression model AUC of 0.726 [CI 0.711-0.74, p = 0.147] whereas the RF model AUC was significantly different than the FIB-4 performance with an AUC of 0.849 [CI 0.838-0.86, p < 0.001]. Additionally, the RF model performed the best overall with respect to accuracy (0.759 [0.724, 0.778]), precision (0.633 [0.572, 0.690]), recall (0.727 [0.643, 0.820]), and F1 score (0.674 [0.660, 0.686]). The most important features contributing to the RF model's performance was an interaction term between FIB4 value & diabetes status, followed by hypertension & patient sex. **Conclusion:** In this large cohort of patients with fibrosis data, a machine learning algorithm remarkably outperformed FIB-4 in the detection of patients with clinically significant fibrosis (F2+) using available electronic health record data.

Instituto de Salud Carlos III, [5]Pontificia Universidad Católica de Chile, Santiago de Chile, Chile, [6]Rubió Metabolomics, S.L.U., [7]Virgen del Rocio University Hospital, [8]Marqués de Valdecilla University Hospital, Cantabria University, IDIVAL, Santander, Spain, [9]Clinic University Hospital, University of Valladolid, Valladolid, Spain, [10]Virgen del Rocío University Hospital, Sevilla, Spain, [11]VCU Medical Center, [12]Puerta del Hierro University Hospital, Madrid, Spain, [13]Gregorio Marañón University Hospital, Madrid, Spain, [14]Virginia Commonwealth University

Background: FIB-4 is widely used as a first-line non-invasive liver disease assessment (NILDA) test for fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD). However, patients with indeterminate FIB-4 results require additional evaluation. We evaluated the diagnostic performance of two metabolomics-based models for detecting at least significant fibrosis (F2–F4) or advanced fibrosis (F3–F4) in patients with MASLD and indeterminate FIB-4 values. **Methods:** We included 218 patients with biopsy-confirmed MASLD and indeterminate FIB-4 values, defined as FIB-4 1.30–2.67 in patients $\leq$65 years and FIB-4 2.0–2.67 in those >65 years. The cohort included 94 women (43%), with a mean BMI of 33 ± 7 kg/m², ALT 67 ± 46 U/L, and AST 50 ± 31 U/L. Fibrosis stages were: F0 18.8%, F1 38.8%, F2 18.2%, F3 21.6%, and F4 2.6%. Significant and advanced fibrosis were assessed using two models based on 19 and 13 circulating lipids, respectively. Diagnostic performance was evaluated across probability cutoffs using sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy; optimal cutoffs were selected with the Youden index. **Results:** The 19-lipid model demonstrated good diagnostic performance for detecting significant fibrosis achieving an AUROC of 0.75. The optimal probability cutoff identified by the Youden index was 0.519. At this threshold, the model achieved balanced diagnostic performance, with S 72%, Sp 74%, PPV 66%, NPV 74%, and accuracy 70%. The 13-lipid model demonstrated good discrimination for advanced fibrosis with an AUROC of 0.81. The optimal cutoff identified by the Youden index provided balanced diagnostic performance, with S 82%, Sp 72%, PPV 53%, NPV 92%, and accuracy 75%. Unsurprisingly, the two models showed progressive improvement in Sp and PPV with increasing probability thresholds at the expense of sensitivity, supporting its utility for identifying patients at higher risk of advanced fibrosis within the FIB-4 grey zone. A sensitivity analysis considering OWLiver as the first-line test resulted in 4.6-fold and 5.6-fold increases in the number of participants correctly classified as F2–F4 and F3–F4, respectively, compared with FIB-4. **Conclusion:** Metabolomics-based signatures demonstrated clinically relevant diagnostic performance for detecting both significant fibrosis and advanced fibrosis in MASLD patients with indeterminate FIB-4 values. These findings suggest that metabolomics-based risk stratification may serve as a valuable second-line NILDA to refine fibrosis assessment and improve clinical decision-making in patients within the FIB-4 indeterminate range.

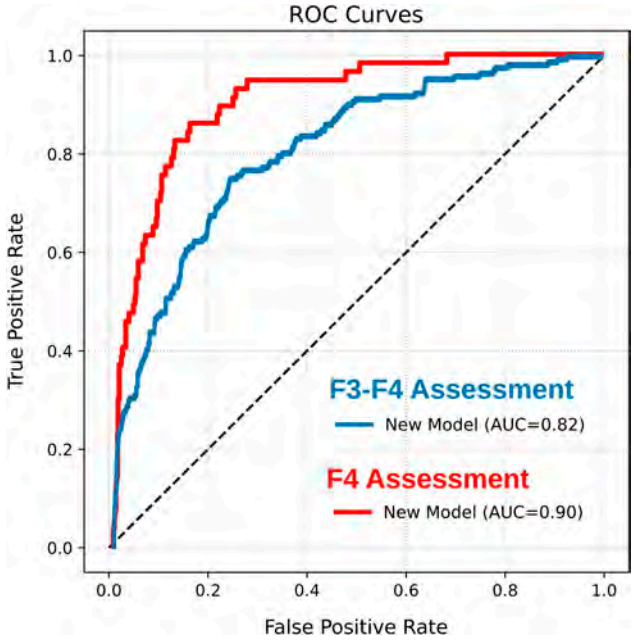
3386 | A METABOLOMICS-BASED EXTENSION OF THE OWLIVER TEST IMPROVES FIBROSIS STAGING IN STEATOTIC LIVER DESEASE



Andres Duarte-Rojo[1] Mazen Noureddin[2] Jesús María Bañales Asurmendi[3] Marco Arrese[4] Ibon Martínez-Arranz[5] Manuel Romero-Gómez[6] Paula Iruzubieta[7] Rocio Aller[8] Richard Sterling[9] Javier Ampuero[10] Jose Luis Calleja[11] Cristina Alonso[12] Luis Ibáñez Samaniego[13] Javier Crespo[7] Arun Sanyal[14], [1]Northwestern Medicine, [2]Houston Methodist Hospital, [3]Biogipuzkoa Health Research Institute, San Sebastian, Spain CIBERehd, Instituto de Salud Carlos III, [4]Pontificia Universidad Católica de Chile, Santiago de Chile, Chile, [5]Rubió Metabolomics, S.L.U., [6]Virgen del Rocio University Hospital, [7]Marqués de Valdecilla University Hospital, Cantabria University, IDIVAL, Santander, Spain, [8]Clinic University Hospital, University of Valladolid, Valladolid, Spain, [9]VCU Medical Center, [10]Virgen del Rocío University Hospital, Sevilla, Spain, [11]Puerta del Hierro University Hospital, Madrid, Spain, [12]Rubio Metabolomics, S.L.U., [13]Gregorio Marañón University Hospital, Madrid, Spain, [14]Virginia Commonwealth University

Background: The OWLiver test is a robust serum lipidomics-based non-invasive liver disease assessment (NILDA) algorithm developed for steatosis and steatohepatitis (including at-risk MASH). Since OWLiver was not specifically designed for fibrosis assessment, we expanded the algorithm framework into a broader metabolomic space and developed complementary models optimized for detecting at least advanced fibrosis (F3–F4) and cirrhosis (F4), irrespective of MASH features **Methods:** A total of 849 biopsy-confirmed patients across fibrosis stages F0–F4 were included (F0: 25.9%; F1: 37.9%; F2: 18.1%; F3: 12.1%; F4: 6.0%). Metabolomic profiling comprised 245 circulating lipid and other metabolite species. Model development followed a standardized machine learning workflow including feature selection and logistic regression, with cross-validation and an independent validation-cohort to ensure robust performance assessment. Two binary classification models were trained for the detection of F3–F4 and F4, using liver biopsy as reference standard. Model's performance was assessed by AUROC, sensitivity, specificity, and Youden index-derived cut-offs. **Results:** Metabolomics-enhanced models showed improved discrimination with increasing fibrosis severity. The model for advanced fibrosis (F3–F4) achieved an AUROC of 0.82, with 75% sensitivity and 77% specificity. The cirrhosis (F4) model showed the highest diagnostic performance, reaching an AUROC of 0.90, with 86% sensitivity and 85% specificity. These findings indicate that broader metabolomic signatures improve classification of clinically relevant fibrosis stages beyond the performance of our previously reported lipid-based OWLiver test. **Conclusion:** Our upgraded OWLiver test, which was specifically designed as a fibrosis NILDA, showed excellent to outstanding diagnostic accuracy for advanced fibrosis and cirrhosis. We achieved this goal by extending the original algorithm

framework into a broader metabolomic space, through dedicated fibrosis models that were agnostic to MASH features. The improved discrimination capacity in subpopulations with advanced fibrosis and cirrhosis may enhance patient stratification and clinical decision-making in steatotic liver disease.

3387 | IN SILICO MULTI-TARGET EVALUATION OF PHYLLANTHUS NIRURI BIOACTIVE COMPOUNDS AGAINST HEPATIC FIBROSIS PATHWAYS: MOLECULAR DOCKING, 300-NS MOLECULAR DYNAMICS, AND MM-GBSA BINDING FREE ENERGY ANALYSIS

Fabian Rodolfo Jimenez Patino[1] William Lituma[1] Alexandra Nataly Culqui Medina[2] Tanishque Verma[3] Hugo Chancay[1], [1]NF Innovations, [2]Universidad Técnica del Norte, [3]Sidda Vetha Multiversity

Background: Micronodular liver cirrhosis remains a major cause of hepatic morbidity with limited antifibrotic therapies. Phyllanthus niruri has demonstrated hepatoprotective, antioxidant, and anti-inflammatory activity in preclinical and clinical studies; however, its molecular antifibrotic mechanisms remain incompletely characterized. This study integrates network pharmacology, molecular docking, molecular dynamics simulation, and clinical biomarker analysis to investigate the antifibrotic potential of key P. niruri bioactive compounds targeting TGF-beta/Smad, Nrf2/HO-1, and NF-kB pathways in hepatic fibrosis.Multi-target phytochemical strategies may offer mechanistic advantages over single-pathway antifibrotic approaches. **Methods:** An integrative computational-clinical approach was applied. Network pharmacology identified fibrosis-related targets of 14 P. niruri bioactive compounds using SwissTargetPrediction, GeneCards, and OMIM. Molecular docking evaluated corilagin, phyllanthin, and hypophyllanthin interactions with TGF-beta1 and SMAD2/3 using AutoDock Vina. GROMACS molecular dynamics simulations and MM/PBSA calculations assessed ligand-protein stability. Clinical fibrosis biomarkers (ALT/AST, Fib-4, APRI, elastography), inflammatory cytokines, and oxidative stress markers were analyzed. HPLC and LC-MS/MS were used for phytochemical standardization.Protein-protein interaction networks were constructed using STRING and Cytoscape to identify hub genes associated with hepatic fibrogenesis. **Results:** Network pharmacology identified 47 shared fibrosis-related targets associated with P. niruri bioactive compounds. Corilagin, phyllanthin, and hypophyllanthin demonstrated high connectivity within TGF-beta/Smad and Nrf2/ARE pathways. Molecular docking showed strong binding affinity of corilagin to TGF-beta1 (-8.3 kcal/mol). Molecular dynamics and MM/PBSA analyses confirmed stability of corilagin-TGF-beta1 and phyllanthin-SMAD3 complexes. Predicted mechanisms included suppression of TGF-beta/Smad signaling, reduction of collagen deposition, modulation of MMP2/TIMP1 imbalance, activation of Nrf2/ARE antioxidant pathways, and inhibition of NF-kB-mediated inflammation. Clinical biomarker analysis correlated reduced inflammatory markers with improved fibrosis indices.KEGG enrichment analysis demonstrated significant association with TGF-β, NF-κB, and oxidative stress-related signaling pathways involved in hepatic fibrosis progression, **Conclusion:** P. niruri bioactive compounds demonstrated a multi-target antifibrotic profile in micronodular cirrhosis through modulation of TGF-beta/Smad, oxidative stress, and inflammatory pathways. Integrative computational-clinical analysis supports P. niruri as a promising candidate for translational antifibrotic therapy development.

3388 | IMPAIRED ENDOGENOUS DNASE I ACTIVITY AND ALTERED EXTRACELLULAR MTDNA PROFILE IN SERUM OF CIRRHOSIS PATIENTS

Zaur Abilov[1] Yoshiko Nanki[1] Arvo Justice[1] Pinzhu Huang[1] Chandra S Shankar[1] Victor Turkowski[1] Gloria Horta[1] Michelle Lai[1] Yury Popov[1], [1]Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States

Background: Mitochondrial DNA (mtDNA) is a pro-inflammatory and pro-fibrogenic damage-associated molecular pattern (DAMP) with a pathogenic role in chronic liver diseases. However, little is known about the circulating mtDNA pathogenic role and its turnover in end-stage liver disease. In this pilot study, we measured extracellular levels of mtDNA and two major endogenous nucleases potentially responsible its breakdown in cirrhosis. **Methods:** DNase I enzymatic activity was measured in serum

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

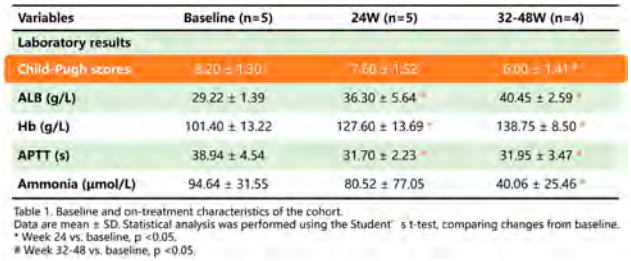
from the pilot cirrhosis cohort due to various etiology (n = 47) and age- and sex-matched healthy controls (n = 10) using fluorometric activity assay. DNase I and DNase1L3 protein levels were measured by ELISA. Absolute quantification of circulating mitochondrial DNA in plasma was performed by novel in-house duplex digital droplet PCR assay. Group comparisons were performed using Mann–Whitney tests, and associations with clinical laboratory parameters, MELD, and Child-Pugh scores analyzed using Spearman correlation. **Results:** In cirrhotic serum, average DNase I activity was decreased over 5-fold, compared with healthy controls (0.51 ± 0.07 μU/mL vs 2.71 ± 0.83 μU/mL, p = 0.0006). DNase I protein levels did not differ significantly between patients with cirrhosis and healthy controls (p = 0.620), whereas DNase1L3 protein levels were near or below detection level. DNase I protein concentration did not correlate with DNase I activity in cirrhosis samples (Spearman r = -0.067, p = 0.746), suggesting a discordance between protein abundance and corresponding enzymatic activity in cirrhosis. Average plasma cell-free mtDNA levels were 5-fold lower in cirrhotics compared to healthy controls (3.39 ± 0.45 copies/ul vs 15.59 ± 5.35, p < 0.0001). In cirrhotic cohort, serum DNase I activity was negatively correlated with ALP (Spearman r = -0.3408, p = 0.0486) and GGT (Spearman r = -0.7110, p = 0.0120) levels. **Conclusion:** Patients with cirrhosis demonstrate markedly suppressed DNase I enzymatic activity despite preserved circulating DNase I protein levels, suggesting the presence of endogenous DNAse I inhibitor(s). Reduced nuclease activity suggests extracellular mtDNA degradation is markedly impaired in cirrhosis, and support further investigation into functional significance of endogenous nuclease inhibitors in cirrhosis. **Disclosures:** Zaur Abilov:Nothing to Disclose, Yoshiko Nanki:Nothing to Disclose, Arvo Justice:Nothing to Disclose, Pinzhu Huang:Nothing to Disclose, Chandra S Shankar:Nothing to Disclose, Victor Turkowski: Nothing to Disclose, Gloria Horta:Nothing to Disclose, Michelle Lai:Nothing to Disclose, Yury Popov:Nothing to Disclose.



3389 | ALLOGENEIC HEPATOCYTE-DERIVED LIVER PROGENITOR-LIKE CELLS ARE ASSOCIATED WITH LIVER FUNCTION IMPROVEMENT AND RECOMPENSATION IN DECOMPENSATED CIRRHOSIS: A POOLED ANALYSIS OF TWO INVESTIGATOR-INITIATED TRIALS

Hexin Yan[1] Weijian Huang[2] Hanyong Sun[1] Xiaosong Chen[1] Meng Li[1] Chenpeng Zhong[1] Xiaoyan Jin[1] Yonghong Yin[2] Weifeng Yu[1] Qiang Xia[1], [1]Renji Hospital Shanghai Jiaotong University School of Medicine, [2]Shanghai Celliver Biotechnology Inc

Background: Allogeneic hepatocyte-derived liver progenitor-like cells (HepLPCs) represent a potential cell-based therapy for cirrhosis. A first-in-human 3+3 investigator-initiated trial (IIT; NCT04806581) demonstrated the safety and tolerability of HepLPCs across three dose levels. A second IIT (NCT06306781) was subsequently initiated to further evaluate preliminary efficacy and dose selection in patients with decompensated cirrhosis. This pooled analysis focused on the medium-dose cohort to assess liver function recovery and recompensation signals. **Methods:** In the second IIT, six patients were enrolled between February and June 2024, including three receiving low-dose HepLPCs (1.0×10^6 cells/kg) and three receiving medium-dose HepLPCs (2.0×10^6 cells/kg). Because follow-up completion was limited in the low-dose cohort, efficacy analyses were performed by pooling medium-dose recipients from both IITs who completed at least 24 weeks of follow-up. Five patients were included: three with HBV-related cirrhosis and two with alcohol-related cirrhosis. Liver function was assessed by Child-Pugh score, albumin, prealbumin, hemoglobin, coagulation parameters, total bilirubin, and blood ammonia at baseline, Week 24, and Weeks 32–48. Recompensation was assessed according to Baveno VII criteria. **Results:** No dose-limiting toxicities were observed in the medium-dose cohort. Among the five evaluable patients, mean Child-Pugh score improved from 8.20 ± 1.30 at baseline to 6.00 ± 1.41 at Weeks 32–48 after treatment (p < 0.05). Two patients, both with HBV-related cirrhosis, achieved hepatic recompensation according to Baveno VII criteria. At Weeks 32–48, albumin and hemoglobin increased, while APTT and blood ammonia decreased significantly from baseline (all p < 0.05). Albumin, hemoglobin, and APTT had already improved significantly by Week 24, suggesting their potential utility as early indicators of treatment response. Prealbumin, PT, and INR showed favorable trends, whereas total bilirubin remained stable during follow-up. **Conclusion:** Medium-dose allogeneic HepLPC therapy was safe and associated with sustained improvement in liver function and clinically meaningful recompensation signals in patients with decompensated cirrhosis. Albumin, hemoglobin, and APTT may serve as early response indicators. Ongoing studies incorporating HVPG assessment and liver histology will further define the therapeutic effects of HepLPCs in decompensated cirrhosis.

3390 | DEVELOPMENT AND EVALUATION OF A PLATELET-INDEPENDENT MODIFIED FIB-4-LIKE SCORE FOR LIVER DISEASE ASSESSMENT: UTILITY IN SETTINGS WITH CONFOUNDED PLATELET COUNTS

Kiandokht Bashiri[1], [1]MedStar Washington Hospital Center

Background: The Fibrosis-4 (FIB-4) index is widely used for noninvasive liver disease assessment; however, its reliance on platelet count limits applicability in patients with thrombocytopenia due to hematologic disorders, chemotherapy, bone marrow suppression, or other non-hepatic etiologies. We aimed to develop and evaluate a platelet-independent modified FIB-4-like score incorporating markers of hepatic synthetic and cholestatic dysfunction. **Methods:** Using the publicly available UCI Indian Liver Patient Dataset (n = 583; 416 with liver disease), we calculated a modified FIB-4-like score as (Age × AST) / (Albumin × $\sqrt{}$ALT), substituting albumin as a marker of synthetic function. Spearman rank correlations were assessed between this score and markers not incorporated in its formula (total bilirubin, direct bilirubin, alkaline phosphatase, A/G ratio, total protein, and gender). Machine learning models (Random Forest, XGBoost) were evaluated with 5-fold stratified cross-validation for liver disease classification. **Results:** The modified FIB-4-like score showed a moderate-to-strong correlations with direct bilirubin (Spearman ρ = 0.483, $p < 0.0001$), total bilirubin (ρ = 0.476, $p < 0.0001$), alkaline phosphatase (ρ = 0.274, $p < 0.0001$), and strong inverse correlations with A/G ratio (ρ = -0.486, $p < 0.0001$) and total protein (ρ = -0.389, $p < 0.0001$). Random Forest achieved accuracy 0.696 and AUC-ROC 0.749; XGBoost showed accuracy 0.691 and AUC-ROC 0.730 in predicting liver disease. **Conclusion:** This platelet-independent modified FIB-4-like score correlates with both cholestatic and synthetic dysfunction markers and may provide a useful alternative to standard FIB-4 in patients whose platelet counts are affected by non-hepatic conditions such as bone marrow disorders or HIT. While performance remains moderate, this proof-of-concept supports further development of accessible, platelet-independent tools for liver disease risk stratification in complex, comorbid populations. Prospective validation in targeted cohorts is warranted.

3391 | PERFORMANCE OF A SALIVA-BASED DIAGNOSTIC TEST FOR LIVER FIBROSIS

Namratha Reddy[1] Abolfazl Jangholi[2] Kim Bridle[3] Hasaranga KLJ[2] Lucas Trevisan Franca de Lima[2] Randi DeArmitt[4] Melyssa Bratton[4] Chamindie Punyadeera[2] George Therapondos[4] Darrell Crawford[5], [1]Greenslopes Private Hospital, [2]Griffith University, [3]The University of Queensland, [4]Ochsner Health, [5]Gallipoli Medical Research

Background: Chronic liver disease (CLD) is a major global health problem which impacts more than one-third of the world's population. Since the risk of adverse liver outcomes increases incrementally with the degree of liver fibrosis, the assessment of liver fibrosis is an essential element of the evaluation of affected patients. Current methods for assessing liver fibrosis are not easily accessed, expensive and/or invasive, resulting in many affected patients either not being identified early or presenting with advanced liver disease when treatment options are limited. To mitigate these barriers, we have developed a saliva test to diagnose liver fibrosis. **Methods:** We measured three fibrosis-related proteins in saliva - hyaluronic acid (HA), tissue-inhibitor of metalloproteinases 1 (TIMP-1), and alpha-2-macroglobulin (A2M) - in patients with liver disease and varying degrees of hepatic fibrosis from two specialist referral centers (Queensland Gastroenterology, Australia and Ochsner Health, USA). Transient elastography (n = 205, Queensland Gastroenterology cohort) and liver biopsy (n = 44, Ochsner Health cohort) were used as comparators. By regression analysis on a discovery cohort, we developed a score (SALF) based on the measurement of these proteins to predict severity of hepatic fibrosis. **Results:** Table 1 shows test performance for detecting liver stiffness measurement (LSM) ±12, LSM ± 8 and fibrosis stage ± F2.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Median SALF for LSM < 8 was 0.011 vs 0.921 for LSM > 8 (P < 0.05) and median SALF for LSM < 12 was 0.012 vs 0.992 for LSM > 12 (P < 0.05). Median SALF for fibrosis < F2 was 0.39 vs 0.67 for fibrosis ≥ F2 (P < 0.05). **Conclusion:** In these two cohorts, the measurement of salivary fibrosis-related proteins provided a reliable guide to the risk of significant hepatic fibrosis. Saliva is a readily accessible and acceptable bio-medium and is ideal for a community and/or point of care-based program to evaluate the possibility of liver fibrosis and the need for further assessment in those with risk factors for liver disease. A community-based test for liver fibrosis will dramatically increase community access to testing and overcome obstacles inherent in current testing strategies.

Table 1: Performance of SALF Score in Validation Cohort

LSM	Marker (Threshold)	AUC	Sensitivity	Specificity
LSM≥8	HA (240 μg/L)	0.73	80%	45%
	TIMP-1 (181 μg/L)	0.67	80%	35%
	A2M (1835 μg/L)	0.74	80%	53%
	SALF (0.11)	***0.83***	***80%***	***76%***
LSM≥12	HA (386 μg/L)	0.74	72%	71%
	TIMP-1 (412 μg/L)	0.78	56%	92%
	A2M (3216 μg/L)	0.84	75%	79%
	SALF (0.20)	***0.88***	***89%***	***78%***
Fibrosis Stage≥F2	HA (83 μg/L)	0.7	63%	73%
	TIMP-1 (102 μg/L)	0.76	78%	67%
	A2M (789 μg/L)	0.64	78%	53%

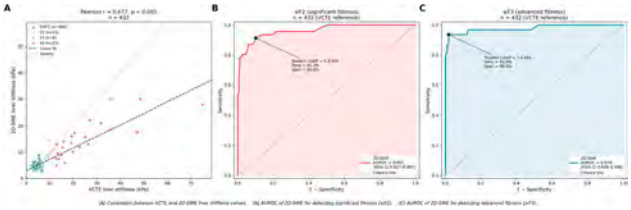
3392 | DIAGNOSTIC ACCURACY OF TWO-DIMENSIONAL SHEAR-WAVE ELASTOGRAPHY (2D-SWE) VERSUS VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY (VCTE) FOR LIVER FIBROSIS STAGING IN A REAL-WORLD COHORT



Joao Marcello de Araujo-Neto[1] Flavia Fernandes[2] Priscila Flores[3] Melina Torres[1] Mauren Machado[1] Larissa Oliveira Miranda[1] Ida Arzolla[1] Marcio Miguez[1] Priscilla Calvet Nelson-Smith[1] Adriana Souza e Silva[1] Christina Bahia[1] Juliana Piedade[2] Vania Cristina de Sant`Anna Rocha-Nunnes[1] Celia Rotstein[1] Claudia Oliveira[4], [1]Federal University of Rio de Janeiro, [2]Hospital Federal de Bonsucesso, [3]Federal Fluminense University, [4]University of Sao Paulo School of Medicine

Background: Vibration-controlled transient elastography (VCTE) has been widely validated over the past two decades and is currently the reference non-invasive method for liver fibrosis staging in clinical practice. Newer ultrasound-based techniques such as two-dimensional shear-wave elastography (2D-SWE), integrated into conventional ultrasound platforms, have recently emerged but still require broader validation. We aimed to evaluate the diagnostic accuracy of 2D-SWE for liver fibrosis staging in a real-world cohort, using VCTE as the reference standard. **Methods:** In this single-center cross-sectional study, 432 consecutive adults with chronic liver disease of mixed etiologies referred for liver evaluation were prospectively assessed on the same day with VCTE (FibroScan, Echosens, Paris, France) and 2D-SWE (Samsung RS85, Samsung Medison, Seoul, South Korea); the controlled attenuation parameter (CAP) was also obtained for steatosis assessment. Both examinations were performed after a minimum 4-hour fasting period, and reliability criteria for VCTE included ≥10 valid measurements with an IQR/median ratio ≤30%. VCTE was used as the reference standard for liver fibrosis staging, applying the thresholds F0/F1 <7.0 kPa, F2 7.0–9.4 kPa, F3 9.5–12.4 kPa, and F4 ≥12.5 kPa. **Results:** In the 432 paired measurements, 2D-SWE showed excellent diagnostic accuracy for the detection of significant fibrosis (≥F2: AUROC 0.961, 95% CI 0.927–0.987, cutoff 5.9 kPa, sensitivity 91.3%, specificity 89.6%), advanced fibrosis (≥F3: AUROC 0.976, 0.938–0.998, cutoff 7.4 kPa, sensitivity 93.5%, specificity 98.0%), and cirrhosis (≥F4: AUROC 0.967, 0.921–0.996, cutoff 7.4 kPa, sensitivity 92.0%, specificity 96.6%). Negative predictive values were 98.9%, 99.5%, and 99.5% for ≥F2, ≥F3, and ≥F4, respectively. Bland–Altman analysis showed a minimal mean bias (+0.7 kPa) but wide 95% limits of agreement (−8.2 to +9.6 kPa). 2D-SWE correlated strong with transient elastography (Pearson r = 0.677; both p < 0.001), with a stepwise increase in median 2D-SWE values across VCTE stages (F0/F1: 4.8 kPa, F2: 6.4 kPa, F3: 9.9 kPa, F4: 13.4 kPa; Kruskal-Wallis p < 0.001). Linear regression of the Fib–SWE bias on CAP revealed no significant association (slope = 0.004 kPa per dB/m, p = 0.31), indicating that hepatic steatosis did not introduce a systematic bias between the two elastography techniques. **Conclusion:** 2D-SWE demonstrated excellent diagnostic accuracy across all fibrosis stages and consistently high NPV for ruling out significant and advanced fibrosis. Its performance was not influenced by the degree of hepatic steatosis. These findings support

3393 | BUBBLE DESTRUCTION CURVE PARAMETERS ON SONAZOID-ENHANCED ULTRASONOGRAPHY REFLECT HEPATIC FUNCTION AND FIBROSIS BEYOND KUPFFER CELL DENSITY: A PROSPECTIVE COMPARISON WITH GADOXETIC ACID–ENHANCED MRI AND PATHOLOGY

Jae Seok Bae[1], [1]Seoul National University Hospital

Background: Kupffer-phase parenchymal brightness on Sonazoid-enhanced contrast-enhanced ultrasonography (Sz-CEUS) is commonly assumed to reflect Kupffer cell (KC) density, but lacks pathological validation. Bubble destruction curve (BDC) analysis—a quantitative parameter from microbubble destruction kinetics in the Kupffer phase—has unclear biological correlates. We evaluated whether Kupffer-phase parenchymal intensity (KPI) and BDC parameters correlate with pathological KC density, hepatobiliary-phase (HBP) enhancement on gadoxetic acid–enhanced MRI (GA-MRI), and noninvasive markers of hepatic function and fibrosis. **Methods:** Ninety-seven patients scheduled for hepatectomy or liver transplantation (68 [70%] HBV; 63 [65%] METAVIR F4) prospectively underwent Sz-CEUS, GA-MRI, and pathology. KPI was measured as median Kupffer-phase parenchymal intensity in a standardized ROI. BDC parameters—attenuation at 10 seconds (Att 10) and Depth (2)—were derived from microbubble destruction time-intensity curves. RSE was measured on HBP MRI; KC density (KCC) by CD68 immunohistochemistry. Spearman and partial correlations adjusted for fibrosis stage were used, with post-hoc F4 subgroup analyses. An AI language model (Claude, Anthropic) was used for language editing; all analyses and conclusions are the authors' responsibility. **Results:** KPI did not correlate with KCC ($\rho = 0.130$, $p = 0.205$) or any reference parameter (RSE, FIB-4, APRI, albumin, total bilirubin; all $p > 0.20$). In contrast, BDC parameters showed consistent associations: Depth (2) correlated with FIB-4 ($\rho = 0.350$), APRI ($\rho = 0.312$), and RSE ($\rho = –0.282$; all $p < 0.01$); similar patterns occurred for Att 10. These BDC associations persisted after fibrosis adjustment (partial ρ 0.275–0.348), indicating information beyond fibrosis stage. RSE itself correlated strongly with FIB-4 ($\rho = –0.565$) and APRI ($\rho = –0.596$; both $p < 0.001$), and KCC was lower in cirrhotic vs non-cirrhotic livers (mean 108 vs 135 CD68+ cells, $p < 0.001$). The BDC–KCC association did not survive fibrosis adjustment. In the F4 subgroup with evaluable BDC (n = 60), BDC–reference associations strengthened (Att 10 vs FIB-4: $\rho = –0.507$, $p < 0.001$; Att 10 vs RSE: $\rho = 0.395$, $p = 0.002$), suggesting BDC may differentiate functional heterogeneity within cirrhotic livers. **Conclusion:** KPI on Sz-CEUS does not reflect pathological Kupffer cell density, challenging a common interpretive assumption. In contrast, BDC parameters from the same examination consistently correlate with noninvasive fibrosis indices, hepatic function markers, and HBP MRI enhancement, with associations preserved after fibrosis adjustment. These findings raise the possibility that BDC reflects properties of the sinusoidal microenvironment (e.g., sinusoidal capillarization) rather than KC number per se, supporting BDC as a candidate noninvasive imaging biomarker of liver function and fibrosis in chronic liver disease.

3394 | SUBCLINICAL BUT PROGRESSIVE: LONGITUDINAL VCTE AND NONINVASIVE LIVER ASSESSMENT IN TELOMERE BIOLOGY DISORDERS

Sana Pirzada[1] Sawsan Fathma[1] Wesam Aleyadeh[1] Tania Machado[2] Bhavisha Patel[2] Emma Groarke[2] Theo Heller[1], [1]Translational Hepatology Section, Liver Diseases Branch, NIDDK, NIH, Bethesda, MD, USA, [2]Hematology Branch, NHLBI, NIH, Bethesda, MD, USA

Background: Telomere biology disorders (TBD) are rare inherited disorders of telomere maintenance genes. Hepatic involvement occurs in 40–72% of patients and can progress to porto-sinusoidal vascular disease (PSVD) or cirrhosis, yet is often subclinical and missed by routine liver biochemistries. Liver biopsy is often impractical due to thrombocytopenia from bone marrow failure. We aimed to define the burden and longitudinal trajectory of noninvasive hepatic abnormalities, including vibration-controlled transient elastography (VCTE), in a large single-center TBD cohort. **Methods:** We retrospectively identified patients with TBD, defined by a pathogenic germline variant or lymphocyte telomere length <10th percentile by flow-FISH with a compatible phenotype, who underwent at least 1 reliable VCTE (IQR/median $\leq 30\%$). Liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) were collected. LSM ≥ 7.0 kPa was considered suggestive of increased likelihood of fibrosis. A composite liver abnormality was defined as ≥ 1 of the following: LSM ≥ 7.0 kPa, alanine aminotransferase (ALT) >110 U/L, gamma-glutamyl transferase (GGT) >36 U/L, or abnormal liver ultrasound (nodular surface, coarse echotexture, splenomegaly ≥ 13 cm, portal vein >13 mm, collaterals, ascites, or regenerative nodules). Aspartate aminotransferase, alkaline phosphatase, bilirubin, and platelet count were excluded because of frequent extrahepatic confounding. Annualized change in LSM was calculated in patients with serial VCTE. **Results:** 50 patients were included. Median age was 40 years (21.8–63.3), 56% were male, and 85.4% were White. Baseline median LSM was 4.7 kPa (4.0–6.9), and 20% (10/50) had LSM ≥ 7.0 kPa. Median CAP was 224.0 dB/m (198.5–273.5). 2% (1/50) and 30% (15/50) of patients showed abnormal ALT and GGT respectively. 78% (39/50) had at least 1 composite liver abnormality, including enlarged portal vein in 10% and splenomegaly in 14%. Among patients with liver abnormalities, the most common genes were TERT (13/39, 33.3%), TERC (9/39, 23.1%), and RTEL1 (7/39, 17.9%).32 patients underwent serial VCTE over a median follow-up of 2.9 years (1.0–4.0). Of these, 43.8% (14/32) had a positive annualized change in LSM, with a median increase of 0.55 kPa/year (0.21–1.09); LSM ranged from 4.0 to 13.7 kPa, and 34.4% (11/32) had a $\geq 20\%$ increase from baseline. Annualized change in LSM correlated with change in portal vein diameter and spleen size ($r=0.93$, $p<0.0001$; $r=0.65$, $p=0.013$). During follow-up, 90.6% (29/32) had at least 1 composite liver abnormality. **Conclusion:** Liver disease in TBD is often underrecognized early in its course. The association between rising liver stiffness and evolving portal hypertensive features suggests that VCTE and imaging may identify clinically meaningful liver disease before overt presentation, particularly in patients with PSVD. These data support routine noninvasive liver surveillance in TBD.

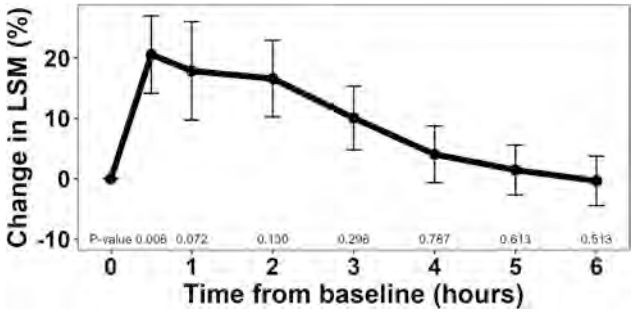
3395 | IMPACT OF GLP1-RECEPTOR ANTAGONISTS ON TIME TO PLATEAUING OF LIVER STIFFNESS MEASUREMENTS



Sunny Sandhu[1] Maria Romero[2] Victoria Fuentes[2] Ruth Canovas[2] Cindy Delgado[2] Sara Patino[3] Farah Alkilani[3], [1]Stanford University School of Medicine, [2]University of Miami Miller School of Medicine, [3]Jackson Memorial Hospital

Background: Patients who receive a liver stiffness measurement (LSM) examination by vibration controlled transient elastography (VCTE) are instructed to fast for at least three hours to ensure accurate results because a meal can increase blood flow to the liver, and therefore, the LSM. GLP1-receptor agonists (GLP-1 RAs) delay gastric emptying, which could lead to a longer period of blood flow to the liver, potentially requiring longer fasting prior to having an VCTE. Our aim was to determine whether GLP1-RAs delay the time to plateauing of LSM following ingestion of a standardized meal. **Methods:** We recruited adults from the hepatology clinic on any GLP1-RA for at least two months, from 9/1/2024-4/30/2026. Participants were instructed to fast for at least 8 hours prior to their visit.

After obtaining informed consent, participants underwent a baseline LSM by VCTE (FibroScan, Echosnes), followed by intake of a standardized liquid meal (Ensure Plus Drink, Abbot). Subsequently participants had LSM examinations after 30 minutes, 1, 2, 3, 4, 5, and 6 hours. All examinations were reviewed and only included if they met reliability criteria established by Echosens (i.e., at least 10 measurements and an IQR/LSM ratio of <30%). We fit a linear mixed effect model to analyze the effect of a meal on liver stiffness, in which time was the covariate and LSM was the outcome, with participant included as a random effect. **Results:** During the study period, 25 participants consented, but only 23 completed the 6-hour exam and were included. Of the 23 included participants, the median age was 61 years, 16 (69.6%) were female, median BMI was 29.5 (IQR: 26.6-40.2), 21 (91.3%) were White race, 17 (73.9%) were Hispanic, and 17 (73.9%) had MASLD. The median baseline fasting LSM was 13.7kPa (IQR: 13.7-21.3kPa). At 30 minutes after ingesting a standardized meal, the mean percent increase in LSM was 20.6% (± 6.4%), and was relatively stable compared to baseline at the 1-hour (17.8% ± 8.1%) and 2-hour (16.5% ± 6.3%) post-meal ingestion timepoints. By 3 hours, the mean percent increase in LSM was 10.1% ± 5.3%, with near normalization to baseline by four hours (Figure). **Conclusion:** In this study of patients on GLP1 RAs, the mean percent change in LSM after ingesting a standardized meal was 10% at 3 hours, similar to established values for patients not on GLP1 RAs. These data suggest that despite alterations in gastric emptying, patients on GLP1 RAs do not require an extended period of fasting prior to having a Fibroscan.

3396 | INTEGRATION OF WAIST CIRCUMFERENCE INTO FIB-4 IMPROVES SCREENING FOR ADVANCED LIVER FIBROSIS IN POPULATION-BASED COHORTS: INSIGHTS FROM NHANES TO A CHINA CLINICAL COHORT

Qiuhong Liu[1] Jie Wang[2] Qi Xia[2] Qing Zhao[2] Wei Wu[2], [1]The First Affiliated Hospital of Zhejiang University School, [2]The First Affiliated Hospital of Zhejiang University School of Medicine

Background: FIB-4 is the standard first-line triage for liver fibrosis screening but frequently underestimates advanced fibrosis in metabolically at-risk individuals. We aimed to evaluate whether anthropometric indices could refine risk stratification within a FIB-4-based framework. **Methods:** We analyzed 5,311 adults from NHANES 2017-2020 (derivation) and 465 patients from a Chinese outpatient cohort (external validation). Advanced fibrosis was defined as liver stiffness measurement (LSM) ≥12 kPa. 10 anthropometric indices were systematically evaluated through multivariable logistic regression (odds ratios [OR]), area under the receiver operating characteristic curve (AUC) and decision curve analysis (DCA). **Results:** Among 5,311 participants, the non-high-risk stratum (FIB-4 <2.67, n =5,175) harbored 138 cases of advanced fibrosis (weighted prevalence 2.9%), accounting for 87.0% of the total advanced fibrosis, while the high-risk stratum (FIB-4 ≥2.67, n =136) identified 30 cases (weighted prevalence 25.6%). While all strata were assessed, significant diagnostic gains from anthropometry were concentrated in the non-high-risk population. Waist circumference (WC) yielded the largest incremental gain compared with only-FIB-4 (AUC 0.874, ΔAUC 0.256; P <0.001) and remained a potent independent predictor (adjusted OR 3.89; P <0.001). A pragmatic WC threshold of 110 cm also effectively enriched risk (AUC 0.807; ΔAUC 0.189; P <0.001). The result was consistent among the FIB-4 <1.3 and 1.3 <FIB-4 <2.67 strata and most subgroups. External Asian validation confirmed a significant improvement in discrimination (AUC 0.756, P =0.017). **Conclusion:** A substantial disease burden overlooked by traditional biochemical triage reside within the FIB-4 non-high-risk population. Incorporating WC as a pragmatic adjunctive tool may offers a simple, scalable strategy to refine risk stratification and prioritize confirmatory assessment.

3397 | THE COMPOUNDING BURDEN OF FRAILTY IN CIRRHOSIS: MORTALITY, DECOMPENSATION, AND BEYOND

Chibuzor Nwachukwu[1] Abdulkarim Ben Yezza[2] Rawan Elkomi[2] Suzan Jamal[3] Somtochukwu Abazu[1] Miriam Michael[4], [1]Howard University Hospital, [2]Howard University Hospital Department of Medicine, [3]Howard University Hospital Deoartment of Medicine, [4]Howard University Hospital; University of Maryland Department of Medicine

Background: Cirrhosis carries significant morbidity and mortality, yet risk stratification beyond MELD remains limited. Frailty, cachexia, malnutrition, and sarcopenia are increasingly recognized as prognostically relevant in chronic liver disease, but large-scale real-world evidence is lacking. To this end, we evaluated whether frailty-proxy burden is independently associated with 1-year mortality in adults with cirrhosis using a large federated health network. **Methods:** We conducted a retrospective cohort study using the TriNetX EMEA Collaborative Network (31,983,306 patients; 32 healthcare organizations). Adults aged 18 or older with cirrhosis (ICD-10: K74.60, K74.69, K70.3, K70.30, K70.31), without hepatocellular carcinoma or prior liver transplant, were stratified by presence or absence of frailty-proxy diagnoses (R54 age-related debility, R64 cachexia, E43/E44/E46 malnutrition, M62.84 sarcopenia). The unmatched cohorts included 2,348 patients with frailty-proxy burden and 19,952 without. Propensity score matching in a 1:1 ratio based on age, sex, and race yielded 2,348 patients per group. The primary outcome was all-cause mortality at 1 year. Analyses included risk comparisons and Kaplan Meier survival evaluation. **Results:** After matching, patients with frailty-proxy burden had significantly higher 1-year mortality than matched controls (25.4% vs 21.5%; risk difference 3.9%, 95% CI 1.5–6.3%; risk ratio 1.18, 95% CI 1.07–1.31; p = 0.0015). Kaplan Meier analysis showed lower survival probability at end of follow-up in the frailty-proxy group (69.6% vs 72.4%; log-rank p = 0.106; HR 1.10, 95% CI 0.98–1.24). Median follow-up was 365 days in Cohort A and 363 days in Cohort B. **Conclusion:** In a large real-world cohort of adults with cirrhosis, frailty-proxy burden identified through routine ICD coding was associated with significantly higher 1-year mortality. These findings suggest frailty screening may offer clinical utility for risk stratification in cirrhosis and support further prospective evaluation of frailty-directed interventions in this population.

3398 | MULTIPARAMETRIC HYPERPOLARIZED-^{13}C-MRI FOR SENSITIVE ASSESSMENT OF EARLY-STAGE LIVER DISEASE

Bukola Adebesin[1] Alexander Zavriyev[1] Lena Hsia[1] Jiangsheng Yu[1] Gabor Mizsei[1] Molly Sheehan[1] Rebecca Wells[1] Kelley Weinfurtner[1] Emma Furth[1] Stephen Kadlecek[1] Terence Gade[1], [1]University of Pennsylvania

Background: Optimal locoregional therapy for hepatocellular carcinoma (HCC) requires maximizing oncologic efficacy while mitigating liver injury. Existing clinical staging systems primarily capture late-stage structural damage and hepatic decompensation, with limited sensitivity to early functional decline. Hyperpolarized (HP)-^{13}C-MRI is a powerful technology capable of non-invasively interrogating real-time cellular metabolism and tissue perfusion. We hypothesize that HP-^{13}C-MRI identifies the metabolic and perfusion remodeling that precede structural and functional decline, providing a more sensitive assessment of hepatic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

reserve that is required to inform the selection of locoregional therapy. **Methods:** Chronic liver disease was induced in male Wistar rats via ad-libitum oral administration of diethylnitrosamine (DEN) in drinking water. Rats were randomized into three cohorts (control, 6 weeks, and 12 weeks of DEN exposure) to capture progressive stages of hepatic fibrosis. Simultaneous HP-MRI of 1-^{13} C pyruvate and ^{13} C urea was performed at 7T using an EPSI sequence. Liver tissue was collected for histopathology and immunohistochemistry (H&E, Sirius red, CD45, and Ki-67). **Results:** At 6 weeks of DEN exposure, HP imaging detected an early significant decline in oxidative metabolism (HP Bicarbonate, $p < 0.01$) alongside a sharp increase in HP lactate production ($p < 0.001$), despite a median METAVIR stage of F0. This early metabolic shift coincided with peak inflammation (CD45+, $p < 0.05$) and elevated cellular proliferation (Ki-67+, $p = 0.07$). By 12 weeks, while bicarbonate levels, inflammation, and proliferation stabilized at 6-week levels, HP pyruvate conversion to lactate and alanine, as well as urea perfusion all significantly declined ($p < 0.01$). Underscoring these shifts, HP alanine, lactate, and urea significantly correlated with fibrosis severity on histology ($p < 0.05$) (Fig. 1A-D). **Conclusion:** Our findings demonstrate that HP-^{13} C-MRI non-invasively detects metabolic and perfusion alterations prior to structural fibrotic remodeling, providing a highly sensitive readout of functional liver reserve.At 6 weeks, HP detected early metabolic shifts within a structurally preserved liver landscape. By 12 weeks, metabolic and perfusion signals declined steeply, reflecting the replacement of functional parenchyma with collagen and microvascular impairment due to sinusoidal capillarization. Critically, HP imaging metrics correlated significantly with histological fibrosis severity, establishing a quantitative structural-functional link that underscores the molecular basis of concurrent architectural and physiological liver decline.In conclusion, this technology offers promise as a powerful non-invasive platform for assessing liver function, providing the precise assessment of hepatic reserve necessary to guide locoregional therapy selection and minimize treatment-induced injury.

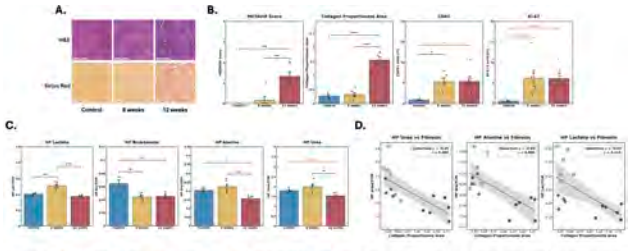

Figure 1: (A) H&E and Sirius red images of the liver from a rat within each of the cohorts. **(B)** Histopathological metrics of fibrosis severity, inflammation, and proliferation for the 3 rat cohorts. The METAVIR score represents the median score of the 3 liver specimens collected per rat. The Collagen Proportionate Area, CD45, and Ki-67 represent the mean of the 3 liver specimens collected per rat. **(C)** HP imaging metrics of cellular metabolism and perfusion for the 3 rat cohorts. TCM = total carbon metabolites (sum of HP pyruvate, lactate, alanine, and bicarbonate). **(D)** Correlation between HP imaging metrics and fibrosis severity on histology for the 3 rat cohorts.

3399 | VARIABLE CONCORDANCE BETWEEN SERUM-BASED FIBROSIS SCORES AND VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY IN A GENDER-DIVERSE SAMPLE IN NEWARK, NJ

Tess Olsson[1] Corey DeSteafno[1] Paul Buensuceso[2] Diana Finkel[3], [1]North Jersey Community Research Initiative (NJCRI), [2]Gilead Sciences, [3]Rutgers New Jersey Medical School

Background: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) has emerged as a leading cause of liver disease in the United States. Non-invasive serum-based tests (NIT), such as the FIB-4, NAFLD Fibrosis Score (NFS), and SAFE score, are used to identify patients at risk for hepatic fibrosis and reduce the need for liver biopsy. However, the relationship between these indices and vibration-controlled transient elastography (VCTE)-defined fibrosis remains poorly characterized, particularly in transgender and gender diverse (TGD) populations. **Methods:** TGD participants (N = 58) were recruited via convenience sampling from a community-based TGD health clinic (March 2025–February 2026) as part of a longitudinal study. Participants completed a survey, venipuncture, and VCTE. NIT (i.e., FIB-4, SAFE, and NFS) were calculated. VCTE fibrosis staging followed manufacturer cutoffs for the liver stiffness measurement (LSM): F0–F1 (< 7.0 kPa), F2 (7–9.9 kPa), and F3–F4 (≥ 10 kPa). Concordance was defined using clinically aligned thresholds for each score relative to VCTE (≥ 10 kPa for FIB-4 and NFS; ≥ 7 kPa for SAFE). **Results:** Concordance between NIT and VCTE varied and was driven primarily by agreement in low-risk classifications. Discordance most commonly reflected misclassification of participants with elevated LSM as low risk. SAFE had the highest discordance relative to VCTE with 19.0% misclassified as low risk, 5.2% misclassified as high risk, 3.5% concordant high risk, and 75.9% concordant low risk. FIB-4 misclassified 6.9% as low risk and 5.2% as high risk, while 87.9% were concordant low risk. NFS demonstrated 84.5% concordant low risk and 3.5% concordant high risk, with 8.6% misclassified as high risk, and 3.4% misclassified as low risk. The majority (91.8%) of the sample had ever taken hormones for gender affirmation, of which the majority (65.6%) were taking estradiol. There were

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

no associations between hormone use and discordant results. Discordant SAFE classification was associated with higher CAP scores (p = 0.020), BMI (p = 0.042), and systolic blood pressure (bp) (p = 0.013). FIB-4 discordance was associated with older age (p = 0.011) and higher systolic bp (p = 0.013). NAFLD Fibrosis Score discordance demonstrated the strongest association with age (p = 0.001) and was associated with higher systolic (p = 0.015) and diastolic bp (p = 0.003). **Conclusion:** NIT demonstrated distinct patterns of discordance with VCTE in a TGD population. SAFE discordance was more strongly associated with steatosis-related measures, whereas FIB-4 and NFS discordance were more strongly associated with age and blood pressure. These findings suggest that commonly used fibrosis scores may capture different underlying risk domains and may differentially misclassify fibrosis risk in gender-diverse populations. Further studies with larger sample sizes should continue to explore this topic.

3400 | EMERGING SERUM BIOMARKERS IN LIVER FIBROSIS: GLOBAL RESEARCH TRENDS FROM A BIBLIOMETRIC ANALYSIS (2010–2025)

Dogan Can Gavcar[1] Nilay Danis[2], [1]Izmir Atatürk Education and Research Hospital, [2]Dokuz Eylül University

Background: Liver fibrosis critically determines the prognosis of chronic liver diseases, making early detection clinically essential. Despite the growing body of publications on serum/plasma biomarkers, the overall trends and thematic structure of this literature remain incompletely characterized. This study aimed to map research trends and the intellectual structure of publications investigating novel experimental serum/plasma biomarkers in liver fibrosis between 2010 and 2025. **Methods:** Publications indexed in the Web of Science Core Collection (SCI-Expanded) from January 2010 to January 2025 were retrieved using a structured search strategy. Studies focused on established non-invasive tests (FIB-4, APRI, NAFLD Fibrosis Score, elastography, ELF) were excluded. A total of 1,325 publications were analyzed. Keyword co-occurrence, co-citation, journal co-citation, and country collaboration networks were constructed using VOSviewer. **Results:** Publication output increased markedly after 2015. Thematic focus shifted from classical extracellular matrix markers toward hepatic stellate cell activation, molecular regulators, and omics-based approaches. Co-citation analysis demonstrated a continuum from fundamental fibrogenesis mechanisms to clinical assessment frameworks. Country collaboration analysis revealed a globally distributed, multi-center research network. **Conclusion:** Future research should prioritize multi-biomarker panels and composite scoring systems over single-marker approaches, alongside analytical standardization and prospective clinical validation.

3401 | THE IMPORTANCE OF ELABELA IN THE DIAGNOSIS OF ADVANCED LIVER FIBROSIS AND CARCINOGENESIS

Monika Pazgan-Simon[1] Grzegorz Popek[2] Ewa Jarowicz[3] Monika Mazur[4] Joanna Górka-Dynysiewcz[5], [1]Department of Infectious Dieases and Hepatology, Wroclaw Medical Inivercity,, [2]Faculty of Computer Science and Telecommunications, Wrocław University of Science and Technology, [3]Regional Specialist Hospital Jerzy Gromkowski, [4]Diagnostyka S.A, Wroclaw, Poland, [5]Department of Pharmaceutical Biochemistry, Faculty of Pharmacy, Wroclaw Medical University

Background: Diagnosing advanced liver disease is a key task for hepatologists today. Traditional biopsy assessment is time-consuming and anxiety-inducing for patients. Liver MRI is a difficult-to-access and expensive procedure. Therefore, we are searching for non-invasive methods for diagnosing advanced fibrosis. Elabela is a hormonal peptide encoded by the APELA gene. It acts via the APLNR receptor. It is produced in embryonic cells, but also in heart, kidney, and endothelial cells, and circulates in serum. Elabela already has an established role in the diagnosis of heart disease, preeclampsia, and acute liver injury.The aim of the project was to evaluate the measurement of Elabela in the diagnosis of advanced fibrosis and hepatic oncogenesis, regardless of the etiology of liver disease. **Methods:** The study included 124 patients with a mean age of 55 years and a mean BMI of 25, including 51 women and 73 men: The study included 125 patients: 32 with no significant fibrosis, 54 with significant fibrosis, 29 with diagnosed hepatocellular carcinoma, and 10 control subjects.Serum elabela levels were measured using an enzyme-linked immunosorbent assay (ELISA) kit (ELK Biotechnology, Denver, USA).Intergroup comparisons were presented as median (interquartile range, IQR) and evaluated using the Levene's test for evaluation of the homogeneity of variance, the Mann-Whitney U-Test for comparison in presence of homoscedasticity, and the non-parametric Brunner-Munzel test for comparison in presence of heteroscedasticity. **Results:** The study demonstrated that serum elabela levels were significantly higher in patients with hepatocellular carcinoma [12.60 (8.12–15.48) ng/mL] compared to no significant fibrosis [11.47 (9.76–12.66) ng/mL, p = 0.00076] and significant fibrosis [6.93 (4.16–11.91) ng/mL, p = 0.0132]. A statistically significant positive correlation was also observed between elabela concentration and disease severity, as assessed by the CTP and MELD scores. **Conclusion:** 1.Elabela appears to be a good marker of advanced fibrosis in patients with liver disease.2. Elabela may serve as a useful biomarker for distinguishing hepatocellular carcinoma from no significant and significant of liver fibrosis.

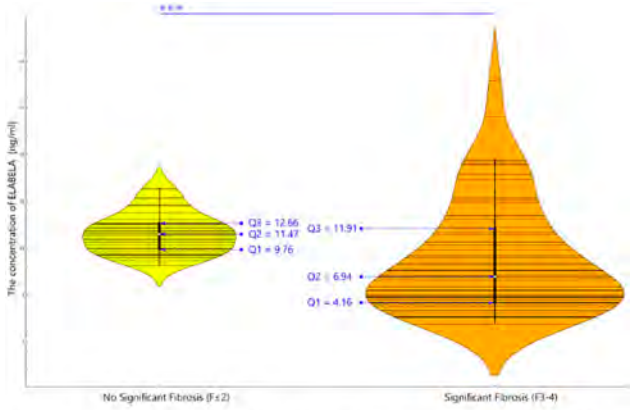

Figure 2. A comparison of the concentration of ELABELA [ng/ml] in patients with No Significant Fibrosis (F≤2) vs patients with Significant Fibrosis (F3-4). A statistically significant difference between the groups was evaluated as *** in Brunner-Munzel Test (used due to heteroscedasticity), p= 0.00030.

3402 | RETINOIC ACID RECEPTOR SIGNALING PROMOTES LIVER NICHE REMODELING AND FIBROSIS RESOLUTION AFTER ALCOHOL CESSATION VIA MACROPHAGE FIBROLYTIC PHENOTYPE SHIFT

Samson Mah[1] Michael Schonfeld[1] Miki Hodel[1] Kruti Nataraj[1] Isabel Aranzazu Pulido Ruiz[1] Steven Weinman[2] Irina Tikhanovich[2], [1]The University of Kansas Medical Center, [2]University of Kansas Medical Center

Background: Abstinence is beneficial for patients with alcohol-associated liver disease (ALD), but disease resolution after alcohol cessation occurs slowly and only in a subset of patients. Mechanisms of fibrosis resolution in ALD are not yet fully understood. Previous work highlights the importance of liver niche remodeling, a process which occurs around areas of fibrosis and involves protein and metabolite mediated cell-cell crosstalk between hepatocytes and non-parenchymal cells. In this work we aimed to study the role of retinol metabolism in ALD resolution. **Methods:** Mice were fed western diet and 20% alcohol in the drinking water (WDA model of ALD) followed by 4 weeks of disease resolution. We used spatial metabolomics and spatial transcriptomics to assess spatially distinct changes during ALD resolution. Mice were treated with bexarotene (50mg/kg), AC-261066 (10 mg/kg), or AM580

(5mg/kg) to activate RAR/RXR, or with BMS493 (5mg/kg) to inhibit RAR/RXR. **Results:** We found that retinoic acid metabolism strongly associated with improved fibrosis resolution. Additionally, retinol metabolites were enriched in liver niches characterized by improved ALD resolution in a mouse model. In agreement with these findings, mice treated with RAR agonist AM580 after alcohol cessation showed improved fibrosis resolution. Spatial transcriptomics analysis of agonist treated mice and controls suggested that RAR activation dramatically altered liver niches such as the progenitor-enriched niche, fibrogenic niche, and inflammation-associated niche, in part through macrophage phenotype shift. We confirmed that RAR activation in macrophages resulted in an accumulation of *Marco* high/*Cd163* high/*Vsig4* high macrophages that showed increased fibrolytic activity *in vitro* and *in vivo*.Previously, we identified Serum Amyloid A (SAA), a known retinol transporter, as an important player in fibrolytic niches. We found that SAA promoted fibrosis resolution in part through RAR signaling. RAR inhibition prevented SAA-mediated macrophage phenotype shift and fibrosis resolution in mice, suggesting that the SAA-RAR axis controls macrophage-mediated niche remodeling required for fibrosis resolution in ALD. **Conclusion:** Retinoic acid signaling is necessary and sufficient for improved fibrosis resolution after alcohol cessation. Targeting RAR may be beneficial for disease resolution in patients with ALD.

3403 | KUPFFER CELL-MEDIATED CLEARANCE OF DENGUE VIRUS FROM THE BLOOD CIRCULATION IS IMPAIRED DURING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Erin Fish[1] Kathryn Carpentier[1] Megan Stumpf[1] David Orlicky[1] Sofia Christensen[1] Bennett Davenport[1] Matthew Burchill[1] Thomas Morrison[1], [1]University of Colorado - Anschutz

Background: Dengue virus (DENV) is the most prevalent mosquito-transmitted virus, causing ~500 million infections and 40,000 deaths annually. Efficient DENV transmission depends on the magnitude and duration of viremia in the blood circulation; and high viremia is associated more severe disease. Patient-specific factors also increase morbidity and mortality during infection, including underlying metabolic dysfunction-associated steatotic liver disease (MASLD). Given the liver's important role in surveilling pathogens in the blood, we hypothesized that the liver's ability to control DENV viremia is fundamentally impaired during MASLD, thus resulting in more severe disease. **Methods:** To investigate mechanisms controlling DENV viremia, we developed a murine model of vascular clearance in which we inoculate mice intravenously (IV) with DENV to mimic high viremia and collect serum 15 – 180 minutes post-inoculation (mpi) to assess viral clearance from the blood circulation by RTqPCR. We evaluated clearance in mice fed standard versus MASLD-inducing diets (high-fat high-cholesterol, high-fat, and methionine-choline-deficient); as well as following Kupffer cell (KC) depletion (clodronate-liposomes or *Clec4f-DTR* mice) and scavenger receptor (SR) blockade (IV poly(I) or dextran sulfate). Immune cell populations of interest were further characterized by flow cytometry and bulk RNA sequencing. **Results:** C57BL/6 mice efficiently cleared DENV from the blood by 30 mpi, but clearance was impaired in mice with MASLD, coinciding with a loss of liver KCs. We then specifically depleted KCs, which also resulted in impaired clearance. Upon KC loss, bone marrow-derived macrophages (BMDMs) repopulate KCs within days. However, one week after KC depletion and repopulation, DENV clearance remained impaired, suggesting that functional differences between tissue-resident KCs and BMDMs contribute to delayed clearance. KCs express several SRs that function in pathogen surveillance of the blood. When mice were injected with SR blocking reagents before DENV inoculation, clearance was impaired. These data suggest a KC-expressed SR mediates clearance. We then performed bulk RNA sequencing on isolated mouse KCs and BMDMs and identified several SRs that are more highly expressed by KCs than BMDMs that may contribute to KCs' ability to efficiently clear DENV. **Conclusion:** Our studies defined key host factors involved in DENV clearance from the blood circulation, including liver KCs and a SR, suggesting that alterations to these cells or molecules may promote high viremia in individuals and populations. Moreover, we found that MASLD-induced loss of KCs impairs clearance of DENV, and that repopulation by BMDMs is not sufficient to restore clearance, suggesting a mechanism for more severe disease in patients with MASLD. Collectively, this work improves our understanding of the role of liver KCs in pathogen defense in both healthy and liver disease states.

3404 | ◆ NONINVASIVE POINT-OF-CARE PRESCREENING STRATEGIES FOR NON-CIRRHOTIC MASH CLINICAL TRIALS USING MACHINE LEARNING

Winston Dunn[1] Mazen Noureddin[2] Elizabeth Brombosz[3] Gražina Binkauskiene[3] Rashmee Patil[4] Rohit Puskoor[5] David Huang[6] Nirupama Esther Jerome[5] John Poulos[7] Alaa Abousaif[8] Aasim Sheikh[9] Alma Laura Ladrón de Guevara[10] Marcelo Kugelmas[11] Mousab Tabbaa[12] Sam Moussa[13] Vlad Ratziu[14] Meena Bansal[15] Jörn Schattenberg[16] Naim Alkhouri[17],
[1]University of Kansas Medical Center, [2]Houston Methodist Hospital, Houston Research Institute, Summit Clinical Research Solutions, [3]Summit Clinical Research Solutions, [4]Pinnacle at San Antonio, Summit Clinical Research Solutions, [5]Pinnacle at Austin, Summit Clinical Research Solutions, [6]Houston Research Institute – Main, [7]Coastal Research Institute, [8]Providence St. Joseph Hospital-Orange, [9]GI Specialists of Georgia, [10]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [11]South Denver Gastroenterology, [12]Clinical Research Institute of Ohio, [13]Adobe Clinical Research, [14]Service D' Hepatogastroenterologie (FR), [15]Icahn School of Medicine at Mount Sinai (ISMMS), [16]Saarland University Medical Center, [17]Summit Clinical Research

Background: Non-cirrhotic MASH clinical trials have high liver biopsy screen-failure rates, largely driven by failure to meet histologic eligibility criteria. Point-of-care (POC) prescreening algorithms using VCTE, including FAST and CAP ≥280 dB/m with LSM ≥8 kPa, have been proposed. We evaluated a machine learning (ML)–based prescreening strategy using point-of-care Piccolo Xpress® Chemistry Analyzer and VCTE variables compared with FAST and a standard VCTE-based strategy. **Methods:** A total of 3,511 patients were included in the derivation cohort, of whom 1,159 had biopsy-confirmed MASH meeting histologic eligibility criteria. Clinical, VCTE, and Piccolo variables underwent SHAP-based feature selection and ML optimization exclusively within the derivation cohort to avoid data leakage. External validation was independently performed in an independent cohort of 3,618 patients, including 1,392 biopsy-confirmed eligible cases. A simulation cohort with 15% prevalence was generated to model community screening and evaluate a 33% liver biopsy screen-success rate. **Results:** The top seven SHAP-ranked variables in descending order were GGT, AST, CAP, weight, height, and LSM. SHAP analysis demonstrated that GGT was the highest-ranking predictor (Figure A). In external validation, the ML-derived POC6MASH score demonstrated significantly superior discrimination compared with FAST and the standard VCTE-based strategy (CAP ≥280 dB/m and LSM ≥8 kPa), achieving an AUC of 0.763 (95% CI 0.747–0.779) versus 0.716 (95% CI 0.699–0.733) and 0.595 (95% CI 0.576–0.614), respectively (all $p < 0.0001$) (Figure B). The superiority of POC6MASH over FAST was consistently observed across all major clinical subgroups, including diabetes status, sex, BMI, and age categories (Figure C). In the simulation cohort targeting a 33% liver biopsy screen-success rate, POC6MASH identified 10.3 biopsy-confirmed eligible cases per 100 screened participants, compared with 7.6 cases for FAST, representing a 35.5% increase in biopsy-confirmed eligible case identification (Figure D). **Conclusion:** A web- and ML–based POC prescreening strategy significantly improved identification of patients meeting histologic eligibility criteria for non-cirrhotic MASH clinical trials compared with conventional prescreening. Notably, GGT emerged as the single most important predictor of histologic eligibility yet is not incorporated into current prescreening algorithms. https://aihepatology.shinyapps.io/POC7MASH/

3405 | ◆ FASTING HYPERINSULINEMIA IS MORE TIGHTLY ASSOCIATED WITH PROGRESSIVE LIVER DISEASE IN MASLD THAN POSTPRANDIAL INSULIN LEVELS

Fernando Bril[1] Michael McPhaul[2] Kenneth Cusi[3], [1]University of Alabama at Birmingham, [2]UT Southwestern, [3]University of Florida

Background: The development of MASLD, and its progression to MASH and clinically significant fibrosis are closely linked to insulin resistance and hyperinsulinemia. However, insulin levels may be quite different in the fasting versus postprandial state, representing different pathophysiologic processes. While fasting hyperinsulinemia may reflect hepatic insulin resistance, postprandial hyperinsulinemia also accounts for skeletal muscle insulin resistance. Little is known as to whether fasting or postprandial hyperinsulinemia preferentially drives liver disease in patients with MASLD. **Methods:** We included in this study patients with available liver histology, as well as an oral glucose tolerance test with insulin levels available at 0, 30, 60, 90, and 120 minutes (n = 222). Patients on insulin therapy were excluded (only metformin and sulfonylureas were allowed). Based on median fasting insulin levels (< 11.5 vs. ≥ 11.5 μU/mL) as well as median incremental insulin levels[MM1] during the OGTT (< 6405 vs. ≥ 6405 μU/mL · min), patients were divided in 4 groups: low fasting and postprandial levels ('both LOW'), high fasting and low postprandial levels ('HIGH fasting only'), low fasting and high postprandial levels ('HIGH postprandial only'), and high fasting and postprandial levels ('both HIGH'). A subset of patients (n = 122) underwent a hyperinsulinemia euglycemic clamp to measure insulin sensitivity. **Results:** A total of 222 patients were included (53 ± 11 years, 77% male, 34.1 ± 4.4 kg/m^2, 65% with diabetes, A1c 6.4 ± 0.9%). **Table 1** summarizes the characteristics of the 4 groups and overall results. As can be observed, all groups had similar liver fat accumulation (p = 0.24), and except for the 'both LOW' group, they also had similar BMI. Patients in the 'HIGH postprandial only' group had the second worst whole-body insulin sensitivity based on Matsuda Index and insulin-stimulated glucose uptake. Despite this, this group had lower liver fibrosis (mean stage 0.3 ± 0.6, p < 0.001 against other groups) and lower overall activity score (NAS: 3.2 ± 1.6, p = 0.006). Only 4.3% of this group had clinically significant fibrosis, as compared to 26.7% and 18.8% in the 'HIGH fasting only' and 'both HIGH' groups, respectively (p = 0.004). Of note, the group with 'HIGH postprandial only' had a similar prevalence of clinically significant fibrosis as the 'both LOW' group. **Conclusion:** Our results suggest that fasting insulin, rather than postprandial insulin levels, may play a more central role in liver disease progression in MASLD. These findings raise the possibility that chronic basal hyperinsulinemia may be more relevant to hepatic inflammation and fibrogenesis than exaggerated meal-stimulated insulin responses. Further studies are needed to determine whether interventions specifically aimed at reducing fasting hyperinsulinemia may alter the natural history of MASLD and fibrosis progression.

	Both LOW (n=66)	HIGH fasting (insulin) only (n=45)	HIGH postprandial (insulin) only (n=47)	Both HIGH (n=64)	p value

(SADUS), University of Seville, Seville, Spain, [7]Pablo de Olavide University, Seville, Spain, [8]Radiology Department, Virgen del Rocío University Hospital, Seville, Spain, [9]Virgen del Rocio University Hospital

Background: MASLD is a major cause of chronic liver disease, for which lifestyle interventions are the first-line therapy and improve steatosis and fibrosis; however, the molecular mechanisms underlying fibrosis regression remain poorly understood. We aimed to characterize longitudinal proteomic changes and identify differential signatures between fibrosis responders and non-responders. **Methods:** A prospective longitudinal study included 96 MASLD patients undergoing a combined dietary and supervised exercise intervention. Clinical and imaging assessments were performed at baseline, 3, and 6 months. Fibrosis regression was defined as a >19% reduction in liver stiffness by magnetic resonance elastography. Circulating proteomic profiling using HPLC–mass spectrometry was conducted at all time points in 46 patients, who were stratified as fibrosis responders (n = 13) and non-responders (n = 28). **Results:** Differential proteomic expression analysis comparing baseline and 6 months post-intervention identified changes in 75 proteins with a raw p-value <0.05 and log2 fold change (log2FC) >1. However, after adjustment for multiple comparisons, only two proteins remained statistically significant. Both proteins, PSMA4 (log2FC = −1.91; p = 0.025) and PCBP1 (log2FC = −1.91; p = 0.042), were significantly downregulated in patients who exhibited fibrosis improvement, suggesting their potential association with a favorable response to the lifestyle intervention and a shift towards improved cellular homeostasis, with reduced proteostasis- and oxidative stress-related signaling. Functional enrichment analysis identified 34 significantly altered biological processes, of which the 15 most relevant are shown in Fig.1. Thirteen of these pathways displayed a positive normalized enrichment score (NES), indicating increased activity in patients who exhibited fibrosis improvement. Among the most prominent processes were extracellular matrix organization, extracellular structure organization, and vasculature development. The enrichment of these pathways in fibrosis responders likely reflects active tissue remodeling and repair processes, rather than ongoing fibrogenesis, supporting a dynamic model of fibrosis regression. **Conclusion:** Fibrosis regression following lifestyle intervention in MASLD patients is associated with a coordinated shift in the circulating proteome, characterized by the downregulation of stress-related proteins, including PSMA4 and PCBP1, together with the activation of biological pathways involved in extracellular matrix remodeling and tissue repair. These findings support a model in which fibrosis improvement reflects an active process of hepatic reprogramming, marked by resolution of cellular stress and dynamic tissue remodeling, highlighting potential proteomic signatures of therapeutic response.

3407 | ◆ LINKING LIVER TO BRAIN: THE MEDIATING ROLE OF LIVER STIFFNESS IN MASLD-ASSOCIATED NEUROVASCULAR DYSFUNCTION

Zhuoru Jiang[1] Qian Chen[1] Jun Chen[2] Jie Li[3], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, [2]Mayo Clinic Rochester, [3]Nanjing Drum Tower Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly linked to cognitive decline, yet the specific hepatic drivers of neurovascular coupling (NVC) dysfunction remain poorly understood. This study aimed to investigate the independent contributions of liver stiffness and steatosis to NVC alterations and to elucidate the mechanistic pathways within the liver-brain axis. **Methods:** A total of 130 participants (98 MASLD patients and 32 age- and education-matched healthy controls) underwent comprehensive clinical assessment,

neuropsychological testing, and multi-modal MRI. Liver stiffness and fat content were quantified using MR elastography (MRE) and MRI-proton density fat fraction (PDFF). NVC was indexed by the ratio of CBF to regional homogeneity (ReHo). Multivariable regression and mediation analyses were employed to identify independent predictors and mechanistic pathways. **Results:** Compared to healthy controls and patients with low liver stiffness (MASLD_low), patients with high liver stiffness (MASLD_high) exhibited significantly reduced NVC values, primarily localized to the bilateral superior temporal gyrus (TPOsup). Multivariable regression revealed that liver stiffness, rather than steatosis or liver enzymes, was the sole independent predictor of NVC deficits (P < 0.001). Furthermore, mediation analysis demonstrated that the impact of hepatocellular injury on neurovascular function was fully mediated by elevated liver stiffness (indirect effect 95% CI: 0.054–0.285). **Conclusion:** These findings suggest that MRE-defined liver stiffness is associated with altered resting-state perfusion-functional coupling in MASLD and may serve as a promising imaging marker of early neurological involvement.

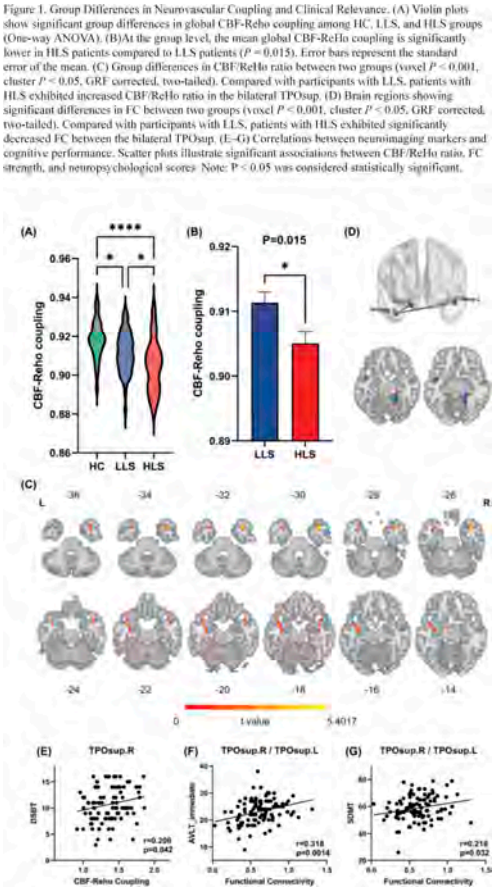

Figure 1. Group Differences in Neurovascular Coupling and Clinical Relevance. (A) Violin plots show significant group differences in global CBF-Reho coupling among HC, LLS, and HLS groups (One-way ANOVA). (B)At the group level, the mean global CBF-ReHo coupling is significantly lower in HLS patients compared to LLS patients (P = 0.015). Error bars represent the standard error of the mean. (C) Group differences in CBF/ReHo ratio between two groups (voxel P < 0.001, cluster P < 0.05, GRF corrected, two-tailed). Compared with participants with LLS, patients with HLS exhibited increased CBF/ReHo ratio in the bilateral TPOsup. (D) Brain regions showing significant differences in FC between two groups (voxel P < 0.001, cluster P < 0.05, GRF corrected, two-tailed). Compared with participants with LLS, patients with HLS exhibited significantly decreased FC between the bilateral TPOsup. (E–G) Correlations between neuroimaging markers and cognitive performance. Scatter plots illustrate significant associations between CBF/ReHo ratio, FC strength, and neuropsychological scores. Note: P < 0.05 was considered statistically significant.

★ 3408 | ◆ 4-HYDROXY-2-NONENAL DIRECTLY INDUCES MITOCHONDRIAL ULTRASTRUCTURAL INJURY IN MASLD

Hidenori Kido[1] Takuya Seike[1] Masahiro Yanagi[1] Andon Mladenov[1] Eishiro Mizukoshi[2] Tetsumori Yamashima[1] Taro Yamashita[1], [1]Kanazawa University, [2]Kanazawa Medical University

Background: Oxidative stress and mitochondrial dysfunction are key features of MASLD progression, but mechanisms linking lipid peroxidation to hepatocellular organelle injury remain unclear. 4-Hydroxy-2-nonenal (4-HNE), a reactive aldehyde derived from omega-6 polyunsaturated fatty acids, accumulates in MASLD and modifies proteins and membranes through covalent adduct formation. We investigated whether HNE directly induces mitochondrial ultrastructural injury in hepatocytes. **Methods:** We analyzed liver tissues from 28 patients (MASLD, n = 25; non-MASLD, n = 3) and HNE-treated models. HepG2 cells were treated with 100 μM HNE. Male C57BL/6 mice received saline, 5 mg/kg HNE, or 10 mg/kg HNE three times weekly (n = 15/group), with livers collected at 4 and 8 weeks. Female Japanese macaques received saline (n = 2) or intramuscular HNE at 5 mg/week for 24 weeks (n = 3), with serial blood tests, ultrasonography, and liver biopsy. Cell mitochondria were assessed by Mito-Tracker time-lapse imaging and TEM. In liver tissues, HNE accumulation was evaluated by Western blotting and immunohistochemistry. Mitochondrial ultrastructure was scored by TEM and quantified using ImageJ for electron density, cross-sectional area, and aspect ratio. Statistical comparisons were performed using the Mann–Whitney U test, and correlations were assessed using Spearman's rank correlation coefficient. **Results:** MASLD patients showed greater hepatic HNE accumulation than non-MASLD controls (p = 0.008) and higher mitochondrial TEM injury scores (p = 0.039). Mitochondrial TEM scores correlated with hepatic HNE accumulation (r = 0.502, p = 0.01) and NAFLD activity score (r = 0.750, p < 0.0001). In HepG2 cells, time-lapse imaging and TEM revealed disruption of individual mitochondrial membranes and reduced mitochondrial number after HNE treatment. In HNE-treated mice and macaques, hepatic HNE deposition was accompanied by spherical mitochondrial deformation and disrupted cristae. Quantitative analysis of > 500 mitochondria/group showed increased electron density, enlarged cross-sectional area, and aspect ratios closer to 1 in HNE-treated groups, indicating mitochondrial swelling and spherical remodeling (all p < 0.0001). **Conclusion:** HNE accumulation is associated with disease activity and mitochondrial ultrastructural injury in MASLD liver. Across cell, mouse, and

nonhuman primate models, HNE directly induced mitochondrial membrane disruption, cristae disorganization, swelling, and spherical remodeling. HNE may be a pathogenic mediator linking lipid peroxidation to mitochondrial injury in MASLD and a potential therapeutic target.

3409 | DOES LIPODYSTROPHY CONTRIBUTE TO LEAN MASLD? A PLASMA PROTEOMIC STUDY

Wesam Aleyadeh[1] Maria Mironova[2] Carolin Victoria Schneider[3] Rebecca Brown[4] Yaron Rotman[1], [1]National Institute of Diabetes and Digestive and Kidney Diseases; National Institutes of Health, [2]UCSD, [3]RWTH Aachen, [4]NIDDK, NIH

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is defined by hepatic steatosis in the presence of metabolic risk factors. A subset of people with MASLD are lean, yet it is unclear if these represent a distinct entity or are similar to adiposity-associated MASLD. In lipodystrophy (LD), a rare disorder of adipose tissue deficiency characterized by severe insulin resistance, hepatic steatosis and steatohepatitis can occur in the absence of obesity. Genetic LD-like features may contribute to MASLD pathogenesis. We hypothesized that some people with lean MASLD share pathophysiologic features with LD and developed a plasma proteomic score to identify LD-like features in MASLD. **Methods:** Plasma proteins were measured using SomaScan 7K in patients aged ≥ 12 years with LD (n = 24) or MASLD (n = 16). Analytes were filtered for cross-platform compatibility between SomaScan and the UK Biobank (UKB) Olink proteomic assay to enable external validation. Differentially expressed proteins (FDR q < 0.05) were used for unsupervised hierarchical clustering. A parsimonious score was derived by elastic net logistic regression with nested cross-validation (10 folds, 10 repeats). The score was applied to UK Biobank (UKB) participants with available proteomics (n = 22,287) to seek individuals with LD-like phenotype. **Results:** LD and MASLD patients in the derivation group had marked insulin resistance (median HOMA-IR 11.6 [IQR 6.6–29.5] in LD vs 6.5 [5.8–9.5] in MASLD), with similar rates of steatohepatitis and cirrhosis among those biopsied. Of 7,481 measured proteins, 1,816 passed cross-platform filtering and 116 were differentially expressed. Unsupervised hierarchical clustering and principal component analysis showed complete separation of LD from MASLD. A 5-protein (SFRP1, GBA, F9, TIMP4, FCN1) LD-likelihood score > 0.65 differentiated the groups with no overlap ($p < 0.001$), with a cross-validated AUC of 0.961 (95% CI 0.893–1.000) and Brier score of 0.083. There were 7320 UKB participants with BMI < 25, of whom 31 (0.4%) had high (> 0.65) LD-likelihood. 1127 individuals had potential lean steatotic liver disease (SLD) (ALT > 40 and/or GGT > 40), of whom only < 5 (< 0.4%) had high LD-likelihood. Using unsupervised clustering based on all 116 differentially expressed proteins, subjects with potential lean SLD and high LD scores did not cluster with patients with LD. In a subset of 763 UKB participants with MR-PDFF-defined steatosis, no lean individual had high LD-likelihood. The score was not correlated with hepatic fat fraction, and body composition measures were similar across score categories. **Conclusion:** A 5-protein plasma proteomic score distinguishes LD from MASLD. Most individuals with lean SLD have proteomic features consistent with "regular" MASLD. Our findings do not support a contribution of LD to lean MASLD.

Shah[1] Tatiana Kisseleva[2] Amit Majithia[1] Claude Sirlin[1] David Gonzalez[1] Rohit Loomba[2], [1]UCSD, [2]University of California, San Diego

Background: MASLD is present in up to 30% of adults globally. Iron overload may affect approximately 30% of people with MASLD and is prognostic for fibrosis progression. The aim of this study was to examine whether hepatic iron in MASLD reflects an independently heritable axis or is genetically co-inherited with steatosis and fibrosis in a unique well-characterized twin cohort. **Methods:** From a prospectively enrolled twin cohort we identified an analytic cohort of 118 subjects – 42 monozygotic and 17 dizygotic pairs with available clinical laboratory data, MRI-PDFF, MRE and R2* on both co-twins and plasma proteomics (approximately 850 proteins measured with Orbitrap-Astral MS), and six MASLD-GWAS SNPs (*PNPLA3, MBOAT7, TM6SF2, GCKR, HSD17B13, MARC1*). Univariate and bivariate AE models, which partition phenotypic variance into additive genetic (A) and unique environmental (E) components, were used to estimate heritability (h^2) and genetic correlation (rA), with age, sex, and race as covariates. Protein-level associated SNPs were estimated using mixed-effects model with family as random intercept. **Results:** This twin-study (N = 118) included 24 participants with MASLD (MRI-PDFF > = 5%) and 94 participants without MASLD (MRI-PDFF < 5%). MASLD twins had higher median BMI (32.3 vs 23.5 kg/m^2), triglycerides (156 vs 72 mg/dL), ALT (22 vs 17 U/L), PDFF (9.0 vs 2.1%), liver stiffness by MRE (2.6 vs 2.2 kPa), and R2* (53.5 vs 45.3 s^{-1}), lower HDL (45 vs 64 mg/dL) – all $p < 0.001$. The traits measured by imaging, including steatosis, fibrosis and hepatic iron content, were heritable, $h^2(PDFF) = 0.78$, $h^2(MRE) = 0.44$, $h^2(R2^*) = 0.64$, as well as serum ferritin ($h^2 = 0.46$, $p = 0.002$).(Fig. 1A) Hepatic iron shared modest heritable architecture with steatosis (rA = 0.34, p = 0.03) but not fibrosis (rA = 0.08, NS). This iron-specific signal converged at transferrin receptors: serum TFR2 ($h^2 = 0.47$) and TFR1 ($h^2 = 0.63$) were strongly inversely genetically correlated with hepatic iron (rA = −0.57 and rA = −0.48, both p = 0.006) but did not correlate with steatosis (rA = −0.02 and −0.03, NS).(Fig. 1B) Furthermore, *MBOAT7* T risk allele significantly lowered serum TFR2 (pQTL $\beta = -0.58$, $p < 0.001$).(Fig. 1C) **Conclusion:** Hepatic iron content in MASLD is heritable, phenotypically distinct from yet partially co-inherited with steatosis. The heritable transferrin-receptor axis tracks hepatic iron through distinct mechanisms. TFR1 follows classical iron-deficiency feedback and increases when iron stores are low. The inverse relationship TFR2-iron is unexpected, since it is normally stabilized by transferrin and increases with iron. The opposite pattern fits inherited low TFR2 acting upstream to raise hepatic iron, like in hemochromatosis type 3, assuming circulating TFR2 reflects hepatic signaling. Transferrin receptor axis along with *MBOAT7* genotype should be further explored as driver of MASLD pathophysiology and disease biomarker.

3411 | A "HOT" INJURY-FIBROGENIC ENDOTYPE IDENTIFIES PATIENTS WITH METABOLIC DYSFUNCTION AND STAGE 2 OR 3 FIBROSIS WHO WILL PROGRESS TO CIRRHOSIS WITHIN FOUR YEARS

Ekaterina Smirnova[1] Mary Erickson[2] Vlad Ratziu[3] Mary Rinella[4] Rina Levya[5] Diana Leeming[6] Andressa de Zawadzki[6] Morten Karsdal[6] Jennifer Sayne[1] Arun Sanyal[1], [1]Virginia Commonwealth University, [2]Alfasigma, [3]Service D' Hepatogastroenterologie (FR), [4]The University of Chicago, [5]Alpfasigma, [6]Nordic Bioscience

Background: Fibrosis can progress or regress in those with pre-cirrhotic MASH and only a 10-20% develop cirrhosis. There is an unmet need to identify those most likely to progress and develop cirrhosis. **Hypothesis:** Distinct fibrogenic endotypes exist within populations with histologically similar MASH and endotypes reflecting injury-inflammation (hot) fibrogenic endotype are more likely to progress. **Methods:** A retrospective analysis of the placebo arm of the REGENERATE trial (NCT02548351) was performed. Four serum biomarkers were evaluated at baseline: VCIM (inflammation), ProC3, Endotrophin (fibrogenesis) and CTXIII (fibrolytic). K-medoid clustering was performed using baseline clinical, laboratory, histological data and outcomes over 48 months. The distribution of these parameters and biomarkers was evaluated across clusters. Regression analyses were used to model profiles at risk of progression to cirrhosis. **Results:** A total of 307 individuals with biopsy-confirmed MASH (stage 1: n = 31, stage 2: n = 124 and stage 3: n = 152) with complete data were analyzed. 1-stage (n = 82) and 2-stage progression (n = 8) with 41 cases of progression to cirrhosis (n = 34 from stage 3, n = 7 from stage 2) occurred by month 48. Fibrosis regression occurred in 69 cases. Three subpopulations were identified via clustering analyses. Cluster 3 was characterized by higher (vs clusters 1 and 2) baseline PROC3, AST, ALT, GGT, FIB4, ELF and liver stiffness measurement (LSM). 36/67 (54%) in cluster 3 progressed to cirrhosis compared to 4/136 (3%) in cluster 1 and 1/104 (1%) in cluster 2 ($p < 0.001$ for both). Those in cluster 3 also experienced greater rates of 1- (n = 36/67, 54%) and 2-stage fibrosis progression (n = 6/67, 9%) compared to cluster 1 (1-stage: n = 27 (20%) and 2-stage (n = 1 (0.7%)) and cluster 2 (1-stage: n = 19, 18%, and 2-stage: n = 1, 1%) $p < 0.001$ for all. Cluster 3 also had lower rates of regression ($p < 0.001$ vs other clusters). Although progression and regression rates were similar for clusters 1 and 2, cluster 2 had significantly lower steatosis, inflammation, ballooning, AST, ALT, GGT, A1C, FIB-4, ELF and LSM. Regression models allowed identification of those at risk of progression to cirrhosis (cluster 3) with an AUROC 0.78. **Conclusion:s:** A "hot" injury-fibrogenesis predominant endotype identifies individuals who will progress to cirrhosis. This is likely to inform future therapeutic targeting, trial-design and precision medicine approaches.

3412 | KINETIC MODELING OF HEPATIC METABOLISM MAPS MITOCHONDRIAL HETEROPLASMY THRESHOLDS DRIVING CIRCULATING METABOLITE SIGNATURES IN MASH

Carlos Pirola[1] Silvia Sookoian[2], [1]CENITRES, UMAI-CONICET, [2]CONICET-UMAI

Background: Mitochondrial DNA (mtDNA) variants in OXPHOS-encoding genes correlate with histological severity in MASH. However, the quantitative link between specific heteroplasmy burdens and systemic metabolic alterations remains poorly defined. We developed a physiology-based kinetic model to dynamically explore the impact of mtDNA-encoded respiratory chain impairment on perturbations in the TCA cycle and one-carbon metabolism in the liver. **Methods:** We constructed a kinetic model of human hepatocyte metabolism by extending the HEPATOKIN1 framework, comprising 209 reactions across the cytosol, mitochondria, endoplasmic reticulum, and extracellular space. All enzymatic and transport processes were modeled using reversible Michaelis-Menten kinetics with explicit thermodynamic displacement. For respiratory chain complexes I, III, and IV, the rate laws were modified to incorporate the electrochemical driving force of the mitochondrial membrane potential. To simulate disease progression, we mapped mtDNA heteroplasmy burden (0–1) to effective enzymatic capacity (Vmax) using a cooperative Hill function with a phenotypic threshold (K50) at 60% heteroplasmy. Steady-state fold-changes were validated against patient-derived serum metabolomics and liver proteomics. **Results:** Simulations demonstrated that a 65% loss in Complex I capacity—consistent with observed heteroplasmy burdens—precisely recapitulated systemic shifts in TCA cycle intermediates and redox state. Specifically, the model predicted malate accumulation (+28% vs +27–31% observed) and succinate (+32% vs +29.5% observed), with corresponding fumarate depletion (−28% vs −24% observed). While predicted lactate levels (+45%) exceeded observed serum levels (+10%), they correctly captured the direction and order of magnitude of the hepatic redox shift. Furthermore, the model linked betaine insufficiency to a 38% reduction in flux through the mitochondrial dimethylglycine dehydrogenase (DMGDH) reaction, identifying a critical bottleneck in one-carbon metabolism. **Conclusion:** This work provides a mechanistic bridge between mitochondrial genetics and the metabolic landscape of MASH. By identifying a 60% heteroplasmy threshold as a trigger for TCA cycle disruption and betaine depletion, these findings suggest that personalized assessment of mitochondrial functional reserve could improve patient stratification and identify the metabolic thresholds that drive disease progression.

★ 3413 | FADS2 RS174583 TT GENOTYPE IDENTIFIES PNPLA3 GG CARRIERS WITH AT-RISK MASH AND A PRO-FIBROGENIC LIPID SIGNATURE

Shunsuke Ikejima[1] Kazuyoshi Kon[1] Hyeon-Cheol Lee[2] Kumiko Arai[1] Kyoko Fukuhara[1] Reiko Yaginuma[1] Kei Ishizuka[1] Hiroo Fukada[1] Akira Uchiyama[1] Shunhei Yamashina[1] Takehiko Yokomizo[2] Kenichi Ikejima[1], [1]Juntendo University Graduate School of Medicine, [2]Juntendo University School of Medicine

Background: At-risk MASH represents a high-risk subgroup of metabolic dysfunction-associated steatotic liver disease (MASLD) with increased risk of cardiovascular events and progression to cirrhosis and hepatocellular carcinoma. In animal models, we have previously shown that reduced expression of fatty acid desaturases (FADS) promotes steatohepatitis. This study investigated the impact of single nucleotide polymorphisms (SNPs) in FADS genes on hepatic lipid profiles and susceptibility to at-risk MASH. **Methods:** We enrolled 51 patients with biopsy-proven MASLD diagnosed between 2021 and 2025 who provided informed consent for SNP analysis. At-risk MASH was defined as NAFLD activity score ≥ 4 and fibrosis stage ≥ 2. Genomic DNA was extracted from peripheral blood, and SNPs were genotyped using TaqMan PCR. In a subset of patients, hepatic lipidomics was performed by LC–MS, and lipid species with $p < 0.05$ and a fold change (FC) ≥ 1.5 between FADS2 rs174583 TT and non-TT genotypes were identified. Cardiovascular burden, including clinical cardiovascular disease and CT-detected atherosclerotic findings, was assessed from medical records. **Results:** Among the 51 MASLD patients, 20 satisfied the criteria for at-risk MASH. While none of the PNPLA3 (rs738409) GG, MBOAT7 (rs641738) CC, TM6SF2 (rs58542926) CT, FADS1 (rs174556) TT, or FADS2 (rs174583) TT genotypes were individually associated with at-risk MASH, a logistic regression model including two SNPs and their interaction term revealed a significant PNPLA3 GG × FADS2 TT interaction for at-risk MASH (interaction OR 29.7, $p = 0.010$). Among 26 carriers of PNPLA3 GG, 10 had at-risk MASH. In this subgroup, univariate analysis identified age, BMI, TM6SF2 CT, FADS1 TT, and FADS2 TT as associated factors, whereas multivariate analysis demonstrated FADS2 TT as the only independent risk factor for at-risk MASH ($p = 0.047$). Notably, cardiovascular burden was observed in 80% of patients with the FADS2 TT genotype, compared with 13% of those with the CC or CT genotypes ($p = 0.002$). Of 13 hepatic lipid species significantly associated with FADS2 TT, α-hydroxyceramides (ahCer d18:1/22:0, d18:1/h24:1, d18:1/h24:0), hydroxy-hexosylceramide (hHexCer d18:1/h24:0), phosphatidylcholine (PC 16:0/20:1), phosphatidylethanolamine (PE 22:6/16:1), and phosphatidylinositol (PI 18:1/20:4) showed strong positive correlations with fibrosis stage ($r \geq 0.7$), whereas cholesterol ester (CE 18:3n-6) and phosphatidylcholine (PC 18:0/18:3n-3) showed strong negative correlations. **Conclusion:** In PNPLA3 GG carriers, the FADS2 rs174583 TT genotype identifies a distinct subgroup characterized by at-risk MASH, frequent cardiovascular burden, sphingolipid accumulation, and depletion of PUFA-containing cholesterol esters and phosphatidylcholines. These findings highlight FADS2-related lipid remodeling as a key modifier linking genetic susceptibility to hepatic fibrosis and cardiometabolic risk.

3414 | SODIUM-GLUCOSE COTRANSPORTER-2 INHIBITOR MITIGATES KIDNEY INJURIES BY OXIDATIVE STRESS REDUCTION AND ACTIVATION OF AMPK–ADIPONECTIN SIGNALING IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Jee-Fu Huang[1] Hugo Y-H Lin[1] Yu-Min Ko[2] Ming-Lun Yeh[1] Wan Long Chuang[3] Ming-Lung Yu[1], [1]Kaohsiung Medical University Hospital, [2]Tajen University, [3]Kaohsiung Medical University

Background: Metabolic dysfunction associated steatotic liver disease (MASLD) contributes to chronic kidney disease (CKD) development. The protective efficacy of sodium-glucose cotransporter-2 inhibitor (SGLT2i), a cardiometabolic drug, in alleviating renal injury in MASLD remains elusive. We constructed a MASLD mouse model aiming to investigate the potential mitigation of renal tubular injury by SGLT2i. **Methods:** Metabolic dysfunction-associated steatohepatitis (MASH) were induced in 8-week-old C57BL/6 male mice using a high-fat diet (HFD) with 5% fructose for 24 weeks. Mice were divided into two groups: dapagliflozin (DPG) group (1 mg/kg/day) and the vehicle group. Metabolic parameters and renal function were assessed through biochemical assays and transmission electron microscopy for mitochondrial ultrastructure analysis. **Results:** DPG-treated mice did not

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

exhibit significant weight loss compared to the vehicle group ($p = 0.11$). However, DPG group significantly improved glucose handling ($p = 0.03$ for fasting glucose levels; $p = 0.02$ for glucose tolerance) and the insulin resistance was alleviated ($p < 0.0001$ for HOMA-IR). Furthermore, DPG group mitigated renal function deterioration, as evidenced by lower serum creatinine ($p = 0.01$) and proteinuria ($p = 0.01$). *In vitro*, dapagliflozin directly protected palmitic acid-treated HK-2 cells against lipotoxicity by significantly reducing tubular reactive oxygen species (ROS) levels ($p = 0.03$). DPG group elicited a dose-dependent increase in AMPK phosphorylation at 0.5 and 1μM ($p = 0.001$ and $p < 0.0001$, respectively). This activation was successfully abrogated by the co-administration of the AMPK inhibitor dorsomorphin ($p < 0.0001$). **Conclusion:** The study demonstrated the renoprotective effects of DPG in MASLD. The engaged mechanisms included oxidative stress reduction and activation of AMPK–adiponectin signaling.

★ 3415 | METABOLIC–ALCOHOL SPECTRUM OF STEATOTIC LIVER DISEASE AND RISK OF INCIDENT GOUT: A MULTI-NATIONAL COHORT STUDY IN KOREA, JAPAN, AND THE UNITED KINGDOM

Yeowool Kang Sang Yi Moon[1] Min kook Son[2] Joon Yong Park[1], [1]Department of Internal Medicine, Dong-A University College of Medicine, [2]Department of Physiology, Dong-A University College of Medicine

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is closely linked to insulin resistance and cardiometabolic dysfunction, both of which may contribute to hyperuricemia and gout. Insulin resistance and fructose metabolism increase hepatic uric acid production, whereas alcohol consumption impairs renal uric acid excretion, suggesting mechanistic links between steatotic liver disease (SLD) and gout. However, large-scale multinational evidence regarding the metabolic–alcohol spectrum of SLD and incident gout remains limited. We investigated the association between SLD subtypes and gout risk using three population-based cohorts from Korea, Japan, and the United Kingdom. **Methods:** We performed a retrospective cohort study using the Korean National Health Insurance Service–Health Screening Cohort, the Japanese Medical Data Center database, and the UK Biobank. Participants were classified as no SLD without cardiometabolic risk factors, no SLD with risk factors, MASLD without alcohol consumption, MASLD with alcohol consumption, metabolic dysfunction–associated alcohol-related liver disease (MetALD), or alcohol-related liver disease (ALD). Incident gout was identified using diagnostic codes, and hyperuricemia was additionally assessed in the Japanese cohort. Adjusted hazard ratios (HRs) and 95% confidence intervals (CIs) were estimated using multivariable Cox proportional hazards models controlling for demographic factors, metabolic comorbidities, kidney function, smoking, and physical activity. **Results:** Across all cohorts, gout risk increased progressively along the metabolic–alcohol spectrum of SLD. In the Korean cohort, compared with individuals without SLD and without cardiometabolic risk factors, adjusted HRs for gout were 2.33 (95% CI, 2.09–2.59) for MASLD without alcohol consumption, 2.62 (95% CI, 2.35–2.93) for MASLD with alcohol consumption, 3.02 (95% CI, 2.67–3.42) for MetALD, and 3.11 (95% CI, 2.66–3.64) for ALD. Similar graded associations were consistently observed in the Japanese and UK cohorts. In Japan, associations were stronger when hyperuricemia was included as an outcome. A significant interaction between MASLD and alcohol consumption was observed (P for interaction < 0.001), suggesting synergistic effects on gout risk. **Conclusion:** Across three large cohorts from Asia and Europe, SLD across the metabolic–alcohol spectrum was independently associated with increased gout risk. These findings support the combined contribution of metabolic dysfunction and alcohol exposure to gout development and highlight the importance of integrated metabolic and lifestyle risk assessment in patients with SLD.

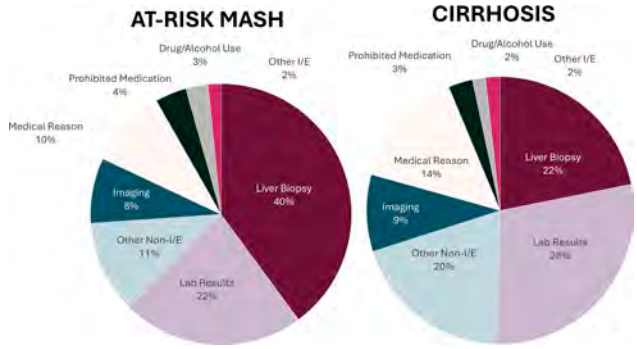
3416 | WHY DO MASH AND MASH CIRRHOSIS TRIALS FAIL TO ENROLL? INSIGHTS FROM OVER 5,000 SCREEN FAILURES IN PHASE 3 STUDIES



Mazen Noureddin[1] Winston Dunn[2] Elizabeth Brombosz[3] Gražina Binkauskiene[3] Rashmee Patil[2] Rohit Puskoor[4] David Huang[5] Nirupama Esther Jerome[4] John Poulos[6] Alaa Abousaif[7] Aasim Sheikh[8] Alma Laura Ladrón de Guevara[9] Marcelo Kugelmas[10] Mousab Tabbaa[11] Sam Moussa[12] Sudha Kodali[13] Vlad Ratziu[14] Meena Bansal[15] Jörn Schattenberg[16] Naim Alkhouri[17], [1]Houston Methodist Hospital, Houston Research Institute, Summit Clinical Research Solutions, [2]Pinnacle at San Antonio, Summit Clinical Research Solutions, [3]Summit Clinical Research Solutions, [4]Pinnacle at Austin, Summit Clinical Research Solutions, [5]Houston Research Institute – Main, [6]Coastal Research Institute, [7]Providence St. Joseph Hospital-Orange, [8]GI Specialists of Georgia, [9]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [10]South Denver Gastroenterology, [11]Clinical Research Institute of Ohio, [12]Adobe Clinical Research, [13]JC Walter Jr Transplant Center, Houston Methodist Hospital, [14]Service D' Hepatogastroenterologie (FR), [15]Icahn School of Medicine at Mount Sinai (ISMMS), [16]Saarland University Medical Center, [17]Summit Clinical Research

Background: High screen failure rates continue to be a major barrier to the development of pharmacotherapies for MASH. As more therapies progress to phase 3 trials, there is a growing need to understand the barriers to recruitment for these studies. The purpose of this study is to identify the major reasons for screen failure for phase 3 clinical trials in a large multicenter cohort of potential clinical trial participants. **Methods:** Potential participants in phase 3 trials were identified from a multicenter database of patients screened for inclusion in MASH and MASH cirrhosis clinical trials. The primary reason for screen failure was captured systematically by medical science representatives on the clinical trial team. Separate descriptive analyses were performed for trials targeting MASH vs MASH cirrhosis. **Results:** In phase 3 studies of patients with at-risk MASH (n = 3397 of 8636 screen fails), the most common reason for screen failure was liver biopsy (51.5% F0/F1; 13.1% F4; 79.7% did not have hepatocyte ballooning; Figure 1), followed by laboratory results, most frequently low AST/ALT (6.8% of those screened for phase 3 MASH trials), AST results alone (4.8%), HbA1c (2.9%), and bilirubin (2.0%; Figure 1). Common reasons for screen failure not related to inclusion/exclusion (I/E) criteria were concerns about study compliance (3.1%) and withdrawal of consent (2.1%). In phase 3 studies of MASH cirrhosis (n = 1766 of 5135 screen fails), laboratory results were the primary cause of screen failure, most frequently bilirubin (7.4%), albumin (3.5%), HbA1c (3.1%), ELF score (2.5%), and INR (2.1%). Of the patients who screen failed on biopsy, 22.7% were F0/F1, 67.5% were F2/F3, and 77.4% had NAS < 4. The most common non-I/E reasons for screen failure were concerns about study compliance (4.6%) and subject withdrawal (4.9%). **Conclusion:** In this large analysis for screening failure for MASH phase 3 studies we found that biopsy and laboratory results are major hurdles to enrollment in phase 3 trials for MASH and MASH cirrhosis. These trials may benefit from enhanced pre-screening algorithms to identify potential

participants most likely to qualify for enrollment. The role of ballooning assessment in at-risk MASH trials, along with NAS requirements for biopsy-confirmed MASH cirrhosis studies, warrants reconsideration by the hepatology community.

3417 | ENVIRONMENTAL POLLUTANT EXPOSURES ARE ASSOCIATED WITH FIBROSIS SEVERITY IN METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Matt Cave[1] Matthew Smith[2] Jianzhu Luo[1] Young-Mi Go[2] Christina Pinkston[3] Shesh Rai[3] Dean Jones[4] Naga Chalasani[5] Niharika Samala[6], [1]University of Louisville, [2]Emory University, [3]University of Cincinnati, [4]Emory University, Children's Healthcare of Atlanta, [5]Indiana University Medical Center, [6]Indiana University

Background: Environmental pollutants are disease modifying factors that may impact the severity of metabolic dysfunction associated steatotic liver disease (MASLD). A pilot exposomics study of 140 subjects with MASLD demonstrated that fluorene exposures were associated with the severity of hepatic steatosis and fibrosis. Here, a larger validation study is performed on fibrosis. **Methods:** Exposomics (GC-MS^2) was performed in 366 serum samples from IU MASLD prospective observational study. MASLD was diagnosed based on the AASLD guidelines. Fibrosis severity was determined by liver stiffness measurement (LSM) using vibration controlled transient elastography (VCTE). Exposome-wide association studies (EWAS) were performed using quantile normalized and log2 transformed linear exposure and LSM using ANOVA models in R. Statistical significance was set at FDR < 0.20. **Results:** Subjects were 42% female, 96% White with mean age of 53.3 years and mean BMI of 35.7 kg/m^2 . Type 2 diabetes (DM2) was present 49%, dyslipidemia in 51% and hypertension in 59%. Of the 146 unique pollutants detected with annotations confirmed by authentic standards, 11 were associated with hepatic fibrosis, of which 5 were associated with worse fibrosis. Dichloro diphenyl ethylene (DDE) a metabolite of the insecticide DDT, was the most statistically significant ($p = 0.00001$, FDR = 0.002). Benzoic acid, a food preservative commonly found in sugar-sweetened beverages, was detected in 100% of these serum samples ($p = 0.001$, FDR = 0.08). Fluoranthene, a polycyclic aromatic hydrocarbon similar to fluorene, ($p = 0.01$, FDR = 0.19), tis(2-butoxyethyl) phosphate (TBEP), an organophosphate flame retardant ($p = 0.007$, FDR = 0.16) and 2-amino-4-nitrotoluene, used in dye/pigment manufacturing was also associated with fibrosis severity. Six pollutants, bensulfuronmethyl, ethylheptanotate, 25-hydroxycholesterol, dimethoxy benzidine, ethyl myristate and tris(tribromoneopentyl) phosphate (TBNP) were negatively associated with fibrosis severity. **Conclusion:** Environmental pollutants- DDE (insecticide), benzoic acid (food additive), TBEP (flame retardant), 2-amino-4-nitrotoluene (pigments/dyes), and fluoranthene (dyes/incomplete combustion) were associated with worse fibrosis in individuals with MASLD. Reverse causality cannot be excluded and future research on these pollutants is warranted.

Table 1: Environmental Exposures Associated with Fibrosis Severity in the MASLD Cohort (N=366)

Chemical Name	Chemical Classification	P value	FDR	Directionality
DDE	Insecticide metabolite	0.00001	0.002	Positive
Benzoic Acid	Food additive (preservative)	0.001	0.08	Positive
Tris(2-butoxyethyl) phosphate (TBEP)	Flame Retardant	0.007	0.16	Positive
2-amino-4-nitrotoluene	Dyes and Pigments	0.010	0.19	Positive
Fluoranthene	Polycyclic aromatic hydrocarbon	0.010	0.18	Positive
Bensulfuronmethyl	Herbicide	0.002	0.08	Negative
Ethylheptanoate	Food additive (flavoring)	0.002	0.08	Negative
25-hydroxycholesterol	Endogenous oxysterol	0.002	0.08	Negative
Dimethoxy benzidine	Dyes and Pigments	0.002	0.08	Negative
Ethyl myristate	Food additive (flavoring), personal care products	0.003	0.09	Negative
Tris(tribromoneopentyl) phosphate (TBNP)	Flame Retardant	0.004	0.11	Negative

3418 | STATIN INITIATION MODIFIES THE LIPID METABOLOMIC PROFILE IN PEOPLE WITH HIV AND MASLD

Kara Wegermann[1] Xiaoyue Yan[2] Joseph Lucas[2] Rebecca Mangus[3] Zhong Li[3] Amreen Dinani[1] Cynthia Moylan[3] Susanna Naggie[4], [1]Duke University School of Medicine, [2]Vital Statistics LLC, [3]Duke University, [4]Duke Clinical Research Institute

Background: MASLD affects up to 40% of people with HIV (PWH), but prevention and treatment strategies are limited. Although statins are associated with lower MASLD prevalence and progression in the general population, data in PWH are sparse. The aim of this study was to characterize plasma lipidomic alterations associated with statin initiation in PWH with MASLD. **Methods:** We examined 50 PWH with MASLD from the Duke HIV Research Database and Repository before and after starting moderate or high intensity statins. MASLD was defined by hepatic steatosis index > = 36. We analyzed the Biocrates Q500 assay and a separate oxylipin panel on blood samples 6 months prior, and approximately 1 year after, statin initiation. One-sample paired t-tests were used to compare metabolites pre- and post-statin initiation, with statistical significance defined as $p < 0.05$ and FDR < 0.10. **Results:** Of 50 PWH included, 33 (66%) were assigned male sex at birth and 33 (66%) reported Black race. The median age was 53 years [IQR 48-57]. Median BMI was 33.6 kg/m2 and 9 (18%) had diabetes. Median HSI was 42.7 [IQR 40.2-49.9] and FIB-4 was 1.2 [0.9-1.5]. Untargeted metabolomic profiling identified 63 metabolites that differed significantly post-statin versus pre-statin; all were lipids and all were reduced following statin initiation (Figure). The most common classes were hexosylceramides (N = 16), sphingomyelins (N = 13), phosphatidylcholines (N = 12), ceramides (N = 10), cholesterol esters (N = 7) and triglycerides (N = 3). Gene set enrichment analysis revealed 6 pathways associated with metabolites that differed after statin initiation: amino acids related ($p < 0.001$, FDR < 0.001), sphingolipids ($p < 0.001$, FDR < 0.001), glycosylceramides ($p < 0.001$, FDR < 0.001), ceramides ($p = 0.0005$, FDR = 0.0006), cholesterol esters ($p = 0.0005$, FDR = 0.001), and carboxylic acids ($p = 0.03$, FDR = 0.09). **Conclusion:** Changes in plasma metabolite levels following statin initiation were largely restricted to lipid species and pathways previously found to be relevant to steatotic liver disease risk and progression. Our prior work demonstrating elevated ceramides, triglycerides, and select amino acids in PWH with MASLD suggests that statins act on steatotic liver disease-associated lipid perturbations. Whether these metabolomic changes translate into improvements in MASLD progression warrants further study.Figure Legend: Cluster diagram showing plasma metabolites before (left side of figure) and after (right side of figure) statin initiation. Blue indicates lower relative metabolite level, while red indicates higher relative metabolite level, when pre- and post-statin levels were compared. Metabolites are grouped by class.

3419 | UNDERUTILIZATION OF THE FIB-4 INDEX TO IDENTIFY LIVER DISEASE IN PATIENTS WITH METABOLIC DYSFUNCTION IN PRIMARY CARE

Mirjana Grocic[1] Husam Mikati[1] Richard Sterling[1] Alex Krist[1] Tamas Gal[2] Amanda Robinson[2] Roy Sabo[3], [1]Virginia Commonwealth University Hospital Systems, [2]Virginia Commonwealth University, [3]Viriginia Commonwealth University

Background: MASLD affects ~30% of adults and is associated with type 2 diabetes (T2DM), hypertension (HTN), dyslipidemia (DL), and obesity. ADA, AGA, and AASLD guidelines recommend the FIB-4 index to identify patients (pts) who may have liver fibrosis. FIB-4 is not routinely used by primary care providers (PCPs). With therapies, i.e. thyroid hormone receptor beta and glucagon-like peptide-1 (GLP-1) receptor agonists (RA), identifying pts at risk may prove beneficial. We hypothesize that underuse of FIB-4 results in underdiagnosis of MASLD and low referral rates to GI/Hepatology. **Methods:** Data were extracted from the Epic Systems electronic health record (EHR) at VCU Health System under approved IRB protocol. The analytical data set included pts aged 18—70 with ≥ 1 ambulatory visit 12/4/2021 to 11/30/2025. Extracted variables included demographics, BMI, encounter data including history of GI/Hepatology visits, lab values necessary for FIB-4 index calculation (AST/ALT/platelets), low-density lipoprotein (LDL), high-density lipoprotein (HDL), total cholesterol, triglycerides, HBV surface antigen, hepatitis C antibody, and GLP-1 RA use. Diagnostic indicators were derived from EHR data to identify liver diseases (MASLD/HBV/HCV), T2DM, and HTN. Pts seen in the ED or hospitalized were excluded and data were analyzed across all FIB-4 groups (<1.3, 1.3—2.7, >2.7). **Results:** The final cohort comprised 359,994 unique pts (mean age 45.8, 57% Female, 50% White, 15% T2DM, 35% HTN, 39% obesity, and liver disease [6% MASLD, 11.2% other]). Only 45% (163,991) had lab data to calculate FIB-4 (median 1.03: 64.4% <1.3, 27.8% 1.3—2.7, 7.7% >2.7). Pts without FIB-4 had missing AST (93.6%), ALT (96.7%), platelets (77.7%), and low liver disease prevalence (5.2%). Pts with FIB-4 <1.3 were younger ($p < .001$) and had lower metabolic and liver disease rates compared to pts with higher FIB-4 ($p < .001$). GI/Hepatology referral was 13.6% with FIB-4 <1.3, 19.7% with FIB-4 1.3—2.7, and 27.8% with FIB-4 >2.7. GLP-1 use was lowest with FIB-4 >2.7 (9.6%) compared to FIB-4 <2.7 (13%; $p < .001$). (Table 1) **Conclusion:** Despite the ease of calculation, FIB-4 is underutilized by PCPs, with most pts missing ≥ 1 component. Most pts with FIB-4 >1.3 are not referred to GI/Hepatology, suggesting a disconnect between FIB-4 calculations and proposed workup and consultation. More evidence is needed on the value of FIB-4 calculations in PCP routine care and integration criteria/parameters.

3420 | DOSE-DEPENDENT IMPROVEMENTS IN HEPATIC AND CARDIOMETABOLIC BIOMARKERS WITH ELECOGLIPRON IN ADULTS WITH MASLD

Jonathan Stine[1] Melanie Davies[2] Sue Pedersen[3] Roy Rasalam[4] Stephen Rush[5] Peter Johansson[5] Erika Morizzo[6] Sonali Singh[7] Jennie Lin[7] Ehsan Parvaresh Rizi[5] C David Sjöström[5], [1]Penn State College of Medicine, [2]Diabetes Research Centre, University of Leicester, Leicester, UK, [3]C-ENDO Diabetes & Endocrinology Clinic Calgary, Calgary, AB, Canada, [4]Alfred Health (Endocrinology and Diabetes), University of Melbourne, Melbourne, Australia, [5]AstraZeneca, Gothenburg, Sweden, [6]AstraZeneca, Cambridge, UK, [7]AstraZeneca, Boston, MA, USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is closely linked to obesity and cardiometabolic risk. Weight loss pharmacotherapies have been shown to improve hepatic biomarkers. We performed a post hoc analysis of the VISTA phase 2b trial to evaluate the effects of elecoglipron 50 mg and 75 mg on hepatic and cardiometabolic markers in adults living with obesity or overweight without type 2 diabetes. **Methods:** This analysis included adults with MASLD at baseline, defined by Fatty Liver Index (FLI) $\geq$60. The primary endpoint was proportion of participants achieving MASLD resolution, defined as FLI <30, with FLI <60 indicating values below the steatosis rule-in threshold. Changes from baseline to week 36 were assessed for alanine aminotransferase (ALT), body weight (BW), waist circumference (WC) and other metabolic parameters. Binary responder endpoints included clinically meaningful reduction in WC (>5 cm or >5%), and ALT (>17 IU/L). Furthermore, outcomes by achieved percent BW reduction at pre-specified thresholds (>5%, >7%, >10%) were explored. Mixed-effects models for repeated measures and logistic regression were used with prespecified covariate adjustment. Confidence intervals were not adjusted for multiplicity. **Results:** The analysis included 194 participants with FLI $\geq$60 (n=125 elecoglipron, n=69 placebo). Elecoglipron demonstrated improvements in hepatic and cardiometabolic biomarkers at week 36 across both 50 mg and 75 mg doses, with larger effects observed with 75 mg. 18.4% of participants receiving elecoglipron 75 mg achieved definitive MASLD resolution versus 2.3% with placebo (OR 5.8, 95% CI 0.9-38.3) and 11.4% receiving elecoglipron 50 mg (OR 2.0, 95% CI 0.3-15.4). Reduction in FLI below the steatosis threshold (<60) was observed in 40.8% elecoglipron 75 mg group vs. 7.0% placebo (OR 10.8, 95% CI 2.5-46.8) and 31.4% elecoglipron 50 mg group (OR 4.2, 95% CI 0.9-19.5). MASLD resolution was observed alongside a greater mean reduction in ALT (-9.2 IU/L for 75mg, -8.8 IU/L for 50 mg versus -0.8 IU/L for placebo) with 28.0% and 17.1% achieving ALT responder thresholds with 75 mg and 50 mg respectively, versus 9.1% with placebo. Clinically meaningful WC reduction occurred in 73.1% of 75 mg elecoglipron participants versus 21.4% of placebo participants (OR 8.9, 95% CI 3.5-22.8) and 69.4% of 50 mg elecoglipron participants (OR 6.9, 5% CI 2.5-18.8). Higher rates of MASLD resolution were observed with both doses of elecoglipron versus placebo across multiple thresholds of BW loss. **Conclusion:** Elecoglipron was associated with greater rates of MASLD resolution than placebo with dose-dependent improvements in noninvasive hepatic, metabolic, and cardiometabolic biomarkers in participants with MASLD and overweight/obesity.

High School, [2]Stanford University Medical Center, [3]UCLA

Background: Depression is increasingly recognized as an important comorbidity of MASLD. However, national data on changes in its prevalence and access to mental health care use (MHU) over the years is limited. We aimed to characterize the temporal trends and predictors of depression and MHU among those with depression. **Methods:** We analyzed U.S. adults (≥18 years) from the National Health and Nutrition Examination Survey (NHANES) 2005 – 2023 using NHANES survey weights to ensure representativeness of the US population. MASLD was defined by hepatic steatosis (US Fatty Liver Index ≥ 30 or controlled attenuation parameter ≥ 302 dB/m), ≥1 cardiometabolic risk and without significant alcohol use. Depression was defined by the presence of depressive symptoms through the Patient Health Questionnaire-9 score ≥ 5. Among those with depression, MHU was assessed via survey querying a history of seeing mental health professional(s) in the past year. **Results:** We analyzed 19,576 adults: 6,448 (32.9%) with MASLD and 13,128 (67.1%) without. Those with MASLD were more likely to have depression (26.3% vs 20.3%, $p<0.0001$) and depressed adults with MASLD were less likely to utilize mental health service than depressed adults without MASLD (18.5% vs 22.56%, $p=0.011$). Among those with MASLD, depression was more common in females (vs. males: 34.5% vs 20.4%), with low income (income-to-poverty ratio <1 vs. ≥1: 39.0% vs. 24.7%) and most prevalent among non-Hispanic (NH) Black followed by NH White, Hispanic, Other and Asian adults (30.3%, 26.8%, 24.4%, 23.4% and 16.9%, respectively), all $P<0.0001$. In depressed adults with MASLD, MHU decreased with older age (>20%, 15-18%, and 10.8% in <50, 50-69 and >70 years), lower education, lower income, and lowest in Asian adults (7.1% vs 18-38% for other groups), all $P<0.0001$. Between 2005 and 2023 (**Figure 1A**), depression became more prevalent in both the MASLD (22.4% to 28.4%, P_{trend}=0.033) and non-MASLD groups (16.7% to 26.2% ($P_{trend}<0.0001$); however, there was no significant changes in MHU in either group (P_{trend} =0.282 and 0.412). In multivariable adjusted models (**Figure 1B**), MASLD was associated with higher odds of depression (adjusted odds ratio [aOR]: 1.57, 95% CI: 1.43 – 1.72, $p<0.0001$), with older age, male sex, Asian race, having higher education or income, and being foreign-born associated with lower odds of having depression (all $P<0.05$); while factors associated with lower odds of MHU were also older age, lower education or income, and being foreign born, with MASLD also trending towards a lower odds of MHU (aOR: 0.82, 95% CI: 0.66 – 1.01, $p=0.067$). **Conclusion:** US adults with MASLD were more likely to suffer from depression but less likely to seek mental health care. The prevalence of depression also increased over time but without corresponding increase in MHU. These findings support integrating mental health screening and care in MASLD management, especially for higher risk subgroups.

3422 | BOTH NUTRITIONAL INTERVENTION AND LOW-DOSE ORAL SEMAGLUTIDE DECREASE HEPATIC FAT IN ADOLESCENTS WITH POLYENDOCRINE METABOLIC OVARY SYNDROME AND HEPATIC STEATOSIS

Gabriel Medrano[1] Nazeen Morelli[1] Jaclyn Lo[1] Grayson Carey[1] Meredith Ware[1] Yesenia Garcia-Reyes[1] Carly Faulkner[2] Allison Shapiro[1] Melanie Cree[1], [1]Children's Hospital Colorado, University of Colorado Anschutz Medical Campus, [2]Children's Hospital Colorado

Background: Polyendocrine metabolic ovary syndrome (**PMOS**), formerly known as PCOS, is a hyperandrogenic condition affecting up to 20% of females with obesity and is associated with increased risk of metabolic dysfunction-associated steatotic liver disease (**MASLD**). Despite the high prevalence of MASLD in adolescent-onset PMOS, there are

currently no approved pharmacologic therapies. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) improve hepatic steatosis and fibrosis in adults, yet effects in youth remain unclear. We investigated if low-dose oral semaglutide treatment reduces hepatic fat in adolescents with obesity, hepatic steatosis (**HS**), and PMOS compared with dietary intervention. **Methods:** Adolescents with PMOS and obesity were enrolled in a 16 week partially randomized trial (n = 54, 12-21 years, BMI ≥ 90th percentile for age and sex; NCT03919929). Girls received either 16 weeks of oral semaglutide (**SEMA**, Rybelsus©) or intensive nutritional counseling (**DIET**). The dose of SEMA was 3 mg/day for 4 weeks followed by 7 mg/day for 12 weeks. Participants completed pre and post intervention visits with hepatic fat fraction quantified via MRI, and anthropometric measurements and fasting labs were obtained. Data from a subset of participants with HS (liver fat of ≥ 5.5%) are in this analysis (SEMA n = 24, DIET n = 9). Separate linear mixed effect models were used to examine change in hepatic fat (%), weight (kg), aspartate aminotransferase (AST, IU/L), alanine aminotransferase (ALT, IU/L), fasting glucose (mg/dL), HbA1c (%) from baseline to END.Data are shown as mean [SE], statistical significance was defined as $p < 0.1$. **Results:** After 16 weeks, both SEMA (-4.6 [0.84]) and DIET (-2.5 [0.6]) lost weight, with more in SEMA vs DIET ($p = 0.04$). Hepatic fat decreased in both (DIET: pre = 10.6 [2.0], post = 7.8 [1.9]; SEMA: pre = 13.1 [1.2], post = 9.8 [1.2]), with no difference in change between groups ($p = 0.75$). The relationship between change in hepatic fat and change in weight was not different between groups ($p = 0.97$). ALT and AST decreased in SEMA (ALT = -6.8 [2.9];AST = -2.0 [2.2]) compared to no change in DIET (ALT = 0.0 [3.1]; AST = 3.4 [4.4]), yet change between groups was not different ($p = 0.14$ and $p = 0.29$, respectively). Fasting glycerol, a marker of lipolysis, decreased more with SEMA ($p < 0.01$). Change in fasting glucose was similar for SEMA and DIET, but HbA1c decreased more in SEMA ($p = 0.09$). **Conclusion:** Sixteen weeks of dietary intervention or low-dose oral semaglutide both decreased hepatic fat in adolescents with PMOS, HS, and obesity. These data confirm the rapidity of decreases in hepatic fat in the setting of minimal weight loss. Future work with a larger cohort and longer duration of treatment with a stronger GLP1-RA are needed.

3423 | PERIPHERAL IMMUNE PROFILES DURING INTERFERON THERAPY IN CHRONIC HEPATITIS B PATIENTS WITH AND WITHOUT MASLD

Yingying Lin[1] Ke Yin[1] Jiarui Zheng[1] Jilian Fang[1] Shuzhen Jiang[1] Guangjun Song[1] Qian Jin[1] Xu Cong[1] Ran Fei[1] Huiying Rao[1] Bo Feng[2] Yan-Di Xie[1] Feng Liu[1], [1]Peking University People's Hospital, Peking University Hepatology Institute, Infectious Disease and, [2]Peking University People's Hospital

Background: Chronic hepatitis B (CHB) frequently occurs with metabolic dysfunction-associated steatotic liver disease (MASLD), but whether MASLD modifies peripheral immune-cell changes during interferon (IFN) therapy remains unclear. We assessed peripheral blood mononuclear cells (PBMCs) and clinical responses during IFN therapy in CHB patients with and without MASLD. **Methods:** We enrolled HBeAg-negative CHB patients receiving IFN-based therapy. A total of 41 patients were included, comprising 22 with CHB alone and 19 with CHB and concomitant MASLD. Clinical data and PBMCs were collected at weeks 0, 12, 24, and 48. NK, T, and NKT cells, B-cell subsets, and monocyte/myeloid subsets were quantified by flow cytometry. Treatment response was defined as a reduction in log10 HBsAg of ≥ 1 from baseline. On-treatment changes were analyzed using linear mixed-effects models (LMMs), and associations between immune-cell changes and log10 HBsAg decline were assessed using Spearman correlation analysis. **Results:** At baseline, CHB+MASLD patients had higher GGT, triglyceride levels, and platelet counts and lower HDL-C, consistent with a metabolic phenotype. During IFN therapy, log10 HBsAg declined significantly over time in both groups (LMM time effect, $P < 0.001$). However, neither the overall difference between CHB and CHB+MASLD nor the group-by-time interaction was significant. Treatment response rates were similar between groups [CHB: 8(36.4%); CHB +MASLD: 7(36.8%)]. However, aminotransferase trajectories differed: ALT and AST increased transiently at week 12 and then declined in CHB alone, whereas both enzymes peaked at week 24 in CHB+MASLD, suggesting delayed aminotransferase elevation during IFN therapy. Flow cytometry showed significant on-treatment changes in multiple peripheral immune-cell subsets. Response-stratified LMMs identified response-by-time interactions for CD27+ NK cells, transitional B cells, plasma cells, and CD14-CD16- myeloid/monocyte-like cells. PCA indicated treatment-related shifts in the overall immune-cell profile, with different patterns between CHB and CHB+MASLD patients. HBsAg decline was associated with changes in CD57+ NKT cells, CD57+ T cells, NKG2A+ NK cells,

mDCs, and CD14-CD16- myeloid/monocyte-like cells. Stratified analyses suggested different immune correlates of HBsAg decline: M1-like monocytes and CD57+ NKT cells in CHB, and CD14-CD16- myeloid/monocyte-like cells and B cells percentage in CHB+MASLD. **Conclusion:** IFN therapy was associated with marked changes in peripheral immune-cell subsets. Concomitant MASLD did not affect short-term response, but was linked to distinct biochemical trajectories and immune-cell response patterns. Larger studies are needed to validate these findings and define the immune mechanisms of IFN response in CHB with MASLD.

3425 | SPLEEN STIFFNESS AND SEVERITY OF MUSCLE FAT QUANTITY ARE INDEPENDENT DETERMINANTS OF NEUROCOGNITIVE FUNCTION IN COMPENSATED CIRRHOSIS DUE TO METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Arun Sanyal[1] Mohammad Siddiqui[2] Mikael Forsgren[3] Manal Abdelmalek[4] Amon Asgharpour[1] Richard Sterling[1] Jasmohan Bajaj[1] Samar Okaily[5] Ekaterina Smirnova[1], [1]Virginia Commonwealth University, [2]UVA, [3]AMRA Medical AB, [4]Mayo Clinic Rochester, [5]VCU

Background: Sarcopenia and myosteatosis are associated with overt hepatic encephalopathy. However, in compensated cirrhosis due to MASLD, the effects of muscle volume versus fat quantity in specific compartments on neurocognitive function are unknown especially after correcting for confounders (visceral adipose tissue (VAT) volume, liver function, fibrosis-burden and portal hypertension). **Aims:** To define (1)alternations in specific muscle compartments (2) the relationship of muscle volume vs fat in limb vs central muscles on neuro-cognitive function in MASH cirrhosis. **Methods:** A prospective study of compensated MASH. Muscle fat was quantified as the muscle fat infiltration (MFI); MFI, muscle and adipose tissue volumes (total, abdominal subcutaneous, and visceral) were quantified by highly reproducible MRI methods. Liver- and spleen-stiffness measurements (LSM, SSM) served as surrogates for fibrosis burden and portal hypertension respectively. Neuro-cognitive function was assessed from the Stroop test off-time (psychomotor function), on-time (cognitive flexibility) and difference in on- and off-times (higher time = worse cognition). Concordance was determined from Pearson correlation. Multiple regression was used to determine determinants Stroop off and ontime. **Results:** 127 individuals with compensated MASH cirrhosis were evaluated. The cohort was predominantly white (90%) and female (69%). Mean LSM was 23 kPa and CAP was 287 db/m while SSM was 46 kPa. Laboratory showed (mean): bilirubin 0.85 mg/dl, AST 44 IU/l, ALT 44 IU/l, albumin 4.2 gm/dl, INR 1.1, creatinine 0.85 mg/dl. Mean off-time was 79 sec and on-time was 95 sec with 5.5 (off time) and 5.8 (on-time) runs needed. There was strong concordance between ASAT and VAT as well as between spinal erector and thigh muscle volume and MFI ($p < 0.01$ for all). There was strong concordance between right and left side and between anterior vs posterior thigh for muscle parameters ($p < 0.001$ for all). Regression analyses (univariate followed multivariate) identified SSM, MFI (either spinal or thigh) and VAT to be independent predictors of off-time, on-time and their difference. LSM, CAP, BMI, total adipose tissue and ASAT, muscle volumes, liver enzymes and function were not significantly associated. **Conclusion:s:** SSM and MFI rather than sarcopenia or liver stiffness are key determinants of psychomotor and cognitive flexibility outcomes of neuro-cognitive functions in compensated MASH cirrhosis.

	Coefficients	p	$r_{partial}$
Spleen stiffness	0.65	<0.0001	0.75
Spinal MFI	1.8	0.008	0.44
Spinal Muscle volume	28	n.s.	0.18
VAT	-2.6	n.s.	-0.3
LSM	-0.1	n.s.	-0.22
Bilirubin	-0.9	n.s.	-0.045

F-ratio 8.35, p< 0.0001, n.s. = not significant

3426 | THE LEAN MASLD PARADOX: WORSE LIVER BIOMARKERS WITH LOWER ADVANCED LIVER DISEASE BURDEN

Hassan Sinan[1] Jazmin Mexia Cabrales[1] Fatima Shafiq[1] Madonna Johnson[1] Philip Juliano[1] Frances Lee[2],
[1]Icahn School of Medicine at Mount Sinai / Elmhurst,
[2]Icahn School of Medicine at Mount Sinai

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease and is associated with obesity and metabolic syndrome. Lean MASLD has emerged as a distinct phenotype that may still carry significant fibrosis risk despite lower metabolic burden. Our aim is to compare fibrosis burden and liver disease severity between lean and non-lean MASLD patients, with a focused subgroup analysis in Hispanic patients. **Methods:** We conducted a cross-sectional study on inpatient adults with MASLD between January 2025 and January 2026 at a large urban safety-net hospital in a major metropolitan area. Lean was defined as BMI < 25 kg/m^2 (< 23 for Asian patients). Patients with other chronic liver diseases such as hepatitis B, hepatitis C, alcohol-related liver disease, autoimmune hepatitis, primary biliary cholangitis, and primary sclerosing cholangitis, were excluded. Noninvasive testing for fibrosis was assessed using FIB-4 and SAFE scores. Multivariable logistic regression evaluated lean status as a predictor of advanced fibrosis , defined as FIB-4 > 2.6 , and cirrhosis, based on imaging, adjusting for demographics, metabolic comorbidities, and liver biochemistries. A pre-specified subgroup analysis was performed in Hispanic patients. **Results:** A total of 1,545 patients with MASLD were included. 471 (30.5%) were classified as lean and 1,074 (69.5%) as non-lean. Lean patients were significantly older than non-lean patients (56.0 vs 52.8 years, $p = 0.001$), had lower triglyceride levels (148.0 vs 257.1, $p = 0.001$) and mean lower systolic blood pressure (129.2 vs 133.1 mmHg, $p = 0.004$). Lean patients had significantly higher AST: ALT ratios (1.83 vs. 1.60, $p < 0.001$) and higher FIB-4 score (6.27 vs 5.32, $p = 0.05$) with the FIB-4 stage distribution differing between groups ($p = 0.016$) with lean patients more frequently classified within the F4–F6 fibrosis category (56.8% vs 52.5%). However, lean patients had lower mean SAFE score (194.3 vs 218.6, $p = 0.019$) and lower rates of cirrhosis (6.8% vs. 11.2%, $p = 0.010$). On multivariate analysis, lean status was independently associated with lower odds of cirrhosis (adjusted OR 0.46, 95% CI 0.29–0.69, $p < 0.001$). In a subgroup analysis, compared to their non-lean Hispanic counterparts, lean Hispanic patients had higher AST:ALT ratios (1.84 vs. 1.65, $p = 0.02$), but had lower odds of cirrhosis (adjusted OR 0.47, 95% CI 0.27–0.80, $p = 0.006$) and lower odds of advanced fibrosis (adjusted OR 0.59, 95% CI 0.37–0.93, $p = 0.02$). **Conclusion:** Lean MASLD patients demonstrated a distinct clinical and biochemical profile compared to non-lean MASLD patients. Despite exhibiting higher AST:ALT ratios and elevated FIB-4 scores, lean patients had lower rates of cirrhosis and lower odds of advanced liver disease. These findings highlight the heterogeneity of MASLD and reinforce the importance of individualized fibrosis risk stratification.

3427 | PERFORMANCE OF THE METABOLIC DYSFUNCTION-ASSOCIATED FIBROSIS 5 (MAF-5) SCORE, FIBROSIS-4 (FIB-4) INDEX, AND ASPARTATE AMINOTRANSFERASE-TO-PLATELET RATIO INDEX (APRI) FOR IDENTIFYING SIGNIFICANT LIVER FIBROSIS IN A SAUDI COHORT: THE GENESIS STUDY

Saleh Alqahtani[1] Shadan AlMuhaidib[2] Basmah Khoja[3] Feras Altunisi[2] Bandar Al-Judaibi[3] Abdullah Alharbi[4] Alwaleed Almojel[5] Dieter Broering[3] Faisal Sanai[6] Waleed Alhazzani[2], [1]King Faisal Specialist Hospital & Research Center, [2]Research and Innovation Institute, Ministry of Defense Health Services, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [4]Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [5]King Fahad Military Medical Complex, Dhahran, Saudi Arabia, [6]King Abdulaziz Medical City, King Abdullah International Medical Research Center, Jeddah, KSA

Background: Non-invasive scores are recommended to triage patients at risk of significant liver fibrosis. The Metabolic Dysfunction-Associated Fibrosis 5 (MAF-5) score was recently derived and externally validated in European and Latin American populations. Performance in Middle Eastern cohorts is limited. We evaluated MAF-5, the Fibrosis-4 (FIB-4) Index, and the Aspartate Aminotransferase-to-Platelet Ratio Index (APRI) against vibration-controlled transient elastography (VCTE)-defined significant fibrosis in the Saudi GENESIS cohort. **Methods:** We analyzed 2,979 adults with valid VCTE and laboratory data enrolled in GENESIS. The reference outcome for fibrosis was liver stiffness measurement (LSM) ≥8 kPa by VCTE, indicating significant fibrosis. We calculated FIB-4, APRI, and MAF-5 using published formulas. APRI used a constant aspartate aminotransferase (AST) upper limit of normal of 40 U/L. We assessed discrimination using the area under the receiver operating characteristic curve (AUC). We reported sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy at prespecified high-risk cutoffs with Wilson 95% confidence intervals (CIs). **Results:** LSM ≥8 kPa was present in 57 of 2,979 participants (1.9%) in the GENESIS cohort. MAF-5 achieved the highest discrimination (AUC 0.868, 95% CI 0.821–0.916) and demonstrated higher discrimination than APRI (AUC 0.665, 95% CI 0.583–0.747) and FIB-4 (AUC 0.651, 95% CI 0.580–0.721). At the high-risk cutoff, MAF-5 (>1) detected 75.9% (95% CI 63.1–85.4) of cases with 84.3% specificity (95% CI 82.9–85.7). FIB-4 (>2.67) and APRI (>1.50) detected 1.8% (95% CI 0.3–9.4) and 0.0% (95% CI 0.0–6.4) of cases, respectively. PPV was low across all scores (MAF-5 9.1%, FIB-4 5.9%, APRI 0.0%), reflecting the low prevalence of significant fibrosis in this cohort. Overall accuracy was 84.2% for MAF-5, 97.4% for FIB-4, and 97.8% for APRI; the apparently higher accuracy of FIB-4 and APRI reflects their near-universal classification of participants as low-risk in a low-prevalence cohort rather than true diagnostic performance. **Conclusion:** MAF-5 showed better discrimination and substantially higher sensitivity for VCTE-defined significant fibrosis than FIB-4 and APRI in this Saudi cohort. FIB-4 and APRI at standard high cutoffs missed the majority of cases with LSM ≥8 kPa. These findings, limited by the small number of fibrosis cases, support further evaluation of MAF-5 in regional fibrosis screening pathways.

Table 1. Diagnostic performance of MAF-5, FIB-4, and APRI for liver stiffness measurement ≥8 kPa in the GENESIS cohort (n = 2,979).

Score	AUC (95% CI)	High-risk cutoff	Sensitivity, % (95% CI)	Specificity, % (95% CI)	PPV, % (95% CI)	NPV, % (95% CI)	Accuracy, % (95% CI)
MAF-5	0.868 (0.821–0.916)	>1	75.9 (63.1–85.4)	84.3 (82.9–85.7)	9.1 (6.7–12.0)	99.4 (99.0–99.7)	84.2 (82.7–85.5)
FIB-4	0.651 (0.580–0.721)	>2.67	1.8 (0.3–9.4)	99.4 (99.0–99.6)	5.9 (1.0–27.0)	97.9 (97.3–98.4)	97.4 (96.7–97.9)
APRI	0.665 (0.583–0.747)	>1.50	0.0 (0.0–6.4)	99.9 (99.7–100.0)	0.0 (0.0–56.1)	97.9 (97.3–98.4)	97.8 (97.2–98.3)

Abbreviations: APRI, Aspartate Aminotransferase-to-Platelet Ratio Index; AUC, area under the receiver operating characteristic curve; CI, confidence interval; FIB-4, Fibrosis-4 Index; MAF-5, Metabolic Dysfunction-Associated Fibrosis 5; NPV, negative predictive value; PPV, positive predictive value.

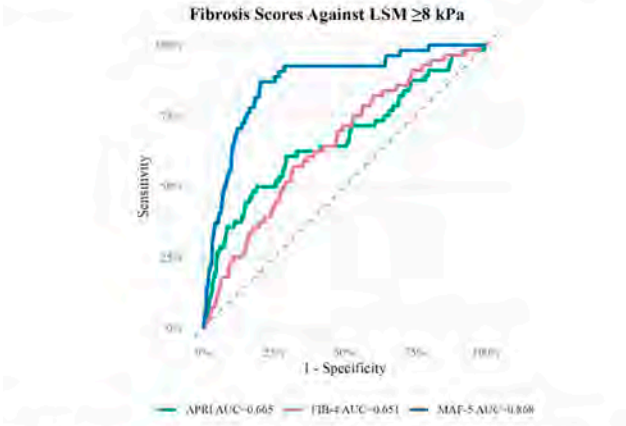

Figure 1. Receiver operating characteristic curves for the Metabolic Dysfunction-Associated Fibrosis 5 (MAF-5) score, the Fibrosis-4 (FIB-4) Index, and the Aspartate Aminotransferase-to-Platelet Ratio Index (APRI) against liver stiffness measurement (LSM) ≥8 kPa in the GENESIS cohort. The diagonal dashed line represents non-informative discrimination.

3428 | MASLD AS A PREDICTOR OF HEPATOTOXICITY AND CLINICAL OUTCOMES IN LUNG CANCER PATIENTS RECEIVING IMMUNE CHECKPOINT INHIBITORS: A PROPENSITY-MATCHED STUDY

Adham Obeidat[1] Muralidhar Idamakanti[1] Ahmad Alqam[2] Christopher Chang[2], [1]Presbyterian Medical Group, [2]University of New Mexico

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is increasingly recognized as a systemic metabolic disorder that may influence cancer outcomes, immune response, and susceptibility to liver injury. Although immune checkpoint inhibitors (ICIs) have significantly improved outcomes in lung cancer, hepatotoxicity remains an important immune-related adverse event. Data evaluating the impact of MASLD on ICI-related hepatotoxicity and other clinical outcomes in lung cancer are limited. We aimed to assess the association between MASLD and hepatotoxicity-related and systemic outcomes among lung cancer patients treated with ICIs. **Methods:** We performed a retrospective cohort study using the TriNetX Research Network. Adult lung cancer patients receiving immune checkpoint inhibitors (ICIs) were stratified by the presence or absence of MASLD. After propensity score matching for baseline demographic and clinical characteristics, 17,589 patients remained in each cohort. Post-matching outcomes included acute liver injury, acute liver failure, hyponatremia, ICU admission, hemolytic anemia, acute kidney injury (AKI), sepsis, gastrointestinal immune-related adverse events, and all-cause mortality. Associations were reported as odds ratios (ORs) with 95% confidence intervals (CIs). **Results:** After propensity matching, baseline characteristics were well balanced between cohorts. MASLD was associated with higher odds of acute liver injury (OR 2.38, 95% CI 1.88–3.02) and acute liver failure (OR 3.17, 95% CI 2.43–4.13). Increased odds of AKI, sepsis, hyponatremia, and GI immune-related adverse events were also observed (Table 1). Despite this, MASLD was associated with lower all-cause mortality (OR 0.78, 95% CI 0.73–0.84) and reduced ICU admission (OR 0.35, 95% CI 0.21–0.60). Kaplan-Meier analysis similarly demonstrated lower mortality in the MASLD cohort (HR 0.78, 95% CI 0.73–0.83; log-rank $P < 0.001$). **Conclusion:** In this large propensity-matched analysis, MASLD was associated with significantly increased odds of liver-related toxicity and systemic complications, including AKI, sepsis, hyponatremia, and GI immune-related adverse events. To our knowledge, this represents one of the largest real-world studies evaluating MASLD as a predictor of ICI-related hepatotoxicity in lung cancer. Although lower mortality was observed in the MASLD cohort, this finding should be interpreted cautiously given the potential for residual confounding and selection bias. These findings suggest MASLD may identify a high-risk subgroup warranting closer hepatic and systemic toxicity surveillance during ICI therapy.

Table 1. Propensity-Matched Analysis of Hepatic and Systemic Outcomes by MASLD Status in Lung Cancer Patients Receiving ICIs

Outcome	MASLD events / N	MASLD risk	No MASLD events / N	No MASLD risk	Risk difference (95% CI)	Risk ratio (95% CI)	Odds ratio (95% CI)	P value
Acute liver injury	234 / 17,589	1.33%	99 / 17,589	0.56%	0.77% (0.57 to 0.97)	2.36 (1.87-2.99)	2.38 (1.88-3.02)	<0.001
Acute liver failure	226 / 17,589	1.28%	72 / 17,589	0.41%	0.88% (0.68 to 1.07)	3.14 (2.41-4.09)	3.17 (2.43-4.13)	<0.001
Hyponatremia	1,907 / 17,589	10.84%	1,644 / 17,589	9.35%	1.50% (0.87 to 2.12)	1.16 (1.09-1.23)	1.16 (1.10-1.26)	<0.001
ICU admission	18 / 17,589	0.10%	51 / 17,589	0.29%	-0.19% (-0.28 to -0.10)	0.35 (0.21-0.60)	0.35 (0.21-0.60)	<0.001
Mortality	1,710 / 17,589	9.72%	2,124 / 17,589	12.08%	-2.35% (-3.00 to -1.70)	0.81 (0.76-0.85)	0.78 (0.73-0.84)	<0.001
Hemolytic anemia	52 / 17,361	0.30%	34 / 17,411	0.20%	0.10% (-0.00 to 0.21)	1.53 (1.00-2.36)	1.54 (1.00-2.37)	0.050
AKI	1,621 / 17,589	9.22%	1,428 / 17,589	8.12%	1.10% (0.51 to 1.69)	1.14 (1.06-1.22)	1.15 (1.07-1.24)	<0.001
Sepsis	1,326 / 17,589	7.54%	1,164 / 17,589	6.62%	0.92% (0.39 to 1.46)	1.14 (1.06-1.23)	1.15 (1.06-1.25)	<0.001
GI irAEs (Gastritis and colitis)	633 / 14,375	4.40%	525 / 15,287	3.43%	0.97% (0.53 to 1.41)	1.28 (1.14-1.44)	1.30 (1.15-1.46)	<0.001

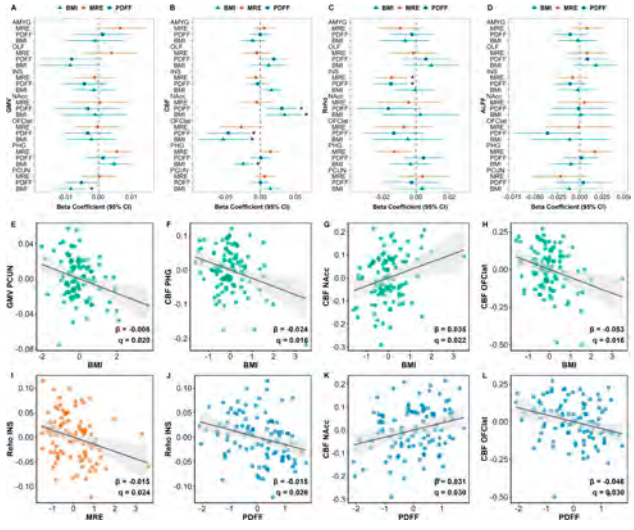
3429 | HETEROGENEOUS BRAIN INVOLVEMENT IN MASLD: INSIGHTS FROM CONTINUOUS AND PHENOTYPE-BASED ANALYSES



Zhuoru Jiang[1] Qian Chen[1] Jun Chen[2] Jie Li[3], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, [2]Mayo Clinic Rochester, [3]Nanjing Drum Tower Hospital

Background: Previous studies have shown that liver fibrosis is associated with changes in brain imaging. However, the relationship between other dimensions of MASLD and brain imaging remains unclear. This study

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

aims to determine which brain regions are associated with different parameters of MASLD, and then to observe the brain changes of MASLD subtypes according to these parameters. **Methods:** This study included 34 healthy controls and 101 MASLD patients. Regression models were used to examine associations of body mass index (BMI), hepatic fat content, and liver stiffness with brain structure, function and perfusion of pre-defined regions across the continuous disease spectrum. K-means clustering based on systemic metabolic and hepatic indices was applied to identify distinct clinical phenotypes and compare their neuroimaging profiles. **Results:** Higher BMI was associated with lower gray matter volume in the precuneus, increased cerebral blood flow in the nucleus accumbens, and reduced cerebral blood flow in the lateral orbitofrontal and parahippocampal regions. Higher hepatic fat content showed a similar perfusion pattern, whereas liver stiffness demonstrated a more limited association pattern and was linked mainly to reduced regional homogeneity in the insula. The subgroup characterized by severe obesity and steatosis exhibited the most pronounced brain abnormalities, whereas the liver stiffness-dominant phenotype showed less extensive alterations. **Conclusion:** The neurological involvement of MASLD is better characterized using complementary continuous and phenotype-based frameworks than by viewing the disease as a uniform entity. The findings suggest that obesity-related burden and hepatic steatosis are more strongly associated with multimodal brain abnormalities than liver stiffness in this cohort., highlighting the importance of moving beyond liver-centered evaluation in MASLD.

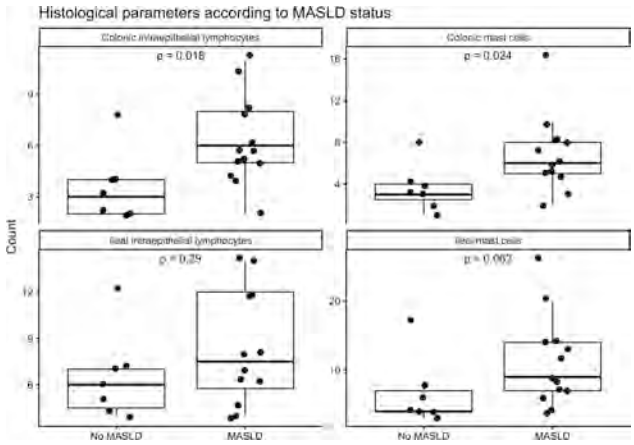
3430 | HIGH-DIMENSIONAL MASS CYTOMETRY PROFILING OF CIRCULATING IMMUNE ALTERATIONS IN MASLD AND DRUG-INDUCED STEATOSIS

Raúl J. Andrade[1] Daniel Di Zeo-Sánchez[2] Marina Villanueva[3] Vanesa Garrido-Rodríguez[4] Irene Díaz Alberola[3] Ángela Remesal Doblado[3] Gonzalo Matilla Cabello[2] Antonio Segovia-Zafra[3] José Pinazo Bandera[5] Miren Garcia Cortes[5] Francisco Ruiz Cabello[6] Mercedes Robles-Díaz[2] Eduardo García Fuentes[7] Camilla Stephens[2] M Lucena[2],
[1]IBIMA-Plataforma Bionand / Universidad de Málaga / CIBERehd, [2]IBIMA-Plataforma Bionand, UMA, CIBERehd, [3]IBIMA-Plataforma Bionand, UMA, [4]IBIMA Plataforma Bionand, UMA, [5]IBIMA-Plataforma Bionand, HUVV, [6]IBS, Hospital Universitario Virgen de las Nieves, [7]IBIMA-Plataforma Bionand, CIBERehd

Background: Immune mechanisms contributing to MASLD progression and drug-induced steatosis (DIS) remain incompletely characterized. We applied high-dimensional single-cell mass cytometry (CyTOF) to define circulating immune alterations across MASLD fibrosis stages and compare MASLD with DIS. **Methods:** Peripheral blood was obtained from 32 healthy controls (HC), 17 patients exposed to steatogenic drugs with normal liver tests (CON), 13 DIS patients, 16 MASLD patients with F0-F1 fibrosis, and 15 MASLD patients with F2-F4 fibrosis. Whole blood was analyzed by CyTOF using a 30-marker panel. PBMC and granulocyte populations were identified by unsupervised FlowSOM and PhenoGraph clustering, respectively. Cell frequencies and median marker intensities were compared using Kruskal-Wallis/Dunn tests with Benjamini-Hochberg correction. **Results:** 38 PBMC metaclusters and 17 granulocyte clusters were identified. Compared with HC, MASLD F0-F1 and F2-F4 patients showed 29 and 28 significantly altered immune parameters, respectively. Regardless of fibrosis stage, MASLD patients exhibited higher frequency of an activated γδ T-cell-enriched metacluster, reduced CD127 expression in CD4+ T-cell subsets with mixed Th phenotypes and in MAIT/NKT-like cells. MASLD with F2-F4 showed additional loss of MAIT/NKT-like cells and lower frequency of activated plasmacytoid dendritic cells than HC. Differences between MASLD fibrosis stages were limited to the granulocyte compartment, where F2-F4 patients showed lower CD45RA expression than F0-F1 patients in several neutrophil clusters. DIS showed no significant differences compared with CON or MASLD F0-F1, but displayed higher activated pDC frequency than MASLD F2-F4.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



Conclusion: MASLD was associated with a circulating immune profile consistent with chronic immune activation and altered immune regulation, involving γδ T cells, reduced CD127 expression in T-cell subsets, and granulocyte remodeling. The additional reduction of MAIT/NKT-like cells in MASLD F2-F4 may reflect overactivation or exhaustion of innate-like T cells, potentially contributing to advanced disease by limiting their regulatory functions. These findings highlight the potential of immune profiling for patient risk stratification and monitoring in steatotic liver disease, paving the way for more personalized patient management. 3431 | INTESTINAL MUCOSAL AND IMMUNE ALTERATIONS IN MASLD: A PILOT STUDY

Nicolás Ortiz-López[1] Tamara Alarcón[1] María Jesús Vera[2] Camila Farías[2] Rodrigo Valenzuela[2] Jaime Poniachik[1], [1]Hospital Clínico Universidad de Chile, Santiago, Chile, [2]Universidad de Chile, Santiago, Chile

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) has been increasingly associated with alterations in the gut–liver axis. However, intestinal histological findings in MASLD remain poorly characterized in humans. We aim to characterize histological alterations in the intestinal mucosa in patients with MASLD. **Methods:** In this prospective cross-sectional pilot study, consecutive adults undergoing screening colonoscopy were recruited. Participants with known inflammatory bowel disease, functional gastrointestinal disorders, or other chronic liver diseases were excluded. Ileal and colonic biopsies were obtained, and all participants subsequently underwent FibroScan®. MASLD was defined by the presence of hepatic steatosis and at least one cardiometabolic risk factor. Histological evaluation was performed by a blinded gastrointestinal pathologist using hematoxylin-eosin, alcian blue, and Giemsa stains. **Results:** Twenty patients were included (13 with MASLD and 7 without MASLD). Median age was 60 (47–65) years in the MASLD group and 62 (55–65) years in the non-MASLD group. Patients with MASLD had significantly higher body mass index. Colonic intraepithelial lymphocyte counts per 100 enterocytes were significantly higher in MASLD patients compared with controls (6 [2–11] vs 3 [2–8], p = 0.018). Colonic mast cell density per high-power field was also increased in MASLD (6 [2–16] vs 3 [1–8], p = 0.024). Ileal mast cell counts showed a similar trend in MASLD patients (9 [4–26] vs 4 [3–17], p = 0.062). Colonic immune alterations were more pronounced than ileal changes (Figure). Additional histological findings, including epithelial erosions, architectural alterations, mucin depletion, and cytoplasmic vacuolization, were observed without significant between-group differences. Correlation analyses demonstrated a positive correlation between colonic mast cell density and liver stiffness measurements (rho = 0.49, p = 0.048), while colonic intraepithelial lymphocyte counts showed a similar non-significant trend (rho = 0.46, p = 0.061). **Conclusion:** MASLD was associated with increased colonic immune cell infiltration, particularly intraepithelial lymphocytes and mast cells. The observed correlations between colonic immune cell density and liver stiffness measurements suggest a potential link between intestinal immune activation and liver disease severity in MASLD. These findings support a potential role of intestinal immune activation in MASLD pathophysiology and further reinforce the relevance of the intestine within the gut–liver axis.

3432 | LISINOPRIL FOR FIBROSIS AND HEPATOCELLULAR CARCINOMA RISK MODULATION IN MASLD WITH ADVANCED FIBROSIS: RESULTS FROM A PHASE IIA MULTICENTER CLINICAL TRIAL

Ju Dong Yang[1] Manal Abdelmalek[2] Cynthia Moylan[3] Augusto Villanueva[4] Douglas Dieterich[5] Masha Kocherginsky[6] Latifa Bazzi[6] Tia Schering[7] Kelly Benante[7] Yujin Hoshida[8] Courtney Katz[8] Osama Khattab[1] Ashley Kim[1] Manaf Alsudaney[1] Mai Abdusamad[1] Ekihiro Seki[1] Jieun Kim[1] Luz Maria Rodriguez[9] Asad Umar[9] Gary DellaZanna[9] Mazen Noureddin[10] Seema Khan[11], [1]Karsh Division of Gastroenterology and Hepatology, Cedars-Sinai Medical Center, Los Angeles, CA, USA, [2]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, USA, [3]Division of Gastroenterology, Duke University Health System, Durham, NC, USA, [4]NYU Langone Health, [5]Tisch Cancer Institute, Icahn School of Medicine at Mount Sinai, New York, NY, USA, [6]Department of Preventive Medicine, Northwestern University Feinberg School of Medicine, Chicago, IL,, [7]Robert H. Lurie Comprehensive Cancer Center, Northwestern Memorial Hospital, Chicago, IL, USA, [8]Division of Digestive and Liver Diseases, University of Texas Southwestern Medical Center, Dallas, T, [9]Division of Cancer Prevention, NCI, Bethesda, MD, USA, [10]Lynda K. and David M. Underwood Center for Digestive Disorders Sherrie & Alan Conover Center for Liv, [11]Department of Surgery, Northwestern University Feinberg School of Medicine, Chicago, IL, USA

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is an emerging leading cause of hepatocellular carcinoma (HCC). The renin–angiotensin system contributes to hepatic fibrogenesis and carcinogenesis. Lisinopril, an angiotensin-converting enzyme inhibitor, has demonstrated anti-fibrotic and anti-inflammatory effects in preclinical models and may reduce HCC risk. This phase IIa study evaluated the effect of lisinopril on fibrosis and HCC-related biomarkers in patients with MASLD and advanced fibrosis. **Methods:** Multicenter, single-arm phase IIa clinical trial enrolled adults with MASLD and advanced fibrosis based on liver histology or screening transient elastography (TE) between12-25kPa with a target enrollment goal of 45. Participants received lisinopril 10 mg daily for 24 weeks. The primary endpoint was the change in PRO-C3. Secondary endpoints included changes in PRO-6, hepatic steatosis (CAP by TE), liver stiffness by magnetic resonance elastography [MRE] and TE, FIB-4, NFS, and inflammatory cytokines. Exploratory endpoints included changes in PLSec, liver enzymes, hepatic steatosis (MRI PDFF) and blood pressure. We hypothesized that treatment of MASLD with advanced fibrosis using lisinopril will lead to improvement in PRO-C3 values, which will correlate with decrease in measurements of MASLD disease activity. **Results:** A total of 35 patients (median age 63, female 43%, Hispanic 31%) were enrolled and started the intervention. Participants had a median liver stiffness of 15.7 kPa and CAP of 309 dB/m at baseline. The primary endpoint, change in PRO-C3, did not demonstrate a significant difference after 24 weeks of lisinopril therapy (**Table**). Despite this, significant improvements were observed in several key secondary endpoints. Hepatic steatosis decreased as measured by CAP (mean 320 to 307 dB/m; $p = 0.04$), and liver stiffness measured by MRE improved (mean 4.78 to 4.48 kPa; $p = 0.04$). Exploratory analyses demonstrated additional favorable changes. Systolic blood pressure significantly decreased (133 to 127 mmHg; $p < 0.01$). Alkaline phosphatase also declined (102 to 94 U/L; $p = 0.03$), suggesting potential improvement in cholestatic or inflammatory pathways. The prognostic liver secretome signature (PLSec), a novel biomarker associated with HCC risk, showed a trend toward reduction (3.26 to 2.81; $p = 0.09$). Lisinopril was generally well-tolerated. Grade ≥ 3 adverse events were infrequent ($n = 4$) and included infection and gastrointestinal events, not related to intervention. **Conclusion:** Lisinopril did not significantly improve PRO-C3 but demonstrated favorable changes in steatosis (CAP) and liver stiffness (MRE), with promising signals in PLSec, an exploratory HCC surrogate biomarker. The treatment was safe and supports further investigation in larger trials.

Table

Parameter	Baseline	Post-Treatment	P-value
PRO-C3 (ng/mL)	48	49	0.7
PRO-C6 (ng/mL)	14.1	13.6	0.6
CAP (dB/m)	320	307	0.04
MRE stiffness (kPa)	4.78	4.48	0.04
TE stiffness (kPa)	16.1	16.7	0.8
FIB-4 score	2.10	2.17	0.2
NFS	0.02	-0.01	0.9
Systolic BP (mmHg)	133	127	<0.01
MRI PDFF (%)	9	8	0.6
AST(U/L)	46	43	0.6
ALT(U/L)	55	51	0.2
Bilirubin (mg/dL)	0.75	0.76	0.7
ALP (U/L)	102	94	0.03
PLSec	3.26	2.81	0.09

3433 | SEX-STRATIFIED DIETARY CORRELATES OF MASLD IN SAUDI ADULTS: LOWER CAFFEINE INTAKE AMONG WOMEN IN THE GENESIS COHORT

Saleh Alqahtani[1] Tagreed Mazi[2] Shadan AlMuhaidib[3] Samar Alqussayer[3] Habeeb Razack[2] Basmah Khoja[4] Layan Alsubki[5] Saleh Alessy[5] Jehan Mahdi[6] Sara Khalil[6] Mona Ismail[7] Khalid AlNaamani[8] Waleed Alhazzani[3], [1]King Faisal Specialist Hospital & Research Center, [2]King Saud University, Riyadh, Saudi Arabia, [3]Research and Innovation Institute, Ministry of Defense Health Services, Riyadh, Saudi Arabia, [4]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [5]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [6]King Fahad Armed Forces Hospital, Jeddah, Saudi Arabia, [7]Imam Abdulrahman Bin Faisal University, [8]The Medical City for Military and Security Services, Muscat, Oman

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide, yet sex-stratified dietary correlates remain poorly characterized in Middle Eastern populations. We aimed to characterize sex-stratified dietary intake patterns associated with MASLD in Saudi adults enrolled in the prospective GENESIS cohort. **Methods:** We conducted a cross-sectional analysis within the prospective, population-based GENESIS study across seven primary care centers in Saudi Arabia between March 2024 and June 2025. Eligible adults underwent clinical assessment, laboratory testing, standardized vibration-controlled transient elastography (VCTE)-based hepatic phenotyping, and structured dietary assessment using a food frequency questionnaire (FFQ). MASLD was defined as controlled attenuation parameter (CAP) ≥ 268 dB/m with ≥ 1 cardiometabolic risk factor. We compared FFQ-derived intake of energy, macronutrients, fatty acids, and micronutrients between participants with and without MASLD, stratified by sex, using non-parametric tests. **Results:** Of 2,979 participants in the GENESIS cohort (mean age 41.9 years), 1,486 were men (49.9%) and 1,493 were women (50.1%). MASLD was present in 649 men (43.7%) and 462 women (30.9%). Participants with MASLD reported higher total daily energy intake than those without MASLD (2,729 versus 2,616 kcal/day, $P = 0.04$), and similar patterns were observed for several micronutrients, carotenoids, and saturated fatty acids across both sexes. Caffeine intake showed a sex-stratified pattern. Women with MASLD reported lower caffeine intake than those without MASLD (77.4 versus 104.3 mg/day; interquartile ranges [IQRs] 57.9–135.9 and 63.4–165.1, respectively; $P < 0.001$), representing a 25.8% relative difference. In men, caffeine intake did not differ between groups (143.2 versus 143.6 mg/day, $P = 0.86$). **Conclusion:** In this cross-sectional analysis within a prospective Saudi cohort, MASLD was associated with higher reported overall dietary intake, while lower caffeine intake was observed as an exploratory sex-stratified correlate among women with MASLD. This inverse association was observed despite higher total energy intake in the MASLD group, distinguishing caffeine from the broader dietary pattern and warranting further evaluation in energy-adjusted and metabolic-adjusted analyses. These findings support

prospective evaluation of caffeine intake as a sex-stratified dietary correlate of MASLD risk.

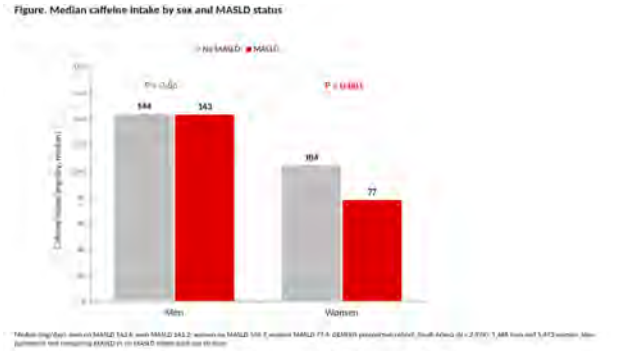

Figure 1. Sex-specific differences in caffeine intake by MASLD status.
GENESIS prospective cohort, Saudi Arabia (N = 2,979); 1,486 men (649 with MASLD) and 1,493 women (462 with MASLD). Median caffeine intake (mg/day): men without MASLD 143.6 versus men with MASLD 143.2 (P=0.86); women without MASLD 104.3 versus women with MASLD 77.4 (P<0.001). Group differences within each sex stratum assessed using non-parametric tests.

3434 | DOACS IN MASLD: ARE WE TARGETING FIBROSIS BY ACCIDENT?

Candy Lin[1] Mark Thursz[1] Shahid Khan[1] Fernando Lorra[1] Michael Yee[2] Pinelopi Manousou[1], [1]Imperial College London, [2]Imperial College Healthcare Trust

Background: Fibrosis stage is the main determinant of liver-related and all-cause mortality in metabolic dysfunction-associated steatotic liver disease (MASLD), yet effective antifibrotic therapies remain limited. Thrombin and Factor Xa promote fibrogenesis via protease-activated receptor (PAR) signalling in hepatic stellate cells. Direct oral anticoagulants (DOACs) inhibit these proteases and are commonly prescribed in patients with MASLD. We therefore hypothesised that DOAC exposure would be associated with reduced fibrosis progression in MASLD. **Methods:** We conducted a retrospective cohort study of adults with MASLD at Imperial College Healthcare NHS Trust (2017-2026), assessing fibrosis longitudinally using Fibrosis-4 (FIB-4) and transient elastography (TE) in a subset of patients. Exposure was defined as an active DOAC prescription at baseline. Consecutive patients receiving DOACs were compared with BMI and T2DM-matched MASLD control patients not receiving DOAC therapy. ANCOVA was used to compare follow-up FIB-4 between the DOAC-exposed group and the controls, adjusting for baseline FIB-4, age, sex, BMI, T2DM and hypertension. **Results:** Among 455 patients, 117 (25.7%) were DOAC-exposed. DOAC-exposed patients were older (median 65 vs 63 years, $p = .023$) and had higher baseline FIB-4 (2.16 vs 1.55, $p < .001$). Unadjusted FIB-4 change did not differ between groups (median ΔFIB-4: 0.03 vs 0.04, $p = .844$). In adjusted analyses, DOAC exposure was not associated with follow-up FIB-4 (β = -0.35, 95% CI -1.18-0.48; p = .405). Baseline FIB-4 was the strongest predictor of follow-up FIB-4 (β = 1.20, 95% CI 0.68-1.72; $p < .001$). TE-based analyses were consistent (ΔLSM: -0.9 vs -0.5kPa; p = .849). **Conclusion:** DOAC exposure was not associated with fibrosis progression in this cohort. Competing fibrogenic drivers (including lipotoxicity, inflammation and compensatory profibrotic pathways not targeted by anticoagulation) limit clinical translation of experimental antifibrotic effects. Prospective studies, including randomised controlled trials, evaluating histological or imaging-based endpoints, longer follow-up and detailed exposure stratification in people with MASLD are warranted.

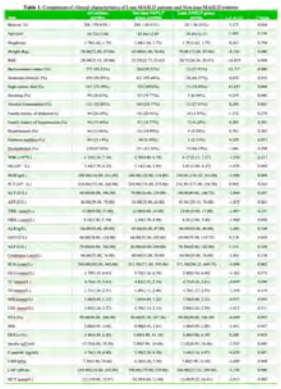
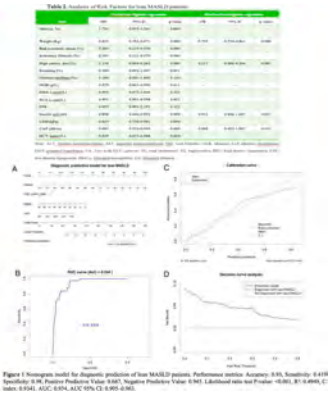
3435 | A NON-INVASIVE DIAGNOSTIC PREDICTION MODEL FOR LEAN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE PATIENTS



Weihua Cao[1] Yao Xie[1] Minghui Li[1], [1]Beijing Ditan Hospital, Capital Medical University



Background: Lean metabolic dysfunction-associated steatotic liver disease (Lean MASLD) is increasingly recognized, yet distinguishing it from non-lean MASLD remains a clinical challenge due to overlapping features. This study aimed to develop and validate a non-invasive diagnostic prediction model specifically for identifying Lean MASLD patients. **Methods:** This retrospective study included patients who underwent liver biopsy were diagnosed with MASLD at Beijing Ditan Hospital. Patients were categorized into Lean MASLD (BMI < 24 kg/m², n = 43) and Non-lean MASLD (BMI ≥ 24 kg/m², n = 440) groups. Clinical, laboratory, and transient elastography data were compared. Univariate and multivariate logistic regression analyses

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

were performed to identify independent predictors of Lean MASLD, which were then used to construct a nomogram. **Results:** A total of 483 biopsy-proven MASLD patients were retrospectively enrolled. Compared to the Non-lean group, the Lean MASLD group had significantly lower weight (median 65.00 vs. 79.00 kg, P < 0.001), BMI (23.29 vs. 28.71, P < 0.001), insulin (7.80 vs. 13.82 μU/ml, P < 0.001), liver stiffness measurement (LSM, 6.20 vs. 7.40 kPa, P < 0.001), and controlled attenuation parameter (CAP, 198.00 vs. 268.00 dB/m, P < 0.001), and a lower prevalence of high-caloric diet (34.88% vs. 80.00%, P < 0.001),in Table 1. Multivariate analysis confirmed lower weight (OR = 0.793, P < 0.001), lower insulin (OR = 0.915, P = 0.021), lower CAP (OR = 0.988, P = 0.011), and absence of a high-caloric diet (OR = 0.217, P = 0.001) as independent negative predictors for Lean MASLD in Table 2. The resulting nomogram demonstrated excellent discrimination, with an AUC of 0.934 (95% CI: 0.905-0.963), specificity of 0.98, and a significant likelihood ratio test (P < 0.001) in Figure 1. **Conclusion:** A highly specific nomogram based on readily available clinical parameters can effectively discriminate Lean MASLD from Non-lean MASLD. This tool may assist clinicians in the non-invasive identification of Lean MASLD, facilitating targeted management.

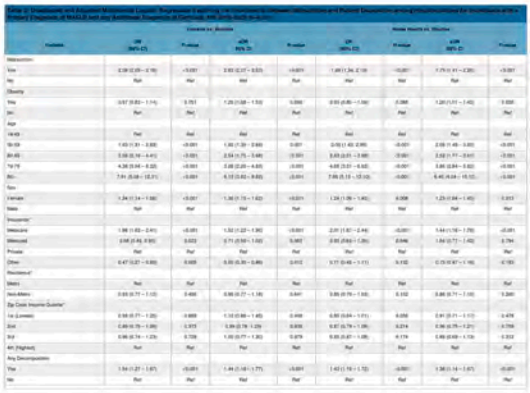
3436 | MALNUTRITION AND OBESITY ARE INDEPENDENTLY ASSOCIATED WITH NON-ROUTINE DISCHARGE AMONG HOSPITALIZED PATIENTS WITH MASLD CIRRHOSIS



McKenna Andrews[1] Paul Scott[2] Melissa White-Archer[2] Chakradhar Reddy[3], [1]East Tennessee State University Department of Internal Medicine, [2]East Tennessee State University, [3]East Tennessee State University Division of Gastroenterology

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of cirrhosis and liver-related hospitalization in the United States. We evaluated the association of malnutrition and obesity with inpatient outcomes among hospitalizations involving MASLD cirrhosis. **Methods:** Hospitalizations with a primary diagnosis of MASLD/NAFLD/ MASH (ICD-10: K76.0, K75.81) were selected from the Nationwide Inpatient Sample (2016-2023), Healthcare Cost and Utilization Project, Agency for Healthcare Research and Quality. Alcohol-related liver disease or viral hepatitis were excluded. Malnutrition was defined using ICD-10 codes E40–E46 or R64, and obesity using E66.x codes excluding E66.3. The primary outcome was discharge disposition; secondary outcomes included length of stay and total hospital charges. Weighted descriptive statistics and chi-square analyses were performed. Multinomial logistic regression models evaluated relationships between malnutrition, obesity, and discharge disposition before and after adjustment for demographic and clinical covariates, including decompensation events. An interaction term assessed whether obesity modified the effect of malnutrition on patient disposition. **Results:** Among 4,350 hospitalizations, most patients were older than 59 years (70.2%), female (63.7%), White (79.8%), and insured by Medicare (61.6%). Malnutrition was present in 14.7% and obesity in 33.2% of hospitalizations. Malnutrition was significantly associated with discharge disposition, length of stay, and total hospital charges (all p < 0.001). After excluding in-hospital deaths (N = 149), 4,201 hospitalizations were included in regression analyses. In adjusted models, malnutrition (aOR 2.83, 95% CI 2.27–3.53; p < 0.001) and obesity (aOR 1.28, 95% CI 1.08–1.53; p = 0.006) were associated with increased odds of transfer to another facility and discharge with home health services (malnutrition: aOR 1.79, 95% CI 1.41–2.26; p < 0.001; obesity: (aOR 1.20, 95% CI 1.01–1.42; p = 0.035) compared to routine discharge. No significant interaction was observed between malnutrition and obesity before (p = 0.655) or after adjustment (p = 0.790). Stratified analyses showed malnutrition remained associated with higher odds of transfer among both obese (aOR 2.59, 95% CI 1.65–4.06; p < 0.001) and non-obese patients (aOR 2.91, 95% CI 2.26–3.75; p < 0.001). Malnutrition was associated with home health discharge only among non-obese patients (aOR 1.86, 95% CI 1.42–2.43; p < 0.001). **Conclusion:** Among hospitalizations involving MASLD cirrhosis, both malnutrition and obesity were independently associated with increased odds of non-routine discharge. Malnutrition demonstrated the strongest association with adverse disposition outcomes regardless of obesity status. These findings support nutritional screening in hospitalized patients with MASLD cirrhosis.

3437 | PHYSICIANS' KNOWLEDGE, ATTITUDES, AND PRACTICES REGARDING PHYSICAL ACTIVITY IN MASLD MANAGEMENT: A CROSS-SECTIONAL SURVEY FROM SAUDI ARABIA

Salvatore Petta[1] Faisal Abaalkhail[2] Saad Alghamdi[3] Mohammed Alghamdi[4] Reem AlAhmed[2] Amwaj Alanazi[2] Sadeem Aldarwesh[2] Alanoud AlAdel[5] Ciro Celsa[1] Grazia Pennisi[1] Gabriele Di Maria[1] Saleh Alqahtani[2], [1]University of Palermo, Palermo, Italy, [2]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital and Research Center, [4]King Fahad Military Medical Complex, Dhahran, Saudi Arabia, [5]King Saud University, Riyadh, Saudi Arabia

Background: Physical activity is a cornerstone intervention for metabolic dysfunction-associated steatotic liver disease (MASLD), yet its implementation in clinical practice remains suboptimal. In Saudi Arabia, local data on physician-level implementation gaps remain limited. We assessed physicians' knowledge, attitudes, and practices regarding physical activity in the management of MASLD across Saudi Arabia. **Methods:** This cross-sectional survey (December 2025–January 2026) included hepatologists and other physicians managing patients with MASLD across Saudi Arabia. A 30-item questionnaire, developed by expert hepatologists and assessed for face and content validity, measured physical-activity knowledge, attitudes, clinical practices including counseling and referral, guideline use, and perceived barriers. Responses were compared by specialty (hepatologists vs. non-hepatologists) and experience (<10 vs. ≥ 10 years) using chi-square or Fisher's exact tests, with p-values adjusted using the Benjamini-Hochberg false discovery rate correction. **Results:** Among 171 physicians (63.7% hepatologists), 87.7% rated physical activity as "very important" in MASLD management. Knowledge gaps were substantial: only 58.5% correctly identified MASLD prevalence in Saudi Arabia, and only 23.4% correctly identified advanced fibrosis prevalence in the general population, with no significant difference by specialty or experience for either item. Guideline adherence differed markedly: 33.9% of non-hepatologists followed no clinical guidelines vs. 5.5% of hepatologists ($p<0.001$). Although 52.0% counseled at every visit, 76.6% spent <3 minutes doing so, with low use of written materials (8.2%) or specialist referrals (11.1%). Primary barriers were time constraints (62.6%), lack of resources (52.0%),

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and limited referral options (50.3%). Interest in additional training was high (70.8%), particularly among non-hepatologists. **Conclusion:** Despite broadly positive attitudes, Saudi physicians reported significant knowledge gaps and implementation barriers for physical activity counseling in MASLD. The low rate of guideline use among non-hepatologists represents a critical quality-of-care gap. Targeted educational interventions, enhanced guideline dissemination to non-specialists, and improved access to exercise specialists may help translate evidence into routine clinical practice.

3439 | PREVALENCE OF CHYLOMICRONEMIA SYNDROME AND SEVERE HYPERTRIGLYCERIDEMIA AMONG PATIENTS WITH HEPATIC STEATOSIS IN THE UNITED STATES

Lana Bridi[1] Ricki Bettencourt[2] Egbert Madamba[2] Matthew Tsai[2] Denise Kalmaz[2] Nedret Copur-Dahi[2] Rohit Loomba[2], [1]University of California San Diego, [2]University of California, San Diego

Background: Dysregulated lipid metabolism is closely linked to steatotic liver disease and impacts management. There is limited data on the prevalence of triglyceride (TG) abnormalities, including chylomicronemia syndrome and severe hypertriglyceridemia (HTG) among individuals with steatosis. The objective is to determine the prevalence of TG disorders among patients who are overweight or obese with MRI-determined hepatic steatosis. **Methods:** This study is a cross-sectional analysis of a prospective cohort study of patients with overweight or obesity and hepatic steatosis, defined by MRI-PDFF $\geq$5%, residing in the Greater San Diego Area. Participants were recruited from primary care clinics and using community-based strategies. They underwent standardized research visits with imaging (MRI-PDFF, MRE, or VCTE with CAP). HTG was defined as $\geq$150 mg/dL, severe HTG as $\geq$500 mg/dL, and chylomicronemia as $\geq$880 mg/dL. Multivariable logistic regression evaluated associations of TG levels with steatosis and fibrosis. **Results:** The study included 855 participants. The mean age was 51.2 ($\pm$13) years, with 52.9% female and 38.2% Hispanic. Type 2 diabetes was present in 24.4%, and 61.0% had obesity. HTG was present in 33.3%, while severe HTG or chylomicronemia were rare (0.7%, n = 6). Participants with HTG had significantly higher prevalence of metabolic syndrome (81.7% vs 28.2%, $p < 0.0001$) and type 2 diabetes (30.5% vs 21.3%, $p = 0.001$); there was no significant difference in obesity rates (62.5% vs 60.1% $p = 0.764$) or FIB-4 score (0.9 vs 0.9, $p = 0.058$). Mean MRI-PDFF differed significantly, measuring 14.3% in severe HTG or chylomicronemia, 14.6% in HTG, and 7.5% in those without HTG ($p < 0.0001$). Mean MRE was significantly higher among those with HTG compared to those without (2.3 kPa vs 2.2 kPa, $p = 0.036$). TGs had a graded association with hepatic steatosis (adjusted OR per 100 mg/dL increase 2.10, 95% CI 1.63–2.72; $p < 0.0001$). Steatosis prevalence rose from 45.7% (Q1) to 79.8% (Q4) (adjusted OR 4.46, 95% CI 2.89–6.89; $p < 0.0001$). TG levels correlated with MRI-PDFF ($\rho = 0.348$), insulin resistance (HOMA-IR $\rho = 0.315$), and inversely with HDL ($\rho = -0.398$) ($p < 0.001$). No significant association was observed between TG level quartiles and advanced fibrosis (p-trend = 0.917). **Conclusion:** While severe HTG and chylomicronemia are rare, HTG is common and shows a strong dose-dependent association with steatosis but not fibrosis. These findings, in conjunction with what is known regarding TG dysregulation in hepatic steatosis pathogenesis, support further investigation into whether TG-lowering interventions could improve liver-related outcomes. The lack of association with fibrosis may reflect the cross-sectional design limitation and insufficient time for HTG exposure to translate into fibrotic change. Future studies should explore if HTG contributes to progression from steatosis to fibrosis longitudinally.

3440 | SAUDI NORM-BASED HEALTH-RELATED QUALITY OF LIFE PROFILES IN INDIVIDUALS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A LATENT PROFILE ANALYSIS FROM THE GENESIS PROSPECTIVE COHORT

Saleh Alqahtani[1] Shadan AlMuhaidib[2] Faisal Sanai[3] Feras Altunisi[2] Haifa Alotaibi[2] Basmah Khoja[4] Layan Alsubki[4] Alwaleed Almojel[5] Eman Alanazi[6] Nouf Al-Turki[7] Alanood Aladel[8] Waleed Alomaim[4] Amr Arafat[9] Waleed Alhazzani[2], [1]King Faisal Specialist Hospital & Research Center, [2]Research and Innovation Institute, Ministry of Defense Health Services, Riyadh, Saudi Arabia, [3]King Abdulaziz Medical City, King Abdullah International Medical Research Center, Jeddah, KSA, [4]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [5]King Fahad Military Medical Complex, Dhahran, Saudi Arabia, [6]Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [7]King Abdulaziz University, Jeddah, Saudi Arabia, [8]King Saud University, Riyadh, Saudi Arabia, [9]Prince Sultan Cardiac Center, Riyadh, Saudi Arabia

Background: Health-related quality of life (HRQoL) in metabolic dysfunction-associated steatotic liver disease (MASLD) remains poorly characterized in Saudi populations, and prior analyses rarely apply local population norms. We aimed to identify Saudi norm-based HRQoL profiles in adults with MASLD in the GENESIS prospective cohort and characterize clinical and demographic differences across profiles. **Methods:** We conducted a cross-sectional analysis of 1,110 adults with MASLD and complete SF-36 data enrolled in the GENESIS prospective cohort across seven primary care centers in three regions of Saudi Arabia between March 2024 and June 2025. MASLD was defined as a controlled attenuation parameter $\geq$268 dB/m on vibration-controlled transient elastography with at least one cardiometabolic risk factor. We assessed HRQoL using the 36-Item Short Form Health Survey (SF-36) and converted crude domain scores to Saudi norm-based T-scores using published Saudi SF-36v2 reference means and SDs (T-score 50 = Saudi mean; 10 points = one SD). We assessed high risk for obstructive sleep apnea (OSA) using the Berlin Questionnaire ($\geq$2 positive categories). We fit latent profile analysis (LPA) models on the 8 SF-36 domain T-scores from 1 to 6 profiles and selected the optimal solution using Bayesian Information Criterion (BIC), sample-size adjusted BIC (SABIC), entropy, posterior probability, and class size. We compared variables across profiles using Kruskal-Wallis and chi-square tests. **Results:** The 4-profile solution provided the best fit (BIC 77,045.2; SABIC 76,908.6; entropy 0.922; average posterior probability 0.958). We identified four profiles: High Saudi norm-based HRQoL (n = 684, 61.6%), Mixed low-vitality/emotional HRQoL (n = 178, 16.0%), Physical-functioning limitation (n = 158, 14.2%), and Severe role/vitality-emotional limitation (n = 90, 8.1%). The Severe profile had the highest prevalence of high risk for OSA (64.4% vs 28.8% in the High HRQoL profile) and the highest hypertension prevalence (38.9% vs 18.0%). The Physical-functioning limitation profile was the oldest (median age 58.0 years) and had the highest dyslipidemia prevalence (62.0%). The High HRQoL profile was younger (median age 44.0 years), predominantly male (68.0%), and showed the lowest cardiometabolic burden. Profiles differed significantly in age, sex, BMI, high-OSA-risk classification, cardiometabolic risk factor count, diabetes, hypertension, dyslipidemia, and thyroid disease (all $p < 0.001$). **Conclusion:** Four clinically meaningful HRQoL profiles characterize Saudi adults with MASLD, with high OSA risk, age, and cardiometabolic burden distinguishing the profiles. The Severe role/vitality-emotional limitation profile identifies a small high-burden subgroup that warrants targeted clinical

attention. These findings support population-specific HRQoL assessment in MASLD care and inform stratified interventions in Saudi Arabia.

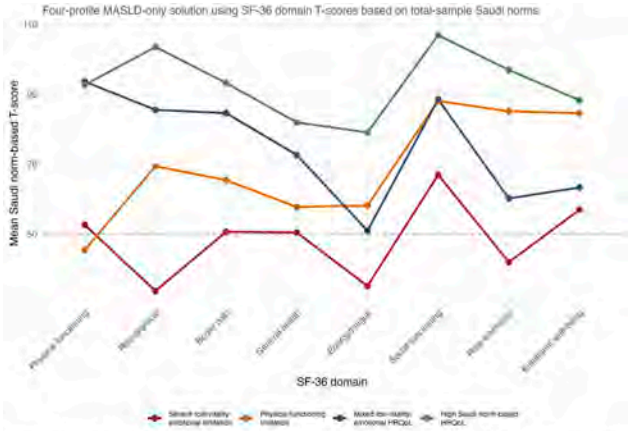

Figure 1. Saudi norm-based SF-36 mean T-score profiles in adults with MASLD from the GENESIS prospective cohort (n=1,110). Lines show mean T-scores for each of the four latent profiles across all eight SF-36 domains: physical functioning, role-physical, bodily pain, general health, energy/fatigue, social functioning, role-emotional, and emotional well-being. The dashed line at T=50 represents the published Saudi SF-36v2 reference means, with 10 points equal to one reference SD. T-scores are not constrained to the 0–100 raw scale range; values above 100 reflect raw scores more than five standard deviations above the Saudi reference mean, consistent with standard SF-36v2 norm-based scoring conventions. Profile sizes: Severe role/vitality-emotional limitation (n=90, 8.1%); Physical-functioning limitation (n=158, 14.2%); Mixed low-vitality/emotional HRQoL (n=178, 16.0%); High Saudi norm-based HRQoL (n=684, 61.6%).

3441 | ROLE OF GLUCAGON- LIKE PEPTIDE- 1 RECEPTOR AGONISTS COMBINED WITH PIOGLITAZONE FOR TREATMENT OF METABOLIC DYSFUNCTION- ASSOCIATED STEATOHEPATITIS

Katherine Ripley[1] Jawairia Memon[2], [1]Univerity of New Mexico Hospital, [2]University of New Mexico

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), formerly nonalcoholic fatty liver disease, affects nearly 40% of U.S. adults and is strongly associated with obesity, insulin resistance, metabolic syndrome, and type 2 diabetes mellitus (T2DM). Current pharmacologic therapies include glucagon-like peptide-1 receptor agonists (GLP-1 RAs), pioglitazone, resmetirom, and sodium-glucose cotransporter-2 inhibitors. GLP-1 RAs improve weight loss and glycemic control, while pioglitazone has demonstrated histologic liver improvement but is limited by weight gain and fluid retention. Given their complementary mechanisms, combination therapy may provide synergistic metabolic and hepatic benefit in MASLD. The aim of this study is to evaluate whether combined GLP-1 RA and pioglitazone therapy improves hepatic and metabolic outcomes compared with GLP-1 RA monotherapy in patients with MASLD. **Methods:** This retrospective cohort study utilized the TriNetX U.S. Collaborative Network, a federated electronic health record database. Adults aged 18–75 years with hepatic steatosis (K76.0) or nonalcoholic steatohepatitis (K75.81) between January 1, 2020, and December 31, 2025, were identified. Patients were grouped based on exposure to GLP-1 RAs with or without concomitant pioglitazone. Patients with alternative chronic liver diseases, including alcoholic liver disease, viral hepatitis, autoimmune hepatitis, and hemochromatosis, were excluded. Propensity score matching balanced demographics, metabolic comorbidities, liver disease severity, and diabetes-related medication use. Outcomes from 1 day to 5 years after index exposure included hepatic fibrosis/cirrhosis, portal hypertension, ascites, esophageal varices, hepatocellular carcinoma, liver enzymes, HbA1c, BMI, and LDL. **Results:** After propensity score matching, 9,634 patients remained in each cohort. Compared with combination therapy, GLP-1 RA monotherapy was associated with lower risk of hepatic fibrosis/cirrhosis (8.71% vs 12.23%; RR 0.71, $p < 0.0001$), nonalcoholic steatohepatitis (11.59% vs 15.16%; RR 0.77, $p < 0.0001$), portal hypertension (2.14% vs 3.24%; RR 0.66, $p < 0.0001$), ascites (2.09% vs 2.72%; RR 0.77, $p < 0.0001$), esophageal varices (1.52% vs 2.32%; RR 0.66, $p < 0.0001$), and hepatocellular carcinoma (0.52% vs 0.76%; RR 0.69, $p = 0.0019$). AST and ALT levels were similar between cohorts. Combination therapy was associated with lower BMI and LDL but higher HbA1c values. **Conclusion:** Combination therapy with GLP-1 RAs and pioglitazone was not associated with improved hepatic outcomes compared with GLP-1 RA monotherapy in patients with MASLD. GLP-1 RA monotherapy demonstrated lower rates of fibrosis, portal hypertension, hepatic decompensation, and hepatocellular carcinoma. Prospective studies are needed to further define the role of combination therapy in MASLD management.

3442 | BREAKFAST SKIPPING AND IRREGULAR MEAL TIMING IN SAUDI ADULTS WITH MASLD: INTERIM FINDINGS FROM A CASE-CONTROL CHRONONUTRITION STUDY

Thuraya Alaidarous[1] Mahmoud M. Abulmeaty[1] Khalid Alswat[2] Faisal Abaalkhail[3] Waleed Alhamoudi[3] Bandar Al-Judaibi[3] Saleh Alessy[3] Saad Alghamdi[3] Lama Amer[3] Saleh Alqahtani[3] Maha Alhussain[1], [1]King Saud University, Riyadh, Saudi Arabia, [2]King Saud University/KKUH, [3]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia

Background: Chrononutrition is a growing field that examines how eating patterns, including meal timing, frequency, and regularity, interact with endogenous circadian rhythms to influence human health. Emerging evidence suggests that disruptions in chrononutrition may adversely affect metabolic homeostasis and hepatic fat accumulation. We aimed to explore differences in chrononutrition patterns between individuals with metabolic dysfunction–associated steatotic liver disease (MASLD) and controls. **Methods:** This interim analysis included 40 participants enrolled to date in an ongoing case–control study, comprising 20 patients with MASLD [SAA1] and 20 controls aged 18–65 years. They were recruited from two tertiary centers in Riyadh, Saudi Arabia. Anthropometric measurements were collected. Chrononutrition patterns were assessed using the Chrononutrition Profile Questionnaire (CP-Q) (Veronda et al 2020). Group differences were assessed using independent-samples t tests for continuous variables and Fisher's exact or chi-square tests for categorical variables, as appropriate. **Results:** In this interim analysis, distinct differences in breakfast-related chrononutrition patterns were observed between groups. Participants with MASLD were significantly more likely to exhibit irregular meal timing compared with controls (80.0% vs. 20.0%; P < 0.001). Breakfast consumption between 6:00 and 9:00 AM was more common among controls (73.7% vs. 26.3%), whereas delayed breakfast intake was more frequently reported among participants with MASLD (70.0% vs. 30.0%; P = 0.027). Weekly breakfast skipping frequency was significantly higher in the MASLD group (3.25 ± 2.53 vs. 1.65 ± 2.23; P = 0.041). Participants with MASLD also had higher body weight and body mass index than controls (87.70 ± 13.16 vs. 65.78 ± 12.11 kg and 32.34 ± 3.98 vs. 23.88 ± 3.55 kg/m², respectively; both P < 0.001) **Conclusion:** Altered breakfast timing, frequent breakfast skipping, and irregular eating patterns were associated with MASLD and higher adiposity/body-composition measures. These interim findings suggest that optimizing meal-timing regularity may represent a modifiable behavioral strategy warranting further evaluation for metabolic health and supporting MASLD management, although confirmation in the full study cohort is needed.

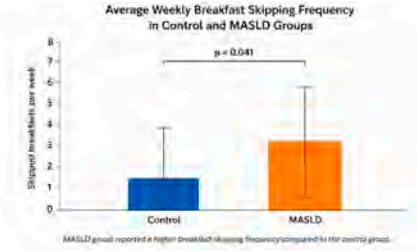

Figure: Comparison of Weekly Breakfast Skipping Frequency between Control and MASLD

Table: Anthropometric Characteristics and Chrononutrition Behaviors of Study Participants by Group

Variable	Control	MASLD	p-value
Age (years)	39.20 ± 7.96	41.65 ± 9.95	0.395
Weight (kg)	65.78 ± 12.11	87.70 ± 13.16	<0.001*
BMI (kg/m²)	23.88 ± 3.55	32.34 ± 3.98	<0.001*
Weekly Breakfast Skipping Frequency	1.65 ± 2.23	3.25 ± 2.53	0.041*
Post-dinner snack frequency	1.75 ± 1.48	2.10 ± 2.02	0.536
Night waking to eat frequency	0.40 ± 0.82	0.10 ± 0.31	0.139
Largest meal			
Breakfast	3 (15.0%)	3 (15.0%)	0.900
Lunch	11 (55.0%)	13 (65.0%)	
Dinner	6 (30.0%)	4 (20.0%)	

An independent samples t-test was used for continuous variables, and a Chi-square test was used for categorical variables(*Fisher's Exact Test was used for categorical variables due to small expected cell counts. Statistical significance was considered at p < 0.05.*

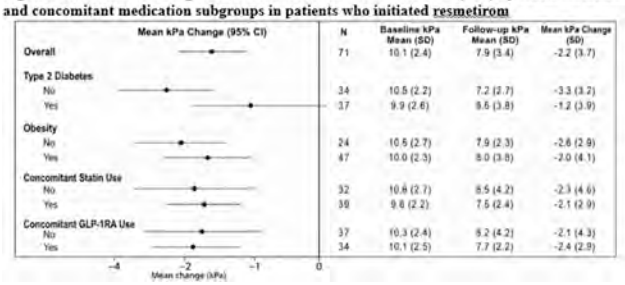
3443 | ◆ TWELVE-MONTH CHANGES IN LABORATORY- AND IMAGING-BASED BIOMARKERS FOLLOWING RESMETIROM INITIATION: A REAL-WORLD ANALYSIS ACROSS CARDIOMETABOLIC AND CONCOMITANT MEDICATION SUBGROUPS



Anthony Martinez[1] Susan Thapa[2] Christina Parrinello[2] Yestle Kim[2] John O'Donnell[2], [1]University at Buffalo, [2]Madrigal Pharmaceuticals, Inc

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Resmetirom is a thyroid hormone receptor β–selective agonist conditionally approved in the United States (US) for adults with noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH) with moderate-to-advanced fibrosis. MASH frequently coexists with obesity, type 2 diabetes (T2D), and use of GLP-1 receptor agonists (GLP-1 RA) and statins. Real-world studies describing biomarker changes across these subgroups are limited. **Methods:** An electronic health record-based retrospective cohort study was conducted using Truveta de-identified data from US health systems linked to third-party dispensing data. Adults ≥18 years with a resmetirom fill on or after March 14, 2024 (index date = first fill) were followed through April 6, 2026. Eligible patients had ≥1 healthcare interaction during the pre-index year, no other or advanced liver disease, and ≥1 year of follow-up. Outcomes included vibration-controlled transient elastography (VCTE)-derived liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) extracted from clinical notes using large language models, liver enzymes (alanine transaminase [ALT] and aspartate aminotransferase [AST]), lipids (low-density lipoprotein cholesterol [LDL-C], high-density lipoprotein cholesterol [HDL-C], and triglycerides [TGs]), and derived scores (FibroScan-AST [FAST] and Steatosis-Associated Fibrosis Estimator [SAFE]). Baseline and follow-up (12 ± 3 months) means, and standard deviations (SD) were estimated. Mean changes were compared using paired t-tests and evaluated across subgroups (obesity, T2D, and concomitant use of GLP-1 RA and statins). **Results:** Among 1,405 patients with ≥1 year of follow-up (median 15.8 months), mean age was 58 years, 63% female, 78% White, 57% T2D, 61% obesity, 50% used GLP-1 RA and 55% used statins. In those with paired measurements, mean LSM decreased at 12 months (-2.2 kPa [3.7], $p < 0.001$). Directionally similar reductions in LSM were observed across subgroups, with overlapping confidence intervals suggesting no clear heterogeneity (**Figure**). Improvements were also observed across all subgroups in CAP, ALT, AST, LDL-c, HDL-c, TG, SAFE, and FAST (all statistically significant except HDL-c). Across subgroups, 28–43% of patients had ≥40 dB/m CAP reduction, 40–59% ≥20% ALT reduction, 38–51% ≥20% AST reduction, and 39–59% ≥0.22 FAST reduction. **Conclusion:** Among patients initiating resmetirom, improvements in imaging- and blood-based biomarkers at 12 months were observed across clinically relevant cardiometabolic and concomitant medication subgroups. Subgroup sample sizes were limited, particularly for imaging measures, and the study was not designed to formally compare treatment response between subgroups. Future analyses with larger samples and longer follow-up will further characterize biomarker changes across clinically relevant subgroups.

Figure. Twelve-month changes in VCTE liver stiffness measurement (kPa) by cardiometabolic and concomitant medication subgroups in patients who initiated resmetirom

3444 | ◆ GLP-1 RECEPTOR AGONIST IS ASSOCIATED WITH LOWER MORTALITY, CARDIOVASCULAR EVENTS, AND ACUTE KIDNEY INJURY IN COMPENSATED CIRRHOSIS: AN ACTIVE-COMPARATOR, NEW-USER STUDY OF 11,972 PATIENTS

Saad Nadeem[1] David Victor[2] Sudha Kodali[2] Tamneet Basra[2] Michelle Jones-Pauley[2] Mazen Noureddin[2] Kavish Patidar[2], [1]Texas A&M College of Medicine, [2]Houston Methodist Hospital

Background: GLP-1 receptor agonists (GLP-1RAs) improve metabolic and liver-related outcomes in metabolic dysfunction-associated steatotic liver disease (MASLD), but evidence in cirrhosis—particularly outside MASLD—is limited and lacks active-comparator data. Whether GLP-1RAs confer extrahepatic benefits beyond those of sodium-glucose cotransporter-2 inhibitors (SGLT2i) remains unknown. **Methods:** We conducted a retrospective active-comparator new-user cohort study within the TriNetX Research Collaborative Network (113 healthcare organizations). Adults with compensated cirrhosis initiating a new GLP-1 RAs (semaglutide or tirzepatide) or SGLT-2i (empagliflozin, dapagliflozin, canagliflozin, or ertugliflozin) within 12 months of cirrhosis diagnosis were 1:1 propensity

score matched (PSM). Covariates matched for included demographics, comorbidities, medications, and labs. Outcomes were assessed over 2 years from the index date. Subgroup analyses by MASLD, alcohol-associated (ALD), and viral cirrhosis. Hazard ratios (HR) were estimated using Cox proportional hazards models. **Results:** After 1:1 PSM, 5,986 GLP-1 RA initiators were matched to 5,986 SGLT2i initiators, with balance achieved for nearly all covariates (SMD < 0.1), except for albumin (SMD 0.17). Compared with SGLT2i initiation, GLP-1 RA initiation was associated with lower 2-year all-cause mortality (4.3% vs 6.8%; HR 0.65; 95% CI, 0.56–0.76; p < 0.001), major adverse cardiovascular events (7.2% vs 10.2%; HR 0.73; 95%CI, 0.63–0.85; p < 0.001), and acute kidney injury (7.4% vs 9.2%; HR 0.83; 95%CI, 0.72–0.96; p = 0.011) (Table 1). No differences in hepatic decompensation, HCC, or transplant between groups. In etiology-stratified analysis, the AKI benefit was concentrated in viral cirrhosis (HR 0.56, 0.33–0.98, p = 0.033), with no significant difference in MASLD cirrhosis (HR 0.88, 95% CI 0.65–1.20, p = 0.42) or ALD cirrhosis. **Conclusion:** In this active-comparator, new-user analysis of adults with recently diagnosed compensated cirrhosis, GLP-1 RA initiation was associated with lower 2-year mortality, MACE, and AKI compared with SGLT2i initiation, without significant differences in hepatic decompensation, HCC, or liver transplantation. Prospective studies are needed to confirm these findings and define the role of GLP-1 RAs in cardiometabolic and renal risk modification among patients with compensated cirrhosis.

Table 1. Primary and secondary outcomes — overall cohort (5,986 matched pairs, 2-year follow-up).

Outcome	GLP-1 RA events / N (risk)	SGLT-2i events / N (risk)	Hazard ratio	95% CI	p-value
PRIMARY OUTCOMES					
All-cause mortality	262 / 6,089 (4.30%)	413 / 6,090 (6.78%)	0.649	0.556–0.758	<0.0001
MACE	301 / 4,167 (7.22%)	401 / 3,930 (10.20%)	0.734	0.632–0.853	<0.0001
SECONDARY OUTCOMES					
Acute kidney injury	349 / 4,708 (7.41%)	423 / 4,618 (9.16%)	0.832	0.722–0.958	0.011
Decompensation (composite)	355 / 5,665 (6.27%)	373 / 5,678 (6.57%)	0.980	0.847–1.133	0.51
Decompensation only	301 / 5,724 (5.26%)	332 / 5,729 (5.80%)	0.931	0.796–1.088	0.21
Hepatocellular carcinoma	91 / 6,046 (1.51%)	88 / 6,054 (1.45%)	1.035	0.774–1.385	0.81
Liver transplant	33 / 6,075 (0.54%)	31 / 6,094 (0.51%)	1.068	0.655–1.741	0.79

3445 | ◆ FIBROSIS PROGRESSION AND CARDIOVASCULAR OUTCOMES IN MASLD WITH GLP1/SGLT2I USE: A PROSPECTIVE LONGITUDINAL STUDY

Rahul Falodia[1] Maryum Shah[2] Ubaid Ahmed[3], [1]All India Institute of Medical Sciences Jodhpur, [2]UAB SOM Montgomery Internal Medicine Residency Program, [3]Dow university of health Sciences

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is now recognized as an independent cardiovascular risk factor, yet fibrosis staging is rarely incorporated into cardiometabolic risk models. Whether histological fibrosis progression confers MACE risk beyond established cardiometabolic predictors or GLP-1 receptor agonist or SGLT2 inhibitor use modifies this risk remains unknown. **Methods:** 1,186 adults with biopsy-confirmed MASLD enrolled in a prospective longitudinal registry (mean age 53.9 years, 41.3% female, 52.6% type 2 diabetes, mean BMI 33.4 kg/m²). Baseline fibrosis was staged F0–F4. Fibrosis progression was defined as $\geq$1-stage worsening on repeat liver biopsy or validated transient elastography at 3 years. GLP-1RA or SGLT2i use was recorded at enrollment (31% of cohort). The primary endpoint was 5-year MACE (composite of non-fatal MI, non-fatal stroke, and cardiovascular death). Three sequential Cox proportional hazards models were constructed: Model 1 (fibrosis stage alone), Model 2 (fibrosis stage + standard cardiometabolic covariates: age, sex, BMI, diabetes, hypertension, dyslipidemia, smoking), and Model 3 (full model adding fibrosis progression and GLP-1RA/SGLT2i use). Discrimination was assessed by Harrell's C-statistic. **Results:** Over 5 years, 211 patients (17.8%) experienced MACE. Fibrosis stage showed a steep gradient of MACE risk: 4.4% (F0), 11.9% (F1), 13.6% (F2), 25.7% (F3), and 41.2% (F4). 3-year fibrosis progression occurred in 17.1% of patients and was significantly more common in patients not receiving GLP-1RA/SGLT2i (19.4% vs. 12.1%, $p < 0.001$). On adjusted Cox regression (Model 2), each unit increase in baseline fibrosis stage independently predicted MACE risk after full cardiometabolic adjustment (HR 1.75, 95% CI 1.56–1.96, $p < 0.001$), demonstrating that fibrosis severity carries prognostic information orthogonal to traditional risk factors. In the full model (Model 3), fibrosis stage remained the dominant predictor (HR 1.84, 95% CI 1.63–2.07, $p < 0.001$); 3-year progression conferred additional independent MACE risk (HR 1.59, 95% CI 1.11–2.28, $p = 0.011$); and GLP-1RA/SGLT2i use was associated with a 61% relative reduction in MACE risk (HR 0.39, 95% CI 0.27–0.56, $p < 0.001$), independent of fibrosis stage and cardiometabolic covariates. **Conclusion:** In MASLD cohort, baseline fibrosis stage and 3-year histological progression are independent determinants of 5-year MACE, with a risk signal that is not captured by conventional cardiometabolic risk factors alone. GLP-1RA and SGLT2i use was associated with both attenuated fibrosis progression and substantially lower MACE risk. These findings support routine fibrosis staging as a cardiovascular risk stratification tool in MASLD and provide mechanistic rationale for prioritizing these agents in patients with advanced fibrosis.

3446 | ◆ MASLD ATTENUATES SEMAGLUTIDE-INDUCED WEIGHT LOSS WHILE CIRRHOSIS PARADOXICALLY ENHANCES IT: A REAL-WORLD ANALYSIS OF 30,767 VETERANS

Binu John[1] Samuel Soon[2] Dustin Bastaich[2] Ashwani Singal[3] Bassam Dahman[2], [1]University of Miami and Miami VA, [2]Virginia Commonwealth University, [3]University of Louisville

Background: Semaglutide promotes significant weight loss in clinical trials, yet its real-world efficacy in patients with metabolic dysfunction-associated steatotic liver disease (MASLD), remains poorly defined. Whether concurrent cirrhosis further modifies weight loss response is unknown. **Methods:** This retrospective cohort study used the Veterans Health Administration (VHA) national database to identify adults who were new users of subcutaneous semaglutide with at least 12 months of follow-up. Patients with active malignancy, hepatic decompensation, hazardous alcohol use, or prior bariatric surgery were excluded. MASLD was identified from imaging reports using validated natural language processing ($\kappa = 0.87$ vs. manual chart review). The primary outcome was percentage weight loss at 6 and 12 months, categorized as $< 5\%$, 5–10%, and $\geq 10\%$. Multivariable logistic and multinomial regression models adjusted for age, sex, race, BMI, diabetes, cirrhosis, and achieved semaglutide dose. **Results:** Among 30,767 new semaglutide users, 17,565 (57.1%) had MASLD and 13,202 had no hepatic steatosis on imaging. The cohort had a median age of 67.5 years and was predominantly male (87.5%). Participants with and without MASLD had similar prevalence of diabetes (91%) with no difference in median HgbA1C (7.7%). Among the 17,565 patients with MASLD, 1193 had cirrhosis. Weight loss demonstrated a dose-dependent pattern across semaglutide doses (0.25–2.4 mg).Compared to controls, MASLD was associated with modestly but significantly lower adjusted odds of achieving $\geq 5\%$ weight loss at both 6 months (aOR 0.92 [5–10%] and 0.95 [$> 10\%$]; both $p \leq 0.033$) and 12 months (aOR 0.92 [5–10%] and 0.90 [$> 10\%$]; both $p < 0.0001$). Conversely, among patients with MASLD, concurrent cirrhosis was paradoxically associated with *higher* adjusted odds of achieving $\geq 5\%$ weight loss at 6 months (aOR 1.08; 95% CI 1.03–1.13; $p = 0.0009$) and 12 months (aOR 1.07; 95% CI 1.02–1.12; $p = 0.003$). **Conclusion:** In this large real-world cohort of veterans, MASLD was independently associated with attenuated semaglutide-induced weight loss at 6 and 12 months, potentially driven by insulin resistance impairing GLP-1 receptor signaling. Paradoxically, among patients with MASLD, cirrhosis was associated with greater weight loss, a finding that may reflect sarcopenia-related loss of lean mass rather than true adipose reduction, underscoring the limitations of weight-based endpoints in this population. These findings have direct implications for patient counseling, dose optimization, and the selection of body composition–based endpoints in future MASLD trials involving GLP-1 receptor agonists.

3447 | ◆ SURVIVAL IMPACT OF GLP-1RA TREATMENT IN MASLD VS METALD: EQUAL BENEFIT, UNEQUAL ACCESS

Dilara Hatipoglu[1] Nadim Mahmud[2], [1]University of Pennsylvania, [2]Hospital of the University of Pennsylvania

Background: Obesity is a major driver of fibrosis progression in steatotic liver disease (SLD). Glucagon-

like peptide-1 receptor agonists (GLP-1RAs) promote weight loss and improve hepatic steatosis, but it remains unclear whether pharmacologic obesity management differs by SLD subtype. **Methods:** We performed a retrospective cohort study using VOCAL, a national Veterans Health Administration registry of patients with chronic liver disease. Adults with BMI ≥ 35 and imaging-confirmed non-cirrhotic SLD were classified as metabolic dysfunction-associated steatotic liver disease (MASLD) or metabolic dysfunction and alcohol-related liver disease (MetALD) using metabolic criteria and AUDIT-C data. We included patients who were obesity treatment-naïve at baseline, including no prior lifestyle program referral (MOVE!), bariatric surgery, or anti-obesity medication use. Follow-up began at date of first imaging-confirmed steatosis and continued until death, maximum follow-up, or 10 years. The first model utilized adjusted Cox proportional hazards regression with time to obesity intervention as the primary outcome. A second time-updated Cox model assessed the association between GLP-1RA exposure and all-cause mortality, including an interaction term between GLP-1RA use and SLD subtype. **Results:** Among 23,332 patients, 19,628 had MASLD and 3,704 had MetALD. Most patients were men (90.1% MASLD, 92.4% MetALD). Compared with MetALD, MASLD patients had higher median BMI (38.2 vs 37.7), diabetes prevalence (33.6% vs 22.9%), and hyperlipidemia (50.1% vs 46.4%). In adjusted analyses, MetALD patients were less likely to receive GLP-1RA therapy (HR 0.83, 95% CI 0.74-0.94, $p = 0.002$; **Figure 1A**) than those with MASLD. Rates of referral to MOVE!, non-GLP-1RA medications, bariatric surgery, and nutrition services were similar. In time-updated intention-to-treat analyses, GLP-1RA use was associated with lower all-cause mortality (HR 0.55, 95% CI 0.44-0.68, $p < 0.001$), while MetALD was associated with higher mortality (HR 1.21, 95% CI 1.08-1.37, $p = 0.002$). The interaction between GLP-1RA use and SLD subtype was not significant ($p = 0.86$), suggesting similar survival benefit across subtypes. Cumulative hazard curves are displayed in **Figure 1B. Conclusion:** Among patients with non-cirrhotic SLD and obesity, MetALD patients were less likely to receive GLP-1RA therapy despite comparable survival benefit to MASLD patients. These findings suggest GLP-1RAs may improve outcomes regardless of SLD subtype and may be underutilized in MetALD.

3448 | ◆ SURVIVAL ADVANTAGE OF GLP-1 RECEPTOR AGONISTS OVER SGLT2 INHIBITORS IN PATIENTS WITH MASLD OR CIRRHOSIS AND CHRONIC KIDNEY DISEASE

Urveesh Sharma[1] Yash Shah[2] Ragesh Thandassery[3], [1]University of Arkansas for Medical Sciences, [2]UAMS, LR, [3]CAVHS, Little Rock

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and cirrhosis frequently coexist with chronic kidney disease (CKD) and type 2 diabetes (T2DM), creating a high-risk population. Both GLP-1 receptor agonists (GLP-1 RAs) and SGLT2 inhibitors (SGLT2is) are widely used in this patient population, and are known to improve cardiometabolic outcomes, but their relative effect on survival when CKD and MASLD/cirrhosis overlap has not been studied well. **Methods:** We conducted a retrospective cohort study using the TrinetX database where adults (≥ 18 years) with pre-existing MASLD or cirrhosis, CKD stages 3-5, and T2DM were divided into two cohorts based on whether they were newly started on a GLP-1 RA or a SGLT2i. We excluded patients with cross-drug class exposure, alcoholic liver disease, viral hepatitis, prior liver transplant, HCC, ESRD, or dialysis. 1:1 propensity score matching (PSM) on demographics, comorbidities, medications, and laboratory values was done. The primary outcome was all-cause mortality at 3 years and was assessed by Kaplan-Meier analysis with log-rank testing. **Results:** After 1:1 PSM, 4,700 patients remained per cohort with well-balanced baseline characteristics. Mean age was 67.9 years; 57.2% were female, 73.7% were White, and 18.7% carried a cirrhosis diagnosis. Mean follow-up was 634 days in both groups. GLP-1 RA users had significantly lower all-cause mortality at 3 years vs SGLT2i users (8.7% vs. 11.6%; RR 0.753, 95% CI 0.666–0.850; $p < 0.001$). On Kaplan-Meier analysis, 3-year survival probability was 85.6% with GLP-1 RAs versus 82.5% with SGLT2is (log-rank $p < 0.001$). Since the proportionality test was significant ($p = 0.001$), a time-averaged Cox HR is reported: HR 0.745 (95% CI 0.656–0.848). This reflects a mortality benefit that widened progressively over the observation period. **Conclusion:** Among patients with coexisting MASLD/cirrhosis, CKD stages 3-5, and T2DM, GLP-1 RA use was associated with roughly 25% lower all-cause mortality compared to SGLT2i use over 3 years, with the benefit appearing to grow over time.

Background: Hypertension is common in metabolic dysfunction-associated steatotic liver disease (MASLD), but the effects of specific antihypertensive drug classes on liver fibrosis and liver-related events (LREs) remain unclear. We evaluated the associations of renin–angiotensin system inhibitors (RASi) and calcium channel blockers (CCB) with liver stiffness changes and long-term LRE risk. **Methods:** We analyzed data from the VCTE-Prognosis cohort, a multicenter prospective study with serial liver stiffness measurements. Outcomes included advanced liver fibrosis (LSM $\geq$ 10 kPa), liver stiffness progression ($\geq$ 20% increase and Baveno category upshift), liver stiffness regression ($\geq$ 20% decrease and Baveno category downshift), and incident LREs. Associations between baseline antihypertensive therapy and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

outcomes were assessed using Cox proportional hazards models with inverse probability of treatment weighting, comparing RASi users versus non-users, CCB users versus non-users. **Results:** 4,302 individuals with MASLD and hypertension were followed for a median of 4.6 years, with 41.2% receiving RASi and 32.0% receiving CCB. RASi use was associated with a higher chance of liver stiffness regression (adjusted HR = 1.220, 95%CI 1.010–1.474; P = 0.039) and a lower risk of long-term LREs (adjusted HR = 0.431, 95%CI 0.261–0.714; P = 0.001), with no significant effect on liver stiffness progression. In contrast, CCB use was associated with lower risks of liver stiffness progression (adjusted HR = 0.681, 95%CI 0.521–0.89; P = 0.005) and LREs (adjusted HR = 0.559, 95%CI 0.326–0.958; P = 0.034), but not liver stiffness regression. Findings were consistent across subgroup and sensitivity analyses. **Conclusion:** Both RASi and CCB were associated with beneficial liver-related outcomes, although with different patterns: RASi was more strongly associated with fibrosis regression, whereas CCB was more strongly associated with reduced fibrosis progression.

3450 | SEMAGLUTIDE AMELIORATES HEPATIC FIBROSIS AND LIPOTOXICITY IN A SYNERGISTIC MURINE MODEL OF CHOLESTASIS AND STEATOSIS

Bao Xiaowen[1] Yan Chen[2] Paul KH Tam[2], [1]Macao university of science and technology, [2]Macau University of Science and Technology

Background: The global surge in metabolic syndrome, and the clinical convergence of metabolic dysfunction-associated steatotic liver disease (MASLD) and chronic cholestatic insults present an escalating challenge. Up to 45% of patients with chronic cholestasis present with concurrent MASLD, which nearly triples the risk of advanced fibrosis and significantly accelerates hepatic decompensation. However, therapeutic options targeting this synergistic "double-hit" pathology remain elusive. This study evaluates the therapeutic efficacy of Semaglutide, a GLP-1 receptor agonist, in mitigating hepatic fibrosis and lipotoxicity utilizing

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

a synergistic murine model of MASLD and bile duct ligation (BDL) designed to recapitulate the complex, multi-factorial disease progression and the high fibro-inflammatory burden observed in clinical overlap syndromes. **Methods:** A comprehensive array of in vivo models was employed, specifically focusing on the synergistic MASLD+BDL composite murine model to simulate clinical cholestatic steatohepatitis. Hepatic functions were evaluated via serum biochemistry. Histopathological architecture was assessed using Oil Red O staining for lipid deposition, alongside Sirius Red and Masson staining to visualize collagen fibril organization. The cellular impact of Semaglutide was evaluated utilizing advanced hepatocyte organoid culture systems coupled with bulk RNA sequencing to profile global transcriptomic alterations. **Results:** Semaglutide administration notably ameliorated the pathological landscape in the synergistic model. Histological examination demonstrated that treatment effectively attenuated hepatic lipid accumulation and significantly abrogated fibrotic remodeling, preserving liver tissue architecture despite the combined metabolic and biliary insult. Ex vivo hepatocyte organoid assays corroborated these findings, demonstrating a direct protective effect of Semaglutide on hepatocyte integrity and survival under co-exposure to lipotoxic and cholestatic stress. Bulk RNA sequencing revealed that Semaglutide treatment leads to a profound restoration of the hepatic transcriptomic profile, modulating key networks involved in lipid homeostasis and extracellular matrix regulation. **Conclusion:** Collectively, these findings indicate that Semaglutide exerts potent anti-steatotic and anti-fibrotic effects in the context of combined metabolic and cholestatic liver injury. By addressing the synergy between MASLD and cholestasis—a clinical scenario characterized by a 3-fold higher risk of advanced fibrosis and high morbidity—this study provides a strong preclinical rationale for repurposing Semaglutide as a targeted therapeutic strategy for patients facing the severe intersection of multi-etiological chronic liver diseases.

3451 | TREATMENT WITH RESMETIROM IMPROVES SYMPTOM BURDEN IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Zobair Younossi[1] Fatema Nader[2] Becky Taub[3] Andrei Racila[1] Maria Stepanova[1], [1]The Global NASH/MASH Council, [2]Center for Outcomes Research in Liver Diseases, CORLD, [3]Madrigal Phramaceutical

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by substantial health-related quality of life (HRQL) impairment and symptom burden. We evaluated the effect of resmetirom on MASH-specific symptoms using the CLDQ-MASH Symptom Questionnaire (CLDQ-MASH-SQ). **Methods:** In this post-hoc analysis of the MAESTRO-NAFLD-1 and MAESTRO-NASH studies, patients with MASH were stratified as early MASH, MASH with F2-F3 fibrosis, and MASH with compensated cirrhosis. Changes in CLDQ-MASH-SQ domain and item scores (8 domains, 36 items; scores range 1-7, higher scores indicate better HRQL, lower symptom burden) from baseline to week 52 treatment with resmetirom or placebo were evaluated. **Results:** A total of 2066 MASH patients were included; baseline symptom burden increased with disease severity across multiple domains ($p < 0.01$). At week 52, patients with early MASH treated with resmetirom demonstrated improvements in Abdominal symptoms and Health distress domains that were not observed with placebo; among MRI-PDFF responders, these mean (95% CI) improvements were +0.16 (0.06, 0.26) and +0.17 (0.08, 0.25), respectively, and were accompanied by greater improvements in anxiety (mean change +0.17 vs. -0.05 in non-responders, $p = 0.045$) and feeling unhappy (+0.14 vs. -0.06, respectively, $p = 0.036$) item scores. In patients with MASH F2-F3, Health distress domain scores improved significantly from baseline across treatment groups. Among patients with MASH cirrhosis, improvement in Health distress domain scores were observed in those with higher baseline liver stiffness, and VCTE responders demonstrated improvements in selected peripheral symptoms. **Conclusion:** Across all stage of MASH, treatment with resmetirom is associated with improvement in multiple aspects of disease-specific symptom burden.

3452 | EARLY EXPERIENCE WITH RESMETIROM IN ADOLESCENTS AND YOUNG ADULTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS: A CASE SERIES

Andrea Tou[1] Brandon Perumpail[1] Jennifer Panganiban[2], [1]Children's Hospital of Philadelphia, [2]The Children's Hospital of Philadelphia

Background: Pediatric metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic dysfunction-associated steatohepatitis (MASH) lack approved pharmacologic therapies. Resmetirom, a thyroid hormone receptor-β agonist, is approved for adults with noncirrhotic MASH and moderate-to-severe fibrosis. Pediatric data are lacking. We report early use of resmetirom in adolescents/young adults with MASH. **Methods:** This single-center case series included 4 patients ≤21 years old with MASH treated with resmetirom. Dosing followed adult labeling (80mg if ≤100kg, 100mg if ≥100kg). Two received monotherapy, with two on concurrent tirzepatide. Serial alanine aminotransferase (ALT), aspartate aminotransferase (AST), gamma-glutamyl transferase (GGT), lipid panel, Magnetic Resonance Imaging-Proton Density Fat Fraction (MRI-PDFF) fat fraction and Magnetic Resonance Elastography liver stiffness measurement (LSM), and FibroScan controlled attenuation parameter (CAP) and LSM data were collected at variable follow-up intervals during clinical care. Clinically meaningful changes are described without inferential statistics. **Results:** Patients were 75% male, median age 19 years (range 18–20). Follow-up ranged from 3–9 months. Case 1 (18 M, monotherapy, at 9 months): ALT 232 to 58 U/L, AST 119 to 38 U/L, MRI-PDFF 25.8 to 10.0% (61% relative reduction), MRE LSM 2.45 to 2.16 kPa, FibroScan LSM 9.4 to 5.3 kPa, triglycerides 285 to 159 mg/dL, and BMI 32.9 to 30.8 kg/m^2 . Case 2 (20 F, concurrent tirzepatide, at 6 months): ALT 69 to 28 U/L, AST 101 to 31 U/L, GGT 286 to 71 U/L, LDL 122 to 92 mg/dL, cholesterol 203 to 169 mg/dL, MRI-PDFF 15.0 to 11.0%, MRE LSM 4.66 to 4.20 kPa, FibroScan CAP 320 to 247 dB/m, FibroScan LSM 16.3 to 10.4 kPa, and BMI 30.7 to 26.8 kg/m^2 (−12% weight loss). Case 3 (20 M, monotherapy, up to 9 months): ALT 101 to 54 U/L, LDL 128 to 58 mg/dL, cholesterol 192 to 116 mg/dL, triglycerides 180 to 137 mg/dL, FibroScan LSM 11.0 to 5.9 kPa (despite persistent CAP elevation), and BMI 29.2 to 29.0 kg/m^2 . Case 4 (19 M, concurrent tirzepatide, at 3 months): ALT 51 to 40 U/L, AST 43 to 29 U/L, and triglycerides 149 to 116 mg/dL. Resmetirom was well tolerated without adverse events. **Conclusion:** This is the first reported use of resmetirom in adolescents with MASH. Resmetirom was well-tolerated and associated with improvements in liver enzymes, steatosis, and liver stiffness. ALT decreased in all patients from baseline, with peak reductions of 61–75% in three patients. Monotherapy was associated with hepatic improvements despite minimal BMI change, consistent with resmetirom's weight-independent mechanism of action. One patient achieved a >30% relative reduction in MRI-PDFF, a threshold linked to histologic improvement. Combination therapy was associated with concurrent weight loss, consistent with complementary incretin effects. Larger prospective studies are needed to establish the safety and efficacy of resmetirom in youth with MASH.

Longitudinal Hepatic, Metabolic, and Imaging Outcomes

3453 | COMPARATIVE SAFETY OF GLP-1 RECEPTOR AGONISTS VERSUS SGLT2 INHIBITORS IN PATIENTS WITH MASLD OR CIRRHOSIS AND CHRONIC KIDNEY DISEASE: RISK OF PANCREATITIS AND ACUTE KIDNEY INJURY

Urveesh Sharma[1] Yash Shah[2] Manesh Gangwani[2], [1]University of Arkansas for Medical Sciences, [2]UAMS, LR

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Both GLP-1 RAs and SGLT2is are increasingly prescribed in patients with MASLD or cirrhosis and CKD, yet their safety profiles in this population have never been directly compared. In a population with already compromised liver and kidney function, even modest drug-related toxicity can translate into serious harm. **Methods:** We conducted a retrospective cohort study using the TrinetX database where adults (≥18 years) with pre-existing MASLD or cirrhosis, CKD stages 3-5, and T2DM were divided into two cohorts based on whether they were newly started on a GLP-1 RA or a SGLT2i. We excluded patients with cross-drug class exposure, alcoholic liver disease, viral hepatitis, prior liver transplant, HCC, ESRD, or dialysis. 1:1 propensity score matching (PSM) on demographics, comorbidities, medications, and laboratory values was done. Primary outcomes were incident acute pancreatitis and incident AKI within 3 years of starting the GLP-1 RA or SGLT2i. Kaplan-Meier analysis with log-rank testing and Cox regression were performed and the proportional hazards assumption was met for both pancreatitis (p = 0.749) and AKI (p = 0.333). **Results:** 1:1 PSM yielded 4,700 patients per cohort. Acute pancreatitis rates were low and statistically comparable between both groups (0.7% vs. 1.0%; HR 0.721, 95% CI 0.455–1.143; log-rank p = 0.162), with no evidence of excess risk with GLP-1 RAs. For AKI, GLP-1 RA users had numerically lower event rates (13.5% vs. 15.6%; RR 0.867, 95% CI 0.754–0.996; p = 0.043), and the time-to-event analysis showed a trend favoring GLP-1 RAs but it did not reach statistical significance (HR 0.869, 95% CI 0.748–1.011; log-rank p = 0.068). **Conclusion:** In patients with MASLD or cirrhosis, CKD, and T2DM, GLP-1 RA use was not associated with increased pancreatitis risk compared to SGLT2is. AKI rates trended lower with GLP-1 RAs, though this did not reach significance on time-to-event analysis. These findings offer reassurance about GLP-1 RA safety in a population with baseline hepatic and renal vulnerability.

Table 1. Safety outcomes at 3 years — GLP-1 receptor agonists vs. SGLT2 inhibitors

Outcome	GLP-1 RA (%)	SGLT2i (%)	HR (95% CI)	RR (95% CI)	p value (log-rank)
Acute pancreatitis	0.7	1.0	0.721 (0.455–1.143)	—	0.162
Acute kidney injury	13.5	15.6	0.869 (0.748–1.011)	0.867 (0.754–0.996)	0.068

HR = hazard ratio; RR = risk ratio; CI = confidence interval; AKI = acute kidney injury. RR not reported for pancreatitis due to low event rates. AKI risk ratio analysis significant at p = 0.043; time-to-event analysis p = 0.068 (non-significant).

3454 | NUTRITIONAL STRATEGIES FOR MUSCLE PRESERVATION DURING SEMAGLUTIDE THERAPY IN MASLD: A STRUCTURED NARRATIVE REVIEW WITH DEVELOPMENT OF LIVER-SPECIFIC CLINICAL TOOLS

Keeranmayee Mishra[1] Bireera Muzaffar[2] Hanna Bowers[3] Ramy Mansour[1], [1]Trinity Health Oakland/ Wayne State University, [2]University of Oklahoma, [3]Ross University

Background: Semaglutide is FDA-approved for MASH with F2–F3 fibrosis, yet 25–40% of weight loss occurs as fat-free mass. In the STEP 1 DEXA subgroup (n = 140), lean mass loss was 6.92 kg (~39% of total). Patients with MASLD face compounded sarcopenia risk (~23% prevalence overall; 30–70% in advanced liver disease) from GLP-1RA-induced lean mass loss superimposed on hepatic catabolic dysfunction. Existing nutritional frameworks (JAMA MEAL mnemonic, ACLM/ASN/OMA/TOS Joint Advisory) were developed for general obesity populations and do not incorporate liver-specific considerations such as overnight catabolism prevention or hepatic monitoring endpoints. We aim to identify the evidence gap at the intersection of GLP-1RA therapy, liver disease, and muscle preservation, and develop paired clinical tools adapting general obesity nutritional guidance for MASLD. **Methods:** A structured narrative review across four evidence streams (GLP-1RA body composition, liver disease sarcopenia/nutrition, GLP-1RA dietary/exercise guidance, and their intersection) was conducted. A patient infographic and clinician companion card were developed with liver-specific adaptations **Results:** Only 5 included studies examined muscle outcomes during GLP-1RA therapy in liver disease, reflecting a critical evidence gap. Preliminary data are mixed: SLIM LIVER (n = 46, PWH with MASLD) showed 9.3% psoas volume decline despite preserved physical function; Kakegawa et al. (n = 21, T2DM/MASLD) reported preserved skeletal muscle area with reduced muscle steatosis. Six liver-specific adaptations were identified: (1) protein 1.2–1.5 g/kg/day per AASLD/ACG; (2) structured late-evening snack with complex carbohydrates and protein to prevent overnight catabolism; (3) complete alcohol abstinence; (4) liver-specific monitoring (VCTE, FIB-4) alongside body composition; (5) zinc supplementation; (6) dose adjustment triggers incorporating sarcopenia red flags and hepatic response. These were operationalized into paired tools: a 10-panel patient infographic and an 8-section clinician card featuring dual-track liver/

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

muscle monitoring aligned with semaglutide dose titration. **Conclusion:** General obesity GLP-1RA nutritional frameworks require meaningful adaptation for MASLD. These paired tools—the first bridging general guidance to liver-specific practice—provide an actionable framework for clinicians prescribing semaglutide for MASH. Prospective validation is warranted.

3455 | GLP-1 RECEPTOR AGONISTS USE IS ASSOCIATED WITH REDUCED NEURODEGENERATIVE AND CEREBROVASCULAR RISK IN MASLD: A PROPENSITY SCORE-MATCHED ANALYSIS

Maya Mahmoud[1] Muhammad Haris Latif[2] Lina Okar[1] Mohamed Awali[3] Kamran Qureshi[1], [1]Saint Louis University, [2]SSM Health St Mary's Hospital, [3]Washington University in St Louis

Background: MASLD is increasingly recognized as a risk factor for neurocognitive impairment and cerebrovascular disease through systemic inflammation, neurodegeneration, and liver-brain axis dysregulation. While GLP-1 receptor agonists (GLP-1 RAs) have demonstrated benefits in improving MASLD disease activity, their comparative effect on neurological outcomes versus DPP-4 inhibitors in this population remains unknown. **Methods:** Using the TriNetX federated electronic health record network, we identified adults with MASLD initiating either a GLP-1 RA (n = 226,194) or a DPP-4 inhibitor (n = 54,351). Cohorts were balanced via 1:1 propensity score matching (PSM) on demographics, metabolic comorbidities, cardiovascular risk factors, laboratory parameters, medication use, and psychiatric disease burden. Primary outcomes including incident dementia, Alzheimer disease, vascular dementia, Parkinson disease, cerebral infarction, mild cognitive impairment, and falls, were assessed at 1 and 5 years following treatment initiation using Kaplan-Meier analysis and Cox proportional hazards modeling. A BMI-stratified sensitivity analysis was performed given residual BMI imbalance after PSM. **Results:** Following PSM, 48,833 patients were included per cohort. GLP-1 RA therapy in patients with MASLD was associated with significantly lower risk of all-cause dementia compared with DPP-4 inhibitor use at both 1 year (HR 0.60, 95% CI 0.47–0.76; $p < 0.001$) and 5 years (HR 0.64, 95% CI 0.57–0.72; $p < 0.001$), as well as reduced risk of cerebral infarction at 1 year (HR 0.67, 95% CI 0.56–0.80; $p < 0.001$) and 5 years (HR 0.72, 95% CI 0.65–0.78; $p < 0.001$). At 5 years, GLP-1 RA use was further associated with lower risks of vascular dementia (HR 0.70, 95% CI 0.55–0.89; $p = 0.003$) and Alzheimer disease (HR 0.70, 95% CI 0.54–0.89; $p = 0.004$). No significant differences were observed for Parkinson disease, mild cognitive impairment, or falls. BMI-stratified sensitivity analyses confirmed the persistence of the dementia association with improved covariate balance, supporting the robustness of these findings. **Conclusion:** Among patients with MASLD, GLP-1 RA therapy was associated with significantly lower risks of dementia, Alzheimer disease, vascular dementia, and cerebral infarction compared with DPP-4 inhibitors, with effects sustained at 5 years. These findings suggest GLP-1 RAs may reduce neurological risk in MASLD through pathways beyond shared glycemic and metabolic improvement. Prospective studies are warranted to clarify underlying mechanisms, including the potential role of liver-brain axis modulation, and to establish causality.

3456 | FGF21-BASED THERAPIES AND DUAL INCRETIN AGONISTS LEAD HISTOLOGIC RESPONSE IN MASH: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

Maheen Afzal[1] Ubaid Ahmed[2] Rahul Falodia[3], [1]University of Alabama at Birmingham, Montgomery, [2]Dow University of Health Sciences, Karachi, Pakistan, [3]All India Institute of Medical Sciences Jodhpur

Background: Metabolic dysfunction–associated steatohepatitis (MASH) is a common liver disease with no universally accepted first-line pharmacotherapy. Multiple drug classes, including FXR agonists, PPAR agonists, GLP-1 receptor agonists, FGF21-based therapies, thyroid hormone receptor-β agonists, and combination regimens, have been evaluated, but their comparative efficacy and safety remain unclear. We performed a systematic review and network meta-analysis (NMA) to evaluate and rank major therapeutic classes based on histologic and non-invasive endpoints in MASH. **Methods:** A comprehensive search of PubMed, CENTRAL, and Scopus was conducted through September 2025. We included RCTs enrolling adults with biopsy-proven MASH. Primary outcomes were MASH resolution without worsening of fibrosis and ≥1-stage fibrosis improvement without worsening of MASH. A Bayesian network meta-analysis using random-effects models was performed. **Results:** Out of 1,924 screened records, 20 RCTs met inclusion criteria. For MASH resolution without worsening of fibrosis, pegozafermin showed the highest efficacy (RR 13.86–21.79). Dual incretin agonists were also ranked among the strongest therapies, with tirzepatide (RR 4.29–6.00) and survodutide (RR 3.20–4.63) showing strong and consistent benefits. Semaglutide demonstrated moderate, dose-dependent efficacy (RR 2.15–3.45), while resmetirom showed similar mid-range effects (RR 2.02–2.65). Vitamin E showed no benefit over placebo.For ≥1-stage fibrosis improvement without worsening of MASH, pegozafermin showed strong antifibrotic efficacy (RR up to 15.59, 95% CrI 1.87–129.93). Tirzepatide 15 mg (RR 4.19) and survodutide 6 mg (RR 1.56) also showed significant benefit, reflecting dual incretin activity. Resmetirom (80–100 mg) showed moderate benefit (RR 1.68–1.79), while semaglutide showed modest antifibrotic activity (RR 1.13–1.40).For the composite endpoint, FGF21-based therapies showed the greatest efficacy, with pegozafermin (RR 4.19, 3.93, 3.27 across doses) and efruxifermin (RR 3.33, 3.08, 2.77) showing the strongest effects. Dual incretin agonists showed moderate benefit (tirzepatide RR 1.75–1.90; survodutide RR 1.77), while dapagliflozin showed a weaker signal (RR 2.27). Semaglutide showed minimal benefit (RR 0.90–1.04), and vitamin E showed modest, low-precision effect (RR 1.71). **Conclusion:** Across both key histologic outcomes—MASH resolution and ≥1-stage fibrosis improvement—FGF21-based therapies and dual incretin agonists demonstrated the strongest efficacy, outperforming other drug classes. Resmetirom showed moderate, consistent antifibrotic benefit, while semaglutide produced modest improvements. Traditional agents had minimal effect. Overall, FGF21-based therapies and dual incretin agonists appear to be the most promising disease-modifying treatments for MASH.

Health Physicians, [7]Tufts Medical Center, [8]University of Texas Southwestern, [9]Saint Louis University, [10]Children's Hospital of Orange County, [11]All Children's Hospital, [12]CHEO, [13]The Children's Hospital of Philadelphia

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD), with its severe form metabolic dysfunction-associated steatohepatitis (MASH), affects up to 10% of children globally and causes significant morbidity and mortality. It has no FDA-approved therapy. Semaglutide is effective in adult MASLD/MASH and conditionally approved for adults with non-cirrhotic MASH, but pediatric effectiveness is unclear. We assessed semaglutide in a multicenter cohort of children with MASLD using histology, MRI, and FibroScan. **Methods:** We retrospectively included 102 children with biopsy- or imaging-confirmed MASLD from 2020-2026 (44 on semaglutide and 58 contemporary controls). Outcomes were NAFLD activity score (NAS), MASH resolution (NAS < 4, lobular inflammation = 0-1, ballooning = 0, no worsening of fibrosis), fibrosis stage, MR elastography (MRE), MRI-proton density fat fraction (PDFF), and FibroScan liver stiffness measurement (LSM) and controlled attenuation parameter (CAP). Analyses used t-tests/chi-squared tests. **Results:** Semaglutide-treated children were older (14.8 vs 12.6 years), with higher BMI (37.8 vs 31.7) and BMI z-score (2.84 vs 2.42), but with similar sex distribution, NAS (4.72 vs 4.33), and fibrosis stage (1.56 vs 1.56). Most subjects reached 2.4 mg weekly as maintenance (70.5%); mean treatment was 53.4 weeks.In 38 children with paired biopsies (14 semaglutide, 24 controls; mean 24.0-month interval), NAS improved by -2.14 vs 0 ($p = 0.002$), and fibrosis stage changed by -0.43 vs +0.17 ($p = 0.06$). Among patients with MASH, semaglutide resolved MASH in 55.6% vs 11.8% ($p = 0.02$; Figure) and improved NAS by > = 3 points in 66.7% vs 5.9% ($p < 0.001$). Notably, semaglutide prevented further worsening of fibrosis in all patients with fibrosis (n = 12).In 32 children with paired MRIs (23 semaglutide, 9 controls; 16.4-month interval), MRE changes did not differ. MRI-PDFF improved more with semaglutide (absolute -16.3% vs -1.7%, $p = 0.003$; relative -70.5% vs +1.3%, $p = 0.006$). Relative MRI-PDFF improvement > = 30% occurred in 91.3% vs 25% ($p < 0.001$; Figure), and > = 60% in 69.6% vs 0% ($p < 0.001$).At 6 months, paired FibroScan was available in 40 children (22 semaglutide, 18 controls). FibroScan LSM change did not differ, but CAP improved (absolute -29.6 dB vs +15.8 dB; relative -8.8% vs +5.7%; both $p < 0.001$). CAP improved by > = 5% in 72.7% vs 16.7% ($p < 0.001$; Figure) and by > = 10% in 59.1% vs 11.1% ($p = 0.002$). At 12 months (n = 24; 12/group), LSM remained nonsignificant, while CAP improved by -47.7 vs +25.0 dB and -13.8% vs +9.5% (both $p < 0.001$); CAP improved by > = 5% in 66.7% vs 16.7% ($p = 0.01$) and by > = 10% in 58.3% vs 8.3% ($p = 0.009$). **Conclusion:** In this first retrospective multicenter pediatric MASLD cohort, semaglutide was associated with histologic MASH resolution and improved MRI-PDFF, and FibroScan CAP, while MRE/Fibroscan LSM changes were not significant. These findings suggest pediatric efficacy and warrant confirmation in RCTs.

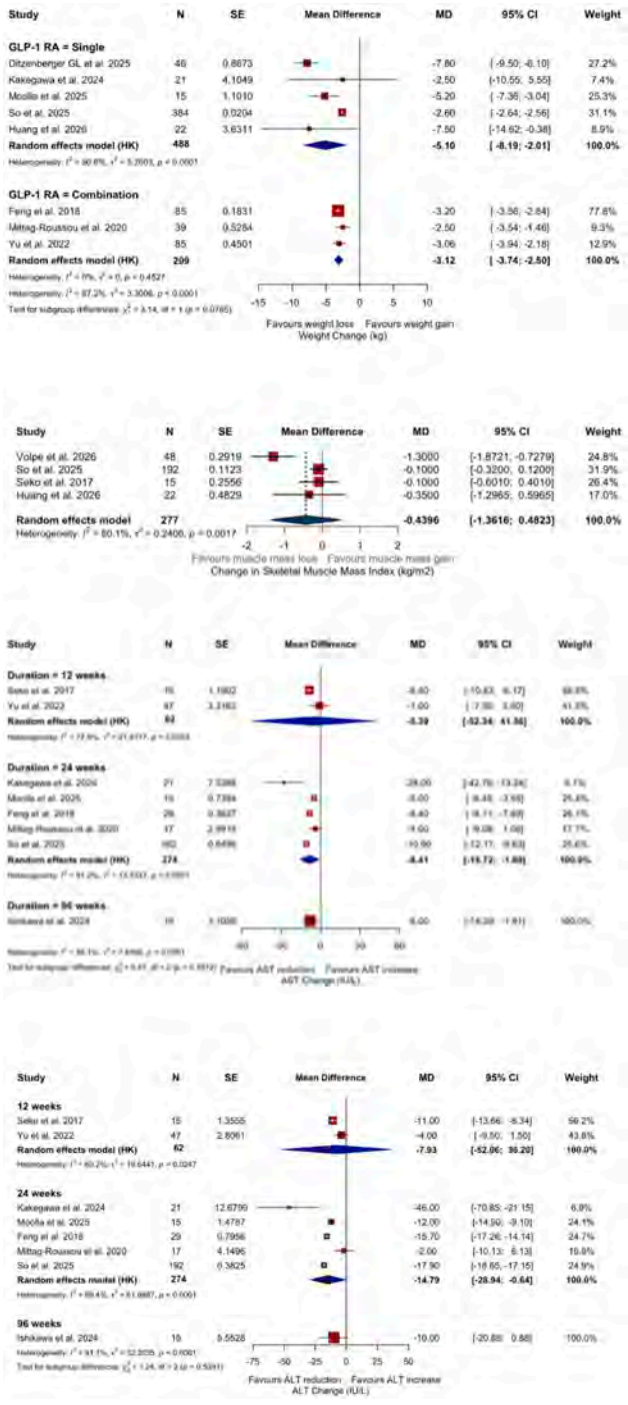
3458 | EFFECTS OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS ON SKELETAL MUSCLE MASS, WEIGHT LOSS, AND LIVER ENZYMES IN MASLD: A SYSTEMATIC REVIEW AND META-ANALYSIS



Era Gupta[1] Priyanshi Mehulkumar[2] Omar Oudit[3] Harmanjeet Singh[4] Mohammed Amaanullah[5] Rewanth Katamreddy[6] Deepak Bharathi Shivananda[7] Aakash Desai[8], [1]Guthrie/ Robert Packer Hospital, PA, USA, [2]Government Medical College, Surat, India, [3]Brookdale UNIVERSITY Hospital Medical Center, NY, USA, [4]Mahatma Gandhi Memorial Medical College, India, [5]DR BR Ambedkar Medical College, India, [6]Guthrie/ Robert Packer Hospital, PA, USA, [7]Bangalore Medical College And Research Institute, India, [8]Allegheny Health Network

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is closely associated with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

obesity and insulin resistance, making weight reduction a key therapeutic target. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) improve weight loss, glycemic control, and hepatic inflammation in MASLD. However, reductions in lean body mass raise concerns regarding sarcopenia. We performed a systematic review and meta-analysis evaluating the effects of GLP-1RAs on skeletal muscle mass, weight, body mass index (BMI), and liver enzymes in MASLD. **Methods:** This review followed PRISMA guidelines. Embase, PubMed, and ScienceDirect were systematically searched for studies evaluating GLP-1RAs in MASLD. Parameters including BMI, AST, ALT, and skeletal muscle indices assessed by bioelectrical impedance analysis were analyzed. Subgroup analyses were performed by treatment duration and regimen, with monotherapy compared against GLP-1RAs combined with oral hypoglycemic agents (combination). Statistical analysis was conducted in RStudio using random-effects models to calculate mean differences (MD), with heterogeneity assessed using the I^2 statistic. **Results:** Ten studies involving 846 patients were included. GLP-1RA therapy demonstrated a trend toward reduction in skeletal muscle index (MD −0.44 kg/m², 95% CI −1.36 to 0.48, p = 0.0017). Significant reductions were observed in body weight (MD −4.60 kg, 95% CI −6.27 to −2.93, p < 0.0001), AST (MD −7.64 IU/L, 95% CI −11.40 to −3.89, p < 0.0001), and ALT (MD −14.79 IU/L, 95% CI −28.94 to −0.64, p < 0.0001). Subgroup analysis demonstrated greater weight reduction with single-agent GLP-1RA therapy (MD −5.10 kg, 95% CI −8.19 to −2.01, p < 0.0001) compared with combination regimens (MD −3.12 kg, 95% CI −3.74 to −2.50, p = 0.4527). Duration-based subgroup analysis showed progressive weight reduction over time, with the greatest reduction observed at 48 weeks (MD −7.80 kg, 95% CI −9.50 to −6.10), compared with 24 weeks (MD −2.93 kg, 95% CI −3.78 to −2.08, p = 0.0028) and 12 weeks (MD −3.06 kg, 95% CI −3.94 to −2.18). For liver enzymes, single-agent GLP-1RA therapy demonstrated greater AST reduction (MD −9.99 IU/L, 95% CI −21.43 to 1.45, p < 0.0001) compared with combination therapy (MD −6.14 IU/L, 95% CI −11.41 to −0.88, p = 0.0540). Similarly, ALT reduction was greater with single-agent therapy (MD −15.00 IU/L, 95% CI −27.70 to −2.30, p < 0.0001) compared with combination regimens (MD −8.41 IU/L, 95% CI −18.83 to 2.01, p < 0.0001). Duration-based subgroup analysis demonstrated the greatest AST and ALT reductions at 24 weeks (AST: MD −8.41 IU/L, 95% CI −15.72 to −1.09, p < 0.0001; ALT: MD −14.79 IU/L, 95% CI −28.94 to −0.64, p < 0.0001). **Conclusion:** GLP-1RAs in MASLD were associated with significant reductions in weight and liver enzymes, while demonstrating a trend toward lower skeletal muscle index. Larger studies are needed to define the long-term impact of GLP-1RAs on sarcopenia risk in MASLD.

3459 | VITAMIN E INITIATION IS ASSOCIATED WITH FEWER LIVER-RELATED EVENTS IN ADVANCED MASH: A SEQUENTIAL TARGET TRIAL EMULATION IN THE NASH CRN

Eduardo Vilar-Gomez[1] Wanzhu Tu[1] Yi Zhao[1] Jeanne Clark[2] Brent Neuschwander-Tetri[3] Rohit Loomba[4] Arun Sanyal[5] Naga Chalasani[6], [1]Indiana University School of Medicine, [2]Rutgers RWJ Medical School, [3]Saint Louis University School of Medicine, [4]University of California, San Diego, [5]Virginia Commonwealth University, [6]Indiana University Medical Center

Background: Vitamin E improves histologic MASH in randomized trials, but its effect on major liver-related events (LREs) in advanced fibrosis remains uncertain. Because conventional observational analyses may be biased by delayed treatment initiation and time-varying confounding, we emulated a sequential target trial in NASH CRN prospective studies to estimate the association between vitamin E initiation and LREs. **Methods:** We used NASH CRN prospective data from 2005–2021, including Database 2 and post-trial follow-up from placebo arms of PIVENS and FLINT. The cohort included 476 adults with biopsy-proven MASH and advanced fibrosis: 328 with bridging fibrosis and 148 with compensated cirrhosis. Prevalent vitamin E users were excluded, consistent with an incident-user design. Vitamin E use was systematically obtained from structured medication inventories at regular visits and defined as the first recorded therapeutic use $\geq$200 IU/day after time zero. Eligibility and covariates were updated at sequential trial starts every 60 days during the first 5 years. We compared initiation within 365 days versus no initiation within 365 days using clone-censor-weight methods and weighted Cox models; covariates were well balanced after weighting. The primary endpoint was first centrally adjudicated LRE: hepatic decompensation, hepatocellular carcinoma, liver transplantation, or liver-related death. **Results:** Ninety-nine patients initiated vitamin E, with a median recorded use of 5.8 years, and 60 patients experienced a first LRE. The strategy-type ITT analysis accrued 54,657 weighted clone-person-years in the pooled sequential trial pseudo-population. In the strategy-type ITT analysis, vitamin E initiation was associated with lower LRE risk (HR, 0.75; 95% CI, 0.63–0.89), with 5-year absolute risk reduction (ARR) of 6.45%, number needed to treat (NNT) of 16, and 0.90-year gain in 10-year restricted mean event-free survival. Per-protocol analysis showed a stronger association (HR, 0.71; 95% CI, 0.57–0.89), with a 5-year ARR of 6.87%, NNT of 15, and 1.03-year event-free survival gain. Vitamin E initiation was not associated with non-liver mortality in strategy-type ITT (HR, 1.00; 95% CI, 0.61–1.64) or per-protocol analyses (HR, 0.87; 95% CI, 0.52–1.47). **Conclusion:** In adults with MASH and advanced fibrosis, vitamin E initiation was associated with fewer incident LREs in a sequential target trial emulation. These findings support individualized consideration of vitamin E in selected high-risk patients and further evaluation of vitamin E as a potential strategy to reduce liver-related complications.

Figure. Cumulative Probability of an Initial Liver-Related Event by Vitamin E Initiation Strategy

Abbreviations: ARR, absolute risk reduction; CI, confidence interval; HR, hazard ratio; ITT, intention-to-treat; NNT, number needed to treat; PP, per-protocol.
Legend. Cox-specific weighted models were used for the first liver-related event, defined as hepatic decompensation, hepatocellular carcinoma, liver transplantation, or liver-related death, comparing vitamin E initiation (≥200 IU/day) versus no initiation in adults with MASH and advanced fibrosis. Panels display inverse probability–weighted cumulative probability curves from Cox models.
Panel A (left) shows the strategy-type intention-to-treat analysis, in which patients remain in their assigned strategy after the 365-day grace period regardless of subsequent treatment initiation.
Panel B (right) shows the per-protocol analysis, in which patients are censored at the time of deviation from their assigned strategy.
Hazard ratios with 95% confidence intervals, E-values, absolute risk reductions, and numbers needed to treat are reported inside each panel.

3460 | POST-12-MONTH CARDIOVASCULAR AND MORTALITY OUTCOMES IN MASLD

Leith Ghani[1] Diwanshu Soni[1] Majd Aboona[2] Pooja Rangan[3] Chih Hua Chung[3] Yu Cin Chang[3] Mark Wong[3] Moises Nevah Rubin[4] Rohit Nathan[3] Karn Wijarnpreecha[1] Mike Fallon[5] Farah Husain[6] Ma Ai Thanda Han[7], [1]University of Arizona College of Medicine-Phoenix, [2]University of Arizona College of Medicine - Phoenix, [3]Banner University Medical Center- Phoenix, [4]Banner University Medical Center, [5]University of Arizona, [6]Oregon Health & Science University, [7]University of Arizona College of Medicine Phoenix

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is closely linked to cardiovascular risk. While bariatric surgery, GLP-1 receptor agonists (GLP-1 RA), and SGLT2 inhibitors (SGLT2i) are established treatments for obesity and metabolic disease, direct comparative data on major adverse cardiovascular events (MACE) and mortality across these interventions in MASLD patients remain limited. **Methods:** This retrospective multicenter cohort study utilized data from the Banner Health System. MASLD patients were identified using ICD codes for non-alcoholic fatty liver disease plus at least one of five metabolic criteria. Patients were categorized into four intervention groups: bariatric surgery, GLP-1 RA, SGLT2i, or combination therapy. Multinomial propensity score-based inverse probability of treatment weighting (IPTW) was applied to reduce baseline selection bias, adjusting for age, sex, BMI, race, tobacco use, hypertension, hyperlipidemia, and diabetes mellitus. A post 12-month landmark analysis was employed to mitigate immortal-time bias. Propensity score-matched survival analyses were performed. The primary outcome was MACE after 12 months post-intervention; secondary outcome was all-cause mortality following the landmark period. **Results:** The cohort included 8,619 patients: 5.8% underwent bariatric surgery, 39.3% received GLP-1 RA, 23.4% received SGLT2i, and 31.5% received combination therapy. After IPTW adjustment, compared to bariatric surgery, the post-12-month MACE risk was significantly higher in the GLP-1 RA group (HR 2.22, 95% CI 1.40–3.55, $p = 0.001$), SGLT2i group (HR 2.15, 95% CI 1.32–3.50, $p = 0.002$), and combination therapy group (HR 1.84, 95% CI 1.15–2.93, $p = 0.010$). No statistically significant differences in 12-month mortality were observed across pharmacologic groups (GLP-1 RA: HR 1.97, 95% CI 0.60–6.46, $p = 0.262$; SGLT2i: HR 1.88, 95% CI 0.54–6.52, $p = 0.323$; combination: HR 0.71, 95% CI 0.20–2.45, $p = 0.584$) **.** Propensity score-matched survival curves for post-12-month MACE and all-cause mortality are displayed in Figure 1. **Conclusion:** Bariatric surgery demonstrated a more favorable post 12-month landmark MACE risk compared with pharmacologic interventions. Propensity score-matched survival analysis suggested a significant survival benefit with bariatric surgery; however, this was not confirmed in IPTW- adjusted mortality models, warranting cautious interpretation. These findings underscore the need for prospective trials examining cardiovascular and survival outcomes across metabolic interventions in MASLD.

★ 3461 | REAL-WORLD EFFECTIVENESS AND SAFETY OF RESMETIROM IN PATIENTS WITH MASH: A DESCRIPTIVE COHORT STUDY

Michelle Maguire[1] Anthony Michaels[1] James Hanje[1] Ruchi Bhatia[1] Pranav Penninti[1] Kathy Foreman[1] Gretchen Calhoun[1] Charlie McGuire[1] Shireen Saa[1], [1]Ohio Gastroenterology Group

Background: Resmetirom received accelerated FDA approval in March 2024 for noncirrhotic MASH with moderate-to-advanced fibrosis (F2–F3). Real-world data on outcomes, persistence, and interdisciplinary care models remain limited. We describe clinical characteristics, noninvasive test (NIT) outcomes, and treatment persistence of patients prescribed resmetirom in a hepatology practice with integrated clinical pharmacist and nurse practitioner (NP) MASH clinic support. **Methods:** This single-center, retrospective study included adults who started resmetirom between March 14, 2024 and March 31, 2026. Baseline demographics, fibrosis stage, ALT, and BMI were collected. Follow-up included ALT at 3, 6, and 12 months and fibrosis reassessment (primarily vibration-controlled transient elastography [VCTE]) at 6 and 12 months. Fibrosis stage changes were examined by GLP-1 receptor agonist (GLP-1 RA) use and $\geq$5% body weight loss. **Results:** Of 244 patients prescribed resmetirom, 226 initiated therapy (mean age 58.5 years; 39.3% $\geq$65 years; 57.2% female; 70.8% with diabetes/prediabetes; 75% with obesity; 38% on baseline GLP-1 RA, 19% added GLP-1 RA during treatment). Baseline fibrosis was F2 in 45.1%, F3 in 46.9%, and F3-4 in 7.96%. Staging was by elastography in 92.5% (VCTE 84.5%) and biopsy in 7.5%. Mean baseline VCTE was 10.67 kPa; mean ALT 53.16 U/L. At 3 months (n = 164), mean ALT decreased 9.8%; 37.2% achieved ALT < 30 U/L. At 6 months (n = 145), mean ALT decreased 9.5%; 49.7% achieved ALT < 30 U/L and 44.1% achieved $\geq$30% ALT reduction. Among 127 patients with paired VCTE at 6 months, mean stiffness decreased 1.43 kPa; 75% improved (mean 3.65 kPa reduction) and 41.4% achieved $\geq$25% kPa reduction. Mean CAP decreased 50.1 (14.8%). At 12 months (n = 68 paired VCTE), mean kPa decreased 2.84 (25.3%, p = 0.009); 81% improved (mean 4.30 kPa reduction) and 66.2% achieved $\geq$25% kPa reduction. Mean CAP decreased 53.3 (16%, p = 0.58). Fibrosis at 12 months (n = 85): F0-1 57.6%, F2 18.8%, F3 21.2%, F4 2.4%. At 6 months, 35.7% (80/224) lost $\geq$5% body weight with higher F0-1 rates (45% vs 36.9%). At 12 months, 21.9% (49/224) lost $\geq$5%, with F0-1 rates of 63% vs 50%. GLP-1 RA use showed a similar trend (F0-1: 46.6% vs 37% at 6 months; 60% vs 54% at 12 months). Persistence was 87.6% (28/226 discontinued); adverse events accounted for 13 discontinuations. 93.4% were seen by MASH clinic pharmacist and/or NP. **Conclusion:** In this large real-world cohort, resmetirom demonstrated significant improvement in liver stiffness (p = 0.009) and progressive ALT improvements through 12 months. Fibrosis regression to F0-1 occurred in over half of patients at 12 months. CAP reduction was not statistically significant. Weight loss and GLP-1 RA use appeared to provide incremental benefit. Persistence was high, supported by an integrated pharmacist and nurse practitioner care model. These findings complement trial data and support resmetirom effectiveness in routine practice.

3462 | CORRELATION ANALYSIS BETWEEN RNA SEQUENCING OF MASH ANIMAL MODELS AND HUMAN DATA

Sitong Zhang[1] Hong Sheng Cheng[2] Damien Chua[3] Yu Xuan Liu[2] Yan Zhou[4] Jiliang Zhang[4] Wenjie Gao[4] Nguan Soon Tan[2] Letian Kuai[4], [1]WuXi AppTec Co., Ltd., [2]Lee Kong Chian School of Medicine, Nanyang Technological University, Singapore, [3]Lee Kong Chian School of Medicine, Nanyang Technological University Singapore, [4]In Vivo Pharmacology Unit, WuXi Biology, WuXi AppTec, China

Background: Affecting 5-8% of the global population, Metabolic Dysfunction-Associated Steatohepatitis (MASH) is a growing public health concern that demands novel therapeutic strategies. Its complex and multifactorial pathogenesis suggests a need for multifaceted treatment modalities but selecting appropriate animal models that accurately reflect human disease is crucial for translational success. Through a human transcriptomic-guided analysis, we aim to identify the strengths of different MASH models, thereby refining the selection process for drug evaluation and enhancing predictability of preclinical studies. **Methods:** Well-recognized rodent MASH models were generated using the GAN diet (Gubra Amylin NASH diet), CDAHFD (Choline-Deficient, L-amino acid-defined, High-Fat Diet), LIDPAD (Liver Disease Progression Aggravation Diet), and HFD (High-Fat Diet) plus CCl4 (Carbon Tetrachloride). Corresponding healthy control groups were established for each model. Liver samples were collected for transcriptional profiling. A human transcriptomic-guided analysis was performed, comparing the transcriptional profiles of rodent MASH models and human MASH patients. **Results:** All murine MASH models exhibited an increase in NAS and liver fibrosis scores compared to healthy controls. The CDAHFD and HFD+CCl4 models showed more severe liver fibrosis, while the LIDPAD and GAN diet models exhibited significant insulin resistance and metabolic abnormalities. Transcriptomic analysis revealed substantial perturbations in lipid metabolism, xenobiotic metabolism, inflammation, and extracellular matrix regulation across these models, collectively capturing distinct pathological stages and mechanistic facets of human MASH progression. The CDAHFD and HFD plus CCl4 models replicated fibrogenesis, as evidenced by enrichment of TGF-β signaling and disrupted choline metabolism. The GAN diet and LIDPAD model captured the progressive transition from steatosis to inflammatory and fibrotic remodeling, enabling rapid progression of MASH while preserving key metabolic features of disease evolution. **Conclusion:** Collectively, these findings demonstrate that transcriptomic profiling extends model evaluation beyond conventional histological assessment by providing a mechanistic and quantitative framework to resolve how individual models engage disease-driving pathways relevant to human MASH. This approach reveals that distinct murine models preferentially capture different pathological stages and biological programs, thereby refining interpretation of model-specific strengths and limitations. By integrating histological and transcriptional alignment with human disease, the study establishes a more objective and translationally relevant strategy for selecting preclinical models and improving prediction of therapeutic responses prior to clinical testing.

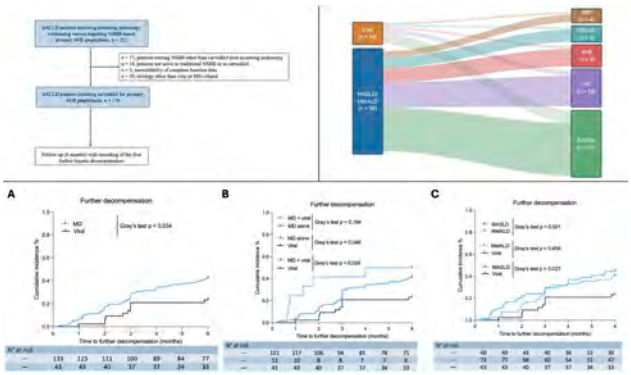
3463 | METABOLIC DYSFUNCTION IS ASSOCIATED WITH FURTHER HEPATIC DECOMPENSATION DESPITE CARVEDILOL IN DECOMPENSATED ADVANCED CHRONIC LIVER DISEASE



Mario Romeo[1] Viktor Domislovic[2] Fiammetta Di Nardo[1] Carmine Napolitano[1] Paolo Vaia[1] Claudio Basile[1] Giuseppe De Girolamo[3] Moris Sangineto[3] Borna Cutic[2] Anna Mrzljak[2] Alessandro Federico[1] Marcello Dallio[1], [1]Hepatogastroenterology Division, University Hospital Luigi Vanvitelli, 80138 Naples, Italy, [2]Liver Transplant Center, University Hospital Center Zagreb, 10000 Zagreb, Croatia, [3]C.U.R.E. (University Center for Liver Disease Research), Liver Unit), Foggia, 71121, Italy

Background: Metabolic dysfunction (MD) is increasingly recognized as a major determinant of cirrhosis progression and may attenuate the response to non-selective beta-blockers (NSBB). Whether MD influences the risk of further hepatic decompensation in patients with decompensated advanced chronic liver disease (dACLD) receiving carvedilol-based primary prophylaxis remains unknown. **Methods:** In this multicenter cohort study, consecutive adults with dACLD and esophageal varices requiring primary

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

prophylaxis were enrolled at three European tertiary centers. All patients started carvedilol and were prospectively followed for 6 months. Patients were classified according to the presence of MD, including metabolic dysfunction-associated steatotic liver disease (MASLD), metabolic dysfunction-associated alcohol-related liver disease (MetALD), and mixed MD plus viral etiologies, and compared with patients with viral-related cirrhosis without MD. The primary endpoint was first further hepatic decompensation, defined as new or recurrent ascites, overt hepatic encephalopathy, acute variceal bleeding, spontaneous bacterial peritonitis, or hepatorenal syndrome-acute kidney injury. Death and liver transplantation were treated as competing events. **Results:** Among 176 included patients, 133 (75.6%) had MD and 43 (24.4%) had viral-related cirrhosis without MD. Baseline liver function, Child-Pugh class, MELD score, and variceal characteristics were comparable between groups. During follow-up, 66 patients (37.5%) developed further hepatic decompensation. The 6-month cumulative incidence was significantly higher (42.1% vs 23.3%) in patients with MD than in those without MD [SHR: 2.06, 95% CI 1.19-3.52; $p = 0.009$]. After adjustment for serum albumin, diabetes, body mass index, mean arterial pressure, and recruiting center, MD remained independently associated with the outcome [adjusted SHR 1.98, 95% CI 1.15-3.45; $p = 0.015$]. Lower serum albumin was also independently associated with further decompensation. Excess risk was driven predominantly by non-bleeding events, particularly ascites. Carvedilol exposure, target dose achievement, hemodynamic changes, and treatment discontinuation rates were similar across etiological groups. No significant differences were observed between MASLD and MetALD patients. **Conclusion:** MD is independently associated with a nearly twofold higher risk of further hepatic decompensation despite guideline-directed carvedilol therapy in dACLD. These findings support the concept of a distinct metabolic phenotype of portal hypertension and suggest that patients with MD may require closer monitoring and personalized management strategies beyond standard therapeutic approaches.

3464 | SGLT-2 INHIBITOR USE AND LIVER-RELATED OUTCOMES IN T2DM-ASSOCIATED MASLD: A PROPENSITY-SCORE MATCHED ANALYSIS

Jashanveer Johal[1] Bianca Patel[1] Archana Salek[2] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Abdallah Hussein[1] Yecheskel Schneider[1] Jason Hyman[3], [1]Virtua Health, [2]Viruta Health, [3]Einstein Medical Center, Philadelphia

Background: SGLT-2 inhibitors reduce hepatic steatosis, intrahepatic inflammation, and fibrogenic signaling through insulin-sensitizing and weight-independent mechanisms, making them a biologically compelling candidate in MASLD. Despite accumulating preclinical and trial data, real-world evidence quantifying their impact on hard liver-related outcomes — cirrhosis progression, hepatic decompensation, and transplantation — in patients with comorbid T2DM and MASLD remains limited. **Methods:** We performed a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (~192 million patients). Adults with concurrent T2DM and MASLD/NASH initiating an SGLT-2 inhibitor (without GLP-1 RA use) were matched 1:1 to T2DM/MASLD patients receiving neither drug class. Both cohorts excluded pre-existing cirrhosis, HCC, or viral hepatitis. Outcomes included cirrhosis progression, hepatic decompensation, liver transplantation, HCC incidence, inpatient admission burden, all-cause mortality, and new CKD $\geq$ stage 3. **Results:** After 1:1 PSM, 38,033 patients per arm were analyzed. SGLT-2 inhibitor use was associated with significantly lower rates of cirrhosis progression (0.23% vs. 0.68%; RR 0.34; HR 0.42, 95% CI 0.33–0.53), hepatic decompensation (1.77% vs. 4.28%; RR 0.41; HR 0.49, 95% CI 0.45–0.54), and liver transplantation (0.05% vs. 0.20%; RR 0.25; HR 0.31, 95% CI 0.19–0.51). HCC events were absent in both cohorts, consistent with the protracted natural history of hepatocarcinogenesis. Among hospitalized patients, SGLT-2 users had fewer inpatient encounters (mean 7.5 vs. 9.4; $p < 0.001$). All-cause mortality was markedly lower in the SGLT-2 arm (6.79% vs. 14.84%; RR 0.46). New CKD incidence was similar on point-in-time

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

analysis, though time-to-event modeling suggested early divergence likely reflecting the transient hemodynamic GFR effect prior to long-term renoprotection. **Conclusion:** In this large propensity-matched cohort of patients with T2DM and MASLD, SGLT-2 inhibitor use was associated with substantial reductions in cirrhosis progression, hepatic decompensation, liver transplant need, and all-cause mortality. Reductions of 59–75% across hard hepatic endpoints suggest disease-modifying potential well beyond glycemic control, supporting earlier, more deliberate use of SGLT-2 inhibitors as a hepatoprotective strategy in this high-risk population.
Disclosures: Jashanveer Johal:Nothing to Disclose, Bianca Patel:Nothing to Disclose, Archana Salek: Nothing to Disclose, Mahmoud Al-Bataineh:Nothing to Disclose, Brandon Cunha:Nothing to Disclose, Abdallah Hussein:Nothing to Disclose, Yecheskel Schneider: Nothing to Disclose, Jason Hyman:Nothing to Disclose.

3465 | INTENSIVE LDL REDUCTION AND HEPATIC DISEASE PROGRESSION IN MASLD WITHOUT PRIOR ACS: A PROPENSITY SCORE–MATCHED THREE-WAY COHORT ANALYSIS

Jashanveer Johal[1] Brandon Cunha[1] Mahmoud Al-Bataineh[1] Archana Salek[1] Bianca Patel[1] Abdallah Hussein[1] Yecheskel Schneider[1] Jason Hyman[2], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Statins are increasingly recognized as potentially hepatoprotective in MASLD, with preclinical evidence suggesting anti-inflammatory and antifibrotic effects. Whether achieving more intensive LDL targets confers incremental hepatic benefit in real-world populations remains uncharacterized. **Methods:** We conducted three parallel propensity score–matched retrospective cohort analyses using the TriNetX Global Collaborative Network (191.9 million patients). All patients carried a diagnosis of MASLD, were on statin therapy, and had most recent on-treatment LDL within pre-defined thresholds. Patients with prior ACS were excluded. Three pairwise comparisons were performed: LDL <55 vs. <100 mg/dL ($n \asymp 15{,}475$/arm), LDL <70 vs. <100 mg/dL ($n \asymp 36{,}133$/arm), and LDL <55 vs. <70 mg/dL ($n \asymp 19{,}507$/arm), balanced via 1:1 PSM over a 6–120 month follow-up. Outcomes included cirrhosis, hepatic fibrosis, HCC, portal hypertension, hepatic decompensation, serologic hepatic dysfunction, HRS/ARF, and liver transplantation. **Results:** Across all three comparisons, lower achieved LDL targets were paradoxically associated with a dose-dependent gradient of higher hepatic event rates on KM analysis. In the <55 vs. <100 comparison, LDL <55 was associated with significantly higher hazard of cirrhosis (HR 1.18; $p = 0.005$), hepatic fibrosis (HR 1.18; $p = 0.019$), portal hypertension (HR 1.18; $p = 0.049$), serologic hepatic dysfunction (HR 1.11; $p = 0.018$), and HRS/ARF (HR 1.14; $p = 0.001$). In the <70 vs. <100 comparison, LDL <70 was associated with higher hazard of cirrhosis (HR 1.10; $p = 0.020$), hepatic fibrosis (HR 1.19; $p = 0.0002$), portal hypertension (HR 1.14; $p = 0.022$), hepatic decompensation (HR 1.11; $p = 0.009$), serologic hepatic dysfunction (HR 1.06; $p = 0.032$), and HRS/ARF (HR 1.07; $p = 0.011$). In the <55 vs. <70 comparison, LDL <55 demonstrated higher hazard of cirrhosis (HR 1.12; $p = 0.037$), serologic hepatic dysfunction (HR 1.08; $p = 0.039$), and HRS/ARF (HR 1.08; $p = 0.030$). HCC and liver transplant were not significantly different across any comparison. **Conclusion:** Lower achieved LDL targets in statin-treated MASLD patients without prior ACS were associated with a consistent, dose-dependent gradient of worse hepatic outcomes. These findings most likely reflect reverse causation — impaired hepatic cholesterol synthesis in advanced liver disease driving lower observed LDL — rather than statin toxicity. These data do not support restricting statin use in MASLD, but underscore the need for fibrosis stage–stratified analyses and prospective studies evaluating lipid targets in this population.
Disclosures: Jashanveer Johal:Nothing to Disclose, Brandon Cunha:Nothing to Disclose, Mahmoud Al-Bataineh:Nothing to Disclose, Archana Salek:Nothing to Disclose, Bianca Patel:Nothing to Disclose, Abdallah Hussein:Nothing to Disclose, Yecheskel Schneider: Nothing to Disclose, Jason Hyman:Nothing to Disclose.

3466 | RESMETIROM IN MASLD: 12-MONTH REAL-WORLD CLINICAL OUTCOMES

Lauren Rivera[1] Sameera Shuaibi[1] Ian Tobal[1] Ricardo David Espinosa[1] James Gore[1] Ruona Ebiai[1] Amanda Mooney[1] Taylor Shano[1] Jill Rovira[1] Erin Biggs[1] Claire Ozoral[1] George Therapondos[1], [1]Ochsner Health

Background: Resmetirom became the first FDA-approved therapy for non-cirrhotic MASLD with moderate to advanced fibrosis. Real-world outcomes data on resmetirom use remain limited. This study evaluates early outcomes and adverse events associated with resmetirom use at 12 months. **Methods:** This retrospective observational study at Ochsner Health (April–September 2024) included adults $\geq$ 18 years with confirmed fibrosis who received resmetirom for at least three months with follow-up data. The primary endpoint was clinical response at 12 months based on ALT/AST changes or $\geq$1-stage fibrosis change by VCTE, MRE, or biopsy. ALT/AST were measured at baseline and 12 months, with median changes assessed by

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Wilcoxon signed-rank test. Secondary endpoints included GLP 1- use, access barriers, and time to approval and fill, adverse events, treatment discontinuation, hospitalizations, mortality, hepatotoxicity, and BMI/weight changes. **Results:** Resmetirom was prescribed for 136 patients, with 130 (95.6%) receiving insurance approval. Among 76 patients with at least 3 months of treatment and 12-month fibrosis assessment, 75% showed at least 1 fibrosis stage improvement, 19.7% remained unchanged, and 5.3% experienced worsening. Financial assistance was required for 86 patients, and 31 required appeals. Mean time to insurance approval and fill was 12 and 13 days, respectively. Among patients with at least 3 months of treatment, 38.9% were current GLP-1 users, 16.8% had previous use, and 44.3% never used GLP-1s. Serum ALT levels decreased from a median of 44.0 U/L at baseline to 36.0 U/L at 12 months (median change -3.0 U/L; p = 0.001), whereas AST levels showed no significant change over the same period, with medians of 35.0 U/L at baseline and 32.0 U/L at 12 months (median change 0.0 U/L; p = 0.555). Resmetirom was well tolerated, with low discontinuation rates and no significant differences in hospitalization, mortality, hepatotoxicity, or BMI/weight. **Conclusion:** Twelve-month outcomes in the real-world show that resmetirom treatment is associated with fibrosis improvement in F2/3 MASLD. With good tolerability and few safety concerns, resmetirom appears at least as effective in the real world as in clinical trials. Resmetirom demonstrated high access with specialty pharmacy support, highlighting the importance of healthcare access and coordinated care. In addition, we observed exposure to GLP-1 medications in approx. 50% of our cohort which may have treatment implications in the future given the approval of semaglutide for F2/3 MASLD.

Fibrosis Stage	Baseline	12 months
F0	0 (0.0%)	13 (11.5%)
F1	0 (0.0%)	31 (27.4%)
F2	48 (42.5%)	21 (18.6%)
F3	61 (54.0%)	10 (8.9%)
F4	4 (3.5%)	1 (0.9%)
Fibrosis Stage Trend	**Frequency**	**Percent**
Improved	57	75.00%
Unchanged	15	19.74%
Worsened	4	5.26%

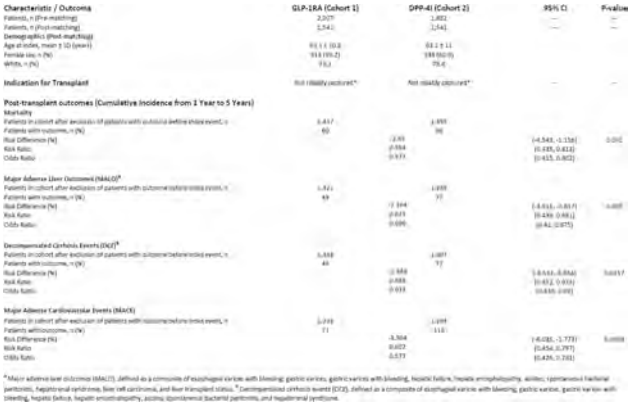
3467 | GLP-1 RECEPTOR AGONISTS ARE ASSOCIATED WITH REDUCED RISK OF MORTALITY, CARDIOVASCULAR EVENTS, AND HEPATIC DECOMPENSATION IN PATIENTS WITH MASLD-RELATED CIRRHOSIS: A PROPENSITY SCORE-MATCHED ANALYSIS



Allan Zhang[1] Mohamad Ali Ibrahim[2] Kimberly Taing[1] Prasun Jalal[2], [1]University of Texas Southwestern Medical Center, [2]Baylor College of Medicine

Background: GLP-1 receptor agonists (GLP-1RAs) have demonstrated hepatic and cardiovascular benefits in patients with metabolic dysfunction-associated steatotic liver disease (MASLD), though their impact on clinical outcomes in patients with established cirrhosis remains incompletely characterized. This study evaluated long-term hepatic and cardiovascular outcomes among patients with T2DM and MASLD cirrhosis treated with GLP-1RAs compared with dipeptidyl peptidase-4 inhibitors (DPP-4is). **Methods:** Using the TriNetX Research Network, adult patients with T2DM and established MASLD cirrhosis were identified and stratified in cohorts by new exposure to GLP-1RAs (semaglutide, liraglutide, or tirzepatide) or DPP-4is (sitagliptin, saxagliptin, linagliptin, or alogliptin). Patients with hepatocellular carcinoma (HCC), autoimmune or cholestatic liver disease, viral hepatitis, alcohol-associated liver disease, decompensated cirrhosis, or other chronic liver diseases prior to index event (date of medication initiation) were excluded. Outcomes included mortality, major adverse liver outcomes (MALO), decompensated cirrhosis events (DCE), and major adverse cardiovascular events (MACE) assessed by cumulative incidence between 1 and 5 years after index. Cohorts were propensity score matched (PSM) 1:1 for demographics, metabolic comorbidities, cardiovascular risk factors, medication exposure, and laboratory metrics. **Results:** Among 3,859 eligible patients, 2,007 patients receiving GLP-1RAs and 1,852 patients receiving DPP-4is were identified, with 1,541 patients remaining in each cohort after PSM. GLP-1RA therapy was associated with significantly reduced risk of mortality (RR 0.594, 95% CI 0.435-0.813, P = 0.001), MALO (RR 0.621, 95% CI 0.438-0.881, P = 0.007), DCE (RR 0.646, 95% CI 0.452-0.924, P = 0.0157), and MACE (RR 0.602, 95% CI 0.454-0.797, P = 0.0003) compared with DPP-4i treatment over 5 years of follow-up. **Conclusion:** In patients with T2DM

and MASLD cirrhosis, GLP-1RA therapy was associated with decreased long-term hepatic and cardiovascular complications compared with DPP-4i therapy. These findings support the potential role of GLP-1RAs in treatment of MASLD cirrhosis and warrant prospective studies to further determine their influence on hepatic outcomes and disease progression. Limitations include retrospective design and reliance on accuracy of administrative data.

3468 | COMPARATIVE EFFICACY OF INCRETIN-BASED AGONISTS AND THR-BETA AGONISTS FOR MASH RESOLUTION AND FIBROSIS IMPROVEMENT: A SYSTEMATIC REVIEW AND META-ANALYSIS

Keeranmayee Mishra[1] Apurba Mishra[2] Mrudula Alla[1] Chirag Doshi[3] Rakshana Ravichandran[1] Ravi Patel[1] Aditya Kohli[1] Ramy Mansour[1], [1]Trinity Health Oakland/ Wayne State University, [2]Nootan Medical College, Gujarat, India, [3]Banas Medical College, Gujarat,India

Background: GLP-1 receptor mono-agonists (liraglutide, semaglutide), GLP-1-based polyagonists (tirzepatide, survodutide, pemvidutide), and thyroid hormone receptor-beta (THR-beta) agonists (resmetirom) have each demonstrated histological efficacy for metabolic dysfunction-associated steatohepatitis (MASH) in randomized controlled trials. Whether weight loss mediates MASH resolution across drug classes, and whether weight-independent hepatic mechanisms achieve comparable histological improvement, has not been systematically examined. **Methods:** A systematic review following PRISMA 2020 guidelines searched through April 2025 for randomized, placebo-controlled trials evaluating pharmacological agents for biopsy-confirmed MASH with histological endpoints. For multi-dose trials, the highest dose arm was selected for analysis (semaglutide 0.4 mg/day, survodutide 4.8 mg/wk, pemvidutide 1.8 mg/wk). The primary outcome was MASH resolution without worsening of fibrosis (risk ratio). The secondary outcome was fibrosis improvement by at least one stage without worsening of MASH. Subgroup analyses were performed by drug class. To understand if greater weight loss leads to higher rates of MASH resolution,we performed an exploratory analysis to compare these two factors across the included studies.An AI-assisted tool and R software were used to assist with literature review, data verification, and manuscript editing; final was verified by the authors, who assume full responsibility for the accuracy and integrity of this work. **Results:** Seven trials (N = 2,064; 1,167 active, 897 placebo) were included. The pooled risk ratio for MASH resolution was 3.04 (95% CI 2.11-4.39; I-squared = 72%; GRADE: moderate). The pooled risk difference was 0.38 (95% CI 0.28-0.49; NNT = 3). By class, GLP-1 mono-agonists achieved a risk ratio of 2.51 (95% CI 0.90-6.98), polyagonists 3.80 (95% CI 1.26-11.49), and resmetirom 3.11 (95% CI 2.14-4.52). Subgroup differences were not significant under random-effects assumptions (p = 0.49). For fibrosis improvement (5 trials; N = 1,375), the pooled risk ratio was 1.52 (95% CI 1.30-1.79; I-squared = 0%; GRADE: high). Exploratory meta-regression showed a positive association between weight loss and MASH resolution among incretin-based agents, while resmetirom achieved comparable benefit with minimal weight change. This analysis is exploratory (k = 7) and underpowered. **Conclusion:** All three pharmacological classes significantly improve MASH resolution versus placebo (NNT approximately 3). Fibrosis improvement is consistent across incretin classes (high GRADE certainty). While weight loss contributes to MASH resolution among incretin-based agents, resmetirom achieves comparable histological improvement through weight-independent hepatic mechanisms, supporting mechanistically complementary therapeutic strategies and potential combination approaches.

3470 | COMPARATIVE EFFECTIVENESS OF BARIATRIC SURGERY, GLP-1 A, AND SGLT2I ON COMPOSITE LIVER OUTCOMES IN PATIENTS WITH MASLD: A MULTICENTER IPTW AND PROPENSITY SCORE-MATCHED SURVIVAL ANALYSIS

Diwanshu Soni[1] Leith Ghani[2] Majd Aboona[2] Pooja Rangan[3] Chih Hua Chung[4] Yu Cin Chang[4] Mark Wong[4] Karn Wijarnpreecha[2] Rohit Nathan[4] Moises Nevah Rubin[4] Michael Fallon[4] Farah Husain[3] Ma Ai Thanda Han[4], [1]University of Arizona College of Medicine- Phoenix, [2]University of Arizona College of Medicine-Phoenix, [3]University of Arizona College of Medicine – Phoenix, [4]University of Arizona College of Medicine - Phoenix

Background: Metabolic dysfunction-associated steatoic liver disease (MASLD) is the leading cause of chronic liver disease globally and a major contributor to cirrhosis-related complications, including ascites, varices, hepatic encephalopathy, hepatocellular carcinoma (HCC), and liver transplantation. Bariatric surgery, glucagon-like peptide-1 receptor agonists (GLP-1 RA), and sodium-glucose cotransporter-2 inhibitors (SGLT2i) have each been associated with improved outcomes; however, comparative data evaluating composite liver outcomes remain limited. We aim to compare the effects of these interventions on incident liver-related events in patients with MASLD. **Methods:** We conducted a multicenter, retrospective cohort study across the Banner Health System, including adults with MASLD receiving bariatric surgery, GLP-1 RA, SGLT2i, or combination therapy between July 2012 and December 2023. Patients with other etiologies of liver disease, BMI < 30 kg/m^2, or a < 12 months of follow-up were excluded. The primary outcome was liver-related events (LRE) – ascites, varices, and/or hepatic encephalopathy. The secondary outcomes included composite liver events consisting of LRE, HCC, and/or liver transplantation. A 1-year landmark analysis was performed. Propensity scores for the four treatment groups were estimated using multinomial logistic regression and applied as inverse probability of treatment weights (IPTW) in Cox proportional-hazards models, with bariatric surgery as the reference group. Propensity score-matched Kaplan-Meier (KM) curves were used to compare event-free survival across groups. **Results:** After multinomial IPTW adjustment, bariatric surgery was associated with the lowest risk of LRE and composite liver outcomes. Compared with bariatric surgery, GLP-1 RA therapy was associated with increased risk of LRE (aHR 2.55, 95% CI 1.38-4.69; p = 0.003), Composite 1 (aHR 2.43, 95% CI 1.36-4.33; p = 0.003), and Composite 2 (aHR 2.52, 95% CI 1.42-4.46; p = 0.002). SGLT2i therapy was also associated with increased risk of LRE (aHR 2.00, 95% CI 1.04-3.86; p = 0.038), Composite 1 (aHR 2.18, 95% CI 1.18-4.03; p = 0.013), and Composite 2 (aHR 2.18, 95% CI 1.18-4.01; p = 0.012). Combination therapy showed a non-significant trend toward higher LRE risk (aHR 1.78, 95% CI 0.96-3.28; p = 0.064), but higher risk of Composite 1 (aHR 1.81, 95% CI 1.01-3.24; p = 0.045) and Composite 2 (aHR 1.81, 95% CI 1.02-3.23; p = 0.044). Propensity score-matched KM analysis demonstrated superior liver event-free survival with bariatric surgery across all outcomes (Figure 1). **Conclusion:** In MASLD patients, bariatric surgery demonstrated superior liver-related and composite outcomes compared with GLP-1 RA and SGLT2i therapies after 1-year landmark, multinomial IPTW-adjusted, and propensity score-matched KM analyses. Future studies should stratify these outcomes based on fibrosis stage.

3471 | GLP-1 THERAPY PROVIDES SUPERIOR LIVER STIFFNESS CHANGE OVER LIFESTYLE-MEDIATED WEIGHT LOSS IN SUSPECTED MODERATE TO SEVERE METABOLIC DYSFUNCTION ASSOCIATED STEATOHEPATITIS AND SUSPECTED CIRRHOSIS

Nicholas Kruzdlo[1] Joseph Scaravalle[1] Stephanie Oliveros-Diaz[1] Kirsten Hobson[1] Elisabeth Verwest[1] Lily Lu[1] Raymond Bell[1] Yovanni Rosario[1] Cameron Rolph[1]

Isabelle Crotsley[1] Guy Neff[1], [1]Covenant Metabolic Specialists

Background: Weight loss is central to managing Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) and Metabolic Dysfunction Associated Steatohepatitis (MASH), and metabolic dysfunction-associated cirrhosis. GLP-1 receptor agonists now offer a pharmacologic pathway to weight loss alongside lifestyle modifications. It is currently unclear if GLP-1-mediated weight loss produces additional hepatic fibrosis reduction benefits compared to lifestyle-mediated weight loss. This study evaluated whether GLP-1 associated weight loss produces greater liver stiffness change (% kPa) compared to lifestyle modification, and whether this relationship differs by fibrosis severity across minimal, mild-moderate, and moderate-severe strata. **Methods:** A retrospective analysis was performed on 200 patients who completed baseline and follow-up visits within 11–36 months with FibroScan, weight, medication, and clinical data recorded at both time points. After excluding patients who experienced weight gain between visits, linear regression modeled % kPa change, chosen to normalize outcomes across strata with substantially different baseline ranges, against GLP-1 use, change in weight, age, sex, baseline kPa, and follow-up duration. This was applied across the full cohort (3–38.6 kPa, n = 130) and three baseline kPa strata: minimal (3–6 kPa, n = 52), mild-moderate (6.1–9.9 kPa, n = 55), and moderate-severe (10–38.6 kPa, n = 23). Weight loss was comparable between subgroups within each stratum, and weight change was included as a covariate to isolate the independent effect of GLP-1 on kPa reduction. **Results:** GLP-1 use produced a significant decrease in % kPa across the full cohort ($\beta = -16.58$, $p = 0.006$). Stratified analysis revealed no significant difference between modalities in minimal or mild-moderate fibrosis strata. In moderate-severe fibrosis, GLP-1 use was associated with a greater reduction in fibrosis compared to lifestyle-mediated weight loss ($\beta = -31.33$, $p = 0.013$). Age was inversely associated with fibrosis reduction across the full cohort ($p < 0.001$), and longer follow-up duration predicted greater improvement in the moderate-severe fibrosis cohort ($p = 0.031$). **Conclusion:** In patients with moderate-to-severe fibrosis, GLP-1 therapy was associated with 31.3% greater liver stiffness reduction compared with lifestyle-mediated weight loss despite comparable weight loss between modalities, suggesting a weight loss independent antifibrotic effect. In contrast, no significant difference was observed between modalities at lower fibrosis stages (kPa 3–9.9), supporting lifestyle modification as equally effective at lower fibrosis stages. At kPa ≥ 10, GLP-1 therapy may provide additional antifibrotic benefits and may warrant preferential consideration. Older age independently predicted attenuated fibrosis response ($p < 0.001$), underscoring the need for age and stage-stratified treatment in MASLD/MASH.

Table 1. Multivariable Linear Regression — Predictors of % kPa Change by Fibrosis Stratum

Negative coefficients indicate reduction in liver stiffness. % kPa change used to normalize outcomes across strata with substantially different baseline ranges. N = 130

Variable	GLP-1 (n)	Lifestyle (n)	Total (n)	Coefficient (% kPa)	95% CI	p-value
GLP-1 Use by Fibrosis Stratum						
Minimal fibrosis (3–6 kPa)	20	32	52	−3.80	−23.1, 15.5	0.694
Mild-moderate fibrosis (6.1–9.9 kPa)	18	37	55	−5.24	−18.8, 8.3	0.441
Moderate-severe fibrosis (10–38.6 kPa)	17	6	23	**−31.33**	−55.1, −7.5	**0.013**
Full Cohort (3–38.6 kPa)						
GLP-1 Use (all fibrosis strata combined)	55	75	130	**−16.58**	−28.2, −4.9	**0.006**
Significant Covariates						
Age (all fibrosis strata combined)	55	75	130	**+0.90**	0.38, 1.42	**< 0.001**
Follow-up duration (moderate-severe cohort)	17	6	23	**−1.85**	−3.5, −0.19	**0.031**

1.) GLP-1 receptor agonist use defined as documented use for ≥3 months within the follow-up visit window.
2.) Weight loss was comparable between GLP-1 and lifestyle subgroups; change in weight was included as a covariate to isolate the independent effect of GLP-1 use.
3.) Age coefficient is positive (+0.90), indicating older age is associated with less fibrosis reduction across the full cohort.

3472 | REAL-WORLD CHANGES IN NON-INVASIVE LIVER FIBROSIS STAGE AND BIOMARKERS AFTER RESMETIROM FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Emilee Hall[1] Dauris Rosario[1] Nancy Reau[1], [1]Rush University Medical Center

Background: Resmetirom is approved for metabolic dysfunction-associated steatohepatitis (MASH) with fibrosis. We evaluated real-world changes in non-invasive fibrosis stage and metabolic markers after resmetirom initiation in a tertiary hepatology clinic. **Methods:** We performed a retrospective cohort study of adults initiated on resmetirom between June 2024 and May 2025 (data cut-off 1 December 2025). Fibrosis stage was derived from liver stiffness measurement (LSM) by transient elastography (TE; FibroScan) or magnetic resonance elastography (MRE) at baseline and at most recent follow-up when available. Paired LSM-derived stage and laboratory values were compared pretreatment vs most recent follow-up using Wilcoxon signed-rank or paired t tests, as appropriate. Alanine aminotransferase (ALT) response was defined as at least a 30% reduction. Associations of statin use and glucagon-like peptide 1 receptor agonist (GLP-1 RA) use with LSM stage improvement (any decrease in stage) were explored using multivariable logistic regression. **Results:** Thirty-four patients were included (mean age 55.3 years; 58.8% female; mean body mass index 35.8 kg/m2). Mean time on resmetirom was 14 months. Twenty-five had paired LSM (TE or MRE)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

over a median of 9.2 months (interquartile range [IQR] 7.1 to 11.5). Fibrosis stage improved in 21 of 25 (84.0%), was unchanged in 2 (8.0%), and worsened in 2 (8.0%) (Z = -4.04, p < 0.001). Median ALT decreased from 42.5 (IQR 28.3 to 76.3) to 36.5 (IQR 25.8 to 48.3) IU/L (Z = -2.06, p = 0.040), and median aspartate aminotransferase (AST) decreased from 47.0 (IQR 23.3 to 68.5) to 31.5 (IQR 23.0 to 38.8) IU/L (Z = -2.82, p = 0.005). ALT response occurred in 13 of 34 (38.2%). Low-density lipoprotein (LDL) cholesterol decreased from a mean of 101.6 to 76.7 mg/dL (mean change -24.9 mg/dL, p = 0.001), while glycated hemoglobin (HbA1c) showed no significant change (p = 0.236). In multivariable logistic regression, neither statin use nor GLP-1 RA use was associated with likelihood of LSM stage improvement (likelihood ratio p = 0.37; statin p = 0.22; GLP-1 RA p = 0.76). **Conclusion:** In this real-world cohort, resmetirom therapy was associated with significant improvement in non-invasive fibrosis stage assessed by TE or MRE, reductions in aminotransferases, and lower LDL cholesterol over approximately 9 months. Larger studies with longer follow-up are needed to confirm durability and identify predictors of response.

3473 | SEMAGLUTIDE IN MASLD REDUCES LIVER FAT AND ENERGY INTAKE, BUT DOES NOT IMPROVE DIET QUALITY

Sana Pirzada[1] Sara Turner[2] Shanna Yang[2] Kayla Airaghi[2] Natalie Vallone[2] Harish Gopalakrishna[1] Elenita Rivera[1] Yaron Rotman[1], [1]Translational Hepatology Section, Liver Diseases Branch, NIDDK, NIH, Bethesda, MD, USA, [2]Nutrition Department, Clinical Center, NIH, Bethesda, MD, USA

Background: Obesity and unhealthy diets are linked to incidence and severity of metabolic dysfunction-associated steatotic liver disease (MASLD). GLP-1 receptor agonists decrease energy intake and improve obesity and MASLD. We aimed to assess how longitudinal changes in energy intake, macronutrients, diet quality, and food choices during semaglutide treatment affect liver fat content in adults with MASLD. **Methods:** In a prospective mechanistic trial (NCT03884075), adults with biopsy-proven MASLD were treated for 30 weeks with semaglutide (1.0 mg/wk). Three-day food records were collected at baseline and weeks 2, 12, and 30. Diet quality was assessed using the Healthy Eating Index (HEI; range 0-100). Objective energy intake and food choice were assessed by ad libitum food array, weighed pre- and post-consumption at baseline and week 30. Liver fat content was measured by MR spectroscopy and body composition by DEXA at baseline and week 30. **Results:** Twenty-nine participants were included (age 44.7 ± 10.6 years, 59% female, BMI 35.1 ± 5.8 kg/m2). At week 30, participants lost 8.1 ± 6.6% body weight, 14.0 ± 10.6% fat mass, 2.8 ± 3.6% lean mass, and 8.7 ± 4.9% liver fat. Reductions in BMI and body fat correlated with reduction in liver fat ($r = 0.45$, $p = 0.012$ and $r = 0.38$, $p = 0.048$, respectively). Energy intake (baseline 1590 ± 137 kcal/d) decreased significantly by week 2, reached nadir at week 12 (1235 ± 79 kcal, $p < 0.001$) and remained lower through week 30. Macronutrient distribution (baseline 46.5% carbohydrate, 33.6% fat, 17.5% protein) remained similar at all time points. Total HEI decreased modestly from 65.8 ± 2.3 at baseline to 56.2 ± 2.3 at week 30 (p for trend = 0.04) with HEI component scores for seafood and plant proteins and unsaturated:saturated fat ratio significantly decreasing by weeks 12 and 30 (all $p < 0.05$). Similarly, total energy intake on ad libitum food array decreased at week 30 (940.7 ± 545.0 kcal) versus baseline (1129.6 ± 57.7 kcal, $p < 0.010$), without change in macronutrient composition. Reduction in energy intake correlated with decrease in total body fat ($r = 0.46$, $p = 0.017$) and BMI ($r = 0.44$, $p = 0.018$), and was non-significantly associated with liver fat reduction. Changes in total HEI scores were not associated with changes in weight, body composition, or liver fat, and did not modulate the effects of weight change on liver fat content. **Conclusion:** In adults with MASLD, semaglutide decreases energy intake on self-reported and objective measures of food intake, but does not lead to changes in macronutrient composition or improved diet quality. Changes in energy balance (and resultant decreased adiposity) but not in food quality drive liver fat reduction. To improve diet quality as well, semaglutide treatment alone does not suffice in the absence of additional dietary counseling.

3474 | SGLT2 INHIBITOR USE IS ASSOCIATED WITH LOWER ODDS OF ASCITES IN PATIENTS WITH CIRRHOSIS AND TYPE 2 DIABETES: A CROSS-SECTIONAL STUDY

José Ávila Rojo[1] Ximena Ayala Arredondo[2] Ignacio Garcia Juarez[3] Froylan Martinez Sanchez[2] Orfanel Pineda Arzate[2] Liz Toapanta-Yanchapaxi[2], [1]Instituto Nacional de Ciencias Medicas y Nutricion, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, [3]The National Institute of Medical Science and Nutrition

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2-i) have shown favorable cardiorenal and metabolic effects, and emerging evidence suggests a potential role in portal hypertension and fluid retention in cirrhosis. However, data regarding the association between SGLT2-i use and ascites in patients with cirrhosis remain limited. **Methods:** We conducted a cross-sectional study including adults with cirrhosis and T2DM evaluated at a tertiary referral center. Demographic, clinical, and biochemical variables were collected. Ascites was categorized as absent, grade 1, or grade 2–3. Logistic regression analysis was performed to evaluate the association between SGLT2-i use and the presence of ascites.Objective: To evaluate whether iSGLT2 use is associated with lower presence and severity of ascites in patients with cirrhosis and type 2 diabetes mellitus, as well as its relationship with liver disease severity parameters, including Child-Pugh, MELD-Na, MELD 3.0, serum sodium, and serum creatinine. **Results:** A total of 316 patients were included. Overall, 58.5% were women, with a mean age of 65.3 ± 10.6 years and a mean BMI of 27.3 ± 5.3 kg/m2. MASLD was the most common etiology of cirrhosis (39.2%). Moreover, 27.2% of patients received SGLT2-i therapy, including dapagliflozin (13.3%) and empagliflozin (13.9%). Ascites was present in 50.6% of patients, with grade 1 in 34.8% and grade 2–3 in 15.8%. Patients with ascites had significantly lower SGLT2-i use compared with those without ascites (15.6% vs 39.1%, $p < 0.001$). Patients with ascites also had higher MELD-Na scores, higher MELD 3.0 scores, lower serum sodium levels, and more advanced Child-Pugh stage (all $p < 0.001$). In multivariable logistic regression analysis, SGLT2-i use was independently associated with lower odds of ascites (OR 0.288, 95% CI 0.169–0.492; $p < 0.001$). **Conclusion:** In this cross-sectional study of patients with cirrhosis and type 2 diabetes, SGLT2-i use was independently associated with lower odds of ascites. These findings support the potential role of SGLT2-i in fluid-related complications of cirrhosis and warrant prospective studies to further evaluate their therapeutic impact.

Baseline Characteristics

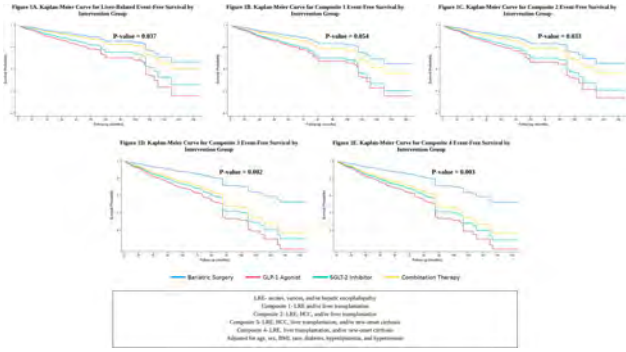
3475 | COMPARATIVE EFFECTIVENESS OF BARIATRIC SURGERY, GLP-1 RA, AND SGLT2I ON LIVER OUTCOMES IN NON-CIRRHOTIC MASLD: A MULTICENTER IPTW AND PROPENSITY SCORE-MATCHED SURVIVAL ANALYSIS



Leith Ghani[1] Diwanshu Soni[2] Majd Aboona[3] Pooja Rangan[4] Chih Hua Chung[5] Yu Cin Chang[5] Mark Wong[5] Karn Wijarnpreecha[2] Rohit Nathan[5] Moises Nevah Rubin[6] Mike Fallon[7] Farah Husain[8] Ma Ai Thanda Han[1], [1]University of Arizona College of Medicine Phoenix, [2]University of Arizona College of Medicine-Phoenix, [3]University of Arizona College of Medicine - Phoenix, [4]Banner University Medical Center- Phoenix, [5]Banner University Medical Center-P, [6]Banner University Medical Center, [7]University of Arizona, [8]Oregon Health & Science University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common cause of chronic liver disease worldwide and is associated with progressive hepatic fibrosis and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

liver-related morbidity, including cirrhosis. Early intervention in non-cirrhotic disease may reduce progression. While bariatric surgery, glucagon-like peptide-1 receptor agonists (GLP-1 RA), and sodium-glucose cotransporter-2 inhibitors (SGLT2i) have each demonstrated benefit in MASLD, comparative data on liver outcomes in non-cirrhotic patients remain limited. We compared these interventions on liver-related outcomes in non-cirrhotic MASLD. **Methods:** This multicenter retrospective cohort study across the Banner Health System included adults with non-cirrhotic MASLD treated with bariatric surgery, GLP-1 RA, SGLT2i, or combination therapy between July 2012 and December 2023. Patients with other etiologies of liver disease, BMI < 30 kg/m², or < 12 months of follow-up were excluded. The primary outcome was liver-related events (LRE) - ascites, varices, and/or hepatic encephalopathy; secondary outcomes were four progressively inclusive composites (Composites 1-4). A 1-year landmark analysis was performed. Propensity scores for the four groups were estimated by multinomial logistic regression and applied as inverse probability of treatment weights (IPTW) in Cox proportional-hazards models, with bariatric surgery as reference. Propensity score-matched survival curves compared event-free survival across groups. **Results:** After multinomial IPTW adjustment, bariatric surgery was associated with the lowest risk of liver-related and composite outcomes. Compared with bariatric surgery, GLP-1 RA was associated with increased risk of LRE (aHR 2.11, 95% CI 1.10-4.07; p = 0.026), Composite 1 (aHR 2.02, 1.09-3.73; p = 0.024), and Composite 2 (aHR 2.10, 1.14-3.86; p = 0.017); risks for SGLT2i and combination therapy trended higher but were non-significant. When new-onset cirrhosis was incorporated (Composites 3 and 4), all three therapies carried significantly increased risk versus bariatric surgery: for Composite 3, GLP-1 RA (aHR 2.63, 1.59-4.36; p < 0.001), SGLT2i (aHR 2.22, 1.28-3.85; p = 0.005), and combination therapy (aHR 1.98, 1.19-3.29; p = 0.009), with comparable findings for Composite 4. Propensity score-matached survival analysis showed superior liver event-free survival with bariatric surgery across all outcomes (Figure 1). **Conclusion:** In non-cirrhotic MASLD, bariatric surgery was associated with superior liver-related and composite outcomes compared with GLP-1 RA, SGLT2i, and combination therapy after 1-year landmark and multinomial IPTW-adjusted analyses. Differences were most pronounced for composites incorporating new-onset cirrhosis, suggesting progression to cirrhosis is the predominant early liver event in this population. Future studies should stratify by fibrosis stage.

3476 | POTENTIAL INFLUENCE OF PNPLA3 GENOTYPE ON SEMAGLUTIDE RESPONSE IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE: REAL-WORLD DATA IN KOREAN COHORT

Hee Sun Cho[1] Pil Soo Sung[1] Jaejun Lee[1] Jung Hoon Cha[2], [1]The Catholic University of Korea, [2]The Catholic University Liver Research Center

Background: Semaglutide is widely used for obesity and metabolic-associated steatotic liver disease (MASLD), but real-world data in Korean populations remain limited. Genetic variants in PNPLA3 are known to be associated with MASLD progression. We aimed to evaluate the real-world clinical outcomes of semaglutide and to determine whether the PNPLA3 genotype affects therapeutic response in Korean patients. **Methods:** We retrospectively enrolled 137 patients who received once-weekly semaglutide at 2 tertiary hospitals (Seoul St. Mary's Hospital and Eunpyeong St. Mary's Hospital) in Korea between March and December 2025. Clinical outcomes, including weight loss and changes in liver fibrosis and steatosis markers, were assessed. To evaluate the impact of the PNPLA3 genotype on treatment response, outcomes were compared according to genotype, and the association between PNPLA3 variants and therapeutic response was analyzed. **Results:** At 3 and 6 months, 99

(72.3%) and 73 (53.3%) patients achieved weight reduction, with mean losses of 5.15 kg (6.13%) and 7.55 kg (9.50%), respectively; at 6 months, 57 (78.1%), 33 (45.2%), and 10 (13.7%) achieved ≥5%, ≥10%, and ≥15% weight loss. Among patients with paired FibroScan data (n = 38), mean liver stiffness decreased from 7.65 to 5.74 kPa (P < 0.001), and mean CAP decreased from 315 to 271 dB/m (P < 0.001). APRI, AST, and ALT also showed significant reductions at 6 months (all p < 0.001). The PNPLA3 variant homozygous genotype (GG) showed a tendency toward an attenuated therapeutic response to semaglutide compared with the GC/CC genotype, with fewer responders observed for ALT at 6 months, CAP, and TE. Responder analyses revealed fewer responders among GG carriers, with the 6-month ALT response approaching statistical significance (p = 0.082). **Conclusion:** In this multicenter real-world Korean cohort, once-weekly semaglutide was associated with significant weight loss and improvements in hepatic steatosis and fibrosis-related markers. The PNPLA3 genotype may be served as a potential biomarker for predicting therapeutic response to semaglutide.

3477 | TWELVE-MONTH CHANGES IN LABORATORY AND IMAGING-BASED BIOMARKERS IN PATIENTS WHO HAVE INITIATED RESMETIROM: A REAL-WORLD RETROSPECTIVE COHORT ANALYSIS USING ELECTRONIC HEALTH RECORDS

Susan Thapa[1] Christina Parrinello[1] Yestle Kim[1] John O'Donnell[1] Anthony Martinez[2], [1]Madrigal Pharmaceuticals, Inc, [2]University at Buffalo

Background: Resmetirom is a thyroid hormone receptor β-selective agonist, conditionally approved in the United States (US) for adults with noncirrhotic metabolic dysfunction-associated steatohepatitis with moderate-to-advanced fibrosis. Emerging real-world data have shown improvements in blood- and imaging-based biomarkers, but follow-up durations and sample sizes remain limited. This study evaluated characteristics and 12-month changes in biomarkers in patients who initiated resmetirom. **Methods:** This retrospective cohort study used Truveta deidentified electronic health record (EHR) data from US health systems linked to third-party medication dispensing data. Patients aged ≥ 18 years were indexed at first resmetirom fill on or after March 14, 2024 and followed through April 6, 2026. During the 1-year pre-index baseline period, patients were required to have ≥1 documented healthcare interaction (visit, prescription or treatment, lab test, procedure, diagnosis) and no evidence of other causes of liver disease (e.g., alcohol use, hepatitis) or advanced liver disease (e.g., cirrhosis). Analyses were restricted to patients with ≥1 year of observed follow-up. Biomarkers included alanine transaminase (ALT), aspartate aminotransferase (AST), low-density lipoprotein cholesterol (LDL-C), high-density lipoprotein cholesterol (HDL-C), triglycerides (TGs), FibroScan-AST (FAST) score, Steatosis-Associated Fibrosis Estimator (SAFE) score, and liver stiffness measurement (LSM) and controlled attenuation parameter (CAP) from vibration-controlled transient elastography (VCTE) (LSM and CAP extracted from unstructured EHR clinical notes using large language models). Means and standard deviations (SDs) were calculated at baseline (closest value within 1 year prior to index) and follow-up (value closest to 12 months ± 3 months), as well as mean changes and p-values from paired t-tests. **Results:** There were 1,405 patients with ≥1 year of observed follow-up (median 15.8 months) after resmetirom initiation, with a mean age of 58 years, 63% female, 78% White, 40% from the South, 61% hypertension, 74% dyslipidemia, 57% type 2 diabetes, 61% obesity, 50% concomitant GLP-1 use and 55% concomitant statin use. Among patients with both baseline and follow-up measurements, all evaluated biomarkers showed statistically

significant improvements 12 months after resmetirom initiation (**Table**). Improvements were also observed across key thresholds: 54% and 49% with ≥25% and ≥30% decrease in LSM kPa, respectively; 37% with ≥40 dB/M decrease in CAP; 37% with ≥17 U/L and 48% with ≥20% decrease in ALT; and 48% with ≥0.22 decrease in FAST. **Conclusion:** In this descriptive analysis, 12-month improvements in blood- and imaging-based biomarkers were observed in patients who initiated resmetirom. Changes in VCTE LSM were, on average, consistent with a shift into a lower fibrosis risk category.

Table. Twelve-month changes in blood- and imaging-based biomarkers in patients who initiated resmetirom

Biomarker	N with baseline and follow-up	Baseline Mean (SD)	Follow-up Mean (SD)	Change Mean (SD)	P-value	Days from Baseline to Follow-up Value Mean (SD)
ALT, U/L	661	57.3 (45.7)	39.5 (26.9)	-16.8 (42.8)	<0.001	360.2 (42.7)
AST, U/L	660	43.2 (32.3)	33.0 (19.2)	-10.2 (30.9)	<0.001	360.2 (42.7)
LDL-c, mg/dL	367	92.9 (38.8)	78.1 (33.3)	-14.8 (34.0)	<0.001	360.8 (47.9)
HDL-c, mg/dL	370	43.4 (14.8)	44.6 (14.8)	1.1 (9.8)	0.02	360.9 (47.6)
TG, mg/dL	378	170.1 (113.7)	127.2 (75.5)	-42.9 (93.4)	<0.001	361.6 (47.2)
SAFE score	370	116.6 (98.7)	92.9 (103.8)	-23.7 (80.5)	<0.001	345.9 (35.6)
VCTE LSM, kPa	71	10.1 (2.4)	7.9 (3.4)	-2.2 (3.7)	<0.001	351.1 (46.2)
VCTE CAP, dB/m	60	309.6 (51.2)	275.3 (53.1)	-34.3 (65.2)	<0.001	351.1 (46.2)
FAST score	50	0.45 (0.21)	0.26 (0.16)	-0.19 (0.19)	<0.001	351.3 (34.3)

P-values were calculated from paired t-tests.
Abbreviations: ALT, alanine transaminase; AST, aspartate aminotransferase; CAP, controlled attenuation parameter; FAST, FibroScan-AST; HDL-c, high-density lipoprotein cholesterol; LDL-c, low-density lipoprotein cholesterol; LSM, liver stiffness measurement; SAFE, Steatosis-Associated Fibrosis Estimator; TG, triglycerides; VCTE, vibration-controlled transient elastography.

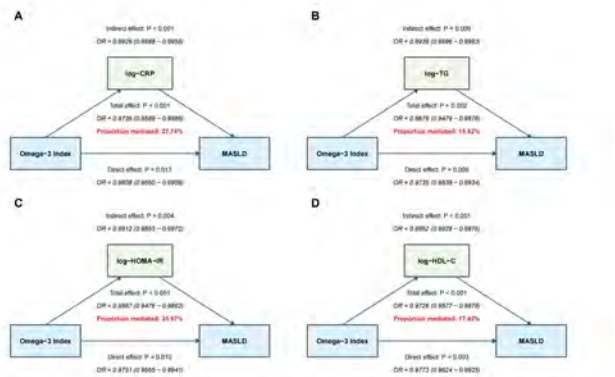
3478 | RED BLOOD CELL OMEGA-3 INDEX IS INVERSELY ASSOCIATED WITH THE PREVALENCE OF MASLD AND MASLD-ASSOCIATED SIGNIFICANT FIBROSIS: A CROSS-SECTIONAL MEDIATION ANALYSIS OF NHANES 2021–2023

Siyu Jiang[1] Jiwei Wang[1] Yicheng Zhu[2] Yunxing Huang[3] Qing Xie[1] Zhujun Cao[1], [1]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, [2]Faculty of Biochemistry, University of British Columbia, [3]Shenzhen college of international education



Background: An imbalance characterized by excessive omega-6 intake or a skewed omega-3/omega-6 ratio can exacerbate liver injury and promote the transition to steatohepatitis. The red blood cell (RBC) omega-3 index provides a stable, integrated reflection of habitual fatty acid status during the prior 2-4 month. We evaluated its association with metabolic dysfunction-associated steatotic liver disease (MASLD) and significant fibrosis in a nationally representative population under the updated diagnostic criteria. **Methods:** We analyzed 4,735 adults from the NHANES 2021-2023 cycle. MASLD was defined by a controlled attenuation parameter (CAP) > = 274 dB/m plus cardiometabolic criteria. Notably, significant fibrosis (liver stiffness measurement [LSM] > 8.0 kPa) was evaluated exclusively conditional on the MASLD population. Given the high outcome prevalences (>10%), we utilized survey-weighted Poisson regression as the primary framework to generate conservative adjusted prevalence ratios (aPRs), rigorously preventing the effect size overestimation (inflated ORs) inherent in logistic regression. Mediation analyses explored the roles of systemic inflammation (hs-CRP), insulin resistance (HOMA-IR), and lipid metabolism (triglycerides [TG], HDL-C). Missing data were handled via multiple imputation. **Results:** The weighted prevalence of MASLD was 40.1%, and significant fibrosis within the MASLD cohort was 22.2%. In fully adjusted conservative Poisson models, each 1% absolute increase in the RBC Omega-3 Index was independently associated with a 5% lower prevalence of MASLD (aPR: 0.95, 95% CI: 0.92-0.99, P = 0.017) and an 11% lower prevalence of significant fibrosis (aPR: 0.89, 95% CI: 0.81-0.99, P = 0.038). Mediation analysis indicated that the protective association between the RBC Omega-3 Index and MASLD was largely accounted for by concurrent metabolic and inflammatory pathways. Systemic inflammation (hs-CRP) and insulin resistance (HOMA-IR) were the potential mediators, accounting for 27.74% (P < 0.001) and 25.97% (P = 0.004) of the effect, respectively, followed by TG (18.52%, P = 0.006) and HDL-C (17.42%, P < 0.001). Conversely, the inverse association of significant fibrosis was specifically and significantly mediated by the inflammatory pathway (hs-CRP: 13.30%, P = 0.014). **Conclusion:** A higher RBC Omega-3 index is associated with a lower prevalence of MASLD and significant fibrosis. Using conservative Poisson models, we establish that the benefits against MASLD are overwhelmingly (nearly 90%) mediated by quantifiable improvements in insulin sensitivity, inflammation, and lipid profiles, whereas fibro-protection is predominantly anti-inflammatory. Maintaining optimal

3479 | COMPARATIVE REAL-WORLD EFFECTIVENESS OF RESMETIROM, INJECTABLE SEMAGLUTIDE, AND COMBINATION THERAPY IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Ngan Nguyen[1] Giavanna Carr[1] Sanjaya Satapathy[1] Stefani Morscher[1] Husneara Rahman[1], [1]Northwell Health - North Shore University Hospital

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by hepatic inflammation, steatosis, and progressive fibrosis. Resmetirom and glucagon-like peptide-1 receptor agonists (GLP-1RAs) have independently demonstrated efficacy in MASH; however, comparative real-world effectiveness data and outcomes with combination therapy remain limited. **Methods:** We performed a retrospective cohort study of adults with MASH treated between April 2023 and April 2025 at a single tertiary liver center. Patients received resmetirom monotherapy, injectable semaglutide monotherapy, or combination therapy consisting of resmetirom with semaglutide or tirzepatide. Baseline demographics, fibrosis stage, steatosis measurements, liver biochemistries, and cardiometabolic parameters were collected. The primary outcome was improvement in fibrosis and steatosis by transient elastography at 6 and 12 months. Secondary outcomes included alanine aminotransferase (ALT) normalization and changes in weight, hemoglobin A1c, and lipid parameters. **Results:** A total of 108 patients were included. Mean age was 55.6 years, 51.9% were female, and mean body mass index was 32.1 kg/m². Type 2 diabetes mellitus and dyslipidemia were present in 33.0% and 52.7% of patients, respectively. Fibrosis stages ranged from F0–F4, including 11.1% with advanced fibrosis (F4). Treatment distribution included 45 patients (41.7%) receiving resmetirom monotherapy, 30 (27.8%) semaglutide monotherapy, and 33 (30.6%) combination therapy.At 12 months, fibrosis improvement occurred in 20.0% of patients on resmetirom monotherapy, 16.7% on semaglutide monotherapy, and 48.5% on combination therapy ($p = 0.0216$). No significant differences were observed between groups in fibrosis improvement at 6 months or in steatosis improvement at either 6 or 12 months. ALT normalization at 6 months occurred more frequently in the combination therapy group (44%) compared with resmetirom monotherapy (37%) and semaglutide monotherapy (19%) ($p = 0.008$), although this difference was not sustained at 12 months. Within the combination cohort, initiation of resmetirom prior to incretin-based therapy demonstrated numerically greater improvements in fibrosis and steatosis at 12 months. No significant intergroup differences were observed in cardiometabolic outcomes. **Conclusion:** In this real-world cohort of patients with MASH, combination therapy with resmetirom and an incretin mimetic was associated with greater fibrosis improvement at 12 months. Although steatosis outcomes were similar across groups, combination therapy demonstrated early biochemical improvement and favorable liver stiffness outcomes. Sequential initiation with resmetirom prior to incretin-based therapy may provide additional benefit. These findings support the potential role of combination therapy strategies and highlight the need for prospective validation studies.

Table 1. Primary Outcome

Primary Outcome	Resmetirom Monotherapy (n=45)	Semaglutide Monotherapy (n=30)	Combination Therapy* (n=33)	P-value
Fibrosis improvement at 6 months, n (%)	11 (24.4)	2 (6.7)	8 (24.2)	0.105
Fibrosis improvement at 12 months, n (%)	9 (20.0)	5 (16.7)	16 (48.5)	**0.022**
Steatosis improvement at 6 months, n (%)	10 (22.2)	2 (6.7)	8 (24.2)	0.127
Steatosis improvement at 12 months, n (%)	7 (15.6)	6 (20.0)	11 (33.3)	0.181

*Combination therapy included resmetirom with semaglutide or tirzepatide.

3480 | IMPACT OF GLP-1 RECEPTOR AGONISTS ON LIVER ENZYMES AND NONINVASIVE FIBROSIS MARKERS IN PATIENTS WITH ULCERATIVE COLITIS AND OBESITY: A MATCHED COHORT STUDY

Budoor Alqinai[1] Swapna Gayam[1], [1]West Virginia University

Background: Patients with moderate ulcerative colitis (UC) and obesity are at increased risk for metabolic dysfunction-associated steatotic liver disease (MASLD) and hepatic fibrosis. The impact of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) on liver enzymes and noninvasive fibrosis markers in this population is not well established. **Methods:** We performed a retrospective matched cohort study using electronic health records from a single tertiary academic center (2022–2024). Adults with moderate UC and obesity (BMI $\geq$30 kg/m²) who initiated liraglutide or semaglutide for metabolic indications and remained on therapy for $\geq$12 weeks were included. A 1:1 matched control cohort of patients with moderate UC and obesity not receiving GLP-1 RAs was constructed, matched on age, sex, BMI, baseline partial Mayo score, and concomitant UC therapy. The primary outcome was change in alanine aminotransferase (ALT) at 12 weeks. Secondary outcomes included changes in aspartate aminotransferase (AST), FIB-4, and APRI scores. Multivariable linear regression adjusted for age, sex, baseline liver enzymes, BMI, and weight loss. **Results:** 85 GLP-1 RA-treated patients were matched to 85 controls with well-balanced baseline characteristics. At 12 weeks, GLP-1 RA therapy was associated with significantly greater reductions in ALT (-24.8 ± 16.9 U/L vs -5.6 ± 11.2 U/L, $p < 0.001$) and AST (-16.7 ± 12.8 U/L vs -3.9 ± 8.8 U/L, $p < 0.001$). Noninvasive fibrosis markers also improved more in the GLP-1 RA group, with greater reductions in FIB-4 score (-0.31 ± 0.24 vs -0.06 ± 0.19, $p < 0.001$) and APRI (-0.18 ± 0.15 vs -0.04 ± 0.12, $p < 0.001$). GLP-1 RA therapy was well tolerated, with no serious hepatic complications and adverse event rates comparable to controls. In multivariable analysis, GLP-1 RA use remained independently associated with ALT reduction after adjustment for weight loss and other baseline factors (adjusted β = -18.6, 95% CI -23.4 to -13.8, $p < 0.001$). **Conclusion:** In patients with moderate ulcerative colitis and obesity, GLP-1 RA therapy was associated with significant improvements in liver enzymes and noninvasive fibrosis markers compared with matched controls, along with a favorable safety profile. These findings suggest a potential hepatoprotective benefit of GLP-1 RAs in this high-risk population. Prospective studies are warranted to confirm these findings and evaluate long-term hepatic outcomes.

Disclosures: Budoor Alqinai:Nothing to Disclose, Swapna Gayam:Nothing to Disclose.

3481 | REAL-WORLD CHARACTERISTICS AND CLINICAL EFFECTIVENESS OUTCOMES AMONG MASH PATIENTS INITIATING RESMETIROM

Jeevin Sandhu[1] Gene Felber[2] Tara McKinley[2] Christina Parrinello[2] Samantha Clark[3] Francis Lobo[2] Parvez Mantry[1], [1]Methodist Dallas Medical Center, [2]Madrigal Pharmaceuticals, [3]Medicus Economics

Background: The FDA approved resmetirom for adults with noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH) with moderate-to-advanced fibrosis on March 14, 2024, based on the results of the MAESTRO-NASH trial. Real-world evidence (RWE) for the effectiveness of resmetirom remains limited. This study aimed to describe patient characteristics and treatment effectiveness among US patients initiating resmetirom in a cohort of patients diagnosed with MASH. **Methods:** Data from the Methodist Dallas Medical Center EMR systems were used for this study. The cohort included adults with $\geq$1 resmetirom prescription between March 14, 2024, and January 21, 2026, with the first observed prescription designated = index date. Patients were required to have continuous healthcare engagement during the 12-month baseline period ($\geq$1 encounter, observation, or medication request in each 6-month interval). Patients with advanced liver disease or liver disease due to other causes during the 12-month baseline period were excluded. Follow-up was from index to last encounter. Effectiveness outcomes included changes in biomarkers (from structured data) and noninvasive liver measures (VCTE extracted using NLP from progress notes) at 6 and 12 months ± 90 days. Wilcoxon signed-rank tests were used to assess changes, with statistical significance defined as $p < 0.05$. All variables were summarized using descriptive statistics. VCTE data will be reported in the full presentation. **Results:** A total of 443 patients met the study criteria (mean age, 60.03 years; 58.7% female; 46.0% White and 33.4% Hispanic/Latino). Baseline key comorbidities included type 2 diabetes (62.5%), obesity (61.2%), hyperlipidemia (72.5%), and hypertension (74.7%). Concurrent

use of GLP-1 receptor agonists was observed in 37.2% of patients. After resmetirom initiation, clinically meaningful improvements were observed in key liver enzymes. At 6 and 12 months, among patients with available data, the following changes in biomarkers versus baseline were observed: 1) AST change (median): -1.00 U/L and -3.00* U/L ($p < 0.05$ at 12 months); 2) AST median percentage change: -3.78% and -9.38%; 3) ALT change (median): -4.00* U/L and -6.50* U/L ($p < 0.05$ at 12 months); 4) ALT median percentage change: -10.26% and -17.80%; 5) $\geq$17 U/L reduction in ALT: achieved by 31.4% and 27.9% of patients, respectively; and 6) $\geq$20% decrease in ALT: achieved by 41.5% and 47.7% of patients, respectively (see Table 1).*The Wilcoxon signed-rank test showed a statistically significant difference between paired measurements ($p < 0.05$). **Conclusion:** In this retrospective real-world analysis, clinically meaningful 6- and 12-month improvements in liver-specific biomarkers were observed in patients prescribed resmetirom. Further study with longer follow-up is needed to assess long-term effectiveness.

Table 1: Changes in Liver Enzymes at 6 and 12-months in MASH patients initiating resmetirom

Measurement	Timepoint	N	Baseline Median (IQR)	Median at Timepoint (IQR)	Median Change (IQR)	Median % Change (IQR)
ALT (U/L)	6 Months	159	37 (26, 57.5)	34 (24, 45)	-4* (-20, 7)	-10.26 (-42.37, 30.91)
	12 Months	86	38.5 (26.25, 54.75)	31.5 (24.25, 42.75)	-6.50* (-19.75, 5.75)	-17.8 (-42.19, 14.27)
AST (U/L)	6 Months	160	33 (24, 47)	31 (24, 42)	-1 (-13, 7.25)	-3.78 (-29.16, 27.17)
	12 Months	86	33 (25, 46.25)	29 (23, 41.75)	-3.00* (-13, 4.75)	-9.38 (-34.59, 15.41)

3482 | RESMETIROM IN MASH AND HIV: A SINGLE-CENTER DESCRIPTIVE COHORT

Alexander Zhu[1] Inioluwa Dada[1] Anthony Martinez[1],
[1]University at Buffalo

Background: Resmetirom is the first FDA-approved therapy for metabolic dysfunction-associated steatohepatitis (MASH) with significant fibrosis. People living with HIV (PLWH) carry a substantial burden of MASH and progressive fibrosis, driven by chronic immune activation, antiretroviral therapy (ART)-associated metabolic effects, and ectopic fat deposition at lower BMI than in the general population. Yet PLWH are commonly excluded from MASH trials due to concerns of drug-drug interactions, and to our knowledge, no real-world data on resmetirom in this population have been reported. We describe our single-center experience with resmetirom in PLWH with MASH. **Methods:** We retrospectively reviewed all adults prescribed resmetirom for MASH with significant fibrosis at our center between April 2024 and December 2025. Patients with HIV and confirmed resmetirom exposure (notes and/or pharmacy fill records) were included; those with unclear initiation or compliance were excluded. Baseline demographics, comorbidities, ART regimen, dosing, duration, adverse events (AEs), and serial vibration-controlled transient elastography (VCTE) and ALT values were extracted from the medical record. Response was defined a priori as $\geq$25% reduction in liver stiffness (kPa) at approximately 12 months. **Results:** Six PLWH (5.3% of 114 resmetirom-treated patients) were identified. Median age was 58 years (37–70); 4 were male; race/ethnicity was evenly split among African American, Hispanic, and White. Median BMI was 34 kg/m^2 (25–46). Comorbidities included hypertension (n = 5), dyslipidemia (n = 4), and type 2 diabetes (n = 2). All were on integrase inhibitor- or NNRTI-based regimens without pharmacologic boosters: bictegravir/emtricitabine/tenofovir alafenamide (n = 4), dolutegravir/lamivudine (n = 1), and emtricitabine/rilpivirine/tenofovir alafenamide (n = 1). Median ALT was 44 U/L. Median FIB-4 was 1.5. Four received 100 mg and two 80 mg daily. Median duration was 12.5 months (10.8–24.5). One patient discontinued due to diarrhea; one had a 4-month patient-initiated interruption with reinitiation; no other AE-related events occurred. Paired baseline and 12-month VCTE were available for only 2 patients; both met responder criteria (liver stiffness 8.1 to 5.6 and 11.1 to 6.4 kPa) with fibrosis-stage regression. ALT was available for 5 patients: among 4 with follow-up near 12 months, ALT decreased in 3; the fourth had a normal baseline ALT that remained within normal limits; a fifth had an early decrease (27 to 21 U/L at 3 mo) but no later follow-up. **Conclusion:** In this first real-world cohort of resmetirom in PLWH, the drug was tolerated on contemporary unboosted ART regimens, with one discontinuation for diarrhea, a known resmetirom effect. Liver stiffness and ALT improved in most evaluable patients. These data support the feasibility of resmetirom in PLWH and merit further study of resmetirom in this population.

3483 | EFFECT OF RESMETIROM ON LIVER STIFFNESS IN MASH: A REAL-WORLD LONGITUDINAL ANALYSIS

Alexander Zhu[1] Inioluwa Dada[1] Anthony Martinez[1],
[1]University at Buffalo

Background: Resmetirom is the first FDA-approved therapy for non-cirrhotic MASH with moderate to advanced fibrosis. AASLD guidance recommends assessment at 12 months, with ≥25% reduction in vibration-controlled transient elastography (VCTE) liver stiffness as the response threshold. Real-world reports to date have largely described single-timepoint changes at 3–6 months, and longitudinal data characterizing how liver stiffness evolves throughout the first year of therapy remain limited. Our aim was to characterize the trajectory of liver stiffness during treatment and to evaluate 12-month outcomes in a real-world cohort. **Methods:** We conducted a single-center retrospective cohort study of 114 adults with MASH initiated on resmetirom. The trajectory cohort had a baseline VCTE within 12 months before or 1 month after initiation and ≥1 on-treatment VCTE (n = 57, 129 scans). The effectiveness cohort was a subset with paired 12-month VCTE (n = 32). Liver stiffness trajectory was modeled by a log-linear mixed-effects regression with random patient intercepts; paired changes were compared by Wilcoxon signed-rank test. Effectiveness outcomes assessed at 12 months were median change in kPa, ≥25% reduction in kPa, and regression or progression of VCTE-derived fibrosis stage. Safety outcomes were treatment discontinuation due to adverse effects and treatment interruption. **Results:** Baseline characteristics: median age 57 years, 51% female, 45% with type 2 diabetes; effectiveness cohort baseline VCTE stage was 44% F2, 47% F3, 9% F4, with median liver stiffness 11.0 kPa (IQR 9.0–12.5). Of 3 patients staged F4 by baseline VCTE, all had clinical or histologic evidence of VCTE overestimation (BMI-related confounding [n = 1]; biopsy-proven F2 or F3 within 24 months [n = 2]). Liver stiffness declined during therapy at −24.1% per year (95% CI −30.2% to −17.4%, p < 0.001). Model-predicted decline in kPa was approximately 13% at 6 months, 19% at 9 months, and 24% at 12 months. Among 32 patients with paired 12-month VCTE, median kPa decreased from 11.0 to 7.3 (median change −39.4%, p < 0.001), and 20/32 (62.5%) met the ≥25% threshold. VCTE-derived stage regressed in 22/32 (68.8%, p < 0.001) and progressed in 4/32 (12.5%); among baseline F3 patients (n = 15), 12 (80%) regressed and none progressed. 9/114 (7.9%) discontinued due to adverse effects, most commonly abdominal pain or diarrhea; 4/114 (3.5%) temporarily interrupted treatment and resumed. **Conclusion:** In this real-world cohort, liver stiffness declined continuously from the start of resmetirom therapy, with model-predicted decline of approximately 13% by 6 months and 24% by 12 months. These findings suggest that interval VCTE may provide an earlier objective signal of treatment response, complementing the AASLD-recommended 12-month reassessment and offering potential utility for shared decision-making and patient counseling during the first year of therapy.

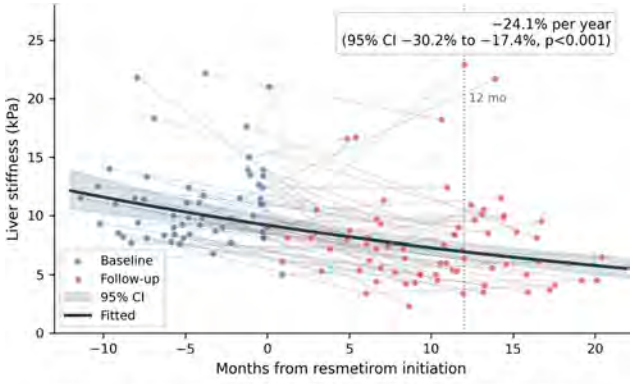

Figure 1. Liver stiffness trajectory during resmetirom therapy. Baseline (blue) and follow-up (red) liver stiffness measurements (kPa) by VCTE, with gray lines connecting serial scans for each patient. The bold dark line shows the mixed-model fitted mean with shaded 95% CI; liver stiffness declined an estimated 24.1% per year (95% CI −30.2% to −17.4%, p<0.001). n = 57 patients, 129 scans.

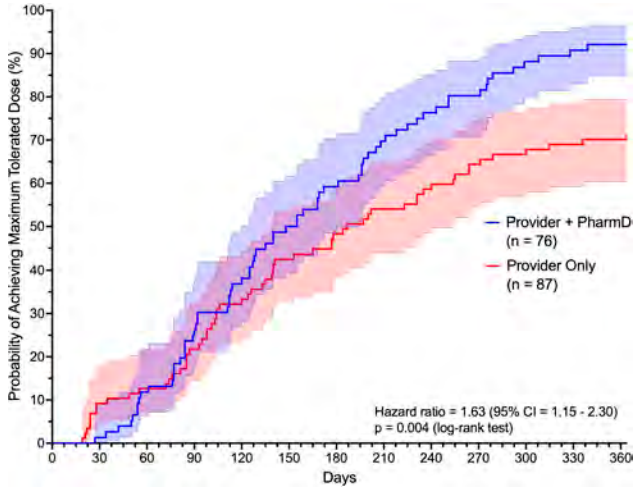
3484 | PHARMACIST-DIRECTED GLP-1 AGONIST THERAPIES FOR STEATOTIC LIVER DISEASE: A REAL-WORLD COHORT STUDY



James Vu[1] Maria Golovkina[2] Tina Ho[2] Khang Nguyen[2] Jazmin Valencia Chavez[2] Jeremiah Duby[2] Albert Do[2],

[1]UC Davis Medical Center, [2]University of California Davis Medical Center

Background: Incretin-based therapies (GLP-1 agonists) have clinical benefits for multiple metabolic diseases, including metabolic dysfunction-associated steatotic liver disease (MASLD). Clinical pharmacists support incretin-based therapy provision through therapy initiation, patient education, dose titration, adherence support, and adverse effect management. Despite routine reliance on pharmacist-directed patient care, there are limited data for steatotic liver disease with metabolic contributor to disease. We aim to study whether pharmacist management of GLP-1 agonists affects process- and clinical outcomes in patients with MASLD and metALD in a large tertiary health care system. **Methods:** This was a historical cohort study of adults aged ≥18 years with MASLD and metALD initiating GLP-1 therapies from January 1, 2023, to November 1, 2025. Patients were stratified as (1) pharmacist-directed cohort with therapy monitoring and adjustment by a clinical pharmacist, or (2) no pharmacist involvement. Clinical outcomes were defined as time to maximum tolerated dose and time to first titration. We compared clinical characteristics between groups and performed comparisons between time-to-event outcomes using log-rank test and Cox proportional hazard regression. **Results:** The analysis cohort included 183 patients, with 81 receiving pharmacist-led therapy and 102 without pharmacist management. The mean age (58.9 vs. 58.0 years, p = 0.32) proportion of female patients (63.0% vs. 59.8%, p = 0.66) did not differ between groups at baseline The pharmacy group was more likely to be prescribed tirzepatide (50.6% vs 34.3%, p = 0.03) and more likely to have MASLD as the prescription indication (28.4% vs 5.9%, p = 0.001). Pharmacy involvement was associated with a significantly higher likelihood of increasing beyond the initial titration dose (HR 1.48, 95% CI 1.02-2.13, p = 0.04). Pharmacy involvement was also associated with significantly earlier achievement of maximum tolerated doses (HR 1.63, 95% CI 1.15-2.30, p = 0.004). Pharmacist co-management was associated with significantly greater weight loss at 26 weeks (–6.9% vs. –4.6%, p = 0.032) but not at 52 weeks (–8.1% vs. –7.3%, p = 0.655). **Conclusion:** Pharmacy involvement improved timeliness of GLP-1 therapy optimization for patients with steatotic liver disease, and was associated with faster therapy titration. We find that such involvement may accelerate early weight loss through support with titration, adherence, and side-effect management, which may enable decisions for next therapies if needed. Further characterization of pharmacist-led interventions my refine patient-centered treatment approaches, and scaling efforts would enable cost justification to larger populations.

3485 | PLASMA CELL-FREE DNA METHYLATION RECOVERS SEMAGLUTIDE PHARMACOLOGY IN MASH TRIALS DESPITE AN UNINFORMATIVE MRI-PDFF ENDPOINT

Rohit Loomba[1] Soheil Damangir[2] Egbert Madamba[1] Seema Singh[1] Chong Lu[2] Leila Bazargan[2] Hamed Amini[2], [1]University of California, San Diego, [2]Hepta Bio, Inc.

Background: Phase 2 trials can miss their endpoints because of small samples and heterogeneous response, even for drugs that would succeed at Phase 3. Semaglutide is a clear example: Newsome 2021 missed biopsy fibrosis improvement and Flint 2021 missed MRE liver stiffness, yet Phase 3 ESSENCE confirmed fibrosis improvement in a larger and longer trial. We asked whether plasma cfDNA methylation can read drug-engaged biology directly at the molecular and pathway level, distinguishing real drug action from statistical artefact when endpoints are uninformative. **Methods:** SAMARA randomized 35 patients with at-risk MASH (defined by FAST) to semaglutide or placebo for 52 weeks. Paired plasma cfDNA whole-methylome sequencing at baseline and end-of-treatment was processed with a custom-built AI platform, LiquidTransformer. MRI-PDFF responders were defined as PDFF percent change > 15% and absolute

change > 5%. Methylation changes defining the drug effect and the baseline responder state were tested for cell-type, transcription-factor, ligand-perturbation and pathway enrichment against the measured methylome background. **Results:** Responders were similarly distributed across arms, leaving the PDFF endpoint uninformative for treatment effect. Yet treatment-arm methylation read canonical semaglutide pharmacology across organs. In the liver, hepatocyte programs were activated while five bile-duct subtypes were coherently suppressed, the cellular signature of reduced ductular reaction and mechanistically upstream of the fibrosis improvement that ESSENCE later confirmed at biopsy. Drug-affected gene sets matched the methylation fingerprints of three relevant ligand stimulations: FGF21 (8.1-fold), galanin (6.1-fold) and leptin (17-fold, all $p < 0.001$), engaging the canonical MASH and feeding-regulation drug axes. Drug-activated genes were enriched for hepatic nuclear-receptor regulons including NR1I2 (PXR) and RARA; drug-suppressed regulons were dominated by GFI1, FOXQ1, GATA3 and YY1 cell-state TFs. Genes distinguishing MASH responders at baseline overlapped drug-effect genes 4.6- and 7.5-fold in the opposite direction (hypergeometric $p < 0.001$); same-direction overlap was not significant. These findings suggest that MASH is biologically heterogeneous, and that responders are the patients whose pre-treatment state is the specific dysregulation semaglutide can reverse. **Conclusion:** Plasma cfDNA methylation recovered organ-resolved semaglutide pharmacology, FGF21- and leptin-class ligand fingerprints, and the mechanistic link between baseline responder state and drug action in a trial where the MRI-based response stratification did not separate arms. ESSENCE has since validated semaglutide's fibrosis efficacy at scale, confirming the biology detected here from blood. Plasma cfDNA methylation thus provides a mechanism-resolved readout of MASH drug engagement that extends beyond clinical endpoints.

3486 | RISK OF HEPATIC DECOMPENSATION WITH GLP-1 RECEPTOR AGONISTS VERSUS SGLT2 INHIBITORS IN PATIENTS WITH MASLD OR CIRRHOSIS AND CHRONIC KIDNEY DISEASE

Urveesh Sharma[1], [1]University of Arkansas for Medical Sciences

Background: Hepatic decompensation is a major driver of morbidity in metabolic dysfunction-associated steatotic liver disease (MASLD) and cirrhosis, and the risk increases when chronic kidney disease (CKD) coexists. Both GLP-1 receptor agonists (GLP-1 RAs) and SGLT2 inhibitors (SGLT2is) have shown hepatic benefits in early-phase studies, but the evidence regarding one class performing better than the other at preventing hard liver endpoints in patients with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

concurrent CKD remains limited. **Methods:** We conducted a retrospective cohort study using the TrinetX database where adults (≥18 years) with pre-existing MASLD or cirrhosis, CKD stages 3-5, and T2DM were divided into two cohorts based on whether they were newly started on a GLP-1 RA or a SGLT2i. We excluded patients with cross-drug class exposure, alcoholic liver disease, viral hepatitis, prior liver transplant, HCC, ESRD, or dialysis. 1:1 propensity score matching (PSM) on demographics, comorbidities, medications, and laboratory values was done. The primary outcome was a hepatic decompensation composite: ascites, variceal bleeding, hepatic encephalopathy, hepatic failure, HCC, or liver transplant, within 3 years. Kaplan-Meier analysis with log-rank testing and Cox regression were performed. The proportional hazards assumption was met (p = 0.968). **Results:** After matching, 4,700 patients per group were analyzed. Mean age was 67.9 years, 57.2% were female, 18.7% had cirrhosis, 97.4% had CKD stage 3, and mean BMI was 35.3 kg/m2. The hepatic decompensation composite occurred at similar rates in both groups (GLP-1 RA: 134/4,318 [3.1%] vs SGLT2i: 126/4,219 [3.0%]; HR 1.049, 95% CI 0.823-1.338; log-rank p = 0.698). Three-year event-free survival was 94.8% and 95.0%, respectively. **Conclusion:** In patients with MASLD or cirrhosis, CKD, and T2DM, GLP-1 RA and SGLT2i use were associated with comparable rates of hepatic decompensation over 3 years, and both drug classes appear similarly effective at preventing liver-specific complications in this population. This suggests that the choice between them may be guided by other factors, like their differing effects on cardiovascular and mortality endpoints rather than liver-specific outcomes.

Table 1. Hepatic decompensation outcomes at 3 years — GLP-1 receptor agonists vs. SGLT2 inhibitors

Outcome	GLP-1 RA n/N (%)	SGLT2i n/N (%)	HR (95% CI)	3-yr event-free survival	p value (log-rank)
Hepatic decompensation composite†	134/4,318 (3.1)	126/4,219 (3.0)	1.049 (0.823–1.338)	94.8% vs. 95.0%	0.698

† Composite of ascites, variceal bleeding, hepatic encephalopathy, hepatic failure, HCC, or liver transplant. HR = hazard ratio; CI = confidence interval; HCC = hepatocellular carcinoma.

3487 | REAL WORLD PRESCRIBING PATTERNS OF PROVIDERS IN PATIENTS WITH MASH FIBROSIS AND CARDIOMETABOLIC DISEASE

Clara McNatt[1] Allysa Saggese[1] Tatyana Kushner[1] Sonal Kumar[1], [1]Weill Cornell Medicine

Background: Metabolic-dysfunction associated steatohepatitis (MASH) is the liver manifestation of the metabolic syndrome (MS). Prior to March 2024, management relied on lifestyle modifications and therapies for cardiometabolic comorbidities. We aimed to characterize real-world prescribing patterns of providers treating patients with MASH fibrosis and cardiometabolic disease before and after the approvals of resmetirom and semaglutide. **Methods:** We conducted a retrospective cohort study using the TriNetX research network. Patients with MASH fibrosis were identified using the diagnosis codes for steatohepatitis/steatosis (K75.81 or K76.0) and liver fibrosis (K74.0). Cardiometabolic comorbidities included type 2 diabetes (T2D), thyroid disorders, lipid disorders and hypertension. Medications evaluated included statins, GLP-1 receptor agonists (GLP-1 RAs), anti-hypertensives and metformin. Prescribing frequency and sequence were compared pre- and post-March 2024 using line of treatment (LOT) analyses. **Results:** Patients were 53% female, 71% white, 11-15% Hispanic or Latino, 7-11% Black or African American, and 7-9% Asian. Prior to March 2024, statins were the most common first-line cardiometabolic therapy (>40%). GLP-1 RAs were least frequently used prescribed first (13%) (Figure 1). After March 2024, statins and antihypertensives remained the most common first-line therapy, with GLP-1RAs, resmetirom and metformin prescribed in less than 15% of patients (Figure 1). Patients were more likely to be prescribed a GLP-1 RA if they were female (p < 0.0001), white (p < 0.0001), or Black (p = 0.0180), or if they had a diagnosis of T2D, hypertension, hyperlipidemia, or thyroid disease (all p < 0.0001). Asian patients were less likely to be prescribed a GLP-1 RA (p < 0.0001). GLP-1 RA prescriptions increased steadily between 2019 and 2023, declined after March 2024 and increased again after August 2025 (Figure 1). Resmetirom was steadily prescribed first in 10% of patients with MASH fibrosis since March 2024 (Figure 1). Statins remain the most frequent first prescription; however, overall number of prescriptions have declined. GLP-1 RAs and antihypertensive prescriptions have remained consistent, while metformin prescriptions have declined since March 2024. **Conclusion:** In patients with MASH fibrosis and cardiometabolic disease, statins remain the most commonly prescribed medication. Use of MASH-directed therapies remains relatively limited in routine clinical practice. The modest uptake of newly approved MASH therapies highlights potential gaps in implementation and warrants further investigation into provider, patient and system level factors that may influence treatment. Limitations of this study include the reliance on ICD10 coding in a larger research network and the aggregation of all GLP-1 RAs into a single treatment category.

3488 | DOES GLP-1RA THERAPY HAVE AN IMPACT ON MUSCLE FUNCTION IN PATIENTS WITH MASLD?

Jasmin Ravindra[1] Fernando Iorra[1], [1]Imperial College London

Background: Glucagon like peptide-1 receptor agonists (GLP-1RAs) are increasingly prescribed in patients with metabolic-dysfunction associated steatotic liver disease (MASLD). However, MASLD patients have an increased susceptibility to sarcopenia. Despite this, the impact of GLP-1RA-induced weight loss on muscle function and mass in this population remains poorly characterised. This study aimed to evaluate the effect of GLP-1RA therapy on muscle function, body composition, and quality of life in patients with MASLD. **Methods:** This prospective cohort study, conducted at a specialist metabolic liver centre in Northwest London from November 2015 to April 2026, enrolled consecutive adult patients with MASLD. Patients receiving GLP-1RA therapy (n = 54) were matched by age and gender to those not receiving GLP-1RA therapy (n = 76). Muscle function, body composition, quality of life and physical activity were measured using the hand grip and five times sit-to-stand-test (FTSST), bioelectrical impedance analysis, the Short Form 36 (SF-36) and the International Physical Activity Questionnaire respectively. **Results:** Hand grip remained stable over time in both cohorts (GLP-1RA: 27.3kg-29.6 kg, p = 0.3654; no-GLP-1RA: 27.6kg-28.3 kg, p = 0.9656), with no significant between-group difference at end of follow-up (p = 0.687). FTSST also remained consistent in both groups (GLP-1RA: 11.00s-10.78s, p = 0.7582; no-GLP-1RA: 10.82s-10.39s, p = 0.0827) and not significant between groups (p = 0.397). Muscle mass decreased numerically in both cohorts (GLP-1RA: 55.7kg-52.6kg, p = 0.3832; no-GLP-1RA: 51.8kg-49.9kg, p = 0.6019) without a significant intergroup difference (p = 0.795). No SF-36 domain changed significantly in the GLP-1RA cohort though bodily pain worsened significantly in no-GLP-1RA cohort by the end of the study period (p = 0.034). **Conclusion:** GLP-1RA therapy was not associated with an impairment of muscle function or mass in MASLD patients, a reassuring preliminary finding given the high risk of sarcopenia in this group. Multi-centre randomised trials incorporating standardised functional assessments and imaging-based body composition are needed to definitively characterise GLP-1RA effects on the MASLD-skeletal muscle axis.

3489 | A CME VIRTUAL PATIENT CASE SIMULATION IMPROVED CLINICIAN PERFORMANCE IN MANAGING MASH

Shari Dermer[1] Julie Schrand[1] Roderick Smith[1] Sonal Kumar[2] Anita Kohli[3], [1]Medscape Education, [2]Weill Cornell, [3]Arizona Liver Health

Background: As there are now treatment options available for metabolic dysfunction-associated steatohepatitis (MASH) identification of candidates for these treatments is increasingly important in the care pathway. This study evaluated the effect of online virtual patient simulation (VPS)-based CME in improving the assessment and management of MASH, including risk-stratification, evaluation of liver fibrosis, and treatment initiation. **Methods:** An online VPS platform allowed learners to order tests, and select treatments supported by an extensive database matching the scope and depth of actual practice. Learners received immediate feedback in a short-form clinical guidance (CG) based on current evidence. Learners were permitted to modify their decisions post-CG. Pre- to post-CG decisions were compared using a McNemar's test with $P < .05$ as significant. The intervention launched on September 12, 2025, and data were collected through January 12, 2026. **Results:** We report on data from n = 38 to 51 gastroenterologists/ hepatologists (GI/heps) and n = 112 to 135 NP/PAs who participated in the virtual cases. Significant performance-based improvements were made in patient cases following CG (%pre vs % post; *P*-value). **Selecting noninvasive modalities for risk-stratification** : Performance improved by 8% (86% vs 94%; $P < .01$) and 18% (53% vs 71%; $P < .001$) for GI/heps and NP/PAs, respectively in case 1.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

For case 2, GI/heps had 10% (82% vs 92%; $P < .01$) and NP/PAs had 16% (63% vs 79%; $P < .001$) improvement in performance. **Staging of liver fibrosis:** Performance improved by 14% (47% vs 61%; $P < .001$) and 19% (24% vs 43%; $P < .001$) for GI/heps and NP/PAs, respectively in case 1. For case 2, GI/heps had 26% (42% vs 68%; $P < .001$) and NP/PAs had 31% (14% vs 45%; $P < .001$) improvement in performance. **Choosing evidence-based therapies:** Performance improved by 45% (22% vs 67%; $P < .001$) and 29% (6% vs 35%; $P < .001$) for GI/heps and NP/PAs, respectively in case 1. For case 2, GI/heps had 26% (24% vs 50%; $P < .001$) and NP/PAs had 30% (17% vs 47%; $P < .001$) improvement in performance. **Conclusion: Discussion:** Although there was increased performance in clinical decision-making with CG, most initial decisions indicate gaps in diagnosing F2/F3 MASH and in selecting appropriate evidence-based treatments.Reference:Kumar S., Kohli A. 3490 | LEVOTHYROXINE DOES NOT PROTECT AGAINST MAJOR ADVERSE LIVER OUTCOMES IN PATIENTS WITH MASLD AND HYPOTHYROIDISM: A PROPENSITY SCORE-MATCHED ANALYSIS

Rowan Bandaranaike[1] Travis Rutland[2] Samuel Tarwater[2] Tyler Black[2] George Nelson[3], [1]Southeast Health Hospital, [2]Digestive Health Specialists, [3]University of Alabama at Birmingham

Background: Hypothyroidism is associated with metabolic dysfunction-associated steatotic liver disease (MASLD) progression through shared metabolic pathways. Resmetirom, the first FDA-approved treatment for MASH, acts via liver-selective thyroid hormone receptor-β (THR-β) agonism. Whether systemic levothyroxine replacement affects hard clinical liver outcomes: cirrhosis, HCC, and liver failure in patients with established MASLD has not been evaluated in large real-world cohorts. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network (44 U.S. health systems). Adults ($\geq$18 years) with MASLD (K76.0, K75.81) and hypothyroidism (E03.9, E03.8, E89.0, E02) were stratified by levothyroxine use; competing liver etiologies were excluded. One-to-one PSM balanced cohorts on age, sex, race, ethnicity, obesity, diabetes, dyslipidemia, and hypertension. The primary composite outcome, major adverse liver outcomes (MALO), comprised incident cirrhosis, hepatocellular carcinoma, liver transplant, ascites, and hepatic failure, assessed over 10 years via Kaplan-Meier analysis and Cox regression. Sensitivity analyses included E-value calculation for unmeasured confounding and a negative control outcome (appendicitis) to assess outcome specificity. **Results:** Among 365,579 eligible adults, 1:1 PSM yielded 142,869 patients per cohort with excellent covariate balance (all SMD < 0.02). Levothyroxine users had significantly higher MALO risk (5.1% vs 4.1%; RR 1.249, 95% CI 1.207-1.293; $p < 0.001$) and lower 10-year event-free survival (89.69% vs 91.63%; log-rank $p < 0.001$). Cox regression confirmed a 23% higher hazard (HR 1.230, 95% CI 1.187–1.274; $p < 0.001$; proportional hazards assumption confirmed, $p = 0.719$). The E-value was 1.76 (lower CI bound 1.66), indicating an unmeasured confounder would require $\geq$1.76-fold independent associations with both exposure and outcome to explain the result. Appendicitis incidence did not differ between cohorts (RR 1.02, 95% CI 0.99-1.08; $p = 0.07$), confirming absence of systematic detection or healthcare utilization bias. **Conclusion:** In 285,738 total propensity score-matched patients, levothyroxine use was associated with 23% higher MALO risk in MASLD with hypothyroidism over 10 years. These findings suggest systemic thyroid hormone replacement may not confer the hepatoprotective effects observed with liver-selective THR-β agonists. Residual confounding from hypothyroidism severity, including TSH levels unavailable in administrative data, cannot be excluded and likely contributes to the observed association. Studies examining TSH optimization targets and levothyroxine dose adequacy on liver outcomes are needed to guide treatment decisions in the growing population of patients with concurrent MASLD and hypothyroidism.

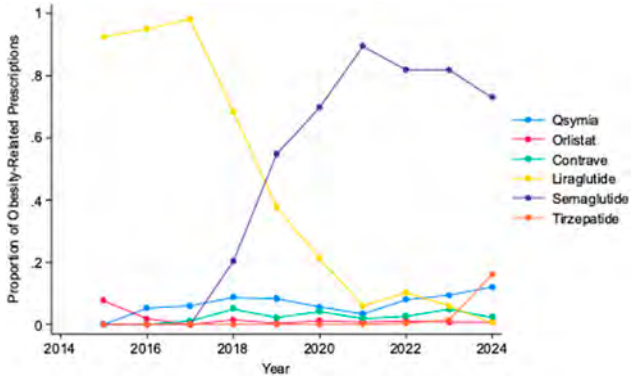
3491 | WHO GETS WEIGHT LOSS THERAPY? ANTI-OBESITY MEDICATION USE IN MASLD AND METALD



Dilara Hatipoglu[1] Nadim Mahmud[2], [1]University of Pennsylvania, [2]Hospital of the University of Pennsylvania

Background: Obesity is a major driver of fibrosis progression in steatotic liver disease (SLD). Lifestyle modification alone is often insufficient, making anti-obesity medications (AOMs) an important therapeutic option. We compared AOM utilization and predictors of prescription in patients with metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

dysfunction-associated alcohol-related liver disease (MetALD) **Methods:** This retrospective cohort study utilized VOCAL, a national Veterans Health Administration registry of patients with chronic liver disease. Adults (≥18 years) with non-cirrhotic steatotic liver disease on imaging, BMI ≥35 kg/m² , and no prior obesity treatment were included. MASLD and MetALD were classified using metabolic criteria and AUDIT-C data according to a validated algorithm. Multivariable logistic regression identified predictors of receiving any AOM. Trends in individual AOM use over time were assessed with linear regression. A post hoc subgroup analysis was performed by diabetes status. **Results:** Among 23,333 veterans in the cohort, 19,629 (84.1%) had MASLD and 3,704 (15.9%) had MetALD. Overall, 5,971 (25.6%) received at least one AOM. GLP-1 receptor agonists (GLP-1RAs) were the most prescribed class. Compared with MASLD, patients with MetALD were less likely to receive GLP-1RAs overall (18.5% vs 25.1%, $p<0.001$), including semaglutide (16.6% vs 23.1%, $p<0.001$) and liraglutide (2.1% vs 3.4%, $p<0.001$), while use of other AOMs was similar. Over time, liraglutide use declined (β = −0.11, 95% CI −0.139 to −0.084; p < 0.001), while semaglutide (β = 0.085, 95% CI 0.046 to 0.125; p = 0.001) and tirzepatide (β = 0.019, 95% CI 0.003 to 0.036; p = 0.025) use increased significantly (Figure 1).In adjusted analysis, diabetes mellitus was the strongest predictor of receiving any AOM (OR 3.53, 95% CI 3.26-3.83), while female sex (OR 1.52, 95% CI 1.37-1.70) and higher BMI (OR 1.06 per kg/m², 95% CI 1.05-1.07) were also independently associated with treatment. MetALD was independently associated with lower odds of AOM receipt compared with MASLD (OR 0.80, 95% CI 0.73-0.89), including in non-diabetics (OR 0.83, 95% CI 0.74-0.94). **Conclusion:** AOMs remain underutilized in patients with SLD. Patients with MetALD were less likely to receive AOMs, particularly GLP-1RAs, independent of diabetes status, suggesting disparities in obesity pharmacotherapy utilization and opportunities to improve fibrosis risk mitigation.

3492 | COMPARATIVE ANALYSIS OF THE EFFICACY OF GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS VERSUS BARIATRIC SURGERY IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE IN A LARGE, INTEGRATED HEALTHCARE SYSTEM IN NORTHERN CALIFORNIA

Molly Chou[1] Miguel Nunez[2] Mehrnaz Siavoshi[3] Varun Saxena[2] Sreepriya Balasubramanian[4] Brock Macdonald[5] Suk Seo[6] Krisna Chai[7] Jeffrey Lee[1] Neil Mehta[2] Nizar Mukhtar[1], [1]Kaiser Permanente San Francisco Medical Center, [2]University of California, San Francisco, [3]Kaiser Permanente, [4]Kaiser Permanente Roseville Medical Center, [5]Kaiser Permanente, San Rafael, [6]Kaiser Permanente Antioch Medical Center, [7]Kaiser Permanente Santa Clara

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease globally and is strongly linked to obesity. Both bariatric surgery and glucagon-like peptide-1 receptor agonists (GLP-1 RAs) improve steatosis, fibrosis, weight, and cardiometabolic outcomes. However, no large-scale studies have directly compared these interventions in MASLD. This study aims to compare the effectiveness of GLP-1 RAs to bariatric surgery for patients with MASLD in a large community practice setting—the Kaiser Permanente Northern California (KPNC) healthcare system—to inform best practices in management. **Methods:** This retrospective cohort study included adults (≥18 years) with MASLD diagnosed between 1/1/2014 and 12/31/2022 within KPNC who underwent bariatric surgery (Roux-en-Y gastric bypass, sleeve gastrectomy, or gastric banding; N = 5,258) or received a GLP-1 RA for at least 6 months over a 12-month period (N = 26,976). Analyses used propensity score-adjusted Cox proportional hazards models starting from the date of bariatric surgery or GLP-1 RA initiation. The primary outcomes were: 1) progression to cirrhosis among patients without baseline cirrhosis, 2) occurrence of a composite outcome that includes hepatic decompensation, hepatocellular carcinoma, liver transplantation, and death among patients with baseline cirrhosis, and 3) occurrence of major adverse cardiovascular events (MACE) among patients with baseline cirrhosis. **Results:** Among the 32,234 patients, mean age was 50.6 years; 64% were female, 44% White, 23% Hispanic, 13% Asian, and 7% Black. Treatment was initiated a mean of 4.8 years after MASLD diagnosis. On the date of treatment initiation, 2.3% of patients had cirrhosis; over 50% had diabetes, hypertension, or hyperlipidemia; and 9% had chronic kidney

disease. Compared to patients who underwent bariatric surgery, patients who received GLP-1 RAs were more likely to be older (mean, age 51 vs. 47 years; $p < 0.001$), male (39% vs. 23%; $p < 0.001$), and non-White (57% vs. 51%; $p < 0.001$); to take longer to initiate treatment (5.3 vs. 2.1 years; $p < 0.001$), have a lower BMI (mean, 37.8 vs. 40.7; $p < 0.001$), and a lower rate of baseline cirrhosis (2.1% vs. 3.1%; $p < 0.001$); and to have higher rates of diabetes (64% vs. 24%; $p < 0.001$), hypertension (61% vs. 43%; $p < 0.001$), hyperlipidemia (57% vs. 36%; $p < 0.001$), and chronic kidney disease (10% vs. 5%; $p < 0.001$) (Table 1). Analyses are ongoing and preliminary results for primary outcomes will be provided. **Conclusion:** Patients who received GLP-1 RAs differed from those who underwent bariatric surgery in age, gender, race, BMI, baseline cirrhosis rate, and presence of co-morbidities, including those pre-disposing to MASLD. Data regarding progression to cirrhosis, rates of hepatic complications, and MACE will be discussed.

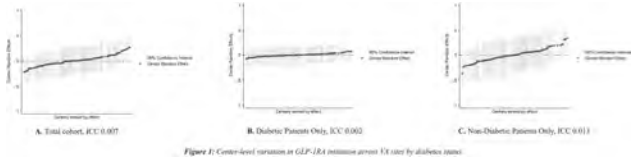
3493 | WHO GETS GLP-1RA THERAPY? SPECIALTY CARE STRONGLY PREDICTS TREATMENT IN MASLD AND METALD



Dilara Hatipoglu[1] Nadim Mahmud[2], [1]University of Pennsylvania, [2]Hospital of the University of Pennsylvania

Background: GLP-1 receptor agonists (GLP-1RAs) are increasingly used for obesity management and may improve liver-related outcomes in steatotic liver disease (SLD). However, provider- and center-level determinants of GLP-1RA initiation remain unclear. We evaluated patient, specialty care, and site-level predictors of GLP-1RA use in veterans with MASLD and MetALD. **Methods:** This was a retrospective cohort study using VOCAL, a national Veterans Health Administration registry of chronic liver disease representing 128 centers. Adults ($\geq$18 years) with non-cirrhotic SLD on imaging, BMI $\geq$35 kg/m², and no prior obesity treatment were included. MASLD and MetALD were classified using metabolic criteria and AUDIT-C data. The outcome was GLP-1RA initiation after steatosis diagnosis. Exposures included post-diagnosis healthcare utilization, specialty follow-up, and number of specialties seen. Multivariable logistic regression identified predictors of GLP-1RA initiation. Mixed-effects models with VA site as a random intercept evaluated center-level variation. Prespecified subgroup analyses were performed by diabetes status. **Results:** Among 23,333 veterans, 51.2% established care with at least one new specialty after steatosis diagnosis. Greater specialty exposure was associated with GLP-1RA initiation (OR 1.52, 95% CI 1.46-1.57, $p < 0.001$). Endocrinology had the highest odds (OR 2.53, 95% CI 2.35-2.73, $p < 0.001$), followed by hepatology (OR 1.33, 95% CI 1.19-1.48, $p < 0.001$) and gastroenterology (OR 1.30, 95% CI 1.21-1.39, $p < 0.001$), while primary care was not associated with GLP-1RA prescribing. Diabetes was strongly associated with increased use (OR 3.45, 95% CI 3.22–3.70, $p < 0.001$), while MetALD (OR 0.83, 95% CI 0.75-0.91, $p < 0.001$) and higher FIB-4 category (OR 0.85, 95% CI 0.80–0.87, $p < 0.001$) were associated with lower use. In non-diabetic patients, primary care showed modest association, while specialty care remained a strong predictor. Center-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

level variation was minimal overall (ICC 0.007) but higher in non-diabetic patients (ICC 0.013), demonstrated in **Figure 1. Conclusion:** GLP-1RA prescribing in SLD is strongly associated with specialty care, particularly endocrinology. Patients with MetALD and higher fibrosis risk were less likely to receive therapy, indicating gaps in treatment among higher-risk groups. Center-level variation was minimal overall but greater among non-diabetics, suggesting more heterogeneous obesity driven prescribing pathways in this subgroup.

3494 | HIGHER RISK OF CIRRHOSIS WITH BARIATRIC SURGERY COMPARED WITH GLP-1RA THERAPY IN ALD PATIENTS WITH OBESITY

Sheng-Yin Chen[1] Hanyou Loh[2] lingyu bao[3], [1]Massachusetts General Hospital, [2]Canton Medical Education Foundation, [3]Children's Hospital at Montefiore

Background: Alcohol-associated liver disease (ALD) and class I obesity confer an increased risk of advanced liver disease. While both bariatric surgery and glucagon-like peptide-1 receptor agonist (GLP-1RA) are recommended treatment for this population, alcohol use may pose harm in those who undergo bariatric surgery. We aimed to compare the effectiveness of bariatric surgery versus GLP-1RA-based therapies in preventing cirrhosis among patients with ALD and class I obesity. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network (66 healthcare organizations). Adults aged ≥18 years with ALD and obesity who underwent bariatric surgery or initiated GLP-1RA therapy between 1/1/2010 and 5/31/2023 were included. The body mass index (BMI) group of 30–35 kg/m² was chosen to ensure the comparability of both arms. Patients with pre-existing liver cirrhosis, prior bariatric surgery, or GLP-1RA exposure were excluded. The index date was defined as the date of bariatric surgery or first GLP-1RA prescription. Follow-up continued until 5/25/2026 or until the incident cirrhosis. Propensity score matching (PSM) adjusted for demographics, BMI, metabolic and psychiatric comorbidities, laboratory test, medication use, and healthcare utilization. Cox proportional hazards analysis was used to compare risk between groups. **Results:** A total of 5,355 patients met the inclusion criteria, including 669 patients undergoing bariatric surgery and 4,686 receiving GLP-1RA therapy. After 1:1 PSM, 489 patients remained in each group with balanced baseline characteristics. Mean age after matching was 54.1 ± 13.4 years in the bariatric surgery group and 54.3 ± 11.2 years in the GLP-1RA group. Mean BMI was 32.4 ± 5.0 versus 33.9 ± 4.1 kg/m², respectively. Patients in the bariatric surgery group demonstrated a significantly higher cumulative incidence of liver cirrhosis compared with the GLP-1RA cohort during follow-up. Bariatric surgery was associated with a higher risk of cirrhosis (HR 2.42, 95% CI 1.70-3.46) compared to GLP-1RA therapy. When categorized by sex, the risk of cirrhosis is similar between males (HR 2.87, 95% CI 1.70-4.85) and females (HR 2.37, 95% CI 1.36). Sensitivity analysis demonstrated a significantly higher risk for decompensated cirrhosis (HR 4.33, 95% CI 2.70-6.94). **Conclusion:** In this propensity score-matched cohort, GLP-1RA therapy was associated with a lower observed risk of incident cirrhosis and decompensated cirrhosis than bariatric surgery in patients with ALD and class I obesity. Prospective studies are warranted to validate the findings and to determine the role of alcohol cessation in patients who receive bariatric surgery.

3495 | ASSOCIATION OF GLP-1 USE AND END-STAGE LIVER DISEASE EVENTS IN US ADULTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Dominic Nunag[1] Christina Parrinello[2] Nipun Atreja[2] Arushi Chadha[1] Samantha Clark[1] Matthew Davis[1] Blake Thomas[2] Francis Lobo[2] John O'Donnell[2] Anthony Martinez[3], [1]Medicus Economics LLC, [2]Madrigal Pharmaceuticals Inc, [3]University at Buffalo

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is an inflammatory and progressive form of metabolic dysfunction-associated steatotic liver disease and is associated with end-stage liver disease (ESLD) complications. Because obesity and type 2 diabetes (T2D) are key metabolic drivers of MASH, many patients are eligible for GLP-1 receptor-targeting therapies. Assessments of ESLD outcomes in GLP-1 trials are limited by short follow-up duration and small sample sizes. We evaluated the relationship between GLP-1 use and risk of progression to ESLD among patients with MASH using real-world data. **Methods:** This retrospective cohort study used Optum Market Clarity data from December 5, 2015, through December 31, 2024. Adults with a MASH diagnosis code, evidence of obesity and/or T2D, and $\geq$24 months of continuous enrollment were eligible for study entry. Patients with other causes of liver disease or severe MASH-related complications during the 24-month pre-index period were excluded. Following the pre-index period, GLP-1 initiators (semaglutide or tirzepatide [any dose]; first fill defined as the index date) were 1:1 propensity score matched to controls of the same age, sex, and indication (obesity and/or T2D) who met the inclusion criteria as of the index date but did not have prior GLP-1 use (i.e. risk-set sampling). Outcomes included compensated and decompensated cirrhosis, hepatocellular carcinoma, liver transplant, or death. Time to first ESLD event was estimated overall and by indication using Kaplan-Meier analyses and marginal Cox models, with censoring at disenrollment or end of data availability. **Results:** The matched sample included 4,627 patients each in the GLP-1 user and non-user cohorts. Overall, 59.9% of patients were female, mean (SD) age was 51.6 (11.6) years, and 85.7%, 78.8%, and 64.6% had obesity, T2D, and both conditions, respectively. Mean (median) follow-up was 17.5 (14.7) and 18.0 (14.9) months in the GLP-1 user and non-user cohorts, respectively. In survival analyses, the cumulative incidence of ESLD events at 6, 12, and 24 months was 2%, 4%, and 8% among GLP-1 users and 2%, 4%, and 6% among GLP-1 non-users, respectively (HR = 1.05; p = 0.56). Event rates were not significantly different between cohorts in subgroup analyses of patients with obesity, T2D, and both conditions (all p > 0.05). **Conclusion:** In this real-world matched cohort of adults with MASH, no statistically significant difference in ESLD risk was observed between GLP-1 users and non-users. Comparable ESLD event rates suggest that longer-term studies are needed to better understand the potential impact of GLP-1 therapies on MASH progression.

Hofstra/Northwell at Vassar brothers medical center, [5]Baptist Memorial Hospital- Golden Triangle

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is strongly associated with obesity, type 2 diabetes mellitus, and increased cardiovascular morbidity. Tirzepatide has demonstrated significant metabolic benefits; however, comparative real-world data evaluating its effectiveness against other GLP-1 receptor agonists in MASLD remain limited. We compared mortality, cardiovascular, and hepatic outcomes among MASLD patients treated with tirzepatide versus GLP-1 receptor agonists. **Methods:** We performed a retrospective cohort study using the TriNetX US Collaborative Network. Adult patients with MASLD receiving tirzepatide or GLP-1 receptor agonists were identified. Propensity score matching (1:1) was performed to balance demographics and comorbidities between cohorts. Outcomes were assessed over a 1-year follow-up period and included all-cause mortality, major adverse cardiovascular events (MACE), stroke, myocardial infarction (MI), cirrhosis, and hepatocellular carcinoma (HCC). **Results:** Before matching, 65,454 patients receiving tirzepatide were compared with 153,060 patients receiving GLP-1 receptor agonists. After propensity matching, 65,452 patients remained in each cohort. Tirzepatide use was associated with significantly lower all-cause mortality compared with GLP-1 receptor agonists (0.5% vs 0.9%; RR 0.52, 95% CI 0.46–0.60; HR 0.63, $p < 0.001$). Patients treated with tirzepatide also had lower risk of MACE (2.5% vs 3.3%; RR 0.78, $p < 0.001$), stroke (1.4% vs 1.6%; RR 0.85, $p < 0.001$), myocardial infarction (1.2% vs 1.5%; RR 0.75, $p < 0.001$), and hepatocellular carcinoma (0.5% vs 0.6%; RR 0.76, $p < 0.001$). There was no significant difference in progression to cirrhosis between groups (4.0% vs 3.9%; RR 1.02, $p = 0.56$). Kaplan-Meier analysis demonstrated improved overall survival and lower cardiovascular event rates in the tirzepatide cohort. **Conclusion:** In this large multicenter propensity-matched analysis, patients on tirzepatide demonstrated reduced mortality, cardiovascular events, and HCC risk compared with GLP-1 receptor agonists among patients with MASLD. These findings suggest tirzepatide may provide additional cardiometabolic and hepatic benefits in MASLD management. Prospective randomized studies are warranted to further define its long-term impact on hepatic disease progression and clinical outcomes.

3497 | CARDIOVASCULAR OUTCOMES WITH GLP-1 RECEPTOR AGONISTS VERSUS SGLT2 INHIBITORS IN PATIENTS WITH MASLD OR CIRRHOSIS AND CHRONIC KIDNEY DISEASE

Urveesh Sharma[1] Yash Shah[2] Manesh Gangwani[2] Ragesh Thandassery[3], [1]University of Arkansas for Medical Sciences, [2]UAMS, LR, [3]CAVHS, Little Rock

Background: Patients with metabolic dysfunction-associated steatotic liver disease (MASLD) or cirrhosis and chronic kidney disease (CKD) face a disproportionately high cardiovascular burden. While both GLP-1 receptor agonists (GLP-1 RAs) and SGLT2 inhibitors (SGLT2is) have shown cardiovascular benefits in diabetic populations, no study has directly compared them in patients with both MASLD or cirrhosis and CKD. **Methods:** We conducted a retrospective cohort study using the TrinetX database where adults ($\geq$18 years) with pre-existing MASLD or cirrhosis, CKD stages 3-5, and T2DM were divided into two cohorts based on whether they were newly started on a GLP-1 RA or a SGLT2i. We excluded patients with cross-drug class exposure, alcoholic liver disease, viral hepatitis, prior liver transplant, HCC, ESRD, or dialysis. 1:1 propensity score matching (PSM) on demographics, comorbidities, medications, and laboratory values was done. The primary outcome was 3-year major adverse cardiovascular event (MACE), a composite of acute myocardial infarction (MI), cerebral infarction and intracerebral hemorrhage. Secondary outcomes included the individual MACE components. Kaplan-Meier analysis with log-rank testing and Cox regression were used. The proportional hazards assumption was satisfied for the MACE composite ($p = 0.250$) and for MI ($p = 0.704$). For cerebral infarction, the proportionality test was significant ($p = 0.029$), so the HR is reported as a time-averaged estimate. **Results:** GLP-1 RA use was associated with significantly lower MACE (6.3% vs 8.5%; HR 0.721, 95% CI 0.606-0.857; log-rank $p < 0.001$). Three-year MACE-free survival was 89.8% versus 86.9%. For individual components, GLP-1 RA use was associated with lower acute MI risk (3.8% vs 5.6%; HR 0.668, 95% CI 0.544-0.821; log-rank $p < 0.001$) and lower cerebral infarction risk (2.9% vs 3.9%; time-averaged HR 0.747, 95% CI 0.589-0.948; log-rank $p = 0.016$). **Conclusion:** In patients with concurrent MASLD or cirrhosis, CKD, and T2DM, GLP-1 RAs were associated with a 28% relative reduction in MACE compared to SGLT2is, with lower rates of both MI and stroke contributing to this difference. These findings point to a meaningful cardiovascular advantage for GLP-1 RAs in this high-

3498 | MORTALITY, HEPATIC, AND CARDIOVASCULAR OUTCOMES ASSOCIATED WITH ATYPICAL ANTIPSYCHOTIC EXPOSURE IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A PROPENSITY-MATCHED REAL-WORLD STUDY

Yetunde Akande[1] Cherechi Nwabueze[2] Gedion Amdetsion[1] Philip Sarpong-Mensah[1] Emmanuel Ansah[1] Ayokunle Abegunde[3], [1]John H Stroger Jr. Hospital of Cook County, [2]John H. Stroger Jr. Hospital of Cook County, [3]Division of Gastroenterology and Hepatology. John H Stroger Jr. Hospital of Cook County

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects approximately 30% of adults globally and confers substantial hepatic and cardiovascular risk. Antipsychotic medications promote weight gain, dyslipidemia, and insulin resistance, which are core drivers of MASLD progression. However, their independent impact on discrete clinical outcomes in this population remains poorly characterized. **Methods:** We conducted a retrospective cohort study using the TriNetX Network. Adults (≥18 years) with a diagnosis of MASLD were identified and stratified based on exposure to atypical antipsychotics. Propensity score matching (1:1) was performed on demographics, comorbidities, and clinical covariates. Outcome included mortality, MACE, stroke, MI, cirrhosis, and HCC, which were assessed over a 3-year follow-up window. Risk analysis and Kaplan-Meier survival analyses with log-rank testing were performed; risk ratios (RR), and hazard ratios (HR) with 95% confidence intervals (CI) are reported. **Results:** After propensity score matching (PSM), each cohort comprised 112,178 patients. Antipsychotic use was associated with significantly higher rates of mortality (16.4% vs. 9.6%), MACE (15.0% vs. 10.9%), stroke (5.9% vs. 4.1%), and MI (6.1% vs. 5.2%), all $p < 0.001$. Conversely, antipsychotic-exposed patients had lower rates of cirrhosis (3.6% vs. 5.2%) and HCC (1.3% vs. 1.8%), both $p < 0.001$. **Conclusion:** In this large propensity score-matched analysis, antipsychotic use among patients with MASLD was independently associated with significantly increased risks of all-cause mortality and adverse cardiovascular outcomes, including MACE, stroke, and MI. Paradoxically, antipsychotic exposure was associated with lower rates of cirrhosis and HCC. These findings highlight the importance of close cardiovascular risk assessment and monitoring in MASLD patients receiving antipsychotic therapy and warrant further investigation into the mechanisms underlying the observed reduction in hepatic complications.

3499 | PEG-IFN&ALPHA;-2B AMELIORATES METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS THROUGH THE GUT-LIVER AXIS

Tuo Shao[1] Enfei Qiang[1] Qian Zhu[1] Weifeng Zhao[1] Raymond Chung[2], [1]The First Affiliated Hospital of Soochow University, [2]Division of Gastroenterology and Hepatology, Mass General Brigham

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is driven by hepatic steatosis, inflammation, fibrosis, and gut-liver axis dysfunction. Type I interferons regulate lipid metabolism and immunity, but whether PEG-IFNα-2b protects against MASH through gut microbiota and bile acid remodeling remains unclear **Methods:** Diet-induced MASH mice were treated with PEG-IFNα-2b. Liver injury, steatosis, inflammation, fibrosis, intestinal barrier integrity, gut microbiota, bile acid profiles, and hepatic transcriptomic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

changes were evaluated by biochemistry, histology, qPCR, immunofluorescence, 16S rRNA sequencing, bile acid metabolomics, and RNA sequencing. **Results:** PEG-IFNα-2b improved liver injury in MASH mice, reducing liver-to-body weight ratio and serum ALT, AST, LDL, total bilirubin, and triglycerides, while increasing HDL. Histology showed reduced lipid droplets, ballooning, and collagen deposition. PEG-IFNα-2b suppressed lipogenic genes (ACC1, ACC2, Srebp1c, FASN), increased PPARα and FGF21 expression, and enriched fatty acid oxidation pathways. Treatment also decreased hepatic and intestinal IL-6, IL-1β, TNF-α, and F4/80, while increasing IL-10. In the intestine, PEG-IFNα-2b restored villus architecture, increased goblet cells, upregulated Claudin-1 and Occludin, enhanced Reg3b, Reg3g, IL-22, and mucin-related genes, and reduced circulating lipopolysaccharide.16S rRNA sequencing showed that PEG-IFNα-2b reduced potentially harmful taxa, including Erysipelatoclostridium and Enterobacteriaceae, and enriched Lactobacillus, Akkermansia muciniphila, and Clostridium. Bile acid profiling revealed decreased primary/conjugated bile acids (TCA, GCA, GCDCA, TUDCA) and increased secondary bile acids, including UDCA and LCA. UDCA negatively correlated with intestinal FXR-FGF15 signaling and positively correlated with hepatic Cyp7a1 and Cyp8b1. Consistently, PEG-IFNα-2b decreased intestinal FXR and FGF15 expression, increased hepatic Cyp7a1 and Cyp8b1, reduced serum total bile acids, and promoted fecal bile acid excretion. **Conclusion:** PEG-IFNα-2b alleviates experimental MASH by activating hepatic PPARα-FGF21 signaling, restoring intestinal barrier integrity, reshaping gut microbiota, increasing secondary bile acids, suppressing intestinal FXR-FGF15 signaling, and promoting bile acid synthesis and fecal excretion. These findings support PEG-IFNα-2b as a potential microbiota-bile acid–targeted therapy for MASH.

3500 | CARDIOMETABOLIC ADVANTAGE WITHOUT HEPATIC TRADEOFF: TIRZEPATIDE VERSUS SEMAGLUTIDE ACROSS THE MASLD/MASH SPECTRUM IN TYPE 2 DIABETES (T2DM)

Mohammad Alabbas[1] Akram Alnounou[2] Riddhi Machchhar[3] Omar Sims[1] Richard Sterling[4], [1]Cleveland Clinic Foundation, [2]Department of Internal Medicine, Western Michigan University Homer Stryker M.D. School of Medicine,, [3]Department of Internal Medicine, Hackensack Meridian Health Ocean University Medical Center, Brick,, [4]Virginia Commonwealth University

Background: Tirzepatide and semaglutide are increasingly used in T2DM with MASLD/MASH, but comparative real-world outcomes across liver-disease stage are limited. We compared hepatic, cardiovascular, hospitalization, mortality, and cirrhosis-related outcomes after tirzepatide versus semaglutide initiation in adults with noncirrhotic MASLD/MASH and MASLD/MASH-related compensated cirrhosis. **Methods:** Using TriNetX Research Network data from 110 healthcare organizations, we identified adults with T2DM and MASLD/MASH initiating tirzepatide or semaglutide. Patients were stratified as noncirrhotic or compensated cirrhosis; compensated cirrhosis required cirrhosis codes without prior decompensation. Exclusions included prior hepatic decompensation, malignancy, competing liver disease, transplant, end-stage renal disease/dialysis, HIV, or prior comparator exposure. Tirzepatide and semaglutide users were 1:1 propensity-score matched on demographics, comorbidities, medications, and laboratory values. Outcomes were assessed from day 1 after index through 1 and 3 years. The primary outcome was major adverse liver outcomes (MALO: decompensation-related events, hepatocellular carcinoma, liver transplantation, or death); secondary outcomes included hospitalization, first hepatic decompensation, ascites-related complications, major adverse cardiac event (MACE), mortality, incident cirrhosis, and ascites. **Results:** In the noncirrhotic cohort, 23,282 tirzepatide users were matched to 23,282 semaglutide users. At 1 year, hospitalization (12.9% vs 12.8%; HR 1.02, 95% CI 0.97–1.08; p = 0.409) and MALO (0.9% vs 0.9%; HR 0.95, 0.78–1.15; p = 0.599) did not differ, while MACE was lower with tirzepatide (8.4% vs 9.2%; HR 0.92, 0.86–0.98; p = 0.005). At 3 years, MALO (1.6% vs 1.7%; p = 0.683), first decompensation (1.0% vs 1.0%; p = 0.859), mortality (0.6% vs 0.7%; p = 0.713), and incident cirrhosis (1.2% vs 1.3%; p = 0.731) were similar; MACE remained lower with tirzepatide (10.1% vs 11.1%; HR 0.92, 0.87–0.97; p = 0.004). In compensated cirrhosis, 1,101 patients were matched per group. At 1 year, MALO (5.0% vs 4.4%; p = 0.483), first decompensation (3.5% vs 3.2%; p = 0.584), and MACE (13.0% vs 15.4%; RR 0.84, 0.68–1.03; p = 0.105) did not differ. At 3 years, MALO (8.0% vs 8.0%; p = 0.995), first decompensation (5.9% vs 6.1%; p = 0.988), mortality (1.5% vs 2.5%; p = 0.109), ascites (3.9% vs 4.5%; p = 0.566), and MACE (15.2% vs 17.8%; RR 0.85, 0.71–1.03; p = 0.112) were similar. **Conclusion:** Tirzepatide and semaglutide showed similar hepatic, hospitalization, mortality, and cirrhosis/decompensation-related outcomes through 3 years across noncirrhotic MASLD/MASH and compensated cirrhosis. Tirzepatide was associated with lower MACE in noncirrhotic MASLD/MASH, with a nonsignificant directional reduction in compensated cirrhosis. Prospective head-to-head studies are warranted.

3501 | CHARACTERIZATION AND THERAPEUTIC RESPONSE OF PATIENTS WITH METABOLIC-DYSFUNCTION ASSOCIATED STEATOHEPATITIS (MASH) AFTER 12 MONTHS OF TREATMENT WITH RESMETIROM

Larissa Lushniak[1] Chukwuemeka Oko[2] Alice Parish[3] Donna Niedzwiecki[3] Amreen Dinani[1], [1]Duke University School of Medicine, [2]Duke University Hospital, [3]Duke University

Background: Resmetirom has been conditionally approved to treat individuals with metabolic dysfunction-associated steatohepatitis (MASH) and significant fibrosis (≥ F2 fibrosis) since March 2024. The ongoing phase 3 trial relied on biopsy-proven data, yet treatment response in practice based on non-invasive liver disease assessments (NILDAs) remains unknown. This study aims to describe the characteristics of individuals who are prescribed resmetirom, assess 12-month response, and characterize the efficacy and tolerability at a single tertiary care center. **Methods:** This is a retrospective cohort study of adults with MASH and ≥ F2 fibrosis who were prescribed resmetirom from 3/15/2024 to 5/1/2025 at Duke University Healthcare System. Baseline characteristics were described for all prescribed resmetirom. For those who started resmetirom, outcomes are summarized at baseline and after 12 months of treatment. The primary endpoint is change in liver stiffness measurement (LSM) via transient elastography (TE) from baseline to 12 months. The secondary endpoints include change in ALT, hemoglobin A1c, lipid profiles, and body-mass index (BMI), as well as additional NILDAs such as enhanced liver fibrosis score (ELF), MR elastography (MRE), calculated FAST score, and controlled attenuation parameter (CAP) via TE. Changes were assessed using paired tests. **Results:** Of the 91 prescribed resmetirom, 70 (77%) started treatment. Among those who started, 44% were female, 84% were White, 56% had private insurance, with a mean (SD) age of 57 years (13.7) and BMI of 33.6kg/m^2 (6.4). Statins were the most common concurrent medication (64%), followed by GLP-1 receptor agonists (39%). Most (89%) had TE performed at baseline, while 26% had MRE. By 12 months, 50/70 were still on resmetirom. The primary reason for discontinuation was gastrointestinal side effects, usually within 6 months. Unadjusted analyses of primary and secondary outcomes are shown in Table 1. After 12 months of treatment, patients had a significant decrease in LSM ($p = 0.02$) and ALT ($p < 0.01$) as well as CAP, FAST score, triglycerides, LDL, and BMI. **Conclusion:** In this real-world cohort of patients with fibrotic MASH with comprehensive NILDA assessment, resmetirom was prescribed predominantly to middle-aged adults with a high burden of metabolic comorbidities. It demonstrated good tolerability with strong treatment retention. At 12 months, treatment was associated with early improvements in noninvasive markers of liver disease severity and metabolic health. This is consistent with the results of the published phase 3 trial. Planned multivariable analyses adjusting for age, sex, GLP-1 receptor agonist use, diabetes status, and baseline fibrosis stage will further clarify predictors and the magnitude of treatment response.

Table 1: Treatment response outcomes

Median (Q1, Q3)	T1: Baseline (N=70)	T2: 12 months (N=50)	Diff (Δ)	p-value

3502 | BASELINE DEMOGRAPHIC AND CLINICAL CHARACTERISTICS OF PATIENTS RECEIVING RESMETIROM, GLP-1 AGONIST, AND COMBINATION THERAPY FOR MASH: A REAL-WORLD U.S. CLAIMS ANALYSIS

Anthony Yu[1] Zulkarnain Pulungan[1] Gabrielle Miller[1], [1]Inovalon

Background: Following approval of resmetirom (Rezdiffra), limited evidence exists describing real-world utilization patterns among patients with metabolic dysfunction-associated steatohepatitis (MASH). This study evaluated demographic and clinical characteristics of patients initiating Rezdiffra, glucagon-like peptide-1 receptor agonists (GLP-1 RAs), including semaglutide (Wegovy), and combination therapy in a large U.S. claims database. **Methods:** This retrospective study utilized de-identified claims data from the Inovalon MORE² Registry from March 1, 2023 to March 31, 2026. Patients with a MASH diagnosis code receiving Rezdiffra and/or GLP-1 therapy and ≥12 months continuous enrollment prior to first treatment claim were included. Patients were grouped into three mutually exclusive cohorts: Rezdiffra monotherapy, Rezdiffra with concomitant GLP-1 therapy, and GLP-1 monotherapy. Wegovy users were evaluated as subgroups within GLP-1-containing cohorts. Baseline demographics, comorbidities, and liver-specific diagnostic procedures were assessed descriptively. **Results:** Among 6,504 eligible Rezdiffra-treated patients, 3,541 (54.4%) received Rezdiffra monotherapy and 2,963 (45.6%) received concomitant GLP-1 therapy. Of all Rezdiffra-treated patients, 364 (5.6%) received concomitant Wegovy. Among 260,943 eligible GLP-1 monotherapy users, 37,643 (14.4%) received Wegovy.Rezdiffra monotherapy patients were older than GLP-1 monotherapy patients (mean age: 53.6 vs 51.4 years). Females predominated across cohorts, highest among dual-therapy users (69.0%). Dual-therapy patients demonstrated higher comorbidity burden than monotherapy cohorts. Obesity prevalence was 77% in the dual-therapy cohort versus 60% in the Rezdiffra monotherapy cohort and 71% in the GLP-1 monotherapy cohort. T2DM prevalence was 82%, 35%, and 75%, respectively.Baseline liver disease assessment was substantially more common in Rezdiffra-containing cohorts than GLP-1 monotherapy cohorts. Liver elastography was performed in 69.0% of Rezdiffra monotherapy patients and 69.7% of dual-therapy patients versus 7.2% of GLP-1 monotherapy patients. Liver biopsy was observed in 11.4%, 10.5%, and 0.8% of patients, respectively. ELF testing and magnetic resonance elastography followed similar patterns. **Conclusion:** Adoption of FDA-approved combination therapy with Rezdiffra and Wegovy remains limited, with only 5.6% of Rezdiffra-treated patients receiving concomitant Wegovy. Combination therapy use appears concentrated among patients with substantial cardiometabolic comorbidity burden. Rezdiffra-treated patients demonstrated substantially greater utilization of liver-specific diagnostic procedures than GLP-1-treated patients, highlighting potential differences in care pathways and the need for broader implementation of non-invasive liver disease assessment strategies in routine clinical practice.

Disclosures: Anthony Yu:Nothing to Disclose, Zulkarnain Pulungan:Nothing to Disclose, Gabrielle Miller: Nothing to Disclose.

3503 | GLP-1 RECEPTOR AGONIST USE AND HISTOLOGIC MASH SEVERITY DISCORDANT FROM NON-INVASIVE TESTING: A SINGLE-CENTER OBSERVATIONAL COHORT

Joseph Scaravalle[1] Nicholas Kruzdlo[2] Elisabeth Verwest[2] Stephanie Oliveros Diaz[2] Lily Lu[2] Kirsten Hobson[2] Cameron Rolph[2] Isabelle Crotsley[2] Yovanni Rosario[2] Raymond Bell[2] Guy Neff[2], [1]Covenant Metabolic Specialists LLC, [2]Covenant Metabolic Specialists, LLC

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have demonstrated therapeutic potential in metabolic dysfunction-associated steatohepatitis (MASH), though real-world histologic data remains limited when controlling for noninvasive testing. We evaluated whether GLP-1 RA use was independently associated with lower odds of biopsy-confirmed MASH with significant fibrosis after adjustment for FibroScan, demographic, and metabolic covariates. **Methods:** We retrospectively analyzed patients screened for a MASH clinical trial who completed FibroScan and liver biopsy within 90 days. Study eligibility was defined as biopsy-confirmed MASH with a NAFLD Activity Score (NAS) ≥4 and fibrosis stage F2–F3. Patients with cirrhosis (F4 fibrosis) were excluded. Covariates included age, sex, body mass index (BMI), FibroScan controlled attenuation parameter (CAP), liver stiffness measurement (LSM), and type 2 diabetes mellitus (T2D). GLP-1 RA exposure was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

defined as continuous use for at least 6 months prior to the index visit with ongoing therapy at biopsy. The outcome of interest was biopsy-confirmed MASH meeting trial criteria (NAS $\geq$4, F2-3). **Results:** After excluding 18 patients with F4 fibrosis, 83 patients met inclusion criteria, including 11 receiving GLP-1 RA therapy. Baseline FibroScan parameters were comparable between groups (avg CAP 322.1 vs 329.6, p = 0.54; avg LSM 12.2 vs 12.3 kPa, p = 0.95), as were age and BMI; T2D prevalence differed significantly (100% vs 51%, p < 0.001). After adjustment for CAP, LSM, BMI, T2D, age, and sex, GLP-1 RA use was independently associated with lower odds of meeting biopsy criteria (OR 0.07, 95% CI 0.007–0.67, p = 0.021). Male sex was also associated with lower odds (OR 0.36, 95% CI 0.13–0.95, p = 0.040). Age, T2D status, CAP, LSM, and BMI were not significantly associated with the outcome. **Conclusion:** In this single-center retrospective cohort, GLP-1 RA use was associated with lower odds of biopsy-confirmed MASH with significant fibrosis, even among patients with comparable FibroScan CAP and LSM (OR 0.07, 95% CI 0.007–0.67). Given the small exposure group (n = 11) and unmeasured confounders including A1c and weight-loss trajectory, these findings are hypothesis-generating. If confirmed, they suggest non-invasive parameters may underestimate histologic response to GLP-1 therapy and support prospective investigation.

3504 | PUTTING MASH ON PRIMARY CARE'S RADAR: FINDINGS FROM AN EDUCATIONAL ACTIVITY ON SCREENING AND MANAGEMENT

Jaime Symowicz[1] Amy Corum[1] Jay Shubrook[2] Naim Alkhouri[3], [1]Med-IQ, [2]Touro University California College of Osteopathic Medicine, [3]Clinical Research Institute of Ohio

Background: More than 95% of patients with or at high risk of developing metabolic dysfunction–associated steatohepatitis (MASH) are seen in primary care settings. Although many primary care professionals (PCPs) recognize that MASH incidence is increasing, they do not have a clear understanding of their role. To address these gaps, we designed an online educational activity that allowed clinicians to work through recommended risk stratification pathways for screening and management. **Methods:** This educational activity comprised 2 modules; the first focused on applying screening pathways for primary and secondary fibrosis risk stratification in patients with MASH risk factors, and the second addressed selecting MASH management strategies based on patients' fibrosis risk stratification and comorbidities. Rich media assets were integrated to improve the learner experience and were combined with data tracking to reveal insights about knowledge gaps and practice behaviors. Faculty experts then presented guidance and supporting evidence. **Results:** To date, 1,050 learners participated in the activity, with 602 claiming CE credit. Learners more frequently recognized patients who were candidates for MASH screening (87%; n = 1,015) than those who were not (51%; n = 1,174). They also spent less time in the case scenario for a patient who was a candidate for MASH screening (31 vs 50 seconds). During the education, 40% and 27% of learners correctly identified an ELF blood test and VCTE, respectively, as appropriate follow-up testing for a patient with a high-risk FIB-4 (n = 958 nonunique responses). Notably, 86% of learners correctly identified a high-risk patient as needing referral to gastroenterology/hepatology (n = 964). When asked about their practice settings, only 28% had access to an EHR system that prompted them to calculate FIB-4 scores and order additional testing for secondary risk stratification; only 30% had access to transient elastography (n = 599). Learners took ~56 seconds to select a care plan for a patient with stage F3 fibrosis, hypertension, obesity, and dyslipidemia. They recommended pioglitazone, resmetirom, and semaglutide at similar frequency prior to the FDA approval of semaglutide for MASH. Following the FDA approval, they recommended resmetirom and semaglutide at greater frequency than pioglitazone. Postactivity competence gains were observed in recognizing

appropriate initial fibrosis risk stratification, follow-up testing, and management strategies. Lastly, 29% of learners (n = 609) planned to make changes; the top 3 were increasing screening, increasing use of FIB-4 tool, and starting treatment. **Conclusion:** This educational activity used an engaging format to increase PCPs' knowledge and competence related to risk stratification pathways for screening and managing MASH, while also uncovering additional educational needs and practice barriers.

3505 | HEPATIC STEATOSIS REDUCTION WITH GLP-1 AND LIFESTYLE-MEDIATED WEIGHT LOSS IN MASLD/MASH: A RETROSPECTIVE CONTROLLED ATTENUATION PARAMETER (CAP) SCORE ANALYSIS

Nicholas Kruzdlo[1] Joseph Scaravalle[1] Stephanie Oliveros-Diaz[1] Elisabeth Verwest[1] Kirsten Hobson[1] Isabelle Crotsley[1] Lily Lu[1] Raymond Bell[1] Cameron Rolph[1] Yovanni Rosario[1] Guy Neff[1], [1]Covenant Metabolic Specialists

Background: Weight loss is a fundamental intervention for the management of Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD) and Metabolic Dysfunction Associated Steatohepatitis (MASH). GLP-1 receptor agonists offer an effective pharmacologic pathway to weight loss alongside traditional lifestyle modifications. Prior studies have demonstrated hepatic fat reduction with GLP-1 use, but none have directly compared equivalent weight loss achieved pharmacologically versus through lifestyle modification alone. The independent contribution of the GLP-1 mechanism to hepatic steatosis reduction remains unclear. The minimum % body weight loss threshold required for statistically significant hepatic steatosis reduction in a real-word MASLD/MASH population also remains undefined. We sought to identify this threshold and determine if steatosis outcomes differ between GLP-1 and lifestyle mediated weight loss using CAP score. **Methods:** A retrospective cohort of 200 patients with baseline and follow-up FibroScan, body weight, demographic, and medication data collected 11–36 months apart (mean 19.6 months, comparable across cohorts) was identified, excluding patients who underwent bariatric surgery, or received investigational MASH therapies. 70 additional patients were then excluded due to weight gain, resulting in a final analytic cohort of 130 patients with 0–24.2% body weight loss. Patients were stratified into five weight loss strata: 0–2.49% (reference), 2.5–4.99%, 5–8.99%, 9–12.49%, and ≥12.5%. GLP-1 use was defined as documented use for ≥ 3 months. Multivariable linear regression modeled CAP changes against weight loss category, GLP-1 use, age, sex, baseline CAP, and follow-up duration. Interaction terms were included to evaluate modality effects on CAP reduction. **Results:** Significant CAP reductions occurred at 9–12.49% and ≥12.5% weight loss versus the reference group. Weight loss below 9% did not produce significant CAP reduction. Baseline CAP independently predicted degree of change. Both GLP-1-treated (n = 55) and lifestyle-only (n = 75) subgroups demonstrated significant reductions at ≥9% weight loss. GLP-1 interaction terms were non-significant across all strata (all $p > 0.05$), indicating no significant difference in CAP reduction between modalities. **Conclusion:** Weight loss exceeding 9% was associated with a significant predicted CAP reduction of ~60 dB/m, consistent with a clinically meaningful one-grade histologic steatosis improvement based on biopsy-validated CAP thresholds. Hepatic steatosis reduction appeared comparable between modalities, suggesting weight loss magnitude, rather than modality, may be the primary determinant of hepatic steatosis improvement. These findings support targeting ≥9% body weight loss in MASLD/MASH patients, with similar steatosis benefits anticipated whether achieved pharmacologically or through lifestyle intervention alone.

Table 1. Multivariable Linear Regression — Predictors of Change in CAP Score (dB/m)

Negative coefficients indicate reduction in hepatic steatosis (improvement). N = 130.

Weight Loss Cohort (reference: 0 – 2.49% body weight loss)

Variable	Cohort (n)	Coefficient	95% CI	p-value
0 – 2.49% Weight Loss (reference group)	47	—	—	—
2.50 – 4.99% Weight Loss	21	+2.51	−23.2, 28.3	0.847
5.00 – 8.99% Weight Loss	22	−10.57	−40.0, 12.9	0.373
9.00 – 12.50% Weight Loss	17	**−77.24**	−110.6, −43.9	**< 0.001**
> 12.51% Weight Loss	23	**−58.17**	−88.6, −27.5	**< 0.001**
Significant Covariate				
Baseline CAP score	130	**−0.45**	−0.63, −0.28	**< 0.001**

1.) Reference group: patients with 0 – 2.49% body weight loss were the omitted comparator category.

2.) Model adjusted for: baseline CAP, age, sex, months between initial visit and follow up, and GLP-1 agonist use (yes/no).

3.) Interaction terms (WL category × GLP-1 use) were tested for all four WL cohorts and were non-significant across all groups (all p > 0.05).

4.) CAP = controlled attenuation parameter. A negative coefficient indicates reduction in hepatic steatosis.

Table 2. Cohort Breakdown by GLP-1 Agonist Use and Lifestyle Intervention

Cohort	Total Population (n)	GLP-1 Use (n)	Lifestyle (n)
0 – 2.49% Weight Loss (reference group)	47	11	36
2.50 – 4.99% Weight Loss	21	10	11
5.00 – 8.99% Weight Loss	22	8	14
9.00 – 12.50% Weight Loss	17	11	6
> 12.51% Weight Loss	23	15	8
Total	130	55	75

GLP-1 = glucagon-like peptide-1 agonist. Lifestyle mediated population reflects patients who achieved weight loss through diet and lifestyle modification without GLP-1 pharmacotherapy.

3506 | METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS SYSTEMATIC REVIEW: FROM DIAGNOSIS TO NEWEST AVAILABLE MEDICATIONS AND OUTCOMES, TWO AGENTS ARE BETTER THAN ONE

Marie Balfour[1] Wesley Robertson[1] Yao (Michelle) Lan[2] Michelle Nguyen[1] Yuri Kwon[1] Daniel Mai[3] Kirellos Mikhail[4] Matthew Ghebrial[1] Moura Girgis[5] Beshoy Yanny[1], [1]University of California, Irvine, [2]UCI Health, [3]University of California, Irvine Medical Center, [4]UCLA, [5]Cal State Long Beach

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is a growing public health and economic challenge. A subset of patients can progress to metabolic dysfunction–associated steatohepatitis (MASH), a more advanced inflammatory phenotype associated with progressive fibrosis and hepatocellular injury. In this study, we aim to evaluate the efficacy of Resmetirom and glucagon-like peptide-1 (GLP-1) medications in the treatment of MASH. **Methods:** A literature review was conducted across PubMed and ClinicalTrials.gov through April 2026. Randomized controlled trials in phase 3 or higher, case reports, and retrospective studies were included. The primary outcomes investigated were improvement of transaminase levels, improvement in lipid levels, weight loss, side effects, improvement in fibrosis achieved by kilopascal (Kpa), and improvement in steatosis based on Controlled Attenuation Parameter (CAP) score. **Results:** Seven studies with 1766 total patients [GU1] were included. The percentage change in median for aminotransferase levels ranged from –23.07% to –58.5% in treatment groups and –9% to –16.51% in control groups. The percentage change in median for low density lipoprotein ranged from –3.41% to –33.7% in treatment groups and –13% to –16.47% in control groups. The percentage change in median for triglycerides ranged from –13% to –21.83% in treatment groups and –9% to –14.17% in control groups. The treatment groups showed significant improvements in weight loss ($p = 0.0005$). Treatment groups showed statistically significant increased rates of nausea and vomiting ($p < 0.05$). [GU2] The percentage change in median Kpa ranged from –9.86% to –22.64% in treatment groups and –7.86% to –22.4% in control groups. The percentage change in median CAP score ranged from –6% to –17.75% in treatment groups and –10.85% in a control group. **Conclusion:** Dual therapy with Resmetirom and GLP-1 agonist showed better improvement in metabolic risk factors, including improvement in cholesterol level, triglyceride level, and weight loss, which were statistically significant when compared to single agent.

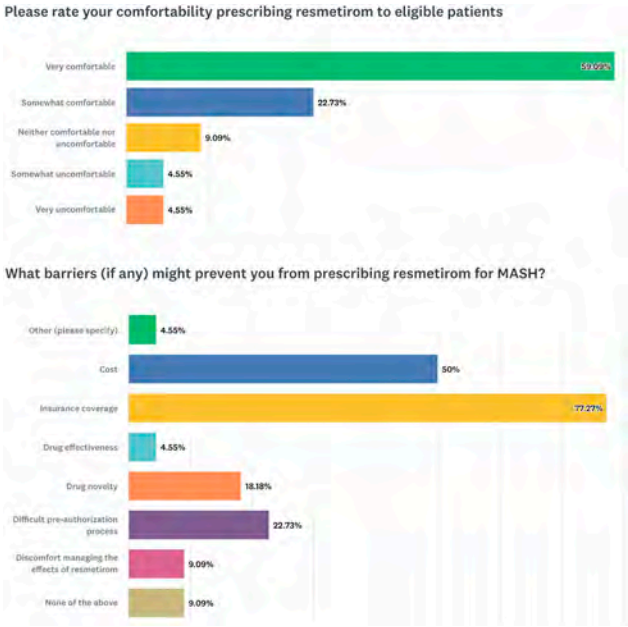
3507 | REAL WORLD PRACTICE AND ATTITUDES TOWARDS TREATING ELIGIBLE AT-RISK MASH PATIENTS WITH RESMETIROM IN AN URBAN SETTING



Aanya Sachdeva[1] Eesha Sachdeva[2] Brandy Mozingo-Thompson[3] Jahnavi Hansaria[3] Mitchell Mah'moud[2], [1]George Washington University School of Medicine and Health Sciences, [2]Duke University School of Medicine, [3]Raleigh Medical Group Gastroenterology

Background: Metabolic dysfunction associated steatohepatitis (MASH) is a growing public health concern. Curbing its impact requires early identification, risk stratification, and prompt treatment. In 2024, the FDA approved resmetirom for treatment of at-risk MASH patients identified through non-invasive testing (NIT). In this study, we examined the practice and attitudes towards resmetirom prescription for at-risk patients identified through ultrasound elastography in an urban U.S. city. **Methods:** Patient data, including NIT, was collected across community-based centers in North Carolina's Research Triangle Area between March 2025 and March 2026. Ultrasound elastography was used to identify at-risk patients who were eligible for resmetirom. Electronic health records were cross-referenced to determine whether at-risk patients were prescribed resmetirom.To understand physician attitudes towards resmetirom prescription, an eight-question survey was designed and distributed. Responses were received from twenty-three practicing physicians across the community-based centers. The survey asked how physicians treat MASH patients, their comfortability prescribing resmetirom, and their likelihood of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

prescribing resmetirom in the future. **Results:** A total of 489 ultrasound elastography exams were conducted over the 12 months described above. Of those scans, 145 patients were found to have a fibrosis stage of F2 or F3. Of those eligible MASH patients, 38 (26%) were prescribed resmetirom.Seven in ten (70%) physicians report prescribing resmetirom for MASH patients in the past year, and half of those somewhat or strongly agree that the quality of life of those patients has improved. The most frequently cited attractive attributes of resmetirom as a prescribing physician were the lack of side effects and tolerability of the treatment (35%), its ability to reverse fibrosis (30%), and its ease of use as a once-daily pill (26%).The majority (59%) of responding physicians report being very comfortable prescribing resmetirom to eligible patients. The most commonly cited barriers to resmetirom prescription were insurance coverage (77%), cost (50%), the difficult preauthorization process (23%), and drug novelty (18%). Four in five (77%) physicians reported being very likely to prescribe resmetirom for MASH over the next year. **Conclusion:** Roughly three-quarters (74%) of eligible patients were not prescribed resmetirom. Despite physician comfort and reported likelihood of prescribing resmetirom, various administrative and structural factors, including insurance coverage, cost, and the required preauthorization process, may serve as barriers to the medication's prescription.Increased prescriber education and improved authorization services are essential to ensure that all eligible patients receive treatment.Future studies should examine the effectiveness of interventions on resmetirom prescription patterns.

3508 | REAL-WORLD CHARACTERISTICS, TREATMENT PATTERNS, AND CLINICAL OUTCOMES AMONG PATIENTS WITH MASH INITIATING RESMETIROM

Isobel McEwen[1] Meena Bansal[2] Christina Parrinello[3] Francis Lobo[3] Douglas Welch[3] Lindsey Sheehan[4] Parvez Mantry[5] Nezam Afdhal[6], [1]Trio Health, [2]Icahn School of Medicine at Mount Sinai (ISMMS), [3]Madrigal Pharmaceuticals, [4]UK HealthCare, [5]Methodist Dallas Medical Center, [6]Liver Institute for Education & Research

Background: Resmetirom is the first FDA-approved therapy for adults with noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH) and moderate-to-advanced fibrosis. Although MAESTRO-NASH demonstrated histologic benefit, real-world data remain limited. This study characterized patients initiating resmetirom in US clinical practice and evaluated 6- and 12-month changes in biochemical and noninvasive liver measures. **Methods:** This retrospective cohort study used deidentified Trio Health EMR data covering over 75 million lives across the United States, 2 out of 3 data sources are represented here. Adults with at least one resmetirom prescription from March 14, 2024 to January 21, 2026 were included; the first prescription served as the index date. Continuous healthcare engagement during the 12-month baseline period was required, defined as at least one encounter, observation, or medication request in each 6-month interval. Patients with advanced liver disease or other causes of chronic liver disease during baseline were excluded. Effectiveness outcomes included changes in structured biomarkers and noninvasive liver measures; VCTE-derived measures were extracted from progress notes using natural language processing. Paired changes from baseline to 6 and 12 months (+/- 90 days) were assessed using Wilcoxon signed-rank tests, with $p < 0.05$ considered statistically significant. **Results:** Overall, 4,886 patients met study criteria (mean age 59.1 years; 60.3% female; 67.6% White). Common baseline comorbidities included type 2 diabetes (45%), obesity (53.9%), dyslipidemia (61.5%), and hypertension (61.8%). GLP-1 receptor agonist use was observed in 28.4% of patients at baseline and 27.4% during follow-up. Among patients with available paired data, resmetirom initiation was associated with clinically meaningful improvements in liver enzymes, lipids, and noninvasive fibrosis/steatosis measures (Table). At 6 and 12-months, respectively, 40.6% and 45.8%

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

achieved at least a 20% ALT decrease. FAST decreased by at least 0.22 units in 36.2% and 43.6% of patients, and CAP decreased by at least 40 dB/m in 43.4% and 54%. LSM decreased by at least 25% in 36.5% and 45.5% of patients and by at least 30% in 29.8% and 38.6%. Among patients with F-scores recorded at baseline and 12 months after resmetirom initiation (n = 128 for F-score), at least 1-stage improvement was observed in 36.7%, and at least 2-stage improvement was observed in 23.4%. **Conclusion:** In this large US real-world cohort, resmetirom-treated patients demonstrated early 6- and 12-month improvements in biomarkers and noninvasive measures of fibrosis and steatosis. These findings support the emerging real-world effectiveness of resmetirom, although longer follow-up and analyses accounting for missing paired assessments are needed to confirm durability and clinical impact.

Measurement	Timepoint	N	Baseline Median (IQR)	Median at Timepoint (IQR)	Median Change (IQR)	Median % Change (IQR)

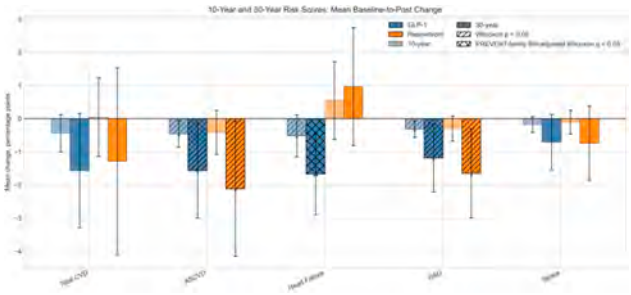
3509 | THE IMPACT OF MASLD PHARMACOTHERAPY ON ESTIMATED CARDIOVASCULAR RISK: A PREVENT SCORE ANALYSIS OF RESMETIROM AND GLP-1–BASED THERAPY



Sandra Elmasry[1] Fares Jamal[2] Alejandro Gonzalez[3] Taylor Viggiano[3] Geoff Thomas[3] Blanca Lizaola-Mayo[1] David Chascsa[1], [1]Mayo Clinic Arizona, [2]Department of Internal Medicine, Mayo Clinic, Phoenix, AZ, U, [3]Mayo Clinic

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is associated with a 1.5-fold increased cardiovascular disease risk. Resmetirom and semaglutide are approved for F2-F3 MASH. These therapies have been evaluated using selected cardiometabolic risk factors, but impact on integrated estimated cardiovascular risk has not been standardized. We applied the 2023 AHA PREVENT equations, recently developed race-free tools estimating 10- and 30-year overall cardiovascular, ASCVD, and heart failure risk, to evaluate risk changes among patients with MASLD treated with resmetirom or GLP-1 therapy. **Methods:** We conducted a retrospective multicenter cohort study of patients with MASLD treated with approved therapy. Patients were included if they received resmetirom for $\geq$12 months or semaglutide 2.4 mg weekly for $\geq$3 months. Liver, cardiometabolic, and PREVENT risk data were collected at baseline and post-therapy follow-up. Paired changes were assessed using Wilcoxon signed-rank and paired t-tests; between-group differences used Mann-Whitney and Welch t-tests. Benjamini-Hochberg correction was applied, with a heart-failure-specific sensitivity correction. **Results:** We identified 25 resmetirom-treated and 73 GLP-1–treated patients. Paired PREVENT data were available for 16 and 38 patients, respectively, with median post-therapy follow-up of 409 and 106 days. As shown in Figure 1, GLP-1 therapy was associated with reductions across multiple PREVENT estimates, with the strongest signal for 30-year heart failure risk, which remained significant after correction. Resmetirom was associated with unadjusted reductions in long-term ASCVD and CAD risk and significant lipid reductions. Direct comparisons showed no significant differences in total CVD, ASCVD, CAD, or stroke risk change. GLP-1 therapy showed greater improvement in estimated heart failure risk than resmetirom in unadjusted analyses, persisting after sensitivity correction. Results are summarized in Figure 1 **Conclusion:** Using AHA PREVENT as a standardized cardiovascular risk framework, GLP-1–based therapy demonstrated the strongest improvement in estimated heart failure risk, while resmetirom showed greater reductions in estimated ASCVD and CAD risk. These

findings suggest comorbidity profiles may help guide MASLD pharmacotherapy selection, including adjunctive or combination approaches when cardiovascular risk modification is a priority. Larger cohort studies are needed to confirm these preliminary findings.

3510 | HUMANIZING DYSLIPIDEMIA IN MASH: A PCSK9-DRIVEN DYSLIPIDEMIA GAN DIO MASH MODEL

Jacob Nøhr-Meldgaard[1] Susanne Pors[2] Denise Oró Bozzini[2] Louise Humle Kruse[2] Henrik Hansen[2] Monika Lewinska[2] Kristoffer Voldum-Clausen[2], [1]Gubra A/S, [2]Gubra

Background: Dyslipidemia, characterized by hypercholesterolemia and hypertriglyceridemia, is a central component of metabolic dysfunction-associated steatohepatitis (MASH) pathogenesis. While being highly instrumental in drug development, preclinical models of MASH often fail to recapitulate a human-like lipoprotein profile. To enhance translational relevance, the present study aimed to establish a humanized dyslipidemia profile in the GAN diet-induced obese (DIO) mouse model of MASH through AAV-mediated PCSK9 overexpression. **Methods:** Male C57BL/6 mice were fed the GAN diet (high fat, fructose, and cholesterol) for 39 weeks prior to study start. Only mice with biopsy-confirmed MASH (NAFLD Activity Score (NAS) ≥ 5) and fibrosis (stage F2-F3) were included and stratified into treatment groups (n = 18 pr. group). One week after single AAV-PCSK9 injection, GAN DIO-MASH mice were administered (SC) vehicle, semaglutide (GLP-1 receptor agonist, 30 nmol/kg, once daily), efruxifermin (FGF21 analogue. (EFX, 1 mg/kg, biweekly), or alirocumab (PCSK9 inhibitor, 10mg/kg) for 8 weeks. Endpoints included plasma lipid biochemistry. **Results:** AAV-PCSK9 GAN DIO-MASH mice exhibited markedly elevated circulating levels of LDL-cholesterol, total cholesterol, and triglycerides compared with chow-fed mice and AAV-CAG GAN DIO-MASH controls. MASH severity remained stable throughout the study period in AAV-PCSK9 GAN DIO-MASH mice. Semaglutide, EFX, and alirocumab all significantly improved LDL hypercholesterolemia and hypertriglyceridemia. Semaglutide and EFX additionally reduced HDL-cholesterol levels, whereas alirocumab increased HDL-cholesterol levels. **Conclusion:** AAV-mediated PCSK9 overexpression in the GAN DIO-MASH mouse model induces a robust, human-relevant dyslipidemic phenotype characterized by LDL hypercholesterolemia and hypertriglyceridemia. Pharmacological intervention with semaglutide, EFX, and alirocumab differentially improved the dyslipidemic profile. These findings highlight the utility of the AAV-PCSK9 GAN DIO-MASH mouse model for evaluating lipid-modulating therapies in MASH and support its translational relevance for therapeutic development.

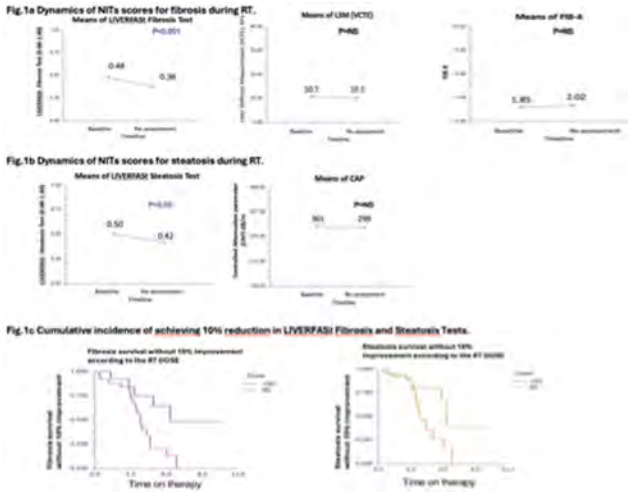
3511 | A MULTIMODAL NONINVASIVE APPROACH TO INITIATION AND MONITORING OF RESMETIROM THERAPY IN MASH - UPDATE



Mona Munteanu[1] Jeevin Sandhu[2] Shaheen Mehrara[3] Akash Pagadala[4] Ashwini Mehta[5] John Lee[6] Obinna Okolo[3] Parker Woods[3] Parvez Mantry[3], [1]Fibronostics US Inc., [2]Methodist Dallas Medical Center, [3]Methodist Dallas Medical Center, Liver Institute, Dallas, US, [4]University of Southern California, Los Angeles, US;, [5]Methodist Dallas Medical Center, Division of Hepatology, Dallas, Texas, US, [6]Fibronostics U.S., Inc, New Orleans, US

Background: LIVERFAST (Fibronostics US, Inc.) is a new blood-based NIT that assesses quantitatively fibrosis, activity, and steatosis. Aims: To assess the dynamics of LIVERFAST, FIB-4 and VCTE and CAP in monitoring patients on Resmetirom therapy (on-RT) [fibrosis/steatosis $\geq$ 10% regression rate (10%RR) from baseline to repeated NIT]. **Methods:** On-RT patients with baseline (t0) and repeated (t1) NITs have been included retrospectively. Statistics included Kaplan Meier non-parametric censored at 10% RR from t0, Tukey-Kramer Multiple-Comparison Test and subgroup analysis for dose/GLP-1 receptor agonists (GLP-1RA)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

analysis. **Results:** N = 147 Eligible patients without RT discontinuation, 62% 80mg-dose, 39%-male, 55%-T2D, 46% GLP-1RA, mean(se) age 62.4(1.3), BMI 33.7(0.7), ALT 44(4), FIB4 1.79(0.14). T0-prevalence of F2F3 were 61%(LFAST) and 44%(VCTE). Median (max) delays(mths) t0-to-t1 were 3.4(LFAST), 7.6 (VCTE) and 6.7(FIB4). 67pts. with t0-FIB4 had no change at t1, (1.85vs2.02), or AST (44vs36), platelets count (230vs224*10^9), all p = ns, and ALT (53vs40, p < 0.05). 30 pts had repeated VCTE (median t0-10.7 vs t1-10.1Kpa) and CAP (t0-301 vs t1-299dB/m), all p = ns regardless the dose or the association with GLP-1RA. 44pts achieved t1-LFAST with median scores (t0vst1): fibrosis (0.48vs0.38,p < 0.001), steatosis (0.50vs0.42, p < 0.05), activity (0.45vs0.42,p = ns), mainly in the 80mg group (n = 27) and in either groups of RT-alone or in combination to GLP-1RA for fibrosis (p < 0.05). LFAST-fibrosis 10%RR from t0 has been achieved more within 80mg-RT group than within 100mg-RT at 3 and 6mths, respectively: 23.8%vs20.7% and 79.2% vs37.5%, overall logrank p < 0.05). LFAST-steatosis 10%RR from t0 has been achieved more within 80mg-RT group (overall logrank p < 0.05). The significant decrease t0-to-t1 in the total cholesterol has neither impacted the ApolipoproteinA1 [131 vs 146mg/dl] or LFAST-fibrosis score. **Conclusion:** RT-Initiation based on NITs is efficient and allows further non-invasive monitoring. LIVERFASt is an efficient monitoring test that reflects histology remodeling and provides earlier insights into disease progression and RT response. A significant improvement (≥ 10%) in LIVERFASt fibrosis and steatosis scores have been observed after the 3rd month of RT mainly in the 80mg group. FIB-4 and VCTE/CAP scores showed limited change at reassessment.

3512 | TRANSLATIONAL EFFICACY VERSUS REAL-WORLD EFFECTIVENESS OF CHIGLITAZAR IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A SYSTEMATIC REVIEW AND NARRATIVE SYNTHESIS

Choudhary Ahmed Maqbool[1] Ubaid Ahmed[2] Rahul Falodia[3], [1]University of Alabama at Birmingham, Heersink School of medi, [2]Dow University of Health Sciences, [3]All India Institute of Medical Sciences Jodhpur

Background: Chiglitazar is a novel pan-peroxisome proliferator-activated receptor (PPAR) agonist that activates PPAR-α, -γ, and -δ to improve metabolic homeostasis and reduce hepatic lipid accumulation. Evaluating how controlled trial efficacy translates into heterogeneous real-world populations is essential to defining its therapeutic utility. **Objective:** To compare the clinical efficacy and real-world effectiveness of chiglitazar for hepatic steatosis and fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** A systematic literature search identified prospective human studies evaluating chiglitazar in MASLD or metabolic dysfunction-associated steatohepatitis (MASH). Owing to heterogeneity in study designs and comparator strategies, findings were synthesised qualitatively using a narrative efficacy-effectiveness framework. **Results:** Two prospective studies met inclusion criteria: a Phase II randomized controlled trial (RCT) and a real-world observational cohort study.In the efficacy setting, 104 patients with MASLD, hypertriglyceridemia, and insulin resistance received chiglitazar 48 mg (n = 42), 64 mg (n = 41), or placebo (n = 21) for 18 weeks. MRI-PDFF showed marked dose-dependent reductions in liver fat content of -28.1% and -39.5% versus -3.2% with placebo (p < 0.05 and p < 0.001). Alanine aminotransferase decreased by -38.0 U/L and -51.5 U/L compared with -17.2 U/L in placebo-treated patients. Controlled attenuation parameter (CAP) values decreased by -13.7 dB/m and -20.5 dB/m versus +7.7 dB/m with placebo. However, liver stiffness measurements (LSM) did not significantly differ between groups.In the effectiveness setting, 235 patients with type 2 diabetes and MASLD received flexible-dose chiglitazar alongside background antidiabetic therapy. After 1:1 propensity score matching, 31 comparable patient pairs were analysed over 24 weeks. Chiglitazar produced greater

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

CAP reduction than other glucose-lowering therapies (-28.38 vs. -16.74 dB/m; between-group difference -11.64 dB/m; P = 0.038). Benefits remained consistent across age, sex, BMI, and concomitant SGLT-2 inhibitor or GLP-1 receptor agonist use. Similar to the RCT, LSM changes did not significantly differ between treatment groups (P = 0.813). Safety profiles were favourable across both studies. **Conclusion:** Chiglitazar demonstrates a highly successful clinical translation from experimental efficacy to real-world effectiveness, successfully engineering substantial reductions in hepatic steatosis across both rigidly structured clinical trial cohorts and unselected, multi-morbid type 2 diabetes populations. Its therapeutic impact on the non-invasive regression of liver fibrosis is limited in the short term, indicating that longer follow-up windows are methodologically mandatory to confirm its true long-term antifibrotic potential.

3513 | REAL-WORLD EFFECTIVENESS OF 1 YEAR OF RESMETIROM MONOTHERAPY IN AT-RISK METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS PATIENTS IN A COMMUNITY BASED HEPATOLOGY PRACTICE

Rida Nadeem[1] Anita Kohli[1] Richard Manch[1] Justin Reynolds[1] Ann Moore[1] Tessa Janovsky[1] Jessica Omana Castaneda[1] Himanshi Kapoor[1] Abderrahman Benmaghnia[1] Saba Asadipour[1] Cody Chen[1] Noor Virk[1], [1]Arizona Liver Health

Background: Resmetirom, a selective thyroid hormone receptor-β agonist, has demonstrated histologic efficacy in the treatment of metabolic dysfunction–associated steatohepatitis (MASH). However, real-world data evaluating treatment response is limited. We aimed to assess hepatic and metabolic responses to resmetirom in a real-world MASH population treated for a minimum of one year using changes in NITs. **Methods:** We conducted a retrospective real-world study of adults with presumptive F2 or F3 MASH (at-risk MASH) treated with resmetirom in an outpatient hepatology practice. Patients who had completed at least one year of resmetirom therapy were included (n = 361). Patients on GLP-1 or GIP analog therapies were excluded from analysis. Liver disease activity and fibrosis were assessed at baseline and follow-up using NITs including serum aminotransferases, fibrosis scores (e.g., FIB-4, FAST), and vibration-controlled transient elastography (VCTE). Treatment response was defined as improvement in liver enzymes and percent changes in hepatic steatosis and fibrosis NITs. Secondary outcomes included changes in lipid parameters and resmiterom tolerability. **Results:** 361 patients who completed atleast 52 weeks of resmiterom were included (mean age 58 years; 47% male; mean BMI 39.7 kg/m²). 51.5% of patients had T2DM, 36.8% dyslipidemia, and 58.4% hypertension. After 52 weeks of treatment, 57.9% of patients had a one stage or greater reduction in liver fibrosis by VTCE. Mean reduction in VCTE kpa was 37.2%. Mean reduction in hepatic steatosis as measured by VCTE CAP was 29.1%. Decrease in hepatic inflammation at 52 weeks seen with mean reduction of AST and ALT 11.5 IU/L and 25.44 IU/L respectively. Total cholesterol reduced by a mean of 22.16 mg/dL, LDL cholesterol by 27.19 mg/dL, triglycerides by 71.6 mg/dL, and HDL increased by a 6.5 mg/dL after 52 weeks. Approximately 10% of patients discontinued therapy due to adverse events. **Conclusion:** In a real-world clinical setting, 52 weeks of resmetirom treatment was associated with significant improvements in hepatic fibrosis and steatosis, as well as multiple biochemical and cardiometabolic parameters in patients with at-risk MASH. Therapy was safe and well tolerated across a diverse patient population with multiple comorbidities. These findings support the efficacy of resmetirom in a real world patient population where NITs are routinely used to intiate and guide therapy.

3514 | TREATMENT CONTINUITY WITH RESMETIROM: A REAL-WORLD STUDY OF ADHERENCE AND PERSISTENCE IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Francis Lobo[1] Yun Han[2] Nipun Atreja[1] Gene Felber[1], [1]Madrigal Pharmaceuticals, [2]Precision AQ

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: MASH, a serious form of fatty liver disease linked to metabolic health problems (e.g., obesity, diabetes), is a leading cause of liver-related mortality and an increasing burden on healthcare systems globally. The United States (US) Food and Drug Administration (FDA) approved resmetirom (Rezdiffra®) in conjunction with diet/exercise for adults with MASH on 3/14/2024. Meaningful resmetirom clinical benefit is dependent on sustained persistence/adherence for ≥52 weeks. This study quantified the real-world persistence/adherence of resmetirom in a large, geographically representative administrative claims database. **Methods:** A retrospective cohort analysis was conducted using the McKesson Compile™ Multi-Payer Closed Claims ReadyData (captures 80 US payers [commercial, Medicare, Medicaid]). Adults ≥18 years who newly initiated resmetirom between 3/14/24-2/28/25 were identified (first paid prescription with non-zero days supply = index date). New users were required to have continuous enrollment in both the 12-month pre- and post-index periods. Exclusion criteria included ICD-10 codes indicative of liver cirrhosis or alternative causes of liver disease (or related complications/conditions) during the 12-month pre-index period or missing demographic data. Persistence was calculated as time from resmetirom initiation to discontinuation (≥60-day gap following expected end date of last resmetirom prescription fill) or end of the 12-month post-index period (whichever came first). Adherence was measured among persistent patients using proportion of days covered (PDC), with the number of days of resmetirom on hand divided by the number of days the patient was considered persistent (6 or 12 months). Days supplied from overlapping prescription fills were adjusted to avoid overcounting (only one day of drug supply was credited/calendar day). **Results:** Total of 373 patients with ≥2 resmetirom fills over the 12-month post-index period were included. Mean (SD) age was 55.9 (13.4) with the majority in the 45-64 age group (53.9%) (27.1% ≥65, 11.8% 35-44, 7.2% 18-34). Over half of the sample were female (60.3%). For the first 6 months of the 12-month post-index period, 82.3% of patients were considered persistent. Persistent patients exhibited high adherence, with a mean (SD) PDC of .897 (.114). The overwhelming majority (83.7%) of the sample exhibited high adherence (≥80% PDC). Over the 12-month post-index period, 60.9% of the sample were considered persistent, with mean (SD) persistent days of 299.5 (96.6). Mean (SD) PDC was .901 (.075), with 89.4% of the persistent patients being considered as having high adherence. **Conclusion:** High adherence/persistence to resmetirom observed in this real-world cohort underscore its acceptability and tolerability in routine clinical practice, supporting its long-term use for MASH management.

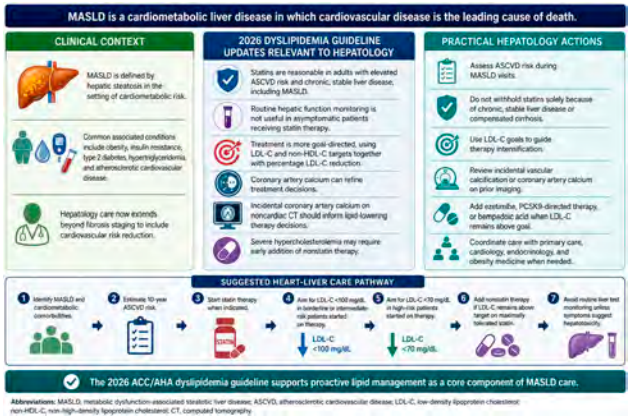
3515 | IMPLICATIONS OF THE 2026 ACC/AHA DYSLIPIDEMIA GUIDELINE FOR PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE



Pranav Ramamurthy[1], [1]University of Massachusetts Chan Medical School

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a multisystem metabolic disorder in which cardiovascular disease remains the leading cause of death. The 2026 ACC/AHA/AACVPR/ABC/ACPM/ADA/AGS/APhA/ASPC/NLA/PCNA Guideline on the Management of Dyslipidemia replaces the 2018 cholesterol guideline and introduces clinically important updates in lipid thresholds, subclinical atherosclerosis imaging, combination therapy and safety monitoring. These changes are highly relevant to hepatologists, who increasingly co-manage metabolic risk in patients with MASLD. **Methods:** We performed a narrative review of the 2026 multisociety dyslipidemia guideline with focused extraction of recommendations applicable to chronic stable liver disease, MASLD, compensated cirrhosis, diabetes and hypertriglyceridemia. Recommendations were contextualized within contemporary MASLD guidance emphasizing multidisciplinary cardiometabolic care. **Results:** The 2026 guideline formally states that in adults at elevated ASCVD risk with stable liver disease, including MASLD, statin therapy is reasonable, directly countering persistent underuse of statins in hepatology practice. The guideline also states that routine hepatic function monitoring is not useful in asymptomatic statin-treated patients. In primary prevention, treatment is now more explicitly goal-directed with stricter targets and recommendations for serial LDL-C monitoring. In severe hypercholesterolemia, maximally tolerated statin therapy with early addition of ezetimibe, PCSK9 inhibitors, bempedoic acid and in selected cases inclisiran, is recommended to achieve target LDL-C thresholds. For hepatologists, one of the most practice-changing updates is the stronger integration of coronary artery calcium (CAC). CAC greater than 0 supports lipid-lowering therapy, and incidental CAC on noncardiac CT

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

should inform statin initiation or intensification. This is particularly relevant because patients with MASLD frequently undergo abdominal and thoracic imaging where subclinical atherosclerosis may be identified. Additional relevant updates include stronger treatment targets in diabetes, incorporation of non-HDL-C and apoB in selected patients with elevated triglycerides, and structured triglyceride management, all of which align with the common dyslipidemic phenotype seen in MASLD. **Conclusion:** The 2026 ACC/AHA dyslipidemia guideline reframes lipid management as a core component of hepatology care. Its explicit endorsement of statin safety in stable liver disease, use of LDL-C goal-based intensification and incorporation of incidental CAC provide a practical framework for hepatologists to reduce cardiovascular mortality in MASLD. These updates support a more proactive heart-liver model of care and should be incorporated into hepatology clinic workflows and multidisciplinary MASLD management pathways.

Disclosures: Pranav Ramamurthy:Nothing to Disclose.

3516 | A 12-MONTH REAL-WORLD ASSESSMENT OF CLINICAL CHARACTERISTICS AND BIOMARKER CHANGES FOLLOWING RESMETIROM INITIATION IN PATIENTS WITH MASH: A DESCRIPTIVE COHORT STUDY USING ELECTRONIC MEDICAL RECORDS IN THE UNITED STATES

Yestle Kim[1] John O'Donnell[1] Romina Fakhraei[2] Christina Parrinello[1] Karissa Johnston[2] Yael Silberberg[3] Andrew Kennedy[2] Emily Mercer[2] Robert Eisdorfer[3] Karin Keren[3] Rajagopal Chadalavada[4] Naim Alkhouri[5] Pradeep Bekal[4], [1]Madrigal Pharmaceuticals, [2]Broadstreet HEOR, [3]Latica, [4]Gastro Health, [5]Summit Clinical Research

Background: Resmetirom (Rezdiffra™), a THR-β agonist, is conditionally FDA-approved for adults with noncirrhotic MASH and moderate-to-advanced fibrosis. We descriptively assessed real-world clinical characteristics and early mean changes in liver and metabolic biomarkers among patients with ≥12 months of follow-up after resmetirom initiation. **Methods:** This descriptive, retrospective cohort study used the Latica real-world repository from the Gastro Health integrated delivery system and included adults with ≥1 resmetirom prescription between April 2024 and April 2025 (index date: first prescription) and ≥12 months of follow-up; those with end-stage liver disease during the 2-year pre-index were excluded. Baseline (12 months pre-index) demographics, comorbidities, concomitant medications, and laboratory measurements (AST, ALT, platelets, lipid markers FibroScan AST [FAST] score, vibration-controlled transient elastography liver stiffness measurement [VCTE LSM]) were captured and, when available, reassessed during follow-up. Responder endpoints were defined as a FAST score reduction of ≥0.22, ALT reduction of ≥17 U/L or 20%, and LSM reductions of ≥25% or ≥30% from baseline. **Results:** Of 2,147 patients who initiated resmetirom, 658 (31%) met inclusion. Mean age was 58.6 years (SD: 12.9). The cohort was predominantly female (56%), White (37%), and commercially insured (71%). At baseline, median BMI was 33.1 kg/m^2 with 68% classified as obese and 25% as overweight. The most common comorbidities were hypertension (76%), dyslipidemia (71%), obesity (70%), and type 2 diabetes (61%); 88% had two or more of these cardiometabolic conditions. At baseline, 128 patients (20%) were using a GLP-1RA, of whom 13 (2% of overall cohort) switched to resmetirom at index. Overall, 235 patients (36%) had concomitant GLP-1RA use during follow-up, including 120 patients (18% of overall cohort) who initiated a GLP-1RA post-index. Among patients with both baseline and follow-up values, statistically significant median reductions were observed in ALT (n = 410; -6.5 U/L), AST (n = 409; -4.0 U/L), BMI (n = 525; -0.6 kg/m²), body weight (n = 526; -1.8 kg), VCTE LSM (n = 112; -2.2 kPa), CAP (n = 112; -30.0 dB/m), and FAST scores (n = 85; -0.1); all p ≤ 0.001. Statistically significant reductions were also observed in total cholesterol (n = 24; -12.1 mg/dL; p = 0.049) and triglycerides (n = 24; -43.2 mg/dL; p = 0.009). Overall, 50% of patients achieved a ≥17 U/L reduction in ALT, 47% a ≥25% LSM response, 38% a ≥30% LSM response, and 35% a ≥0.22 reduction in FAST scores. **Conclusion:** In this real-world cohort, patients initiating resmetirom showed improvements in liver and blood-based biomarkers over the first 12 months, supporting

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

3517 | CASE-BASED ONLINE CME IMPROVES ASSESSMENT AND IDENTIFICATION OF PATIENTS WHO ARE CANDIDATES FOR MASH PHARMACOTHERAPY

Shari Dermer[1] Julie Schrand[1] Aman Rajpal[2] Sonal Kumar[3] Roderick Smith[1], [1]Medscape Education, [2]Alameda Health System, [3]Weill Cornell Medicine

Background: Management of metabolic dysfunction-associated steatohepatitis (MASH) requires assessing patients for liver fibrosis using noninvasive modalities and identifying patients who are candidates for pharmacologic therapy. **Methods:** This study evaluated the effect of online certified continuing healthcare professional education on the assessment and management of MASH, including the identification of patients who are candidates for pharmacologic therapy for MASH. Learners participated in an online educational activity on MASH that featured video with synchronized slides. A repeated pairs pre-/post-assessment study design study including a 4-item, multiple choice competence questionnaire and a confidence assessment question was used and McNemar's test ($P < .05$) assessed educational effect. The activity launched December 5, 2025 and data were collected through May 7, 2026. **Results:** We report on data from gastroenterologists/hepatologists (GI/heps, n = 163) and NP/PAs (n = 333) who participated in the activity. Data are presented as absolute % change pre- to post-education. Overall, competence increased by 31% for GI/heps and by 55% for NP/PAs. after education. **Evidence-based risk stratification** : There was an 8% increase (58% pre/66% post; $P < .01$) for GI/heps and a 13% increase (43% pre/56% post; $P < .001$) in competence related to interpretation of FIB-4 and ELF scores. **Identifying candidates for liver-directed pharmacotherapy:** There was an 11% increase (55% pre/66% post; $P < .01$) for GI/heps and an 18% increase (36% pre/54% post; $P < .001$) for NP/PAs in interpreting results from VCTE to determine if patients meet guideline-based criteria for treatment with pharmacotherapy. **Managing cardiometabolic comorbidities:** GI/heps had a 56% shift and NP/PAs had a 69% shift in confidence in their ability to manage cardiometabolic comorbidities associated with MASH. **Conclusion:** Online case-based certified education improved competence in risk stratification and identification of patients who are candidates for MASH therapy. However, results prior to

★ 3518 | THE EFFECT OF SEMAGLUTIDE ON LIVER HISTOLOGY IN METABOLIC DYSFUNCTION ASSOCIATED STEATOHEPATITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Angelica Mariano[1] Aegan Matthew Amican[1] Godofredo Vistal[1], [1]Manila Doctors Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease, affecting over 30% globally. Defined by hepatic fat accumulation within the context of metabolic syndrome, it poses a major public health challenge and is a leading cause of liver-related illness and death. A significant subset of MASLD progresses to metabolic dysfunction-associated steatohepatitis (MASH) and the worst outcome is Liver Cirrhosis. Histologically, MASH involves hepatocyte injury and lobular inflammation, which primarily drives hepatic fibrogenesis. Liver fibrosis progression is the single most important prognostic factor in MASLD, directly correlating with the risk of cirrhosis, hepatic failure, hepatocellular carcinoma, the need for liver transplantation, and all-cause mortality. **Methods:** The study conducted in accordance with PRISMA guidelines. We performed a systematic search of PubMed/MEDLINE, Embase, Cochrane Central Register of Controlled Trials (CENTRAL), and ClinicalTrials.gov for RCTs published in the last 20 years. Meta-analysis was performed using RevMan 5.4 tool. **Results:** The search identified three large-scale RCTs that met the strict inclusion criteria, enrolling a total of 1,233 patients between the selected studies. The pooled analysis of all three trials found statistical significance in histological improvement in steatohepatitis without worsening fibrosis odds ratio of 3.43 (95% CI 2.59-4.53, $p < 0.001$) and improvement in fibrosis without worsening steatohepatitis odds ratio 1.73 (95% CI 1.29, 2.33, $p < 0.0003$). **Conclusion:** In conclusion, the meta-analysis demonstrates that semaglutide has beneficial histologic effects: both in Steatohepatitis and Fibrosis in patients with MAFLD with F2-F3 Fibrosis, with a well-tolerated safety profile. However, the results are limited by the small number of included studies and clinical heterogeneity, which restricts the generalizability of these findings across the spectrum of MAFLD.

3519 | COMPARISON OF EFFECTIVENESS BETWEEN PHENTERMINE/TOPIRAMATE AND LIRAGLUTIDE IN OBESE PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Young Eun Chon[1] Yeonjung Ha[1] Kwan Sik Lee[1] Sung Jun Park[1], [1]CHa University

Background: Anti-obesity drugs improve hepatic inflammation in patients with metabolic dysfunction–associated steatotic liver disease (MASLD). We aimed to compare the effects of phentermine/topiramate and liraglutide in obese MASLD patients. **Methods:** This retrospective study included 438 obese MASLD patients who received phentermine/topiramate (n = 320) or liraglutide (n = 118) for more than 12 months. Steatosis was assessed using the hepatic steatosis index (HSI) and controlled attenuation parameter (CAP). Fibrosis was assessed using the fibrosis index based on four factors (FIB-4) and liver stiffness (LS). Changes in steatosis and fibrosis were compared at 12 months after treatment. **Results:** After propensity score (PS) matching, 108 patients were equally assigned to the two treatment groups. After 12 months of treatment, HSI (40.584→36.556 in phentermine/topiramate; 40.284→ 39.347 in liraglutide) and CAP (321→299 dB/m in phentermine/topiramate; 306→288 dB/m in liraglutide) decreased significantly in both groups (all $p < 0.05$). However, FIB-4 (0.838→0.717; $p = 0.025$) and LS (6.0→4.9 kPa; $p = 0.011$) decreased significantly only in the liraglutide group. The phentermine/topiramate group showed a significantly greater reduction in steatosis from baseline to 12 months, as assessed by HSI (−9.32% vs. −1.87%; $p < 0.001$) and CAP (−10.15% vs. −5.22%; $p < 0.001$), compared with the liraglutide group. In contrast, the percent changes from baseline to 12 months in FIB-4 (1.58% vs. −3.83%; $p = 0.297$) and LS (−7.37% vs. −12.50%; $p = 0.144$) were not significantly different between the two groups. **Conclusion:** In obese patients with MASLD, phentermine/topiramate resulted in greater improvement in hepatic steatosis; however, fibrosis regression was comparable between the treatment groups.

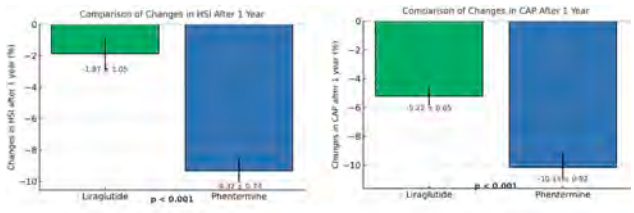

Figure 1. Comparison of steatosis improvement in obese MASLD patients treated with liraglutide and phentermine/topiramate (A) HIS (B) CAP

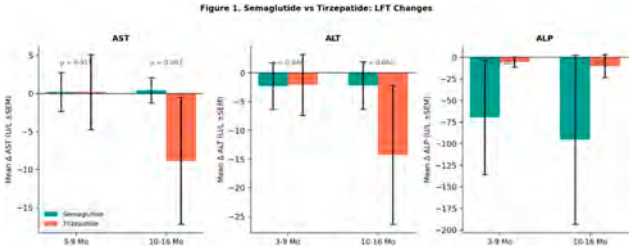
3520 | REAL-WORLD OUTCOMES AMONGST MASLD PATIENTS TREATED WITH RESMETIROM PLUS SEMAGLUTIDE VERSUS TIRZEPATIDE: A SINGLE-CENTER OBSERVATIONAL ANALYSIS



Rukmoni Balasubramanian[1] Anjali Rajagopal[1] Christian Tallo[1] Megan Carugati[1] Parvir Aujla[1] Roopjeet Bath[1], [1]University of Connecticut

Background: Resmetirom, a liver-targeted thyroid hormone receptor-β agonist, is the first FDA-approved pharmacotherapy for metabolic dysfunction-associated steatotic liver disease (MASLD) with moderate-to advanced fibrosis. GLP-1 receptor agonists (GLP-1RAs) are frequently co-prescribed given overlapping cardiometabolic comorbidities. Real-world data on hepatic outcomes by incretin agent is limited. We compare fibrosis regression and hepatic biochemistry between resmetirom plus semaglutide versus tirzepatide in a single-center cohort. **Methods:** We performed a retrospective subgroup analysis of 29 MASLD patients receiving resmetirom (80 or 100 mg daily) with a specified incretin agent: semaglutide (n = 16) versus tirzepatide (n = 13). Liver biochemistry (AST, ALT, and ALP) was asssessed at 3-9 and 10-16 months. Fibrosis response was assessed using serial imaging-based fibrosis stage from fibroscan, ultrasound elastography or MR elastography reports at 3-9 months, 10-16 months, with modalities reported as fibrosis stage. Patients with shorter treatment durations lacked repeat imaging. Baseline variables were compared by t-tests; outcome changes by Mann-Whitney U tests. **Results:** Baseline fibrosis stage was similar between semaglutide and tirzepatide groups (2.73 ± 0.56 vs. 2.77 ± 0.60; p = 0.871). Baseline AST and ALP were not significantly different, while baseline ALT was numerically higher in the tirzepatide group (44.3 ± 21.8 vs. 31.2 ± 12.9 U/L; p = 0.054). No statistically significant between-group differences were observed in AST, ALT, or ALP at either follow-up window (Figure 1). At 10-16 months, AST changed by +0.4 ± 5.3 vs. -8.9 ± 22.1 U/L (p = 0.883), ALT by -2.2 ± 13.0 vs. -14.3 ± 31.9 U/L (p = 0.660), and ALP by -95.5 ± 309.7 vs. -10.0 ± 35.2 U/L (p = 1.000). There was no statistically significant imaging-based fibrosis change by incretin agent. Best available fibrosis stage change was -0.83 ± 0.52 in semaglutide (n = 6) versus -1.08 ± 1.69 in tirzepatide (n = 6; p = 0.935). Descriptively, when both incretin groups were pooled, paired imaging showed significant fibrosis regression from 2.96 ± 0.62 to 2.00 ± 1.11 (mean change -0.96 stages; Wilcoxon p = 0.023). **Conclusion:** No statistically significant differences were detected in AST, ALT, ALP, or fibrosis stage change between resmetirom plus semaglutide versus tirzepatide; these comparisons were

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

underpowered and should be interpreted as hypothesis-generating. Descriptively, when pooled as a resmetirom plus incretin cohort, patients with paired imaging demonstrated significant fibrosis regression, consistent with a potential additive hepatic benefit of combination therapy. Larger prospective studies are needed to confirm these preliminary findings.

3521 | EFFICACY OF SILYBIN PHOSPHOLIPID COMPLEX IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Qianli Zhao[1] Manman Xu[1] Pengfei Yu[1] Junfeng Li[2] Ming Kong[1] Yu Chen[1], [1]Fourth Department of Liver Disease, Beijing You'an Hospital Affiliated to Capital Medical University, [2]The First Hospital of Lanzhou University

Background: Silybin-phospholipid complex is a commonly used hepatoprotective agent. In vitro studies have demonstrated its effects in reducing hepatic steatosis and liver fibrosis. The aim of this study was to evaluate the clinical efficacy of silybin-phospholipid complex in improving liver fat content and fibrosis in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** MASLD patients admitted to Beijing You'an Hospital and the First Hospital of Lanzhou University between January 1, 2020 and December 31, 2025 were retrospectively included. Patients were assigned to a treatment group receiving silybin-phospholipid complex monotherapy or to a control group without treatment. Changes in liver fat content, fibrosis indices, and liver function parameters were analyzed. The primary endpoints were reductions in liver fat content and fibrosis indices, and secondary endpoints were improvements in liver function tests. **Results:** A total of 231 patients were included (177 in the treatment group, 54 in the control group). After 3 and 6 months of continuous therapy, the treatment group showed greater decreases in ALT (Diff 0–3M: −15 vs −5; Diff 0–6M: −16 vs −1) and AST (Diff 0–3M: −8 vs −2.5; Diff 0–6M: −7 vs −0.5) compared with the control group. Controlled attenuation parameter (CAP) values were lower in the treatment group (3M: 258.47 ± 61.78 vs 289.73 ± 61.82; 6M: 272.81 ± 43.16 vs 283.91 ± 47.27), with a significant reduction at 6 months (Diff 0–6M: −13 vs 5, p = 0.024). In a subset of patients with regular follow-up, multivariable GEE analysis confirmed a significant CAP reduction in the treatment group (β = −16.31, p = 0.0138). For liver fibrosis, both groups showed decreased LSM, but the treatment group had a greater reduction (Diff 0–3M: −0.55 vs −0.1; Diff 0–6M: −0.3 vs −0.1). FIB-4 decreased more in the treatment group compared with control at 3 months (0.0 vs 0.0318, p = 0.014) and 6 months (−0.122 vs −0.0219, p = 0.044). Similarly, APRI declined more in the treatment group at 3 months (−0.078 vs −0.0099, p = 0.042) and 6 months (−0.09 vs −0.0282, p = 0.010). **Conclusion:** Silybin-phospholipid complex appears to reduce liver fat content and attenuate fibrosis in patients with MASLD, representing a potential therapeutic option for clinical management of this condition.

3522 | ESTIMATING REAL WORLD CLINICAL AND ECONOMIC IMPLICATIONS OF GLP-1 PERSISTENCE AND DOSING IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Florencio Calderon[1] Lester Lachuk[1] Nipun Atreja[2] Francis Lobo[2], [1]Sapere Health Solutions [2]Madrigal Pharmaceuticals

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Background: Recent studies estimate that metabolic dysfunction-associated steatohepatitis (MASH) cases in the United States are expected to increase 82.6% by 2039. MASH has significant ramifications in liver-related sequelae (cirrhosis, cancer, decompensation) and cost burden[1] . Real-world disparities in GLP-1 semaglutide's therapeutic dose exposure and premature discontinuation[2-5] limits overall efficacy and effectiveness for MASH. Wastage modeling based on real-world data can identify disparities within estimated clinical outcomes and the consequential economic impact of MASH treatment. **Aim:** To elucidate the estimated clinical effects of Wegovy (semaglutide) dependent on real-world dose exposure, persistence, and consequential economic wastage. **Methods:** We developed a wastage model that leverages a Markov state-transition structure to estimate the number of clinical responders and progressors, discontinuations, and economic wastage from the use of Wegovy (semaglutide) in a MASH population. Optimal dose responders were defined as maintaining persistence on the 2.4mg dose by 72 weeks as in the ESSENCE trial and yielding the clinical response of fibrosis improvement without steatosis worsening. Economic wastage was defined by the excess medical and pharmacy costs experienced by a commercial health plan for all MASH patients treated with Wegovy who did not reach fibrosis improvement with FDA approved therapeutic dose by the end of time horizon. To inform the real-world 72-week persistence and dose states, an Optum Market Clarity Dataset cohort of 1,013 patients initiating SC semaglutide with a target dosage of 2.4 mg/week for weight management (Wegovy) was used. Probabilistic and deterministic sensitivity analyses were completed for parameters of uncertainty inclusive of fibrosis mix and non lean mix. **Results:** In a modeled commercial population of 80,000 members, an estimated 100 patients will be diagnosed and eligible (F2/F3) for MASH treatment with Wegovy (semaglutide). Of the 100 patients, 24 remain persistent at 72 weeks of which 3.25 patients will be optimal dose responders. Additionally, 29 patients will experience fibrosis progression (20 new F4 and 9 new F3). It is estimated that a commercial health plan would experience a wastage of $1.3M total cost (pharmacy and medical) to yield one optimal dose responder. **Conclusion:** Our wastage model demonstrates that the low persistence of MASH patients on an optimal dose of semaglutide (2.4mg) in the real-world environment, compared to the clinical trial, results in a higher number of progressors, a lower number of responders, and significant economic wastage to be experienced by commercial health plans.Witkowski M et al. *Pharmacoeco.* 2022;40:751-776Do D et al. *JAMA Netw.* 2024;7:e2413172Gleason PP et al. *JM Care Spec Pharm.* 2024;30:860-867Polonsky WH et al. *Diabetes.* 2025;74:786-PAlvarez G et al. *Obesities.* 2025;5:90

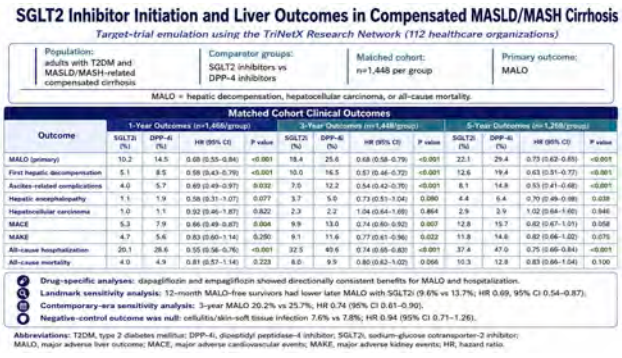
3523 | ◆ SODIUM-GLUCOSE COTRANSPORTER-2 INHIBITORS (SGLT2I) VERSUS DPP-4 INHIBITORS (DDP-4I) INITIATION IN TYPE 2 DIABETES MELLITUS (T2DM) WITH MASLD/MASH-RELATED COMPENSATED CIRRHOSIS: A TARGET-TRIAL EMULATION OF MAJOR ADVERSE LIVER OUTCOMES (MALO) AND MAJOR ADVERSE CARDIOVASCULAR EVENTS (MACE)



Mohammad Alabbas[1] Akram Alnounou[2] Ahmad Alhusen[3] Kenan Abou Chaer[4] EzzElDien A. Ibrahim[5] Omar Sims[1] Richard Sterling[6], [1]Cleveland Clinic Foundation, [2]Department of Internal Medicine, Western Michigan University Homer Stryker M.D. School of Medicine,, [3]Department of Internal Medicine, Advocate Illinois Masonic Medical Center, Chicago, IL, USA, [4]Department of Internal Medicine, Detroit Medical Center/Wayne State University, Detroit, MI, USA, [5]Department of Medicine, University of Missouri-Columbia 1 Hospital Dr, Columbia, Missouri, USA 65212, [6]Virginia Commonwealth University

Background: Adults with T2DM and MASLD/MASH-related compensated cirrhosis face high risks of hepatic decompensation, hospitalization, cardiovascular and kidney events, and death. Whether SGLT2i reduce hard liver outcomes in this population is uncertain. We emulated a target trial comparing SGLT2i versus DPP-4i initiation. **Methods:** Using the TriNetX Research Network (112 healthcare organizations), we identified adults with T2DM and MASLD/MASH-related compensated cirrhosis initiating an SGLT2i or DPP-4 inhibitor. Time zero was the first qualifying prescription. Patients with prior exposure to

either class, hepatic decompensation, MALO components, hepatocellular carcinoma, transplant, competing liver diseases, ESRD/dialysis, HIV, or malignancy were excluded. SGLT2i and DPP-4i initiators were 1:1 propensity-score matched on demographics, comorbidities, medications, and laboratory values. The primary outcome was MALO: hepatic decompensation, hepatocellular carcinoma, or death. Secondary outcomes included first decompensation, ascites-related complications, hepatic encephalopathy, MACE, MAKE, hospitalization, and mortality. Outcomes were assessed at 1, 3, and 5 years with Kaplan-Meier methods. **Results:** Before matching, 4,446 SGLT2i and 2,130 DPP-4i initiators were eligible; 1,448 pairs formed the main 3-year cohort with all post-match SMD < 0.10. At 3 years, SGLT2i initiation was associated with lower MALO (18.4% vs 25.6%; HR 0.68, 95% CI 0.58–0.79), first decompensation (10.0% vs 16.5%; HR 0.57, 95% CI 0.46–0.72), ascites-related complications (7.0% vs 12.2%; HR 0.54, 95% CI 0.42–0.70), MACE (9.9% vs 13.0%; HR 0.74, 95% CI 0.60–0.92), MAKE (9.1% vs 11.6%; HR 0.77, 95% CI 0.61–0.96), and hospitalization (32.5% vs 40.6%; HR 0.74, 95% CI 0.65–0.83; all $p \leq 0.022$). Hepatic encephalopathy, hepatocellular carcinoma, and mortality did not significantly differ. MALO reductions were consistent at 1 year (10.2% vs 14.5%; HR 0.68, 95% CI 0.55–0.84) and 5 years (22.1% vs 29.4%; HR 0.73, 95% CI 0.62–0.85). Dapagliflozin and empagliflozin analyses, stratified analyses across albumin, BMI, eGFR, HbA1c, and age, 12-month landmark sensitivity analysis, contemporary-era analysis, E-values, and a null negative-control outcome supported robustness. **Conclusion:** In adults with T2DM and MASLD/MASH-related compensated cirrhosis, SGLT2i initiation was associated with lower MALO, hepatic decompensation, ascites-related complications, cardiovascular and kidney events, and hospitalization versus DPP-4i initiation, without excess hepatic encephalopathy, hepatocellular carcinoma, or mortality. These data support prospective trials of SGLT2i as a liver-relevant metabolic strategy in compensated MASLD/MASH cirrhosis.

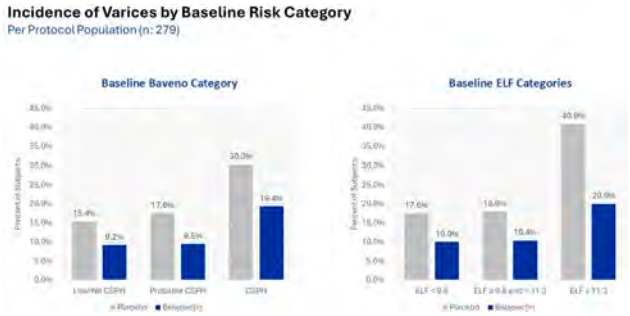
3524 | ◆ BASELINE BAVENO PORTAL HYPERTENSION AND ELF RISK STRATIFICATION PREDICT VARICEAL DEVELOPMENT IN COMPENSATED MASH CIRRHOSIS: FINDINGS FROM THE NAVIGATE TRIAL



Naim Alkhouri[1] Raj Vuppalanchi[2] Eric Lawitz[3] Khurram Jamil[4] Seth Zuckerman[4] Naga Chalasani[5], [1]Summit Clinical Research, [2]Indiana University School of Medicine, [3]The Texas Liver Institute, University of Texas San Antonio, [4]Galectin Therapeutics, [5]Indiana University Medical Center

Background: Development of esophageal varices (EV) in compensated cirrhosis reflects worsening portal hypertension and increased risk of decompensation. - Baveno VI criteria and Enhanced Liver Fibrosis (ELF) score, enable risk stratification for clinically significant portal hypertension (CSPH) and risk of decompensation, respectively. NAVIGATE is a global, randomized, placebo-controlled trial that evaluated belapectin, a galectin-3 inhibitor, in patients with compensated MASH cirrhosis without baseline varices. Belapectin demonstrated a lower incidence of new varices at 18 months versus placebo. Here, we assessed the relationship between baseline Baveno VI and ELF risk categories and incidence of varices, we also evaluated treatment effects across risk strata. **Methods:** Subjects underwent upper endoscopy at baseline and 18 months with central blinded review. Incidence of new EV was assessed across Baveno portal hypertension categories (low/no risk, probable CSPH, definite CSPH) and predefined ELF categories (< 9.8, ≥ 9.8–< 11.3, ≥ 11.3). Analyses were conducted in subjects with evaluable endoscopy at both timepoints. For this analysis, both belapectin dose groups (2 mg/kg and 4 mg/kg) were combined and compared with placebo. Comparisons were performed using the chi-square test. **Results:** Baveno stratification (n = 115 low/no CSPH, 59 probable CSPH, 100 definite CSPH) demonstrated increasing incidence of varices with greater portal hypertension severity

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(11.3%, 11.9%, and 23.0%, respectively; p = 0.08 and p = 0.02 across category comparisons vs CSPH). Within each Baveno category, incidence of varices remained lower with belapectin versus placebo (9.2% vs 15.4%, 9.5% vs 17.6%, and 19.4% vs 30.3%, respectively).Similarly, incidence of new varices increased stepwise with higher baseline ELF category (n = 57, 156, 67), with rates of 12.3%, 12.8%, and 26.9%, respectively. The highest ELF category ($\geq$ 11.3) had a significantly greater incidence compared with lower categories (p = 0.04 and p = 0.01). Within each ELF stratum, belapectin-treated subjects had consistently lower incidence of varices compared with placebo (10.0% vs 17.6%, 10.4% vs 18.0%, and 20.0% vs 40.9%, respectively). **Conclusion:** In NAVIGATE, baseline Baveno and ELF risk categories demonstrated increased risk, with Baveno CSPH category and ELF $\geq$ 11.3 associated with significantly greater incidence of varices at 18 months. Belapectin treatment was associated with lower variceal incidence compared with placebo. These findings support baseline risk stratification as a strategy for enrichment and treatment effect detection in future Phase 3 variceal prevention trials in MASH cirrhosis.

3525 | ◆ CO-ADMINISTRATION OF THYROID HORMONE RECEPTOR B AGONIST ALG-055009 AND INCRETIN RECEPTOR AGONISTS LEADS TO SYNERGISTIC FAT MASS LOSS AND MODULATION OF KEY MOLECULAR PATHWAYS IN THE LIVER AND ADIPOSE TISSUE OF DIET-INDUCED OBESE MICE

Peter Althoff[1] Jieun Song[1] Kusum Gupta[1] Lillian Adame[1] Dinah Misner[1] Tse-I Lin[2] Lawrence Blatt[1] Julian Symons[3] Sushmita Chanda[1] Xuan Luong[1], [1]Aligos Therapeutics, Inc., [2]Aligos Belgium BV, [3]Aligos Therapeutics

Background: ALG-055009 is a potent, selective thyroid hormone receptor β (THR-β) agonist that has demonstrated significant reductions in liver fat (placebo-adjusted median relative reductions up to 46.2%) and atherogenic lipids in clinical subjects with presumed metabolic dysfunction-associated steatohepatitis (MASH) and stage 1-3 liver fibrosis. Thyroid hormone is crucial in regulating metabolism, and THR activation has been shown to enhance energy expenditure and promote weight loss. Here, the ability of ALG-055009 to augment the weight loss effects of approved incretin receptor agonists (RAs) was assessed in diet-induced obese (DIO) mice. **Methods:** Mice were fed a high-fat diet for 23-25 weeks to induce obesity. In Part I, mice were treated once daily with vehicle, oral 1 mg/kg ALG-055009, subcutaneous incretin RAs, 10.0 nmol/kg semaglutide (SEMA), 3.0 nmol/kg tirzepatide (TIRZEP_lo), 10.0 nmol/kg tirzepatide (TIRZEP_hi), or combinations of ALG-055009 with incretin RAs for 4-5 weeks. In Part II, SEMA treatment was discontinued in the SEMA monotherapy and SEMA + ALG-055009 groups, and animals were continued on either vehicle treatment or ALG-055009 maintenance therapy and monitored for 4 more weeks. Assessments included body weight (BW), body composition, and tissue-specific gene expression via RT-qPCR. **Results:** ALG-055009 in combination with incretin RAs resulted in profound, synergistic weight loss in DIO mice, with up to 39-40% decreases in body weight within 4-5 weeks. Notably, the additional weight loss conferred by ALG-055009 was from reduction of fat mass without changes to lean mass or food intake. Administration of ALG-055009 to animals already receiving SEMA still produced meaningful effects, with significantly greater reductions in body weight and fat tissue mass compared to animals on SEMA monotherapy. Following SEMA withdrawal, animals regained nearly all lost weight, while those maintained on ALG-055009 preserved 48–57% of weight loss and 47–57% of fat mass reduction. Gene expression analysis showed that combination therapy synergistically modulated several key genes in the liver to restore hepatic heath, while ALG-055009 uniquely shifted the liver towards a less fibrotic and more metabolically functional state. **Conclusion:** In DIO mice, ALG-055009 drove synergistic, fat-selective weight loss when combined with incretin RAs, likely via browning of white adipose and increased energy expenditure. Combination therapy also synergistically modulated hepatic gene expression, promoting a less fibrotic, more metabolically functional liver. Beyond its clinical efficacy in MASH, THR-β agonism is potentially a powerful, complementary strategy to combat obesity by enhancing the magnitude and durability of incretin RA-mediated weight loss.

Background: Metabolic dysfunction-associated steatohepatitis (MASH) affects ~40 million people in the U.S. and E.U. and can progress to cirrhosis, hepatocellular carcinoma, and death. Fibroblast growth factor 21 (FGF21) is a pleiotropic regulator of metabolic function and fibrosis, making it a promising therapeutic target for MASH. Several engineered FGF21 analogs, administered chronically as subcutaneous injections, have reached approval or are in clinical development for patients with MASH and MASH-related cirrhosis. KRIYA-497, a one-time adenovirus associated vector 1 FGF21 (AAV1.FGF21) intramuscular (IM) gene therapy, drives sustained skeletal muscle expression of native human FGF21. Previous studies showed AAV1.mFGF21 reverses steatohepatitis and fibrosis in animal models of MASH. Here, we evaluate whether AAV1.FGF21 administration normalizes the hepatic transcriptional state toward that of healthy livers in a preclinical model of MASH, providing rationale for RESTORE, a Phase 1/2 first-in-human trial of KRIYA-497. **Methods:** Liver tissue was obtained from 70-week-old C57BL/6J mice treated with low- or high-dose AAV1.mFGF21, alongside untreated high-fat diet (HFD) and chow controls, as previously described (Jimenez et al., *Mol Ther*, 2024). Bulk RNA-seq was performed; HFD-responsive genes were classified as fully or partially rescued (significant return toward chow), unchanged, or otherwise altered. Mouse profiles were then compared with human liver transcriptome data (Govaere et al., *Sci Transl Med*, 2020) from the European NAFLD registry comprising histologically characterized MASH samples from 206 patients across the liver fibrosis spectrum. **Results:** HFD altered ~20% of the liver transcriptome versus chow. Low-dose AAV1.mFGF21 fully or partially rescued 47% of HFD-responsive genes; high-dose AAV1.mFGF21 fully or partially rescued 74%, including normalization of transcripts associated with fibrosis, inflammation, and lipid metabolism. In cross-species principal component analysis, HFD livers co-localized with human F3/F4 MASH, while high-dose AAV1.mFGF21 livers shifted toward chow controls and human NAFL/F0-F1, consistent with reversion toward a healthy hepatic state. **Conclusion:** One-time IM AAV1.FGF21 reverts the MASH liver transcriptome toward a healthy phenotype in a mouse model of MASH, establishing the anti-fibrotic and anti-inflammatory potential of KRIYA-497. These data support the translation of KRIYA-497 to the first clinical trial of an AAV gene therapy for MASH (Phase 1/2 RESTORE study), to evaluate safety, tolerability, and metabolic and hepatic outcomes in adults with MASH and clinically significant (> F2) fibrosis.

3527 | ◆ ER-300M (AAV-OSK) IMPROVES LIVER INJURY AND STEATOSIS ENDPOINTS IN THE GAN DIET-INDUCED OBESE AND BIOPSY-CONFIRMED MOUSE MODEL OF MASH

Kasia Broniowska[1] Lisa Stanek[1] Sadie Crocker[1] Richard Davis[1] Xiaohong Cao[1] Michel Wathier[1] Michael Feigh[2] Sharon Rosenzweig-Lipson[1], [1]Life Biosciences Inc., [2]Gubra

Background: Metabolic dysfunction–associated steatohepatitis (MASH) is a progressive liver disease associated with fibrosis and altered DNA methylation. In optic neuropathies, epigenetic restoration via expression of OCT4, SOX2, and KLF4 (OSK) has been linked to improved cellular function and regenerative capacity while maintaining cellular identity without de-differentiation. ER-300m is an adeno-associated virus (AAV) vector delivering OSK for hepatic expression. We evaluated ER-300m in the GAN diet-induced obese (DIO) and biopsy-confirmed mouse model of MASH. **Methods:** Male C57BL/6JRj mice were fed the GAN diet, which is high in saturated fat, fructose, and cholesterol, for 36–38 weeks and underwent liver biopsy to confirm MASH pathology (steatosis score 3, inflammation score ≥ 2, fibrosis stage F2–F3). Mice were randomized based on fibrosis staining. GAN DIO-MASH mice received vehicle or ER-300m (IV) and were evaluated after ~10 weeks using plasma biochemistry, liver weight, quantitative histology, ELISA, immunohistochemistry (IHC), and whole genome bisulfite sequencing. **Results:** ER-300m improved multiple clinically relevant liver injury and metabolic endpoints relative to vehicle. ER-300m significantly reduced plasma ALT and AST and lowered plasma total bile acids and total cholesterol compared with vehicle. ER-300m also reduced liver weight and decreased the percent of hepatocytes containing lipid droplets, indicating improvement in steatosis-associated pathology.

Histologic score outcomes showed an increased proportion of animals achieving ≥1-point improvements in NAFLD activity score and steatosis score versus vehicle. IHC confirmed hepatic transduction and transgene expression, with 13% SOX2-positive cells detected in the liver. Consistent with IHC findings, ELISA analysis demonstrated robust transgene protein expression: SOX2 levels were 9.16 ± 1.1 ng/mg (mean ± SEM) with no endogenous SOX2 detected in vehicle-treated animals, while KLF4 levels were 1.43 ± 0.13 ng/mg versus 0.06 ± 0.03 ng/mg in vehicle controls. Whole genome bisulfite sequencing showed that ER-300m treatment restored DNA methylation profiles toward lean controls. **Conclusion:** ER-300m improved liver injury, steatosis and DNA methylation in a biopsy-confirmed MASH model, with clear evidence of hepatic SOX2 and KLF4 expression. Given the role of epigenetic dysregulation in MASH, these findings support continued evaluation of epigenetic restoration as a therapeutic strategy for metabolic liver disease. These data demonstrate that OSK-induced epigenetic restoration transcends organs and provides evidence of the transformational ability of OSK to reverse or prevent diseases of aging.

3528 | ◆ IMPROVEMENT IN NON-INVASIVE BIOMARKERS AFTER ONCE-WEEKLY UTREGLUTIDE (GL0034) TREATMENT FOR 24 WEEKS IN SUBJECTS WITH AT-RISK MASH: A PHASE 2A STUDY

Rajamannar Thennati[1] Vinod Burade[2] Richard Pratley[3] Rohit Loomba[4], [1]High Impact Innovations–Sustainable Health Solutions (HISHS), Sun Pharmaceutical Industries Limited, [2]High Impact Innovations – Sustainable Health Solutions (HISHS), Sun Pharmaceutical Industries Limit, [3]AdventHealth Translational Research Institute, Orlando, USA, [4]Chief, Division of Gastroenterology and Hepatology, Professor of Medicine, University of California

Background: Utreglutide (UTG, GL0034), a novel, once-weekly glucagon-like peptide-1 (GLP-1) receptor agonist, demonstrated safety in phase 1 study in individuals with overweight and obesity. In phase 1b/2a study, improvements in MASH biomarkers were evident in subjects with MASLD. Herein, interim data from phase 2a study in at-risk MASH subjects with 24 week once-weekly UTG dosing schedule is presented. **Methods:** In this randomized, double-blind, placebo-controlled, parallel group, multicenter study 60 participants, both male and female, aged 18 to 75 years with a BMI ≥30 kg/m^2 and ≤ 50 kg/m^2 or BMI ≥ 27.0 kg/m^2 along with at least one of the comorbidities (current or new diagnosis of T2DM with HbA_{1c} < 10% or hypertension or dyslipidemia); MRE liver stiffness ≥ 2.7 kPa and < 5.0 kPa and liver fat content ≥ 8.5% as assessed by MRI-PDFF were randomized (2:1) to subcutaneous UTG doses with dose escalation schedule (4×0.35, 4×0.75, 4×1.5, 4×3.0, 4×4.5 mg) of 20 weeks and final dose period (4.5 mg-cohort 1 and 6.0 mg-cohort 2) of 4 weeks or placebo once-weekly for 24 weeks.Safety, tolerability, and key efficacy along with exploratory biomarkers were assessed at baseline (BL) and week 24. In this interim analysis a pooled data of treatment and placebo group with N = 29 has been provided. The efficacy markers presented include BMI, body weight (BW), waist circumference (WC), liver fat content by MRI-PDFF, liver stiffness by magnetic resonance elastography (MRE), controlled attenuated parameter (CAP) mean as assessed by FibroScan@, alanine aminotransferase (ALT) and HbA_{1c}. **Results:** Utreglutide was well-tolerated and related adverse effects were mainly gastrointestinal including nausea, vomiting, and diarrhea which were mild to moderate. Pooled data of N = 19 for UTG treatment and pooled placebo N = 10 is presented. The mean BW reduction at week 24 from BL was 11.3 kg (9.7%, $p < 0.0001$), accompanied by 7.9 cm reduction in WC ($p = 0.0006$) and the decrease in BMI was -3.9 kg/m^2 ($p < 0.0001$). The mean percent change in relative liver fat content as assessed by MRI-PDFF from BL to week 24 was -35.1% ($p < 0.0001$) and half of the study participants achieved ≥30% relative liver fat reduction. Interestingly, in a short duration of 24 weeks dosing MRE liver stiffness reduction was significant ($p = 0.0123$). The CAP mean reduced by 40.4 dB/m. In addition, the subjects with ≥17 U/L ALT reduction were 40% and the mean change in ALT was -10.8 U/L. A meaningful reduction in HbA_{1c} of 0.58% ($p < 0.0001$) was observed. The placebo group showed little or no change at week 24 from baseline for all the parameters, except for CAP mean (see Table). **Conclusion:** Once-weekly utreglutide dosing for 24 weeks in subjects with at-risk MASH was well tolerated and produced improvements in body weight, hepatic steatosis, MRE liver stiffness, ALT and HbA_{1c} levels. The magnitude and pattern of response are clinically relevant, demonstrating utreglutide's potential as a GLP-1–based therapy for MASH.

3529 | EFFICACY OF EFRUXIFERMIN ON LIVER INJURY BIOMARKERS ACROSS THE MASLD/MASH SPECTRUM: A META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Hima Varsha Voruganti[1] Rohit Sekandlapuram[2] Ravi Patel[3] Aashay Dharia[4] Shravya Ginnaram[5] Pratiksha Moliya[6] Hasan Al-Obaidi[7] Yagnesh Nandikanti[8] Roshitha Bheemaneni[9] Manasa Ginjupalli[4], [1]North Alabama Medial Center, [2]Montefiore Medical Center/ Albert Einstein College of Medicine, [3]Trinity Health Oakland, [4]Brooklyn Hospital Center, [5]HCA Florida Citrus Hospital/USF Morsani College of Medicine, [6]University of Nebraska Medical Center, [7]University of Toledo, [8]Sidhartha Medical College, [9]Gandhi Medical College

Background: Efruxifermin, an Fc-FGF21(Fc-fused fibroblast growth factor 21) analogue, has shown promising results, with histologic outcome data generally trending toward benefit in randomized trials of precirrhotic MASH(Metabolic dysfunction-associated steatohepatitis) and compensated cirrhosis caused by MASH. Here, we conducted a meta-analysis to synthesize the effects of Efruxifermin on circulating fibrosis and liver injury biomarkers across the spectrum of disease severity. **Methods:** We conducted a random-effects meta-analysis of placebo-controlled randomized trials of Efruxifermin in MASLD/MASH, evaluating changes in ELF (Enhanced Liver Fibrosis score) score, Pro-C3(N-terminal propeptide of type III collagen), ALT(Alanine aminotransferase), AST(Aspartate aminotransferase), GGT(Gamma-glutamyl transferase), ALP(Alkaline phosphatase), and urate. Mean differences were used for all biomarkers except Pro-C3, which was analyzed using standardized mean differences. In trials with multiple Efruxifermin dose arms, the shared placebo group was split across comparisons to avoid double-counting participants. **Results:** Across 4 randomized trials, Efruxifermin favored improvement

in all pooled biomarker outcomes. In all-stage analyses, pooled effects were: ELF score, MD -0.718 (95% CI, -0.861 to -0.574); Pro-C3, SMD -4.510 (-5.065 to -3.954); ALT, MD -15.692 U/L (-23.392 to -7.992); AST, MD -12.448 U/L (-18.125 to -6.771); GGT, MD -24.672 U/L (-34.427 to -14.918); ALP, MD -8.269 U/L (-12.365 to -4.174); and urate, MD -0.609 mg/dL (-0.769 to -0.448). Heterogeneity was low for ELF, GGT, ALP, and urate, moderate for AST and Pro-C3, and highest for ALT, consistent with biologic differences across fibrosis stages. Stage-stratified analyses supported benefit in both F1-F3 and F4 populations. **Conclusion:** Efruxifermin was associated with broad improvement in fibrosis, liver injury, and metabolic stress biomarkers across the MASLD/MASH spectrum, including compensated cirrhosis caused by MASH. These findings support biomarker responsiveness across disease stages and reinforce the potential disease-modifying activity of Efruxifermin.

★ 3530 | STEATOHEPATITIS AND FIBROSIS-RELATED OUTCOMES FOR RESMETIROM AND CO-PRESCRIPTIONS WITH GLP1 RECEPTOR AGONISTS, VITAMIN E, AND STATINS

Resham Ramkissoon[1] Alekhya Mannava[1] Japhet Amoah[1] Samir Barazi[1] Akash Chavan[1] Adily Elmi[1] Julie Gartland[1] Jaime Abraham Perez[1] Naemat Sandhu[2] Stanley Cohen[3] Seth Sclair[2], [1]Case Western Reserve University/University Hospitals, [2]University Hospitals Cleveland Medical Center, [3]Case Western Reserve University

Background: Resmetirom is the first FDA-approved therapy for at-risk MASH, granted accelerated approval based on the MAESTRO NASH Study. As a thyroid hormone receptor beta agonist, resmetirom increases hepatic fatty acid oxidation and suppresses lipogenesis, with demonstrated LDL reduction. Expert panel recommendations in 2024 advised against concomitant use of GLP-1 receptor agonists and resmetirom. We aimed to characterize prescribing patterns of clinicians treating patients with resmetirom at a large US referral center. **Methods:** Using TriNetX, we identified all patients prescribed resmetirom at our health system and performed chart review of patients treated for at-risk MASH from March 2024–December 2025. Comparative statistical analysis was performed using two-sided t-test and chi-squared analysis. **Results:** 119 eligible patients were treated. 68 (51%) were female, mean age 57.2 years, 92% Caucasian, mean BMI 35.3 kg/m², and mean weight 116 kg. 71 (59.7%) had co-prescriptions for a GLP-1, 70 (58.8%) a statin, and 10 (8.4%) vitamin E. Of GLP-1 co-prescribed patients, 38 were on a GLP-1, on average of 15 months before resmetirom, while 31 started a GLP-1 an average of 9.4 months after. Patients prescribed a GLP-1 after resmetirom had higher GI side effects (16/38) compared to those already on a GLP-1 (1/31). GLP-1-naive patients at resmetirom initiation had mean LSM and CAP of 11.6 kPa and 312, improving to 8.4 kPa and 264 at 12 months. Patients already on a GLP-1 had mean LSM and CAP of 10.8 kPa and 325 at initiation, and 13.7 kPa and 271 at 12 months. Fibrosis regression was similar with and without vitamin E. No increased hepatic adverse events or rhabdomyolysis occurred with concomitant statin use, and LDL reduction was preserved with or without statins. **Conclusion:** This real-world study demonstrates that concomitant resmetirom and GLP-1 use is common, with nearly 60% of patients having treatment overlap. GLP-1-naive patients on resmetirom had greater LSM reduction compared to those on existing GLP-1, representing a population with advanced fibrosis despite GLP-1 therapy necessitating resmetirom. Patients on stable GLP-1 who then started resmetirom had fewer GI side effects; clinicians should be aware of potential GI intolerance when adding a GLP-1 after resmetirom. Vitamin E was seldomly used and had no significant impact on 12-month liver stiffness. No increase in adverse events was observed with statin co-prescription, and LDL reduction was preserved. In clinical practice, resmetirom demonstrates good efficacy for MASH with moderate fibrosis despite GLP-1 therapy.

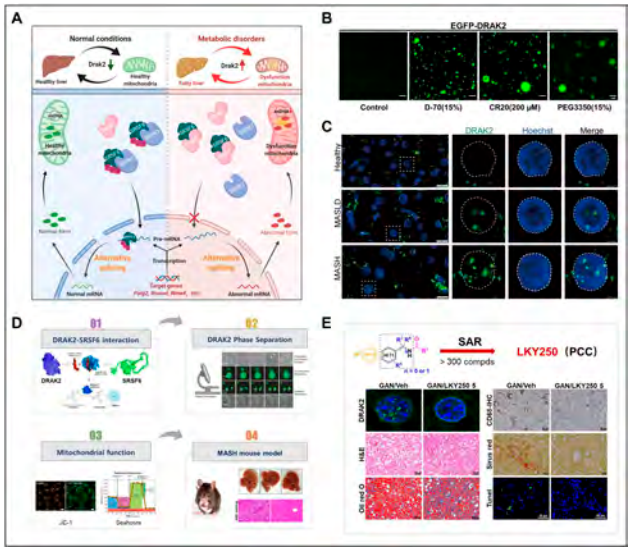
3531 | ◆ PNPLA3, TM6SF2 AND HSD17B13 GENOTYPES DO NOT IMPACT HISTOLOGIC TREATMENT RESPONSE TO SURVODUTIDE IN A MASH PHASE II STUDY

Arun Sanyal[1] Daniel Mazo[2] Malgorzata Borowska[2] Julian Schwab[2] Panagiotis Papavasileiou[2] Corinna Schoelch[2] Raphael Hesse[2], [1]Virginia Commonwealth University, [2]Boehringer Ingelheim

Background: Genetic variation, particularly in *PNPLA3*, *TM6SF2* and *HSD17B13*, is a major determinant of susceptibility and progression in metabolic dysfunction–associated steatohepatitis (MASH). Survodutide, a glucagon receptor/ glucagon-like peptide-1 (GLP-1) receptor dual agonist, is being developed for MASH and obesity. This pharmacogenomic analysis from the MASH phase II study evaluated whether *PNPLA3*, *TM6SF2* and *HSD17B13* genotypes influences two predefined histological endpoints. **Methods:** Participants underwent baseline genotyping for *PNPLA3* variant rs738409 (I148M), *TM6SF2* variant rs58542926 and *HSD17B13* variant rs72613567. In addition, an unweighted polygenic risk score (PRS) was calculated from these three variants. Associations between genotypes/PRS and (1) histological resolution of MASH without worsening of fibrosis, and (2) fibrosis improvement without worsening of MASH were assessed. Their effect modifications were evaluated by fitting a multivariable logistic regression model, including a treatment-by-genotype interaction term. Within each single nucleotide polymorphism (SNP)/ PRS genotype stratum, response rates between active treatment and placebo were compared using Fisher's exact test. The p-values were adjusted for multiple hypothesis testing using False discovery rate. **Results:** *PNPLA3*, *TM6SF2* and *HSD17B13* genotypes as well as a PRS calculated from these 3 variants did not impact histological treatment response to survodutide. Rates of MASH resolution without fibrosis worsening, and fibrosis improvement without worsening of MASH were comparable across genotypes ($p = 0.782$ and $p = 0.984$, respectively) and PRS groups ($p = 0.816$ and $p = 0.694$, respectively). Survodutide demonstrated consistent efficacy independent of *PNPLA3*, *TM6SF2* and *HSD17B13* variant status, including the risk alleles. No evidence of effect modification by genotype was detected. **Conclusion:** In this phase II trial in participants with MASH, *PNPLA3*, *TM6SF2* and *HSD17B13* genotypes did not influence response to survodutide with respect to two histological endpoints. These findings suggest that the efficacy of survodutide treatment is independent of *PNPLA3*, *TM6SF2* and *HSD17B13* genetic variation, supporting its therapeutic potential across genetically diverse patient populations. **Disclosures:** Arun Sanyal: Nothing to Disclose, Daniel Mazo:Boehringer Ingelheim International GmbH: Employee, Malgorzata Borowska:Nothing to Disclose, Julian Schwab:Boehringer Ingelheim Pharma GmbH&Co.KG: Employee, Panagiotis Papavasileiou: Nothing to Disclose, Corinna Schoelch:Nothing to Disclose, Raphael Hesse:Boehringer Ingelheim: Employee.

3532 | RESEARCH ON THE PATHOLOGICAL MECHANISM OF DRAK2 IN MEDIATING MASH PROGRESSION AND NOVEL DRUG DISCOVERY



Yufeng Li[1] Yidan Huang[2], [1]Shanghai Institute of Materia Medica, CAS, [2]Shanghai Institute of Materia Medica, Chinese Academy of Sciences

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease driven by lipotoxicity, yet how lipid overload is transduced into inflammation and fibrosis remains incompletely understood. Dysregulated RNA splicing contributes to MASH pathogenesis. DRAK2 (STK17B) is a DAPK family kinase linked to cell survival and proliferation. DRAK2 is upregulated in MASLD/MASH. Our previous work showed DRAK2 binds SRSF6, regulates alternative splicing of mitochondrial genes (e.g., *Polg2*), and drives mitochondrial dysfunction (Cell Metabolism, 2021). Here, we further investigate the underlying mechanism and identify a small-molecule inhibitor targeting DRAK2-SRSF6 interaction and DRAK2 phase separation. **Methods:** Human liver biopsies, GAN-diet fed mice, primary hepatocytes, and purified proteins were used. Multi-omics, Co-IP, RNA-seq, and alternative splicing analysis were performed. Phase separation was assessed by turbidity, FRAP, and mutagenesis. A NANOBIT-based screen was conducted to discover inhibitors of DRAK2-SRSF6 interaction. LKY250 was validated in vitro and in a therapeutic MASH model. **Results:** DRAK2 was markedly upregulated in MASLD/ MASH patients and model mice. Hepatic DRAK2 deletion suppressed steatosis-to-MASH progression. DRAK2 directly bound SRSF6, inhibited its phosphorylation by SRPK1, and regulated alternative splicing of mitochondrial function-related genes, including pathological splicing of *Polg2* which reduced mtDNA

replication efficiency and impaired mitochondrial homeostasis. In further studies, we found that DRAK2 underwent aberrant liquid-to-solid phase transition under lipotoxic stress, forming condensates that sequestered SRSF6 and spliceosomal components, leading to spliceosome solidification and widespread splicing errors. Through screening, we identified LKY250, a first-in-class inhibitor that disrupts DRAK2-SRSF6 interaction and DRAK2 condensation. LKY250 restored splicing fidelity, preserved mitochondrial integrity, and attenuated inflammation and fibrosis in MASH mice. **Conclusion:** DRAK2 drives MASH by both SRSF6-mediated splicing regulation and phase separation-induced spliceosome dysfunction. Targeting DRAK2-SRSF6 interaction or DRAK2 condensation with LKY250 offers a promising therapeutic strategy for the inflammatory-fibrotic axis of advanced MASH.

3533 | SAFETY AND EFFICACY OF J2H-1702, A NOVEL 11β-HSD1 INHIBITOR, IN MASLD: A PHASE 2A RANDOMIZED CONTROLLED TRIAL

Dae Won Jun[1] Joo Hyun Oh[2] Hyun Chin Cho[3] Eileen Yoon[4] Gi-Ae Kim[5], [1]Department of Gastroenterology, Hanyang University, [2]Department of Gastroenterology, CHA University College of Medicine, Bundang, Korea, [3]Department of Internal Medicine, Gyeongsang National University, [4]Department of Gastroenterology, Hanyang University College of Medicine, [5]Department of Internal Medicine, Kyung Hee University

Background: Intrahepatic glucocorticoid excess, mediated by 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1), is a validated mechanism driving hepatic steatosis and metabolic dysfunction. J2H-1702, a novel selective 11β-HSD1 inhibitor, demonstrated favorable metabolic and antifibrotic effects in preclinical models. We evaluated the efficacy and safety of J2H-1702 in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** In this multicenter, randomized, double-blind, and placebo-controlled trial, 87 patients with MASLD were randomly assigned to oral administration of J2H-1702 50 mg, 100 mg, 200 mg, or placebo once daily for 12 weeks in a 1:1:1:1 ratio. MASLD was defined as magnetic resonance imaging-proton density fat fraction (MRI-PDFF) $\geq$8% and magnetic resonance elastography (MRE) $\geq$2.5 kPa. Co-primary endpoints were percent change in hepatic fat by MRI-PDFF and hepatic stiffness by MRE at week 12. **Results:** All 87 patients were included in the full analysis set (50 mg, n = 22; 100 mg, n = 22; 200 mg, n = 22; placebo, n = 21). At week 12, J2H-1702, especially 200 mg, produced a significant reduction in hepatic fat by MRI-PDFF (−18.7% vs. +3.1%; LS mean difference, −22.3%; p = 0.011), alongside improvements in liver enzymes, body weight, and low-density lipoprotein cholesterol. No significant change in hepatic stiffness by MRE was observed. Treatment-emergent adverse events were mild and comparable across groups. Increases in adrenocorticotropic hormone and dehydroepiandrosterone, consistent with on-target 11β-HSD1 inhibition, were transient and resolved after treatment discontinuation. **Conclusion:** In this exploratory phase 2a study, J2H-1702 showed a reduction in hepatic steatosis, liver enzymes, and cardiometabolic parameters with a favorable safety profile in patients with MASLD over 12 weeks, supporting further clinical development.

3534 | DISCOVRY OF A NOVEL ACLY INHIBITOR FOR MASH TREATMENT AND CLINICAL TRANSLATION

Zhifu Xie[1] Jingya Li[2] Fajun Nan[2], [1]Shanghai Institute of Materia Medica, [2]Shanghai Institute of Materia Medica, Chinese Academy of Sciences

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive liver disease characterized by excessive lipid accumulation, inflammation, and hepatocyte injury, which can develop into cirrhosis and hepatocellular carcinoma. Hepatic de novo lipogenesis (DNL) is significantly elevated in MASH patients, and ATP-citrate lyase (ACLY) is a key enzyme promoting DNL. Peroxisome proliferator-activated receptor α (PPARα) activation enhances fatty acid oxidation but has limited efficacy in treating hepatic steatosis. The enedioic acid analog 326E, an ACLY inhibitor with proven efficacy in atherosclerosis and hypercholesterolemia (***Acta Pharm***

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Sin B . 2023), has not been investigated for its therapeutic potential in MASH. **Methods:** RNA sequencing and immunohistochemistry were used to analyze ACLY expression in liver samples from MASH patients and mice. Primary mouse hepatocytes and Acly-knockout (Acly-KO) hepatocytes were employed to evaluate 326E's effect on DNL. Multiple MASH models were established, including high-fructose diet (HFrD)-induced, Gan diet-induced ob/ob, and choline-deficient L-amino acid-defined high-fat diet (CDAA-HFD) mouse models, as well as cynomolgus monkey models, to assess 326E's in vivo efficacy. Lipid-targeted metabolomics, BODIPY staining, and biochemical analyses were used to detect lipid accumulation and liver function indices. A phase 1b/2a clinical trial (NCT06491576) was conducted to evaluate 326E's safety and efficacy in MASH patients. **Results:** ACLY expression was significantly upregulated in MASH patients and positively correlated with NAS score, ALT, and AST. 326E selectively inhibited ACLY to reduce DNL in a dose-dependent manner, and this effect was abolished in Acly-KO hepatocytes. In various MASH mouse models, 326E reduced hepatic lipid accumulation, improved steatosis, alleviated inflammation and fibrosis, and regulated lipid metabolism. It dual-targeted ACLY and PPARα (as an allosteric modulator) to enhance fatty acid oxidation and mitochondrial function, which was PPARα-dependent. 326E effectively alleviated MASH symptoms in cynomolgus monkeys and showed good tolerability and oral bioavailability in clinical trials, reducing circulating γ-glutamyl transferase (γ-GGT) levels in MASH (Clinical trial: NCT06491576; ***Cell Metab.***, 2025). **Conclusion:** 326E exerts therapeutic effects on MASH by dual targeting ACLY and PPARα, inhibiting DNL and enhancing fatty acid oxidation. Its favorable preclinical and clinical performance supports its potential as a promising candidate for MASH treatment, warranting further clinical evaluation.

3535 | FIRST-IN-CLASS ORAL IKKK/α INHIBITOR HPN-01 DEMONSTRATES DISEASE-MODIFYING ACTIVITIES THROUGH SUPPRESSION OF HEPATIC FIBROGENESIS AND INFLAMMATION ASSOCIATED WITH MASH

Belle Wang[1] Yongmei Li[1] Min Zhang[1] Amy Pan[1] T Jake Liang[2] Qisheng Li[1], [1]Hepanova, Inc., [2]National Institute of Diabetes, Digestive

Background: Metabolic dysfunction-associated steatohepatitis (MASH) with fibrosis is a leading cause of cirrhosis and hepatocellular carcinoma (HCC). Current therapies primarily target hepatic steatosis but incompletely address inflammation and fibrogenesis, key drivers of disease progression. Hepatic stellate cell (HSC) activation plays a central role in fibrosis development and remains an important unmet therapeutic target. HPN-01 is a first-in-class, orally administered, highly selective long-acting dual IKKα/β inhibitor designed to simultaneously modulate steatosis, inflammation, and fibrosis. We evaluated the mechanistic and comparative efficacy profile of HPN-01, with emphasis on its anti-fibrotic and anti-inflammatory activities. **Methods:** Mechanistic studies investigated IKKα-regulated pathways involved in hepatic inflammation, lipogenesis and fibrogenesis using transcriptomic analyses by RNA-Seq. Anti-fibrotic activity was evaluated in diet-induced MASH animal models through histopathology, collagen deposition, fibrosis scoring, and molecular analyses of key inflammatory and fibrogenic mediators. Comparative efficacy studies were performed against resmetirom. Clinical safety and pharmacokinetic (PK) characteristics were assessed in a randomized, placebo-controlled Phase 1 study in healthy volunteers (25–150 mg; n = 8/cohort). **Results:** HPN-01 directly suppresses multiple IKKα-regulated pathways involved in hepatic inflammation, fibrogenesis and HSC activation. Treatment significantly reduced expression of fibrosis- and inflammation-associated mediators including MCP-1, LOX, TGF-β, and ITGA2, accompanied by reductions in α-SMA expression, collagen-I deposition, and fibrosis scores. Concurrent improvements in steatosis and inflammatory activities resulted in reduced NAS scores in MASH models. Compared with resmetirom, HPN-01 demonstrated greater suppression of key fibrogenic pathways, stronger attenuation of liver inflammation, and improved protection against liver injury without ALT/AST elevation. While resmetirom primarily improved lipid parameters, HPN-01 exhibited disease-modifying activities centered on inflammation and fibrosis pathway regulation. HPN-01 additionally suppressed HCC progression and tumor burden in preclinical models. In a Phase 1 study, HPN-01 was well tolerated without dose-limiting toxicities and demonstrated an extended half-life, supporting infrequent oral dosing. **Conclusion:** HPN-01 is a mechanistically novel first-in-class IKKα/β inhibitor that directly suppresses MASH-related liver injury including inflammation, fibrogenesis and steatosis in preclinical models. Its unique anti-fibrotic/inflammatory activities, favorable safety profile, and long-acting PK support further clinical development as

3536 | AN ORAL INHIBITOR OF CBP/β-CATENIN SIGNALING IMPROVES HEPATIC STEATOSIS, FIBROSIS,

Kenzaburo Yamaji[1] Risa Kono[1] Ryusei Furusawa[1] Tadashi Imafuku[2] Sadahiro Iwabuchi[2] Shinichi Hashimoto[2] kiminori Kimura[3] Takeshi Okanoue[4] Kyoko Tsukiyama-Kohara[5] Michinori Kohara[1], [1]Tokyo Metropolitan Institute of Medical Science, [2]Wakayama Medical University, [3]Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, [4]Saiseikai Suita Hispital, [5]Kagoshima University

Background: Metabolic dysfunction associated steatohepatitis (MASH) is a progressive liver disease. However, an effective treatment strategy has yet to be established. We have previously reported on the efficacy of PRI-724, a second-generation, selective CBP/β-catenin antagonist. PRI-724 recovered from liver fibrosis and inflammation induced by choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) in mice. However, PRI-724 must be administered intravenously. It is a prodrug that is rapidly hydrolyzed *in vivo* to form its active metabolite, C-82. In this study, we investigated the efficacy of oral C-82 administration in an MASH animal model and elucidated its mechanism of action. **Methods:** To establish an obese mouse model of MASH, we used two mouse models, C57/BL6J mice fed GAN (Gubra-Amylin NASH) diet for 46 weeks or 7 weeks of age db/db mice. C-82 was administered orally in GAN diet-fed mice once daily for 12 weeks or in db/db mice once daily for 10 weeks. The efficacy of C-82 was evaluated based on the resolution of fatty liver disease, improvements in liver function, and reductions in liver fibrosis. Furthermore, glucose tolerance tests and analyses of changes in skeletal muscle strength and mass were conducted to assess hepatocyte function. **Results:** GAN diet-fed mice exhibited obesity, hypercholesterolemia, and liver fibrosis characterized by steatosis, lobular inflammation, hepatocyte damage, and collagen deposition. Prothrombin time (PT) activity (%) decreased significantly by week 46. Administering C-82 to GAN diet-fed mice significantly reduced body weight and serum total cholesterol levels. PT (%) improved from 38.8 ± 11.2% to 63.3 ± 31.6%. Additionally, hepatic lipid droplets and hepatic type I and III collagen expression levels (markers of liver fibrosis) were significantly reduced. Serum ALT levels, which were elevated in MASH model mice, decreased significantly, indicating an anti-inflammatory effect. Furthermore, glucose AUC values were significantly reduced, indicating improved glucose tolerance. Although muscle mass in db/db mice was lower than that in age-matched C57BL/6J mice, it was significantly higher in db/db mice treated with C-82 (C57BL/6J = 502.6 ± 47.8 mg/100 g BW, db/db vehicle = 159.6 ± 20.9 mg/100 g BW, db/db C-82 = 250.6 ± 58.5 mg/100 g BW). Furthermore, grip strength in C-82-treated db/db mice was significantly higher than in the untreated group. **Conclusion:** Oral administration of C-82 improves MASH-like liver damage (steatosis, dysfunction, and inflammation) and liver fibrosis. Furthermore, improvements in glucose tolerance and increases in muscle strength and mass were observed. C-82, an oral inhibitor of the CBP/β-catenin signaling pathway, demonstrates potent therapeutic effects on MASH-associated liver fibrosis, steatosis, glucose tolerance, and muscle loss.

3537 | SEMAGLUTIDE VERSUS SGLT2 INHIBITORS IN MASLD/MASH-RELATED COMPENSATED CIRRHOSIS: A TARGET-TRIAL EMULATION OF MAJOR ADVERSE LIVER OUTCOMES (MALO) AND MAJOR ADVERSE CARDIOVASCULAR EVENTS (MACE)

Mohammad Alabbas[1] Akram Alnounou[2] Ahmad Alhusen[3] Riddhi Machchhar[4] Omar Sims[1] Richard Sterling[5], [1]Cleveland Clinic Foundation, [2]Department of Internal Medicine, Western Michigan University Homer Stryker M.D. School of Medicine,, [3]Department of Internal Medicine, Advocate Illinois Masonic Medical Center, Chicago, IL, USA, [4]Department of Internal Medicine, Hackensack Meridian Health Ocean University Medical Center, Brick,, [5]Virginia Commonwealth University

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Adults with type 2 diabetes mellitus (T2DM) and MASLD/MASH-related compensated cirrhosis have high risks of decompensation, cardiovascular events, hospitalization, and death. Semaglutide and SGLT2 inhibitors (SGLT2i) are metabolic therapies, but comparative data on hard cirrhosis outcomes are limited. **Methods:** We emulated a target trial in the TriNetX Research Network (112 healthcare organizations). Adults with T2DM, MASLD/MASH, and compensated cirrhosis initiating semaglutide or an SGLT2i on or after January 1, 2018, were included. Patients with prior exposure to either class, hepatic decompensation/MALO components, HCC, transplant, ESRD/dialysis, HIV, malignancy, or other liver diseases were excluded. New users were 1:1 propensity-score matched on demographics, comorbidities, medications, and laboratory values. The primary outcome was major adverse liver outcome (MALO: decompensation, HCC, liver transplantation, or death). Secondary outcomes included hospitalization, first decompensation, MACE, mortality, acute kidney injury (AKI), encephalopathy, ascites, and ascites-related complications. Supportive analyses included Kaplan–Meier, drug-specific, subgroup, 12-month MALO-free landmark, E-value, and negative-control analyses. **Results:** After matching, 1,703 semaglutide and 1,703 SGLT2i initiators were well balanced (all SMD < 0.10). At 1 year, semaglutide was associated with lower MALO (6.8% vs 9.7%; RR 0.70, 95% CI 0.56–0.88; $p < 0.01$), hospitalization (18.8% vs 22.8%; RR 0.82, 95% CI 0.72–0.94), first decompensation (5.0% vs 6.9%; RR 0.72, 95% CI 0.55–0.94), MACE (16.0% vs 19.9%; RR 0.80, 95% CI 0.70–0.93), and mortality (1.5% vs 3.0%; RR 0.49, 95% CI 0.31–0.79; all secondary $p \leq 0.02$). MALO-free probability was 92.4% versus 88.7% (HR 0.64, 95% CI 0.50–0.81; $p < 0.001$). AKI, encephalopathy, ascites, and ascites-related complications did not differ. At 3 years, hospitalization remained lower (28.8% vs 32.0%; RR 0.90, 95% CI 0.81–1.00; $p = 0.04$), whereas MALO, MACE, mortality, decompensation, AKI, and ascites-related outcomes were not significantly different. Drug-specific comparisons versus empagliflozin and dapagliflozin were directionally consistent; the strongest MALO signal occurred with HbA1c $\geq 7\%$ (5.2% vs 9.0%; RR 0.58, 95% CI 0.38–0.87). In landmark analysis, late ascites-related outcomes favored SGLT2i; the negative-control outcome was null. **Conclusion:** In T2DM with MASLD/MASH-related compensated cirrhosis, semaglutide initiation was associated with early reductions in liver and cardiometabolic events versus SGLT2i, without excess AKI or ascites-related events. Benefit attenuated over time except for hospitalization, while landmark findings suggest a potential later SGLT2i advantage for fluid/ascites phenotypes, supporting prospective phenotype-guided trials of GLP-1 receptor agonist, SGLT2i, and combination strategies.

3538 | NOVEL ANTISENSE OLIGONUCLEOTIDES ENHANCE ENDOGENOUS FGF21 EXPRESSION AND AMELIORATE DYSLIPIDEMIA AND HEPATIC STEATOSIS IN PRECLINICAL METABOLIC DISEASE MODELS

Lingdi Zhang[1] Lansha Peng[1] Jian Li[1] Surendra Jain[1] Rich Thai[1] Xing Xian Yu[1] Yanfeng Wang[1] Xuehai Liang[1], [1]Arnatar Therapeutics INC

Background: Fibroblast growth factor 21 (FGF21) is a liver-derived metabolic hormone that regulates lipid metabolism, fatty acid oxidation, and inflammation. Pharmacologic FGF21 analogs have demonstrated clinical activity. However, increasing endogenous FGF21 may offer advantages by preserving physiologic regulation and tissue-specific responses. We developed ART7, a proprietary dual-functional antisense oligonucleotide (ASO) that increases endogenous FGF21 expression by simultaneously stabilizing FGF21 mRNA and enhancing translation. This study evaluated the pharmacologic activity and efficacy of the lead ASO candidate ART7 and active compounds in preclinical models of metabolic disease. **Methods:** FGF21-upregulating ASOs were evaluated in human, nonhuman primate, mouse, and rat cell lines. FGF21

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

expression was assessed by qRT-PCR, Western blotting, and ELISA. In vivo pharmacodynamic and efficacy studies were conducted in normal mice and rats, with proof-of-concept studies performed in diet-induced obese (DIO) mice and LDL receptor knockout (LDLR−/−) mice. Plasma lipids, liver histology, FGF21 protein expression, and downstream metabolic pathway markers were analyzed. **Results:** ART7 increased FGF21 mRNA expression by approximately 50–100% and elevated FGF21 protein levels by approximately 50–200% across multiple species and cell types in vitro. In vivo, subcutaneous administration induced sustained plasma FGF21 upregulation lasting 4–5 weeks after dosing. In DIO mice, ART7 treatment reduced liver weight, hepatic fat accumulation, AST, and cholesterol levels, while increasing markers associated with fatty acid oxidation and suppression of inflammatory signaling pathways. In LDLR−/− mice, ART7 reduced triglycerides by up to 56%, LDL-C by >35%, and non-HDL cholesterol by >35%, without lowering HDL-C. Significant reductions in hepatic steatosis (~60–75%), liver fat content, and plasma nonesterified fatty acids (NEFA) were also observed. Additional active ASOs demonstrated comparable or improved lipid-lowering efficacy, achieving triglyceride reductions of up to 70%. In head-to-head studies, FGF21-targeting ASOs achieved triglyceride lowering comparable to or greater than that achieved with FGF21 analogs. **Conclusion:** ART7 FGF21-upregulating ASOs represent a novel therapeutic strategy that enhances endogenous FGF21 expression and produces durable improvements in plasma lipid profiles and hepatic steatosis across multiple preclinical models. These findings support further development of FGF21-targeting ASOs as long-acting therapies for severe hypertriglyceridemia (SHTG) and metabolic liver disease.

3539 | EFFICACY AND SAFETY OF LIVPHCD™ CAPSULES VERSUS PLACEBO IN METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE: A MULTICENTER, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Chun-Jen Liu[1] Cheng Tiong[2] Yi-Hsiang Huang[3] Tung-Hung Su[1] Wei-Yu Kao[2] Chun-Chao Chang[2] Hsing-Jung Yeh[2] Wen-Chao Chen[2] Ya-Chun Wang[4] Wen Chuan Huang[4], [1]National Taiwan University Hospital, [2]Taipei Medical University Hospital, [3]Taipei Veterans General Hospital, [4]TCM Biotech International Corp.

Background: Metabolic dysfunction-associated fatty liver disease (MASLD) is the most common liver disease around the world. LivPhcD™ Capsule have shown hepatoprotective effects in both animal and human data. The aim of this clinical study (LivPhcD-001) is to assess LivPhcD™ Capsules's efficacy and safety in patients with MASLD. **Methods:** This clinical trial, LivPhcD-001, is a multicenter, randomized, double-blind, placebo-controlled, 36-week study that was initiated at 3 medical centers in Taiwan. Adults with FibroScan™ confirmed MASLD, defined as having a hepatic steatosis level with a controlled attenuated parameter (CAP) score of 238 dB/m or higher, with stage F0 to F3 fibrosis, were randomly assigned (1:1:1:1) to receive placebo or LivPhcD™ Capsules, low dose: 2 capsules, intermediate dose: 4 capsules, or high dose: 6 capsules per day. The primary endpoint was the proportion of patients with improvement in hepatic steatosis of at least 10% of CAP, based on analyses of baseline, week 24, and week 36 by FibroScan™. Prespecified secondary and exploratory efficacy and safety endpoints were also evaluated. **Results:** Totally, 125 patients with MASLD were screened, and 110 were randomized to receive either 2, 4, or 6 capsules of LivPhcD™ Capsule (n = 27, 28, 27) or placebo (n = 28). By Week 36, the treatment groups showed improvements in hepatic steatosis and biochemistry. Low and high dose groups showed a statistically significant reduction in CAP. MRI-PDFF in the high dose group decreased by 2.348% while the placebo group increased by 2.158%. A significant ALT improvement was also observed as early as week 24 in the intermediate and high dose groups ($P < 0.05$). At week 36, serum ALT level was significantly reduced in the low (-4.9 U/L), intermediate (-5.4 U/L), and high (-3.0 U/L) dose groups, whereas increased in the placebo group (6.5 U/L). Furthermore, the high dose group demonstrated lipid-lowering effects, with placebo-adjusted reductions of 19 mg/dL in total cholesterol and 19.5 mg/dL in LDL-C ($P < 0.05$). **Conclusion:** Patients with MASLD, treated with LivPhcD™ Capsule over 36 weeks demonstrated clinical benefits in reducing hepatic fat content, as evidenced by the consistent improvements in CAP and MRI-PDFF, alongside the stabilization of liver biochemistry. Notably, the significant reductions of LDL-C and total cholesterol showed that LivPhcD™ Capsule may offer additional cardiometabolic protection beyond its hepatic effects. These findings indicate the therapeutic potential of LivPhcD™ Capsule in addressing both liver steatosis and the associated cardiovascular metabolic risks in the MASLD population, and also support its continuing clinical development.(ClinicalTrials.gov,

3540 | SYNERGY OF SOAT2-INHIBITOR PRD001 WITH RESMETIROM IN REDUCING MASH AND FIBROSIS IN OBESE LDLR-/-.LEIDEN MICE

Eveline Gart[1], [1]TNO

Background: Metabolic-dysfunction associated steatohepatitis (MASH) is characterized by hepatic lipid accumulation and inflammation. Sterol *O*-acyltransferase 2 (SOAT2), formerly known as ACAT2, plays a key role in intestinal cholesterol absorption and hepatic secretion. Pharmacological inhibition of SOAT2 reduces cholesterol uptake, thereby limiting hepatic lipid accumulation and secretion. Combining a SOAT2-inhibitor with resmetirom, a thyroid hormone receptor-β (THR-β) agonist that promotes lipid oxidation, could provide complementary reductions in fat and plasma lipids. This study aimed to assess the effects of PRD001, a SOAT2-inhibitor, combined with resmetirom on MASH and liver fibrosis. **Methods:** 20-week high-fat diet (HFD) without cholesterol supplementation fed Ldlr-/-.Leiden mice received vehicle, resmetirom (3 mg/kg), or resmetirom + PRD001 (30 mg/kg) for 12 weeks. **Results:** Resmetirom and the combination treatment reduced body weight and fat mass, while increasing lean body mass as % of body weight. Fecal neutral sterol excretion, mainly driven by cholesterol excretion, was significantly increased with resmetirom and tended to be further enhanced when combined with PRD001. Resmetirom decreased plasma lipids and apoB with a significant further decrease for both when combined with PRD001. Lipoprotein profiles confirmed that this additional decrease was primarily due to a further decrease in VLDL- and LDL-cholesterol. Hepatic triglycerides and cholesterol esters were significantly decreased as well with resmetirom and combination with PRD001 led to a significant further decrease in hepatic cholesterol ester content. Hepatic macrovesicular steatosis, microvesicular steatosis, inflammation and fibrosis were all significantly reduced upon resmetirom treatment with a further decease in macro- and microvesicular steatosis when combined with PRD001. Hepatic gene expression confirmed involvement of (lipid)metabolism, inflammation pathways and mitochondrial pathways with more significant genes when resmetirom was combined with PRD001. **Conclusion:** Using an advanced translational MASH model, we demonstrate resmetirom improved MASH and hepatic fibrosis. Adding PRD001 provided additional benefits on cholesterol excretion, plasma lipids, lipoproteins and steatosis highlighting the complementary mechanisms of PRD001 and resmetirom. Given the CVD risk in MASH patients, the observed lowering of atherogenic lipoproteins underscore substantial clinical advantages for the combination treatment.

3541 | | CLINICAL OUTCOMES ASSOCIATED WITH GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONIST-STATIN COMBINATION VS MONOTHERAPY IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE - A TARGET TRIAL EMULATION STUDY

Mindie Nguyen[1] Hong Fan[2], [1]Stanford University Medical Center, [2]Stanford University

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is a multisystem condition characterized by intertwined metabolic, hepatic, and cardiometabolic risks. Although glucagon-like peptide-1 receptor agonists (GLP-1 RAs) and statins have been associated with improved hepatic and cardiometabolic outcomes, evidence on the real-world effectiveness of their combined use across different background treatment contexts remains limited. Our goal was to examine the associations of GLP-1 RA-statin combination therapy with hepatic and extrahepatic outcomes among patients with MASLD according to background treatment context. **Methods:** We conducted a large real-world cohort study emulating a target trial using a nationally representative claims database (Merative™ MarketScan®). Using an active-comparator new-user design with time-conditional propensity score matching, we compared add-on statin therapy versus continuation of GLP-1 RA monotherapy among GLP-1 RA initiators, and add-on GLP-1 RA therapy versus continuation of statin monotherapy among statin initiators, and evaluated the associated risks of cirrhosis, decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), cardiovascular disease (CVD), chronic kidney disease (CKD), and non-liver cancers among patients with MASLD. **Results:** Among GLP-1 RA initiators, add-on statin use was associated with lower risks of cirrhosis (hazard ratio [HR], 0.65; 95% CI, 0.53–0.80), DCC (HR, 0.65; 95% CI, 0.50–0.84), and non-liver cancers (HR, 0.73; 95% CI, 0.59–0.90) compared with GLP-1 RA monotherapy. Conversely, among statin initiators, add-on GLP-1 RA use was associated with a lower risk of CVD in the overall population (HR, 0.74; 95% CI, 0.61–0.89) and with lower risks of cirrhosis and DCC in metabolically high-risk subgroups (e.g., higher CCI, diabetes). Protective associations were more pronounced in metabolically high-risk subgroups in both sequential add-on cohorts. No significant associations were observed for other outcomes, and findings were consistent across sensitivity analyses. **Conclusion:** In this real-world MASLD population, GLP-1 RA-statin combination therapy was associated with significant clinical benefits compared with either monotherapy, with patterns of benefit varying by background treatment context that likely reflect differences in dominant clinical risk pathways. Findings support individualized and complementary treatment strategies in MASLD, in which GLP-1 RAs and statins may be used to target residual hepatic, metabolic, and cardiovascular risk according to patients' dominant disease pathways and background treatment context.

3542 | ANTISENSE-MEDIATED UPREGULATION OF HNF4α IMPROVES LIVER FIBROSIS IN PRECLINICAL MODELS OF MASH AND TOXIN-INDUCED LIVER INJURY

Lingdi Zhang[1] Terry Lin[1] Surendra Jain[1] Jian Li[1] Rich Thai[1] Lansha Peng[1] Xing Xian Yu[1] Yanfeng Wang[1] Xuehai Liang[1], [1]ARNATAR THERAPEUTICS INC

Background: HNF4α is a master transcription factor essential for hepatic differentiation, metabolic homeostasis, and liver function. Reduced hepatic HNF4α expression is associated with metabolic dysfunction-associated steatohepatitis (MASH), liver fibrosis, cirrhosis, and hepatocellular carcinoma. Although restoration of HNF4α expression has demonstrated therapeutic benefit in preclinical models, safe and clinically feasible strategies to precisely enhance endogenous HNF4α expression remain limited. Here, we developed antisense oligonucleotides (ASOs) using Arnatar's ACT-UP1™ upregulation platform to specifically enhance endogenous HNF4α protein translation and evaluated their therapeutic potential in preclinical liver fibrosis models. **Methods:** GalNAc-conjugated ACT-UP1 ASOs targeting the HNF4α 3′UTR were screened in cells across multiple species, followed by *in vivo* pharmacodynamic evaluation after subcutaneous administration.

The lead candidate, ART10, was evaluated in choline-deficient, L-amino acid-defined high-fat diet (CDAHFD)-induced MASH/fibrosis and carbon tetrachloride (CCl4)-induced liver fibrosis mouse models. Hepatic HNF4α expression and fibrosis markers, including αSMA and Collagen I, were quantified by Western blot. Downstream mRNA markers were analyzed by qRT-PCR. Fibrosis and steatosis were assessed by picrosirius red staining and histopathology. Plasma ALT and AST were measured as indicators of liver injury. **Results:** ACT-UP1 ASOs increased HNF4α protein expression by approximately 50–150% across *in vitro* systems and elevated hepatic HNF4α protein up to two-fold *in vivo*, with activity sustained for more than 3 weeks following dosing. In the CDAHFD-induced model, ART10 restored hepatic HNF4α expression, improved hepatic steatosis, and, importantly, reduced liver fibrosis, as demonstrated by decreased picrosirius red staining and reduced αSMA expression. In the CCl4-induced fibrosis model, ART10 also increased hepatic HNF4α protein, reduced fibrosis-associated markers, improved liver histopathology, and lowered plasma ALT and AST levels. ART10 treatment increased expression of downstream HNF4α target genes, including Albumin, F7, and Otc, while reducing expression of fibrosis and inflammatory markers, such as Col1a1, Acta2, and TNFα. ART10 was well tolerated in mice and no significant abnormalities were observed at doses up to 200 mg/kg. **Conclusion:** ASO-mediated translational upregulation of HNF4α using the ACT-UP1 platform restored hepatic HNF4α expression and reduced liver fibrosis, steatosis, and liver injury in multiple preclinical disease models, supporting ASO-mediated HNF4α upregulation as a promising disease-modifying therapeutic strategy for liver fibrosis.

3543 | SPIRONOLACTONE IS ASSOCIATED WITH ALT REDUCTIONS IN REPRODUCTIVE-AGED WOMEN WITH MASH: RESULTS OF A PILOT RANDOMIZED CONTROLLED TRIAL

Amanda Laguna[1] Ala Koreitem[1] Marcelle Cedars[1] Michael Ohliger[1] Helen Oberweis-Manion[1] Norah Terrault[2] Monika Sarkar[1], [1]University of California, San Francisco, [2]Keck Medical Center of USC

Background: Rates of metabolic dysfunction-associated steatohepatitis (MASH) have risen significantly over the past three decades, particularly in young adults. While higher androgen levels increase risk for presence and severity of MASH, the potential role of androgen receptor blockade on MASH-related outcomes has not been studied. **Methods:** This was a double-blind, pilot randomized controlled trial conducted at our center from 2017-2022 in reproductive-aged women with biopsy-confirmed MASH (n = 17). Participants were randomized 2:1 to spironolactone 100mg daily (n = 11) or placebo (n = 6). Study duration was 6 months with optional extension to 12 months, with end of study measures including metabolic labs, liver tests, magnetic resonance elastography (MRE), and proton-density fat fraction (PDFF). Between-group differences were evaluated using a Hodges-Lehmann estimate. Adjusting for baseline ALT, a linear mixed model was used to compare ALT levels at 6 months and 12 months. **Results:** Median ages in the spironolactone and the placebo groups were 35 and 27 years old, respectively (p = 0.48), with a lower percentage in the spironolactone group reporting Hispanic ethnicity (36% vs 83%, p = 0.13). Presence of polyendocrine metabolic ovarian syndrome (PMOS), formerly known as polycystic ovary syndrome, was more common in the spironolactone group (55% vs 33%, p = 0.62). Most of the participants had baseline biopsy-proven stage 1 (47%) or stage 2 (47%) fibrosis, and a smaller proportion had baseline stage 3 fibrosis (6%). Baseline ALT levels (71 U/L vs 59 U/L), body mass index (40 kg/m^2 vs 35 kg/m^2), presence of dyslipidemia (36% vs 33%), median HOMA-IR (5.4 vs 6.3), PDFF (19.6 vs 23.9%), and liver stiffness by MRE (2.5 kPa vs 2.2 kPa) were not significantly different between the spironolactone and placebo groups. On average, the ALT levels in the spironolactone group after 6 months of treatment were 77.0 units lower compared to those in the placebo group (95% CI, –201.0 to –10.0; p = 0.011; Figure 1A). Eleven patients (n = 8 spironolactone and n = 3 placebo) continued treatment to 12 months; both median free testosterone (95% CI, -52.5 to -0.60; p = 0.02) and total testosterone (95% CI -0.41 to -0.009; p = 0.032; Figure 1B) showed greater decline in the spironolactone vs the placebo group. There were no significant changes in BMI, lipid level, HOMA-IR, PDFF or MRE at 6 or 12 months. ALT levels were significantly lower in the spironolactone group at 12 months after adjusting for baseline ALT; the between-group difference in ALT levels was 131 U/L in the spironolactone vs placebo group (95% CI 33.5 to 229, p = 0.011). **Conclusion:** Spironolactone was associated with ALT reductions in reproductive-aged women with MASH. These data support the need to explore hormonal modulation as a potential mechanism for MASH treatment in the rising population of young female adults

3544 | MULTI-OMIC DISSECTION OF THE DIRECT MECHANISM OF ACTION OF EFRUXIFERMIN-MEDIATED REVERSAL OF LIPOTOXICITY IN PRIMARY HUMAN HEPATOCYTE

Michail Kokkorakis[1] Suyavaran Arumugam[2] Wajahat Mehal[2] Tim Rolph[3] Erik Tillman[3], [1]Yale School of Medicine, [2]Yale University, [3]Akero Therapeutics, a Novo Nordisk Company, Boston, United States

Background: Efruxifermin (EFX), a long-acting FGF21 analog, is in phase 3 development for MASH, yet the extent to which its therapeutic benefit derives from direct hepatocyte-autonomous action versus extrahepatic systemic effects remains unclear. We characterized the direct hepatocyte response to EFX using bulk RNA-sequencing and quantitative 4D-DIA proteomics in palmitate (PA) stressed primary human hepatocytes (PHH). **Methods:** PHH (single donor) were exposed to vehicle (Ctrl), PA (200 µM), or PA + EFX (10 nM) co-administered. Transcriptome (trans) was profiled at 4, 12, and 20h; proteome (prot) at 8, 16, and 24h. Differential expression analysis used DESeq2 (RNA) and limma (protein) with significance adjusted at $P < 0.05$ and $|\log2FC| > 0.5$. Pathway-level mean log2FC was computed across curated gene sets (MitoCarta, OXPHOS, fatty acid oxidation [FAO], TCA cycle, glycolysis/gluconeogenesis, ER stress, unfolded protein response (UPR), reactive oxygen species (ROS), translation). A rescue index was defined as the fraction of PA-dysregulated features whose direction of change was reversed by EFX co-treatment. Cross-omic discordance was assessed by matching RNA and protein significance status at corresponding timepoint pairs. **Results:** PA significnatly and extensively remodeled the trans (n = 7,581) and prot (n = 2,970 proteins), with induction of transcripts for UPR (mean log2FC +1.43 at 12 h, +1.68 at 20 h), ER stress (+1.04 at 20 h), suppression of OXPHOS (−1.02 at 12 h) and translation-machinery proteins (−0.63 at 24 h). EFX co-administration broadly reversed this signature: rescue index 81% (RNA, 20 h) and 97% (protein, 24 h). All 26 of 26 PA-perturbed FAO proteins were direction-reversed by EFX (24 of 26 with statistical significance), further rescue of gluconeogenesis (+1.70), glycolysis (+1.15), TCA (+0.56), and translation machinery (+0.44). GLYAT (log2FC +8.3) and ALDH1L1 (log2FC +4.6) were highly induced. 60–70% of EFX-modulated proteomic changes lacked a corresponding trans change at matched RNA timepoints (1,459 of 2,080 at 16 h; 1,261 of 2,095 at 24 h), implicating a substantial post-transcriptional component in the EFX response. PA expanded the mitochondrial proteome (+1.07 at 8 h), and EFX reversed it toward Ctrl by 24 h (−0.34). **Conclusion:** In primary human hepatocytes, PA induces extensive transcriptomi and proteomic reprogramming consistent with lipotoxicity, characterized by upregulation of the UPR and ER stress response, and downregulation of key metabolic pathways (FAO, glycolysis/gluconeogenesis, TCA cycle, protein translation). EFX reverses the lipotoxic transcriptional and proteomic signature induced by PA. A substantial post-transcriptional component implicates translational regulation and protein-stability control as a previously underappreciated layer of FGF21 signaling in human hepatocytes, consistent with the regulation of UPR and ER stress response pathways.

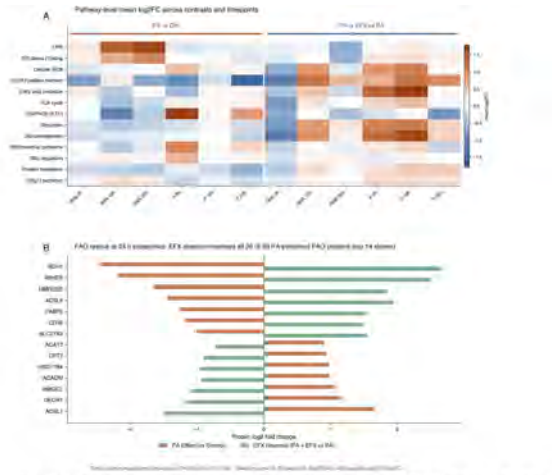

Figure. (A) Pathway-level mean log2FC across PA vs Ctrl and PA + EFX vs PA at all RNA-seq (4, 12, 20 h) and proteomics (8, 16, 24 h) timepoints. (B) Fatty acid oxidation proteins rescued by EFX co-administration at 24 h proteomics (top 14 shown of 26 PA-perturbed FAO proteins; EFX direction-reversed all 26, with 24 of 26 reaching statistical significance). Selection: significant in PA vs Ctrl (padj<0.05, |log2FC|>0.5) and showing opposite-direction log2FC in PA + EFX vs PA. Red bars = PA effect (vs Ctrl); green bars = EFX reversal (PA + EFX vs PA).

3545 | REAL-WORLD POST-MARKETING SAFETY PROFILE OF RESMETIROM COMPARED WITH PHASE 3 CLINICAL TRIAL: A FAERS PHARMACOVIGILANCE STUDY

Cherechi Nwabueze[1] Yetunde Akande[1] Chimezirim Ezeano[2] Eunice Omeludike[3] Ridwan Lawal[4] Ihunanya Kanu[5] Nzubechukwu Okeke[6] Ifekunwa Osanakpo[7] Ayokunle Abegunde[1], [1]John H. Stroger Jr. Hospital of Cook County, [2]Advocate Aurora Healthcare, [3]Piedmont Athens Regional Medical Center, [4]University of Texas Rio Grande Valley, [5]Baptist Memorial Hospital- Golden Triangle, [6]Zucker School of Medicine at Hofstra/ Northwell at Vassar Brothers Medical Center, [7]Carle Foundation Hospital

Background: Resmetirom is a newly approved therapy for metabolic dysfunction-associated steatohepatitis (MASH) and real-world safety data is limited. We aimed to characterize post-marketing adverse events and evaluate disproportionality signals for resmetirom. **Methods:** We analyzed data from the FDA Adverse Event Reporting System (FAERS) from 2024-2025. Case reports identifying resmetirom as the primary suspect were isolated and deduplicated. Adverse events (AE) were categorized using MedDRA preferred terms. Disproportionality analyses were conducted using reporting odds ratios (RORs) with 95% confidence intervals (CIs) comparing resmetirom-associated reports with all other drugs in FAERS database. Stratified sub-analyses evaluated safety outcomes across age, sex, polypharmacy (≥ 5 concurrent medications), and concomitant statin use. **Results:** A total of 1,279 unique resmetirom-associated FAERS reports were identified. Among reports with available demographic data, 66% were female, mean age was 56.7 ± 13.0 years (94% aged ≥ 65 years), with polypharmacy (31%) and concurrent statin use (16%). Gastrointestinal AEs predominated, including diarrhea (242), nausea (228), vomiting (76), constipation (60), and abdominal pain (58), while pruritus was reported in 207 cases. Hepatic AEs included alanine aminotransferase elevation (113), aspartate aminotransferase elevation (110), bilirubin elevation (53), 6 reports of drug-induced liver injury and rare cases of acute-on-chronic liver failure. Gallbladder-related AEs included cholelithiasis (9), cholecystitis (7), and cholangitis (3). Among reports with serious outcomes (370), hospitalization occurred in 24%, death in 13%, life-threatening events in 2.2%, and disability in 1.6%. Strong disproportionality signals were identified across all domains, with hepatic AEs showing the highest signal (ROR 12.17; 95% CI 10.43-14.21). Significant signals were also seen for GI events (ROR 3.94; 95% CI 3.53–4.39), driven by diarrhea (ROR 5.03), nausea (ROR 4.50), and vomiting (ROR 2.46), as well as gallbladder-related events (ROR 3.62). Hepatic AEs were absent in patients < 45 years but occurred in 14.8% of those 45–64 years and 14.7% of those ≥ 65-years. Polypharmacy was associated with higher hepatic (22.2% vs 11.1%) and GI event reporting rates (41.9% vs 31.5%). Concurrent statin use was associated with increased hepatic (29.3% vs. 11.8%), GI (39.9% vs 33.8%), and gallbladder-related events (3.5% vs. 1.4%). GI and hepatic reporting frequencies were comparable between sexes. **Conclusion:** Post-marketing resmetirom safety data align with Phase 3 trial findings for GI adverse events but demonstrate stronger hepatobiliary signals, particularly in older adults, those with polypharmacy, and concomitant statin users. While causality cannot be established, these findings support ongoing surveillance and targeted clinical monitoring as real-world resmetirom use expands.

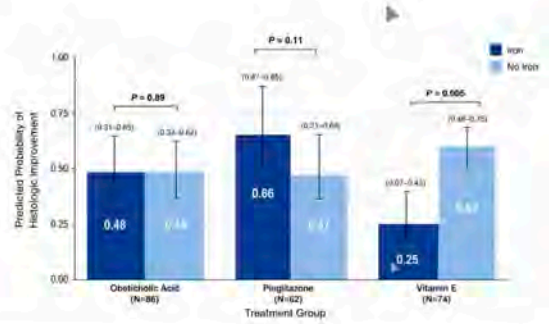
Seattle, [2]Liver Institute Northwest, [3]Department of Epidemiology, Bloomberg School of Public Health, Johns Hopkins University, Baltimor, [4]Laboratory of Pathology, National Cancer Institute, Bethesda, MD, [5]University of California, San Diego, [6]Division of Gastroenterology and Hepatology, University of California at San Diego, La Jolla., [7]Division of Gastroenterology and Hepatology, University of California San Francisco, California,, [8]Cleveland Clinic, [9]Virginia Commonwealth University, [10]Division of Gastroenterology and Hepatology, Saint Louis University School of Medicine, St. Louis, [11]Indiana University Medical Center, [12]Division of Gastroenterology and Hepatology, Duke University, Durham, North Carolina, USA.



Background: Metabolic dysfunction-associated Steatotic liver disease (MASLD) affects ~ 30% of the global population with a subset progressing to MASH, which is associated with increased risk of cirrhosis and liver-related morbidity. Hepatic iron deposition is observed in 35-48% of patients with MASLD and has been implicated in hepatocellular injury and fibrogenesis through oxidative stress-mediated mechanisms. Prior studies have reported associations between hepatic iron deposition patterns and advanced histologic disease severity. However, the impact of hepatic iron on response to pharmacologic therapy in MASH has not been evaluated. We aimed to determine whether baseline hepatic iron deposition influences treatment response in patients enrolled in NASH CRN trials. **Methods:** We conducted a pooled secondary analysis of adults with biopsy-proven MASH enrolled in the NASH Clinical Research Network. 374 patients (201 from PIVENS and 173 from FLINT) with baseline and end of treatment liver biopsies with iron staining data were included. Participants randomized to obeticholic acid (n = 87), pioglitazone (n = 62), vitamin E (n = 76) or placebo (n = 149) were included. The primary outcome was histologic improvement, defined as ≥ 2-point reduction in NAFLD Activity Score (NAS) without worsening of fibrosis. Multivariable logistic regression was used to evaluate the association between iron deposition and histologic improvement, including interaction terms between iron deposition and treatment group. Models were adjusted for age, sex, Hispanic ethnicity, BMI, and diabetes. Adjusted predicted probabilities of histologic improvement were estimated for each combination of iron deposition and treatment group using marginal effects from the fitted model. Additional analyses stratified by treatment group were performed. **Results:** Mean age was 49 yrs, 63% were female, 13% Hispanic, and mean BMI was 34.3 ± 6.6. Hepatic iron deposition was present in 38% of baseline biopsies. The mean NAS score was comparable between patients with and without iron deposition (5.1 vs 5.2, p = 0.46). Response to Vitamin E was significantly influenced by iron deposition (P for interaction = 0.001), while no significant effect modification was observed for obeticholic acid or pioglitazone. In treatment-stratified analyses, Vitamin E treated patients with iron deposition had lower odds of histologic improvement compared to those without iron deposition (aOR-0.16 (95% CI 0.04-0.57), p = 0.005) (T1).The predicted histologic improvement among Vitamin- E treated with iron deposition was 0.25 (0.07-0.43), compared with 0.62 (0.48-0.75) among those without iron deposition (F1) **Conclusion:** Presence of stainable hepatic iron is associated with the attenuation of histological response to Vitamin E. We hypothesize that increased oxidative stress generated by hepatic iron deposition limits the efficacy of Vitamin E among patients with MASH

Table 1. Stratified analysis – logistic regression analysis of iron deposition on histologic improvement by treatment group*

	Odds Ratio (95% PI) for Histologic Improvement	P
Any iron vs. no iron – Obeticholic acid group (N=86)	1.07 (0.43 – 2.66)	0.89
Any iron vs. no iron – Pioglitazone group (N=62)	3.03 (0.79 – 11.67)	0.11
Any iron vs. no iron – Vitamin E group (N=74)	0.16 (0.04 – 0.57)	0.005

*Individual logistic regression models for each treatment group; outcome was histologic improvement, and primary covariate was any iron deposition vs. no iron deposition. Models were adjusted for age, sex, Hispanic ethnicity, and BMI. Obeticholic acid model N=86 and vitamin E model N=74 due to missing BMI in 3 participants.

Figure 1- Predicted probability of histologic improvement by iron deposition and treatment group*

* Adjusted predicted probabilities from logistic regression model with interaction terms for iron deposition and treatment group; models adjusted for age, sex, Hispanic ethnicity, BMI, and diabetes status.

3547 | COMPARATIVE EFFICACY OF MONO- AND DUAL-INCRETIN AGONISTS FOR HISTOLOGIC OUTCOMES IN MASH: A SYSTEMATIC REVIEW AND META-ANALYSIS WITH NARRATIVE SYNTHESIS OF EMERGING TRIPLE INCRETIN AGONIST DATA

Gunjan Malhotra[1] Gurkirat S. Brar[2] Simrat Kaur Parmar[3] Ankuriti Singla[4] Hargun Malhotra[5] Christine Bruno[1] Anish Chopra[1], [1]Northwest Health Porter, [2]Dayanand Medical College, [3]Punjab Institute of Liver and Biliary Sciences, SAS Nagar, Mohali, Punjab, India, [4]Carle Foundation Hospital, [5]Sri Guru Ram Das University of Health Sciences

Background: Metabolically-dysfunction-associated steatohepatitis (MASH) is a progressive liver disease and the leading indication of liver transplantation, with semaglutide representing the first approved pharmacotherapy as of 2025. Mono- and dual-incretin-based therapies targeting glucagon-like-peptide-1(GLP-1), glucose-dependent insulinotropic polypeptide, and glucagon receptor pathways have demonstrated reductions in hepatic steatosis, inflammation, and fibrosis, whereas evidence for triple agonists remains limited to radiologic outcomes. We performed a PRISMA-compliant systematic review and meta-analysis of incretin-based therapies with a narrative synthesis of triple agonist data. **Methods:** Randomized controlled trials published through April 2026 were included. Six biopsy-confirmed trials (n = 1,371) evaluating mono GLP-1 receptor agonists (semaglutide, liraglutide) and dual incretin agonists (tirzepatide, survodutide, pemvidutide) assessed MASH resolution without worsening fibrosis as the primary outcome. A parallel radiologic subanalysis included six trials (n = 556) reporting $\geq$30% reduction in MRI-PDFF. Pooled risk ratios were estimated using Mantel-Haenszel random-effects models with REML. Heterogeneity was assessed using I^2 and Cochran's Q, with robustness evaluated through leave-one-out sensitivity analyses. Small-study effects were explored using contour-enhanced funnel plots, and risk of bias was assessed using Cochrane Risk of Bias 2.0. **Results:** Incretin-based therapies significantly increased MASH resolution without worsening fibrosis compared with placebo (RR 3.19, 95% CI 2.15–4.75; $p < 0.001$). Between-study heterogeneity was substantial ($I^2 = 74.4\%$; $\tau^2 = 0.147$), but pooled estimates remained consistent; the test for subgroup differences between mono- and dual-incretin agonists was not significant ($\chi^2 = 3.15$, $p = 0.207$)Radiologically, incretin therapy was associated with a greater likelihood of $\geq$30% MRI-PDFF (RR 5.54, 95% CI 4.03–7.61; $p < 0.001$) without heterogeneity ($I^2 = 0\%$, Q $p = 0.53$). Leave-one-out analyses confirmed robustness (biopsy RR range 2.86–3.72; MRI-PDFF RR range 5.27–6.54). Funnel plots showed no asymmetry, though interpretation was limited by a small trial count (k = 6). The retatrutide phase 2a substudy demonstrated substantial reductions in liver fat (up to 86% at 48 weeks) and cardiometabolic improvements, but lacked biopsy-confirmed endpoints, precluding quantitative analysis. **Conclusion:** Mono- and dual-incretin agonists significantly improve histologic and radiologic outcomes in MASH with consistent effects across drug classes. No definitive class differences can be established without head-to-head trials. Evidence for triple agonists remains limited to early radiologic outcomes, and phase 3 biopsy-confirmed data for retatrutide are needed to

define its histologic efficacy and clinical role.

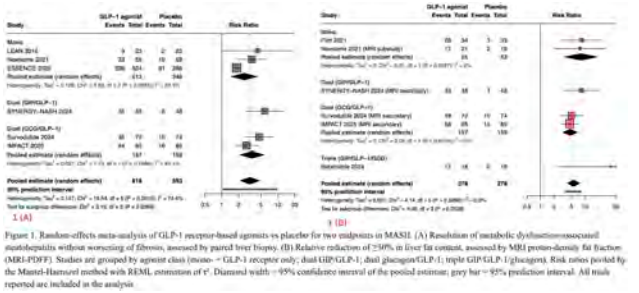

Figure 1. Random-effects meta-analysis of GLP-1 receptor-based agonists vs placebo for two endpoints in MASH. (A) Resolution of metabolic dysfunction-associated steatohepatitis without worsening of fibrosis, assessed by paired liver biopsy. (B) Relative reduction of ≥30% in liver fat content, assessed by MRI proton-density fat fraction (MRI-PDFF). Studies are grouped by agonist class (mono- = GLP-1 receptor only; dual GIP/GLP-1; dual glucagon/GLP-1; triple GIP/GLP-1/glucagon). Risk ratios pooled by the Mantel-Haenszel method with REML estimation of τ^2. Diamond width = 95% confidence interval of the pooled estimate; grey bar = 95% prediction interval. All trials reported are included in the analysis.

3548 | EFRUXIFERMIN IMPROVED FIBROSIS IN PARTICIPANTS WITH MASH CIRRHOSIS AND MULTIPLE CARDIOMETABOLIC COMORBIDITIES: A POST HOC ANALYSIS OF THE SYMMETRY PHASE 2B TRIAL

Mary Rinella[1] Alex Liberman[2] Sonja Billes[2] Meena Jain[2] Mazen Noureddin[3], [1]The University of Chicago, Pritzker School of Medicine, [2]Akero Therapeutics, a Novo Nordisk company, [3]Houston Methodist Hospital

Background: Individuals with MASH and multiple cardiometabolic (CM) comorbidities are at higher risk for adverse outcomes. Efruxifermin improved fibrosis and CM parameters in phase 2b trials in participants with MASH. We evaluated the efficacy of efruxifermin in subgroups of participants with MASH and compensated cirrhosis (F4c) based on the number of CM comorbidities at baseline. **Methods:** This post hoc analysis included participants with MASH and biopsy-defined F4c from the SYMMETRY randomized placebo-controlled trial (NCT05039450). Participants were grouped by the number of baseline CM comorbidities: T2D, obesity, hyperlipidemia, and hypertension. We evaluated the change from baseline at Week 96 in fibrosis improvement and additional efficacy measures. **Results:** Most participants had ≥2 CM comorbidities at baseline (1 comorbidity n = 5, 2 n = 35, 3 n = 62, 4 n = 79). Baseline characteristics were generally more severe for participants with 3 or 4 comorbidities (mean ± SD LSM 25.1 ± 13.7 kPa, ELF 10.5 ± 0.8, TG 156 ± 74 mg/dL, HOMA-IR 13.0 ± 11.6, HbA1c 6.8 ± 1.1%) than the group with ≤2 comorbidities (mean ± SD LSM 22.2 ± 11.8 kPa, ELF 10.5 ± 0.9, TG 132 ± 54 mg/dL, HOMA-IR 7.1 ± 5.9%, HbA1c 6.2 ± 0.9). Regardless of the number of comorbidities at baseline, 96 weeks of treatment with efruxifermin vs placebo resulted in improvements in fibrosis and CM parameters (Table). Efruxifermin was generally well tolerated. Mild to moderate gastrointestinal events were more common with efruxifermin than placebo. **Conclusion:** Participants with MASH and compensated cirrhosis and more CM comorbidities had worse measures of disease severity, indicating higher risk of clinical outcomes. In these participants, efruxifermin improved fibrosis and other efficacy measures at Week 96. Phase 3 trials of efruxifermin in MASH with moderate to severe (F2/F3) fibrosis or cirrhosis are ongoing.

Table. Summary of Week 96 efficacy measures in participants with F4c MASH by number of baseline cardiometabolic comorbidities.

	≤2 comorbidities			3-4 comorbidities

3549 | TIRZEPATIDE VS. CAGRISEMA IN TREATING OBESE PATIENTS WITH TYPE 2 DIABETES MELLITUS AND METABOLIC DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE

Savvoula Savvidou[1] Aikaterini Damianakou[1] Elektra Augousti-Varela[1] Miltiadis Chalkias[1] Ioannis Stergiou[1], [1]"G.GENNIMATAS" General Hospital of Thessaloniki

Background: Recent research has been focused on the development of more effective anti-obesity drugs like the dual glucogen like peptide (GLP)-1 / gastric inhibitory polypeptide (GIP) agonist, tirzepatide, and the combination of GLP-1 semaglutide with the amylin analogue cagrilintide, named CagriSema. Aim of this study was to compare the efficacy of these two pharmacological agents in a small cohort of obese patients with type 2 diabetes mellitus (T2DM) and metabolic dysfunction associated steatotic liver disease (MASLD). **Methods:** Data was recorded retrospectively from consecutive patients who were treated with subcutaneous weekly injections of either tirzepatide 15mg (=group 1) or CagriSema 2.4mg (=group 2) for a six-month period following gradual drug titration as indicated per study protocols. Apart from recordings of glycated haemoglobulin (HbA1c), body weight and lipidemic profile, liver biochemistry as well as non-invasive scores of fibrosis (FIB-4 and Liver Risk score) were calculated. Statistical comparison between groups was performed with chi-square and Mann-Whitney U test, while Wilcoxon signed rank test for paired samples was used in order to investigate drug efficacy. **Results:** A total of 30 patients with obesity, T2DM and MASLD were included, with their baseline characteristics shown in Table 1. Group 1 patients were almost 1 decade younger and had higher baseline ALT. Both groups included mostly MASLD patients with low risk for advanced fibrosis (FIB-4 < 1.30) and minimal to

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

low risk for liver-related outcomes (Liver Risk score < 10).Treatment led the total of participants to lose weight (median -8,46kg, range -1.6 to 20.2kg, Δ = -9.4% from baseline), to improve glycemic control (median HbA1c -1.75%, range -0.8 to 2.4%), to reduce total cholesterol (median drop -20.4mg/dL) and to improve ALT by median 20U/L (IQR -9 to -31) (Wilcoxon signed rank test, p < 0.01). When comparing two groups, CagriSema led to higher weight loss (-16.4% vs.-5.9%, p < 0.001), even though there was no benefit regarding all other parameters investigated. **Conclusion:** The results of this small, short-term, intervention study showed that both tirzepatide and CagriSema were effective in improving body weight, glycemic control, lipids and hepatic biochemisty when administered to patients with obesity, T2DM and MASLD.

3550 | IMEGLIMIN MITIGATES LIVER INJURY IN A NONDIABETIC MASH MODEL THROUGH IMPROVEMENT OF MITOCHONDRIAL FUNCTION

Kosuke Kaji[1] Norihisa Nishimura[1] Shinya Sato[1] Masafumi Oyama[1] Tatsuya Nakatani[1] Tadashi Namisaki[2] Hitoshi Yoshiji[1], [1]Department of Gastroenterology, Nara Medical University, [2]Nara medical university

Background: Metabolic dysfunction–associated steatohepatitis (MASH) may develop and progress to fibrosis even in individuals without diabetes. Impaired mitochondrial function is considered a key driver of disease progression by reducing fatty acid oxidation, increasing oxidative stress, and promoting hepatocellular injury and fibrogenesis. Imeglimin is an antidiabetic drug known to improve mitochondrial bioenergetics, but its potential hepatoprotective effects independent of glucose metabolism remain poorly characterized. This study investigated whether imeglimin ameliorates liver injury and fibrosis in a nondiabetic model of MASH by restoring mitochondrial function. **Methods:** Male C57BL/6J mice were fed a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) for 8 weeks to establish a nondiabetic MASH model. Mice received oral imeglimin (100 or 200 mg/kg, twice daily) or vehicle. Hepatic steatosis, inflammation, apoptosis, and fibrosis were evaluated using histological and biochemical analyses. Mitochondrial function was assessed by examining oxidative stress, mitochondrial biogenesis, and fatty acid oxidation–related pathways. In vitro experiments were performed using palmitic acid (PA)-treated human hepatocytes to assess the effects of imeglimin on lipid accumulation, inflammatory responses, apoptosis, mitochondrial membrane potential, respiratory chain activity, and oxygen consumption. **Results:** CDAHFD-fed mice developed steatohepatitis and liver fibrosis without evidence of hyperglycemia. Treatment with imeglimin markedly improved hepatic steatosis, inflammatory activity, and hepatocyte ballooning. These improvements were associated with recovery of genes involved in fatty acid oxidation and a substantial reduction in hepatic reactive oxygen species levels. Imeglimin also promoted mitochondrial biogenesis, as indicated by increased expression of PGC-1α and TFAM, while reducing hepatocyte apoptosis and macrophage-driven inflammatory responses. As a result, hepatic fibrotic changes were significantly attenuated. In cultured hepatocytes, imeglimin reduced PA-induced lipid accumulation, inflammatory cytokine expression, and apoptotic cell death. Furthermore, imeglimin restored mitochondrial membrane potential, enhanced respiratory chain complex activity, increased oxygen consumption, and stimulated mitochondrial biogenesis. **Conclusion:** Imeglimin alleviates liver injury and fibrosis in a nondiabetic MASH model by improving mitochondrial function, promoting fatty acid oxidation, and limiting oxidative stress–induced hepatocyte damage. These glucose-independent hepatoprotective actions suggest that imeglimin could be a promising therapeutic strategy targeting mitochondrial dysfunction in MASH.

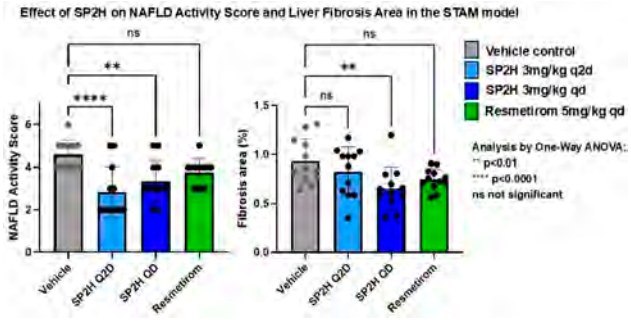
3551 | TARGETED DEGRADATION OF STING (STIMULATOR OF INTERFERON GENES) BY SP2H REDUCES NAFLD ACTIVITY SCORE AND LIVER FIBROSIS IN A MOUSE MODEL OF MASH



Magnus Strandh[1] Hannes Baukmann[2] Roman Fudim[2] Martin Jakobsen[3] Claus Olesen[1] Marco Schmidt[2] Richard Bethell[1], [1]Sulis Therapeutics, Copenhagen, Denmark, [2]Biotx.ai GmbH, Potsdam, Germany,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

[3]Department of Biomedicine, Aarhus University, Denmark

Background: As well as inducing inflammation, STING has been reported to regulate metabolic pathways and induce fibrosis, and its genetic depletion in mice protects against the development of MASLD and MASH. SP2H is a potent and highly selective targeted STING degrader that causes deep depletion of STING in the liver and other peripheral organs in mice. To date, drug-target Mendelian Randomization (MR), a genetic epidemiology approach that uses inherited genetic variants as "natural" experiments to assess the causal effects of altering drug target expression on disease outcome, has not been applied to STING and MASLD. **Methods:** The effect of genetic variants on STING expression was assessed using expression quantitative trait locus data from the GTEx consortium. The effects of these variants on MASLD risk and on expression biomarkers were assessed using inverse-variance weighted MR, weighted median MR and MR-Egger regression methods to account for correlated variants. The effect of SP2H in the STAM model of MASH was assessed in male C57BL6 mice (n = 12/group). Mice received a low dose of streptozotocin at age two days and were then fed a high fat diet starting at four weeks of age. Mice were treated with vehicle, or one of two SP2H regimens (3mg/kg sc qd or 3mg/kg sc q2d), or resmetirom (5mg/kg po qd) for three weeks, starting at age five weeks. At week eight the liver fibrosis area, assessed by Sirius Red staining, and NAFLD Activity Scores (NAS) in fixed liver tissue samples were quantified by pathologists blinded to group assignment. **Results:** A significant positive correlation between STING expression and MASLD risk was found using data from the GWAS metaanalysis of the eMERGE, Estonian Biobank, UK Biobank and Finngen cohorts. This result was supported by significant correlations between STING expression and biomarkers that have been shown to be correlated with the risk of MASLD from individual GWAS cohorts. The effect estimates in all the MR studies were positive.Both SP2H dose regimens led to numerical reductions in all three components of NAS in STAM mice, leading to > 1.0 reductions in the NAS compared to the vehicle control group ($p < 0.0001$ for SP2H q2d, $p < 0.01$ for SP2H qd, 1-way ANOVA). The higher dose of SP2H also significantly reduced liver fibrosis area compared to the control group ($p < 0.01$, 1-way ANOVA). While resmetirom treatment resulted in numerical reductions in NAS and liver fibrosis, these effects did not reach statistical significance. SP2H was well tolerated, with no clinical signs, in both dose groups. **Conclusion:** The MR analysis provides robust evidence that STING expression is positively correlated with the risk of developing MASLD in large population cohorts. In the STAM model, both SP2H treatment regimens resulted in significant reductions in NAS, and the higher dose also had a significant antifibrotic effect. These translational data provide strong support for the clinical development of SP2H as a treatment for MASLD and MASH.

3552 | LANIFIBRANOR IMPROVES LIVER SINUSOIDAL ENDOTHELIAL CELL DYSFUNCTION AND VASCULAR ALTERATIONS ACROSS ALL STAGES FROM MASH TO CIRRHOSIS

Guillaume Wettstein[1] Pierre-Emmanuel Rautou[2] Shivani Chotkoe[3] Wilhelmus Kwanten[4] Valerie Paradis[5] Jordi Gracia-Sancho[6] Manal Abdelmalek[7] Sven Francque[3], [1]Inventiva, [2]Université Paris-Cité, Inserm, Centre de recherche sur l'inflammation; AP-HP, Hôpital Beaujon, Servi, [3]Department of Gastroenterology and Hepatology, Antwerp University Hospital, Belgium, [4]University Hospital Antwerp, [5]Université Paris-Cité, Inserm, Centre de recherche sur l'inflammation; AP-HP, Hôpital Beaujon, Depar, [6]IDIBAPS - Hospital Clínic Barcelona, [7]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is traditionally characterized by steatosis, inflammation and fibrosis. However, growing evidence indicates that vascular dysfunction is an additional and crucial hallmark of disease pathogenesis. Liver sinusoidal endothelial cell (LSEC) capillarisation, increased intrahepatic vascular

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

resistance and portal hypertension have been shown to develop early in the disease course, already at the stage of isolated steatosis, and to contribute to disease progression to steatohepatitis and progressive fibrosis through impaired hepatic microcirculation, inflammation and fibrogenesis. We assessed the effects of the pan-PPAR agonist lanifibranor on LSEC phenotype and on vascular abnormalities across the spectrum from isolated steatosis over MASH to cirrhosis. **Methods:** Human liver biopsies from patients with MASLD/MASH enrolled in the NATIVE Phase2b study were examined by CD34 staining. Also, preclinical models of early MASLD, MASH and cirrhosis, were analyzed. In the latter, LSEC capillarisation was also evaluated using CD34 staining and additionally by ultrastructural analyses using Scanning Electron Microscopy (SEM) and Transmission Electron Microscopy (TEM). Furthermore, LSEC phenotypes, portal pressure, intrahepatic vascular resistance and the determinants hereof were extensively studied in experimental models. **Results:** In human MASLD liver biopsies, we demonstrated a progressive pattern of sinusoidal remodelling across inflammation grades and fibrosis stages, ranging from preserved fenestrae in isolated steatosis to pronounced capillarisation in advanced fibrotic and cirrhotic MASH. In preclinical models, LSEC capillarisation was detected at the earliest stages of MASLD, including isolated steatosis, and progressively worsened with increasing inflammation and fibrosis. Increased CD34 staining, impaired endothelial function and elevated intrahepatic vascular resistance were consistently observed before the development of advanced fibrosis. In these models, lanifibranor improved LSEC fenestrae frequency and porosity observed by TEM and SEM. These changes were associated with reduced portal pressure and, in the models of cirrhosis, reduced features of decompensation (*e.g.*, ascites). In patients treated with lanifibranor, CD34 staining patterns significantly decreased compared to placebo, demonstrating an improvement of liver endothelial alterations. **Conclusion:** Vascular dysfunction represents an early and central feature of MASH pathophysiology. LSEC alterations occur early in the disease course, contribute to early-onset portal hypertension and to disease progression and ultimate severity. Lanifibranor improves LSEC alterations and associated intrahepatic vascular abnormalities across multiple stages of disease, supporting the development of lanifibranor in MASH patients, including those suffering from advanced disease/cirrhosis.

3553 | EVALUATION OF TAURINE AS TREATMENT IN DIET-INDUCED METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Yongtao Wang[1] Jonathan Williams[2] Tanvi Patel[1] Wenyu Lin[1] Kenneth Tanabe[1] Snehal Chaudhari[2] Raymond Chung[1], [1]Massachusetts General Hospital and Harvard Medical School, [2]University of Wisconsin-Madison

Background: Taurine is a naturally occurring amino sulfonic acid vital for cardiovascular, neurological, and muscular function, playing crucial roles in nerve growth, cellular hydration, and antioxidant defense. While we have observed a depletion of taurine across several metabolic dysfunction-associated steatohepatitis (MASH) models, its therapeutic potential remains unclear. Here, we hypothesize that taurine supplementation can prevent and alleviate liver injury and fibrosis. **Methods:** Eight-week-old male Wistar rats were fed a choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD) for 6 weeks to induce MASH. After the initial 2 weeks of diet induction, rats were treated with either taurine (1 g/kg body weight) *ad libitum* in drinking water or a water control for the remaining 4 weeks (n = 8 per group). Molecular, biochemical, and histological assessments were subsequently performed. **Results:** In prior work, hepatic taurine deficiency and the down-regulation of its key regulatory gene, cysteine dioxygenase 1 (*Cdo1*), were observed in both CDAHFD and Gubra Amylin NASH (GAN) diet-induced MASH models. Bioinformatics analysis confirmed decreased *Cdo1* expression in GAN-induced MASH livers, which negatively correlated with inflammatory and profibrogenic markers. This decreased hepatic taurine content was also observed in human MASH. In the CDAHFD model, taurine supplementation successfully restored hepatic taurine content and rescued the suppressed *Cdo1* expression. Consequently, taurine treatment led to an increase in body weight, improved serum liver chemistry indices (total bilirubin and albumin), and attenuated hepatic lipid accumulation. Histological analysis via the NAFLD Activity Score (NAS) revealed that taurine supplementation significantly reduced hepatocyte ballooning. Furthermore, taurine intervention ameliorated liver fibrosis, as evidenced by reduced collagen deposition, improved fibrosis scores,

and the downregulation of inflammatory and profibrogenic genes. **Conclusion:** Taurine supplementation mitigates hepatic taurine deficiency and alleviates liver damage and fibrosis in a CDAHFD-induced MASH model via a *Cdo1*-dependent pathway. These findings suggest that taurine supplementation holds therapeutic promise for the treatment of MASH and related progressive liver diseases.

3554 | METABOLIC AND IMMUNOREGULATORY EFFECTS OF CBG IN MASLD AND MASH *IN VITRO* AND *IN VIVO*

Fariha Tasnim[1] Kira Villarreal[1] Cayla Jackson[1] Dexter Chiong[1] Nicholas Pullen[1] Yuyan Han[1], [1]University of Northern Colorado

Background: Emerging evidence suggests activation of different immune cell populations is involved in the progression of MASLD to its advanced stage, MASH. Thus, along with lipogenic, oxidative, and fibrotic markers, exploring immune cell activation and recruitment can enhance the understanding of MASLD pathogenesis and identify therapeutic targets. Previous studies have showed that, CBG, a non-psychotropic cannabinoid, reduces low grade chronic inflammation in MCD diet-induced MASH in mice. However, its role on macrophage polarization as well its effects on HFD diet induced MASLD mice models that better recapitulate metabolic dysfunction remain unexplored. **Considering this, the study explores the efficacy of CBG in MASLD and MASH-associated metabolic dysfunction, inflammation, and the underlying molecular mechanism. Methods:** To find the potential of CBG in reducing the metabolic syndrome, serum insulin and adiponectin (insulin-sensitizing hormone) levels were evaluated by ELISA. Additionally, A combination of free fatty acids (palmitic and oleic acid) followed by CBG treatment was applied to evaluate lipid accumulation in an immortalized hepatocyte cell line (FL83B). To test CBG's effect in MASLD and MASH-associated inflammation, the general leukocyte population (CD45+), ductal proliferation (CK19), and liver resident macrophages (F4/80) were assessed by IHC. To evaluate the effect of CBG on macrophage polarization, infiltrating monocyte-derived macrophages— pro-inflammatory M1 (CD86) and anti-inflammatory M2 (CD206) were assessed by flow cytometry in hepatic non-parenchymal cells (NPC) and in bone marrow derived macrophages (BMDMs). The inflammatory cytokines, IL-6, and IFN-γ in BMDM supernatants were assessed by ELISA. Finally, to understand the mechanisms of disease pathogenesis, nuclear receptor (PPARγ, a CBG agonist), the fatty acid transporter (CD36), de novo lipogenesis (DNL) enzyme (ACC1), transcription factor (SREBP-1c), and a mitochondrial beta oxidation biomarker (PPARα) were evaluated using the Western blot. **Results:** CBG treatment significantly increased serum adiponectin levels in male mice and showed a trend of decrease in insulin levels in female mice. In vitro, CBG treatment significantly reduced intracellular lipid accumulation in the FL83B cell line. Regarding inflammation, CBG reduced leukocyte and Kupffer cell population, ductular proliferation and secretion of proinflammatory cytokines—IL-6 and IFN-γ. CBG also reduced M1 macrophage populations in both NPCs and in BMDMs. Additionally, CBG showed an increased trend for both PPARα and PPARγ level, with no change in CD36 and ACC1 level. **Conclusion:** Our findings highlight the promising therapeutic potential of CBG in MASLD and MASH and support further investigation of CBG in mitigating disease progression by targeting hepatic inflammation and metabolic dysregulation.

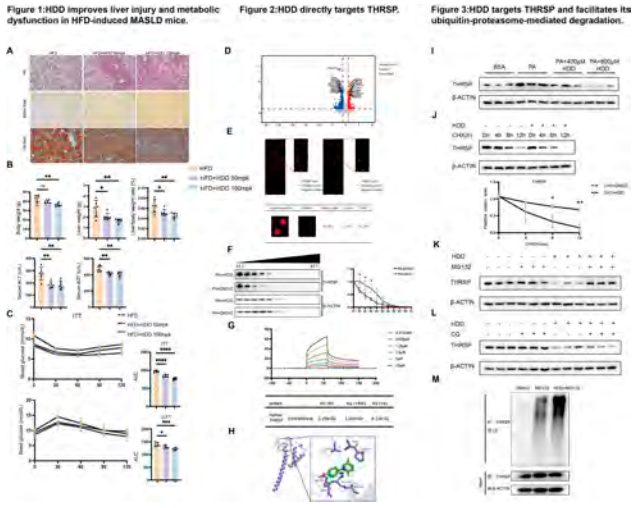
3555 | HYDRONIDONE ALLEVIATING MASLD-ASSOCIATED LIVER FIBROSIS BY TARGETING THRSP



Yufei Yang[1] Qichao Ge[1] Yuecheng Guo[1] Junjun Wang[1] Hanjing Zhangdi[1] Zhuqiong Lu[1] Jie Jian[1] Guangwen Chen[1] Ying Luo[2] Ling Zhang[2] Hui Dong[1] Lungen Lu[1], [1]Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, [2]Continent Pharmaceuticals Co. ,Ltd., Beijing, China

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a chronic liver disease characterized by hepatic steatosis, inflammation, hepatocellular injury, and liver fibrosis, yet effective therapeutic targets remain limited.Hydronidone(HDD) has demonstrated favorable therapeutic efficacy against liver fibrosis in patients with hepatitis B in both Phase II and Phase III clinical trials. In this study, we investigated the therapeutic effects of HDD on MASLD and explored the underlying molecular mechanism. **Methods:** Male mice aged 6–8 weeks were fed a high-fat diet (HFD) and administered HDD by oral gavage at doses of 50 mpk and 100 mpk. A protein microarray was employed to identify the therapeutic targets of HDD, which were further validated by **cellular thermal shift assay (CETSA), surface plasmon resonance (SPR),** and **molecular docking analyses**. Protein expression levels were determined by Western blotting (WB). **Results:** HDD significantly improved hepatic steatosis and fibrosis in HFD mouse models. HDD reduced THRSP expression in liver tissues

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and hepatocytes.Protein microarray, SPR, CETSA, and molecular docking confirmed that HDD directly binds THRSP.MG132 treatment restored HDD-induced THRSP reduction, whereas chloroquine failed to rescue THRSP expression, suggesting that HDD promotes THRSP degradation through the ubiquitin–proteasome pathway rather than the lysosomal pathway.Ubiquitination assays demonstrated that HDD enhanced THRSP ubiquitination. **Conclusion:** HDD alleviated hepatic steatosis and fibrosis in MASLD models.Mechanistically, HDD directly targeted THRSP and promoted its ubiquitin–proteasome-dependent degradation, thereby improving lipid metabolic disorders and liver injury.

3556 | SEMAGLUTIDE, TIRZEPATIDE AND RETATRUTIDE PROMOTE METABOLIC BENEFITS AND SHOW DIFFERENT EFFECTS ON LIVER FAT REDUCTION IN OBESE HAMSTERS

Francois Briand[1] Estelle Grasset[1] Natalia Breyner[1] Claire Bigot[1] Thierry Sulpice[1], [1]Physiogenex

Background: Semaglutide (SEMA), a GLP-1 receptor, Tirzepatide (TIRZE), a GIP/GLP-1 receptors dual agonist, and retatrutide (RETA), a GIP/GLP-1/glucagon receptors triple agonist, have all demonstrated significant body weight loss and liver fat reduction in patients with obesity. Here our aim was to compare the metabolic effects of these drugs in the free choice diet-induced obese and dyslipidemic hamster, a preclinical model with a human-like lipoprotein metabolism used to assess new therapies targeting obesity and MASH. **Methods:** Obesity and MASH were induced with a 20-week free choice diet, which presents hamsters with a choice between control chow diet or high fat/high cholesterol (HF/HC) diet, and normal water or 10% fructose water. Obese hamsters were then treated subcutaneously Q3D for 5 weeks with vehicle, SEMA 15nmol/kg, TIRZE 15nmol/kg or RETA 15nmol/kg. **Results:** SEMA, TIRZE and RETA significantly reduced body weight and altered food preference with greater chow diet intake and lower HF/HC diet and 10% fructose water intake. The weight lowering effect was associated with significant reduction in fat and lean mass. However, the lean mass was not different after 5 weeks of treatment for both TIRZE and RETA. SEMA, TIRZE and RETA significantly reduced glycemia and insulinemia, leading to lower HOMA-IR index of insulin resistance: -67%, -68% and -83%, respectively (all $p < 0.001$ vs. vehicle). The three drugs significantly reduced plasma free fatty acids and triglycerides, lower VLDL- and LDL-cholesterol but unchanged HDL-cholesterol levels. Although histopathological scoring was not improved, there was a 58% and 44% reduction in hepatic triglycerides content with TIRZE ($p < 0.01$) and RETA ($p < 0.05$), respectively, while semaglutide showed a weaker effect (-23%, not significant). While SEMA and TIRZE had no effect, RETA significantly reduced the hepatic expression of genes involved in inflammation and fibrosis. **Conclusion:** SEMA, TIRZE and RETA demonstrate multiple metabolic benefits in obese hamsters. Our preclinical setting will help to assess the efficacy of novel obesity and MASH therapies versus those drugs.

[2]Boehringer Ingelheim International GmbH, [3]Saarland University Medical Center, [4]Summit Clinical Research, [5]Boehringer Ingelheim Pharma GmbH & Co., [6]Virginia Commonwealth University

Background: Survodutide is a glucagon receptor and glucagon-like peptide-1 (GLP-1) receptor dual agonist under investigation for treatment of metabolic dysfunction-associated steatohepatitis (MASH). Treatment with survodutide showed improvement in steatohepatitis and liver fibrosis in a 48-week phase 2 trial in people with MASH and fibrosis stages F1–F3. We describe the design of an ongoing phase 3 trial of survodutide for treatment of compensated MASH cirrhosis (LIVERAGE™ - Cirrhosis), an area of urgent unmet need. **Methods:** In this trial in ~1590 participants in 36 countries (NCT06632457), the main eligibility criteria include age ≥18 years, BMI ≥27 kg/m^2 (≥25 kg/m^2 for Asian participants), compensated MASH cirrhosis diagnosed by current or historical liver biopsy or determined by definitions based on histology, metabolic comorbidities and/or liver fibrosis non-invasive tests, adapted from the Liver Forum criteria; and magnetic resonance imaging-proton density fat fraction (MRI-PDFF) ≥5% or FibroScan® with controlled attenuation parameter (CAP™) ≥288 dB/m. Key exclusion criteria include current or previous significant alcohol consumption, other chronic liver disease, or hepatic decompensation event, Model for End-stage Liver Disease (MELD) score >12, albumin <3.5 g/dL, international normalised ratio of prothrombin time >1.3, total bilirubin >1.2x upper limit of normal [ULN], platelets <100,000/µL, aspartate and/or alanine aminotransferase ≥5x ULN. Participants are randomized 2:1 to double-blind, once-weekly, subcutaneous injections of either survodutide up-titrated to 6.0 mg or placebo. The study period of this event-driven trial is estimated to be ~4.5 years. The primary endpoint at End of Study (EoS) is time to first occurrence of a composite endpoint: all-cause mortality, liver transplant, hepatic decompensation, worsening of MELD score to ≥15, or progression to clinically significant portal hypertension (CSPH) defined as 'high-risk' gastroesophageal varices (GOVs). Key secondary endpoints at Week 76 are shown in the figure. At EoS, key secondary endpoints are occurrence of all-cause hospitalization, time to first occurrences of progression to CSPH, any of the hepatic decompensation events listed in the figure or worsening of MELD score to ≥15, or any adjudication confirmed components of the composite endpoint: cardiovascular death, non-fatal stroke, non-fatal myocardial infarction, ischemia-related coronary revascularization, or heart failure events. Safety evaluation is based on treatment-emergent adverse events and laboratory tests. **Results:** Recruitment of participants began in November 2024. Follow-up is estimated to end in 2029. **Conclusion:** The phase 3 LIVERAGE™ - Cirrhosis trial will investigate the effects of survodutide on liver-related outcomes, and all-cause mortality in people with compensated MASH cirrhosis, as well as its tolerability and safety.

3558 | NEBULA-1 AND NEBULA-2: PHASE 3, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIALS IN PROGRESS OF EFIMOSFERMIN ALFA IN PARTICIPANTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH) AND COMPENSATED CIRRHOSIS

Mazen Noureddin[1] Naga Chalasani[2] Meena Bansal[3] Laurent Castera[4] Rohit Loomba[5] Arun Sanyal[6] Margaret James Koziel[7] Stuart Kendrick[8] Beth Ann Reedy[9] Theresa Peterson[9] Andrea Ribeiro[10] Patricia Mendez[9] Jörn Schattenberg[11], [1]Houston Methodist Hospital and Houston Research Institute, Houston, TX, USA, [2]Indiana University School of Medicine, Indianapolis, IN, USA, [3]Icahn School of Medicine at Mount Sinai, New York, NY, USA, [4]Service d'Hépato-gastroentérologie, Hôpital Haut-Lévêque, CHU de Bordeaux, Pessac, France, [5]MASLD Research Center, University of California at San Diego, La Jolla, CA, USA, [6]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, Richmond, VA, USA, [7]Boston Pharmaceuticals, Cambridge, MA, USA, [8]GSK, Stevenage, UK, [9]GSK, Collegeville, PA, USA, [10]GSK, Madrid, Spain, [11]Saarland University Medical Center, Homburg and Saarland University, Saarbrücken, Germany

Background: MASH with compensated cirrhosis (F4) is becoming a leading cause of liver transplantation, death, and development of hepatocellular carcinoma, with high unmet medical need and no approved therapies. Efimosfermin alfa, a long-acting fibroblast growth factor 21 analog, demonstrated statistically significant improvements in steatohepatitis, fibrosis, non-invasive tests, and liver/metabolic biomarkers in a Phase 2 study (NCT04880031) in participants with MASH F2/F3, and is being investigated in an ongoing Phase 2 trial in participants with MASH with cirrhosis (NCT06920043), supporting further evaluation in advanced disease. **Methods:** NEBULA-1 and NEBULA-2 are randomized, double-blind, placebo-controlled, multicenter phase 3 studies to evaluate the safety and efficacy of efimosfermin alfa in adults aged 18–75 years with compensated cirrhosis due to MASH, identified either noninvasively (NEBULA-1) or confirmed by historical or fresh biopsy (NEBULA-2). In NEBULA-1, participants will receive efimosfermin alfa or placebo. In NEBULA-2, participants will receive efimosfermin alfa or placebo with an optional open-label extension. Eligibility includes, but is not limited to, compensated cirrhosis, absence of prior liver decompensation, and stable dosing of antidiabetic or antilipid medications. **Results:** The primary endpoint of NEBULA-1 is time to composite clinical outcome (all-cause mortality, liver transplantation, hepatic decompensation events, and an increase in Model for End-Stage Liver Disease score) compared with placebo. In NEBULA-2, the primary endpoint is fibrosis improvement of ≥ 1 stage without worsening of MASH. Secondary endpoints include reduction from baseline in liver stiffness (assessed by vibration-controlled transient elastography [VCTE-LSM]) and in Enhanced Liver Fibrosis (ELF) score, as well as safety, tolerability, and health-related quality of life (HRQoL). **Conclusion:** NEBULA-1 and NEBULA-2 will evaluate the safety and efficacy of efimosfermin alfa in MASH with cirrhosis, using accepted regulatory primary endpoints with meaningful secondary and exploratory endpoints spanning noninvasive liver, metabolic, and measures of HRQoL. The data will inform whether efimosfermin alfa can modify disease progression and improve clinical outcomes in this high-risk population with a significant unmet need.

3559 | TREATMENT PERSISTENCE AMONG PATIENTS PRESCRIBED RESMETIROM IN A US CLAIMS-BASED COHORT

Ruth Dixon[1] Zi Wang[1] Chia-Chen Teng[1] John Barron[1] Blake Thomas[2] Karen Phillips[2] Yestle Kim[2] Francis Lobo[2], [1]Carelon Research, [2]Madrigal Pharmaceuticals

Background: Resmetirom is the first FDA conditionally approved therapy for MASH with moderate-to-advanced liver fibrosis (F2–F3). Understanding the real-world treatment journey, especially long-term resmetirom persistence is essential for optimizing clinical integration. **Methods:** Patients were identified from Carelon Research Healthcare Integrated Research Dataset (HIRD). This US-based study was a non-interventional, retrospective cohort study of patients aged ≥18 years with ≥1 claim for resmetirom fill between 01 April 2024 and 31 October 2025 (intake period). The index date was the earliest resmetirom fill during the intake period. Patients were required to have ≥1-year continuous enrollment before index date. The study defined the lookback period as the day before the index date back to October 1, 2015. Liver biopsy status within three years of index date was used to create patient subgroups.We report resmetirom persistence (therapy without a gap of ≥60 days between prescription fills) at 6 and 12 months post-index. Proportion of Days Covered (PDC) is a patient level adherence measure. **Results:** Of 1,592 patients, PDC and persistence were assessed for patients eligible at 6 months (n = 880) and 12 months (n = 392) post-index. At 6 months post-index, median PDC was 93.0% (IQR 78.0% – 98.0%) while persistence was 81.0% with similar rates between biopsy and non-biopsy groups. At 12 months post-index, median adherence (PDC) was 87.0% (IQR 65.0% – 95.0%); and 89.0% [71.0%–96.0%] with biopsy vs 87.0% [61.0% – 94.0%] without biopsy, p-value = 0.367. Persistence was 68.4% overall (75.0% with biopsy; 66.0% without biopsy), p-value = 0.116. See table attached (Table 1) **Conclusion:** In this real-world study among MASH patients being treated with resmetirom, high PDC's at 6 and 12 months, together with high persistence, suggest that many patients can maintain long-term, continuous resmetirom therapy in routine practice, supporting its feasibility as a chronic treatment option.

Table 1: Resmetirom persistence at 6 and 12-months

	Overall	With Biopsy[1]	Without Biopsy[2]	P-value
Number of patients, N	**1,592**	**339**	**1,253**	
6-month post index				
Patients with 6-month eligibility post-index, n (%)	880 (55.3%)	213 (62.8%)	667 (53.2%)	0.002
Rezdiffra Treated Days				0.489
Mean (SD)	148.8 (47.3)	150.7 (45.6)	148.2 (47.9)	
Median (IQR)	170.0 (142.8-180.0)	171.0 (145.0-181.0)	170.0 (142.0-180.0)	
Adherence - Proportion of Days Covered (PDC), mean (SD)	81.0% (26.0%)	82.0% (25.0%)	81.0% (26.0%)	0.489
Adherence - Proportion of Days Covered (PDC), Median (IQR)	93.0% (78.0%-98.0%)	93.0% (79.0%-99.0%)	93.0% (77.0%-98.0%)	
Adherence (PDC≥80%), n (%)	634 (72.1%)	157 (73.7%)	477 (71.5%)	0.594
Persistence[3], n (%)	713 (81.0%)	173 (81.2%)	540 (81.0%)	NR
12-month post index				
Patients with 12-month eligibility post-index, n (%)	392 (24.6%)	104 (30.7%)	288 (23.0%)	0.004
Rezdiffra Treated Days				0.367
Mean (SD)	270.6 (106.8)	278.7 (106.2)	267.7 (107.1)	
Median (IQR)	320.0 (236.8-348.0)	324.5 (261.0-351.5)	320.0 (224.8-345.0)	
Adherence - Proportion of Days Covered (PDC), mean (SD)	74.0% (29.0%)	76.0% (29.0%)	73.0% (29.0%)	0.367
Adherence - Proportion of Days Covered (PDC), Median (IQR)	87.0% (65.0%-95.0%)	89.0% (71.0%-96.0%)	87.0% (61.0%-94.0%)	
Adherence (PDC≥80%), n (%)	242 (61.7%)	71 (68.3%)	171 (59.4%)	0.138
Persistence, n (%)	268 (68.4%)	78 (75.0%)	190 (66.0%)	0.116

3560 | CANNABIS USE AND HEPATIC DISEASE PROGRESSION IN MASLD: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Jashanveer Johal[1] Archana Salek[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Bianca Patel[1] Abdallah Hussein[1] Jason Hyman[2] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Cannabinoid receptor signaling exerts biologically opposing effects on the liver — CB1 activation promotes hepatic lipogenesis and stellate cell activation, while CB2 activation is anti-inflammatory and antifibrotic. Whether cannabis use modifies MASLD disease trajectory remains unresolved and increasingly clinically relevant given rising use prevalence. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised adults with MASLD and documented cannabis use disorder. Cohort 2 comprised MASLD patients without cannabis use. Both cohorts excluded alcoholic fatty liver, alcohol dependence, opioid dependence, and chronic viral hepatitis. 1:1 PSM yielded 53,311 patients per arm over a 6–120 month follow-up. Outcomes included incident cirrhosis, ascites, HCC, hepatic encephalopathy (HE), esophageal varices, SBP, all-cause mortality, and inpatient encounters. **Results:** Cannabis use was associated with lower rates across all hepatic progression endpoints. Incident cirrhosis was lower on both cumulative risk (2.6% vs. 4.1%; RR 0.64; $p < 0.001$) and KM analysis (HR 0.82, 95% CI 0.76–0.88; $p < 0.001$). Incident ascites was lower on cumulative risk (3.6% vs. 4.8%; RR 0.76; $p < 0.001$), though KM analysis was borderline (HR 0.95; $p = 0.076$). Incident HCC showed the most striking reduction (0.24% vs. 0.71%; RR 0.34; HR 0.44, 95% CI 0.36–0.54; $p < 0.001$). Incident HE was significantly lower (1.6% vs. 2.6%; HR 0.75; $p < 0.001$), as were esophageal varices (0.80% vs. 1.83%; HR 0.53; $p < 0.001$) and SBP (0.49% vs. 0.71%; HR 0.81; $p = 0.011$). All-cause mortality was significantly lower with cannabis use (7.1% vs. 11.2%; HR 0.80; $p < 0.001$). Inpatient encounter rates were paradoxically higher in the cannabis arm (44.8% vs. 42.0%; HR 1.32; $p < 0.001$), with shorter median time to first encounter (1,002 vs. 1,712 days). **Conclusion:** In this large propensity-matched cohort, cannabis use in MASLD was associated with significantly lower rates of cirrhosis, HCC, HE, esophageal varices, SBP, and all-cause mortality. These findings are directionally consistent with CB2-mediated hepatoprotective mechanisms and challenge the assumption that cannabis use accelerates MASLD progression. Residual confounding cannot be fully excluded, and higher inpatient utilization warrants further investigation. Prospective studies with controlled cannabis exposure characterization are needed to establish causality and inform clinical counseling.

3561 | NLT-101 PROTECTS AGAINST LIPOTOXIC HEPATOCELLULAR INJURY DEPENDENT ON NUCLEAR ENVELOPE LAMIN B1

Michael Cooreman[1] Stefan Hoenow[2] Thomas Ryan[3] Daniel Bakowski[3] Christopher Shepard[1], [1]Nula Therapeutics, [2]Apollo VC, [3]Sygnature discovery

Background: Lipotoxicity is critical for the pathogenesis of Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) as a stressor of the endoplasmic reticulum (ER) and by reducing nuclear envelope lamin B1 (LMNB1), which regulates expression of lipid metabolism related genes. We have previously shown that NLT-101, a selective partial estrogen receptor alpha (ERa) agonist which mediates insulin-sensitizing effects, prevents the palmitate-induced decrease of LMNB1. We further investigated the effects of NLT-101 and 17a-estradiol (17aE2) on the Unfolded Protein Response (UPR), aimed at restoring ER homeostasis and cell survival following lipotoxic stress. **Methods:** 100 uM palmitate, a saturated fatty acid (FA) that induces cellular lipotoxicity, or oleate, an unsaturated FA that protects from lipotoxicity, was added to HepG2 cell cultures for 6 hours. Treatment with NLT-101, 17aE2 and 17bE2, with concentrations ranging from 0.1 to 10 uM, was applied starting 30 min before beginning of lipotoxic stress. The ratio of spliced to unspliced

XBP1 (sXBP1/uXBP1) was measured by qRT-PCR as a representation of the Unfolded Protein Response (UPR) to endoplasmic reticulum stress. Dependency of XBP1 splicing on the presence of ERa and NE LMNB1 was evaluated using the selective ERa degrading PROTAC ARV-471 and an LMNB1 knock-out (LMNB1-/-) cell line, respectively. Viable cells as percentage of BSA control were assessed with the CellTiter-Glo luminicent Cell Viability Assay. **Results:** The ratio of sXBP1/uXBP1 in palmitate 100 uM stressed HepG2 cells increased significantly with both 17aE2 and NLT-101, but not with 17bE2 exposure, while no effect of either NLT-101 or 17aE2 was seen in LMNB1 -/- cells or in cells treated with ARV-471. In the absence of palmitate lipotoxic stress, no increase in XBP1 spicing occurred with NLT-101 or 17aE2 exposure. No increase in XBP1 splicing was seen in oleate treated cells. Dose-dependent cell death was observed with palmitate, with 100 uM palmitate reducing cell viability to 65% after 18 hours. Oleate had no comparable effect on cell viability. Both NLT-101 and 17aE2, but not 17bE2, increased cell viability of cells under palmitate stress in a dose-dependent way, with 10uM NLT achieving 100% rescue; this effect was entirely absent in LMNB1 -/- cells. Cell viability rescue aligned with XBP-1 splicing for NLT-101 and 17aE2 ligands. **Conclusion:** NLT-101 and 17aE2 protect a hepatocellular cell line against lipotoxicity-induced cell death through a similar pathway involving the UPR, which is dependent on ERa and nuclear envelope lamin B1. These data support the evaluation of the therapeutic potential of NLT-101 for MASLD.

3562 | INCRETIN-BASED THERAPIES FOR BIOPSY-CONFIRMED NON-CIRRHOTIC MASH: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED PLACEBO-CONTROLLED TRIALS

Hima Varsha Voruganti[1] Rohit Sekandlapuram[2] Ravi Patel[3] Shravya Ginnaram[4] Aashay Dharia[5] Pratiksha Moliya[6] Hasan Al-Obaidi[7] Yagnesh Nandikanti[8] Roshitha Bheemaneni[9] Manasa Ginjupalli[5], [1]North Alabama Medial Center, [2]Montefiore Medical Center, Bronx, [3]Trinity Health Okland, [4]HCA Florida Citrus Hospital/USH Morsani College of Medicine, [5]Brooklyn Hospital Center, [6]University of Nebraska Medical center, [7]University of Toledo, [8]Siddhartha Medical College, [9]Gandhi Medical College

Background: Metabolic dysfunction-associated steatohepatitis (MASH) has limited disease-modifying treatment options. Incretin-based therapies have shown promising histologic effects, but differences in fibrosis-stage eligibility and endpoint definitions have complicated cross-trial interpretation. **Methods:** We searched PubMed, Embase, and the Cochrane Library for randomized controlled trials of incretin-based therapies in adults with biopsy-confirmed non-cirrhotic NASH/MASH. Eligible studies required a placebo or standard-care comparator, treatment duration ideally $\geq$48 weeks, and reporting of at least 1 histologic endpoint: NASH/MASH resolution or improvement without worsening fibrosis, or $\geq$1-stage fibrosis improvement without worsening NASH/MASH. Studies were excluded from the primary non-cirrhotic analysis if they included cirrhosis/F4, were imaging-only, biomarker-only, non-randomized, or used combination therapy with unequal background treatment. Active-dose arms were pooled within study, and random-effects risk ratios were used for meta-analysis. Armstrong et al., 2016 (LEAN) was excluded from the primary model and retained only for sensitivity analysis because the study included compensated cirrhosis/F4 participants. **Results:** Four trials met criteria for the primary analysis: Newsome et al., 2021 (Phase 2 Semaglutide), Sanyal et al., 2025 (ESSENCE), Hartman et al., 2024 (SYNERGY-NASH), and Sanyal et al., 2024 (Phase 2 Survodutide). Incretin-based therapies significantly improved histologic activity response without worsening fibrosis versus placebo (RR 2.83, 95% CI 1.75-4.56; I^2 = 72.0%). They also improved fibrosis without worsening MASH/NASH (RR 1.56, 95% CI 1.30-1.86; I^2 = 0%). Sensitivity analysis including Armstrong et al., 2016 (LEAN) yielded similar results for histologic activity response (RR 2.91, 95% CI 1.86-4.56; I^2 = 65.9%) and did not materially change the fibrosis estimate (RR 1.56, 95% CI 1.31-1.87; I^2 = 0%). **Conclusion:** In placebo-controlled biopsy-based trials, incretin-based therapies showed a compelling histologic signal in non-cirrhotic MASH, combining a strong likelihood of steatohepatitis improvement with a consistent fibrosis benefit. These findings support incretin-based agents as leading disease-modifying candidates for biopsy-confirmed non-cirrhotic MASH and justify continued class-specific, longer-term evaluation.

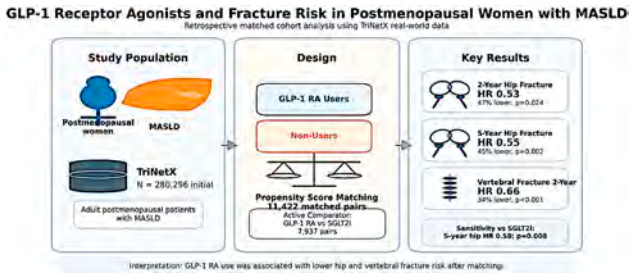
3563 | ASSOCIATION BETWEEN GLP-1 RECEPTOR AGONISTS AND FRACTURE RISK IN POSTMENOPAUSAL WOMEN WITH MASLD: A RETROSPECTIVE COHORT STUDY USING TRINETX



Ridwan Lawal[1] Guy Loic Nguefang Tchoukeu[2] Bright Nwatamole[3] Cherechi Nwabueze[4] Oladoyin Ogunbayo-Jolaoye[5] Sarpong Boateng[6] Basile Njei[7], [1]University of Texas Rio Grande Valley, [2]Texas Tech University Health Science Center, Permian Basin, [3]Zucker School of Medicine at Hofstra/Northwell at Vassar Brothers Medical Center, Poughkeepsie, [4]John H. Stroger Jr. Hospital of Cook County, [5]University of Illinois Chicago Peoria, [6]Yale New Haven Health, Bridgeport Hospital, [7]Yale University

Background: Postmenopausal women with metabolic dysfunction-associated steatotic liver disease (MASLD) face elevated fracture risk driven by the intersection of estrogen deficiency, chronic inflammation, and metabolic dysregulation. Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) demonstrate pleiotropic benefits in glycemic control, weight reduction, cardiovascular protection, and MASH resolution, but their effects on skeletal outcomes in this population remain undefined. This study evaluated the association between GLP-1 RA use and fracture risk among postmenopausal women with MASLD over a 5-year follow-up period. **Methods:** We conducted a retrospective study using the TriNetX federated research network. Postmenopausal women ≥ 50 years with MASLD were divided into GLP-1 RA users and non-users. Propensity score matching (PSM) on 38 baseline covariates, demographics, comorbidities, medications, and laboratory values produced 11,422 patients per arm. The primary outcome was pathologic (fragility) fracture; secondary outcomes included site-specific fractures at the hip, vertebra, wrist, and humerus. An active-comparator sensitivity analysis compared GLP-1 RA users (n = 7,937) against sodium-glucose cotransporter-2 (SGLT2) inhibitor users (n = 7,937) after separate PSM. Hazard ratios (HR) were estimated using Cox proportional hazards regression with Kaplan-Meier survival analysis. Outcomes were assessed at 2-, 3-, and 5-year windows. **Results:** In the primary analysis, GLP-1 RA use was associated with a statistically significant 47.2% reduction in hip fracture risk at 2 years (HR 0.528, 95% CI 0.301–0.927; $p = 0.024$) and a 34.3% reduction in vertebral fracture risk (HR 0.657, 95% CI 0.521–0.828; $p < 0.001$). At 5 years, hip fracture reduction persisted at 45.2% (HR 0.548, 95% CI 0.370–0.812; $p = 0.002$). The pathologic fracture primary outcome did not reach significance at any time point. In the SGLT2 inhibitor active-comparator analysis, GLP-1 RA use was associated with a significant 42.9% reduction in humerus fracture at 2 years (HR 0.571, 95% CI 0.376–0.867; $p = 0.008$) and a 42.5% reduction in hip fracture at 5 years (HR 0.575, 95% CI 0.380–0.870; $p = 0.008$). **Conclusion:** GLP-1 RA use in postmenopausal women with MASLD was associated with consistent and clinically meaningful reductions in site-specific fractures, particularly at the hip and vertebra, across multiple follow-up intervals. These findings, reinforced by sensitivity analyses against an active comparator, suggest that GLP-1

3564 | NEW THERAPY, OLD EQUITY QUESTIONS: RACIAL DISPARITIES IN RESMETIROM USE FOR MASLD

Chimezirim Ezeano[1] Ihunanya Kanu[2] Sarpong Boateng[3] Guy Loic Nguefang Tchoukeu[4] Emeka Stanley Obi[5] Cherechi Nwabueze[6] Ifelunwa Osanakpo[7] Goodness Joseph[8] David Narvaez-De los Rios[9] Onyinyechukwu Ozumba[10] Chimezie Madu[11] Angel Umahi[12], [1]Advocate Aurora Healthcare, [2]Baptist Memorial Hospital- Golden Triangle, [3]Yale New Haven Health, Bridgeport Hospital, [4]Texas Tech University Health Science Center, Permian Basin, [5]Brookdale University Hospital and Medical Center, [6]John H. Stroger Jr. Hospital of Cook County, [7]Carle Foundation Hospital, [8]Nnamdi Azikiwe University Teaching Hospital, [9]Universidad Icesi, [10]Dept of Internal medicine Cape fear valley North Carolina, [11]Department of General Practice, Bradford Teaching Hospitals , NHS Foundation Trust, UK, [12]University of Lancashire School of medicine and dentistry

Background: Resmetirom use is expanding for metabolic dysfunction-associated steatohepatitis, but early adoption may not reach all patient groups equally. We compared patients with metabolic dysfunction-associated steatotic liver disease (MASLD) with and without resmetirom exposure to describe early race and ethnicity signals in real-world use. **Methods:** We performed a retrospective real-world baseline comparison of MASLD patients with resmetirom exposure versus MASLD patients without resmetirom exposure. Demographic, race/ethnicity, laboratory, diagnosis, and medication characteristics were compared using P values and standardized mean differences (SMD). Insurance coverage, income, and education level data were limited. **Results:** The resmetirom cohort included 747 patients and the comparator cohort included 169,839 patients. Patients receiving resmetirom were slightly older (57.6 ± 13.0 vs 56.1 ± 15.7 years; P = 0.0086; SMD 0.1046). Hispanic ethnicity was equally represented (12% vs 12%; P = 0.7018; SMD 0.0142). Race composition showed the most notable equity-relevant differences. Black or African American patients represented 5% of the resmetirom cohort versus 9% of comparators (P = 0.0008; SMD 0.1367), while unknown race represented 20% versus 16% (P = 0.0002; SMD 0.1288). White race was similar (64% vs 65%; P = 0.5074; SMD 0.0242). Patients receiving resmetirom had higher body mass index (33.8 ± 6.92 vs 32.8 ± 7.61; P = 0.0008; SMD 0.1338), lower total cholesterol (157 ± 44.1 vs 172 ± 51.9; P < 0.0001; SMD 0.2977), lower low-density lipoprotein cholesterol (83.2 ± 35.7 vs 98.1 ± 38.3; P < 0.0001; SMD 0.4013), and similar hemoglobin A1c (6.11 ± 1.0 vs 6.08 ± 1.27; P = 0.6841; SMD 0.0192). Antilipemic medication exposure was higher (62% vs 48%; P < 0.0001; SMD 0.2929), as was glucagon-like peptide-1 receptor agonist exposure (39% vs 20%; P < 0.0001; SMD 0.4331). **Conclusion:** In this early real-world MASLD comparison, resmetirom-treated patients differed from untreated comparators by race composition, lipid profile, body mass index, and cardiometabolic medication exposure. The lower representation of Black or African American patients should be interpreted as a modest access signal, not proof of independent prescribing inequity, especially given higher unknown race documentation and limited socioeconomic data. As resmetirom use grows, adjusted studies should evaluate fibrosis stage, payer status, specialty access, geography, and treatment eligibility to ensure that MASH-directed therapy does not widen existing liver-disease disparities.

3565 | BEYOND OBESITY: GLP-1RAS VS AMYLIN ANALOGS IN A PRECLINICAL RAT MODEL OF MASH

Sitong Zhang[1] Yan Zhou[2] Miao Yuan[2] Renjie Ding[2] Jiliang Zhang[2] Wenjie Gao[2] Letian Kuai[2], [1]WuXi AppTec Co., Ltd., [2]In Vivo Pharmacology Unit, WuXi Biology, WuXi AppTec, China

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive form of NAFLD associated with obesity, insulin resistance, and type 2 diabetes. GLP-1 receptor agonists (GLP-1RAs) and amylin analogs both induce weight loss and improve metabolic parameters, and have shown promise for reducing hepatic steatosis and inflammation. Direct, controlled comparisons of these drug classes in standardized preclinical MASH models are limited. We therefore compared semaglutide (GLP-1RA) and cagrilintide (amylin analog) with the approved thyroid hormone receptor-β agonist resmetirom in a high-fat diet + CCl4 rat model of MASH to evaluate metabolic and histologic effects. **Methods:** MASH was induced by high-fat diet combined with carbon tetrachloride (CCl_4). Study groups included healthy controls and MASH cohorts treated with vehicle, resmetirom, semaglutide, or cagrilintide. Dosing and schedules were optimized for each compound. Animals were monitored for clinical condition and metabolic parameters throughout 6 weeks of treatment. Endpoints assessed in collected liver tissue included steatosis, inflammation, and fibrosis by conventional histology, digital image analysis, and molecular assays. **Results:** All active treatments produced significant improvements versus vehicle-treated MASH controls. Semaglutide and cagrilintide produced greater and more sustained body-weight reductions than resmetirom. All therapies lowered NAS by approximately 2–4 points and reduced fibrosis area to varying extents. Cagrilintide showed a pronounced anti-fibrotic effect in addition to reducing steatosis and inflammation. Digital histology revealed that cagrilintide more clearly reduced fibrosis in both portal and septal regions compared with semaglutide, consistent with reduced liver injury and structural recovery. Overall, GLP-1RA and amylin analog therapies effectively mitigated key pathological features of MASH in this model. **Conclusion:** In this preclinical MASH model, semaglutide effectively reversed steatosis and inflammation, while resmetirom and cagrilintide had stronger anti-fibrotic effects. The fibrosis reduction observed with the amylin analog suggests that targeting amylin pathways may offer a complementary approach to current treatments and merits further clinical investigation.

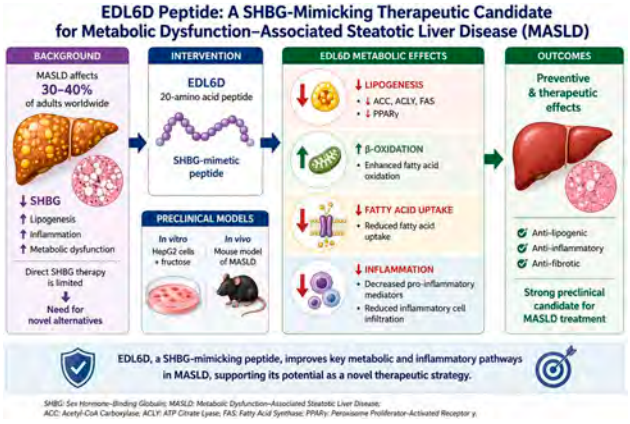
3566 | EDL6D, A BIOACTIVE PEPTIDE PHENOCOPYING SHBG-ASSOCIATED METABOLIC EFFECTS: A NEW PRECLINICAL LEAD COMPOUND FOR TREATING THE METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE



David Martinez Selva[1] Anna Alvarez-Guaita[1] Julia Cabrera-Serra[1] Beatriz Perez-Gonzalez[2] María Teresa Salcedo[3] Lidia Fuertes-Rioja[1] Lorena Ramos-Perez[1] Cristina Hernandez[4] Rafael Simo[5], [1]Vall d'Hebron Research Institute, UAB, [2]Endolipid Therapeutics S.L,, [3]Vall d'Hebron University Hospital, [4]Vall Hebron Institut de Recerca, UAB, [5]rafael.simo@vhir.org

Background: Metabolic dysfunction-associated fatty liver disease (MASLD) is linked to low plasma levels of sex hormone-binding globulin (SHBG). Previous studies showed that SHBG overexpression reduces liver fat accumulation by inhibiting lipogenesis. In the present work, we have developed an SHBG mimetic peptide (EDL6D) that could be used as a new treatment to prevent and treat MASLD development and arrest its progression to MASH. **Methods:** We have first tested the EDL6D effects in in vitro experiments using HepG2 cells treated daily with 30 mM fructose. We next have studied the preventive and therapeutic effects of EDL6D using wild-type mice developing MASLD induced by high fat diet and 30% fructose in the drinking water over 8 and 20 weeks respectively **Results:** Our results clearly showed that the treatment with EDL6D was able to reduce liver fat accumulation and regress MASLD by reducing the mRNA expression and protein levels of key lipogenic enzymes (ACLY, ACC and FAS) as well as PPARγ. Moreover, EDL6D was able to prevent the development of mild fibrosis, which can be attributed to its capacity to downregulates the intrahepatic production of collagen 1A1 (Col1A1) and transforming growth factor beta 1 (TGF-β1). **Conclusion:** In summary, we have shown that EDL6D, an SHBG mimetic peptide reduces de novo and exerts an important anti-inflammatory effect preventing fibrosis development in MASLD mouse models. These results suggested that EDL6D could be used as a new treatment to prevent and treat MASLD development and arrest its

3567 | GLP-1 RECEPTOR AGONISTS AND INCIDENCE OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH METABOLIC STEATOTIC LIVER DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS

Gurjit Mander[1] Yashasavi Sachar[2] Sanewal Singh[3] Mayur Brahmania[4], [1]McMaster University, [2]Western University, [3]University of Waterloo, [4]University of Calgary

Background: Hepatocellular carcinoma (HCC) is an increasingly important complication of metabolic liver disease. GLP-1 receptor agonists (GLP-1RAs) may reduce liver-related risk through effects on weight, glycemic control, insulin resistance, and hepatic inflammation; however, their association with HCC risk in MASLD/MASH populations remains uncertain. **Methods:** We performed a systematic review and meta-analysis of observational cohort studies reporting HCC outcomes among adults with MASLD, MASH, or legacy NAFLD/NASH exposed to GLP-1RAs. The primary comparative analysis pooled adjusted hazard ratios (HRs) for incident HCC using random-effects models with Hartung-Knapp adjustment. Single-arm random-effects meta-analyses estimated the cumulative incidence of HCC among GLP-1RA-exposed participants. **Results:** Sixteen studies were identified, of which 14 adjusted HR estimates were included in the primary comparative meta-analysis. GLP-1RA exposure was associated with lower adjusted hazard of incident HCC compared with comparator groups (HR 0.68, 95% CI 0.50–0.91; p = 0.014). Findings were directionally similar in cirrhosis cohorts (HR 0.72, 95% CI 0.48–1.09) and non-cirrhotic cohorts (HR 0.59, 95% CI 0.24–1.45), with no significant subgroup difference (p = 0.578). In single-arm analyses, 16 GLP-1RA-exposed arms included 380,852 participants and 1,212 HCC events. The pooled cumulative HCC incidence among GLP-1RA users was 0.32% (95% CI 0.13–0.77), with higher incidence in cirrhosis than non-cirrhotic cohorts (0.67% vs 0.14%; p = 0.018). **Conclusion:** Among patients with MASLD/MASH populations, GLP-1RA exposure was associated with a lower adjusted hazard of incident HCC. HCC incidence among GLP-1RA-treated patients was low overall but higher in cirrhosis cohorts. These findings are hypothesis-generating and limited by observational designs, heterogeneity, variable liver disease definitions, and incomplete fibrosis staging. Prospective studies and target-trial emulations are needed to clarify whether GLP-1RAs causally reduce HCC risk.

3568 | DEMOGRAPHIC, CLINICAL, AND MEDICATION USE PROFILES OF PATIENTS PRESCRIBED RESMETIROM : A US CLAIMS-BASED ANALYSIS

Ruth Dixon[1] Zi Wang[1] Chia-Chen Teng[1] John Barron[1] Blake Thomas[2] Karen Phillips[2] Yestle Kim[2] Francis Lobo[2], [1]Carelon Research, [2]Madrigal Pharmaceuticals

Background: Resmetirom received FDA conditional approval in March 2024 as the first pharmacotherapy for metabolic dysfunction-associated steatohepatitis (MASH) with moderate-to-advanced fibrosis. Real-world data describing patients prescribed resmetirom remain limited. **Methods:** This US retrospective cohort study used Carelon Research Healthcare Integrated Research Dataset (HIRD). Adults aged ≥ 18 years with ≥ 1 resmetirom claim between 1 April 2024 and 31 October 2025 and ≥ 1 year of continuous enrollment before the first fill (index date) were included. Baseline demographics, social drivers of health, comorbidities, laboratory values, non-invasive testing (NIT), medication use, and statin intensity were assessed during the year before index. Findings were compared between patients with liver biopsy (LB) and no liver biopsy (NLB) within 3 years before resmetirom initiation. **Results:** Among 2,042 patients with ≥ 1 resmetirom claim, 1,592 met inclusion criteria; 339 (21.3%) had prior LB and 1,253 (78.7%) did not. Higher rates of biopsy were seen in Midwest (26.7%) and among Asian patients (31.3%); lower biopsy utilization

rates were noted in patients with rural residency (15.3%), the bottom 25% Socioeconomic Status Index category (14.9%) and Black race (9.5%). Mean age was 55.4 years; LB patients were younger than NLB patients (53.4 vs 56.0 years). Overall, 54.5% were female and 80.4% commercially insured. Mean ALT and AST were 51.1 U/L and 41.2 U/L, respectively, and were higher in LB patients. Common comorbidities included dyslipidemia (73.0%), hypertension (69.2%), type 2 diabetes (50.1%), and obesity/overweight (58.0%), with higher prevalence among NLB patients. Mean Quan Charlson Comorbidity Index was 2.9. Among patients with available FIB-4 scores, 53.1% were low risk (< 1.3), 38.6% intermediate risk (1.3–2.67), and 8.3% high risk (> 2.67). LB patients were more likely to have intermediate/high-risk scores than NLB patients (54.3% vs 43.0%).All patients underwent ≥ 1 prior NIT; ultrasound (80.0%) and vibration-controlled transient elastography (75.8%) were most common. Median time from last NIT to resmetirom initiation was 69 days (IQR, 29–173), longer in LB versus NLB patients (107 vs 61 days).During the pre-index year, 40.2% used GLP-1 receptor agonists, 35.2% metformin, and 16.1% SGLT2 inhibitors. Statins were used by 49.4% of patients: 17.6% high-intensity, 29.6% moderate-intensity, and 2.2% low-intensity. Statin and GLP-1 receptor agonist use were lower in LB versus NLB patients. **Conclusion:** Most patients initiated resmetirom without prior liver biopsy though differences in baseline characteristics were observed by biopsy status. Patients demonstrated substantial cardiometabolic comorbidity burden and frequent use of multiple metabolic therapies, highlighting the complexity of MASH management.

Table 1: Non-Invasive Testing for Patients Receiving Rezdiffra

	Overall	With Biopsy[1]	Without Biopsy[1]	P-value

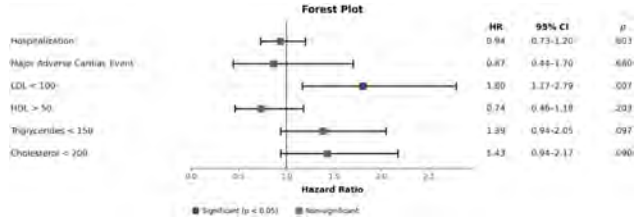
3569 | CARDIOMETABOLIC OUTCOMES OF RESMETIROM IN PATIENTS WITH MASLD: A PROPENSITY-MATCHED COHORT STUDY



Amber Hussain[1] Yusef Saeed[1], [1]University Hospitals Cleveland Medical Center

Background: Resmetirom is a liver-directed, thyroid hormone receptor β-selective agonist approved in March 2024 for adults with metabolic dysfunction-associated steatotic liver disease (MASLD) and moderate to advanced hepatic fibrosis. By targeting disease earlier, it may reduce progression to cirrhosis and need for transplantation. However, its broader cardiometabolic effects remain unclear. This study evaluated clinical and metabolic outcomes associated with Resmetirom use in patients with MASLD compared with matched controls. **Methods:** Using the TriNetX US Collaborative Network, adults (≥ 18 years) between January 31, 2020 and January 31, 2025 were identified. From 1,642,840 patients with cirrhosis, two cohorts were defined: MASLD patients prescribed Resmetirom (n = 854) and MASLD patients not prescribed Resmetirom (n = 3,102,308). The MASLD control cohort was required to have a diagnostic test for liver disease (i.e. FibroScan, MRI, or biopsy) to increase diagnostic certainty. After applying inclusion and exclusion criteria, 1:1 propensity score matching yielded 852 matched pairs. Outcomes at 12 months included hospitalization, major adverse cardiovascular events (MACE, as defined by myocardial infarction, stroke, or all cause mortality), and metabolic endpoints (LDL < 100 mg/dL, HDL > 50 mg/dL, triglycerides < 150 mg/dL, total cholesterol < 200 mg/dL). Kaplan-Meier analysis was used. Event rates were derived as 1 minus survival probability. Hazard ratios (HR) with 95% CI and log-rank p-values were reported. Artificial intelligence tools were used to improve abstract readability, enhance word flow, and optimize figure formatting for presentation purposes. **Results:** Cardiac, metabolic, hepatic, and substance use related comorbidities were matched for. After matching, baseline characteristics were largely balanced. Outcomes are shown in Figure 1 (Forest Plot). No significant difference was observed in hospitalization (15.43% vs 16.09%; HR 0.94, 95% CI 0.73 - 1.20; p = 0.603) or MACE (1.99% vs 2.37%; HR 0.87, 95% CI 0.44 - 1.70; p = 0.680). Resmetirom was associated with improved LDL target attainment (11.75% vs 6.91%; HR 1.80, 95% CI 1.17 - 2.79; p = 0.007). No significant differences were observed for HDL > 50 mg/dL (5.21% vs 7.33%; HR 0.74; p = 0.203),

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

triglycerides < 150 mg/dL (13.25% vs 9.76%; HR 1.39; p = 0.097), or total cholesterol < 200 mg/dL (13.07% vs 9.55%; HR 1.43; p = 0.090). **Conclusion:** Resmetirom was not associated with reduced short-term clinical events but improved LDL target attainment. Although Resmetirom did not significantly affect the other lipid markers (HDL, triglycerides, cholesterol), it was associated with a trend toward improved values. Longer-term studies are needed to determine whether metabolic benefits translate into improved cardiovascular or hepatic outcomes.

3570 | LANIFIBRANOR TARGETS MULTIPLE HEPATIC CELL POPULATIONS TO REDUCE FIBROSIS THROUGH BALANCED PAN-PPAR ACTIVATION

Guillaume Wettstein[1] Sander Lefere[2] Jordi Gracia-Sancho[3] Frank Tacke[4] Manal Abdelmalek[5] Sven Francque[6], [1]Inventiva, [2]HospitalHepatology Research Unit, dpt. of Internal Medicine and Pediatrics, Ghent University, [3]IDIBAPS - Hospital Clínic Barcelona, [4]Department of Hepatology & Gastroenterology, Charité - Universitätsmedizin Berlin, Germany., [5]Mayo Clinic Rochester, [6]Department of Gastroenterology and Hepatology, Antwerp University Hospital, Belgium

Background: Fibrosis is the strongest predictor of liver-related morbidity and mortality in metabolic dysfunction-associated steatohepatitis (MASH). Fibrogenesis results from complex interactions between multiple hepatic cell populations including hepatocytes, Kupffer cells, liver sinusoidal endothelial cells (LSECs) and hepatic stellate cells (HSCs). Peroxisome proliferator-activated receptors (PPARs) are key regulators of metabolism, inflammation and fibrogenesis, with distinct but complementary functions across liver cell types. We aimed to highlight how balanced pan-PPAR activation by lanifibranor simultaneously targets multiple cellular drivers of fibrosis in MASH and advanced chronic liver disease (ACLD). **Methods:** The effects of lanifibranor were evaluated across several preclinical models in rodents reproducing key features of MASH and fibrosis, including diet-induced steatohepatitis, CCl_4-induced fibrosis, and ACLD models such as Thioacetamide and bile duct ligation. Liver histology, inflammatory and fibrotic pathways, macrophage phenotype, HSC activation and LSEC dysfunction were assessed using molecular, histological and functional analyses. Human hepatic cells and liver biopsies were also evaluated to characterize the translational relevance of pan-PPAR activation. **Results:** Lanifibranor improved all major histological components of MASH and fibrosis across independent experimental models and in NATIVE clinical trial phase 2b. At the hepatocyte level, PPARα activation promoted fatty acid β-oxidation, reduced lipotoxicity and improved metabolic homeostasis. In macrophages, PPARδ activation shifted inflammatory polarization toward a less pro-inflammatory phenotype, reduced monocyte infiltration and decreased cytokine expression including TNF-α, IL-6 and CCL2. In HSCs, PPARγ activation maintained a quiescent phenotype and directly inhibited fibrogenic activation, reducing expression of α-SMA, TGF-β and collagen genes leading to inhibition of fibrogenesis. Finally, lanifibranor restored LSEC phenotype and improved hepatic microvascular dysfunction through the activation of the three isoforms. By doing so lanifibranor interrupts the pathological crosstalk between injured LSECs, activated HSCs and inflammatory macrophages that promote fibrosis progression. **Conclusion:** Lanifibranor addresses liver fibrosis through coordinated actions on multiple hepatic cell populations involved in MASH pathogenesis. Balanced activation of PPARα, PPARδ and PPARγ simultaneously improves hepatocyte metabolism, dampens macrophage-driven inflammation, restores LSEC function and maintains HSC quiescence. This pleiotropic multicellular mechanism distinguishes pan-PPAR agonism from selective PPAR approaches and supports lanifibranor as a promising antifibrotic therapy for MASH and ACLD.

3571 | 7-METHYLXANTHINE DEMONSTRATES RESMETIROM-COMPARABLE EFFICACY IN A RAT MODEL OF MASH WITH SUPPORTING ANTIFIBROTIC AND ANTI-INFLAMMATORY MECHANISMS

Dinesh Tripathi[1] Arpita Malhan[2] Mridul Guleria[2] Saketh Dinavahi[3] Sundeep Aurora[3] Subheet Jain[2], [1]Institute of Liver and Biliary Sciences, [2]Guru Nanak Dev University, [3]Anari Therapeutics

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a progressive inflammatory and fibrotic liver disease with high cardiometabolic risk and limited pharmacotherapies. Resmetirom, a selective thyroid hormone receptor-β agonist, has recently been approved, but additional, mechanistically distinct agents are needed. 7-Methylxanthine, a xanthine derivative, was evaluated in a diet-induced rat model of MASH with resmetirom as an active comparator to benchmark efficacy. **Methods:** Male Wistar rats (n = 24) received a high-fat diet (60% kcal fat) plus fructose in drinking water for 13 weeks; controls received standard chow. MASH induction was confirmed by body weight, serum biochemistry, ultrasonography, relative organ weight, and NAS/MAS scoring. MASH-positive animals were randomised (n = 6/group) to diseased control (HFD only), 7-methylxanthine (1200 mg/kg BID, oral), or resmetirom (2.5 mg/kg QD, oral) while maintained on HFD. From weeks 14–27, body weight, serum lipids, liver function tests, glucose, bilirubin and liver ultrasonography were assessed; post-treatment histology, MAS/NAS, inflammatory biomarkers and IND-enabling toxicology are ongoing. **Results:** Induction produced obesity, severe dyslipidaemia, elevated transaminases, ALP and bilirubin, Grade III steatosis, increased liver weight and a NAS of 7 vs 1 in controls, confirming severe MASH. During treatment, diseased controls showed continued weight gain and biochemical deterioration, whereas 7-methylxanthine and resmetirom attenuated further weight gain and reduced body weight versus diseased controls despite ongoing HFD. Both treatments lowered total cholesterol, triglycerides, LDL, glucose, transaminases, ALP and bilirubin and restored HDL toward normal; across metabolic and hepatic endpoints, 7-methylxanthine effects were broadly comparable to resmetirom. Ultrasonography showed persistent Grade III steatosis in diseased controls but near-normal echotexture and vascular definition in both active groups, indicating substantial and comparable reversal of fatty infiltration. In parallel, 7-methylxanthine dose-dependently reduced TGF-β1-driven myofibroblast and extracellular matrix markers (α-SMA, fibronectin, vimentin, FSP1) and modulated MMP9, and dampened cytokine/LPS-induced epithelial responses, supporting an antifibrotic and anti-inflammatory mechanism. **Conclusion:** 7-Methylxanthine produced marked improvements in metabolic, biochemical and imaging endpoints in HFD+fructose-induced MASH that were broadly comparable to resmetirom, supporting competitive efficacy versus an approved THR-β agonist in a clinically relevant, diet-driven model. Together with complementary antifibrotic and anti-inflammatory activity and ongoing IND-enabling toxicology, these data support the translational potential of 7-methylxanthine as a hepatoprotective and anti-steatotic candidate for MASH.

Disclosures: Dinesh Tripathi:Anari Therapeutics: Consultant, Arpita Malhan:Nothing to Disclose, Mridul Guleria:Nothing to Disclose, Saketh Dinavahi:Nothing to Disclose, Sundeep Aurora:Nothing to Disclose, Subheet Jain:Nothing to Disclose.

3572 | MACADAMIA NUT SUPPLEMENTATION PROTECTS AGAINST MASLD-INDUCED ALTERATIONS IN LIPID AND BILE ACID METABOLISM IN A MOUSE MODEL

Aiswariya Ravi[1] Deekshika Sekar[1] Chandan Krishnamoorthy[1] Sathish Kumar Natarajan[1], [1]Department of Nutrition and Health Sciences, University of Nebraska-Lincoln, Lincoln, NE 68588

Background: Metabolic Associated Steatotic Liver Disease (MASLD) is a significant global health concern, linked to high-fat diets that promote obesity, insulin resistance, hepatic lipid accumulation, liver inflammation, and disruptions in lipid and bile acid metabolism. MASLD significantly affecting 47% of the U.S. population, while Metabolic Associated Steatohepatitis (MASH) affects approximately 2-7% of Americans. The molecular mechanisms underlying MASLD pathogenesis and diet-based nutritional interventions are still under investigation. Macadamia nuts (MN), rich in monounsaturated fatty acids, have been shown to prevent lipopolysaccharide (LPS)- induced proinflammatory responses and exhibit established anti-inflammatory properties. We hypothesize that dietary supplementation of macadamia nuts restores lipid and bile acid dysregulation in high-fat, fructose, and cholesterol-containing diets (FFC)-induced MASLD in the rodent model. **Methods:** Eight-week-old C57BL/6J mice were divided into four groups: Control, FFC, FFC + 5% MN, and FFC + 10% MN, containing the diet for either 16 or 24 weeks. Glucose tolerance tests (GTT) and insulin tolerance tests (ITT) were measured to evaluate metabolic function. Fecal samples were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

collected for microbial analysis. After 16 and 24 weeks, blood and tissue samples were collected. Serum bile acid levels were measured using targeted LC-MS/MS. Liver tissues were examined for pathological MASH scoring. Hepatic and intestinal gene and protein expression were assessed by qPCR and immunoblot analyses. **Results:** FFC diets with 5% or 10% of Macadamia nuts showed improved GTT and ITT, ce at 24 weeks compared to MN-FFC diet-fed mice. Liver histopathology revealed an improvement in the NASH score, with a significant decrease in hepatic steatosis scores in both MN-FFC diet-fed groups after 16 weeks of the study. Serum bile acid analysis showed a non-significant change at 16 weeks; however, at 24 weeks, a significant decrease in cholic acid and its conjugated bile acids, taurocholic acid and taurodeoxycholic acid, was observed, indicating improved bile acid metabolism in MN-diet groups. We also observed a significant decrease in sterol regulatory binding proteins SREBP1 and SREBP2 at 16 and 24 weeks. The pro-inflammatory cytokine TNF-α showed a significant decrease at 16 weeks, indicating improved lipid metabolism and cholesterol biosynthesis with MN-FFC diet-fed groups compared to FFC alone. Additionally, the intestinal mRNA expression profile showed a significant decrease in Mucin 2 and TNF-α at both 16 and 24 weeks in MN-FCC, denoting dramatic improvements from MASLD-induced intestinal barrier dysfunction. **Conclusion:** Together, these data indicate that a diet containing macadamia nuts, rich in MUFA, improves liver injury by restoring the MASLD pathophysiology, suggesting its potential as a nutritional intervention for preventing MASLD-related complications.

3573 | REAL-WORLD USE OF RESMETIROM FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS IN A COMMUNITY-BASED OUTPATIENT HEPATOLOGY CLINIC

Giselle Ellis[1] Emily Ellis[2] Anthony Michaels[3] Adam James Hanje[3], [1]OhioHealth Riverside Methodist Hospital, [2]Riverside Methodist Hospital, [3]Ohio Gastroenterology Group

Background: Resmetirom, a liver-directed thyroid hormone receptor beta-selective agonist, received FDA approval in March 2024 for adults with MASH and F2-F3 fibrosis. In MAESTRO-NASH, resmetirom demonstrated MASH resolution in up to 29.9% of patients and fibrosis improvement by ≥ 1 stage in up to 25.9% at 52 weeks ($P < 0.001$ for both). Real-world data on prescribing patterns, response, tolerability, and access remain limited. This study evaluated resmetirom use in an interprofessional outpatient hepatology clinic within a large community-based hospital system. **Methods:** Investigators performed retrospective chart review of all patients prescribed resmetirom at a single hepatology clinic staffed by physicians, nurse practitioners, and a clinical pharmacist between March 2024 and March 2026. Patients who never filled the prescription were excluded. Baseline demographics, fibrosis stage, diagnostic modality, insurance type, and GLP-1 receptor agonist (GLP-1RA) use were collected. Outcomes included changes in liver stiffness (kPa), controlled attenuation parameter (CAP), and transaminases at 6 and 12 months. Adverse events and discontinuation rates were recorded. **Results:** Of 161 patients prescribed resmetirom, 22 never filled and were excluded; 2 additional patients were excluded due to insufficient data. At baseline, 84.7% were staged via elastography; whereas, 13.9% of patients had biopsy-confirmed diagnosis. Patients' average age was 55 years-old; 57% were female, and the 80% were Caucasian. The insurance breakdown was: 50.4% commercial, 18.3% Medicaid, 24.8% Medicare, 8.8% charitable. 90.5% had obesity (BMI > 30), 14.6% prediabetes, 61.3% diabetes; 46.7% were on a GLP-1RA at baseline, increasing to 55.5% during therapy. At 6 months ($n = 58$), liver stiffness (9.8 ± 2.1 to 8.6 ± 3.8 kPa, $p = 0.01$) and CAP (289 ± 88 to 255 ± 82, $p = 0.01$) improved significantly compared to baseline, with trends for improvement in AST (36.7 to 33.8, $p = 0.08$) and ALT (46.2 to 40.3, $p = 0.065$). At 12 months ($n = 30$), kPa (10.6 ± 1.7 to 9.6 ± 6.4, $p = 0.169$) and CAP (314 ± 45 to 285 ± 45, $p = 0.219$) trended toward improvement compared to baseline; AST (42.7 to 35.7, $p = 0.022$) and ALT (56.7 to 36.2, $p = 0.002$) improved significantly. 11 patients (8%) of those included were lost to follow-up, which contributed to the limited numbers for repeat imaging. Diarrhea occurred in 17.5%, nausea 12.4%, and 5% reported vomiting, constipation, pruritus, or other GI effects . Discontinuation due to adverse effects was 16.8%. **Conclusion:** Resmetirom is prescribed across a broad range of fibrosis stages and payer types in community practice, with noninvasive testing as the predominant diagnostic modality. Early treatment response was observed at 6-12 months. While GI side effect rates were lower than MAESTRO-NASH, the discontinuation rate was notably higher, suggesting real-world tolerability and patient support strategies warrant further study.

3574 | ADVANCING GLP-1 RA USE IN OBESITY-RELATED MASH: IMPACT OF A MULTIDISCIPLINARY CME PROGRAM

Meg Coulehan[1] Mathew Wong[1] Tamima Ashraf[1] Stephanie Giuliani[1] Emily Kitterman[1] Vlad Ratziu[2] Diana Barb[3], [1]Answers in CME, [2]Service D' Hepatogastroenterologie (FR), [3]UF Health

Background: Due to the growing prevalence of MASH driven by the obesity epidemic, the significant impact of advanced fibrosis on long-term patient outcomes, and the emergence of glucagon-like peptide-1 (GLP-1) receptor agonist (RA)-based options targeting this condition, it is imperative for clinicians to stay informed about the latest advancements in therapeutic strategies to optimize outcomes for obesity-related liver disease. To assess whether digital, short-form, continuing medical education (CME) can enhance clinicians' knowledge and competence related to the impact of obesity on MASH and the role of GLP-1 RA-based therapies in managing MASH. **Methods:** Endocrinologists, gastroenterologists, and hepatologists from a global audience participated in a 15-minute on-demand e-learning module titled "Bridging Disciplines to Advance Care in MASH: Exploring GLP-1 RAs for Obesity-Related Liver Disease", presented by an endocrinologist and a hepatologist. This activity launched on September 19, 2025. Pre- and post-activity assessments were used to collect information regarding learners' baseline scores as well as the impact of the education on knowledge and competence. Assessments were analyzed in aggregate and at the individual level. **Results:** As of March 12, 2026, 7,718 learners participated in the program, with the leading specialties being endocrinologists (42%) and gastroenterologists (46%) (data collection is ongoing). A subset of responses (n = 1,800) were collected from pre- and post-test assessments. Endocrinologists showed greater gains (73% baseline, +11%) than hepatologists (80%, +7%). Post-education, learners demonstrated an improvement in knowledge/competence related to the impact of obesity on MASH progression (13%), the role of current/emerging GLP-1 RAs for managing MASH (9%), and strategies to optimize obesity-related MASH outcomes (12%). Using learners' self-reported number of patients seen per week (6-14), this program potentially impacted 63,512 patient interactions. More than 80% of learners intended to change practice based on this education, and more than 50% expressed interest in receiving further education. **Conclusion:** Digital, short-form, CME, including multidisciplinary perspectives, improved clinicians' knowledge and competence related to the impact of obesity on MASH progression and the role of GLP-1 RAs in managing MASH. This program also identified persisting educational needs and interests among learners.

3575 | GASTROINTESTINAL TOLERABILITY OF PEMVIDUTIDE WITHOUT DOSE TITRATION IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS FROM THE PHASE 2B IMPACT TRIAL

Mazen Noureddin[1] Silvia Urbina[2] Shaheen Tomah[3] John Suschak[4] Scot Roberts[2] Rachel Garner[2] Christophe Arbet-Engels[2], [1]Houston Methodist Hospital, [2]Altimmune, Inc., [3]Altimmune, [4]Altimmune, Inc

Background: Pemvidutide is a balanced 1:1 glucagon/GLP-1 dual receptor agonist that contains the EuPort side chain, which provides for weekly dosing and slows entry into the circulation, possibly contributing to improved tolerability. In IMPACT, a 48-week, phase 2b, randomized, placebo-controlled, double-blind trial in patients with biopsy-confirmed F2/F3 MASH (NCT05989711), we assessed the incidence, severity, and clinical impact of commonly reported gastrointestinal (GI) adverse events (AEs). **Methods:** 212 patients were randomized 1:2:2 to receive once-weekly subcutaneous pemvidutide (1.2 mg or 1.8 mg) administered without dose titration, or placebo for 48 weeks. Safety was monitored throughout the trial and data regarding the incidence of GI AEs of interest were analyzed. **Results:** The mean age was 53 years, mean BMI was 39 kg/m^2, 58% were female, and 43% had type 2 diabetes. Pemvidutide was generally well tolerated in this MASH population. Most patients completed study treatment as planned, with treatment completion rates of 85.4%, 84.7%, and 76.7% in the pemvidutide 1.2 mg, pemvidutide 1.8 mg, and placebo groups, respectively. Treatment discontinuations due to AEs were rare, occurring in 0.0% and 1.2%, in the 1.2 mg and 1.8 mg groups, compared to 3.5% in the placebo group. GI TEAEs were reported in 41.5%, 64.7%, and 41.9% of patients in 1.2 mg, 1.8 mg, and

placebo groups, respectively. Nausea, diarrhea, constipation, and vomiting were the most common GI AEs (reported by ≥5% of patients overall) and followed a dose-dependent pattern, with GI AEs at the 1.2 mg dose roughly equivalent to placebo. Two patients (2.3%) discontinued the study due to GI AEs in the placebo group and one patient (1.2%) in the 1.8 mg group. No GI serious AEs related to drug study and no severe GI TEAEs were reported. All GI AEs were mild to moderate, with the majority of GI AEs occurring within the first 4-8 weeks of treatment followed by marked diminution regardless of the cohort analyzed. **Conclusion:** In patients with MASH, pemvidutide was generally well tolerated with fewer AE discontinuations than placebo. GI AEs were mild to moderate and followed a dose-dependent pattern. The pharmacokinetic profile of pemvidutide, conferred by the EuPort side chain, may contribute to its observed tolerability. These findings support simple 1 or 2 step titration regimens to exploit the inherent tolerability of the 1.2 mg dose while providing escalation to 1.8 mg and higher for improved tolerability over the non-titrated dose.

Mount Sinai, New York, NY, USA, [4]Saarland University Medical Center, Homburg and Saarland University, Saarbrücken, Germany, [5]MASLD Research Center, University of California at San Diego, La Jolla, CA, USA, [6]Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, Richmond, VA, USA, [7]Boston Pharmaceuticals, Cambridge, MA, USA, [8]GSK, Stevenage, UK, [9]GSK, Collegeville, PA, USA, [10]GSK, Oy, Helsinki, Finland, [11]Service d'Hépato-gastroentérologie, Hôpital Haut-Lévêque, CHU de Bordeaux, Pessac, France

Background: MASH with stages F2/F3 fibrosis is associated with increased liver-related morbidity and mortality but there are limited approved treatment options available. Treatment with efimosfermin alfa, a long-acting fibroblast growth factor 21 analog given every 4 weeks, demonstrated MASH resolution and improvements in fibrosis, hepatic fat, and both fibrosis-related and metabolic biomarkers compared with placebo, along with an acceptable safety and tolerability profile in a Phase 2 Part B trial (NCT04880031). **Methods:** ZENITH-1 (NCT07221227) and ZENITH-2 (NCT07221188) are randomized, double-blind, placebo-controlled, multicenter Phase 3 trials enrolling approximately 1200 and 1250 participants, respectively. Participants are adults aged 18–75 years with biopsy-confirmed (ZENITH-1) or known/suspected MASH (ZENITH-2) and F2/F3 fibrosis. In ZENITH-1, participants are randomized to one of two doses of efimosfermin alfa or placebo given subcutaneously every 4 weeks. In ZENITH-2, participants are randomized to receive the same dosages as ZENITH-1, but treatment duration differs. Independent data monitoring and clinical event adjudication committees are established for both trials. Both trials are ongoing with enrollment underway; completion is planned for December 2031 for ZENITH-1 and March 2028 for ZENITH-2. **Results:** Primary endpoints in ZENITH-1 include histologic outcomes ($\geq$1-stage fibrosis improvement without worsening of MASH or MASH resolution without fibrosis worsening) at 52 weeks, with an additional analysis at Month 48 of a composite of liver-related clinical outcome events; safety and tolerability are assessed throughout. Primary endpoints in ZENITH-2 include incidence and severity of adverse events and incidence of Grade 3 or 4 laboratory abnormalities over 52 weeks. Secondary endpoints include changes in noninvasive fibrosis measures (Enhanced Liver Fibrosis score), measurements of liver stiffness and steatosis, as well as metabolic biomarkers in both trials. Assessments of bone health, including imaging and biomarkers, are evaluated in ZENITH-1. Adverse events of special interest in both trials include gastrointestinal events of Grade $\geq$3, hepatic decompensation or other liver events requiring increased monitoring or discontinuation from the study, hypersensitivity reactions, injection site reactions, and changes to the menstrual cycle. **Conclusion:** The findings of the Phase 3 ZENITH-1 and ZENITH-2 trials will provide critical insights into the clinical efficacy, durability of response, and safety profile of efimosfermin alfa for the treatment of MASH with F2/F3 fibrosis. These trials will help inform future treatment strategies in MASH.

3577 | PATIENT CHARACTERISTICS, TREATMENT PATTERNS, AND CHANGES IN LIVER FUNCTION LABORATORY TESTS AMONG RESMETIROM TREATED PATIENTS IN A REAL-WORLD MASH POPULATION

Earl Burrell[1] Nipun Atreja[2] Meena Bansal[3] Cynthia Gutierrez[1] Aaron Crowley[1] Damon Van Voorhis[1] Joanna MacEwan[1] Blake Thomas[2] Francis Lobo[2] John O'donnell[2], [1]Genesis Research Group, [2]Madrigal Pharmaceuticals, [3]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: Metabolic dysfunction-associated steatohepatitis (MASH) involves fat buildup leading to inflammation and liver scarring. Resmetirom was the first therapy approved by the United States (US) Food & Drug Administration in March 2024 for treatment of MASH with moderate or advanced fibrosis. Due to the recent approval of resmetirom, there remains a need for real-world evidence. This study aimed to capture treatment patterns and lab changes among MASH patients (pts) using resmetirom in a real-world US setting. **Methods:** This was a descriptive and retrospective study of adult pts with ≥ 1 paid claim for resmetirom on or after 3/14/2024 (study period: 3/14/2023-12/31/2025) in the Optum de-identified Market Clarity database. Pts with record of ≥1 diagnosis for non-MASH liver conditions, cirrhosis-related complications, or heavy-metal exposures in the 12-month pre-index period were excluded. Baseline demographics, clinical characteristics, and treatment patterns were summarized. Changes in liver function tests (LFTs) and relevant labs (alkaline phosphatase [ALP], alanine aminotransferase [ALT], aspartate aminotransferase [AST], total bilirubin, albumin, high-density lipoproteins [HDLs], low-density lipoproteins [LDLs], and triglycerides) between baseline and 9 months of follow-up were evaluated using paired T-tests among pts with labs at both baseline and 270 days post-index (± 45 days). **Results:** A total of 2,429 pts met the inclusion criteria. Mean (standard deviation [SD]) age was 61.3 yrs (12.8 yrs) and 61.7% of pts were female. Among pts with body mass index (BMI) information, mean (SD) BMI was 34.0 (6.3). Over half of pts were obese (59.3%) or had type 2 diabetes (T2D) (52.3%). At baseline, 34.8% of pts were prescribed glucagon-like peptide 1 receptor agonists (GLP-1 RAs). Follow-up results are shown in **Table** . Overall mean (SD) proportion of days covered (PDC) was 0.73 (0.33). Among these, 42.9% of pts had ≥9 months of follow-up with a mean (SD) 9-month PDC of 0.66 (0.34) and 48.9% reached PDC≥80%. At 9 months of follow-up, pts with available labs had a significant decrease in ALT (n=98; -12.6 U/L; 95% confidence interval [CI], -18.4, -6.8; $P<0.001$), AST (n=98; -8.8 U/L; 95% CI, -14.0, -3.6; $P=0.001$), and triglycerides (n=32; -27.2 mg/dL; 95% CI, -44.4, -9.9; $P=0.003$). **Conclusion:** This study provides an extended look at the early uptake of resmetirom in a real-world setting. At baseline, ≥50% of pts were obese and had T2D, with many pts having already initiated a GLP-1 RA. After 9 months of follow up, nearly half of pts were considered adherent (PDC≥80%). Pts also had significant decreases in several LFTs and triglycerides at 9 months. Further follow-up studies are needed to continue observing this trend.

3578 | SAFETY AND EFFICACY OF LACTOBACILLUS DELBRUECKII SUBSP. LACTIS CKDB001 IN PATIENTS WITH METABOLIC-ASSOCIATED STEATOTIC LIVER DISEASE: A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED PHASE II CLINICAL TRIAL

Jung Hee Kim[1] Ki Tae Suk[1], [1]Hallym university College of medicine

Background: Lactobacillus delbrueckii subsp. lactis CKDB001 is a probiotic derived from raw milk fermentation with hepatoprotective and metabolic effects mediated through bile acid metabolism, lipid handling, and gut–liver axis signaling. This study evaluated its safety, clinical efficacy, and gut microbiome–metabolome modulation in patients with metabolic dysfunction–associated steatotic liver disease (MASLD). **Methods:** In this randomized, double-blind, placebo-controlled trial, patients with MASLD received CKDB001 (5.0 ×109 CFU/day, one capsule twice daily; n = 46) or placebo (n = 43) for 12 weeks. Primary outcomes were changes in serum AST and ALT. Secondary outcomes included liver function markers, lipid and glucose metabolism parameters, and fatigue. Exploratory outcomes assessed anthropometry, hepatic steatosis and stiffness by transient elastography, and gut microbiome and metabolome profiles using anintegrative multi-omics. **Results:** Eighty-nine participants (mean age 44.7 years; mean BMI 29.9 kg/m2) were included, with comparable baseline characteristics between groups and no withdrawals. CKDB001 was well tolerated, with no differences in adverse events or aminotransferase levels compared with placebo. Favorable trends were observed in insulin resistance and hepatic steatosis. Significant reductions in waist and hip circumference were observed exclusively in the intervention group (all $p < 0.005$). Multi-omics analyses revealed stable microbial diversity but intervention-specific shifts in microbial taxa and metabolites at Week 12. Treatment-by-time interactions were identified for 8 taxa and 12 metabolites, including increases in L.delbrueckii and the butyrate-producing Faecalibacterium duncaniae (all $p < 0.001$). Lipid-related and bioactive metabolites involved in inflammation and host signaling were significantly altered. Correlation analyses linked L. delbrueckii with indole-3-butyric acid and 17α-hydroxyprogesterone, andF. duncaniae with arachidonic acid–related metabolites, indicating coordinated microbe–metabolite modulation. **Conclusion:** CKDB001 supplementation modulated key metabolites and lipid mediators associated with gut–liver axis signaling in patients with MASLD. These findings suggest a mechanistic basis for its metabolic benefits and support further large-scale studies to evaluate its potential as a therapeutic target for MASLD.

3579 | COMPARATIVE HEPATIC OUTCOMES OF TIRZEPATIDE AND SEMAGLUTIDE IN PATIENTS WITH MASLD/MASH, OBESITY, AND TYPE 2 DIABETES MELLITUS: A MATCHED COHORT STUDY

Moataz Aboeldahb[1] Ahmed Ibrahim[2] EzzElDien Ibrahim[3] Sherif Elhanafi[4], [1]Department of Medicine, Division of Hospital Medicine, University of Colorado School of Medicine, An, [2]San Joquin General Hospital, [3]Department of Medicine, University of Missouri-Columbia 1 Hospital Dr, Columbia, Missouri, USA 65212, [4]Division of Gastroenterology, University of Texas at Tyler School of Medicine, Tyler, Texas, USA

Background: Diabetic and obese patients commonly have metabolic dysfunction-associated steatotic liver disease (MASLD) and metabolic-associated steatohepatitis (MASH). Both tirzepatide and semaglutide have demonstrated cardiometabolic benefits including weight reduction, improved glycemia, and cardiovascular outcomes. The aim of this study is to assess the effect of tirzepatide compared to semaglutide on hepatic outcomes in patients with MASLD/MASH in a large real-world US population. **Methods:** We performed a retrospective cohort study using the TriNetX U.S. Collaborative Research Network (2010–2024). Adult patients ($\geq$18 years) with MASLD/MASH, BMI $\geq$30 kg/m², and type 2 diabetes were identified using validated ICD-10 codes. The exposure group consisted of patients receiving tirzepatide, while the comparison group included patients receiving semaglutide. Propensity score matching (1:1) was performed based on demographics, comorbidities (hypertension, heart failure, chronic kidney disease, hyperlipidemia, alcohol use, and smoking), and liver-related laboratory parameters (ALT, AST, GGT, bilirubin, albumin, INR, creatinine, sodium, and platelet count). The primary outcomes were the incidence of liver cirrhosis, hepatocellular carcinoma (HCC), and hepatic decompensation. The secondary outcome was liver enzyme normalization (ALT $\leq$30 U/L, AST $\leq$30 U/L) over a 2-year follow-up period. **Results:** Before matching, 8,382 patients on tirzepatide and 55,592 patients on semaglutide were identified. After matching, 8,382 patients remained in each cohort. All clinical variables had standardized differences $<$0.1, consistent with well-matched covariates, including baseline AST (38.2 ± 20.1 vs 39.1 ± 23.6 U/L) and ALT (45.5 ± 29.7 vs 46.6 ± 31.2 U/L). In the matched analysis, progression to liver cirrhosis (2.4% vs 2.6%; HR: 0.957, 95% CI: 0.786–1.166, p = 0.199), HCC (0.3% vs 0.4%; HR: 0.810, 95% CI: 0.478–1.371, p = 0.431), and hepatic decompensation (1.7% vs 1.5%; HR: 1.132, 95% CI: 0.888–1.443, p = 0.074) were observed in the tirzepatide vs semaglutide groups, respectively. Liver enzyme normalization rates for ALT (56.2% vs 57.5%; HR: 0.971, 95% CI: 0.857–1.100, p = 0.214) and AST (84. vs 9%85.7%; HR: 0.921, 95% CI: 0.803–1.058, p = 0.918) were similar between groups. **Conclusion:** In this large real-world cohort, tirzepatide demonstrated comparable hepatic outcomes to semaglutide in patients with MASLD/MASH, obesity, and type 2 diabetes, supporting its potential role in the management of MASLD/MASH.Further prospective randomized studies are needed to further validate these observations and assess long-term liver-related outcomes.

steatotic liver disease (MASLD). This study aimed to determine the most important MASLD-associated dietary factors potentially targetable for dietary intervention. **Methods:** We prospectively enrolled 150 healthy controls and 779 patients with MASLD from the Midwestern US. Clinical history, body composition by body impedance analyzer, liver stiffness measurement (LSM) by Transient Elastography (TE), dietary history using validated ASA24 and DHQ3 questionnaires were obtained at enrollment. Carbon isotope ratio (CIR, $^{13}C/^{12}C$), a biomarker of dietary added sugar intake, and nitrogen isotope ratio (NIR, $^{15}N/^{14}N$), a biomarker of animal protein intake, expressed as delta values in permil (‰, parts per thousand) relative abundance of heavy isotope, were measured in plasma samples from 360 subjects with an elemental analyzer and continuous-flow isotope ratio mass spectrometry. Impact of fructose supplementation on MASLD development was studied *in vitro* in a liver acinus microphysiological system (LAMPS) platform following supplementation of medium with glucose or fructose. **Results:** Among patients with MASLD, 429 had F0/F1 (mild), 212 F2/3 (moderate), and 138 F4 fibrosis (cirrhosis). The trends of male gender ($p = .0023$), age, type 2 diabetes, body mass index, waist circumference, use of GLP1 receptor agonist medications (all $p < .0001$) progressively increased from healthy controls to cirrhosis. Self-reported total energy, carbohydrate, whole grain, refined grain, and fiber intake were not significantly different amongst the groups. However, self-reported added sugar ($p = .047$) progressively increased and added sugar/fiber ratio ($p = .0005$) progressively decreased from healthy controls to cirrhosis. Plasma CIR ratios were strongly correlated with disease stage (healthy controls -20.20, mild -19.75, moderate -19.63, advanced -19.43, with less negative numbers representing higher added sugar intake; $p < .0001$). NIR ratios were similar in healthy controls and early and moderate MASLD groups, but lower in advanced MASLD (8.18, 8.19, 8.17, and 7.97, respectively, $p = .01$). Compared to the first tertile of CIR, the odds ratio (95% confidence interval) of fibrosis progression over one year was 2.6 (0.58, 11.71) for the second tertile, and 4.97 (1.17, 21.08; $p_{trend} = .0183$) for the third tertile. There was no difference in fibrosis progression risk between NIR tertiles. In the in vitro LAMPS model, additional fructose supplementation resulted in significantly greater steatosis, stellate cell activation, and Collagen Type 1 Alpha 1 production compared to matched glucose supplementation conditions. **Conclusion:** Higher dietary added sugar intake is associated with higher MASLD risk in both patients and in a LAMPS model *in vitro*. Strategies specifically targeting dietary added sugar may be critical for MASLD management.

Table 1. Plasma Carbon Isotope Ratios (CIR) And Nitrogen Isotope Ratios (NIR) By Fibrosis Stage.

Fibrosis Stage	No. of subjects	CIR, Mean (95% CI)*‡	NIR, Mean (95% CI)†‡
Healthy controls	86	-20.20 (-20.48, -19.92)	8.18 (8.01, 8.34)
MASLD F0-F1	98	-19.75 (-19.99, -19.50)	8.19 (8.05, 8.35)
MASLD F2-F3	105	-19.63 (-19.88, -19.37)	8.17 (8.02, 8.31)
MASLD F4	71	-19.43 (-19.71, -19.15)	7.97 (7.80, 8.13)
P value		<0.0001	0.0099

* Expressed as $\Delta^{13}C = \frac{(R_{sample} - R_{reference})}{R_{reference}} \times 1000$, R_{sample} is the $^{13}C/^{12}C$ ratio of the test sample, $R_{reference}$ = 0.001124, an internationally recognized standard calibrated to Vienna Pee Dee Belmnite.
† Expressed as $\Delta^{15}N = \frac{(R_{sample} - R_{reference})}{R_{reference}} \times 1000$, R_{sample} is the $^{15}N/^{14}N$ ratio of the test sample, $R_{reference}$ = 0.003677, an internationally recognized standard calibrated to atmospheric nitrogen.
‡The means and 95% CIs were derived from Analysis of Covariance (ANCOVA) with baseline age, sex, race, and smoking status as covariates.

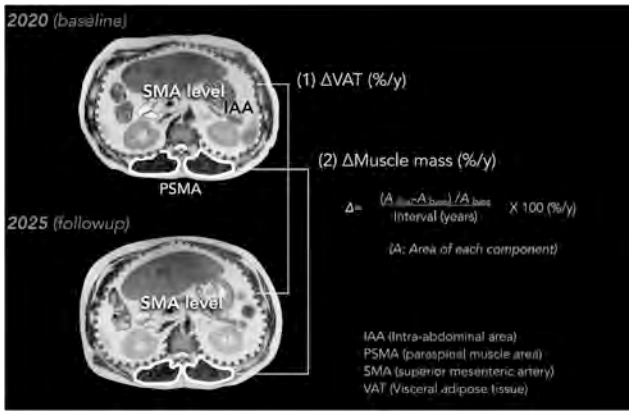
3581 | ◆ THE VISCERAL FAT–MUSCLE TRADE-OFF IN OBESE CHRONIC LIVER DISEASE: INSIGHTS FROM SMA-LEVEL PERIPORTAL VAT



Atsushi Nakamura[1], [1]Nippon kokan hospital

Background: Periportal visceral adipose tissue, including omental and mesenteric VAT, contributes to MASLD progression through the portal vein theory [*Item & Konrad, 2012*], whereby free fatty acids and inflammatory mediators from VAT drain directly into the liver. Although weight reduction is the cornerstone of MASLD treatment and current guidelines recommend at least 5% weight loss, skeletal muscle is closely linked to MASLD pathophysiology and liver-related prognosis. However, the muscular cost of guideline-recommended weight reduction remains unclear in obese CLD. In this synchronized multimodal MRI study, we simultaneously quantified pVAT, skeletal muscle mass, hepatic steatosis, and fibrosis at the SMA level to investigate the hepatic benefits and muscular risks associated with

weight loss. **Methods:** In 286 non-cirrhotic obese CLD patients (age, 60 ± 15 years; 62% male; approximately 60% MASLD), intra-abdominal area (IAA) at the SMA level—capturing periportal adipose tissue—and paraspinal muscle area were quantified by MRI. Longitudinal changes in IAA (ΔpVAT), muscle mass, proton density fat fraction (PDFF), ALT, and liver stiffness (LS) were calculated as annualized rates. Cross-sectional associations were evaluated in the overall cohort (n = 286); longitudinal relationships were assessed in patients with serial MRI examinations under clinical management (n = 141, median follow-up: 36 months). **Results:** In the overall cohort, higher IAA was independently associated with higher LS beyond FIB-4, higher body weight, and lower muscle mass (all $P < 0.01$). In the longitudinal cohort, ALT significantly decreased and serum albumin significantly increased, despite a significant decline in muscle mass. In multivariable analysis of annualized changes, pVAT reduction was independently associated with improvements in PDFF and LS, while greater pVAT reduction showed a nonlinear association with accelerated muscle loss ($R^2 = 0.336$, $P < 0.001$). In MASLD (n = 78), ≥ 4% IAA reduction—corresponding to 5% body weight loss—was achieved in 28% and was more frequent early. This threshold was associated with significant improvements in PDFF, ALT, and LS, but was accompanied by muscle loss (−3.9%/year). Although serum albumin was independently associated with ΔpVAT in the longitudinal multivariable model, albumin did not decrease at this threshold ($P = 0.968$). **Conclusion:** Assessment of VAT at the SMA level allowed IAA to capture hepatic, nutritional, and muscular consequences of visceral fat change beyond body weight alone. VAT reduction conferred hepatic benefit but accelerated muscle loss, while coupled changes in IAA, albumin, and muscle suggested skeletal muscle mobilization to support hepatic protein synthesis. Thus, weight loss remains necessary in obese CLD, particularly MASLD, but protein intake during weight reduction should not be overlooked to limit skeletal muscle catabolism while preserving hepatic benefits.

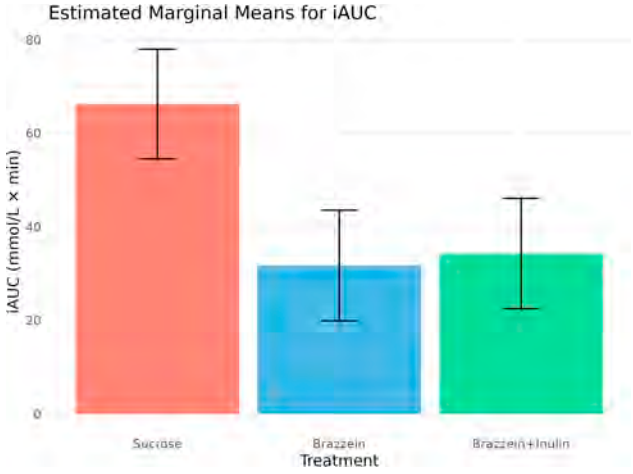
3582 | ◆ BRAZZEIN-SWEETENED ICE CREAM REDUCES POSTPRANDIAL GLYCEMIC EXPOSURE IN MASLD: A RANDOMIZED DOUBLE-BLIND CROSSOVER TRIAL



Vasily Isakov[1] Alexei Goncharov[1] Vladimir Pilipenko[1] Armida Sasunova[1], [1]Federal research Center of Nutrition, Biotechnology & Food Safety

Background: Dietary sugar reduction is a central recommendation in metabolic dysfunction-associated steatotic liver disease (MASLD), but clinical data on natural sweet proteins as sugar substitutes are limited. Brazzein is a heat-stable sweet protein 500–2000 times sweeter than sucrose. We evaluated whether brazzein-sweetened ice cream reduces acute postprandial glycemic exposure versus sucrose-sweetened ice cream in adults with MASLD. **Methods:** In a double-blind, randomized, three-period crossover trial (ClinicalTrials.gov NCT06724913), 101 adults with MASLD consumed 100 g of vanilla ice cream sweetened with sucrose (14 g), brazzein (0.014%), or brazzein plus inulin (0.014% + 4 g) on separate study days under standardized feeding conditions. MASLD was confirmed by ultrasound and vibration-controlled transient elastography. Factory-calibrated continuous glucose monitoring (FreeStyle Libre 2, Abbott Diabetes Care, Witney, UK) assessed glucose at baseline and every 15 min for 150 min after product consumption. The primary endpoint was incremental area under the glucose curve (iAUC0–150). Linear mixed-effects models adjusted for baseline glucose, period, sequence, and diabetes status, with participant as a random effect. **Results:** Participants had mean age 54.6 years, 76% were female, 97% had obesity, and 44% had type 2 diabetes. All participants completed all three periods and consumed the full product portion; no adverse events or tolerability issues were reported. Postprandial glucose trajectories differed significantly by treatment (treatment × time, $P < 0.001$). Compared with sucrose, brazzein reduced tissue glucose from 30 to 135 min, with a maximum difference at 75 min (−0.86 mmol/L; $P < 0.001$); brazzein plus inulin reduced glucose from 45 to 135 min, with a maximum difference at 75 min (−0.64 mmol/L; $P < 0.001$). Model-adjusted iAUC0–150 was 66.3 mmol/L×min (95% CI, 54.5–78.0) for sucrose, 31.7 (19.9–43.6) for brazzein, and 34.3 (22.5–46.1) for brazzein plus inulin, corresponding to 52% and 48% reductions versus sucrose, respectively (both $P < 0.001$). The two brazzein formulations did not differ ($P = 0.94$). Treatment effects on glucose trajectories were more pronounced in participants with diabetes (interaction $P = 0.042$). No period, sequence, or carry-over effects were detected. **Figure:** Model-adjusted iAUC0–150 by treatment. **Conclusion:** In adults with

MASLD, replacing sucrose with brazzein in a real dessert matrix substantially reduced acute CGM-derived postprandial glycemic exposure, with or without added inulin. Brazzein-based sugar replacement may be a practical nutritional strategy to reduce postprandial glycemic burden in MASLD, particularly among patients with concomitant type 2 diabetes.

3583 | EFFECTS OF INTERMITTENT VERSUS CONTINUOUS CALORIE RESTRICTION ON HEPATIC OUTCOMES, BODY COMPOSITION, AND GLYCOMETABOLIC PARAMETERS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Kelsey Wright[1] Margarita Pipinos[1] Cindy Schmidt[1] Yeongjin Gwon[1] Hwi Young Kim[1], [1]University of Nebraska Medical Center

Background: Intermittent fasting (IF) has gained interest as a possible dietary approach for MASLD management. While these lifestyle modification strategies offer benefits such as improvements in cardiometabolic parameters in addition to weight loss-related MASLD improvement, their comparative efficacy on hepatic outcomes, body composition, and glycometabolic parameters have not been fully elucidated compared to continuous calorie restriction (CCR). **Methods:** A systematic review and network meta-analysis (PROSPERO: CRD420251164973) was conducted by searching EMBASE, MEDLINE, CINAHL, Cochrane Library, and Scopus through October 2025. Fifteen randomized trials (N = 710) and one prospective observation study (N = 34) comparing IF to CCR or control in adults with MASLD were included. Primary outcomes were liver fat content and fibrosis; secondary outcomes included body composition, glycemic parameters, and lipid profiles. A random-effects network meta-analysis was performed using the netmeta package in R. **Results:** IF ranked as the highest-ranked intervention by P-score across every hepatic outcome and most body composition and metabolic outcomes. Hepatic Outcomes: IF produced significant reductions in liver fat content (MD = −3.36; 95% CI: −5.34 to −1.39), ALT (MD = −11.50; 95% CI: −20.63 to −2.37), and GGT (MD = −18.46; 95% CI: −33.86 to −3.06) versus control. CCR (MD = −0.38, 95% CI: −0.72 to −0.04) also demonstrated significant reduction in LFC compared with control. No intervention achieved significant fibrosis reduction or reduction in AST. Meta-regression analysis demonstrated that weight change was a significant moderator of treatment effects on LFC (β = −3.10, 95% CI: −5.18 to −1.02) and fibrosis (β = −0.55, 95% CI: −1.02 to −0.07). Body Composition Outcomes: All interventions produced statistically significant weight reductions and BMI reductions as compared with control. IF (MD = −4.06 cm, 95% CI: −5.49 to −2.62) and TRF (MD = −3.21 cm, 95% CI: −4.49 to −1.93) reduced waist circumference as compared to control. No intervention significantly affected lean mass or fat mass versus control. Metabolic Outcomes: IF was the only intervention to significantly reduce fasting glucose (MD = −4.69; 95% CI: −9.24 to −0.14), HOMA-IR (MD = −0.84; 95% CI: −1.69 to −0.005), and triglycerides (MD = −29.93; 95% CI: −54.71 to −5.16) as compared to control. No intervention significantly affected HbA1c, fasting insulin, total cholesterol, LDL, or HDL. **Conclusion:** This network meta-analysis demonstrates that IF is the most consistently effective dietary strategy for adults with MASLD, ranking highest across hepatic, and most anthropometric and metabolic outcomes. Importantly, the hepatic benefits of IF appear to extend beyond weight loss alone, as reductions in liver fat content and fibrosis persisted after controlling for weight change on meta-regression analysis.
