1625 | BEYOND AKI: ACUTE KIDNEY DISEASE PREDICTS POOR OUTCOMES IN DECOMPENSATED CIRRHOSIS. A PROSPECTIVE REAL-WORLD STUDY

Vasileios Lekakis[1] Jiannis Vlachogiannakos[1] George Papatheodoridis[1] Evangelos Cholongitas[2], [1]First Academic Department of Gastroenterology, National and Kapodistrian university of Athens,Greece, [2]First Academic Department of Internal Medicine, National & Kapodistrian University of Athens, Greece

Background: Acute kidney disease (AKD), recently redefined by the ADQI–ICA consensus, captures persistent or subacute kidney dysfunction in cirrhosis, either following acute kidney injury (AKI-AKD) or occurring without overt AKI (NAKI-AKD). Its prognostic impact in stable outpatients with decompensated cirrhosis remains unclear.The aim of the study was to evaluate the impact of AKD and its phenotypes (AKI-AKD and NAKI-AKD) on cirrhosis-related complications and mortality in outpatients with stable decompensated cirrhosis. **Methods:** We conducted a prospective single-center cohort study including 131 adults with clinically stable decompensated cirrhosis and preserved kidney function at baseline. Patients were followed for up to 60 months. AKD and its phenotypes were defined according to ADQI–ICA criteria. Cirrhosis-related complications, hospitalizations, liver transplantation and mortality were prospectively recorded. Associations with outcomes were assessed using cause-specific Cox models adjusted for liver disease severity and competing-risk analyses with liver transplantation as a competing event. **Results:** During a mean follow-up of 26.4 ± 14.2 months, AKD developed in 51/131 patients (38.9%): 33 (64.7%) had NAKI-AKD and 18 (35.3%) had AKI-AKD. AKD patients had more cirrhosis-related complications than those with preserved kidney function, including diuretic-intolerant ascites (35.3% vs 1.4%), hepatic encephalopathy (49.0% vs 10.8%), spontaneous bacterial peritonitis (31.4% vs 4.1%), non-SBP bacterial infections (49.0% vs 10.8%), bacteremia (13.7% vs 1.4%) and acute-on-chronic liver failure (33.3% vs 2.7%). Mortality was higher among AKD patients (70.5% vs 14.9%), and AKD was independently associated with death in competing-risk analysis (sHR 5.32, 95%CI 2.73–10.40; p < 0.001), remaining significant across multivariable models. AKI-AKD identified the highest-risk phenotype, with more infections, longer hospitalization and higher mortality than NAKI-AKD (sHR 2.18, 95%CI 1.80–5.19; p = 0.006). However, NAKI-AKD also conferred increased mortality compared with preserved kidney function (sHR 3.86, 95%CI 1.86–8.02; p < 0.001). AKD resolution occurred mainly in NAKI-AKD patients and was associated with improved survival (sHR 0.10, 95%CI 0.01–0.75; p = 0.025). **Conclusion:** AKD is common in stable outpatients with decompensated cirrhosis and independently predicts complications and death. Phenotypic stratification identifies AKI-AKD as the highest-risk subgroup, while NAKI-AKD represents a clinically relevant and potentially reversible stage of kidney dysfunction.

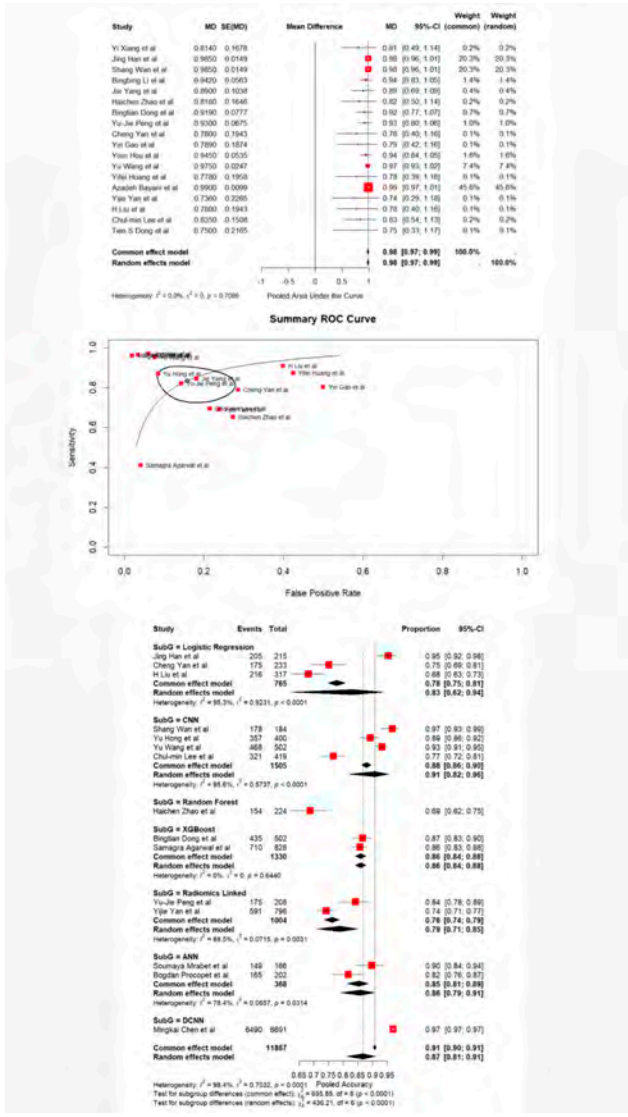
1626 | DIAGNOSTIC PERFORMANCE OF ARTIFICIAL INTELLIGENCE MODELS FOR PREDICTING ESOPHAGEAL VARICES AND VARICEAL BLEEDING RISK IN CIRRHOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS



Era Gupta[1] Aryan Gupta[2] Solomon Anighoro[3] Raja Chandra Chakinala[3] Rewanth Katamreddy[4] Dushyant Singh Dahiya[5] Michelle Bernshteyn[4], [1]Guthrie/ Robert Packer Hospital, PA, USA, [2]Bangalore Medical College

and Research Institute, India, [3]Guthrie/robert Packer Hospital, PA, USA, [4]Guthrie/Robert Packer Hospital, [5]The University of Kansas School of Medicine, KS, USA

Background: Esophageal varices are a major complication of liver cirrhosis and carry substantial morbidity and mortality because of the risk of variceal hemorrhage. Early identification of high-risk varices remains essential for timely surveillance and prophylactic intervention. In recent years, artificial intelligence (AI)- and machine learning (ML)-based models have emerged as promising tools for predicting the presence, severity, and bleeding risk of esophageal varices using clinical, laboratory, imaging, and endoscopic parameters. Several studies have reported favorable predictive performance of these models; however, variability in model architecture, validation strategies, and study methodology has limited the generalizability of existing findings. We performed a systematic review and meta-analysis evaluating the diagnostic performance of AI- and ML-based models for predicting esophageal varices and variceal bleeding risk in patients with cirrhosis. **Methods:** This review was conducted following PRISMA guidelines. PubMed, Google Scholar, and ScienceDirect were systematically searched using a comprehensive strategy. Studies assessing AI models for predicting the presence or bleeding risk of esophageal varices in patients with liver cirrhosis were included. Diagnostic performance measures, including sensitivity, specificity, accuracy, and area under the curve (AUC), were extracted and analyzed. The meta, metadata, and metafor packages, along with mada functions, were used in RStudio. Data were analyzed using random-effects models, and heterogeneity was assessed using the I^2 statistic. **Results:** A total of 23 studies were included in the final analysis. The pooled AUC of AI models was 0.98 (95% CI, 0.97–0.99). The pooled accuracy was 0.87 (95% CI, 0.81–0.91), with convolutional neural network (CNN) models demonstrating the highest accuracy (0.91). The pooled sensitivity and specificity were both 0.85, with 95% confidence intervals of 0.76–0.90 and 0.76–0.91, respectively. **Conclusion:** AI- and ML-based predictive models demonstrate promising diagnostic performance for identifying esophageal varices and assessing variceal bleeding risk in patients with cirrhosis. These tools may improve noninvasive risk stratification and optimize endoscopic surveillance strategies. However, heterogeneity in model development, validation methods, and study quality limits current clinical applicability. Further large-scale prospective studies with standardized validation frameworks are needed to support integration into routine hepatology practice.

Sperduti Nicolo'[2] Domenico Cartoni[3] Shirin Demma[1] Valerio Giannelli[1], [1]Liver Unit, Ospedale San Camillo Forlanini, Rome, Italy, [2]Internal Medicine, Ospedale San Camillo Forlanini, Rome, Italy, [3]Servizi cardiologici integrati, Ospedale San Camillo Forlanini, Rome, Italy

Background: Cirrhotic cardiomyopathy is increasingly recognized as a subclinical cardiac disorder in cirrhosis, often undetected by conventional echocardiography. Left ventricular ejection fraction (LVEF) frequently remains preserved despite early myocardial involvement, limiting its sensitivity for detecting subtle systolic abnormalities. Global longitudinal strain (GLS) is a more sensitive marker of left ventricular systolic performance, but its relationship with portal hypertension severity remains unclear. **Methods:** We retrospectively analyzed 34 patients with cirrhosis of different etiologies who underwent invasive HVPG measurement and transthoracic echocardiography including GLS assessment. Echocardiographic evaluation included LVEF, GLS, E/e', left atrial volume index (LAVI), TAPSE, and pulmonary artery systolic pressure (PAPs). Patients with significant arrhythmic, structural, ischemic, or known heart disease were excluded. Correlations between HVPG and echocardiographic parameters were assessed using Spearman analysis. Exploratory analyses also evaluated portal hypertension-related complications (esophageal varices, ascites, hepatic encephalopathy, hypersplenism), liver disease etiology, and beta-blocker exposure. **Results:** HVPG modestly correlated with worsening GLS values (rho = 0.369, p = 0.019), suggesting a relationship between increasing portal pressure burden and less favorable left ventricular systolic deformation. By contrast, HVPG did not correlate with LVEF (rho = 0.189, p = 0.243), E/e' (rho = −0.022, p = 0.891), or LAVI (rho = −0.069, p = 0.706). A non-significant trend was observed for PAPs (rho = 0.286, p = 0.073).GLS progressively worsened across increasing HVPG quartiles, with median GLS values rising from 17.85% in the lowest quartile to 22.40% in the highest quartile (Kruskal-Wallis p = 0.022). Worsening GLS also correlated with the cumulative burden of portal hypertension-related complications (rho = 0.370, p = 0.031). Exploratory sensitivity analyses did not demonstrate significant correlations between GLS and cirrhosis etiology, particularly MASLD and alcohol-related liver disease, nor with beta-blocker exposure. **Conclusion:** In our cohort, portal hypertension severity correlated with subclinical alterations in left ventricular systolic deformation assessed by GLS despite preserved LVEF and absence of significant correlations with conventional diastolic parameters. These findings support a potential cardio-hepatic hemodynamic interplay in early cirrhotic cardiac involvement and reinforce the concept that conventional echocardiographic parameters may underestimate early myocardial impairment in cirrhosis. Larger prospective studies are warranted to validate these findings and define the clinical role of GLS in the early phenotyping of cirrhotic cardiomyopathy.

1628 | EVALUATING PREDICTIVE MODELS OF CLINICAL OUTCOMES FOLLOWING TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT PLACEMENT FOR ACUTE VARICEAL HEMORRHAGE

Makeda Dawkins[1] Wei Tang[1] Daniel Basta[1] Sarah Rahni[1] Shekher Maddineni[2] Tsipora Huisman[1], [1]Westchester Medical Center, [2]Westchester Medicine Center

Background: Acute variceal hemorrhage (AVH) remains the strongest indication for transjugular intrahepatic portosystemic shunt (TIPS) placement, providing survival benefit and improving transplant-free survival. Many multivariate analyses note increased mortality risk in patients, specifically with a total bilirubin (TB) of or greater than 4 mg/dL. Treatment dilemmas arise particularly in cases of acute severe alcohol-associated hepatitis in which hyperbilirubinemia is driven by inflammation-driven bilirubinostasis, hepatocyte dedifferentiation, and transporters downregulation rather than reduced hepatocyte mass and distortion seen in advanced fibrosis. This study aimed to identify predictors of outcomes after salvage, rescue, preemptive and elective TIPS placement for AVH. **Methods:** In this retrospective cohort study, electronic medical records from a five-year period were reviewed for patients

≥ 18 years old carrying the ICD-10 code 37182. TIPS placed for ascites, gastric varices, or ectopic varices were excluded from the analysis. Simple logistic regression was used to evaluate the association between continuous variables and binary outcomes. Continuous variables were also evaluated using point-biserial correlation. Dichotomous features were analyzed with Fisher's exact test and Cramer's V to assess significance and size. Outcomes were examined according to liver disease etiology, age, comorbid conditions, TB, sodium, Child-Pugh score, and classical MELD. Adverse outcomes included post-TIPS liver failure, rebleeding, mortality, and hepatic encephalopathy. **Results:** This single center study included 65 patients. 44% carried a diagnosis of severe acute alcoholic hepatitis. Additional variables analyzed included: BMI, TB (baseline,1 week, 1 month), Δ TB (1 week, 1 month), freiburg index score, TIPS classification, HVPG (pre-, post- and Δ), AST (1 week, 1 month and Δ), ALT (1 week, 1 month and Δ). There was no statistically significant difference in post-TIPS mortality by TB pre-TIPS ($p = 0.6826$), at 1 Week ($p = 0.4293$), 1 week Δ ($p = 0.1523$), at 1 month ($p = 0.3648$), Δ at 1 month ($p = 0.3648$), total bilirubin >4mg/dL ($p = 0.4213$). The highest TB included was 11.2 mg/dL. There was no statistically significant difference in post-TIPS mortality by classical MELD >18 ($p = 0.5408$). **Conclusion:** No statistically significant association was identified between MELD score or total bilirubin and adverse outcomes following TIPS placement. Although the study was limited by sample size, the findings support level II-2 evidence suggesting hyperbilirubinemia alone is not an absolute contraindication to TIPS placement for AVH and should be considered after multidisciplinary evaluation in the absence of alternative therapies. Furthermore, hyperbilirubinemia in the setting of acute severe alcoholic hepatitis may carry a different post-TIPS prognosis compared with hyperbilirubinemia observed in end-stage liver disease.

1629 | HIGHER MELD SCORES ARE ASSOCIATED WITH WORSE TRANSVERSE COLON BOWEL PREPARATION IN PATIENTS WITH CIRRHOSIS

Tayna Latortue[1] Andrew Kleehammer[1] Ashrita Budharaju[1] Natalie Rosseau[1] Ang Li[1] Josiah McCain[1] Tiffany Chua[1], [1]University of Florida

Background: Patients with cirrhosis frequently undergo colonoscopy for colorectal cancer screening and liver transplant evaluation. Advanced liver disease may predispose patients to suboptimal bowel cleansing. We aimed to evaluate the association between liver disease severity and bowel preparation quality, with emphasis on segment-specific Boston Bowel Preparation Scale (BBPS) scores. **Methods:** We performed a retrospective cohort study at a tertiary academic center. A total of 400 patients with cirrhosis who underwent colonoscopy between 1/1/2015 and 12/30/2020 were initially identified using ICD and CPT codes. Patients were excluded if cirrhosis was not confirmed on manual chart review of if a MELD score was unavailable within 3 months of colonoscopy. Liver disease severity was assessed using MELD, MELD-Na, and MELD 3.0 scores. Patients were stratified into higher and lower liver disease severity groups using cohort-specific median MELD (12.83), MELD-Na (13.53), and MELD 3.0 (14.34) values. Bowel preparation quaality was evaluated using total and segment-specific BBPS scores. Secondary outcomes included cecal intubation rate, cecal intubation time, polyp detection, and repeat colonoscopy recommendations. **Results:** A total of 233 patients met inclusion criteria. Mean total BBPS scores were numerically lower among patients wirh higher MELD scores, although differences in overall BBPS were not consistently significant. In contrast, transverse colon bowel preparation quality was significantly worse in patients with more advanced liver disease. Patients with higher MELD-Na scores had significantly lower transverse BBPS scores compared with lower MELD-Na patients (2.01 ± 0.86 vs 2.27 ± 0.69, $p = 0.04$). Similar findings were observed using traditional MELD stratification (2.01 ± 0.83 vs 2.27 ± 0.72, $p = 0.04$). Right and left colon BBPS scores trended in higher MELD groups but were not statistically significant. Cecal intubation rate, cecal intubation time, polyp detection, and repeat colonoscopy recommendations did not significantly differ between groups. **Conclusion:** Increasing liver disease severity was associated with significantly worse transvere colon bowel preparation quality in patients with cirrhosis undergoing colonoscopy. These findings suggest that advanced liver disease may disproportionately impair clearing of the transverse colon and highlight the importance of optimizing bowel preparation strategies in this high-risk population.

Table 1. Transverse Colon BBPS Scores by MELD-Based Severity Score

Segment-specific bowel preparation quality according to MELD-based severity groups. Values are presented as mean ± SD. Severity groups were defined using cohort-specific median MELD, MELD-Na, and MELD 3.0 values.

MELD-Based Score	Lower Severity Group	Higher Severity Group	p-value
MELD (<12.85 vs ≥12.85)	2.27 ± 0.72	2.01 ± 0.83	0.040
MELD-Na (<13.53 vs ≥13.53)	2.27 ± 0.69	2.01 ± 0.86	0.040
MELD 3.0 (<14.34 vs ≥14.34)	2.25 ± 0.71	2.04 ± 0.85	0.106

1630 | COMPARATIVE PERFORMANCE OF MELD-BASED SCORING SYSTEMS FOR PREDICTING COLONOSCOPY QUALITY IN PATIENTS WITH CIRRHOSIS

Tayna Latortue[1] Andrew Kleehammer[1] Ashrita Budharaju[2] Natalie Rosseau[1] Ang Li[1] Josiah McCain[1] Tiffany Chua[3], [1]University of Florida, [2]Univeristy of Florida, [3]Univerisity of Florida

Background: Patients with cirrhosis are at increased risk for impaired bowel preparation and reduced colonoscopy quality. We compared traditional MELD, MELD-Na, and MELD 3.0 scores in predicting colonoscopy quality outcomes in cirrhosis. **Methods:** We performed a retrospective cohort study at a tertiary academic center. A total of 400 patients with cirrhosis who underwent colonoscopy between 1/1/2015 and 12/30/2020 were identified using ICD and CPT codes. Patients were excluded if cirrhosis was not confirmed on manual chart review or if a MELD score was unavailable within 3 months of colonoscopy. Liver disease severity was assessed using MELD, MELD-Na, and MELD 3.0 scores. Patients were stratified into higher and lower liver disease severity groups using cohort-specific median MELD (12.83), MELD-Na (13.53), and MELD 3.0 (14.34) values. Bowel preparation quality was evaluated using total and segment-specific Boston Bowel Preparation Scale (BBPS) scores. Secondary outcomes included cecal intubation rate, cecal intubation time, polyp detection, and repeat colonoscopy recommendations. **Results:** A total of 233 patients met inclusion criteria. Higher MELD-Na scores were associated with significantly lower transverse colon BBPS compared with lower MELD-Na scores (2.01 ± 0.86 vs 2.27 ± 0.69, $p = 0.04$). Similar findings were observed using traditional MELD stratification ($p = 0.04$). MELD 3.0 demonstrated the strongest association with cecal intubation rate, with lower completion rates in higher MELD 3.0 patients (86.5% vs 94.4%, $p = 0.063$). Traditional MELD was significantly associated with shorter cecal intubation time in higher MELD patients (9.08 vs 11.15 minutes, $p = 0.039$). No scoring was associated with polyp detection or repeat colonoscopy recommendations. **Conclusion:** MELD-based soring systems demonstrated differing relationships with colonoscopy quality outcomes in cirrhosis. MELD-Na was most strongly associated with impaired transverse colon bowel preparation quality, while MELD 3.0 demonstrated the strongest relationship with reduced cecal intubation rates. These findings suggest MELD-based scores may help identify patients at risk for impaired colonoscopy quality in advanced liver disease.

Table 1. Patient Demographics

Patient demographics. Continuous variables presented as mean (SD); categorical variables presented as N (%).

Demographic Variables	Included Patients (N=233)

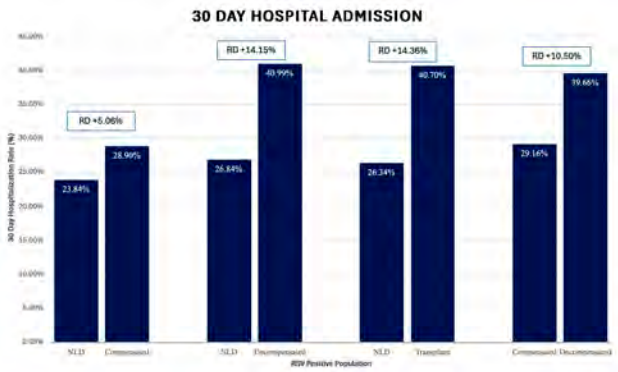
1631 | PREVALENCE AND CLINICAL OUTCOMES OF RESPIRATORY SYNCYTIAL VIRUS ACROSS LIVER DISEASE SPECTRUM – A MULTI-CENTER RETROSPECTIVE COHORT STUDY



Mridula Bethi[1] Khurram Bari[2] Jordan Voss[3], [1]University of Cincinnati Medical Center, [2]University of Cincinnati, University Hospital Inc Program, [3]University of Cincinnati

Background: Respiratory Syncytial Virus (RSV) causes significant morbidity in immunocompromised adults. In 2023, the FDA approved RSV vaccination for adults >60 years old and those aged 50-59 with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

certain comorbidities including chronic liver disease and immunocompromised. RSV burden across the spectrum of liver disease, including after liver transplantation, remains poorly characterized. By evaluating RSV prevalence and clinical outcomes among patients with cirrhosis and liver transplant, we aim to understand the benefits of more widespread adoption of RSV immunization in this population. **Methods:** We performed a multi-center retrospective cohort study between January 2018 – January 2026 using TriNetX. Patients ($\geq$ 18 years old) were stratified into four distinct groups: no liver disease (NLD), compensated cirrhosis, decompensated cirrhosis, and liver transplant recipients. RSV negative and positive populations within each cohort and RSV positive populations across cohorts were analyzed for 30-day hospitalization, composite severe outcomes (ICU, Mechanical Ventialtion, Mortality), mortality, and rates of RSV immunization. The cohorts were propensity score matched on age, sex, ethnicity, and eleven clinical co-morbidities. Risk differences (RD) and Risk ratio (RR) were calculated. **Results:** 94.3 million patients were included. RSV incidence increased progressively as follows: 1.1 per 1,000 patients in NLD, 5.1 in compensated cirrhosis, 6.9 in decompensated cirrhosis, and 8.8 in liver transplant patients. Within matched cohorts, RSV positive patients demonstrated significant increase in 30 day hospitalization, mortality, and composite across compensated, decompensated, and liver transplant groups in comparison to RSV negative patients ($p < 0.0001$). Vaccination rates were 6.3 per 1,000 patients in NLD, 22.3 in compensated, 14.1 in decompensated, and 18.9 in transplant patients. Among RSV positive patients, compared to NLD, 30 day hospitalization was elevated in compensated cirrhosis (RD +5.1%, RR 1.21 (1.09 - 1.35), $p = 0.0003$), decompensated cirrhosis (RD +14.1%, RR 1.53 (1.40 - 1.67), $p < 0.0001$), and transplant patients (RD +14.4%, RR 1.54 (1.33 - 1.80), $p < 0.0001$). Compared to the RSV positive compensated cohort, decompensated RSV positive cohort had a higher 30 day hospitalization (RD +10.5%, RR 1.36 (1.23 - 1.50), $p < 0.0001$) and mortality (RD +4.4%, RR 2.26 (1.65 - 3.07), $p < 0.0001$). **Conclusion:** RSV prevalence and morbidity increase progressively across liver disease severity. RSV positive decompensated cirrhosis, liver transplant, and compensated cirrhosis cohorts have higher hospitalization than those without liver disease. The decompensated cirrhosis cohort had higher 30-day hospitalization and mortality than compensated cirrhosis. Despite elevated RSV risk, vaccination rates remain suboptimal and paradoxically lowest in decompensated cirrhosis underscoring an urgent preventive care gap.

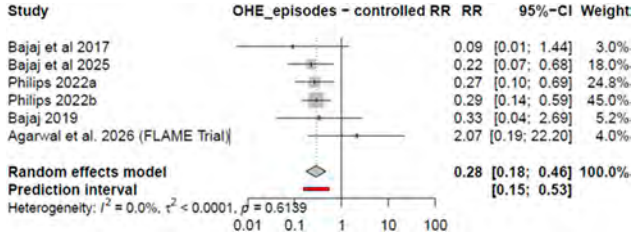
1632 | EFFICACY AND SAFETY OF FECAL MICROBIOTA TRANSPLANTATION FOR HEPATIC ENCEPHALOPATHY: A SYSTEMATIC REVIEW AND META-ANALYSIS



Parul Berry[1] Patricia Bloom[1] Danielle Gerberi[1] Sahil Khanna[2], [1]Mayo Clinic, Rochester, [2]Mayo Clinic Rochester

Background: Gut microbiota dysbiosis is associated with the pathophysiology of hepatic encephalopathy (HE) through hyperammonemia, systemic inflammation, and direct neurotoxin production. Experimental therapies like fecal microbiota transplantation (FMT) for HE may work through modulation of gut microbiota. Despite promising early-phase data, the safety and efficacy of FMT for HE remains uncertain. **Methods:** In this meta-analysis, we included randomized trials, controlled observational studies, single-arm studies, and case series evaluating resolution of covert HE or incidence of overt HE in adults with liver cirrhosis of any etiology. Intervention was FMT by any route of delivery compared with standard of care. Controlled binary outcomes were pooled as risk ratios (RR), continuous outcomes as mean differences in change, and single-arm outcomes separately as proportions. Random-effects models were used. Not all studies reported all outcomes and denominators varied by endpoint. **Results:** After duplicate removal, 1,769 records were screened, and 18 studies (5 randomized controlled trials and 13 nonrandomized studies, including controlled cohorts, single-arm studies, case series, and 1 case report) comprising 618 patients were included. FMT arm had a total of 378 patients with 240 patients in comparator arm. Mean age of population was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

52.6 years with 92% males. Most studies were single centers with 3 multicenter studies. FMT delivery routes were upper gut delivery in 9/18 studies, lower gastrointestinal enema/colonoscopy in 6/18, capsule-only in 2/18, and combined capsule plus enema delivery in 1/18. Among 6 controlled studies reporting OHE recurrence, FMT was associated with reduced risk (RR 0.28, 95% CI 0.18–0.46; $I^2 = 0\%$; $p < 0.001$). FMT was not associated with increased adverse events in controlled studies (5 studies; RR 0.70, 95% CI 0.37–1.33) and decreased serious adverse events (8 studies; RR 0.43, 95% CI 0.25–0.79). Hospitalization was numerically lower but insignificant (4 studies; RR 0.50, 95% CI 0.17–1.48). Mortality was lower in overall controlled analysis (7 studies; RR 0.62, 95% CI 0.42–0.92). Among controlled continuous outcomes, pooled changes were not statistically significant for PHES (5 studies; MD +1.22, 95% CI −0.43 to 2.88), Stroop/EncephalApp time (4 studies; MD −17.3 sec, 95% CI −54.5 to 19.9), serum ammonia (3 studies; MD −12.7, 95% CI −35.3 to 9.8), MELD (4 studies; MD −0.10, 95% CI −1.46 to 1.26), or MELD-Na (3 studies; MD +0.38, 95% CI −0.79 to 1.56). In single-arm studies, pooled proportions were 18.7% for OHE recurrence/events, 22.3% for serious adverse events, and 7.2% for mortality. **Conclusion:** This study suggests that FMT significantly reduces overt HE recurrence without an increase in adverse or serious adverse events. These findings support the advancement of FMT into phase III trials with HE recurrence as a pre-specified primary endpoint to definitively establish its therapeutic role.

1633 | SEVERE STEATOSIS AND OBESITY INFLUENCE THE PROGNOSTIC INTERPRETATION OF LIVER STIFFNESS IN COMPENSATED ADVANCED CHRONIC LIVER DISEASE (CACLD)

Anahita Rabiee[1] Christina Lindenmeyer[2] Atoosa Rabiee[3] Cyrus Mowdawalla[4] Sebastian Arambulo-Castillo[5] Matthew Davidsohn[6] Clara Tow[7] Timothy Ring[8] Kelly Bowen[9] Sobia Laique[2] Diego Drumond Westgeest e Sousa[10] Elliot Tapper[11] Michelle Ng[11] Manhal Izzy[12] Anika Shah[13] Todd Frederick[14] Robert Enders[14] Beatriz Sordi Chara[15] Denise Shkurovich[13] Jessica Davis[3] Qusai Al Zureikat[16] Andres Duarte-Rojo[17] Sarang Thaker[18] Louis Guzman[17] Qijun Yang[2] Juan Abraldes[19] Guadalupe Garcia-Tsao[1] Douglas Simonetto[20] Brett Fortune[21], [1]Yale University, [2]Cleveland Clinic, [3]Washington DC VA Medical Center, [4]Montefiore Medical Center, [5]Albert Einstein College of Medicine, Montefiore Einstein Medical Center, Bronx, United States, [6]Albert Einstein College of Medicine, Montefiore Einstein Medical Center, Brox, NY, United States, [7]Albert Einstein College of Medicine, Montefiore Einstein Medical Center, Bronx, NY, United States, [8]Hepatology and Nutrition, Cleveland Clinic; Cleveland, United States, [9]Department of Gastroenterology, Hepatology and Nutrition, Cleveland Clinic; Cleveland, United States, [10]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, United States, [11]University of Michigan Medical Center, [12]Vanderbilt University Medical Center, [13]Vanderbilt University, [14]California Pacific Medical Center, [15]Yale New Haven Hospital/ Yale School of Medicine, [16]Washington DC Veterans Affairs Medical Center,, [17]Northwestern University, [18]Northwestern University Feinberg School of Medicine, [19]University of Alberta, [20]Mayo Clinic Rochester, [21]Miami Transplant Institute, Jackson Health System

Background: Liver stiffness measurement (LSM) by vibration-controlled transient elastography (VCTE) is widely used for risk stratification in compensated advanced chronic liver disease (cACLD). However, severe obesity and hepatic steatosis may influence LSM independent of fibrosis severity. We evaluated the association of body mass index (BMI) and controlled attenuation parameter (CAP) with hepatic decompensation in a large multicenter U.S. cohort of patients with cACLD. **Methods:** We performed a retrospective multicenter cohort study of patients with cACLD, defined by baseline LSM $\geq$10 kPa by VCTE, across 9 U.S. centers. The primary outcome was hepatic decompensation, defined as ascites, hepatic encephalopathy or variceal bleeding and/or liver-related death. Non-liver related death, liver transplantation, or hepatocellular carcinoma prior to decompensation were treated as competing events. We performed 2 separate analyses to evaluate the role of obesity and CAP in hepatic decompensation. In our primary analysis, patients were stratified based on LSM into three groups: 10 to <15 kPa, 15 to <25 kPa, and $\geq$25 kPa. Within each LSM stratum, primary outcome was compared according to BMI categories (<30, 30 to <35, and $\geq$35 kg/m^2) using univariate Fine–Gray competing risks regression. In a secondary analysis, we used multivariable Fine–Gray competing risks regression model to evaluate the association between CAP (using a threshold of 280 dB/m) and

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hepatic decompensation adjusting for age, baseline albumin, MASLD etiology, and baseline LSM (using a threshold of 25 kPa). **Results:** Among 934 patients with cACLD, median age was 58.5 years, 44.4% were male, median BMI was 32.7kg/m², and the predominant etiology was MASLD (65.5%). Median follow-up was 5 years. Within each LSM stratum, patients with BMI $\geq$35 kg/m² had a significantly lower cumulative incidence of decompensation compared to those with BMI <30. In the secondary multivariable analyses, CAP $\geq$ 280 dB/m was independently associated with lower subdistribution hazard of hepatic decompensation (sHR 0.34, 95% CI 0.19–0.61, p<0.001). LSM $\geq$25 kPa, lower albumin and older age were associated with higher risk of hepatic decompensation (Table 1). **Conclusion:** Severe obesity and higher CAP values were associated with lower rates of hepatic decompensation despite similar liver stiffness measurements. These findings suggest that obesity and hepatic steatosis may affect the prognostic significance of elevated liver stiffness measurements.

Table . Multivariable Fine–Gray model for the 5-year primary outcome

Characteristic	sHR	95% CI	p-value
CAP at index fibroscan			
<280	—	—	
>=280	0.34	0.19, 0.61	**<0.001**

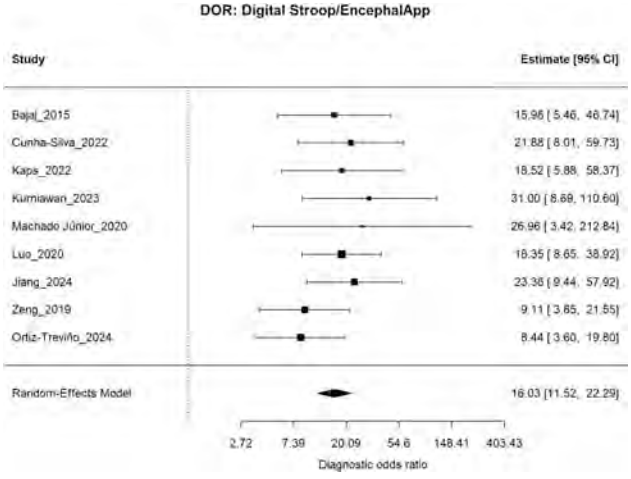
1634 | DIAGNOSTIC ACCURACY OF ENCEPHALAPP/STROOP FOR MINIMAL AND COVERT HEPATIC ENCEPHALOPATHY: A SYSTEMATIC REVIEW AND META-ANALYSIS



Parul Berry[1] Patricia Bloom[1] Danielle Gerberi[1] Sahil Khanna[2], [1]Mayo Clinic, Rochester, [2]Mayo Clinic Rochester

Background: Minimal and covert hepatic encephalopathy (MHE/Covert HE) are common but under-recognized complications of cirrhosis and are associated with impaired quality of life, falls, hospitalizations, and progression to overt HE. EncephalApp/Stroop is a scalable smartphone-based cognitive test for point-of-care assessment, but reported diagnostic accuracy varies across studies. No prior meta-analysis has quantitatively synthesized EncephalApp/Stroop diagnostic accuracy. **Methods:** We performed a systematic review and diagnostic test accuracy meta-analysis to evaluate the performance of EncephalApp/Stroop for detecting minimal/covert HE. Through systematic literature search, we reviewed studies evaluating digital biomarkers in adults with cirrhosis and identified studies evaluating EncephalApp/Stroop's diagnostic accuracy for MHE or covert HE. Two-by-two tables were extracted directly or reconstructed from disease-positive

and disease-negative counts with sensitivity and specificity. Pooled sensitivity and specificity were estimated using bivariate diagnostic test accuracy modeling with summary receiver operating characteristic curve estimation. **Results:** After deduplication, 6789 studies were screened and 207 studies underwent full text review. Nine EncephalApp/Stroop cohorts met criteria for primary diagnostic accuracy of meta-analysis. The reference standard was study-defined psychometric or neurocognitive diagnosis of minimal/covert HE, most commonly the Psychometric Hepatic Encephalopathy Score or locally validated psychometric criteria. Pooled sensitivity was 0.85 (95% CI, 0.79–0.89), specificity was 0.74 (95% CI, 0.65–0.81), and area under the summary receiver operating characteristic curve was 0.87. The diagnostic odds ratio was 16.0 (95% CI, 11.5–22.3), with positive likelihood ratio (LR) of 3.13 and a negative LR of 0.22. Sensitivity heterogeneity was moderate (I^2 = 36.4%, p = 0.127), whereas specificity heterogeneity was substantial (I^2 = 76.4%, p < 0.0001). Study-specific positive thresholds varied, most commonly using On-time + Off-time cutoffs ranging from approximately 186 to 270 seconds, which likely contributed to specificity heterogeneity. In subgroup analyses, for MHE studies (n = 5), pooled sensitivity was 0.83 (95% CI, 0.75–0.89) and specificity was 0.77 (95% CI, 0.71–0.82). For covert HE studies (n = 4), pooled sensitivity was 0.86 (95% CI, 0.79–0.91) and specificity was 0.68 (95% CI, 0.51–0.82). **Conclusion:** The EncephalApp Stroop test shows good diagnostic accuracy for covert HE and MHE. Its high sensitivity and low negative likelihood ratio support its use as a scalable screening tool to help rule out minimal/covert hepatic encephalopathy, while moderate specificity suggests that positive results may require confirmation with established psychometric criteria. Standardized cutoffs and reference standards are needed to improve future validation.

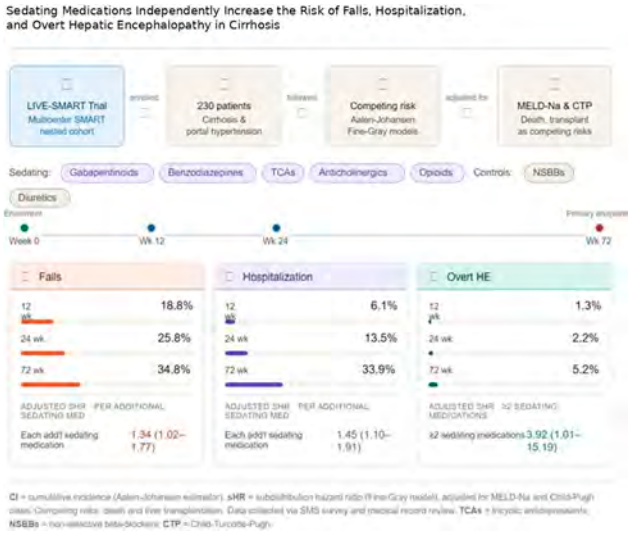
1635 | SEDATING MEDICATIONS INCREASE THE RISK OF FALLS, HOSPITALIZATION, AND HEPATIC ENCEPHALOPATHY IN PATIENTS WITH CIRRHOSIS



Beanna Martinez[1] Samantha Nikirk[1] Sumeet Asrani[2] Xi Chen[1] Marina Serper[3] Elliot Tapper[4], [1]University of Michigan, [2]Baylor Scott & White, [3]University of Pennsylvania Health System, [4]University of Michigan Medical Center

Background: Falls are common and lethal in cirrhotic patients. Medications used to manage symptoms carry problematic side effects like sedation that may increase fall risk. While these same medications are treated with caution in older adults, prospective data evaluating their contribution to fall risk in cirrhosis are lacking. **Methods:** In a prospective cohort study nested within a multicenter Sequential Multiple Assignment Randomized Trial (LIVE-SMART), competing risk was assessed using the Aalen-Johansen estimator and Fine-Gray subdistribution hazard models to track falls over 72 weeks with 230 patients with cirrhosis and portal hypertension. Death and transplantation were treated as competing risk. Data were collected using SMS-based surveys and medical record review. Sedating medications included gabapentinoids, tricyclic antidepressants (TCAs), benzodiazepines, anticholinergics, and opioids. Diuretics and NSBBs were examined as positive controls. **Results:** The overall cumulative fall incidence was 18.8% (95% CI, 13.7–23.9%) at 12 weeks, 25.8% (95% CI, 20.0–31.6%) at 24 weeks, and 34.8% (95% CI, 28.4–41.2%) at 72 weeks. Cumulative fall incidence was higher among participants on anticholinergics (44.4%), gabapentinoids (41.7%), and benzodiazepines (38.9%). In Fine-Gray models adjusted for liver disease severity, each additional sedating medication was independently associated with falls (sHR 1.34, 95% CI, 1.02–1.77) and hospitalization (sHR 1.45, 95% CI, 1.10–1.91). The total number of medications was similarly associated with falls (sHR 1.22, 95% CI 1.02–1.47) and hospitalization (sHR 1.30, 95% CI, 1.09–1.54). Overt HE risk for participants taking two or more sedating medications was nearly four times higher when adjusting for MELD-Na and Child-Pugh Class (sHR 3.92, 95% CI, 1.01, 15.19). Polypharmacy (5 or more medications), nonselective beta blockers (NSBBs), and diuretics were not associated with falls, hospitalization, or HE. **Conclusion:** Sedating medications were independently associated with increased fall risk,

hospitalizations, and HE among patients with cirrhosis and portal hypertension. These findings call for routine medication review as part of fall-risk assessment in cirrhosis, with particular attention to gabapentinoids, benzodiazepines, anticholinergics, and TCAs.

1636 | IMPACT OF THE NUMBER OF REMAINING NATURAL TEETH ON DECOMPENSATION AND SURVIVAL IN PATIENTS WITH COMPENSATED LIVER CIRRHOSIS

Tadashi Namisaki[1] Kosuke Kaji[2] Hitoshi Yoshiji[2], [1]Nara medical university department of gastoenetrology, [2]Nara Medical University

Background: To evaluate the clinical impact of oral health, assessed by the number of remaining natural teeth, on hepatic decompensation and overall survival in patients with compensated liver cirrhosis, and to explore its association with endotoxemia and sarcopenia. **Methods:** This retrospective cohort study included 106 patients with liver cirrhosis classified as Child–Pugh class A who were followed at a single tertiary center between April 2017 and March 2024 . Patients with hepatocellular carcinoma were excluded. Oral health status was assessed by the number of remaining natural teeth at baseline, and patients were stratified into two groups (<20 vs. ≥ 20 teeth). Baseline clinical and laboratory data, including prothrombin activity (PA) and serum sodium (Na), were collected. Sarcopenia was evaluated based on skeletal muscle mass, and endotoxin activity was measured using an endotoxin activity assay (EAA). The primary outcomes were hepatic decompensation and overall survival. Kaplan–Meier analysis and Cox proportional hazards models were used to identify prognostic factors. **Results:** During the follow-up period, 26 patients (24.5%) developed hepatic decompensation and 26 patients died . Patients with fewer than 20 natural teeth had significantly higher rates of both decompensation and mortality compared with those with ≥ 20 teeth. In multivariate analysis, PA $<75\%$ (hazard ratio [HR]: 2.86) and <20 teeth (HR: 2.46) were independent predictors of hepatic decompensation. For overall survival, serum Na ≤ 138 mEq/L (HR: 2.93) and <20 teeth (HR: 2.85) were identified as independent prognostic factors. Kaplan–Meier analysis demonstrated that combining tooth count with PA or Na improved risk stratification, with the highest risk observed in patients with both unfavorable clinical parameters and fewer teeth. The predictive performance of tooth count was comparable to that of conventional markers. Furthermore, patients with fewer than 20 teeth had a significantly higher prevalence of sarcopenia and elevated endotoxin activity, suggesting a mechanistic link between poor oral health, systemic inflammation, and disease progression. In addition, patients with preserved dentition who attended regular dental visits showed the most favorable outcomes. **Conclusion:** The number of remaining natural teeth is a simple and clinically meaningful predictor of hepatic decompensation and mortality in patients with compensated liver cirrhosis. Poor oral health is associated with increased endotoxemia and sarcopenia, indicating potential pathophysiological mechanisms. Incorporating oral health assessment into routine clinical evaluation may improve risk stratification and highlight the importance of multidisciplinary management, including dental care, in patients with cirrhosis.

1637 | QUANTITATIVE ASSESSMENT OF HEMOSTATIC FUNCTION USING A NOVEL MICROFLUIDIC DEVICE IN PATIENTS WITH CIRRHOSIS

Yuhei Matsumoto[1] Norihiro Imai[1] Yuki Takagi[2] Masashi Otsuki[2] Shinya Yokoyama[1] Kenta Yamamoto[1] Takanori Ito[1] Yoji Ishizu[1] Takashi Honda[1] Hiroki

Kawashima[1], [1]Nagoya University Graduate School of Medicine, [2]ZACROS Corporation

Background: Patients with cirrhosis often exhibit bleeding tendencies due to thrombocytopenia and coagulation abnormalities; however, quantitative assessment of global hemostatic function remains challenging. The Total Thrombus-formation Analysis System (T-TAS®) enables evaluation under physiologic flow conditions using a microfluidic device. This study aimed to assess hemostatic function in patients with cirrhosis, including those with thrombocytopenia, using a novel T-TAS HD assay that integrates primary and secondary hemostasis, and to compare it with the conventional T-TAS AR assay in patients with relatively preserved platelet counts. **Methods:** We enrolled 50 hospitalized patients with cirrhosis and platelet counts $\leq$150,000/μL. Bleeding time was measured by the Ivy method under 40 mmHg cuff pressure and a 23G lancet. The HD assay was performed using citrated whole blood, and the AR assay was additionally performed in patients with platelet counts >90,000/μL. Correlations between bleeding time, T-TAS assay parameters, and clinical variables were analyzed. **Results:** Thirteen patients (26%) had prolonged bleeding time ($\geq$5 minutes). Bleeding time significantly correlated with prothrombin activity (PT) (R = -0.693), platelet count (R = -0.620), and HD assay (R = -0.705) (all P < 0.001). Patients with bleeding time $\geq$5 minutes showed significantly lower HD assay values (1317.15 vs 835.42), PT (83.7% vs 46.3%), and platelet count (9.38×10^4/μL vs 5.73×10^4/μL) (all P < 0.001). ROC analysis demonstrated AUC values of 0.942 for the HD assay, 0.897 for PT, and 0.840 for platelet count, indicating superior discriminative ability of the HD assay for prolonged bleeding time. In 16 patients with platelet counts >90,000/μL, AR and HD assays were significantly correlated (R = 0.769, P = 0.0005). The AR assay correlated with bleeding time but not with PT or platelet count. Moreover, the correlation with bleeding time was stronger in the AR assay than the HD assay in patients with platelet counts >90,000/μL. Although bleeding time reflects global hemostatic function under physiologic conditions, its clinical use is limited by complexity. The HD assay strongly correlated with bleeding time and showed superior diagnostic performance compared with conventional parameters. In patients with preserved platelet counts, the AR assay also correlated with bleeding time, suggesting better reflection of global hemostasis than conventional parameters; however, it is not applicable in severe thrombocytopenia, which the HD assay overcomes. **Conclusion:** The novel T-TAS HD assay enables quantitative evaluation of hemostatic function in thrombocytopenic patients with cirrhosis and may facilitate bleeding risk stratification, preprocedural assessment, and patient education. The AR assay remains a useful complementary tool in patients with cirrhosis and preserved platelet counts.

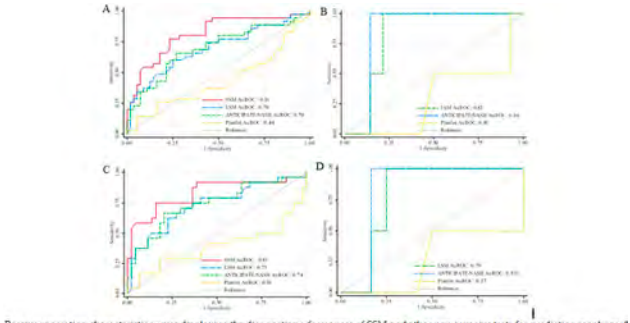
1638 | SEQUENTIAL 100-HZ SPLEEN STIFFNESS AND ANTICIPATE-NASH IMPROVE THE REAL-WORLD DETECTION OF ESOPHAGEAL VARICES: A THAI ADVANCED CHRONIC LIVER DISEASE COHORT



Kwanchat Krairaweengarmwijitr[1] Supatsri Sethasine[2], [1]Vajira Hospital, [2]Faculty of Medine Vajira Hospital

Background: Spleen stiffness measurement (SSM) is an established non-invasive marker of portal hypertension, but its performance in real-world settings with diverse etiologies remains incompletely defined. We evaluated whether a sequential strategy integrating 100-Hz SSM and the metabolic-adjusted ANTICIPATE-NASH model improves the detection of esophageal varices (EV) in patients with advanced chronic liver disease (aCLD). **Methods:** This diagnostic accuracy study was conducted at Vajira Hospital, Bangkok, Thailand, between August 2025 - January 2026. A total of 91 patients with aCLD underwent vibration-controlled transient elastography (100-Hz SSM and liver stiffness measurement [LSM]) followed by endoscopy within 3 months. The ANTICIPATE-NASH score was calculated. The primary outcome was the presence of EV of any grade. High-risk varices were defined as medium-to-large varices or small varices with high-risk stigmata. Diagnostic performance was assessed using area under the receiver operating characteristic curve (AUROC), with subgroup analyses according to SSM strata and non-selective beta-blocker (NSBBs) exposure. **Results:** EV were present in 35/91 patients (38.5%), including 9 (25.7%) with high-risk varices. SSM demonstrated the strongest overall discriminative ability (AUROC 0.81; 95% CI 0.72-0.91), with an optimal cutoff of $\geq$ 40.6 kPa yielding 77.1% sensitivity and 76.8% specificity. LSM and the ANTICIPATE-NASH score showed modest performance (AUROC 0.70), while platelet count performed poorly (AUROC 0.44). Performance varied across SSM strata. In patients with SSM < 21 kPa, LSM and ANTICIPATE-NASH showed higher discrimination (AUROC 0.82 and 0.86, respectively), whereas SSM remained dominant in higher strata. In patients not receiving beta-blockers (n = 68), SSM retained robust performance (AUROC 0.83), and the incremental value of ANTICIPATE-

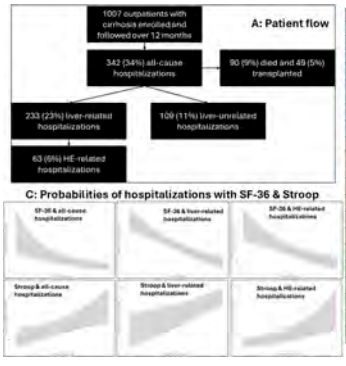
NASH in the low-SSM subgroup persisted. **Conclusion:** In real-world clinical practice, 100-Hz SSM provides robust overall discrimination for EV but exhibits stage-dependent performance. A sequential framework incorporating the ANTICIPATE-NASH model, tailored to Asian metabolic profiles, enhances diagnostic precision and patient safety, particularly in individuals with lower spleen stiffness. This multidimensional approach supports a more refined endoscopic triage and warrants further prospective validation across diverse clinical settings.



Receiver operating characteristic curves displaying the diagnostic performances of SSM and other non-invasive tests for predicting esophageal varices. A: total patients; B: patients with SSM <21 kPa; C: Non-NSBBs use patients; D: Non-NSBBs use patients with SSM <21 kPa

1639 | ALTERED COGNITION AND PATIENT-REPORTED OUTCOMES PREDICT 1-YEAR HOSPITALIZATION RISK IN A MULTI-CENTER OUTPATIENT CIRRHOSIS COHORT

Jasmohan Bajaj[1] Jacqueline O'Leary[2] Jennifer Lai[3] Puneeta Tandon[4] Florence Wong[5] Guadalupe Garcia-Tsao[6] Scott Biggins[7] Philip Vutien[8] Patrick Kamath[9] Hugo Vargas[10] Scott Silvey[11] Brian Bush[11] K Rajender Reddy[12], [1]Virginia Commonwealth University, [2]UTSW, [3]UCSF, [4]University of Alberta, [5]University of Toronto, [6]Yale University, [7]UPMC, [8]UW, [9]Mayo Rochester, [10]Mayo Clinic Arizona, [11]VCU, [12]University of Pennsylvania

Background: The clinical characteristics of patients with cirrhosis are changing, and many continue to have complications despite having a controlled etiology. Patient-reported outcomes (PROs) & cognition could impact clinical outcomes. Aim : In a contemporary cohort, to evaluate the impact of PROs and cognition on risk for future hospitalization in addition to cirrhosis-related parameters. **Methods:** 1007 outpatients with cirrhosis, median MELD 11, 39% compensated, 61% decompensated, all with controlled liver disease etiology (no alcohol, HCV SVR, suppressed HBV), were prospectively enrolled at 11 centers across North America in NACSELD-3 (North American Consortium for the Study of End-Stage Liver Disease). Clinical, comorbidity (Charlson comorbidity index, CCI) and demographic data were captured. All patients underwent baseline testing for SF-36 and Stroop and were systematically followed for 1-year through in-person visits and calls. Outcomes: Non-elective hospitalizations at 1 year. These were grouped as all-cause, liver-related or hepatic encephalopathy (HE) related. Crude comparisons between groups were & logistic regression for the 3 outcomes was performed. **Results:** 1007 patients across 11 sites (61yrs, 69% men, 42% alcohol, 39% compensated , MELD3.0 11) were enrolled. 26% had prior HE, 23% ascites, 31% were on PPIs & 30% on statins. SF-36 general health was 45[30-65] &l Stroop time was 177 [155-206] seconds. Outcomes : 34% had all-cause, 23% liver & 6% HE-related hospitalizations (FigA). 9% died & 5% got LT. Crude comparisons : Pts who got hospitalized (all-cause, liver, or HE) had worse cirrhosis severity, CCI, Stroop time (high = worse) & SF-36 general health (high = good). Multivariable model (Fig B): Age, CCI, Stroop time, SF-36 general health & MELD3.0 predicted risk for all-cause hospitalization. Modifiable risk factors of liver-related hospitalization included PPI (9% rise) & statin (43% decrease). HE was predicted by prior HE as well. Only Stroop time &SF-36 general health score predicted all three hospitalization types (all-cause, liver-related, HE-related) regression.Predicted probabilities of hospitalization-based outcomes at increasing levels of total Stroop Time and SF-36 general health score with plotted probability of each outcome over range of PRO are in figure C (negative with SF-36 & positive with Stroop). **Conclusion:** In a multicenter cohort of >1000 etiology-controlled cirrhosis outpatients; one-third required non-elective hospitalization by 1-year. PROs using SF-36 & cognition using Stroop synergized with liver-related & comorbid conditions to predict future risk of all-cause, liver-related & HE-related hospitalizations. A holistic view of liver health is needed to improve prognostication.

B: Logistic regression for the three outcomes

1640 | SECONDARY SBP PROPHYLAXIS AND LONG-TERM OUTCOMES IN CIRRHOSIS: BEYOND RECURRENCE PREVENTION

Lan Nguyen[1] Sandra Chehayeb[1] Mahinaz Mohsen[2] Anthony Martinez[1], [1]University at Buffalo, [2]Rutgers New Jersey Medical School

Background: Spontaneous bacterial peritonitis (SBP) is a major event in cirrhosis, as bacterial translocation, systemic inflammation, and hemodynamic changes can precipitate further decompensation. Although secondary prophylaxis is recommended to reduce SBP recurrence, its impact on long-term cirrhosis outcomes remains unclear. Thus, we aim to evaluate whether secondary prophylaxis provides benefits beyond preventing SBP recurrence. **Methods:** We performed a retrospective cohort study using TriNetX database global research network. Adults with cirrhosis and at least one SBP episode between 1/1/2010 and 1/1/2026 were included. Patients were stratified by use of secondary prophylaxis, defined as ciprofloxacin, norfloxacin, or trimethoprim-sulfamethoxazole started within one month of SBP. Propensity score matching balanced baseline demographics, comorbidities, and medication use. Outcomes of recurrent SBP, ascites, hepatic encephalopathy (HE), hepatorenal syndrome (HRS), variceal bleeding, multidrug-resistant (MDR) infection, fungal infection, and all-cause mortality were assessed at 3, 6, 12, and 24 months. Hazard ratios (HRs) with 95% confidence intervals (CIs) were calculated using Cox proportional hazards models. **Results:** A total of 1,860 patients received secondary prophylaxis, while 10,538 did not. Prophylaxis was associated with a lower risk of variceal bleeding only at 6 months (HR 0.67, CI 0.47-0.95). However, it was associated with reduced ascites, HE, and all-cause mortality at all time points. A decrease in recurrent SBP was noted at 3 months (HR 0.80, CI 0.68-9.93) and 6 months (HR 0.67, CI 0.47-0.96). Meanwhile, a reduction in HRS emerged later at 12 months (HR 0.72, CI 0.55-0.95) and 24 months (HR 0.73, CI 0.56-0.96). No significant increase in MDR or fungal infections was observed. Detailed results are summarized in Figure 1. **Conclusion:** Secondary SBP prophylaxis was associated with sustained reductions in ascites, HE, and all-cause mortality, with a transient decrease in variceal bleeding. Its effect on recurrent SBP was greatest early after the index episode, while its benefit in HRS appeared delayed. The value of secondary prophylaxis, therefore, may extend beyond preventing SBP recurrence to modifying the disease trajectory. Despite no significant increase in fungal and MDR infections, concerns remained for prolonged use of antibiotics. Future studies should confirm these findings and develop tools to guide individualized prophylaxis duration rather than routine indefinite therapy.

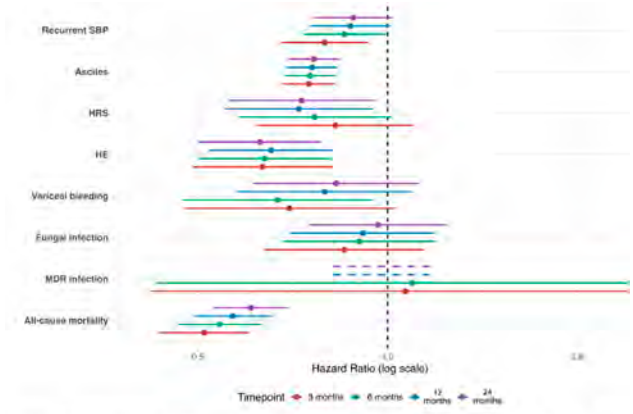

Figure 1. Hazard ratios with 95% confidence intervals for clinical outcomes between patients with and those without secondary SBP prophylaxis at 3, 6, 12, and 24 months after propensity-score matching. The dashed vertical line represents an HR of 1.0, indicating no difference between groups. HRs < 1 favor cohort with secondary SBP prophylaxis. Dashed lines denote outcomes with limited event counts (< 10 events) for stable Cox model estimation.

1641 | ASSESSING PERFORMANCE OF MODELS PREDICTING 30-DAY READMISSIONS IN CIRRHOSIS

Peter Rose[1] Alan Wigg[1] Richard Woodman[2], [1]South Australia Liver Transplant Unit, [2]Flinders University

Background: Patients hospitalized with cirrhosis have high rates of early, unplanned readmission within 30 days. These are expensive and associated with worse outcomes. We performed a scoping review of the literature to assess reporting quality of current models predicting 30-day readmissions in cirrhosis and their performance. **Methods:** Preferred Reporting Items for Systematic Reviews and Meta-analysis extension for scoping reviews (PRISM-ScR) guidelines were followed. PubMed, EMBASE and Web of Science were systemically searched from inception to January 2025. Studies reporting a model predicting 30-day readmissions in cirrhosis were eligible. Adherence to the Transparent Reporting of a multivariable prediction model for Individual Prognosis or Diagnosis (TRIPOD) statement was assessed. Patient sample, type of model, presence of a validation cohort and measures of model performance was analysed. **Results:** Out of thirteen studies proposing prediction models, there were six multicentre databases, two two-centre studies and five single-centre studies, of which one was prospective. Logistic regression was used in eleven studies, Cox regression in two studies and machine learning (ML) models in one study. No studies explicitly documented adherence to TRIPOD or other established reporting guideline. Poorly adhered checklist components were establishment of an appropriate sample size (no studies), missing data handling (three studies) and potential predictor variable handling (two studies). Internal validation was performed in four studies and external validation in three studies. Only one internally validated model demonstrated at least fair discrimination (C-statistic > 0.7). No externally validated nor ML model demonstrated at least fair discrimination. Only five studies provided examples of real-world translation of constructed models. **Conclusion:** Studies reporting prediction models for early readmission in cirrhosis do not adhere to established reporting guidelines. Overall model performance was suboptimal. Inclusion of more sophisticated psychosocial covariates in models and better adherence to reporting guidelines may improve model performance and their clinical utility.

1642 | BALLOON-OCCLUDED RETROGRADE TRANSVENEOUS OBLITERATION FOLLOWING PARTIAL SPLENIC ARTERY EMBOLIZATION FOR GASTRIC VARICES

Miyu Fujita[1] Takeharu Asano[1] Shuhei Yoshikawa[1] Shinichi Asabe[1] Hirosato Mashima[1], [1]Saitama Medical Center, Jichi Medical University

Background: Background:: Gastric varices are characterized by large diameters and high blood flow. Therefore, for the treatment of gastric varices, balloon-retrograde variceal embolization (BRTO) is recommended over endoscopic treatment alone for the prevention of rebleeding. Partial splenic artery embolization (PSE) is expected to reduce portal blood flow and portal pressure, thereby also reducing blood flow to esophageal and gastric varices. We evaluated the efficacy of BRTO in cases at our hospital where it was performed following PSE. **Methods: Methods::** Among the cases treated for gastric varices at our hospital between 2014 and 2024, we included 33 cases that underwent BRTO alone and 10 cases in which PSE was performed first, with BRTO added within 4-8 weeks. We compared and analyzed pre-treatment data (before BRTO and PSE) with data taken 3 months after treatment. The initial post-treatment evaluation was performed within 3-6 months using endoscopy and contrast-enhanced CT. **Results: Results:: 1)** The reduction or disappearance rate of gastric varices after BRTO was 94% (31/33) in the BRTO-alone group and 100% (10/10) in the PSE-first BRTO group. The rate of esophageal variceal worsening within one year after BRTO was 15% (5/33) in the BRTO-alone group and 10% (1/10) in the PSE-first BRTO group. **2)** In the BRTO-alone group, a significant decrease in ammonia levels (57 to 39 μg/dl) and a significant improvement in the prognostic nutrition index (PNI) (42.6 to 45.2) were observed 3 months after treatment. In the PSE-first BRTO group, in addition to significant improvements in ammonia levels (57 to 42.5 μg/dl) and PNI (38.8 to 43.5), a significant increase in platelet count (90,000 to 120,000/μL) was observed. No new cases of portal vein thrombosis were observed postoperatively in either group. **Conclusion: Conclusion::** BRTO following PSE for gastric varices showed a significant decrease in serum ammonia and increases in PNI and platelets. The treatment success rate was high and the rate of postoperative worsening of esophageal varices was

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

low, suggesting it is an effective treatment for gastric varices.

1643 | INCIDENCE AND ASSOCIATED RISK FACTORS FOR RECURRENCE OF HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY (HRS-AKI) IN PATIENTS WITH CIRRHOSIS

Sanjit Kumar[1] Sumit Rungta[1], [1]King Geroge's Medical University

Background: Hepatorenal syndrome-acute kidney injury (HRS-AKI) is a severe complication of cirrhosis. While vasoconstrictors and albumin can achieve initial response, subsequent recurrence poses major therapeutic challenges. The true incidence and independent predictors of HRS-AKI recurrence remain poorly defined. Recurrent HRS-AKI presents significant therapeutic issues, especially in areas with low resources where liver transplantation, the final treatment, may not be easily accessible and optimizing medical management becomes crucial. **Methods:** This longitudinal observational study included cirrhotic patients with ascites who fulfilled ICA criteria for HRS-AKI and achieved complete response to standard medical therapy. Patients were followed for 3 months. Recurrence was defined as $\geq$50% increase in serum creatinine from the lowest post-treatment value, final creatinine >1.5 mg/dL, and meeting HRS-AKI criteria. Clinical, laboratory and hemodynamic parameters were analyzed. Multivariate linear regression identified independent predictors of recurrence. **Results:** Among 72 enrolled patients (mean age 50.4±8.5 years, 86.1% male, mean MELD-Na 28.4±5.6, mean arterial pressure (MAP) 82.3±11.6 mmHg), HRS-AKI recurrence occurred in 21/71 (one patient expired before the first scheduled visit) (29.6%) over 3 months (7.0% at 2 weeks, 4.2% at 4 weeks, 12.7% at 2 months, 5.6% at 3 months). On univariate analysis, patients with recurrence had significantly lower baseline MAP (78.2±11.0 vs. 84.2±11.5 mmHg, p=0.047), higher CTP score (11.3±1.96 vs. 9.96±1.68, p=0.004), higher MELD-Na (31.3±3.9 vs. 26.9±5.6, p=0.002), higher total bilirubin (4.34±2.9 vs. 2.83±2.2 mg/dL, p=0.020), higher INR (2.37±1.11 vs. 1.87±0.65, p=0.022), and lower serum sodium (127.7±5.2 vs. 131.0±4.9 mEq/L, p=0.012). On multivariate analysis, only MAP at 4 weeks (β=-0.239, p=0.027) and MAP at 3 months (β=-0.438, p<0.001) remained independent predictors of recurrence (model R^2=0.777). **Conclusion:** HRS-AKI recurrence occurs in nearly one-third of cirrhotic patients within 3 months of successful initial treatment. While baseline liver disease severity markers (CTP, MELD-Na, bilirubin, INR, sodium) are associated with recurrence in univariate analysis, sustained hemodynamic stability—specifically MAP at 4 weeks and 3 months—is the only independent predictor. These findings highlight that preventing recurrence depends less on initial liver failure severity and more on maintaining systemic perfusion pressure, advocating for prolonged hemodynamic monitoring and MAP-targeted strategies post-HRS-AKI resolution.

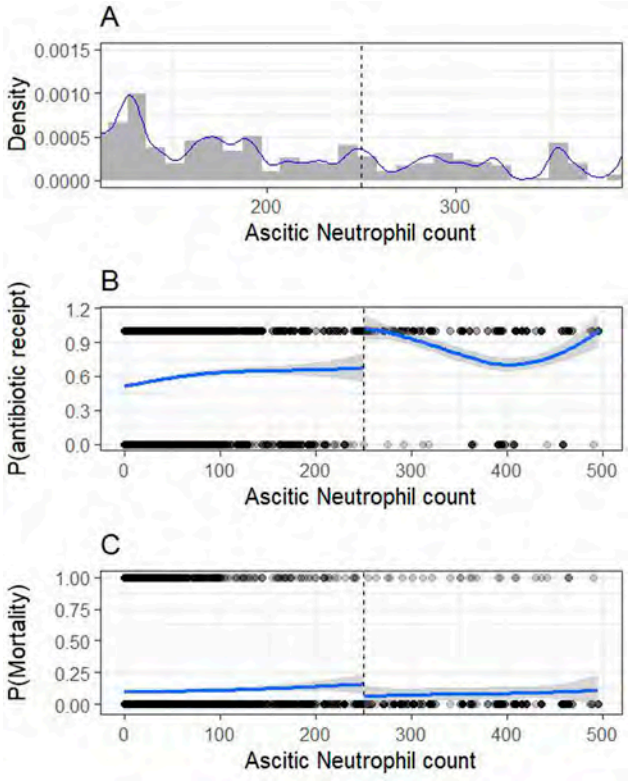
1644 | HOW LARGE IS THE IMPACT OF ANTIBIOTICS ON MORTALITY IN SPONTANEOUS BACTERIAL PERITONITIS? A REGRESSION DISCONTINUITY ANALYSIS IN US VETERANS



Melis Celdir[1] Christine Bricker[2] Tomohiro Tanaka[3], [1]Washington University School of Medicine, [2]Iowa City VA Health Care System, [3]University of Iowa

Background: Spontaneous bacterial peritonitis (SBP) carries high mortality, yet the benefit of antibiotic therapy has not been well quantified. We used a quasi-experimental fuzzy regression discontinuity design (RDD) leveraging the 250 cells/mm³ neutrophil threshold to estimate the causal effect of antibiotics on 90-day mortality. **Methods:** We conducted a retrospective cohort study of Veterans with advanced chronic liver disease and ascites who underwent paracentesis within the VA system (2015-2023). Patients with ascitic neutrophil counts >500 cells/mm³ were excluded to define an appropriate RDD bandwidth. The neutrophil threshold indicator (below vs. at/above 250 cells/mm³) served as an instrumental variable for antibiotic receipt, defined as intravenous antibiotics within 72 hours of paracentesis. Two-stage nonlinear models estimated local average treatment effects. In the first stage, antibiotic receipt was modeled as a function of the threshold indicator, continuous neutrophil count, demographics, liver disease etiology, MELD 3.0, and Elixhauser comorbidities. In the second stage, daily mortality was modeled using generalized estimating equations with robust standard errors, adjusting for age, sex, MELD 3.0, and a flexible baseline hazard. Two specifications were implemented: two-stage predictor substitution (2SPS) and two-stage residual inclusion (2SRI). Missing MELD 3.0 components (2.4-5.7%)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

were handled via multiple imputation. **Results:** Among 2,451 patients (mean age 64.6, 96.1% male, mean MELD 3.0: 19.7). The distribution of ascitic neutrophil counts showed no evidence of manipulation around the threshold (Figure A). Antibiotic receipt probability increased sharply at the 250 cells/mm³ threshold (Figure B), with a corresponding reduction in mortality also suggested at the discontinuity (Figure C). In the first stage regression model, crossing the threshold of 250 was strongly associated with antibiotic receipt ($p < 0.001$). In second-stage models, antibiotic therapy was associated with an approximately 80% reduction in daily hazard of death (2SPS: HR 0.19, 95% CI 0.04-0.95; 2SRI: HR 0.20, 95% CI 0.04-1.02). Modeled 90-day cumulative mortality was 39.7% with treatment versus 98.3% without. **Conclusion:** In this national VA cohort, antibiotic therapy at the 250 cells/mm³ neutrophil threshold was associated with markedly lower 90-day mortality among compliers. These findings reinforce the importance of prompt antibiotic treatment for suspected SBP, and the large observed effect supports further investigation of antibiotic initiation at lower neutrophil thresholds.

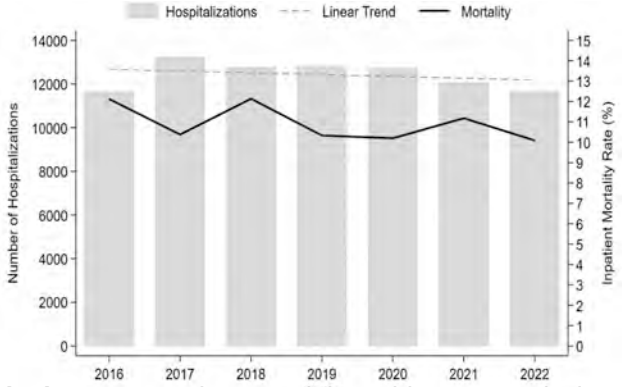
1645 | INPATIENT NATIONAL TRENDS AND PREDICTORS OF HEPATOPULMONARY SYNDROME HOSPITALIZATIONS: A U.S. RETROSPECTIVE ANALYSIS



Islam Rajab[1] Mohamed S. Elgendy[2] Muhammad Saad Jamil[3] Mahmoud Shaaban Abdelgalil[4] Belal Mohamed Hamed[5] EzzElDien A. Ibrahim[6] Abdallfatah Abdallfatah[7] Ameer Awashra[8] Alveen Majeed[9] Mohamed Elnaggar[10] Walid Baddoura[11] Nikolaos Pyrsopoulos[12], [1]St joseph University Medical Center, [2]. Faculty of Medicine, Tanta University, Tanta, Egypt, [3]Department of Medicine, Quaid-e-Azam Medical College Bahawalpur, Pakistan, [4]Faculty of Medicine, Ain- Shams University, Cairo, Egypt, [5]Faculty of Medicine, Al-Azhar University, Cairo, Egypt, [6]. Department of Medicine, University of Missouri-Columbia, MO, USA, [7]Faculty of Medicine, October 6 University, Giza, Egypt, [8]Department of Medicine, An-Najah National University, Nablus, West Bank, Palestine, [9]Internal Medicine Department, Henry Ford St John Hospital, Detroit, MI, USA, [10]Hospital Medicine department, Hartford Healthcare, Hartford CT. USA, [11]Department of Gastroenterology and Hepatology, St. Joseph University Medical Center,Paterson, NJ,USA, [12]Division of Gastroenterology and Hepatology, Department of Medicine, Rutgers New Jersey, USA

Background: Hepatopulmonary syndrome (HPS) is a pulmonary vascular complication of chronic liver disease that carries a clinical and economic burden. Contemporary national data describing inpatient outcomes in HPS remain limited. **Methods:** We performed a retrospective analysis of adult HPS hospitalizations in the National Inpatient Sample during 2016–2022. HPS was identified using the ICD-10-CM code K76.81. Survey-weighted methods generated national estimates. Temporal trends and predictors of in-hospital mortality, length of stay (LOS), and total hospital charges were evaluated using multivariable regression adjusted for demographic, socioeconomic, clinical, and hospital-level factors. **Results:** The cohort included 17,400 HPS hospitalizations. Mean age was 56.0 ± 14.8 years; 50.6% were male, 67.6% were White, and Medicare was the most common payer (41.2%). Most hospitalizations involved comorbidity burden, with 86.6% having a Charlson Comorbidity Index ≥ 3. Across the study period, hospitalization volume and mortality remained stable while unadjusted annual mean LOS did not differ significantly, although adjusted LOS showed a small positive association with calendar year. Overall, in-hospital mortality was 10.9%, mean LOS was 9.7 ± 11.6 days, and mean hospital

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

charges were $143,167 ± $240,908. In the adjusted analysis, mortality was associated with older age, Medicaid insurance, self-pay status, other-payer status, and a Charlson Comorbidity Index ≥3. Female sex was associated with lower mortality, shorter LOS, and lower charges. Higher comorbidity burden, urban teaching hospitals, and large hospital bed size were associated with greater LOS and charges. **Conclusion:** From 2016 to 2022, HPS hospitalizations in the United States showed stable national inpatient outcomes but persistent resource-intensive care. Mortality and utilization were driven by comorbidity burden, insurance status, and hospital characteristics, highlighting the need for earlier recognition, equitable specialty access, and optimized inpatient management.

1646 | HIGHER RISK OF ASCITES AND SPONTANEOUS BACTERIAL PERITONITIS IN ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED CIRRHOSIS COMPARED TO OTHER CIRRHOSIS ETIOLOGIES

Paolo DiSano[1] Anika Mittal[1] Antonio Sanchez[2],
[1]Department of Internal Medicine, University of Iowa,
[2]Division of Gastroenterology and Hepatology, Department of Internal Medicine, University of Iowa

Background: Alpha-1 antitrypsin deficiency (AATD) is an inherited disorder where accumulation of misfolded alpha-1 antitrypsin proteins damages the liver, leading to progressive hepatic fibrosis and cirrhosis. Unfortunately, AATD is still underdiagnosed and recognized at later stages, increasing risk of decompensation. However, data comparing patterns of decompensation in AATD cirrhosis compared to other cirrhosis etiologies are limited. We aimed to evaluate the ascites and spontaneous bacterial peritonitis (SBP) outcomes in patients with AATD-associated cirrhosis compared to those with cirrhosis secondary to other etiologies. **Methods:** Using the TriNetX Research Network, we conducted a retrospective cohort study identifying two cohorts via ICD-10 codes: one cohort with diagnoses of cirrhosis and AATD and a comparison cohort with cirrhosis without AATD. To reduce confounding, patients with concurrent alcohol-associated cirrhosis were specifically excluded from the AATD cohort. Propensity-score matching was performed to balance age, sex, race, and alcohol use disorder. Outcomes analyzed included ascites and SBP using risk ratios, odds ratios, and number of outcome instances. **Results:** After propensity matching, 3005 patients per cohort were identified. The AATD cirrhosis group demonstrated significantly higher rates of ascites compared to non-AATD cirrhosis (39.77% vs 30.28%, Risk Ratio (RR) 1.31, $p < 0.0001$) as well as increased burden of ascites events (mean instances: 9.23 vs 7.35, $p = 0.0038$). Similarly, risk of SBP was greater in the AATD cohort (7.12% vs 4.29%, Risk Ratio (RR) 1.66, $p < 0.0001$). **Conclusion:** To our knowledge, this is the largest real-world study to date analyzing ascites and SBP outcomes in AATD-associated cirrhosis. This study showed AATD-associated cirrhosis is associated with increased risk of both ascites and SBP as well as greater total ascites events compared to cirrhosis of other etiologies, even after excluding concomitant alcohol-associated cirrhosis and propensity-matching for alcohol use. Potential mechanisms may include late recognition of AATD resulting in more advanced portal hypertension at diagnosis, gut microbiome alterations, and impaired immune protection due to defective neutrophil mobilization and phagocytosis. Furthermore, prospective studies are critical to further characterize these risks and determine whether enhanced hepatology surveillance and optimized preventive strategies are needed in this high-risk population.

1647 | SAFETY OF SCREENING COLONOSCOPY IN PATIENTS WITH CIRRHOSIS: A REAL-WORLD ANALYSIS FROM THE TRINETX DATABASE

Ahmed Ibrahim[1] Mohamed Eldesouki[2] Fatima Israr[3] Muhamad Oum[4] Sajid Jalil[5], [1]San Joquin General Hospital, [2]New York Medical College at Saint Michael Medical Center, [3]Santa Clara Valley Medical Center, [4]Saint Agnes Medical Center, [5]Stanford University

Background: Patients with cirrhosis often require colonoscopy for various indications, however, the safety of screening colonoscopy in cirrhosis patients remains poorly defined. We aimed to evaluate post-screening colonoscopy complications in patients with compensated versus decompensated cirrhosis using a large, multicenter database. **Methods:** We queried the TriNetX database to identify adult cirrhotic patients (≥ 45 years) who underwent screening colonoscopy (identified by CPT© codes) between 2010 and 2025. Patients were stratified into compensated, decompensated cirrhosis, and controls. Individuals with high risk for colorectal cancer or prior total abdominal colectomy were excluded. Propensity score matching (1:1) was used to adjust for baseline demographics, comorbidities, and laboratory values. Post-colonoscopy outcomes were assessed within 30 days after colonoscopy using hazard ratios (HR) with 95% confidence intervals (CI). **Results:** We identified 18,862 patients with compensated cirrhosis, 51,945 with decompensated cirrhosis, and 1,257,361 control patients who underwent screening colonoscopy. After matching, when compared to non-cirrhotic controls (N = 48,171 per group), patients with decompensated cirrhosis had significantly higher odds of post-colonoscopy bleeding (1.5% vs. 1.0%; HR 1.52, 95% CI 1.34–1.74, p < 0.001), perforation (0.3% vs. 0.1%; HR 2.70, 95% CI 2.14–3.43, p < 0.001), and infection (3.1% vs. 1.5%; HR 2.02, 95% CI 1.85–2.21, p < 0.001). Decompensated cirrhosis was also associated with increased 30-day overall mortality (2.0% vs. 1.3%; HR 1.46, 95% CI 1.32–1.61, p < 0.001), which could be related to cirrhosis (Table 1).When compared to non-cirrhotic controls, patients with compensated cirrhosis (N = 18,861 per group) had non-significant differences in post-colonoscopy bleeding (HR 0.9, 95% CI 0.69–1.18, P = 0.5), perforation (HR 1.62, 95% CI 0.39-6.76, p < 0.8), and infection (HR 0.97, 95% CI 0.76-1.23, p = 0.07) (Table 2). **Conclusion:** In this large, real-world cohort, screening colonoscopy was safe in patients with compensated cirrhosis. In contrast, there was a significant increased risk of bleeding, perforation, and infection in decompensated cirrhosis patients compared to non-cirrhotic controls. These findings suggest that the severity of liver disease should be a critical consideration when assessing the risks and benefits of surveillance colonoscopy.

Table 1. Clinical outcomes of decompensated cirrhosis vs. non-cirrhotic controls

Outcomes	Decompensated N= 48,171	Control N= 48,171	HR (95% CI)	P value
Bleeding, n (%)	557/36,363 (1.5%)	374/38,374 (1.0%)	1.52 (1.34-1.74)	<0.001
Perforation, n (%)	132/47,230 (0.3%)	32/47,731 (0.1%)	2.70 (2.14-3.43)	<0.001
Infection, n (%)	1,502/48,171 (3.1%)	725/48,171 (1.5%)	2.02 (1.85-2.21)	<0.001
30-day Overall mortality, n (%)	959/48,006 (2.0%)	635/48,060 (1.3%)	1.46 (1.32-1.61)	<0.001

Table 2. Clinical outcomes of compensated cirrhosis vs. non-cirrhotic controls.

Outcomes	Compensated N= 18,861	Control N= 18,861	HR (95% CI)	P value
Bleeding, n (%)	104/15,651 (0.7%)	112/15,621 (0.7%)	0.90 (0.69-1.18)	0.5
Perforation, n (%)	≤10*/18,812 (0.1%)	≤10*/18,779 (0.1%)	1.62 (0.39-6.76)	0.5
Infection, n (%)	129/18,861 (0.7%)	130/18,861 (0.7%)	0.97 (0.76-1.23)	0.8
30-day Overall mortality, n (%)	91/18,809 (0.5%)	114/18,831 (0.6%)	0.77 (0.59-1.02)	0.07

1648 | SBP-ASSOCIATED ACUTE KIDNEY INJURY DEFINES A HIGH-MORTALITY PHENOTYPE BEYOND MELD-NA IN PATIENTS WITH ASCITES

Anmol Anmol[1] Nitesh Bassi[2] Sayan Malakar[2] Amandeep Singh[2] Jahnvi Dhar[2] Virendra Singh[2] Upasna Chauhan[2], [1]Punjab Institute of Liver and biliary sciences,Mohali, [2]Punjab Institute of Liver and Biliary Sciences, Mohali

Background: Spontaneous bacterial peritonitis (SPB) is a major complication of decompensated cirrhosis & ACLF; however, mortality may be driven more by associated renal dysfunction. We aimed to determine SBP-associated AKI predicts in-hospital mortality beyond MELD-Na in patients with ascites. **Methods:** We analyzed a database of patients with ascites. The cohort included patients with ascites and outcomes of death or discharge. Definite SBP was defined by ascitic PMN ≥ 250 cells/mm³. AKI followed standard criteria. Patients were categorized as SBP and SBP+AKI. The primary outcome was in-hospital mortality. Logistic regression assessed mortality predictors, including MELD-Na. Subgroup analysis was conducted in exclusive ACLF and DCLD groups. **Results:** Among 135 patients with ascites, 46 died and 89 were discharged, with 34.1% mortality. SBP occurred in 36 patients, AKI in 59. Mortality by SBP–AKI phenotypes: 11.9% in no SBP/no AKI, 17.6% in SBP, 60.0% in AKI, 63.2% in SBP+AKI (p < 0.001). SBP wasn't significantly linked to mortality (OR 1.57, 95% CI 0.71–3.44; p = 0.262). AKI was strongly linked to death (OR

10.33, 95% CI 4.43–24.08; p < 0.001). MELD-Na was independently linked to death (OR 2.62, 95% CI 1.22–5.62; p = 0.014). Adding SBP–AKI phenotype to MELD-Na improved mortality discrimination from AUROC 0.77 to 0.83. ACLF patients had higher mortality than DCLD: 48.4% vs 18.4% (p = 0.001). In ACLF, mortality rose from 10.5% in no SBP/no AKI to 72.7% with AKI, 76.9% with SBP+AKI (p < 0.001). In DCLD, AKI also increased mortality. **Conclusion:** In ascites patients, mortality was mainly due to AKI rather than SBP alone. SBP-associated AKI indicated a high-risk phenotype and predicted in-hospital mortality beyond MELD-Na, especially in ACLF. Early recognition of renal dysfunction in SBP may enhance risk stratification with decompensated cirrhosis.

Table 1. MELD-Na adjusted mortality model and AUROC comparison

Variable / Model	Adjusted OR / AUROC	95% CI	p value / note
SBP only vs No SBP/No AKI	1.60	0.24–10.73	0.626
AKI only vs No SBP/No AKI	7.02	1.87–26.36	0.004
SBP + AKI vs No SBP/No AKI	15.04	2.60–86.85	0.002
MELD-Na per 10-point increase	2.62	1.22–5.62	0.014
MELD-Na alone	AUROC 0.771		Model discrimination
SBP-AKI phenotype alone	AUROC 0.772		Model discrimination
MELD-Na + SBP-AKI phenotype	AUROC 0.833		Combined model

1649 | IMPACT OF RIGHT HEART FAILURE AND TRICUSPID REGURGITATION ON OUTCOMES IN HOSPITALIZED PATIENTS WITH DECOMPENSATED CIRRHOSIS

Anderson Huang[1] Raffi Karagozian[1] Gregory Fan[1],
[1]Tufts Medical Center

Background: Cirrhosis is associated with substantial morbidity and mortality in the United States. Right heart failure (RHF) and tricuspid regurgitation (TR) may exacerbate hepatic congestion, but their impact on outcomes in decompensated cirrhosis remains unclear. We evaluated the association of RHF and TR with mortality, complications, and healthcare utilization among hospitalizations for decompensated cirrhosis. **Methods:** We performed a retrospective cross-sectional study using the National Inpatient Sample (2016–2020). Adult admissions with cirrhosis and ≥1 decompensating event (hepatic encephalopathy [HE], ascites, hepatorenal syndrome [HRS], spontaneous bacterial peritonitis [SBP], or gastrointestinal bleeding [GIB]) were included. Cardiac cirrhosis, portal vein thrombosis, Budd-Chiari syndrome, and liver transplantation were excluded. Exposures were RHF and TR. The primary outcome was in-hospital mortality. Secondary outcomes included length of stay (LOS), hospitalization cost, cirrhosis-related complications, mechanical ventilation, and discharge disposition. Multivariable analyses adjusted for demographics, obesity, sepsis, Elixhauser Comorbidity Index, and cirrhosis etiology. A sensitivity analysis additionally adjusted for decompensation type. Diagnoses were identified using ICD-10-CM codes. **Results:** Among 1,463,715 hospitalizations, 6,725 (0.5%) had RHF and 16,545 (1.1%) had TR. Both RHF and TR were associated with lower in-hospital mortality (aOR 0.82, 95% CI 0.67–0.99 and aOR 0.67, 95% CI 0.58–0.76, respectively). RHF was not associated with differences in LOS or hospitalization cost, whereas TR was associated with increased LOS (aIRR 1.14) and cost (aIRR 1.15). Both RHF and TR were associated with higher odds of ascites (aOR 2.15 and aOR 2.05) and lower odds of HE, GIB, HRS, SBP, and mechanical ventilation. Both were associated with increased routine discharge and decreased discharge to skilled nursing facilities. After adjustment for decompensation type, RHF was no longer associated with lower mortality (aOR 0.88, 95% CI 0.72–1.08), whereas TR remained associated with lower mortality. No difference was observed in mechanical ventilation in this adjustment model, and other outcomes were otherwise consistent. **Conclusion:** RHF and TR were associated with lower in-hospital mortality among patients hospitalized with decompensated cirrhosis. Both were associated with a higher proportion of ascites-related hospitalizations but lower odds of other decompensating events, including SBP and HRS. TR was additionally associated with increased healthcare utilization. After adjustment for decompensation type, the association between RHF and lower mortality was attenuated, suggesting that differences in mortality were at least partly explained by variation in decompensation event type. In contrast, the association between TR and lower mortality persisted after adjustment.

Table 1: Multivariable Analysis of Outcomes by RHF and TR Status

Outcome	Right Heart Failure (aOR/aIRR, 95% CI)	Tricuspid Regurgitation (aOR/aIRR, 95% CI)
Primary Outcome		
In-hospital mortality	0.82 (0.67-0.99)	0.67 (0.58-0.76)
In-hospital mortality, adjusted for decompensation type	0.88 (0.72-1.08)	0.73 (0.63-0.83)
Resource Utilization		
LOS	1.06 (0.99-1.12)	1.14 (1.10-1.18)
Hospitalization Cost	1.07 (0.99-1.14)	1.15 (1.11-1.20)
Cirrhosis Complications		
Ascites	2.15 (1.84-2.51)	2.05 (1.87-2.26)
Hepatic encephalopathy	0.64 (0.57-0.73)	0.60 (0.55-0.64)
Spontaneous bacterial peritonitis	0.78 (0.61-0.99)	0.61 (0.51-0.73)
Hepatorenal syndrome	0.80 (0.66-0.97)	0.75 (0.66-0.85)
Gastrointestinal bleed	0.55 (0.47-0.65)	0.66 (0.60-0.73)
Clinical Outcomes		
Mechanical ventilation	0.74 (0.60-0.90)	0.83 (0.73-0.94)
Mechanical ventilation, adjusted for decompensation type	0.82 (0.67-1.01)	0.92 (0.81-1.05)

aOR = adjusted odds ratio, aIRR = adjusted incidence rate ratio. All aOR/aIRR compared to patients without RHF/TR. All estimates were adjusted for age, sex, race, obesity, sepsis, Elixhauser Comorbidity Index, and cirrhosis etiologies. Outcomes labeled "adjusted for decompensation type" were additionally adjusted for hepatic encephalopathy, ascites, hepatorenal syndrome, spontaneous bacterial peritonitis, and gastrointestinal bleeding.

1650 | THE ORAL CHOLATE CHALLENGE TEST (HEPQUANT DUO®) STRATIFIES LIVER DISEASE SEVERITY IN ADVANCED CHRONIC LIVER DISEASE

Edward Mena[1] Michael McRae[2] Joanne Imperial[3] Gregory Everson[4], [1]California Liver Reasearch Instituite, [2]Custom DX Solutions LLC, [3]HepQuant LLC, [4]HepQuant

Background: Identifying patients with compensated advanced chronic liver disease who are at increased risk for decompensation remains a central clinical goal. The Disease Severity Index (DSI), derived from the oral cholate challenge test (OCCT), is a quantitative measure of global liver disease severity ranging from 0 (healthy) to 50 (severe dysfunction). This analysis evaluated whether DSI differentiates liver disease severity subgroups according to two clinically relevant thresholds (DSI 18.3 and 24). **Methods:** Data from 17 published studies and real-world cohorts were pooled, representing a total of 1266 participants with baseline OCCT results. The OCCT involved oral administration of deuterium-labelled (d4-) cholate, blood sampling at 20 and 60 minutes, and quantification of the d4-cholate by LC-MS/MS. Test parameters, including DSI, were calculated for each participant. The studies were further subdivided into cohorts based on disease severity (i.e., Child-Pugh class, compensated versus decompensated disease, F1-F3 versus F4, and PSC progressors). Distributions of DSI within each subgroup were visualized by boxplots sorted by median DSI value. **Results:** The cohort had mean age 55 ± 13 years, BMI 31 ± 7 kg/m^2, and 56% were male. Liver disease etiologies included chronic hepatitis C (30%), MASH (26%), alcohol-associated liver disease (6%), primary sclerosing cholangitis (5%), Fontan-associated liver disease (4%), healthy controls (4%), autoimmune hepatitis (3%), cryptogenic cirrhosis (3%), primary biliary cholangitis (1%), and other etiologies (13%). The mean DSI overall was 21 ± 8 and ranged from 3 to 45 (Figure). Median DSI values were relatively low in healthy controls: 8 (range 4–13) in lean controls and 13 (7–17) in overweight controls. Median DSI values were significantly higher for subgroups with greater disease severity: 34 (15–42) for decompensated patients, 37 (15–42) for patients with Child-Pugh C, and 39 (29–42) for patients with end-stage liver disease. In treatment trials, the higher the baseline DSI, the longer it took for effective therapy to demonstrate a decrease in DSI and functional improvement (O'Leary et al. 2014). **Conclusion:** These results support use of DSI cutpoints of 18.3, indicating elevated risk for large esophageal varices and transition to clinically significant portal hypertension, and DSI 24, corresponding to transition from clinical compensation to clinical decompensation. OCCT-derived DSI may provide a quantitative, noninvasive measure of global liver disease severity for use in both clinical practice and clinical trials.

1651 | NATIONAL TRENDS AND DEMOGRAPHIC DISPARITIES IN CARVEDILOL USE FOR PRIMARY PREVENTION OF DECOMPENSATION IN COMPENSATED CIRRHOSIS

Meghana Kakarla[1] Harsha Bopanna[2] Krystal Cruz[3] Mark Shokralla[3] Aaron Jabir[3] Pradeep Yarra[3] Christina Awad[4], [1]infirmary health, [2]Nassau University Medical Center, [3]University of Texas San Antonio, [4]UT health San Antonio

Background: Carvedilol is strongly recommended per Baveno VII guidelines forpreventing first decompensation in compensated cirrhosis with clinically significantportal hypertension (CSPH), defined by hepatic venous pressure gradient ≥10 mmHg orliver stiffness ≥25 kPa, significantly lowering the risk of new ascites and prolongingdecompensation-free survival. Despite these clear benefits, real-world prescribingpatterns and potential demographic disparities in uptake following guideline adoptionremain poorly understood. This study examined national carvedilol prescribing trendsbefore and after Baveno VII dissemination, focusing on demographic differences. **Methods:** Using the TriNetX US Collaborative Network, we identified adults with compensated cirrhosis and portal hypertension across 70 healthcare organizations using ICD 10 codes . Carvedilol exposure was identified using RxNorm codes. Prescribing patterns were evaluated during pre-Baveno VII (2020–2022) and post-Baveno VII (2023–2025) periods using incidence proportion, prevalence, and incidence rate (per 10,000 person-days). Analyses were stratified by age, sex, race, and ethnicity. **Results:** Carvedilol use increased markedly from the pre- to post-Baveno VII period. Overall

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

prevalence more than doubled (12.5% to 25.9%) and incidence rate rose over3-fold (0.74 to 2.31 per 10,000 person-days). Substantial demographic disparities wereevident in both periods:Sex: Men had consistently higher use (post-period prevalence: 26.9% vs. women24.4%; pre-period: 13.2% vs. 11.4%).Age: Adults aged 20–29 showed the highest post-period incidence proportions (19.7–20.1%), representing the largest relative increase from pre-period baselines(3.7–5.7%).Race: Black adults had the highest prevalence in both periods (19.5% pre, 31.2% post)which could be misleading given the fact that carvedilol is also prescribed for other co-morbidities common in black adults. White adults had the lowest (11.9% pre, 24.8%post). Asian (12.4% to 30.2%) and Pacific Islander (14.4% to 30.9%) adults showed thelargest relative increases.Ethnicity: Hispanic/Latino adults showed the greatest relative increase in incidenceproportion (5.6% to 19.6%) despite the lowest pre-period prevalence (10.6%) which isnotable. **Conclusion:** Carvedilol prescribing for compensated cirrhosis with CSPH more thandoubled following Baveno VII, confirming broad guideline adoption. However, persistentdisparities by sex, age, race, and ethnicity were present both before and after guidelinedissemination, suggesting longstanding differences in care delivery rather thandifferential guideline response. These findings underscore the need for targetedimplementation strategies to ensure equitable access to carvedilol therapy.

1652 | AMIKACIN USE AND RISK OF NEPHROTOXICITY IN PATIENTS WITH LIVER CIRRHOSIS HOSPITALIZED FOR SEPSIS

Jaime Poniachik[1] Alonso Saez[1] Carlos Padilla[1] Juan Medel[1] Daniela Simian[1] Gabriel Méndez-Valdés[2] María Gómez[2] Álvaro Urzúa[1] Juan Roblero[1], [1]Hospital Clínico Universidad de Chile, [2]Universidad de Chile

Background: Aminoglycosides are broad-spectrum antibiotics mainly active against gram-negative bacteria. Nephrotoxicity has been reported in 10–20% of cases and may be more frequent in patients with liver cirrhosis. Amikacin is commonly used in sepsis; however, data regarding its nephrotoxic risk in cirrhotic patients remain limited. The aim was to evaluate the association between amikacin use and acute kidney injury (AKI) in patients with liver cirrhosis and sepsis. **Methods:** We conducted a retrospective, observational, analytical study including adult patients with cirrhosis hospitalized for sepsis between 2017 and 2023 who received antibiotic therapy. AKI was defined as an increase in serum creatinine $\geq$0.3 mg/dL within the first 7 days of hospitalization. Clinical variables, AKI, and mortality were compared between patients who received amikacin and those who did not. Multivariate analysis was adjusted for age, sex, Child-Pugh class, and MELD-Na score. Statistical analysis was performed using Stata 15.0, with a significance level of 0.05. **Results:** A total of 227 patients were included, with a median age of 65 years (IQR 54–70); 99 (44%) were women, and 69 (30%) received amikacin. Patients receiving amikacin had a higher frequency of AKI compared with those who did not receive amikacin (35% vs 21%; OR 2.02, 95% CI 1.07–3.78; p = 0.028). In subgroup analyses, AKI was more frequent among patients receiving amikacin with baseline serum creatinine $\geq$2.0 mg/dL, Child-Pugh C cirrhosis, and MELD-Na $\geq$20. In multivariate analysis, MELD-Na score remained independently associated with AKI (OR 1.08, 95% CI 1.02–1.14; p = 0.002), while amikacin use showed a non-significant trend toward increased AKI risk (OR 1.8, 95% CI 0.9–3.5; p = 0.081). **Conclusion:** AKI was more frequent among cirrhotic patients receiving amikacin for sepsis, particularly in those with advanced liver disease. However, after adjustment, liver disease severity, especially MELD-Na score, appeared to be the main factor independently associated with AKI.

Table. Evaluation of the development of renal function deterioration in different groups of patients depending on the use or not of Amikacin

		AKI	No AKI	Valor p
According to baseline serum creatinine				
Creatinine < 1.5 (N = 166)	Amikacin	13 (36)	35 (27)	0.282
	Without Amikacin	23 (64)	95 (73)	
Creatinine 1.5 – 1.99 (N = 33)	Amikacin	4 (33)	4 (19)	0.357
	Without Amikacin	8 (67)	17 (81)	
Creatinine ≥ 2.0 (N =28)	Amikacin	7 (78)	6 (32)	**0.029**
	Without Amikacin	2 (22)	13 (68)	
Initial suspicion of infection by Gram (-) bacteria according to infectious focus				
Suspected Gram (-) infection (N = 171)	Amikacin	21 (48)	41 (32)	0.066
	Without Amikacin	23 (52)	86 (68)	
Without suspicion of Gram (-) infection (N = 57)	Amikacin	4 (28)	4 (9)	0.071
	Without Amikacin	10 (71)	39 (91)	
According to septic shock				
With septic shock (N = 74)	Amikacin	16 (57)	22 (48)	0.437
	Without Amikacin	12 (43)	24 (52)	
Without septic shock (N = 154)	Amikacin	9 (30)	23 (19)	0.165
	Without Amikacin	21 (70)	101 (81)	
According to Child-Pugh Score				
Child-Pugh A – B (N = 104)	Amikacin	10 (34)	18 (24)	0.280
	Without Amikacin	19 (66)	57 (76)	
Child-Pugh C (N = 123)	Amikacin	14 (50)	27 (28)	**0.033**
	Without Amikacin	14 (50)	68 (72)	
According to MELD-Na Score				
MELD-Na < 20 (N = 77)	Amikacin	3 (25)	14 (21)	0.524
	Without Amikacin	9 (75)	51 (78)	
MELD-Na ≥ 20 (N = 150)	Amikacin	21 (47)	31 (30)	**0.034**
	Without Amikacin	24 (53)	74 (70)

1653 | IMPACT OF SPONTANEOUS BACTERIAL PERITONITIS ON MORTALITY AND HEALTHCARE UTILIZATION IN HOSPITALIZATIONS FOR HEPATORENAL SYNDROME: A NATIONAL INPATIENT SAMPLE ANALYSIS (2018–2022)

Nishanth Eluri[1] Brett Cohen[1] Kyle Tio[1] Barbara Halicki[1] Renata Lerer[2], [1]St. Luke's University Hospital, [2]St. Luke's University Hospital Network

Background: Spontaneous bacterial peritonitis (SBP) is a common and serious infection in decompensated cirrhosis and a key precipitant of circulatory dysfunction and hepatorenal syndrome (HRS). The overlap of SBP and HRS may identify a particularly high-risk population, yet contemporary nationwide data on its burden and clinical impact remain limited. We evaluated the association of concurrent SBP with in-hospital mortality and healthcare utilization among US HRS hospitalizations. **Methods:** Using the National Inpatient Sample (2018–2022), HRS hospitalizations were identified and stratified by concurrent SBP status. Survey-weighted logistic regression estimated crude and adjusted odds ratios for in-hospital mortality, adjusting for demographics, comorbidities, and hospital characteristics; survey-weighted comparisons assessed length of stay (LOS) and total charges. **Results:** The weighted HRS subpopulation comprised approximately 262,950 hospitalizations, of which SBP was present in 12.1% (n ≍ 31,695 unweighted).In-hospital mortality was markedly higher among HRS patients with SBP than without (33.0% vs. 25.1%). SBP was associated with higher odds of in-hospital death in both crude (OR 1.47, 95% CI 1.39–1.56, $p < 0.001$) and adjusted (aOR 1.45, 95% CI 1.37–1.54, $p < 0.001$) models.SBP was associated with longer LOS (mean 12.6 vs. 11.1 days; SD 14.0 vs. 13.1; $p < 0.001$) and higher total charges (mean $207,021 vs. $177,273; SD $405,319 vs. $344,272; $p < 0.001$). In-hospital complications were more frequent with SBP, including shock (41.5% vs. 26.7%), ICU admission (29.4% vs. 23.0%), mechanical ventilation (22.1% vs. 18.7%), and vasopressor use (14.1% vs. 9.5%).With respect to comorbidities, HRS patients with SBP had higher rates of malnutrition (26.1% vs. 20.1%), while those without SBP more frequently had DM2 (31.2% vs. 24.6%), hyperlipidemia (20.8% vs. 14.5%), CAD (12.7% vs. 8.0%), and CKD stage 3 (32.7% vs. 27.1%). **Conclusion:** Among US hospitalizations for HR S, concurrent SBP was associated with substantially higher in-hospital mortality and greater healthcare utilization, including markedly higher rates of shock, ICU admission, and organ support. These associations persisted after adjustment, identifying SBP as a marker of severe illness in HRS. The concentration of metabolic comorbidities in the non-SBP group may reflect differences in patient phenotype and coding patterns and warrants cautious interpretation. These findings underscore the prognostic importance of identifying and aggressively managing SBP in patients hospitalized with HRS.

1654 | ATHEROSCLEROTIC CARDIOVASCULAR DISEASE AS A CONTRIBUTOR TO MORTALITY IN OLDER ADULTS WITH CIRRHOSIS: A POPULATION-BASED STUDY

Bland Ahmed[1] Palwasha Farooqi[1] Mahrukh Mahrukh[2] Sahar Zafar[2] Hajra Umar Jaspal[3] Shehryar Rasheed Sohail[4] Arishman Yasin Chaudhary[2] Zainab Attiq[2] Ehsanullah Alokozay[5], [1]Desert Regional Medical Center, Palm Springs, Ca, USA, [2]University Medical and Dental College, University of Faisalabad, Faisalabad, Pakistan, [3]University College of Medicine and Dentistry (UCMD), The University of Lahore, Lahore, Pakistan, [4]Jinnah Sindh Medical University, [5]Faculty of Medicine, Kandahar University, Kandahar, Afghanistan

Background: Cirrhosis is an increasing cause of mortality among older adults in the United States. In addition to hepatic complications, atherosclerotic cardiovascular disease (ASCVD) is an important contributor to adverse outcomes in this population. However, national trends and demographic disparities in ASCVD-related mortality among elderly patients with cirrhosis remain poorly defined. Characterizing these trends is essential for optimizing risk assessment and cardiovascular preventive care in this vulnerable population. **Methods:** Death certificates for adults aged ≥ 65 years with cirrhosis (ICD-10: K74.0-K74.6) as the underlying cause of death and ASCVD (ICD-10: I20–I25, I63, I70,171.1-171.9,172.1-I74, I77.8-177.9) as contributing cause were extracted from the CDC WONDER database from 1999–2025. Age-adjusted mortality rates

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(AAMRs) per 100,000 were calculated using the 2000 U.S. standard population. Joinpoint regression identified annual percent change (APC) and average annual percent change (AAPC). Mortality trends were stratified by age group, sex, race, census region, and urbanization status. **Results:** A total of 17,290 deaths were identified over 27 years. The overall AAMR declined from 1.37 to 1.21 per 100,000 from 1999-2014 (APC: −1.29; 95% CI: −2.32 to −0.55), then significantly rose to 1.82 per 100,000 by 2025 (APC: +3.58; 95% CI: 2.67–4.93), with an overall AAPC of +0.74 (95% CI: 0.41–1.09). Men consistently exhibited higher AAMRs than women, reaching 2.49 per 100,000 in 2025 compared with 1.30 per 100,000 among women. However, women showed a sharper recent rise from 2018–2025 (APC: +6.64; 95% CI: 3.54–15.01) compared with men from 2011–2025 (APC: +2.75%; 95% CI: 2.06–3.82). By age group, the ≥85-year cohort demonstrated the steepest rise from 2015 to 2025 (APC: +7.11), followed by the 75–84-year group (APC: +4.63), while the 65–74-year group showed a non-significant overall trend (AAPC: +0.13). The South showed the highest regional burden (AAPC: +1.81), while the Northeast exhibited a steady overall decline (AAPC: −2.10). Rural areas showed a notable rise from 2009 to 2020 (APC: +2.79), while urban areas had no significant overall change (AAPC: −0.17). **Conclusion:** ASCVD mortality in older adults with cirrhosis followed a biphasic pattern, with a post-2014 resurgence that was most pronounced in the ≥85-year cohort, men, Southern states, and rural communities, highlighting that ASCVD represents a crucial contributor to death in this population.

1655 | USING NON-INVASIVE LIVER FIBROSIS INDICES TO PREDICT VARICEAL BLEEDING IN CIRRHOTIC PATIENTS PRESENTING WITH UPPER GASTROINTESTINAL BLEEDING: A RETROSPECTIVE COHORT STUDY

Yi Nong Song[1] Eddie He[1] Marco Puglia[1], [1]McMaster University

Background: Liver cirrhosis leads to increased portal pressure, predisposing patients to the development of gastroesophageal varices—a complication present in 50–60% of compensated and up to 80% of decompensated cirrhotics. Variceal bleeding carries a 6-week mortality rate of 15–20%, making it one of the most life-threatening complications of cirrhosis. In contrast, non-variceal upper gastrointestinal (GI) bleeding carries a lower mortality rate of 1.1–11%. Differentiating variceal from non-variceal bleeding based solely on clinical presentation remains challenging. Empirically managing all upper GI bleeds as variceal events can lead to unnecessary healthcare expenditures and overtreatment with medications such as vasoactive agents and antibiotics. Non-invasive fibrosis indices have been validated for estimating liver fibrosis and portal hypertension, but their ability to predict variceal bleeding has not been evaluated. Our aim is to assess whether non-invasive liver fibrosis indices can be used to stratify the risk of variceal versus non-variceal upper GI bleeding in patients with cirrhosis. **Methods:** This retrospective cohort study included adult patients admitted to Hamilton Health Sciences between June 6, 2022 and October 23, 2024with a history of cirrhosis and a presenting diagnosis of upper GI or variceal bleeding. Patient data were extracted from electronic medical records and entered into a REDCap database. Non-invasive fibrosis indices (APRI, NFS, BARD, FNI, and FIB-4) were calculated where data were available. Prognostic scores (MELD 3.0 and Child–Pugh) were also calculated for comparison. Statistical analyses included one-tailed t-tests, sensitivity, specificity, area under the receiver operating characteristic curve (AUC) were calculated. **Results:** Table 1 includes diagnostic performance of scores for predicting variceal bleeds. The test with best AUC (FNI) was then compared to other tests with DeLong's test. **Conclusion:** APRI, NFS, and FIB-4 demonstrated modest discriminatory ability (AUC 0.48–0.61). The BARD score showed poor sensitivity but high specificity. APRI and FIB-4 both had high sensitivity, but poor specificity. FNI achieved the highest accuracy (AUC 0.75), though optimal threshold determination was limited by small sample size and resulted in high sensitivity but poor specificity. Differences in AUC between FNI and most non-invasive fibrosis and prognostic scores were not statistically

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

significant, except for BARD, where FNI showed superior discrimination (AUC 0.75 vs 0.45 p = 0.04). Traditional prognostic models including MELD 3.0 and Child-Pugh performed poorly as diagnostic tools, likely reflecting their role inassessing liver disease severity rather than bleeding risk. Larger, prospective studies are warranted to validate these findings and explore integration with additional non-invasive modalities (e.g., transient elastography) to enhance diagnostic accuracy.

Index	n	Optimal Cut-off (Youden's index)	Sensitivity	Specificity	AUC (95% CI)
APRI	60	0.25	100%	3.1%	0.57 (0.43-0.72)
NFS	60	1.68	67.9%	40.6%	0.48 (0.33-0.63)
BARD	60	≥3	17.9%	96.9%	0.61 (0.48-0.75)
FNI	25	0.20	93.3%	0%	0.75 (0.06-0.44)
FIB-4	59	1.06	96.4%	9.7%	0.59 (0.44-0.74)
MELD 3.0	60	24.5	28.6%	75%	0.55 (0.40-0.70)
Child-Pugh	60	12.5	10.6%	90.6%	0.54 (0.39-0.69)

1656 | EARLY PARACENTESIS AND IN-HOSPITAL MORTALITY IN PATIENTS WITH DECOMPENSATED CIRRHOSIS AND SUSPECTED SPONTANEOUS BACTERIAL PERITONITIS AT A SINGLE CENTER IN MEXICO CITY

Alejandra Díaz Jarquín[1] Froylan Martinez Sanchez[2] Jacqueline Cordova Gallardo[3] Samantha Armendáriz Pineda[1] Scarlet Espinosa Castrejón[1], [1]Hospital General Dr. Manuel Gea Gonzalez, [2]Centro de Investigación y Gastroenterología S.C, [3]Hospital General Dr Manuel Gea González

Background: Introduction: Decompensated cirrhosis is a frequent cause of hospital admission and is associated with high mortality, especially when spontaneous bacterial peritonitis (SBP) is suspected. In this scenario, diagnostic paracentesis is useful for confirming the diagnosis and initiating timely treatment. However, in daily clinical practice, it is not always performed immediately after the patient's admission. Although studies have shown that delaying paracentesis is associated with worse outcomes, most of this information comes from populations outside of Latin America and from healthcare systems with different characteristics. **Objectives:** To evaluate the association between early paracentesis (≤ 24 hours from hospital admission) and in-hospital mortality in patients with decompensated cirrhosis and suspected SBP in Mexican population. **Methods: Methods::** This was a retrospective observational study including hospitalized adults with decompensated cirrhosis and SBP at a referral center in Mexico. Patients were classified according to the timing of paracentesis: early (≤ 24 hours) or delayed (> 24 hours). Clinical, laboratory, and survival outcomes were compared between groups. Cox regression analysis was performed to evaluate the association between early paracentesis and in-hospital mortality. **Results: Results::** A total of 102 patients were included. The mean age was 54.7 ± 13.6 years, and 63.7% were men. Early paracentesis was performed in 33.3% of patients, whereas 66.7% underwent delayed paracentesis. In-hospital mortality was significantly lower in the early paracentesis group compared with the delayed group (38.2% vs 61.8%, p = 0.021). Six-month survival was also higher in patients undergoing early paracentesis (58.8% vs 38.8%, p = 0.045). Patients with delayed paracentesis had significantly higher bilirubin levels (14.02 vs 4.52 mg/dL, p = 0.007), AST (104.5 vs 59.5 U/L, p = 0.001), and ALT levels (52.5 vs 31.5 U/L, p = 0.004). On Cox regression analysis, early paracentesis was independently associated with lower in-hospital mortality (HR 0.383, 95% CI 0.164–0.894, p = 0.026). **Conclusion: Conclusion:s:** Early paracentesis within the first 24 hours of admission was independently associated with lower in-hospital mortality in patients with decompensated cirrhosis and suspected SBP. Timely diagnostic paracentesis may represent an important quality-of-care measure in hospitalized patients with cirrhosis

1657 | HEMOSTATIC BLOOD PRODUCT USE IN CIRRHOTIC PATIENTS WITH ACUTE GASTROINTESTINAL HEMORRHAGE: A PROPENSITY-MATCHED ANALYSIS OF REAL-WORLD OUTCOMES

Bolaji Ayinde[1] Abidemi Akinrinmade[2] Bright Nwatamole[3] Ihunanya Kanu[4] Kia Saeian[5], [1]Northeast Georgia Medical Center, [2]SUNY Upstate University, [3]Zucker school of medicine at Hofstra, [4]Baptist Memorial Hospital- Golden Triangle, [5]Medical college of Wiscosin

Background: Current AASLD guidance recommends against liberal hemostatic blood product (HBP) transfusion in acute variceal hemorrhage, citing potential harm including worsening portal pressure and transfusion-related complications. However, large-scale real-world data examining outcomes associated with HBP use across diverse healthcare settings remain limited. This study examined the association between HBP administration and clinical outcomes in cirrhotic patients with acute gastrointestinal (GI) hemorrhage using a multi-institutional real-world data network. **Methods:** Using the TriNetX US Collaborative Network (66 healthcare organizations, 216,202 cirrhotic patients with GI hemorrhage), adult patients with cirrhosis (ICD-10: K74.x, K70.3x) and acute GI hemorrhage (K92.0, K92.1, K92.2, I85.01, I85.11) were identified. Patients receiving fresh frozen plasma, platelets, and/or cryoprecipitate within 3 days of presentation (HBP cohort) were compared to non-recipients. Propensity score matching (1:1) on demographics, comorbidities, medications (octreotide, terlipressin), and MELD component laboratory values (creatinine, bilirubin, INR, sodium), as well as platelets and fibrinogen, yielded 4,806 patients per arm. Risk ratios (RR) and hazard ratios (HR) were estimated over a 45-day follow-up window. **Results:** HBP recipients had significantly higher 45-day mortality (43.2% vs. 15.1%; RR 2.85, 95% CI 2.64–3.08; HR 3.56, 95% CI 3.27–3.88; p0.001). HBP use was also associated with increased ICU admission (25.8% vs. 10.4%; HR 3.00, p0.001), hospital readmission (30.7% vs. 12.3%; HR 2.94, p = 0.008), TRALI/ARDS (4.1% vs. 1.4%; HR 3.22, p = 0.024), and TIPS placement (3.5% vs. 0.9%; RR 3.77, p0.001). Acute kidney injury showed a non-significant trend on risk analysis (RR 1.22, p = 0.159) with a modest signal on survival analysis (HR 1.37, p = 0.029) and evidence of non-proportional hazards. **Conclusion:** In this large, multi-institutional propensity-matched cohort, HBP use was consistently associated with worse short-term outcomes across multiple domains. While residual confounding by indication likely contributes, and the observed effect sizes may overestimate any true causal effect, the magnitude and consistency of these associations reinforce current guideline recommendations against liberal hemostatic transfusion in cirrhotic GI hemorrhage and support the need for prospective, severity-adjusted trials incorporating viscoelastic testing-guided protocols.

1658 | PARACENTESIS TIMING AND MORTALITY RATES IN PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS

Ramanpreet Bajwa[1] Lovepreet Singh[1] Deepa Kumarjiguda[1] Aleena Moin[1] Lifang Zhang[1] Alberto Unzueta[1], [1]Geisinger Medical Center

Background: Patients with cirrhosis who are admitted to the hospital with decompensating events should undergo diagnostic paracentesis to rule out spontaneous bacterial peritonitis (SBP). Timing of paracentesis is crucial in the management of SBP and previous studies have identified that early paracentesis results in better patient outcomes. This study evaluated patients with decompensated cirrhosis and SBP within our institution in order to examine the relationship between paracentesis timing, mortality and readmission rates. **Methods:** We conducted a retrospective chart review of patients with decompensated cirrhosis admitted to our institution from 2016-2023. Inclusion criteria included confirmed spontaneous bacterial peritonitis. We examined timing of paracentesis, mortality at less than 30 days and > 90 days. Secondary outcomes included assessing hospital readmissions. Variables analyzed included administration of empiric antibiotics, MELD 3.0 and Child Pugh scores. All statistical analyses were conducted using SAS Enterprise Guide version 8.3. Statistical significance was assessed

at an alpha level of 0.05. **Results:** A total of 101 patients were included in the analysis. Patients had a mean age of 63.8 years, 54.5% were male, and 99% of the cohort identified as White. Mortality rates were 100% amongst the cohort during the evaluated period. 24 patients underwent paracentesis $\leq$24 hours and 77 patients underwent paracentesis >24 hours (p = 0.9713). In the group who underwent paracentesis $\leq$24 hours, the mortality at 0-30 days and >90 days was 25% and 50% (p = 0.9713) respectively. In the group who underwent paracentesis >24 hours, similar trends were seen with mortality at 0-30 days and >90 days, 27.3% and 44.2 % (p = 0.9479) respectively. Mean MELD 3.0 score in the group with paracentesis $\leq$24 hours was 21.5 (SD 7.37) and 22.7 (SD 7.83) in >24 hours group (p = 0.6085). Empiric antibiotics were given in 47.8% of the cohort. Child Pugh Class B comprised the most patients in both groups. Readmission rates in paracentesis $\leq$24 hours vs >24 hours at 30 days were 33.3% and 28.6% respectively (p = 0.9679). There was no statistically significant association identified between the timing of paracentesis ($\leq$24 hours vs. >24 hours after paracentesis) and MELD 3.0 score, empiric antibiotic use, or Child-Pugh score. **Conclusion:** Patients with SBP have a high mortality rate despite undergoing early paracentesis. Liver transplant evaluation and/or palliative care management should be considered after SBP in most patients.

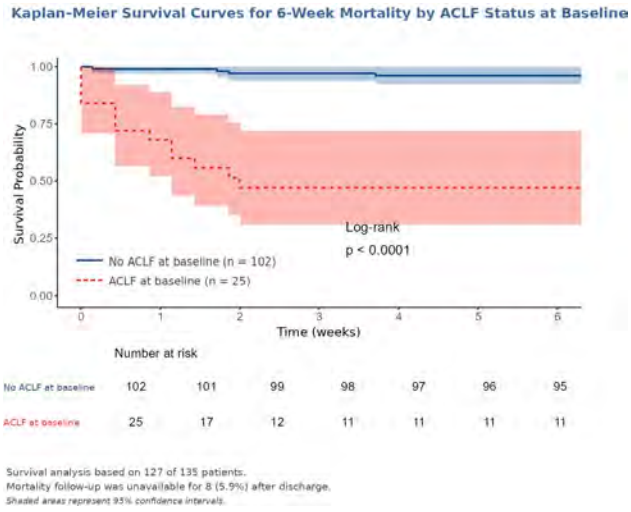
1659 | ACUTE-ON-CHRONIC LIVER FAILURE (ACLF) AND SHOCK AT PRESENTATION PREDICT 6-WEEK MORTALITY IN ACUTE VARICEAL BLEEDING



Aashi Aggarwal[1] Ishaan Gupta[1] Kriti Kriti[1] Trivendar Jangir[1] Tejasvi R[1] Mahendra Rajput[1] Suraj Bhagat[1] Rohit Mehtani[2], [1]Amrita Institute of Medical Sciences and Research Centre, Faridabad, [2]BLK-Max Super Speciality Hospital, Delhi

Background: Portal hypertension–related upper gastrointestinal (GI) bleeding remains a major cause of morbidity and mortality in cirrhosis. Predictors of short-term mortality following acute variceal bleeding (AVB), particularly in Indian cohorts, remain limited. **Methods:** Retrospective analysis of a prospectively maintained database of patients with cirrhosis and portal hypertension–related upper GI bleeding between September 2022 and April 2026 was done. AVB was managed according to international guidelines, including intravenous antibiotics, vasoconstrictors and early upper GI endoscopy. Baseline demographic, clinical, laboratory, and endoscopic variables were analysed. Mortality, rebleeding and further decompensations were assessed at 6-weeks. Univariate and multivariable logistic regression analyses were performed to identify predictors of 6-week mortality in AVB. Kaplan–Meier survival analysis with log-rank testing was performed for 6-week mortality. **Results:** A total of 135 patients were included (81.5% male; age 52.8 ± 13.9 years). Most common cause of cirrhosis was alcohol-related liver disease (66; 48.8%) followed by metabolic-dysfunction associated steatohepatitis (43; 31.9%). Acute variceal bleeding was seen in 62 (45.9%) patients (Esophageal varices–40[29.6%], Gastric varices–10[7.4%], both–7[5.2%] and post EVL ulcer bleed-5[3.7%]). Nineteen patients (14.1%) had bleeding from severe portal hypertensive gastropathy (PHG) and 5(3.7%) from gastric vascular ectasia (GVE). TIPSS was done in 7 patients (5.2%) – 1 rescue, 6 pre-emptive. Six-week mortality was 13.4% (n = 17) while 8 (5.9%) underwent liver transplant. Kaplan-Meier analyses demonstrated significantly reduced survival in patients with ACLF (HR 19.41, 95% CI 6.29–59.92; log-rank p < 0.0001; Figure 1). Among patients with AVB (n = 62), 6-week mortality and rebleeding were 11.3%(n = 7) and 14.5% (n = 9) respectively. Further decompensation occurred in 23 patients (37.1%). Patients who rebled at 6-weeks had higher MELD score when compared to those who did not rebleed (24 [17-31] vs 15.5[7.5-23.5]; p = 0.034). Patients who died within 6-weeks had more severe liver disease (CTP – 12.5 vs 8, p = 0.021; MELD – 39 vs 17, p = 0.006), shock (83% vs 19.1%; p = 0.004), grade 3/4 HE (50.0% vs 10.6%; p = 0.006), AKI (66.6% vs 6.3%; p = 0.002) and ACLF (83.3% vs 6.3%; p < 0.001) at presentation. A multivariable log regression model incorporating HE grade, shock at admission, and creatinine demonstrated strong predictive performance (Nagelkerke $R^2 = 0.763$, p < 0.001). A simpler model comprising only ACLF and shock at admission also predicted mortality ($R^2 = 0.663$, p < 0.001), requiring fewer variables. **Conclusion:** Short-term mortality following AVB appears to be driven predominantly by organ failures and ACLF at presentation. ACLF, shock, HE

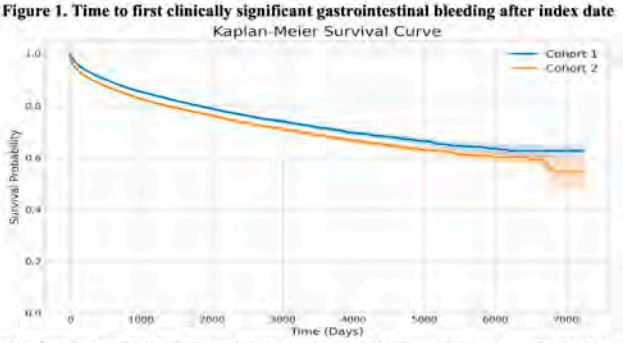
1660 | SELECTIVE SEROTONIN REUPTAKE INHIBITOR USE AND RISK OF GASTROINTESTINAL BLEEDING IN PATIENTS WITH CIRRHOSIS: A PROPENSITY SCORE–MATCHED COHORT STUDY



Mohamed Alharami[1] Omar Khattab[2] Frhaan Zahrawi[3] Omar Alwan[4] Mohammad Alali[5] Judy Sheffeh[6] Fatima Elmustafa[7] Mohammed Barawi[6], [1]Henry Ford Warren Hospital, [2]University of California Riverside, [3]Franciscan Olympia Field Health, [4]Hamilton Medical Center, [5]Henry Ford Macomb, [6]Henry Ford St. John Hospital, [7]Henry Ford Warren

Background: Selective serotonin reuptake inhibitors (SSRIs) have been associated with increased gastrointestinal (GI) bleeding risk in the general population, likely due to serotonin-mediated platelet dysfunction. However, the relevance of this association in cirrhosis is unclear. Cirrhosis is characterized by a "rebalanced hemostasis", and most clinically significant bleeding is driven by portal hypertension rather than platelet dysfunction. Prior studies largely excluded cirrhotic patients and often did not adequately adjust for key confounders such as NSAIDs and anticoagulants. We aimed to evaluate the association between SSRI use and GI bleeding risk in patients with cirrhosis. **Methods:** We conducted a retrospective cohort study using the TriNetX network. Among 123,415,579 patients in the database, 2,416,965 adults with cirrhosis were identified using ICD-10 codes. The exposed cohort included patients initiating SSRIs with no prior use in the preceding 12 months, while controls had no SSRI exposure. Patients with prior GI bleeding, unrelated bleeding disorders, or organ transplantation were excluded. Propensity score matching (1:1) was performed using demographics, liver disease severity, laboratory values, comorbidities, and concomitant medications. The primary outcome was time to first gastrointestinal bleeding event. Secondary outcomes included cumulative bleeding incidence at 30, 90, and 365 days. **Results:** After matching, 61,019 patients were included in each cohort. GI bleeding occurred in 14.2% of SSRI users vs 16.6% of controls. SSRI use was associated with a lower hazard of GI bleeding (HR 0.82, 95% CI 0.80–0.85; $p < 0.0001$). At 30 days, bleeding occurred in 2.0% vs 3.8% (RR 0.53); at 90 days, 3.4% vs 5.3% (RR 0.64); and at 1 year, 6.8% vs 8.9% (RR 0.76), all $p < 0.0001$. Absolute risk differences ranged from −1.76% to −2.10%. Risk reduction was greatest early and attenuated over time but remained significant. **Conclusion:** In this large propensity score–matched study, SSRI use in cirrhosis was not associated with an increased risk of gastrointestinal bleeding and was instead associated with a modest reduction in bleeding. These findings contrast with prior general-population studies and highlight the importance of cirrhosis-specific pathophysiology, in which bleeding is largely portal pressure–driven within a state of rebalanced hemostasis rather than true hypocoagulability. Prior associations may also reflect confounding from concomitant medications. Overall, SSRI therapy appears safe from a bleeding standpoint in cirrhosis and should not be withheld solely due to this concern.

Figure 1. Time to first clinically significant gastrointestinal bleeding after index date

Kaplan–Meier curves compare cirrhotic patients initiating selective serotonin reuptake inhibitors (SSRIs) at index (Cohort 1) versus matched cirrhotic controls without SSRI exposure (Cohort 2). Time zero represents the index date, and follow-up began 1 day after index. Shaded areas indicate 95% confidence intervals. Hazard ratios were estimated using Cox proportional hazards models and compared using the log-rank test. Patients were censored at the time of outcome occurrence or last recorded clinical encounter.

Figure 2. Cumulative risk of gastrointestinal bleeding at 30 days, 90 days, and 1 year after index in SSRI-exposed and matched non-SSRI cirrhosis cohorts.

Horizontal bar plots depict the cumulative incidence of clinically significant gastrointestinal bleeding at fixed follow-up intervals (30 days, 90 days, and 1 year) after the index date among propensity score–matched patients with cirrhosis treated with selective serotonin reuptake inhibitors

1661 | BETA BEATS BLEEDS:

Haniya Waseem[1] Ramish Rafay[1] Muhammad Umair[1] Muhammad Adnan[1], [1]Advent Health Tampa

Background: Patients with cirrhosis and variceal hemorrhage have a high risk of rebleeding and hospital readmission . Guidelines recommend non-selective beta-blockers (NSBBs) as part of secondary prophylaxis, yet these therapies are frequently under-prescribed at hospital discharge. We aimed to improve appropriate NSBB prescribing through a resident-led quality improvement intervention. **Methods:** We conducted a single-center QI project at an academic tertiary care hospital using the PDSA framework. Adult patients with decompensated cirrhosis eligible for secondary variceal prophylaxis were identified through retrospective review of the Epic electronic medical record. The pre-intervention cohort included patients hospitalized between August-Sept 2025. Adult patients ($\geq$18 years) admitted with upper GI bleeding and established decompensated cirrhosis were included. Patients without confirmed cirrhosis or without acute GI bleeding were excluded. Carvedilol was the preferred nonselective beta-blocker (NSBB); however, any prescribed NSBB was considered for analysis. A multifaceted educational intervention was implemented in November 2025, consisting of resident-focused teaching sessions and a hospital-wide awareness campaign (“Beta Beats Bleeds”) with visual reminders placed in physician work areas to reinforce guideline-concordant prescribing. The post-intervention cohort included patients hospitalized between Dec 2025 - Feb 2026. The primary outcome was prescription of nonselective beta-blockers (NSBBs) at hospital discharge. Secondary outcome was 30-day all-cause readmission. Pre- and post-intervention outcomes were compared using chi-square. **Results:** 57 patients were included in the pre-intervention cohort and 65 in the post-intervention cohort. Appropriate NSBB prescribing at discharge increased from 27.8% pre-intervention to 37.7% post-intervention ($p = 0.259$).In subgroup analysis, teaching teams had a significant improvement in prescribing (30.0% vs 69.6%, $p = 0.010$), whereas non-teaching teams showed no meaningful change (26.5% vs 28.6%, $p = 0.84$). 30-day readmission rates decreased from 11.1% to 8.1% following the intervention, though this was not statistically significant ($p = 0.58$). . **Conclusion:** A low-cost, resident led educational intervention improved guideline-concordant NSBB prescribing at discharge, with the greatest impact on teaching services. These findings suggest that education-based strategies are more effective in academic settings, while non-teaching teams may require system-level approaches such as EMR prompts or standardized workflows.Interpretation is limited by the single-center design, small sample size, and short follow-up, reducing power to detect clinical differences.These results show the need for targeted, setting-specific interventions to optimize evidence-based cirrhosis care.

1662 | COMPARATIVE PERFORMANCE OF PROGNOSTIC RISK SCORES FOR PREDICTING POST-TIPS OUTCOMES AT A CANADIAN TERTIARY CARE CENTRE

Yashasavi Sachar[1] Derek Little[2] David Peck[3] Amol Mujoomdar[3] Derek Cool[3] David Hocking[3] Anouar Teriaky[3] Karim Qumosani[3] David Hudson[3] Ephraim Tang[3] Anton Skaro[3] Mayur Brahmania[4] Juan Pablo Arab[5] Mohammad Qasim Khan[3], [1]Western University, [2]Trillium Health Partners, [3]University of Western Ontario, [4]University of Calgary, [5]Virginia Commonwealth University

Background: Transjugular intrahepatic portosystemic shunt (TIPS) can be associated with high-risk mortality in cirrhosis. Multiple prognostic models have been developed to risk-stratify patients with advanced liver disease in this context. We compared the discriminatory performance of commonly used models, including MELD-Na, MELD 3.0, Child-Pugh-Turcotte (CTP), Albumin-Bilirubin Index (ALBI), and Freiburg Index of Post-TIPS Survival (FIPS), for predicting post-TIPS mortality. **Methods:** A retrospective cohort study was generated, consisting of adults undergoing TIPS at a tertiary Canadian center from 2013–2023. Patients undergoing repeat or revisional TIPS were excluded. Baseline demographic and laboratory data closest to the time of procedure were used to calculate each risk model. The primary outcomes were 6-week and 1-year all-cause mortality. Discrimination was assessed using receiver operating characteristic (ROC) analyses and area under the curve (AUC). Optimal thresholds were identified using the Youden index, from which sensitivity and specificity were derived. For CTP, ROC analysis compared Child-Pugh class C versus classes A/B combined. Separate age- and sex-adjusted logistic regression models were fitted for each score-outcome pair. ALBI, FIPS, MELD 3.0, and MELD-Na were modeled as continuous variables, while CTP was modeled as a 3-level categorical variable corresponding to Child-Pugh classes A, B, and C. **Results:** The cohort included 136 patients, with a mean age of 58.7 years, and 58.1% (n = 79) were male. The most common liver disease etiologies were ALD (27.9%), MASLD (26.5%), and MET-ALD (18.4%), followed by viral hepatitis (13.2%). Median (IQR) baseline scores were ALBI -1.72 (-2.18 to -1.42), FIPS -0.36 (-1.09 to 0.08), MELD 3.0 15 (12–19), MELD-Na 16 (13–20), and the majority of patients (69%) were CTP-B. Six-week mortality occurred in 17 patients (12.5%), and 1-year mortality in 24 patients (17.6%). For 6-week mortality, MELD 3.0 showed the highest discrimination (AUC 0.737), followed by CTP (AUC 0.733). For 1-year mortality, MELD 3.0 again performed best (AUC 0.739), followed by MELD-Na (AUC 0.716) and FIPS (AUC 0.695). In adjusted analyses, higher FIPS, MELD 3.0, and MELD-Na were significantly associated with both outcomes; CTP class C, but not class B, was also associated with both outcomes relative to class A, whereas ALBI was not. Full AUC and logistic regression results are shown in Table 1. **Conclusion:** Among commonly used prognostic models assessing mortality after TIPS, MELD 3.0 provided the most consistent

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

discrimination for 6-week and 1-year mortality, while the FIPS model also demonstrated robust prognostic utility in adjusted analyses. Overall model performance was moderate, suggesting that existing risk scores are useful for post-TIPS risk stratification but remain imperfect as standalone decision tools.

Table 1: Logistic Regression and ROC Analysis of Prognostic Risk Scores for 6-Week and 1-Year Mortality After TIPS

Outcome	Score*	AUC	Sensitivity	Specificity	Youden index
6-Week Mortality	ALBI	0.66	0.71	0.64	0.35
	FIPS	0.69	0.47	0.92	0.40

1663 | AVATROMBOPAG IN CIRRHOTIC PATIENTS UNDERGOING INVASIVE PROCEDURES: INSIGHTS FROM REAL-WORLD PRACTICE

Mikolas Holinka[1] Dusan Merta[1] Jan Sperl[1] Tomas Nesnidal[1] Tomas Hucl[1] Sona Frankova[1], [1]Institute for Clinical and Experimental Medicine

Background: Thrombocytopenia-related bleeding is one of the major complications in cirrhosis; therefore, periprocedural bleeding risk management is an essential strategy in planning invasive procedures. Thrombopoietin receptor agonists (TPO-RA) are emerging as the standard for managing thrombocytopenia in cirrhotic patients. Our study aims to assess the efficacy and safety of avatrombopag, TPO-RA, in the prevention of periprocedural bleeding in cirrhotic patients. **Methods:** We retrospectively evaluated a cohort of 42 cirrhotic patients who underwent 59 invasive procedures between 2022 and 2025. The median age was 53 years (range 28–75); 20 patients were female, the median MELD score was 15 (range 9–23) and the median baseline platelet count 37/µL (21–49). The aetiology of liver cirrhosis was alcoholic (16), autoimmune (7), viral (9), MASLD (8) or other (2). The most common procedures were teeth extractions (20/59, 34%), followed by gynaecology procedures (7/59, 11.9%), major abdominal surgeries (6/59, 10.2%), TACE (4/59, 6.8%), colon polypectomy (2/59, 3.4%, and others (20/59, 33.8%). All patients received avatrombopag for 5 days, at 60 or 40 mg daily, depending on platelet counts of less than 40/µL (45 procedures) and 40–50/µL (14 procedures), respectively, in accordance with the manufacturer's recommendations. **Results:** The median increase of platelet count was 43/µl (6–147). In 53 (89.8%) procedures, the platelet count exceeded the required target of 50 platelets /µl before the procedure. None of the procedures was postponed or cancelled owing to thrombocytopenia; platelet transfusion was not administered to any patient before the procedure. In 4 patients (6,8%), a bleeding complication was reported: 1 inguinal hematoma, 1 post-polypectomy bleeding, 1 skin wound bleeding, 1 bleeding after pancreatectomy; the last three events required endoscopy/surgical treatment and blood transfusion administration. Except for one, all bleeding events occurred in patients with an adequate platelet increase before the procedure. None of the pre-procedural clinical characteristics (platelet count, haemoglobin level, MELD score, age) predicted the risk of non-response to avatrombopag or bleeding in the multivariate analysis. No thromboembolic events or deaths were reported. **Conclusion:** Avatrombopag was safe and effective in managing periprocedural thrombocytopenia. Bleeding complications were infrequent and not predictable by baseline clinical or laboratory parameters.

1665 | FALSE-POSITIVE DOPPLER ULTRASONOGRAPHY FOR PORTAL VEIN THROMBOSIS IN DECOMPENSATED CIRRHOSIS: A CASE SERIES WITH FOCUS ON PATIENT CHARECTARISTICS

Harry Trieu[1] Michelle Nguyen[1] Parsia Vazirni[1] Yuri Kwon[1] Beshoy Yanny[1], [1]University of California, Irvine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Portal vein thrombosis in liver cirrhosis is often incidentally diagnosed and has a reported incidence of 10.42% and prevalence of 13.92%. Doppler ultrasonography (DUS) is the first-line imaging modality for PVT and has a sensitivity and specificity ranging from 66-100% [PMID 26684272], however it is limited by body habitus, presence of intestinal gas, and experience of the ultrasonographer. We present three patients with liver cirrhosis who were admitted to the University Medical Center with Doppler ultrasonography of the liver showing PVT and confirmatory multiphase CT or MR venography showing lack of PVT suggesting poor diagnostic value in a certain patient population. In this limited case series we explore the limitations of abdominal doppler ultrasound in patients with decompensated liver cirrhosis **Methods:** Retrospective care series conducted. Three consecutive patients were admitted to the university hospital with decompensated liver cirrhosis. Patient demographics, clinical characteristics, laboratory values, imaging findings, and time interval between DUS and confirmatory imaging were collected and analyzed. **Results:** Three patients 33% female, mean age 53 years old. All patients had large ascites on admission. All patient had thrombocytopenia with mean platelet count of 48,000. History of gastrointestinal bleeding was presents in 100% of patients, esophageal varices present in 100% of patient, and mean MELD 3.0 was noted to be 28. Doppler ultrasound was obtained in 100% of patients in the emergency department and showed portal vein thrombosis in all patients. Cross sectional imaging obtained in all 3 patients showing no evidence of portal vein thrombosis in 100% of the patients. All three high risk patients avoided anticoagulation based on cross sectional imaging. Abdominal doppler ultrasound showed false positive values in 100% of patient. **Conclusion:** Doppler ultrasound of the abdomen has limited utility to evaluate for PVT and high false positive rates in patients with MELD 3.0 score equal to or above 20, thrombocytopenia, hepatosplenomegaly and ascites as shared by our patients. These features may cause marked reduced portal venous flow velocity, which can appear like absent flow or thrombosis on DUS. Consider moving directly to cross sectional imaging in this select group of patients to avoid unnecessary anticoagulation in patients with high risk of bleeding. More studies are needed to risk stratify the appropriateness of doppler ultrasound in decompensated liver cirrhosis patients.

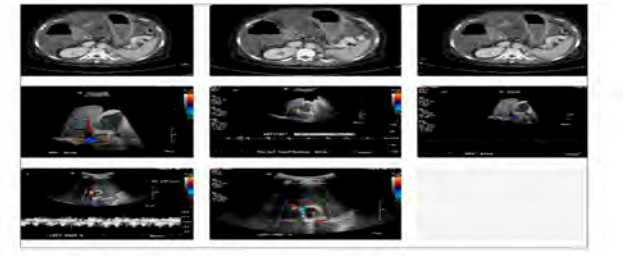

Figure 1 showing discrepancy between results of ultrasound doppler and 4 phase CT of the abdomen highlighting false positive PVT diagnosis

1666 | A CLUSTER ANALYSIS OF COAGULATION DYSFUNCTION IN DECOMPENSATED LIVER CIRRHOSIS PATIENTS

Jinglan Jin[1] Zian Wang[1] Hongqin Xu[1], [1]Department of Hepatology, First Hospital of Jilin University

Background: The coagulation dysfunction could perform as either elevated thromboembolism events or increased bleeding risk in decompensated liver cirrhosis. To find the risk factors and excavate the underlying mechanism of coagulation dysfunction, a cluster analysis was conducted. **Methods:** We selected 619 patients who initially admitted for decompensated liver cirrhosis in stage 3 or 4 according to the 2025 edition of Clinical Diagnosis and Treatment Guidelines for Liver Cirrhosis released by the Chinese Medical Association, without blood system disorders or diseases may cause abnormal coagulation function (nephrotic syndrome, systemic lupus erythematosus, etc.) in Department of Hepatology, First Hospital of Jilin University during 2021 to 2025. Proportions of portal vein thrombosis (PVT), venous thromboembolism (VTE) or non-portal hypertension related bleeding were collected from their inpatient data. **Results:** 3 subgroups were classified through k-means analysis: group 1 (bleeding group), characterized as prolonged APTT with higher bleeding percentages; group 2 (thrombosis group), featured as both increased PVT and VTE cases; group 3 (simple portal hypertension group), featured as only PVT risk elevated. Univariate analysis showed significantly increased total bilirubin level and decreased albumin level in group 1 compared with another groups, while a significant elevated neutrophil rate and reduced lymphocyte rate in group 2. **Conclusion:** In the context of decompensated liver cirrhosis, progressive liver dysfunction may be related towards higher bleeding risk, while neutrophil-mediated inflammation could be considered related to venous thrombosis. However, due to the small proportion of bleeding events observed, specific risk factors correlated with non-hypertension related bleeding should be discovered by deeper investigating patients' medical histories and signs.

1667 | PATIENT JOURNEY MAPPING OF LIVER CIRRHOSIS MANAGEMENT AND HUMAN SERUM UTILIZATION PATTERNS: A MULTICENTER CROSS-SECTIONAL MIXED-METHODS STUDY IN CHINA

Wen Xie[1] Yufei Zhan[1] Ligai Liu[1] Ying Cao[1] Hong Zhao[1] You Deng[2], [1]Beijing Ditan Hospital, Capital Medical University, [2]Beijing Friendship Hospital, Capital Medical University

Background: China bears a substantial burden of liver disease. Although human serum albumin (HSA) is widely used in the treatment of cirrhosis, real-world prescribing patterns and factors influencing its use in China remain poorly characterized. This mixed-methods study aims to examine patient journeys and patterns of HSA use across the cirrhosis care continuum. **Methods:** This multicenter, cross-sectional, mixed-methods study is being conducted across five top-tier hospitals in China, with a planned enrollment of approximately 1,000 patients with cirrhosis, including 30% with compensated and 70% with decompensated disease. The study integrates patient and physician interviews, medical record abstraction, and questionnaire-based data collection. Qualitative interviews focus on care pathways, experiences with HSA use, economic burden, and long-term disease management to characterize clinical decision-making processes and their determinants. Quantitative data include disease stage, complications, healthcare access, financial burden, and patterns of HSA use. **Results:** A patient journey–based structured questionnaire and interview guide have been developed based on clinical pathways and guideline recommendations. Using these tools, this study aims to characterize the real-world care pathways and patterns of HSA use among patients with cirrhosis in China. It will examine HSA utilization across different clinical scenarios and complications, while also assessing concordance with guideline recommendations. Additionally, it will assess the economic burden associated with HSA use and the impact of reimbursement policies on treatment accessibility. Key factors influencing prescribing decisions will be identified, and continuity of long-term management and unmet needs will be assessed from the patient perspective. **Conclusion:** The findings will provide evidence to inform clinical guidelines, optimize resource allocation, and support policy reforms aimed at improving the quality, equity, and efficiency of cirrhosis care in China.

1668 | EFFICACY AND SAFETY OF FECAL MICROBIOTA TRANSPLANTATION FOR PREVENTION OF HEPATIC ENCEPHALOPATHY RECURRENCE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Yusuf Atef[1] Omar Rageh[2] Basma Salhin[3] Ahmed Hany Kamel Elshafie[4] Muhammad Minisy[5] Basma Amin[3] Basma Abushosha[6] Camelia Ciobanu[7] Hazem Abosheaishaa[8]

[1]Faculty of Pharmacy, Ain Shams University, Cairo, Egypt, [2]Faculty of Medicine, Tanta University, Tanta city, Egypt, [3]Faculty of Medicine, Cairo University, [4]Faculty of Medicine, New Ismailia National University, Ismailia city, Egypt, [5]Faculty of Medicine Kasr Al Ainy, Cairo University, [6]Faculty of Medicine Tanta University, Tanta city, Egypt, [7]The Brooklyn Hospital Center, [8]Icahn school of medicine at mount sinai

Background: Hepatic encephalopathy (HE) is a major complication of cirrhosis associated with recurrent hospitalizations and poor clinical outcomes. Gut dysbiosis plays a key role in HE pathogenesis, making fecal microbiota transplantation (FMT) a promising therapeutic strategy. We conducted a systematic review and meta-analysis to evaluate the efficacy and safety of FMT in patients with cirrhosis and HE. **Methods:** A systematic literature search was performed in PubMed, Scopus, Web of science, Embase, and Medline from 1997 until 2026. Randomized controlled trials evaluating FMT in adult patients with HE were included. Studies comparing FMT with placebo or standard care were eligible. Six RCTs met inclusion criteria and two of them were excluded from quantitative synthesis due to non-comparable intervention design and insufficient outcome data. Different FMT administration routes, including capsules, enema, nasogastric tube, and colonoscopy, were included. Data extraction and risk of bias assessment were performed independently by 2 reviewers. Meta-analysis was conducted using a random-effects model, and pooled risk ratios (RRs) with 95% confidence intervals (CIs) were calculated. Statistical heterogeneity was assessed using the I^2 statistic. **Results:** Four randomized comparisons involving 90 patients were included in the quantitative synthesis. FMT significantly reduced the risk of HE recurrence compared with placebo or standard care (RR 0.24, 95% CI 0.09–0.62; P = 0.003), I^2 = 0%. No significant statistical heterogeneity was observed among included studies due to limited sample size. Safety analysis demonstrated that FMT was associated with lower rates of serious adverse events compared with control therapy (RR 0.33, 95% CI 0.11–0.96; P = 0.04), with moderate heterogeneity among studies: I^2 = 56%. Across studies, FMT was administered through multiple delivery routes including oral capsules, enema, colonoscopy, and nasogastric tube. Despite methodological variations in FMT protocols, the direction of treatment effect was consistent across studies. **Conclusion:** FMT may reduce recurrence of hepatic encephalopathy in patients with cirrhosis and was not associated with increased serious adverse events. These findings support the therapeutic potential of microbiome modulation in HE management. Larger multicenter randomized trials are warranted to confirm long-term efficacy and establish standardized FMT protocols.

Background: Primary liver tumors arising in vascular liver disorders (VLD) pose significant diagnostic challenges, and their molecular characteristics remain poorly understood. We aimed to characterize their mutational and transcriptomic landscape and its impact on patient management. **Methods:** Sixty-three liver tumors from 47 VLD patients were analyzed by whole-genome and/or whole-exome and RNA sequencing and compared to 473 hepatocellular adenomas (HCA) and 385 hepatocellular carcinomas (HCC) not developed on VLD with available molecular data. Pathological diagnoses were classified as certain or uncertain based on original reports (n = 63) and expert reviewing (n = 48). A molecular diagnosis was assigned based on driver mutations, copy number variation, and transcriptomic profiles. **Results:** Molecular profiling reduced diagnostic uncertainty from 30% of tumors on initial pathological report and 46% after expert review to 8%, identifying 27 HCC, 1 borderline HCA /HCC, 29 HCA, 5 regenerative macronodules and 1 hepatic angiosarcoma. Among 5 focal nodular hyperplasia-like, 4 were reclassified as regenerative macronodules due to absence of somatic mutations and clustering with non-tumoral liver tissue without forming a distinct transcriptomic entity. The remaining focal nodular hyperplasia-like was reclassified as bex3HCA due to *CTNNB1* exon 3 somatic mutation. Compared to control HCC, VLD-associated HCC occurred more frequently in women ($P < 0.001$) and exhibited enrichment of *CTNNB1* exon 3 mutations ($P = 0.011$), and a lower prevalence of *TP53* mutations ($P = 0.003$). Patients with VLD-associated HCA were less frequently female compared with HCA not developed on VLD (39.1% in VLD versus 86.4% in control, $P < 0.001$). Among women, those with VLD-associated HCA were less likely to have a history of estrogen-based contraception use (50% in VLD versus 89.4% in control, $P < 0.001$). Compared to control HCAs, VLD-associated HCAs exhibited a higher proportion of bex3HCA ($P < 0.001$) and of malignant transformation (14.3% vs. 3%, $P < 0.001$), and a lower prevalence of inflammatory HCAs ($P = 0.008$). *HNF1A*-inactivated HCA in VLD presented an atypical non-steatotic phenotype driven by suppression of lipogenic pathways in both tumor and adjacent non-tumoral liver. **Conclusion:** Comprehensive molecular profiling substantially improves the classification of primary liver tumors arising in VLD and reduces diagnostic uncertainty supporting its integration in clinical practice. Moreover, we uncover a distinct genomic landscape reflecting the strong relationship between these rare chronic liver diseases and the molecular profiles of primary liver tumors.

Background: In the RIPORT study, rivaroxaban 15 mg reduced recurrent venous thrombosis without increased bleeding incidence over a median follow-up of 12 months in patients with non-cirrhotic chronic portal vein thrombosis (NC-PVT). However, long-term outcomes beyond the trial period remain poorly characterized. **Methods:** Multicenter retrospective cohort study including patients previously enrolled in the RIPORT trial and followed in the RIPORT2 extension. Main objective was occurrence of a composite endpoint including death, major bleeding, clinically relevant non-major bleeding (CRNMB)*, recurrent deep vein thrombosis (RVT), and arterial event. Secondary end points were individual events. Data included clinical, biological, radiological, anticoagulation exposure, and NGS results. Lost to follow-up patients were excluded. Follow-up was divided into anticoagulated and non-anticoagulated periods and crude incidence rates were estimated. IRRs were estimated using Univariate Poisson regression. * Defined according to ISTH criteria **Results:** 100/111 patients (60 men; median age 49.8 years), were included in the extension study, with a median follow-up of 7.9 years from RIPORT (IQR 7; 8.5). Risk factors were low-risk thrombophilia in 93 patients (93.9%) and a local cause in 17 (15%). Median exposure time to anticoagulant was 85.9 months (70.3; 96.5) overall. During follow-up, 93 (93%) patients received anticoagulation (DOACs (85%), LMWH (8%), VKAs (13%)). The primary composite endpoint occurred at a significantly lower rate in anticoagulated versus non-anticoagulated exposition (5.77 vs 25.71 per 100 patient-years; IRR 0.22 (0.14; 0.36), $p < 0.001$). Only one mortality event occurred during the non-exposure period (0.83 vs 0.00 per 100 patient-years), following sepsis after severe gastric variceal bleeding. Venous thrombosis recurred in 13 patients in RIPORT, and 8 patients in RIPORT2 (19 patients overall). RVT occurred less frequently during exposure to anticoagulation (0.96 vs 14.10 per 100 patient-years; IRR 0.07 (0.03; 0.17), $p < 0.001$). Incidence of major bleeding was lower during exposed periods to anticoagulation (1.60 vs 5.81 per 100 patient-years; IRR 0.28 (0.11; 0.73), $p = 0.009$). CRNMB and arterial ischemic events were numerically lower during anticoagulation exposure, without statistical significance. **Conclusion:** In non-major risk factor non-cirrhotic PVT, long-term anticoagulation, mainly with reduced dose DOACS, significantly prevents thrombotic and severe bleeding events. As in deep vein thrombosis it seems to be an excellent and safer alternative in this population.

1671 | ◆ INCIDENT PORTAL VEIN THROMBOSIS IN CIRRHOSIS: A LARGE COMPETING-RISK ANALYSIS IDENTIFYING REDUCED PORTAL VEIN VELOCITY AS THE STRONGEST PREDICTOR

Babu Lal Meena[1] Shiv Kumar Sarin[1] Ashok Kumar Choudhury[1] Vinod Arora[1] sarthak Chanana[1] Srinivas Reddy[1] shalini ThaparLaroia[1] Amar Mukund[1] Ankit Bhardwaj[1] Chitranshu Vashishtha[1] Deepti Sharma[1] Manoj Sharma[1] Omkar Rudra[1], [1]Institute of Liver and Biliary Sciences

Background: Portal vein thrombosis (PVT) is a major complication of cirrhosis associated with adverse outcomes. However, predictors of incident PVT accounting for competing clinical events remain inadequately characterized. We evaluated the incidence, predictors, and natural history of incident PVT in a large cohort of patients with cirrhosis using competing-risk methodology. **Methods:** We conducted a retrospective cohort study of consecutive adults with cirrhosis undergoing at least 2 year or more of regular longitudinal follow-up at a tertiary liver center. Patients with baseline PVT, portal cavernoma, or non-cirrhotic portal hypertension, HCC, hepatocellular carcinoma, prior liver transplantation, or on anti-coagulants were excluded. Incident PVT was diagnosed on follow-up imaging. Cumulative incidence functions accounting for death, TIPS, and liver transplantation as competing events were estimated. Independent predictors were evaluated using multivariable Fine–Gray competing-risk regression analysis. **Results:** A total of 4,986 patients with cirrhosis were included (mean age 49.3 ± 11.9 years; 79.2% male). During a mean follow-up of 2.9 ± 0.6 years, 1,445 patients (29.0%) patients developed incident PVT. Alcohol-related liver disease was the most common etiology (43.5%), followed by MASLD (36.6%), viral hepatitis (11.0%), and other causes (8.8%). Mean time to PVT occurrence progressively decreased with worsening Child–Turcotte–Pugh (CTP) class ($p < 0.001$). The cumulative incidence of PVT increased progressively over follow-up, whereas competing events demonstrated substantially lower cumulative incidences. Patients with advanced liver disease (CTP class C) and portal vein velocity < 12 cm/s demonstrated the highest cumulative risk of incident PVT. On multivariable competing-risk regression analysis, portal vein velocity < 12 cm/s emerged as the strongest independent predictor of incident PVT (sub-distribution hazard ratio [sHR] 6.41, 95% confidence interval [CI] 5.35–7.69; $p < 0.001$). Additional independent predictors included serum albumin < 3 g/dL (sHR 2.14, 95% CI 1.86–2.48; $p < 0.001$), increasing CTP class (sHR 1.76, 95% CI 1.61–1.92; $p < 0.001$), presence of portosystemic collaterals (sHR 1.50, 95% CI 1.34–1.68; $p < 0.001$), and male sex (sHR 1.13, 95% CI 1.01–1.28; $p = 0.04$). Spontaneous recanalization occurred in 28% of patients versus 60–75% with anticoagulation. Recanalization was higher in partial versus complete thrombosis and recurrence rates were lower with enoxaparin and DOACs. **Conclusion:** Incident PVT is common in cirrhosis, particularly in patients with advanced liver disease and reduced portal vein velocity. Reduced portal vein velocity was the strongest predictor of incident PVT. Competing-risk analysis provides clinically meaningful thrombotic risk estimation and may improve risk stratification and surveillance in cirrhosis.

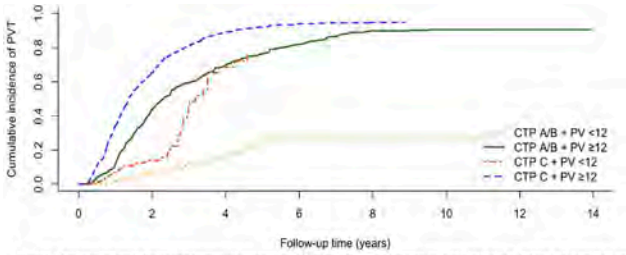

Figure 1. Cumulative incidence of portal vein thrombosis according to combined Child–Turcotte–Pugh class and portal vein velocity. Patients with advanced liver disease (CTP C) and reduced portal vein velocity (<12 cm/s) demonstrated the highest cumulative risk of incident PVT. Death, TIPS and liver transplantation was treated as competing events.

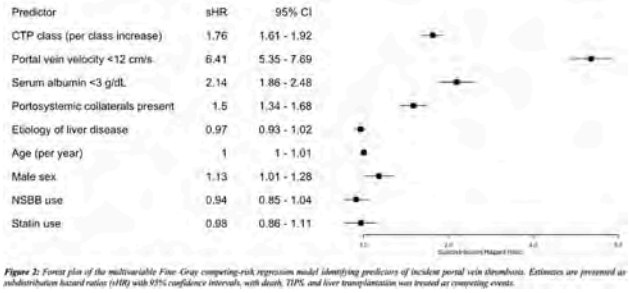

Figure 2: Forest plot of the multivariable Fine–Gray competing-risk regression model identifying predictors of incident portal vein thrombosis. Estimates are presented as subdistribution hazard ratios (sHR) with 95% confidence intervals, with death, TIPS, and liver transplantation was treated as competing events.

College, [3]Set GS Medical College, [4]Sir HN Reliance Foundation Hospital

Background: BCS is a rare but life-threatening hepatic venous outflow disorder. Long-term outcome data from large cohorts is lacking.This study examined clinical profile, treatment response rates, predictors of medical therapy failure, and long-term survival across nearly two decades of follow-up. **Methods:** Retrospective analysis of a prospectively maintained registry at a dedicated BCS clinic (January 2006–January 2025). Clinical presentation, anatomic pattern of venous obstruction, and treatment modality were systematically recorded. Predictors of medical therapy failure were identified by multivariate logistic regression. Survival was estimated using Kaplan–Meier analysis; competing-risk analysis using the Fine–Gray subdistribution hazard model was applied to account for loss to follow-up **Results:** 989 patients were enrolled; median age 29 years (54.5% men). The vast majority (93.6%) presented with chronic disease. Ascites was the dominant presenting feature (72%), followed by jaundice(30.1%), acute variceal haemorrhage(21.4%), and hepatic encephalopathy (6.6%). Isolated hepatic vein obstruction was the most frequent anatomic pattern (56.4%), followed by combined IVC and hepatic vein obstruction (37.1%). Mean MELD score was 14 ± 6.Anticoagulation alone was administered in 60% of patients; 39% underwent endovascular intervention (TIPS 21%, hepatic vein stenting 9%, IVC stenting 6%, balloon angioplasty 3%). Complete response was achieved in only 16% with medical therapy versus 85.6% following endovascular intervention; a 5.4-fold difference. Among medically treated patients, 73% were classified as non-responders. On multivariate logistic regression, low platelet count and low serum albumin at baseline independently predicted failure of medical therapy (both $p < 0.001$). Treatment response was an independent determinant of overall survival ($p < 0.001$ for both modalities). On a per protocol analysis, 73% patients were alive at a median follow-up of 4 years. **Conclusion:** Medical therapy alone achieves complete response in only one in six BCS patients. Endovascular intervention is markedly superior. Low albumin and platelet count should prompt early escalation to intervention. Treatment response was a dominant determinant of survival ($p < 0.001$ for both modalities).

Figure 1. Kaplan–Meier Survival Analysis in Budd–Chiari Syndrome (n=989)

Panel A: Kaplan–Meier survival curves stratified by treatment modality (n=510 with follow-up data). Anticoagulation alone was associated with significantly higher mortality than TIPS (38.2% vs. 25.0%; p=0.009) and hepatic vein stenting alone (38.2% vs. 15.0%; p=0.005). **Panel B:** Survival in patients undergoing endovascular intervention, stratified by treatment response (CR, n=197 vs. PR, n=46). CR was associated with 7.1% mortality versus 87.0% for PR (log-rank p<0.001). Shaded areas represent 95% confidence intervals. **Panel C:** Survival in patients receiving medical therapy, stratified by treatment response (CR, n=149 vs. NR, n=299). CR was associated with 3.4% mortality versus 48.5% for NR (log-rank p<0.001). Shaded areas represent 95% confidence intervals.

AC = anticoagulation, CR = complete response, HVS = hepatic vein stenting, NR = no response, PR = partial response, TIPS = transjugular intrahepatic portocaval shunt.

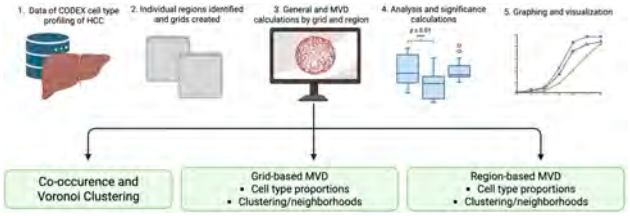
1673 | MICROVESSEL DENSITY DEFINES IMMUNOSUPPRESSIVE SPATIAL NICHES IN HEPATOCELLULAR CARCINOMA



Venika Kakarla[1] Renumathy Dhanasekaran[2], [1]Stanford, [2]Stanford University

Background: Hepatocellular carcinoma (HCC) is one of the most vascularized solid tumors, and pathological angiogenesis is a defining hallmark of its progression. Microvessel density (MVD), a histological measure of intratumoral vascular content, has been associated with poor prognosis in HCC, yet how vascular architecture spatially organizes immune cell neighborhoods has not been systematically characterized at single-cell resolution. **Methods:** We performed spatially resolved, multicellular profiling of endothelial cell neighborhoods across 124 HCC tumors (n = 1,065,284 cells) using CODEX multiplexed spatial proteomics (n = 54 markers). Six complementary analytical approaches were applied: whole-region cell-type proportion analysis, radius-based endothelial interaction mapping, region-averaged and grid-based MVD stratification, cellular co-occurrence in vascular neighborhoods, and Voronoi-based spatial clustering. Findings were validated in an independent cohort of HCC with single-cell spatial proteomics with CODEX (n = 843,647 cells). **Results:** In HCC, high-MVD tumors (n = 32) were enriched for Tregs ($p = 6.0x10-34$), $CD206^+$ macrophages ($p = 0.019$), $PD\text{-}L1^+$ macrophages, and both memory ($p = 3.97\times10^{-4}$) and effector ($p = 0.035$) $CD8^+$ T cells, consistent with an immunosuppressive, exhaustion-prone niche. Low-MVD regions (n = 36) showed greater infiltration of anti-tumor immune cells like $CD4^+$ T cells, neutrophils ($p = 0.026$), and monocytes ($p = 0.016$). Spatial neighborhood analysis revealed that in high-MVD tumors, endothelial cell neighborhoods were significantly enriched with M2-like CD206+ macrophages ($p = 4.68\times10^{-8}$) across spatial radii of 50-200 microns, indicating that high-vascularity HCC establishes a tolerogenic perivascular niche characterized by immunosuppressive macrophage co-localization. High-MVD regions markedly overexpressed tumor-associated stemness marker CK19 and the immune checkpoint PDL1. In an independent validation cohort, MVD-stratified immune distribution patterns were reproduced

across high (n = 61) and low (n = 61) MVD regions. Higher MVD regions again lacked neutrophils ($p = 2.97\times10^{-4}$), effector $CD4^+$ T cells ($p = 2.2\times10^{-4}$), memory $CD8^+$ T cells ($p = 4.4\times10^{-4}$), and monocytes ($p = 7.47\times10^{-6}$). **Conclusion:** Using two independent large-scale spatial atlases for discovery and validation, we demonstrate that angiogenesis defines reproducible immune neighborhoods within HCC. High-MVD regions are characterized by coordinated enrichment of Tregs, M2-polarized macrophages, and aggressive tumor programs. Together, these data reveal that pathological angiogenesis extends beyond vascular expansion to spatially organize immunosuppressive cellular ecosystems, providing a single-cell view of how the vascular niche may contribute to immune evasion in HCC.

1674 | LIVER DISEASE MANIFESTATIONS IN STAT1 GOF DISEASE

Sawsan Fathma[1] Nehna Abdul Majeed[2] Sana Pirzada[1] Wesam Aleyadeh[1] Sharifeh Almasaid[3] Alexandra Freeman[4] Steven Holland[4] Jenna Bergersen[4] Bernadette Redd[5] Christopher Koh[1] David Kleiner[6] Theo Heller[1], [1]NIH/NIDDK, [2]University of Maryland, [3]SUNY Upstate, [4]NIAID/NIH, [5]National Institutes of Health, [6]National Cancer Institute, Bethesda

Background: Signal transducer and activator of transcription 1 (STAT1) gain-of-function (GOF) disease cause impaired dephosphorylation and prolonged nuclear accumulation of phosphorylated STAT1, leading to excessive and sustained interferon signaling. This hyperactivation causes immune dysregulation characterized by chronic mucocutaneous candidiasis and recurrent infection. However, the hepatic manifestations of STAT1 GOF remain poorly defined. We aimed to characterize the presentation and outcomes of liver disease in STAT1 GOF. **Methods:** We performed a retrospective study of patients with genetically confirmed STAT1 GOF evaluated at the National Institutes of Health (NIH) Clinical Center between 1996 and 2026. Clinical, laboratory, imaging, and histopathologic data were analyzed to characterize and describe liver involvement. **Results:** Sixty-eight patients with STAT1 GOF were included; 28 (41%) met criteria for liver disease. At baseline, Alanine and Aspartate aminotransferases were significantly different between two groups (p = 0.006 and 0.015 respectively) while synthetic function, and platelet count, did not differ between the groups. During follow-up, all biochemical markers remained largely normal, but platelet count declined significantly in the liver disease group (median 246.5 to 163.5; $p = 4.1 \times 10^{-6}$), representing the only parameter that differed between groups. Imaging showed hepatomegaly in 24 of 28 patients with liver disease, often with splenomegaly. Liver biopsy in twelve patients revealed porto-sinusoidal vascular disease (PSVD) in five and features suggestive of PSVD in two, closely correlating with declining or persistently low platelet counts. All-cause mortality was higher among patients with liver disease compared with those without liver disease (25% vs 15%). Kaplan–Meier survival analysis demonstrated a trend toward earlier mortality among patients with liver disease. Median age at death was lower in patients with liver disease (29 years) compared with those without liver disease (52.5 years). The Gehan-Breslow-Wilcoxon test approached significance (p = 0.084), suggesting a tendency toward earlier death among patients with liver disease. **Conclusion:** Liver disease is a common manifestation of STAT1 GOF disease and may be associated with increased and earlier all-cause mortality. This cohort showed that histopathology frequently demonstrates PSVD, linking STAT1 GOF to vascular liver pathology. Recognizing and characterizing liver involvement in STAT1 GOF not only improves clinical care for these patients but also offers a unique opportunity to deepen our understanding of PSVD pathophysiology, a condition for which underlying mechanisms remain poorly defined.

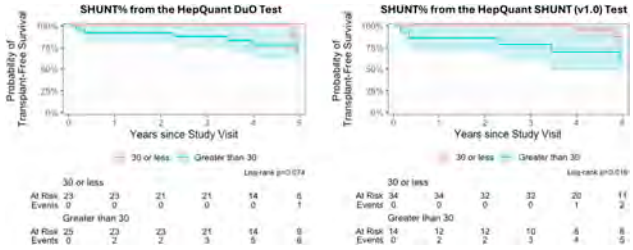
1675 | THE ORAL CHOLATE CHALLENGE TEST (HEPQUANT DUO®) MAY PREDICT TRANSPLANT-FREE SURVIVAL IN FONTAN-ASSOCIATED LIVER DISEASE



Maarouf Hoteit[1] Daniel Ganger[2] Alexis Tomlinson[3] Jack Rychik[3] Michael McRae[4] Joanne Imperial[5] Gregory Everson[6] Yuli Kim[1], [1]Hospital of the University of Pennsylvania, [2]Northwestern Memorial Hospital,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

[3]Children's Hospital of Philadelphia, [4]Custom DX Solutions LLC, [5]HepQuant LLC, [6]HepQuant

Background: Adults with Fontan circulation are at risk for heart failure and progressive Fontan-associated liver disease, but the optimal timing of transplant referral, including consideration of combined heart-liver transplantation, remains uncertain. The oral cholate challenge test (OCCT) quantifies apparent hepatic cholate clearance and estimates portal-systemic shunting, which may reflect both liver dysfunction and adverse Fontan hemodynamics. We hypothesized that elevated SHUNT% quantified by the OCCT may be associated with reduced transplant-free survival. **Methods:** From 2015 to 2022, 50 adults with Fontan circulation from two academic centers underwent cholate challenge testing and were prospectively followed. Participants were administered d4-cholate orally, followed by peripheral venous blood sampling at 20 and 60 minutes. Cholate concentrations were measured by LC-MS/MS, and the degree of portal-systemic shunting (SHUNT%) was estimated. The primary outcome was transplant-free survival. Kaplan-Meier analysis compared participants with SHUNT% $>30\%$ versus $\leq 30\%$ using the log-rank test. Results with the OCCT were compared to the full SHUNT test, which measured the same test parameters but additionally involved intravenously administered 13C-cholate and blood sampling at 0, 5, 20, 45, 60, and 90 minutes. **Results:** The cohort had a median age of 31 years (IQR, 25–38), 52% were female, and generally well-preserved routine laboratory values. Despite the benign clinical and laboratory profile, significant clinical outcomes were observed over a median of 4.4 years (IQR, 3.5–5.5): 6 deaths, 6 transplants, 4 heart failure, 3 HCC, and 3 protein losing enteropathy. Kaplan-Meier analysis demonstrated lower transplant-free survival among participants with SHUNT% $>30\%$ compared with SHUNT% $\leq 30\%$ (Figure). Separation between groups was apparent early and persisted over follow-up. By 5 years, the SHUNT% $>30\%$ group had more cumulative events than the SHUNT% $\leq 30\%$ group, regardless of test version (OCCT: 6 vs 1 events, log-rank $p=0.074$; SHUNT test: 5 vs 2 events, log-rank $p=0.016$). **Conclusion:** Elevated SHUNT% as measured by OCCT is associated with adverse mid-term clinical outcomes in adults with Fontan circulation. If validated, the OCCT could be a useful tool to guide surveillance strategy and timing of transplant referral. The excellent discrimination of SHUNT% at four years suggests the retest interval for OCCT should be 2–4 years. Larger studies are needed, however, to confirm the prognostic threshold and define how this metric should be integrated into clinical decision-making.

1676 | NATURAL HISTORY, CLINICAL SPECTRUM, AND LONG-TERM OUTCOMES OF PORTAL BILIOPATHY IN EXTRAHEPATIC PORTAL VEIN OBSTRUCTION: A 34-YEAR TERTIARY-CENTER EXPERIENCE

Babu Lal Meena[1] Shiv Kumar Sarin[1] Manoj Sharma[1] Rajeev Khanna[1] Ashish Kumar[2] Adarsh Chaudhary[3], [1]Institute of Liver and Biliary Sciences, [2]Sir Ganga Ram Hospital, [3]Medanta Hospital, Gurugram

Background: Portal biliopathy (PB), a term coined in 1992 by our group, has been reported frequently in patients with extrahepatic portal vein obstruction (EHPVO). Long-term data regarding its natural history, therapeutic burden, and progression to secondary biliary cirrhosis (SBC) remain limited. We evaluated the clinical spectrum, radiological characteristics, management strategies, and long-term outcomes of PB in a large longitudinal EHPVO cohort. **Methods:** We analyzed records of consecutive patients with EHPVO managed at two tertiary centers between 1983 and 2017. PB was diagnosed by MRCP/ERCP demonstrating biliary abnormalities in the setting of portal cavernoma after exclusion of other biliary diseases. Demographic, laboratory, radiological, endoscopic, surgical, and outcome data were analyzed. PB was anatomically classified as type 1 (extrahepatic), type 2 (intrahepatic), type 3a (extrahepatic with unilateral intrahepatic involvement), and type 3b (extrahepatic with bilateral intrahepatic involvement). SBC was diagnosed using persistent cholestasis with imaging and/or histological evidence of biliary cirrhosis despite adequate decompression. **Results:** Altogether, 774 patients with complete records were included (67.2% males; mean age

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

20 ± 14 years). Variceal bleeding was the commonest presentation (87.1%). Thrombophilia was identified in 20% of patients, most commonly MTHFR mutation (22.6%) and protein C deficiency (20.6%). At presentation, PB was present in 571/774 (73.8%) patients, although only 7.1% were symptomatic. During follow-up, PB was detected in 767/774 (99.1%) patients, with 26.9% becoming symptomatic. Combined intrahepatic and extrahepatic involvement (type 3b) was the predominant pattern (80.7%). Varicoid morphology was most common (56.2%), followed by fibrotic (29.7%) and mixed morphology (9.7%). Imaging frequently demonstrated ductal irregularity (90.6%), CBD dilatation (83.9%), and CBD angulation < 145° (62.8%). Gallbladder stones and CBD stones were observed in 19.4% and 12.6%, respectively. Among 208 symptomatic patients, 131 (62.9%) required ERCP, with a mean of 6.25 ± 2.6 procedures per patient. Durable symptom relief after a single ERCP session was achieved in only 26%, whereas 74% required repeated interventions. Over the follow-up period, SBC developed in 5.3% at a mean duration of 9.9 ± 2.9 years. Overall mortality was low (1.7%) and was mainly related to cholangitis (46%) and SBC (31%). Cholangiocarcinoma occurred in 0.4% of patients. **Conclusion:** Portal biliopathy is nearly universal in long-standing EHPVO, although symptomatic disease develops in only a minority. Symptomatic PB frequently requires repeated ERCP and shunt surgery; however, progression to secondary biliary cirrhosis and mortality remain uncommon on long-term follow-up.

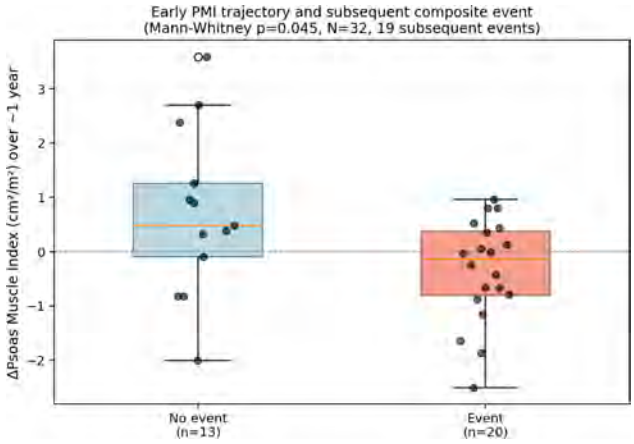
1677 | A VASCULAR MRI SIGNATURE OUTPERFORMS CONVENTIONAL SCORES FOR PREDICTING LIVER-RELATED OUTCOMES IN NON-CIRRHOTIC PORTAL HYPERTENSION



Wesam Aleyadeh[1] Maria Mironova[2] Ahmed Gharib[3] Jaha Norman-Wheeler[4] David Kleiner[5] Bernadette Redd[3] Christopher Koh[4] Theo Heller[6], [1]National Institutes of Health, [2]UCSD, [3]NIH, [4]NIDDK, NIH, [5]National Cancer Institute, Bethesda, [6]NIH/NIDDK

Background: Non-cirrhotic portal hypertension (NCPH), including porto-sinusoidal vascular disorder (PSVD), produces clinically relevant portal hypertension while liver synthetic function remains preserved, usually in the absence of fibrosis. Conventional risk tools were built for cirrhosis and may not capture risk in a predominantly presinusoidal disease. MRI is obtained routinely in these patients, yet its ability to predict outcomes has not been defined. **Methods:** We followed 50 adults with NCPH evaluated with serial protocolized MRI and follow-up for liver-related outcomes. MRIs were reviewed for vascular features of portal hypertension and for psoas muscle index. MR elastography, proton-density fat fraction, and liver iron were available in a subset. The primary endpoint was a composite of new hepatic decompensation, esophageal variceal bleed, liver transplantation, or death. We examined associations using Cox regression, time-dependent AUC at 5 years, and derived a combined imaging score. **Results:** Median age was 50 years, 40% were female, and the leading etiology was common variable immunodeficiency (34%). A porto-sinusoidal vascular lesion was present on biopsy in 74% of the cohort (37 of 50; 79% of those biopsied). Synthetic function was preserved (median MELD-Na 8) despite marked hypersplenism (median platelets 97 $\times 10^9$/L). Over a median 4.0 years, 27 patients (54%) reached the composite endpoint, including 5 deaths, 4 transplants, and 4 variceal bleeds. Porto-systemic collaterals was the strongest predictor for developing LRO (HR 6.07, 95% CI 2.20-16.75, 5-year AUC 0.70), followed by esophageal varices (HR 4.59, AUC 0.68) and periportal venous change (HR 4.47, AUC 0.67). Each outperformed MELD-Na (AUC 0.65), FIB-4 (AUC 0.61), and APRI (AUC 0.57). A simple imaging score combining collaterals, periportal change, and smaller liver length achieved a C-index of 0.66 and 5-year

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

AUC of 0.73. In a landmark analysis, 1-year change in psoas muscle index independently separated patients with LRO from those who remained event-free (median ΔPMI −0.24 vs +0.48, p = 0.046). On MR elastography (n = 10), liver stiffness was low (median 3.5 kPa, 9 of 10 below the 4.7 kPa non-cirrhotic threshold) while spleen stiffness was high (median 12.0 kPa), with a uniformly elevated spleen-to-liver stiffness ratio (median 3.45, all ≥1.23) and normal hepatic fat and iron in every patient. **Conclusion:** In NCPH, a vascular MRI signature anchored by porto-systemic collaterals and periportal venous change predicts decompensation, transplantation, and death more accurately than conventional cirrhosis-based scores, and a simple combination of three routinely reported features stratifies long-term risk. MR elastography confirms a low-liver-stiffness, high-spleen-stiffness phenotype with no parenchymal fat or iron, reinforcing that the prognostic signal is vascular. Prospective validation of the imaging score is warranted.

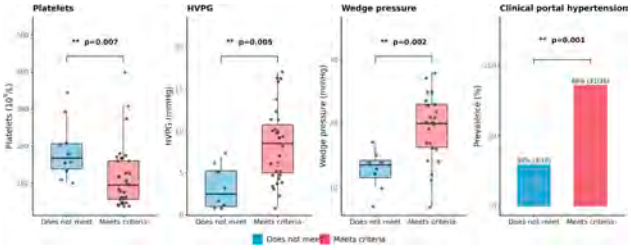
1678 | HISTOLOGIC FEATURES AND MARKERS OF PORTAL HYPERTENSION IN PORTO-SINUSOIDAL VASCULAR DISEASE ACROSS SERIAL BIOPSIES



Wesam Aleyadeh[1] Maria Mironova[2] Jaha Norman-Wheeler[3] Christopher Koh[4] David Kleiner[5] Theo Heller[6], [1]National Institutes of Health, [2]UCSD, [3]NIH, [4]NIDDK, NIH, [5]National Cancer Institute, Bethesda, [6]NIH/NIDDK

Background: Histologic features are central to the diagnosis of porto-sinusoidal vascular disease (PSVD) and define the major and minor criteria of the 2026 consensus. The longitudinal correlation between individual lesions and laboratory or clinical markers of portal hypertension is not established. We assessed associations between histologic features and laboratory, fibrosis, and hemodynamic markers at index and follow-up biopsy. **Methods:** Single-center retrospective cohort at the NIH Clinical Center. Biopsies were scored by one hepatopathologist for three major and three minor consensus features and assigned a histologic criteria score (0/2/5). Laboratory values, fibrosis indices (FIB-4, APRI, transient elastography), composite scores (ALBI, PALBI, MELD 3.0), and hemodynamic measurements (HVPG, wedge and free hepatic venous pressures) were analyzed against histologic features at index and follow-up biopsy. Within-patient concordance across paired biopsies was assessed by Cohen kappa. Multivariable logistic models, ROC analysis, and progressors-to-fibrosis comparisons were also performed. **Results:** Forty-six patients comprised the index cohort (median age 45 years, 41% female; common variable immunodeficiency in 44%). Twenty-one underwent at least one repeat biopsy (27 follow-up biopsies, median interval 4.5 years). At index, 36/46 (78%) met histologic criteria. Meeting criteria was associated with lower platelets (95 vs 168 x10^9 /L, p = 0.007), higher HVPG (8.5 vs 2.5 mmHg, p = 0.004) and wedge pressure (20 vs 14 mmHg, p = 0.002), higher liver stiffness, FIB-4, APRI and PALBI. Clinical portal hypertension was more frequent (86% vs 30%; adjusted OR 14.9, p = 0.002), and all clinically significant portal hypertension (HVPG > = 10) occurred in this group. Isolated regenerative changes showed the inverse pattern, with lower portal pressures. Follow-up biopsies had similar findings: 22/27 (81%) met criteria with lower platelets and higher liver stiffness. Within-patient histologic concordance was modest (Cohen kappa 0.50 for NRH, 0.62 for regenerative changes, 0.46 for meeting criteria, and ≤0.25 for the remaining features). Among 21 paired patients, 7 (33%) experienced composite portal hypertension worsening, most commonly de novo varices (4/9 eligible), collaterals (3/7), or PHG (3/8). Histologic worsening occurred in parallel, with 6/15 (40%) eligible patients acquiring de novo PV stenosis ≥50% by follow-up; all worsened patients were NRH-positive at index, and 6/7 had CVID. **Conclusion:** The histologic criteria for PSVD identify a consistent portal hypertensive phenotype across hemodynamic and laboratory markers at both index and follow-up biopsy. Isolated regenerative changes mark a milder subgroup rather than early disease, suggesting the consensus features are not prognostically equivalent. Modest within-patient concordance indicates that single-biopsy assessment

1679 | INVERSE ASSOCIATION BETWEEN METABOLIC DYSFUNCTION-ASSOCIATED FATTY LIVER DISEASE ACTIVITY AND PORTO-SINUSOIDAL VASCULAR DISEASE

Weihua Cao[1] Yao Xie[1] Minghui Li[1], [1]Beijing Ditan Hospital, Capital Medical University

Background: Porto-sinusoidal vascular disease (PSVD) is a major cause of non-cirrhotic portal hypertension, but its pathogenesis remains unclear. Whether metabolic dysfunction-associated fatty liver disease (MAFLD) contributes to the development of PSVD is still controversial. This study aimed to compare the clinical and pathological characteristics between patients with MAFLD alone and those with MAFLD combined with PSVD, and to explore the association between MAFLD and PSVD. **Methods:** A total of 381 patients with biopsy-proven MAFLD were retrospectively enrolled, including 258 with MAFLD alone and 123 with MAFLD combined with PSVD. Propensity score matching (PSM, 1:2) was performed to balance age, sex, BMI, hypertension, and diabetes history between the two groups. Clinical, biochemical, and pathological parameters were compared before and after matching. Univariate and multivariate logistic regression analyses were used to identify independent factors associated with PSVD. Subgroup analyses were further conducted according to fibrosis stage (F0-1 vs F2-3) and NAS score (<4 vs ≥ 4). **Results:** After PSM, there were no significant differences in age, sex, BMI, hypertension, or diabetes history between the two groups ($P>0.05$) in Table 1. Compared with the MAFLD alone group, the MAFLD+PSVD group had significantly lower NAS score (3.00 vs 4.50, $P<0.001$), lower prevalence of MASH (10.57% vs 31.71%, $P<0.001$), lower steatosis grade ($P<0.001$), lower inflammation grade ($P<0.001$), and lower fibrosis stage ($P<0.001$) in Table 1. Moreover, serum ALT, AST, triglycerides, liver stiffness measurement (LSM), and controlled attenuation parameter (CAP) were all significantly reduced in the MAFLD+PSVD group ($P<0.01$) in Table 1. Multivariate logistic regression showed that CAP (OR = 0.988, 95%CI 0.983-0.994, $P<0.001$) and NAS score (OR = 0.476, 95%CI 0.287-0.789, $P=0.004$) were independent negative correlates of PSVD in Table 2. In the F0-1 subgroup, the PSVD group still had lower NAS score, MASH rate, CAP, and ALT ($P<0.05$) in Table 3. In the F2-3 subgroup, the PSVD group had significantly lower NAS score, MASH rate, ALT, AST, and CAP than the MAFLD alone group ($P<0.01$) in Table 4. Further analysis revealed that the prevalence of PSVD in patients with NAS <4 was 60.2%, significantly higher than that in patients with NAS ≥ 4 (17.3%; OR = 7.37, 95%CI 4.63-11.75, $P<0.001$) in Figure 1. **Conclusion:** The severity of MAFLD is inversely associated with the occurrence of PSVD , suggesting that PSVD tends to develop in the early stages of MAFLD (NAS <4, mild fibrosis) rather than as an advanced complication of MAFLD. This finding challenges the intuitive assumption that “more severe MAFLD confers higher PSVD risk”, and implies a potential reverse selection or hemodynamic interaction between MAFLD and PSVD. Clinically, for MAFLD patients with low NAS score (especially <4) who present with unexplained portal hypertension, the possibility of PSVD should be considered.

Tanwar[2] Baibaswata Nayak[1] Shalimar .[1], [1]AIIMS New Delhi, [2]AIIMS New Delhi

Background: Budd-Chiari syndrome (BCS) is a rare vascular disorder of the liver, characterized by hepatic venous outflow tract obstruction (HVOTO) secondary to thrombosis or intrinsic vascular abnormalities. Obstruction may affect the inferior vena cava (IVC), hepatic veins (HV), or both. Clinical presentation, disease progression, and management vary according to site, extent, and duration of obstruction. The majority of BCS cases are attributed to an underlying hypercoagulable disorder. Despite its clinical significance, data on the genetic causes and biomarkers underlying BCS remain limited. Here in this study, we performed whole-exome sequencing in BCS cases and healthy controls to explore the mutational landscape in BCS-affected subjects. **Methods:** We enrolled BCS (n = 77) and Healthy controls (n = 24) patients. Subjects were prospectively enrolled after informed consent. The study was reviewed and approved by the AIIMS, New Delhi, Institute Ethics Committee as per IEC-629/03.11.2017, RP-19/2018. WES was performed using the Twist Comprehensive Exome kit on the Illumina platform, followed by quality checks and analysis using the GATK pipeline. Pathogenic/likely pathogenic variants were filtered out from the exonic part of the annotated variant calling file. rsID and Cosmic IDs databases were used to define the mutations. Kyoto Encyclopedia of Genes and Genomes (KEGG) and Gene Ontology analysis were done for pathogenic gene variants. Validation of the most frequent pathogenic mutations in cases was done by Sanger sequencing in an Independent BCS Cohort. **Results:** We enrolled patients with mean age 27(15-61) years. Majority of them were females **.** In all cases a total of 10394 genes were observed having a variant. In each of these genes 1-173 variants per gene were observed. C > T transition was the most frequent variant observed in all cases. Pathogenic mutations were observed in the 1732 genes. The most frequent genes that have germline pathogenic mutations were HLA-DRB1(c.A455G, p.Y152C), ABCB5(c.G1094T, p.G365V), MTHFR (c.C788T, p.A263V), and A2ML1 (c.G1436A, p.C479Y). KEGG pathway analysis for all pathogenic mutation showed that Hippo, MYC, NOTCH, PI3K, RTK-RAS, WNT, Cell-cycle TP53 and TGF Beta are the key cellular pathways that were found having a regulatory role BCS patients. In gene ontology analysis, we observed that at the molecular level, these genes having a role in actin and tubulin binding, may be a part of the structural binding process. Genes JAK2, HLA-DRB1, APOH, PROS, PROC were found having druggable targets. **Conclusion:** 1732 genes were having pathogenic/likely pathogenic mutations in our BCS cohort. These genes are involved in Hippo, MYC, NOTCH, PI3K, RTK-RAS, WNT, Cell-cycle TP53 and TGF Beta pathways. Genes JAK2, HLA-DRB1, APOH, PROS, PROC were found to have druggable targets.

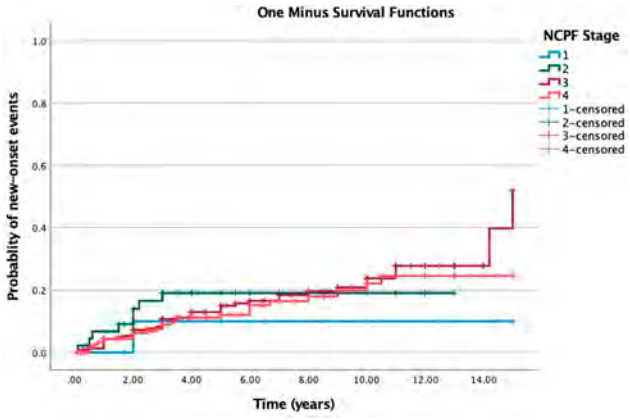
1681 | STAGE-DEPENDENT NATURAL HISTORY, PROGRESSION, AND PREDICTORS OF ADVERSE OUTCOMES IN NON-CIRRHOTIC PORTAL FIBROSIS: VALIDATION OF THE APASL 2024 STAGING SYSTEM



Omkar Rudra[1] Chhagan Bihari[1] Akash Shukla[2] Babu Lal Meena[3] Archana Rastogi[1] Ajay Duseja[4] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences, [2]Seth GS Medical College & KEM Hospital, [3]PGIMER, Chandigarh, [4]Postgraduate Institute of Medical Education & Research

Background: Non-cirrhotic portal fibrosis (NCPF) or portosinusoidal vascular disease (PSVD) is a distinct presinusoidal portal hypertensive disorder with generally preserved hepatic synthetic function despite progressive vascular injury. The APASL 2024 guidelines introduced a four-stage framework for NCPF, but stage-specific natural history and prognostic markers remain insufficiently defined. We aimed to characterize the clinical course, stage migration, and predictors of adverse outcomes in a large multicenter cohort of histologically confirmed NCPF patients. **Methods:** We performed an ambispective analysis of histologically confirmed NCPF patients (Multisociety consensus, 2026) from three Indian centers seen between 2009 and 2024. Histopathological subgroups included obliterative portovenopathy (OPV), OPV with fibrosis (OPV-F), incomplete septal cirrhosis (ISC) and nodular regenerative hyperplasia (NRH). Clinical staging was assigned according to APASL 2024 criteria. Primary outcomes included portal vein thrombosis (PVT), ascites, variceal bleeding, liver transplantation (LT), and mortality. **Results:** Altogether 475 patients met inclusion criteria (median age 35 years; 58.3% male). Baseline stages were Stage I (n = 11, 2.3%), Stage II (n = 45, 9.5%), Stage III (n = 229, 48.2%), and Stage IV (n = 190, 40.0%). The predominant histopathological features were OPV:347 (73.1%) and OPV-F:71 (14.9%). Over a median follow-up of 6 years, transplant requirement and mortality were significantly higher in Stage 4. Independent predictors of clinically significant new onset events included baseline spleen size for

PVT (HR 1.11, 95% CI 1.01–1.21; p = 0.028), serum albumin for ascites (HR 0.64; 95% CI 0.441–0.934; p = 0.020), and baseline LSM for variceal bleeding risk (HR 1.056; 95% CI 1.039–1.073; p < 0.001). Independent predictors of mortality and transplant requirement included age (HR 1.05; 95% CI 1.01–1.10; p = 0.024), histological OPV-F/ISC pattern (HR 4.7; 95% CI 2.4–9.3; p < 0.001), and serum albumin (HR 0.33; 95% CI 0.14–0.78; p = 0.012). **Conclusion:** APASL based staging system clearly identified that early-stage NCPF patients follow a largely uneventful course for years, whereas advanced-stage patients carry a substantial risk of complications. The OPV-F/ISC histology correlates with a higher-risk subgroup, likely to develop complications early.

1682 | INCIDENCE AND MANAGEMENT OF ISCHEMIC HEPATITIS ("SHOCK LIVER") AND PATTERNS OF N-ACETYLCYSTEINE UTILIZATION IN CRITICALLY ILL ADULTS: A RETROSPECTIVE STUDY

Elan Adhami[1] Paul Alvarez[1] Davis Kuruvilla[1] Amanda Julia-Rios[1] John Nahas[1] Aya Akhras[1] Waseem Wahood[2] Samer Wahood[3] Arthur Martinyan[4] Bernardo Reyes[1], [1]HCA Florida Aventura Hospital, [2]University of Miami, [3]Warren Alpert Medical School, [4]FIU Herbert Wertheim College of Medicine

Background: Ischemic hepatitis is an acute liver injury caused by hepatic hypoperfusion and is associated with substantial morbidity and mortality in critically ill patients. Although N-acetylcysteine (NAC) has demonstrated benefit in select causes of acute liver failure, evidence supporting its use in ischemic hepatitis remains limited. This study evaluated outcomes associated with NAC administration in patients with ischemic hepatitis requiring intensive care. **Methods:** We conducted a retrospective cohort study using the TriNetX database. Adult patients (> 18 years old) with ischemic hepatitis were identified using laboratory criteria of alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) ≥ 1000 U/L with lactate dehydrogenase (LDH) ≥ 3750 U/L in the setting of hypotension or ICU-level critical illness. Patients with other causes of liver injury, including cirrhosis, viral hepatitis, alcoholic liver disease, toxic liver injury, acetaminophen toxicity, liver trauma, or prior liver transplantation, were excluded. Cohorts were stratified by receipt of intravenous NAC. Propensity score matching was performed to balance demographics and comorbidities. Outcomes assessed within 30 days included all-cause mortality, vasopressor utilization, and hospital readmission. Kaplan-Meier survival and risk analyses were performed, with p < 0.05 considered significant. **Results:** A total of 4,114 patients were included in this study, including 3,847 patients with no NAC exposure and 267 patients treated with NAC. After propensity score matching, 264 patients remained in each cohort. Baseline demographics and comorbidities were well balanced following matching. There was no significant difference in 30-day mortality between cohorts that were and were not treated with NAC (48.2% vs 51.2%; OR 1.13, 95% CI 0.77–1.66; p = 0.529). Kaplan-Meier analysis similarly demonstrated no significant survival difference (HR 1.09, 95% CI 0.83–1.44; p = 0.655). Vasopressor utilization was also similar between groups (28.8% vs 23.5%; OR 0.76, 95% CI 0.31–1.83; p = 0.540), with no difference in the number of vasopressor-use instances (p = 0.765). Notably, patients receiving NAC had significantly higher rates of hospital readmission compared with patients who did not receive NAC (61.7% vs 50.4%; OR 0.63, 95% CI 0.45–0.89; p = 0.009). **Conclusion:** In this large real-world analysis of critically ill patients with ischemic hepatitis, NAC administration was not associated with improved short-term mortality, survival probability, or vasopressor requirements. NAC use was associated with increased hospital readmission rates. These findings do not demonstrate a clear clinical benefit for NAC in ischemic hepatitis and underscore the need for prospective studies to better define its therapeutic role in this high-risk population.

1683 | CIRCULATING FIBRONECTIN REFLECTS DISEASE SEVERITY AND PREDICTS VARICEAL BLEEDING IN ADVANCED CHRONIC LIVER DISEASE

Georg Kramer[1] Irina Lie-Ungurean[2] Mathias Jachs[2] Lorenz Balcar[2] Benedikt Hofer[2] Lukas Hartl[2] Paul Thoene[2] Marlene Hintersteininger[2] Philipp Schwabl[1] Michael Trauner[2] Mattias Mandorfer[1] Thomas Reiberger[1] Benedikt Simbrunner[1], [1]Medical University of Vienna, [2]Medical University of Vienna, Vienna, Austria

Background: Fibronectin is an extracellular matrix protein with roles in hemostasis, immune signaling, and tissue repair. Its clinical relevance in advanced chronic liver disease (ACLD), however, remains incompletely defined. We therefore evaluated whether circulating fibronectin reflects major pathophysiological domains of ACLD and whether it is associated with subsequent decompensation-related outcomes. **Methods:** Patients with ACLD undergoing hepatic venous pressure gradient (HVPG) measurement were prospectively included, and serum fibronectin levels were assessed at the same time point. Associations between fibronectin and pathophysiological biomarkers were evaluated using correlation analyses and systems modeling. Associations with clinical outcomes were assessed using competing-risk regression models. **Results:** The study cohort comprised 298 patients with a median HVPG of 17 mmHg (IQR 12-21) and a median MELD 3.0 of 12 (IQR 9-17). Fibronectin levels were lower in decompensated compared with compensated ACLD (30.3 vs. 38.8 µg/mL; $p < 0.001$). Fibronectin correlated with markers of hepatic synthesis, particularly cholinesterase (Spearman's $r = 0.64$; $p < 0.001$), and was inversely correlated with MELD 3.0 ($r = -0.47$; $p < 0.001$). While fibronectin was inversely associated with the enhanced liver fibrosis (ELF) score, a marker of extracellular matrix remodeling, in univariable analysis ($r = -0.20$; $p < 0.001$), ELF showed an independent positive association after adjustment for liver function and portal hypertension (standardized $\beta = 0.19$; $p < 0.001$). In systems modeling, hepatic synthetic function was the main determinant of fibronectin variance, with cholinesterase accounting for 37%, followed by fibrinolysis, represented by antiplasmin (14%), and ELF (12%). Higher fibronectin levels were independently associated with variceal bleeding (adjusted subdistribution hazard ratio [aSHR] 4.46; $p = 0.038$), whereas lower fibronectin levels predicted portal vein thrombosis (aSHR 0.20; $p = 0.023$), after adjustment for HVPG, MELD 3.0, or IL-6. No association was observed with other hepatic decompensation events or liver-related mortality. **Conclusion:** Circulating fibronectin correlates with hepatic synthetic capacity and extracellular matrix remodeling and is associated with hemorrhagic and thrombotic complications in ACLD, suggesting that fibronectin may serve as a marker of disturbed hemostatic balance in ACLD.

1684 | ESTABLISHMENT AND VALIDATION OF A RISK PREDICTION MODEL FOR PORTAL VEIN THROMBOSIS IN PATIENTS WITH HEPATIC CIRRHOSIS

Fengjiao Kang[1] Yuan Bian[2] Feng Guo[1], [1]Traditional Chinese Medicine Hospital Affiliated to Xinjiang Medical University, [2]Sichuan Academy of Medical Sciences & Sichuan Provincial People's Hospital

Background: Portal vein thrombosis (PVT) is a serious complication of liver cirrhosis associated with increased morbidity and mortality. Reliable prediction tools to identify high-risk patients in clinical practice remain

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

limited. **Methods:** We retrospectively enrolled 1,463 cirrhotic patients admitted to Sichuan Provincial People's Hospital (January 2018–May 2025), including 133 with PVT and 1,330 without PVT. A total of 99 candidate variables—spanning demographics, comorbidities, medications, laboratory parameters, imaging findings, and liver function scores—were evaluated. Following feature selection, 10 predictors were retained. Six feature-selection methods were combined with seven machine-learning (ML) algorithms (logistic regression, Gaussian naïve Bayes, K-nearest neighbors, support vector machine, GBDT, XGBoost, LightGBM) to construct PVT risk models. Model performance was assessed by 10-fold cross-validation and an independent test set using AUC, accuracy, precision, recall, F1-score, Brier score, calibration curves, and decision curve analysis (DCA). Subgroup analyses were performed by sex, disease severity, splenectomy status, non-selective beta-blocker (NSBB) use, and antithrombotic therapy. SHAP (SHapley Additive exPlanations) values were used for model interpretability. **Results:** The XGBoost model with random forest feature selection achieved the best performance: AUC 0.942 (95% CI 0.912–0.966), recall 0.825, F1-score 0.600, and Brier score 0.073. Subgroup analyses demonstrated robust discrimination across most strata; sensitivity was modestly reduced in patients with low MELD scores, post-splenectomy status, and NSBB use. SHAP analysis identified the top predictors as: alpha-fetoprotein, esophageal varices, Child–Pugh class, fibrinogen, portal vein diameter, sex, procoagulant agent use, diuretic use, bacterial infection, and splenomegaly. **Conclusion:** A machine learning-based model integrating clinical, laboratory, and imaging variables demonstrated excellent discriminative performance (AUC 0.942) for PVT prediction in cirrhotic patients. An interpretable web-based tool was developed to facilitate risk stratification and guide individualized prevention strategies. External multicenter validation is warranted.

1685 | CT-BASED

Yanna Liu[1] Qian Yu[2] Yanglan He[1] Ying Han[1] Hui Liu[1] Chunlei Fan[1] Yanjing Wu[1] A-Juan Zeng[1] Jing Chang[1] Shuzhen Wang[1] Qi Li[1] Yijie Yan[1] Xueying Liang[1] Keke Jin[1] Lingna Lv[1] Yadi Li[1] Fuquan Liu[3] Yu Wang[4] Calvin Pan[5] Huiguo Ding[1], [1]Beijing Youan Hospital, [2]Southeast University, [3]Beijing Shijitan Hospital, [4]Beijing Friendship Hospital, [5]NYU Langone Health, NYU School of Medicine

Background: Porto-sinusoidal vascular disorder (PSVD) is a major cause of non-cirrhotic portal hypertension impacting patient prognosis. Differentiating PSVD from cirrhosis remains challenging due to overlapping clinical features and routine imaging findings. We aimed to develop and validate a CT-based radiomics model, termed *r*PSVD, for differentiating PSVD from cirrhosis, specifically focusing on patients with inconclusive LSM results. **Methods:** This retrospective, multicenter diagnostic study (2010–2023) included 600 portal hypertension patients (200 PSVD, 400 cirrhosis) with CT scans and liver biopsies. Patients were allocated into training cohort (n = 237), internal (n = 234), and external cohorts (n = 129). The *r*PSVD model utilized liver and spleen features selected via minimum redundancy maximum relevance and least absolute shrinkage and selection operator algorithms (Figure A). The primary outcome was diagnostic accuracy, assessed by area under the receiver operating characteristic curve (AUC) and compared with liver stiffness measurement (LSM) using DeLong's test. **Results:** The primary outcome, *r*PSVD performance, achieved AUCs of 0.85 (95% CI, 0.80–0.90), 0.82 (0.76–0.88), and 0.80 (0.70–0.89) in the training, internal, and external validation cohorts, respectively. Combining *r*PSVD and LSM improved performance over LSM alone (AUC 0.91 vs. 0.85, $P < 0.05$) (Figure B&C). In the LSM "gray zone" (10–20 kPa), *r*PSVD significantly outperformed LSM (AUC 0.83 vs. 0.69, $P < 0.05$) and demonstrated higher clinical net benefit in decision-analytic evaluations. **Conclusion:** The CT-based *r*PSVD model is a novel and non-invasive toll for differentiating PSVD from cirrhosis. It provides significant diagnostic value for portal hypertension patients, especially as a secondary test for the target population where LSM results are indeterminate.

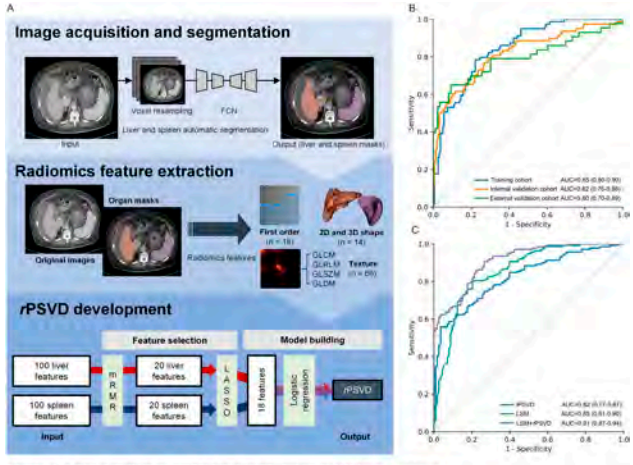

Figure. CT-based radiomics model for distinguishing PSVD from cirrhosis.

1686 | DIAGNOSTIC ACCURACY OF NON-INVASIVE TESTINGS (NITS) FOR FONTAN-ASSOCIATED LIVER DISEASE (FALD): A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

Buddhida Kijdamrongwattanakul[1] Tanawat Jongraksak[1] Amarit Tansawet[2] Pongphob Intaraprasong[1] Sarita Ratana-Amornpin[1] Tarinee Tangcharoen[1] Alisa Limsuwan[1] Abhasnee Sobhonslidsuk[1], [1]Ramathibodi Hospital, Mahidol university, [2]Chulalongkorn university

Background: Fontan-associated liver disease (FALD) causes progressive liver fibrosis and is a key driver of morbidity following the Fontan operation. Although liver biopsy remains the gold standard for liver fibrosis assessment, it is invasive and impractical for routine monitoring. This network meta-analysis (NMA) compared the diagnostic accuracy of non-invasive tests (NITs) such as magnetic resonance elastography (MRE), vibration-controlled transient elastography (VCTE), and serum-based biomarkers for detecting advanced fibrosis in FALD. **Methods:** We conducted a systematic review of studies indexed in MEDLINE, Scopus, and CENTRAL from inception to 31 March 2026. NMA was performed to compare the diagnostic accuracy of NITs for fibrosis assessment in FALD. Studies using liver biopsy or MRE as the reference standard were included. Reported AUCs were pooled using random-effects models with restricted maximum likelihood estimation and stratified by test. Network ranking was performed using AUC as the effect measure, with higher values indicating superior diagnostic performance. Publication bias was assessed using a comparison-adjusted funnel plot. **Results:** Of 1,510 screened articles, seven studies with 633 participants were included. Six and one studies used liver biopsy and MRE as the reference standard. However, only studies using liver biopsy as the reference were included in meta-analysis. Overall, NITs demonstrated modest diagnostic accuracy for advanced FALD, with a pooled AUROC of 0.66 (95% CI: 0.61–0.72). In the network analysis, MRE yielded the highest accuracy with an AUROC of 0.74 (95% CI: 0.59–0.89: SUCRA 0.9), followed by APRI (AUROC 0.68, 95% CI: 0.59–0.77: SUCRA 0.7), FIB-4 (AUROC 0.66, 95% CI: 0.58–0.75: SUCRA 0.6), and VCTE (AUROC 0.65, 95% CI: 0.47–0.83: SUCRA 0.6). SWE demonstrated the lowest diagnostic performance (AUROC 0.48, 95% CI: 0.31–0.66: SUCRA 0.2). **Conclusion:** Non-invasive testings (NITs) showed modest diagnostic accuracy for detecting advanced fibrosis in Fontan-associated liver disease (FALD). MRE demonstrated the best overall diagnostic performance and ranked highest in the network analysis. APRI, an easily available serum-based score, also showed relatively good performance and may be used as a screening tool in patients with Fontan operation. FIB-4 and VCTE demonstrated modest diagnostic accuracy, while SWE showed the lowest performance.

Table 1. League table of non-invasive tests for advanced FALD using liver biopsy as reference.

1687 | TRANEXAMIC ACID-ASSOCIATED HEPATIC VENO-OCCLUSIVE DISEASE/SINUSOIDAL OBSTRUCTION SYNDROME: A FAERS DISPROPORTIONALITY ANALYSIS (1987-2025)

Fidan Gurbanzade[1] Meki Çakmak[2] Alara Apa[1], [1]Acibadem Mehmet Ali Aydinlar University School of Medicine, [2]Bahcesehir University School of Medicine

Background: Tranexamic acid (TXA), a synthetic analog of amino acid lysine, is a potent antifibrinolytic agent. While it is approved by Food and Drug

Administration (FDA) for heavy menstrual bleeding and prevention of bleeding episodes in hemophilia patients undergoing dental procedures, its prophylactic use to reduce hemorrhage has been widely adopted across surgical specialties. However, emerging case reports have suggested a potential association between TXA exposure and hepatic veno-occlusive disease/sinusoidal obstruction syndrome (VOD/SOS), raising concerns regarding a potential thrombotic safety signal. This study aims to evaluate the association between tranexamic acid exposure and VOD/SOS using the FDA Adverse Event Reporting System (FAERS) database. **Methods:** This was an observational, retrospective and pharmacovigilance study based on FAERS, between January 1987 and December 2025. Medical Dictionary for Regulatory Activities (MedDRA) Preferred Terms were used to determine the reaction term, venoocclusive liver disease. Products included in the analysis were Tranexamic Acid (G), Tranexamic Acid (P), and Tranexamic Acid In Sodium Chloride (P). Demographics, indications and outcomes were descriptively summarized. Reporting odds ratio (ROR) with 95% confidence intervals (CI) was calculated to evaluate the disproportionality. An ROR > 1.0 with lower 95% CI above 1.0 was considered significant, pointing to a signal. **Results:** There were 17 reports of VOD/SOS linked to TXA, all occurred after 2020. A significant disproportionality signal was identified: ROR 28.43 (95% CI 17.64 to 45.82); thresholds were met. Cases predominantly involved pediatric patients, with a median age of 56 months; with sex not specified in 82%. Three separate cohorts were determined after stratification by outcome severity: life-threatening events (n = 11) were observed in an age range of 22 months to 59 years with various indications; all hospitalized cases (n = 2) had co-reactions and none of them received TXA as monotherapy; other serious outcomes (n = 4) occurred exclusively in preschoolers and toddlers, two of whom received TXA during hematopoietic stem cell transplantation (HSCT) conditioning for neuroblastoma. Established VOD/SOS-associated agents, particularly busulfan and melphalan, were concomitantly reported in 11 cases (65%), representing a potential source of confounding. Hemorrhage was the leading indication (78%) for tranexamic acid use in this cohort. **Conclusion:** FAERS analysis identified a significant disproportionality signal for VOD/SOS in association with tranexamic acid. Given the inherent limitations of spontaneous reporting systems, these findings should be interpreted cautiously. Further research is required to establish causality. Nevertheless, the potential association with VOD/SOS should be carefully considered during tranexamic acid administration for hemorrhage prophylaxis.

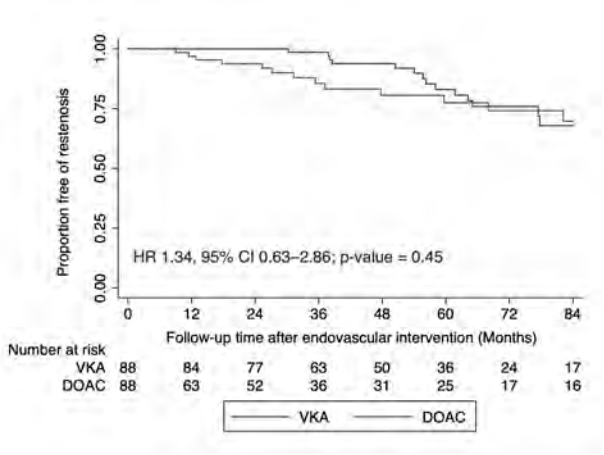
1688 | EFFICACY AND SAFETY OF DIRECT ORAL ANTICOAGULANTS IN BUDD–CHIARI SYNDROME AFTER ENDOVASCULAR INTERVENTION: A PROPENSITY SCORE-MATCHED ANALYSIS



Ayush Agarwal[1] Ankush Garg[1] Shubham Jain[1] Sarthak Saxena[1] Sejal Kotwani[1] Vishal Chauhan[1] Samagra Agarwal[1] Sagnik Biswas[1] Shalimar Shalimar[1], [1]All India Institute of Medical Sciences, New Delhi

Background: Anticoagulation is essential to maintain vessel patency following endovascular intervention in Budd–Chiari syndrome (BCS). Vitamin K antagonists (VKAs) are limited by the need for regular monitoring, while direct acting oral anticoagulants (DOACs) have emerged as potential alternatives, but data in BCS are scarce. We aimed to compare the efficacy and safety of DOACs versus VKAs in patients with BCS following endovascular intervention. **Methods:** We performed a retrospective analysis of a prospectively maintained database of patients with BCS who underwent endovascular intervention at a tertiary care centre in North India. Patients receiving DOACs were compared with those receiving VKAs using propensity score matching (nearest neighbour matching in a 1:1 ratio with a caliper of 0.05), incorporating age, sex, and type of venous obstruction. Outcomes assessed included restenosis and bleeding events. **Results:** A total of 176 patients were included, with 88 patients each receiving DOACs and VKAs. Baseline characteristics were similar between groups (median age 34 [27–40] years; 48% male; level of obstruction: inferior vena cava 2%, hepatic vein 35%, and combined 63%). Among patients receiving DOACs, 55 received dabigatran, 27 apixaban, and 6 rivaroxaban, while all patients in the VKA group received acenocoumarol. Follow-up duration was longer in the VKA group than in the DOAC group (53.8 [IQR 34.7–74.4] months vs 25.3 [IQR 8.1–52.0] months). Restenosis rates were similar in the DOAC and VKA groups (14.8% [95% CI 8.8–23.7] vs 15.9% [95% CI 9.7–25.0]; HR 1.34, 95% CI 0.63–2.86; P = 0.45). Bleeding rates were also similar in the DOAC and VKA groups (20.5% [95% CI 13.3–30.0] vs 30.7% [95% CI 22.0–41.0]; HR 1.18, 95% CI 0.65–2.16; P = 0.58). The proportion of patients experiencing major bleeding (8.0% in the DOAC group vs 12.5% in the VKA group, P = 0.32) was also similar between the two groups. **Conclusion:** DOACs demonstrated comparable efficacy and safety to VKAs in patients with BCS following endovascular intervention, offering a practical

1689 | BETWEEN CLOT AND BLEED: LOW-MOLECULAR-WEIGHT VERSUS UNFRACTIONATED HEPARIN AND 2-, 7-, AND 28-DAY SAFETY OUTCOMES IN ICU-LEVEL CIRRHOSIS

Chimezirim Ezeano[1] David Kramer[2] Rodolfo Alpizar-Rivas[1], [1]Aurora Healthcare, [2]Aurora Health Care

Background: ICU-level patients with cirrhosis have competing thrombotic and bleeding risks, and the safest pharmacologic prophylaxis strategy remains uncertain. We compared short-term bleeding and mortality among patients receiving low-molecular-weight heparin (LMWH) versus unfractionated heparin (UFH). **Methods:** We performed a retrospective TriNetX cohort study of adults aged 18–75 years with ICD-10-coded cirrhosis. ICU-level care was defined by critical-care CPT charges 99291/99292. LMWH included enoxaparin or dalteparin; UFH included injectable heparin. Follow-up began at the first qualifying prophylaxis exposure among patients with ICU-level care, with exposure occurring within 2, 7, or 28 days after a critical-care charge. Other antithrombotic exposures, heparin flushes, and continuous heparin infusions were excluded around index. The primary outcome was coded bleeding; the secondary outcome was all-cause mortality. Venous thromboembolic events were assessed but were not reportable. Propensity score matching was performed separately for each window; no-antithrombotic comparator cohorts were exploratory. **Results:** Pre-match LMWH/UFH: 3,710/4,658 (2d), 3,692/4,699 (7d), 3,717/4,767 (28d); exploratory no-antithrombotic cohorts: 19,452, 18,115, and 17,129. Matched: 3,076, 3,094, and 3,132 per arm before outcome-specific exclusions. LMWH had lower bleeding at 2d (3.0% vs 4.8%; RD -1.7% [-2.8, -0.6]; RR 0.6; HR 0.6; $p = 0.002$), 7d (3.0% vs 5.5%; RD -2.5% [-3.7, -1.4]; RR 0.5; HR 0.5; $p < 0.001$), and 28d (4.5% vs 6.7%; RD -2.3% [-3.6, -1.0]; RR 0.7; HR 0.7; $p = 0.001$). Mortality was lower for LMWH at 2d (1.2% vs 4.8%; RD -3.6% [-4.5, -2.8]; RR 0.3; HR 0.2), 7d (2.8% vs 8.0%; RD -5.2% [-6.3, -4.1]; RR 0.4; HR 0.3), and 28d (6.1% vs 13.1%; RD -7.0% [-8.4, -5.5]; RR 0.5; HR 0.4; all $p < 0.001$). Exploratory: LMWH had lower 28-day mortality than no-antithrombotic (7.0% vs 10.5%; RR 0.7; $p < 0.001$), whereas UFH did not (21.4% vs 19.9%; RR 1.1; $p = 0.14$). **Conclusion:** Among prophylaxed ICU-level patients with cirrhosis, LMWH was associated with lower coded bleeding and mortality than UFH across all windows. Prophylaxis choice reflects clinician judgment about competing thrombotic and bleeding risks; early 2-day separation suggests residual confounding and selection bias rather than treatment effect alone. This supports the need for prospective studies in this patient group. Limitations include code-defined cirrhosis and ICU-level care, residual confounding, and around-index exclusions; these data address safety and survival, not thromboprophylactic efficacy.

1690 | ENDOTHELIAL DYSFUNCTION RATHER THAN PROCOAGULANT STATE IS INDEPENDENTLY ASSOCIATED WITH FIBROGENESIS AND DISEASE PROGRESSION IN ADVANCED CHRONIC LIVER DISEASE

Paula Höfinger[1] Benedikt Simbrunner[1] Ida Villesen[2] Georg Kramer[1] Lorenz Balcar[1] Bernhard Scheiner[1] Rodrig Marculescu[1] Michael Trauner[1] Morten Karsdal[3] Thomas Reiberger[1] Diana Leeming[3] Ton Lisman[4] Mattias Mandorfer[1] Georg Semmler[1], [1]Medical University of Vienna, Vienna, Austria, [2]Odense University Hospital, Odense, Denmark; University of Southern Denmark, Odense, Denmark, [3]Nordic Bioscience, Herlev, Denmark, [4]University of Groningen, Groningen, The Netherlands

Background: Advanced chronic liver disease (ACLD) is characterized by a rebalanced hemostatic system. Experimental studies suggest that a procoagulant state may promote hepatic fibrogenesis and disease

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

progression, however clinical evidence linking endogenous thrombin potential (ETP) to fibrogenesis on a cross-sectional or disease progression on a longitudinal level remains limited.Therefore, we investigated the association between biomarkers of coagulation and endothelial dysfunction on the one hand and fibrogenesis on the other hand, while accounting for portal hypertension severity by adjusting for hepatic venous pressure gradient (HVPG). Moreover, direct clinical endpoints were evaluated. **Methods:** This retrospective study includes 138 patients with ACLD undergoing paired HVPG measurement at the Vienna Hepatic Hemodynamic Laboratory between 2017 and 2020. Biomarkers of coagulation (ETP by thrombomodulin-modified thrombin generation assay and thrombin–antithrombin complex) and endothelial dysfunction (VWF antigen) as well as extracellular matrix remodeling/fibrogenesis (ProC3, ProC4, ProC6, and ELF test) were assessed from blood samples obtained at the time of HVPG measurement. Spearman and HVPG-adjusted partial Spearman correlation analyses as well as univariable Cox regression (in cACLD, the endpoint was first hepatic decompensation, whereas in dACLD the endpoint was liver-related death) analyses were performed. **Results:** Among 138 patients, 52 (37.7%) had cACLD and 86 (62.3%) had decompensated cirrhosis. ETP correlated significantly with ELF (r_s = 0.22, p = 0.012), whereas no significant associations were observed with ProC3, ProC4, or ProC6. TAT was not associated with markers of fibrogenesis. In contrast, VWF showed significant correlations with ProC3 (r_s = 0.20, p = 0.018), ProC6 (r_s = 0.26, p = 0.002), and ELF (r_s = 0.44, p < 0.001). However, after adjustment for disease stage (HVPG) using partial Spearman correlation analyses, ETP and TAT showed no correlation to markers of fibrogenesis, whereas VWF remained significantly associated with ProC6 and ELF. Finally, ETP (HR 1.18, p = 0.129) and TAT (HR 0.81, p = 0.147) were not associated with risk of hepatic decompensation/liver-related death. **Conclusion:** After adjustment for liver disease severity, thrombin generation capacity (ETP) and coagulation activation (TAT) were no longer associated with biomarkers of fibrogenesis in ACLD, whereas endothelial dysfunction (VWF) remained independently associated with ECM remodeling. Whether the latter is due to causal interference (e.g., hepatic sinusoidal crosstalk) or a common cause (e.g., systemic inflammation) remains to be determined.

1691 | TPO RECEPTOR AGONISTS VERSUS PLATELET TRANSFUSION FOR PROCEDURAL THROMBOCYTOPENIA IN CIRRHOSIS: A PROPENSITY-MATCHED COHORT STUDY

Archana Salek[1] Jashanveer Johal[1] Bianca Patel[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Abdallah Hussein[1] Jason Hyman[2] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Thrombocytopenia is a common complication of cirrhosis and frequently defers or complicates invasive hepatic procedures. Platelet transfusion has historically been the standard peri-procedural strategy, but TPO receptor agonists (TPO-RAs) — including romiplostim, eltrombopag, avatrombopag, and lusutrombopag — offer an oral alternative for procedural platelet optimization. Real-world comparative data on downstream outcomes between these strategies remain limited. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 included cirrhotic patients with thrombocytopenia who underwent invasive hepatic procedures (liver biopsy, paracentesis, or portal decompression procedures) and received a TPO-RA within 6 months prior to the procedure, excluding prior HCC, liver transplant, ITP, and ESRD. Cohort 2

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

comprised matched patients receiving platelet transfusion within 1 month prior to the same procedures. 1:1 propensity score matching (PSM) yielded 160 patients per arm. Outcomes assessed over a 6–120 monthfollow-up window included GI bleeding, blood transfusion, hepatic encephalopathy (HE), and all-cause mortality, analyzed by measures of association (MOA) and Kaplan-Meier (KM) survival analysis. **Results:** After PSM, cohorts were well-balanced across demographic and comorbidity variables. GI bleeding occurred in 30.6% of the TPO-RA arm versus 34.4% of the platelet transfusion arm (RR 0.89; 95% CI 0.65–1.22; p = 0.47); KM analysis showed a trend toward improved event-free survival with TPO-RA use (HR 0.79; 95% CI 0.54–1.16; p = 0.24). Blood transfusion rates were 40.0% vs. 48.8% (RR 0.82; p = 0.12), with a KM HR of 0.72 (p = 0.055) favoring TPO-RAs. HE occurred in 41.9% vs. 46.3% (RR 0.91; p = 0.43; HR 0.83; p = 0.27). All-cause mortality was 50.0% in the TPO-RA arm versus 58.1% in the platelet transfusion arm (RR 0.86; p = 0.14), with a median survival of 389 vs. 224 days and a KM HR of 0.80 (p = 0.15). **Conclusion:** In this propensity-matched cohort of cirrhotic patients with thrombocytopenia undergoing invasive hepatic procedures, TPO-RA use was associated with consistently lower point estimates across GI bleeding, blood transfusion requirement, HE, and all-cause mortality compared to platelet transfusion, including a near-significant reduction in transfusion burden (p = 0.055) and a 165-day median survival advantage. While no outcome reached statistical significance, likely reflecting the modest cohort size post-matching, the directional consistency of these findings supports the hypothesis that procedural platelet optimization with TPO-RAs may confer clinical benefit beyond simple platelet count elevation. Larger, prospective trials are warranted to validate these observations and define optimal agent selection and timing in this population.

1692 | *NOT JUST DVT: A RARE CASE OF PORTAL VEIN THROMBOSIS ASSOCIATED WITH HORMONE THERAPY*

Teresa Del Rio Montesinos[1] Teresa Montesinos Roig[2], [1]Virginia Mason Medical Center, [2]Hostos Medical Service

Background: Hormone replacement therapy (HRT) is an established treatment for menopausal symptoms, and evolving regulatory guidance from FDA has expanded therapeutic options for women. As the use of HRT increases, it is important to recognize its potential adverse effects. Well-documented complications include cardiovascular disease, venous thromboembolism (VTE), and endometrial cancer. However, portal vein thrombosis (PVT) is a rare and underreported complication. We present the case of a female patient who was initiated on HRT and subsequently developed PVT, with portosystemic changes. The condition was identified early and managed promptly; however, if left untreated, it could have resulted in significant morbidity or mortality. **Methods:** Patient presented with abdominal fullness and postprandial reflux of acute onset. Baseline laboratory studies were obtained, including CBC and CMP. The CMP revealed abnormalities, including alkaline phosphatase (ALP) 489 U/L, aspartate aminotransferase (AST) 78 U/L, and alanine aminotransferase (ALT) 125 U/L. This prompted a comprehensive hepatic evaluation, which demonstrated an elevated gamma-glutamyl transferase (GGT) of 205 U/L and 5′-nucleotidase of 22 U/L. An abdominal US with splenomegaly. This was followed by a four-phase contrast-enhanced computed tomography (CT) scan of the liver, which revealed chronic portal vein thrombosis (PVT) with porta hepatis, and small gastroesophageal varices. **Results:** A 60 yo F with no pmhx, was initiated on HRT for menopausal symptom of joint pain. Her regimen consisted of oral progesterone 200 mg daily and transdermal estrogen 0.05 mg/day. She had been on this therapy for 6 months prior to the onset of symptoms. Laboratory and imaging confirmed chronic PVT and anticoagulation therapy was initiated with DOAC and HRT was stopped. An EGD performed 3 months after initiation of treatment demonstrated resolution of previously noted varices. **Conclusion:** This case highlights a rare but clinically significant complication of HRT in a patient without prior thrombotic risk factors. While estrogen-containing therapies are known to increase the risk of VTE, thrombosis at atypical sites such as the portal venous system remains poorly characterized and likely underrecognized. Although PVT is rarely reported with menopausal HRT, available evidence suggests hormonal therapy may precipitate thrombosis in unusual vascular territories even in the absence of other risk factors. This case underscores the importance of maintaining a high index of suspicion in patients presenting with nonspecific abdominal symptoms while on HRT. Early recognition and prompt anticoagulation are essential to prevent complications and increased morbidity and mortality. As HRT use grows, clinicians should evaluate thrombotic risk and estrogen route. Further research is needed to clarify this association and guide care.

1693 | RARE BUT RISING: TWO DECADES OF U.S. HOSPITALIZATIONS FOR BUDD–CHIARI SYNDROME

Azfar Hameed[1] Diana Chavez Velasquez[2] Zakia Hameed[3] Jorge Chavez Velasquez[2], [1]Hendrick Medical Center, [2]Universidad Privada Antenor Orrego, [3]CMH Institute of Medical Sciences, Bahawalpur, Pakistan

Background: Budd-Chiari syndrome (BCS) is an uncommon but life-threatening hepatic venous outflow obstruction, frequently linked to prothrombotic disorders, myeloproliferative neoplasms, and oral contraceptive exposure. Heterogeneous presentation contributes to delayed diagnosis. Although Doppler ultrasonography is recommended first-line, published performance estimates vary. We synthesized epidemiology, diagnostic accuracy, etiologies, and treatment outcomes to clarify global burden and real-world results. **Methods:** Multi-source evidence synthesis included: meta-analysis of global incidence and prevalence (6 studies, Europe/Asia); US National Inpatient Sample trend analysis (1998–2017); meta-analysis of imaging accuracy versus venography/surgery (11 studies); nationwide South Korea cohort (2009–2013, n = 424); French national multicenter survey (48 centers); US single-center outcomes cohort (n = 23); and prospective Egyptian outcomes registry (n = 194; TIPS sub-cohort). **Results:** Pooled annual incidence was 1 per million (95% CI 0.225–3) and pooled prevalence 11 per million (95% CI 4–21). US hospitalization rates rose from 4.96 to 10.44 per million from 1998 to 2017 (annual percentage change +4.41%). In South Korea, prevalence was 5.29 per million with female:male ratio 1.8, median age 51 years, and annual case-fatality 2.8%. In France, leading etiologies were myeloproliferative neoplasms (48%), oral contraceptives (35%), and factor V Leiden (16%). In the US cohort, 82% developed ascites, 35% underwent TIPS, and 44% required liver transplantation. Doppler ultrasound pooled sensitivity was 89% (95% CI 81–94%) with specificity 68%, comparable to CT sensitivity 89% (95% CI 77–95%). Ascites typically demonstrates SAAG > 1.1 g/dL with high protein. In the Egyptian registry, post-TIPS 1-year survival was 89.7% with 1-year shunt patency 80.2%. **Conclusion:** BCS is a rare vascular liver disease with an annual incidence of approximately 1 per million globally, yet its hospitalization rate in the US has more than doubled over two decades, underscoring increasing clinical recognition. The condition predominates in women of reproductive age, with myeloproliferative neoplasms, oral contraceptive use, and inherited thrombophilias as the principal modifiable and identifiable risk factors that must be systematically excluded at diagnosis. Doppler ultrasonography is the appropriate first-line modality with sensitivity near 89%, and a high SAAG ascitic fluid profile should prompt immediate vascular imaging even in the absence of classic peritoneal signs. TIPS achieves durable one-year survival approaching 90%, with liver transplantation reserved for refractory cases. Untreated BCS progresses to end-stage liver failure within approximately three years, making early diagnosis a critical determinant of survival.

Etiology and outcomes by published cohort

Parameter	Value	Cohort / n	Source
Myeloproliferative neoplasm (France)	48%	French national survey, 48 centers	[1]
Oral contraceptive use (France)	35%	French national survey	[1]
Factor V Leiden (France)	16%	French national survey	[1]
Myeloproliferative neoplasm (US cohort)	57%	US single-center, n=23	[2]
Required TIPS (US cohort)	35%	US single-center, n=23	[2]
Required liver transplantation (US cohort)	44%	US single-center, n=23	[2]
SAAG in BCS ascites	>1.1 g/dL + protein >2.5 g/dL	Published guideline review	[3]
South Korea: female-to-male ratio	1.8 : 1; median age 51 yrs	Nationwide, n=424	[1]
South Korea: annual case-fatality rate	2.8%	Nationwide, n=424	[1]
Untreated BCS: progression to liver failure	~3 years	Published natural history data	[4]

1694 | EXTENSIVE PORTAL-MESENTERIC VENOUS THROMBOSIS FROM OCCULT JAK2-POSITIVE MYELOPROLIFERATIVE NEOPLASM PRESENTING AS SMALL BOWEL OBSTRUCTION WITH BOWEL NECROSIS

Arshiya Shabnam[1] Utsav Patel[1] Prathima Guntipalli[1] DIsha Patel[1] Rayees Konduru[1], [1]New york medical college

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Portal-mesenteric venous thrombosis (PMVT) secondary to JAK2-positive myeloproliferative neoplasms (MPNs) is a recognized but underdiagnosed entity. However, presentation as acute bowel necrosis requiring emergent surgery — with the MPN entirely occult at the time of thrombotic catastrophe — remains rarely reported. Thrombotic complications may precede hematologic diagnosis by months to years, as characteristic blood count elevations can be masked by portal hypertension, hepatic ischemia, or acute illness, making early recognition clinically challenging. **Methods:** We report a single case of extensive PMVT secondary to an occult JAK2-positive MPN presenting as acute SBO with bowel necrosis. Clinical, laboratory, operative, and follow-up data were reviewed from the inpatient and outpatient medical record. **Results:** A 70-year-old female with hypothyroidism and hypertension presented with acute altered mental status, nausea, vomiting, and abdominal distension. Initial labs revealed hyponatremia (Na 122), hyperkalemia (K 6.3), AKI(Cr 2.55), and markedly elevated ammonia (238 mcmol/L). Notably, Hb was 17.1 g/dL, Hct 51.6%, and platelets 675,000/mcL — findings consistent in retrospect with an underlying MPN. CT abdomen/pelvis showed mesenteric haziness, dilated bowel loops with fecalization, and large-volume ascites (Figure 1A–C). She was intubated and initiated on vasopressors. Given hemodynamic deterioration, emergent exploratory laparotomy revealed 1.9L of murky peritoneal fluid and a 20 cm segment of ischemic, nonviable jejunum adherent to the sigmoid colon with extensive adhesions. Small bowel resection with primary anastomosis was performed. The postoperative course was complicated by septic shock, shock liver (AST 458, ALT 433, ammonia 546 mcmol/L), and AKI without need for RRT. Outpatient workup confirmed JAK2 V617F mutation. Bone marrow biopsy established a diagnosis of polycythemia vera, more likely than prefibrotic primary myelofibrosis. Repeat CTA demonstrated chronic occlusion of the splenic and superior mesenteric veins, partial portal vein occlusion, and evolving collateral formation (Figure 1D). Fibroscan showed S3 steatosis with F2 fibrosis. She was initiated on hydroxyurea 500 mg twice daily and apixaban 5 mg twice daily. **Conclusion:** Finally, PMVT should prompt a thorough thrombophilia workup including JAK2 mutation testing, even in the absence of overt hematologic abnormalities as the progression from MVT to bowel necrosis can be rapid and life-threatening, requiring a low threshold for surgical exploration in patients with peritoneal signs. The complex interplay between the prothrombotic, pro-inflammatory, and endothelial-activating effects of the JAK2 mutation underscores the need for continued research into targeted therapies that address the vascular pathology of MPNs beyond conventional anticoagulation and cytoreduction.

2002 | HEPATOCYTE P53–LIF AXIS DRIVES INFLAMMATORY CELL RECRUITMENT AND EXACERBATES ACUTE LIVER FAILURE.

Jihyun Sung[1] Yuki Makino[1] Seiya Kato[2] Yasuharu Kawamoto[1] Yoichi Sasaki[1] Kenji Fukumoto[1] Yuta Myojin[1] Kazuhiro Murai[1] Yoshinobu Saito[3] Hayato Hikita[3] Takahiro Kodama[4], [1]Department of Gastroenterology and Hepatology, The University of Osaka Graduate School of Medicine., [2]The University of Osaka, [3]Osaka University Graduate School of Medicine, [4]Osaka University

Background: Acute liver failure (ALF) is characterized by massive hepatocyte death, with no effective treatment except liver transplantation. We previously reported that constitutive activation of p53 in hepatocytes induces cell death, resulting in liver fibrosis and carcinogenesis; however, its role in ALF remains unknown. This study aims to define the role of p53 in ALF. **Methods:** RNA-seq analysis of human ALF liver (GDS4387) was performed using the Gene Expression Omnibus (GEO). Acetaminophen (APAP) or anti-Fas antibodies were used to induce ALF in mice. Genetically engineered mouse models included hepatocyte-specific Mdm2-deficient mice (Alb-CreER Mdm2fl/fl + tamoxifen; Mdm2Δhep), Mdm2/p53 double-deficient mice (Alb-CreER Mdm2fl/fl p53fl/fl + tamoxifen; Mdm2/p53Δhep), and Lif-deficient mice (LIF+/-). Human samples included liver biopsy samples (54 ALF and 48 controls for mRNA, 8 ALF for CosMx spatial transcriptomics), and serum samples (54 ALF and 68 controls). Hepatocyte cell lines (HepG2, BNL CL.2), a hepatic stellate cell line (LX-2), and a liver sinusoidal endothelial cell line (TMNK-1) were used for in vitro experiments. **Results:** In the GEO dataset, Hallmark p53 pathway was upregulated in ALF patients. In APAP- and anti-Fas antibody–treated mice, hepatic p53 protein and CDKN1A mRNA levels were increased, indicating activation of the p53 pathway. In Mdm2Δhep mice, p53 activation caused extensive hepatocyte death, elevated ALT and bilirubin levels, increased infiltration of CD11b positive-positive macrophages, and 100% mortality within 7 days. These phenotypes were completely rescued by p53 co-deletion. Single-cell RNA-seq and cytokine assays demonstrated robust induction of inflammatory cytokines, such as Lif, Ccl2, IL6 and IL8, in hepatocytes, non-parenchymal cells, and serum. According to the RNA-seq, Lif was the most prominently upregulated cytokine in the liver of Mdm2Δhep mice. Lif expression was consistently increased in Mdm2Δhep, APAP, and anti-Fas models, as well as in human ALF at both mRNA and serum levels. In vitro, Mdm2 inhibitor (Nutlin-3) increased Lif expression, whereas p53 knockdown suppressed it in HepG2 and BNL CL.2. ChIP-PCR confirmed direct binding of p53 to the Lif promoter. Recombinant Lif induced cytokine expression and amplified Lif production in LX-2 and TMNK-1 cells, indicating activation of non-parenchymal cells. In APAP and anti-Fas models, Lif-deficient mice showed improved outcomes with reduced CD11b-positive macrophage infiltration, while antibody-mediated CD11b depletion attenuated ALF severity. Spatial transcriptomics revealed that Lif-expressing hepatocytes form inflammatory clusters, where CCL2, IL6, and IL8-expressing LSECs and HSCs, along with CD11b-positive cells, were spatially co-localized. **Conclusion:** Hepatocyte p53 activation drives ALF progression through LIF upregulation. p53–LIF axis could be a novel therapeutic target in ALF.

2003 | HIF-1α INHIBITION IN MACROPHAGES PROTECTS AGAINST ACUTE LIVER FAILURE

Zhifu Xie[1] Jingya Li[2], [1]Shanghai Institute of Materia Medica, [2]SIMM

Background: Acute liver failure (ALF) is a life-threatening condition characterized by excessive inflammatory responses that drive hepatocyte death and disease progression. Hypoxia-inducible factor-1α (HIF-1α), a stress-responsive transcription factor in macrophages, promotes the production of pro-inflammatory cytokines such as interleukin-1β (IL-1β). IL-1β, through activation of its receptor (IL-1R) on hepatocytes, induces apoptosis and necrosis, thereby exacerbating liver injury. The therapeutic potential of pharmacological HIF-1α inhibition in ALF remains unclear. **Methods:** Bone marrow–derived macrophages (BMDMs) were employed evaluate the effects of the HIF-1α inhibitor PX-478 on inflammatory cytokine production. An established lipopolysaccharide/D-galactosamine (LPS/D-GalN)-induced ALF mouse model was used to assess the hepatoprotective efficacy of PX-478, administered alone or in combination with a TNFα-neutralizing antibody under both preventive and therapeutic regimens. In parallel, a phytochemical investigation of Phyllanthus franchetianus was conducted to isolate and structurally characterize bioactive constituents. The anti-inflammatory activities of the isolated compounds were evaluated in vitro, and the hepatoprotective effect of the lead compound was subsequently validated in vivo. **Results:** PX-478 selectively suppressed the expression and secretion of IL-1β in BMDMs without affecting TNFα production, which indicates a targeted disruption of the IL-1β-driven inflammatory axis rather than a non-specific broad immunosuppressive effect. In vivo experiments demonstrated that pretreatment with PX-478 markedly attenuated liver injury in lipopolysaccharide/D-galactosamine (LPS/D-GalN)-induced ALF mice, accompanied by a substantial reduction in hepatic inflammatory responses. This finding supports an important role of macrophage HIF-1α in mitigating cytokine storm-mediated liver injury. Furthermore, both preventive and therapeutic administration of PX-478 in combination with TNFα neutralization exerted a synergistic effect, which significantly improved the survival rate and alleviated liver injury in ALF mice. In parallel, we identified PKC-2a, a novel HIF-1α inhibitor isolated from the Chinese medicinal plant Phyllanthus franchetianus. In vitro studies showed that PKC-2a treatment reduced the transcription and secretion of IL-1β, while in vivo experiments confirmed that PKC-2a conferred robust hepatoprotective activity at a low dose (3 mg/kg, oral administration, once daily). **Conclusion:** Pharmacological HIF-1α inhibition (PX-478, PKC-2a) alleviates ALF by targeting IL-1β, with PKC-2a being a promising natural lead for treating inflammation-driven liver injury. **Disclosures:** ZHIFU XIE: Nothing to Disclose, Jingya Li: Nothing to Disclose.

2004 | RECOMBINANT ADAMTS13 AMELIORATES LIVER INJURY AND IMPROVES HEPATIC MICROCIRCULATION IN A MURINE ACUTE-ON-CHRONIC LIVER FAILURE MODEL

Norihisa Nishimura[1] Kosuke Kaji[1] Shinya Sato[1] Akihiko Shibamoto[1] Yui Osaki[1] Hitoshi Mori[1] Tadashi Namisaki[1] Hitoshi Yoshiji[1], [1]Nara Medical University

Background: Acute-on-chronic liver failure (ACLF) is a distinct clinical condition characterized by sudden liver failure in patients with pre-existing chronic liver disease, leading to high short-term mortality. However, effective medical therapies for ACLF remain limited. We have previously reported that an imbalance in the a disintegrin-like and metalloprotease with thrombospondin type 1 motif 13 (ADAMTS13) / von Willebrand factor (vWF) axis contributes to disease progression in liver cirrhosis and exacerbates acute kidney injury associated with ACLF. We also found that recombinant ADAMTS13 (rAD) improves renal injury in an ACLF-like mouse model. In this study, we investigated whether rAD exerts direct therapeutic effects on ACLF-like liver injury. **Methods:** Male C57BL/6J mice were subjected to chronic carbon tetrachloride (CCl_4) administration followed by acute CCl_4 and lipopolysaccharide challenge to induce ACLF-like liver injury. Mice were assigned to control, ACLF, and ACLF + rADAMTS13 groups. Plasma ADAMTS13 activity, VWF antigen, platelet counts, hepatic and renal microcirculatory blood flow, histological changes, and hepatic gene expression were evaluated. Endothelial tube formation assays were performed using human umbilical vein endothelial cells under oxidative stress conditions. **Results:** Compared with untreated ACLF mice, rAD-treated mice showed significant improvements in liver weight, serum AST and ALT levels, platelet counts, serum albumin levels, and hepatic tissue blood flow. Immunohistochemical analysis revealed marked vWF upregulation and excessive platelet aggregation in ACLF mice, which were significantly suppressed by rAD administration. Inflammatory cytokine expression, including TNF-α, IL-1β, and IL-6, as well as infiltration of F4/80-positive inflammatory cells, were markedly reduced in the rAD group. Hepatocellular necrosis and apoptosis were attenuated by rAD treatment. In contrast, CD34-positive endothelial cells and A6-positive hepatic progenitor cells, indicative of angiogenesis and liver regeneration, were

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

significantly increased in rAD-treated mice. *In vitro*, rADAMTS13 partially restored impaired tube formation and increased *VEGFA* and *VEGFR2* expression in HUVECs exposed to oxidative stress. **Conclusion:** Recombinant ADAMTS13 ameliorates liver injury in ACLF by suppressing excessive platelet aggregation, improving hepatic microcirculation, and attenuating inflammation, while promoting angiogenesis and liver regeneration. Given its current clinical availability, rAD may represent a promising therapeutic option for hepatoprotection in ACLF.

2006 | ENDOPLASMIC RETICULUM STRESS ORCHESTRATES THE DDX3X-TFEB AXIS IN DRUG-INDUCED LIVER INJURY

Ling Xu[1] Yao Gao[1] Zihao Fan[1] Feng Ren[1], [1]Beijing Institute of Hepatology/Beijing Youan Hospital, Capital Medical University, Beijing, China

Background: Drug-induced liver injury (DILI) remains a major clinical challenge lacking effective therapeutic options. While endoplasmic reticulum stress (ERS) is implicated in DILI pathogenesis, the underlying regulatory mechanisms remain elusive. This study investigated the role of transcription factor EB (TFEB) in ERS regulation during DILI and characterized its upstream regulatory pathways. **Methods:** Using a murine model of acetaminophen (APAP)-induced liver injury (AILI), we characterized ERS markers, assessed biochemical and histopathological injury severity, and monitored TFEB expression dynamics. To modulate ERS activity, we employed pharmacological intervention (4-PBA) genetic approaches, and using hepatocyte-specific TFEB knockout (TfebΔhep) mice, as well as TFEB knockdown and overexpression strategies to regulate the expression of TFEB. Bioinformatics analysis (GTEx), RNA immunoprecipitation (RIP), and clinical DILI specimens were utilized to elucidate the molecular machinery and translational relevance. **Results:** Pharmacological inhibition of ERS with 4-PBA attenuated liver injury and enhanced TFEB expression and nuclear localization. Genetically, TfebΔhep mice exacerbated APAP-induced injury, whereas TFEB overexpression or genetic rescue of TfebΔhep mice was highly protective. We identified dynamic expression of the expression of DDX3X during AILI; DDX3X knockdown aggravated injury, while its overexpression protected against it. Mechanistically, DDX3X directly bound to TFEB mRNA to enhance its translation and nuclear translocation via Ca^{2+}/calmodulin-dependent protein kinase (CaMK) and GSK3β signaling. Crucially, TFEB knockdown completely abolished the hepatoprotection conferred by DDX3X overexpression. In clinical DILI specimens, hepatic TFEB expression inversely correlated with injury severity; mild-to-moderate cases exhibited elevated nuclear TFEB, whereas severe DILI featured TFEB downregulation and cytoplasmic sequestration. **Conclusion:** ERS drives DILI progression by suppressing TFEB expression and nuclear translocation. The DDX3X-TFEB axis represents a novel regulatory pathway wherein DDX3X exerts robust hepatoprotection by promoting TFEB translation and nuclear localization. These findings position the DDX3X-TFEB axis as a promising therapeutic target and suggest TFEB subcellular dynamics as a potential diagnostic biomarker for DILI.

2007 | HEMODYNAMIC INSTABILITY AND SEVERE LIVER DISEASE SYNERGISTICALLY PREDICT ICU MORTALITY IN GI BLEEDING: A TIME-SERIES ANALYSIS

Innocent Lutaya[1] Brian Xu[1] Vicki Oladoyin[1] Theophilus Boakye[1] Shanelle Brodeur[1] Emmanuel marfo[1] Nicolas Bakinde[1] Abisola Ajayi[1] Shaikhoon Mohammed[1] Chima Amadi[1], [1]Morehouse School of Medicine

Background: Gastrointestinal (GI) bleeding in patients with severe liver disease (SLD) carries substantially higher mortality than GI bleeding in patients without liver disease, driven by portal hypertension, coagulopathy, and impaired hemodynamic reserve. Bedside monitors generate continuous hemodynamic data, but this information is rarely used to predict outcomes. We leveraged time-series hemodynamic data from the Trajectory of Floor-to-ICU Monitoring (TFM) dataset to determine whether MAP instability, combined with severe liver disease markers, improves

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

mortality prediction in ICU patients with GI bleeding. **Methods:** We analyzed the TFM ICU Trajectories dataset, which is a high-frequency multi-parameter ICU monitoring database containing vital signs sampled at 1 to 5 minute intervals for up to 24 hours post-ICU admission. Adult ICU patients with GI bleeding were stratified by SLD status (ICD-coded cirrhosis, portal hypertension, or hepatic failure). Hemodynamic trajectories including heart rate variability (HRV), mean arterial pressure (MAP) variability, vasopressor use, and transfusion requirements were compared. The primary outcome was in-hospital mortality. Multivariable logistic regression with Area Under the Receiver Operating Characteristic curve (AUROC) analysis was used to evaluate predictive performance. **Results:** Among 2,602 ICU patients with GI bleeding, 522 (20.1%) had severe liver disease. SLD patients had significantly higher in-hospital mortality (12.5% vs. 6.4%, $p < 0.001$), greater vasopressor use (10.2% vs. 5.2%, $p < 0.001$), lower MAP variability (SD 0.55 vs. 0.59, $p < 0.001$), and more blood product transfusions ($p = 0.024$). In multivariable logistic regression adjusting for hemodynamic parameters, SLD independently predicted mortality (aOR 1.89, 95% CI 1.30-2.74; $p = 0.001$). The combined hemodynamic + SLD model achieved an AUROC of 0.725, significantly outperforming SLD status alone (AUROC 0.691). **Conclusion:** Severe liver disease independently doubles mortality risk in ICU-admitted GI bleeding patients, with distinct hemodynamic signatures characterized by reduced MAP variability and higher vasopressor requirements. High-frequency hemodynamic data substantially improves mortality prediction, suggesting that real-time monitoring could help identify the highest-risk patients earlier.

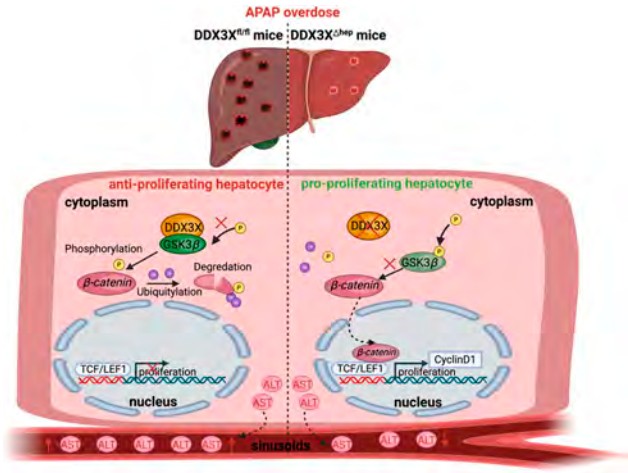
2008 | LARSUCOSTEROL DECREASES MORTALITY IN LPS ENDOTOXEMIA BY REVERSING PROMOTER HYPERMETHYLATION

Yaping Wang[1] Kevin Ren[2] Shunlin Ren[3], [1]Virginia Commonwealth University; Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, [2]Mclean High School, Mclean, VA 22101, [3]Virginia Commonwealth University

Background: Lipopolysaccharide (LPS) drives systemic inflammation and organ injury in experimental endotoxemia. We newly show that LPS acutely induces global promoter CpG hypermethylation, a response largely mediated by DNA methyltransferase-1 (DNMT1). Larsucosterol (25HC3S, DUR928) is an endogenous DNMT1 inhibitor. The current study aim to confirm that larsucosterol reduces mortality in LPS-induced endotoxemia by reversing promoter hypermethylation and restoring pro-survival transcriptional programs. **Methods:** THP-1 cells were differentiated to macrophages with PMA, pretreated with larsucosterol (20 μM, 0.5 h) or vehicle, then exposed to LPS (2 μg/mL, 6 h). Global methylation (LINE-1), promoter CpG methylation of apoptosis/mitochondrial-stress pathways (MAPK; calcium/AMPK), DNMT1 activity, reactive oxygen species (ROS), and expression of PGC-1α and COX-2 were measured. RNA-seq profiled LPS ± larsucosterol effects. In vivo, C57BL/6J mice received LPS to induce endotoxemia and were treated with vehicle or Larsucosterol; survival was monitored to 72 h and liver injury biomarkers (AST, ALT, alkaline phosphatase) were assessed. An independent fecal-suspension polymicrobial sepsis model (16S-validated composition) provided orthogonal validation. **Results:** LPS significantly increased global DNA methylation in macrophages (LINE-1). RNA-seq showed broad reprogramming with 2,722 genes upregulated and 2,731 downregulated, enriched across more than 50 KEGG pathways. Larsucosterol attenuated LPS-induced transcriptional activation, suppressing cytokine–cytokine receptor interaction, MAPK, NOD-like receptor, TNF, and Toll-like receptor signaling pathways. Mechanistically, larsucosterol shifted promoter methylation toward demethylation at anti-apoptotic and mitochondrial-stability genes, reduced DNMT1 activity, lowered oxidants including malondialdehyde (MDA), increased PGC-1α, and decreased COX-2 under LPS/TNFα challenge. In LPS endotoxemia, larsucosterol improved survival versus vehicle and reduced biochemical and histologic liver injury. In

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



the polymicrobial model, controls reached 100% mortality by 14 h, whereas larsucosterol delayed the first death to 26 h, produced at least one complete survivor, and lowered AST/ALT with minimal change in alkaline phosphatase. **Conclusion:** LPS induces endotoxemia by increasing DNA promoter CpG methylation and suppressing anti-apoptotic gene expression. Larsucosterol decreases the LPS-induced promoter CpG methylation and increases the gene expression involved in pro-survival, mitochondrial integrity, reducing oxidative stress, and improves survival in vitro and in vivo sepsis models. These findings indicate that larsucosterol has the potential to serve as an endogenous epigenetic regulator for treating endotoxemia and sepsis.

2009 | DDX3X-GSK3β INTERACTION REGULATES LIVER REGENERATION AND RECOVERY FROM ACETAMINOPHEN-INDUCED LIVER INJURY IN MICE

Zihao Fan[1] Yinkang Mo[1] Jihui Jia[1] Ling Xu[1] Feng Ren[1], [1]Beijing Institute of Hepatology/Beijing Youan Hospital, Capital Medical University, Beijing, China

Background: Drug-induced liver injury is a global health concern, with acetaminophen (APAP)-induced liver injury (AILI) accounting for the majority of cases. Liver regeneration is a critical process in AILI, but the underlying mechanism remains unknown. Here, we investigate the role of DEAD-box helicase 3 X-linked (DDX3X) in liver regeneration after AILI in mice. **Methods:** Liver injury was induced in C57BL/6J mice via APAP (300 mg/kg or 500 mg/kg) overdose. Hepatocyte-specific DDX3X knockout ($DDX3X^{\Delta Hep}$), DDX3X overexpression ($DDX3X^{OE}$) and control ($DDX3X^{fl/fl}$) mice were utilized. Primary hepatocytes and AML-12 cell lines were treated with APAP (20 mM). The expression of DDX3X and its impact on APAP metabolism were measured in mice. Liver injury and regeneration were evaluated after APAP administration. **Results:** Our results revealed hepatic DDX3X expression were upregulated during the early stages of AILI in mice. At 24 hours post-APAP overdose in mice, DDX3X deficiency markedly promoted liver regeneration, as evidenced by increased expression of proliferative markers, including PCNA and Ki67. DDX3X deficiency did not alter the expression of CYP2E1 or hepatic glutathione. Both in vivo and in vitro experiments demonstrated that DDX3X deficiency promoted the phosphorylation of glycogen synthase kinase-3β (GSK-3β) at Ser9 and enhanced β-catenin signaling. In contrast, DDX3X overexpression impaired liver regeneration and suppressed β-catenin signaling in AILI mice. Furthermore, pharmacological inhibition of GSK3β using SB216763 in DDX3XOE mice partially rescued β-catenin signaling and liver regeneration compared with DDX3XOE mice alone. Mechanistically, cytoplasmic colocalization of GSK3β and DDX3X was observed in AML-12 cells and gradually diminished following APAP exposure. This interaction inhibits the phosphorylation of GSK3β at Ser9. **Conclusion:** DDX3X deficiency promotes liver regeneration in AILI by relieving GSK3β inhibition and activating β-catenin signaling. This DDX3X-GSK3β-β-catenin axis thus represents a critical molecular mechanism and a promising therapeutic target for liver regeneration and recovery.

2010 | INFLUENCE OF XENOGENEIC MISMATCH ON HEPATOCYTE CELL THERAPY EFFICACY

Sophie Cazanave[1] Sunil Mallanna[1] Morgan Jamiel[1] Krista Farrington[1] Marcus Lehmann[1] Abhijith Kudva[1] Krina Shah[1] David Broderick[1] Konstantinos Chatziantoniou[1] Julie Morse[1] Tom Lowery[1] Arnav Chhabra[1], [1]Satellite Bio

Background: Hepatocyte transplantation is a promising therapy for liver-based metabolic disorders. Expanded human hepatocytes (EHH), derived from primary human hepatocytes (PHH) retain key hepatic functions and show in vivo activity comparable to PHH in FRG (Fah−/−, Rag2−/−, IL-2RG−/−) mice.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

However, defining the minimum effective engraftment level for human liver cell therapy remains a major barrier to clinical translation, as dose prediction based on preclinical models is confounded by species mismatch effects. Addressing these limitations is essential for accurately translating hepatocyte-based therapies to patients. **Methods:** EHH, PHH and primary mouse hepatocyte (PMH) cells or vehicle media were injected into female FRG mice via intrasplenic injection. We performed a dose-response study with cells in which we varied the duration of NTBC cycling to achieve a range of liver repopulation levels, and therefore different effective engrafted levels (ELs) at the start of NTBC withdrawal from EL1 up to EL3. Engraftment was confirmed by human albumin or immunohistochemistry (IHC). Liver function upon NTBC withdrawal was evaluated by blood biomarkers (ALT, BUN, Bilirubin, Albumin and Prothrombin time (PT)) and animal survival. The minimum EL was extrapolated based on FAH IHC, normalized to cells per kilogram and contextualized against biological activity readouts. **Results:** Increasing levels of engraftment of PHH or EHH were confirmed by plasma human albumin levels at ~0.024 mg/mL at EL1, ~0.286 mg/mL at EL2 and ~5.8 mg/mL at EL3. Upon NTBC withdrawal, we observed a clear relationship between EL and efficacy when compared to non-repopulated vehicle controls (survival $p < 0.0001$, albumin $p < 0.0001$, BUN $p = 0.0083$, PT $p = 0.0004$, bilirubin $p = 0.091$, ALT $p = 0.32$). When estimating the minimum engraftment level required for efficacy, we found that high doses of human cells (> 360 million cells/kg) were required to achieve measurable rescue in FRG mice. Dose-response engraftment of PMH was assessed by FAH-positive staining which represented ~0.37% at EL1, 1.17% at EL2 and 9.31% at EL3 of the total liver area. In contrast to human cells, PMH demonstrated significant improvement in survival and blood biomarkers (survival $p < 0.0001$, albumin $p < 0.0001$, BUN $p = 0.0062$, PT $p < 0.0001$, bilirubin $p < 0.0001$, ALT $p < 0.0001$), upon relatively short NTBC cycling times (20-30 days compared to 75-150 days for EHH and PHH). A minimum engraftment level of 28 million cells/kg of PMH, almost 10-fold lower than PHH or EHH, was required to achieve a comparable benefit in the FRG model, consistent with doses shown to be efficacious in prior clinical case studies. **Conclusion:** This study illustrated the impact of species mismatch on efficacy in nonclinical studies. It also highlighted that cross-species transplantation (human-to-mouse) requires higher repopulation thresholds, underscoring the importance of species-matched data for translation of clinical dose levels.

2011 | ACUTE LIVER FAILURE IN INDIA, 1986–2025: ETIOLOGICAL TRENDS, CLINICAL PROFILE, AND OUTCOMES — A SYSTEMATIC ANALYSIS OF 6,382 PATIENTS FROM 85 STUDIES

Aashik Y S[1] Yashwanth M[1] Ekta Pareek[2] Harshad Devarbhavi[3], [1]St. John's Medical College Hospital, Bangalore, [2]St. John's Medical college Hospitak, Bangalore, [3]St. John's Medical College Hospital, Bangalore, India

Background: Acute liver failure (ALF) in India is predominantly driven by infectious etiologies, in sharp contrast to Western registries where acetaminophen and indeterminate etiologies predominate. The etiological and epidemiological spectrum of ALF in India has evolved considerably over time This study characterizes the etiology, biochemical profile, and outcomes of ALF in India over nearly four decades, with particular emphasis on drug-induced liver injury (DILI). **Methods:** A comprehensive literature search was conducted across major electronic databases. We identified 85 published studies and case reports from India (1986–2025) encompassing 6,382 patients with ALF. Demographics, biochemical parameters (bilirubin, INR, creatinine, and MELD score), etiology, DILI causative agents, hospital stay, mortality, and liver transplantation rates were systematically extracted and analyzed. **Results:** A total of 6,382 patients were identified. Mean age was 26 years, MELD score 32, total bilirubin 11.8 mg/dL, INR 3.8, serum creatinine 1.5 mg/dL, and hospital stay 7.6 days. Overall mortality was 37% (2,357/6,382), and liver transplantation was performed in only 323 patients (5.1%).A striking temporal rise in Hepatitis A-related ALF was observed: of 499 cases reported over 39 years, 279 (56%) occurred in 2023–2025 alone, compared to 220 (44%) in the preceding 37 years (1986–2023), suggesting a rapidly shifting epidemiology.Among 484 DILI cases, 173 resulted in death (35.7%). Anti-tubercular therapy (ATT) was the leading cause (n = 352; 72.7%), accounting for 157 deaths (90.8% of DILI-related mortality). Other causative agents included complementary and alternative medicines (CAM; n = 42; 8.7%), acetaminophen (n = 28; 5.8%), antiepileptics (n = 21; 4.3%), dapsone

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(n = 10; 2.1%), antiretroviral agents (n = 7; 1.4%), and others (n = 24; 5.0%). Case fatality rates by agent were: ATT 45%, antiepileptics 29%, dapsone 20%, acetaminophen 7%, and CAM 5%. Notably, ferrous sulfate (2/2) and pirfenidone (1/1) carried a 100% case fatality rate, though based on limited cases. **Conclusion:** ALF in India is predominantly caused by viral hepatitis, with HEV remaining the leading etiology. A striking recent surge in HAV-related ALF was observed, with 56% of cases occurring in 2023–2025 alone. Undetermined and non A-E hepatitis together account for >35% of cases, representing a critical diagnostic gap. ATT-related DILI dominates drug-induced ALF (72.7%; mortality 45%). Dengue (4%) and Wilson disease (2.4%) are under-recognized causes with significant mortality. Liver transplantation was performed in only 5% which highlights the critical unmet need for expanded transplant access.

Etiology	Total Cases (n)	Total Deaths (n)	Mean MELD score	Mean Age (years)	Mean Bilirubin (mg/dl)	Mean creatinine (mg/dl)
Hepatitis E	1889 (29.6%)	665 (35.2%)	32.8	27.2	17	1.2
Undetermined	1544 (24.2%)	782 (50.6%)	34.4	28.2	15.8	0.8
Non A-E Hepatitis	721 (11.3%)	363 (50.3%)		27.9	23	2.0

2012 | CUPROPTOSIS PROMOTES ACUTE LIVER FAILURE THROUGH CGAS-STING-ASSOCIATED PYROPTOSIS

Xiaoxuan Liu[1] Qi Yang[1] Li Bai[1] Yu Chen[1] Ming Kong[1] Manman Xu[1] Huixin Tang[2], [1]Beijing YouAn Hospital, Capital Medical University, [2]Department of Gastroenterology, Jining No.1 People's Hospital, Jining

Background: Acute liver failure (ALF) is characterized by massive hepatocyte death and severe inflammatory injury with high short-term mortality. Cuproptosis is a newly identified copper-dependent form of regulated cell death. Previous studies in tumor have shown that cuproptosis may promote mtDNA release and activate the cGAS-STING signaling. In addition, STING activation has been reported to promote pyroptosis. However, whether cuproptosis participates in ALF through cGAS-STING-associated pyroptosis remains unclear. **Methods:** Cuproptosis was induced in hepatocytes using $CuSO_4$ plus elesclomol (Cu-ES) with or without TTM treatment, a specific cuproptosis inhibitor. Cuproptosis levels were assessed by cell viability, WB and qPCR detection for key signaling molecules. In vivo, the extent of hepatic damage and cuproptosis levels were evaluated in D-GalN/LPS-induced ALF mice with or without TTM treatment. mtDNA release was detected in the supernatant of Cu-ES-treated hepatocytes with or without TTM treatment. The levels of cGAS-STING signaling and pyroptosis upon cuproptosis activation were assessed. In addition, pyroptosis levels upon STING activation and inhibition were evaluated. Moreover, the levels of cuproptosis and pyroptosis upon cuproptosis activation plus STING inhibition were detected. Finally, the levels of cuproptosis-STING-pyroptosis axis were analyzed in ALF livers. **Results:** Cell viability in Cu-ES-induced hepatocytes was significantly elevated upon TTM treatment. Cuproptosis-related molecules were downregulated in Cu-ES group, which could be reversed by TTM treatment. TTM pretreatment alleviated liver injury and cuproptosis levels in ALF mice. mtDNA levels were significantly increased in Cu-ES-conditioned medium. In macrophages, Cu-ES-conditioned medium increased the expression of cGAS-STING and pyroptosis-related molecules, which was attenuated by TTM pretreatment. Consistently, cGAS-STING signaling and pyroptosis-related molecules were significantly upregulated in ALF mice and partially reversed by TTM treatment. Moreover, DMXAA promoted, whereas STING-IN-2 suppressed, cGAS-STING signaling and pyroptosis in vitro and in vivo. STING-IN-2 reduced pyroptosis- without affecting cuproptosis-related genes, indicating cGAS-STING acts downstream of cuproptosis. IHC staining showed decreased FDX1 and DLAT, together with increased STING and caspase-1 expression in liver tissues from ALF patients. **Conclusion:** Cuproptosis critically involves in the development of ALF. Cuproptosis triggers cGAS-STING signaling and pyroptosis via mtDNA release. cGAS-STING signaling likely acts downstream of cuproptosis and upstream of pyroptosis. Collectively, cuproptosis promotes ALF by activating STING signaling and pyroptosis. Our work provides novel insights into the molecular mechanisms and potential therapeutic targets of ALF.

2013 | MORTALITY BENEFIT OF THERAPEUTIC PLASMA EXCHANGE IN ACUTE AND ACUTE-ON-CHRONIC LIVER FAILURE: A SYSTEMATIC REVIEW AND UPDATED META-ANALYSIS

Rohan Karkra[1] Mahinaz Mohsen[1] Joshua Pagan Busigo[1] Michael Bebawy[1] Steven Rella[1] Muhammad Maan[1] Zaid Tafesh[1] Paul Gaglio[1], [1]Rutgers New Jersey Medical School

Background: Acute Liver Failure (ALF) and Acute-on-Chronic Liver Failure (ACLF) are life-threatening syndromes characterized by rapid hepatic deterioration and multiorgan failure. Mortality estimates for ALF without liver transplant are as high as 50% in ALF and 70% in ACLF. Since both syndromes are characterized by a dysregulated systemic cytokine inflammatory response, therapeutic plasma exchange (TPE) has been proposed as a potential therapy. TPE addresses several pathophysiological mechanisms simultaneously by removing circulating endotoxins, pro-inflammatory cytokines, damage-associated molecular patterns, and ammonia, while replenishing coagulation factors and hepatoprotective proteins. We performed a comprehensive systematic review and updated meta-analysis of TPE in ALF and ACLF. **Methods:** We searched PubMed, Embase, and Cochrane from inception through April 15, 2026. Studies comparing TPE (any volume) against standard medical therapy (SMT) in adults with ALF or ACLF were included. Primary outcomes were 30-day and 90-day all-cause mortality. Pooled odds ratios (ORs) with 95% confidence intervals (CIs) were calculated using the DerSimonian-Laird random-effects model. Heterogeneity was assessed using Cochran's Q and I^2 statistic. This study conformed to PRISMA guidelines. **Results:** A total of 33 studies were included: 27 in ACLF and 6 in ALF, comprising 5,795 patients (TPE: 2,925; SMT: 2,870). ACLF studies contributed 5,609 patients (TPE: 2,830; SMT: 2,779), while ALF studies contributed 186 patients (TPE: 95; SMT: 91). Among 22 ACLF studies reporting sex data, 83.6% of participants were male (N = 3,755); in ALF studies, 31.2% were male (N = 112).In ACLF, 20 studies (N = 4,256) reported 30-day mortality. Crude mortality was 37.9% (812/2,141) with TPE versus 56.4% (1,192/2,115) with SMT, an absolute risk reduction of 18.5%. Meta-analysis showed significantly lower 30-day mortality with TPE (OR 0.43, 95% CI 0.34–0.54; $p < 0.0001$; $I^2 = 56.2\%$).Nineteen ACLF studies (N = 3,274) reported 90-day mortality. Crude mortality was 49.4% (790/1,598) with TPE versus 62.5% (1,047/1,676) with SMT. TPE was associated with lower 90-day mortality (OR 0.56, 95% CI 0.44–0.72; $p < 0.0001$; $I^2 = 51.5\%$).In ALF, 5 studies (N = 186) reported 30-day mortality. Mortality was 29.5% (28/95) with TPE versus 51.6% (47/91) with SMT. Pooled analysis demonstrated significantly lower mortality with TPE (OR 0.33, 95% CI 0.16–0.66; $p = 0.0017$), with no heterogeneity ($I^2 = 0\%$). **Conclusion:** TPE significantly reduces 30-day mortality in both ALF and ACLF. Evidence of a 90-day survival benefit is present in ACLF. TPE also maintains a transplant-free mortality benefit in ACLF. TPE may be considered as a bridge therapy in patients without immediate transplant access.

2014 | CLINICAL CHARACTERISTICS OF HEPATITIS E AND RISK FACTORS FOR PROGRESSION TO LIVER FAILURE IN NORTHWEST CHINA

Xiaoqin Hu[1] Yuzhen Zhao[1] Chongyu Zhang[1] Na Huang[1] Yunyu Zhao[1] Yishan Liu[1] Lanting Zhang[1] Fu Wei[2] Fanpu Ji[1] Dou Qu[1], [1]The Second Affiliated Hospital of Xi'an Jiaotong University, [2]Xi'an People's Hospital (Xi'an Fourth Hospital)

Background: Hepatitis E is one of the leading causes of acute viral hepatitis worldwide. However, systematic surveillance, diagnostic tools, and the widespread use of vaccines for this disease remain relatively limited globally.This study aimed to analyze the clinical characteristics of hospitalized patients with hepatitis E in Northwest China and to identify factors associated with progression to liver failure. **Methods:** A retrospective analysis was conducted on 188 patients with hepatitis E admitted to the Second Affiliated Hospital of Xi'an Jiaotong University between January 2009 and September 2025. Liver failure (LF) was defined according to the Chinese liver failure criteria (INR $\geq$ 1.5 or PTA $\leq$ 40%, and TBil $\geq$ 171 μmol/L). Patients were divided into LF and non-LF groups. Baseline demographics, underlying diseases, clinical signs and symptoms, and laboratory parameters at admission were compared between groups. Continuous variables were analyzed using the Mann–Whitney U test, and categorical variables using the chi-square test. Logistic regression was employed to identify independent risk factors for LF progression and for mortality or liver transplantation. **Results:** Among the 188 patients with hepatitis E virus infection, 145 (77.1%) were male, with a mean age of 54.6 ± 14.4 years. The most common clinical manifestations were gastrointestinal symptoms (fatigue, anorexia, nausea) and jaundice (88.3%). Ascites (27.1%) and cholestasis (21.8%) were the most frequent complications. Baseline cirrhosis was present in 17.0% of patients, and 17.0% had HBV co-infection. Liver failure developed in 61 patients (32.5%). Among these, 15 (24.6%) died or underwent liver transplantation (14 deaths, 1 transplant). Compared with non-LF patients, those with LF were older (P = 0.016) and had higher proportions of males (P < 0.001), alcohol consumption (P = 0.021), and cirrhosis (P = 0.002). Multivariable logistic regression identified male sex (OR = 17.29, 95% CI: 2.72–109.97), cirrhosis (OR = 3.62, 95% CI: 1.11–11.76), higher neutrophil count (NEUT, OR = 1.42, 95% CI: 1.17–1.73), and prolonged thrombin time (TT, OR = 1.28, 95% CI: 1.08–1.51) as independent risk factors for LF (table 1). Higher total cholesterol (TC) was protective (OR = 0.35, 95% CI: 0.21–0.58). A predictive model combining these factors achieved an AUC of 0.90 (95% CI: 0.85–0.95). In the LF subgroup, multivariable analysis confirmed INR (OR = 9.09, 95% CI: 1.39–59.37), total bilirubin (TB, OR = 1.01, 95% CI: 1.01–1.02), and cystatin C (CysC, OR = 6.20, 95% CI: 1.29–29.68) as independent predictors of death. **Conclusion:** Male sex, cirrhosis, higher neutrophil count, and prolonged thrombin time predict progression to liver failure in hospitalized patients with hepatitis E. INR, total bilirubin, and cystatin C identify those at high risk of death.

Table1. Univariate and Multivariate Logistic Regression Analysis of Risk Factors for Liver failure in Patients with Hepatitis E

Variables	Univariate		Multivariate	
	OR (95%CI)	P	OR (95%CI)	P
Age	**1.04 (1.01 – 1.06)**	**0.005**		
Male	**8.89 (2.63 – 30.09)**	**<.001**	**17.29 (2.72 – 109.97)**	**0.003**
Cardiovascular disease	1.53 (0.77 – 3.02)	0.223		
Diabetes	1.56 (0.74 – 3.27)	0.243		
Cirrhosis	**3.38 (1.55 – 7.38)**	**0.002**	**3.62 (1.11 – 11.76)**	**0.033**
Hepatitis B	0.94 (0.41 – 2.12)	0.874		
Neutrophil count	**1.25 (1.09 – 1.43)**	**0.001**	**1.42 (1.17 – 1.73)**	**<.001**
Thrombin time	**1.31 (1.16 – 1.49)**	**<.001**	**1.28 (1.08 – 1.51)**	**0.004**
Albumin	**0.86 (0.81 – 0.92)**	**<.001**		
Total cholesterol	**0.30 (0.19 – 0.46)**	**<.001**	**0.35 (0.21 – 0.58)**	**<.001**

Background: Acute-on-chronic liver failure (ACLF) is associated with high mortality and is frequently precipitated by alcohol-associated hepatitis (AH) or infections. The role of precipitating events in the clinical course of ACLF, as well as the applicability of established prognostic scores, remains incompletely understood but has major implications for therapeutic targets and the design of future clinical trials. The aim of this study was to evaluate biomarkers as predictors of mortality in AH-ACLF with or without concomitant infection. **Methods:** A total of 785 patients with AH from the CANONIC, PREDICT, and ACLARA studies were included. ACLF was defined according to EASL-CLIF and A-TANGO criteria. Baseline characteristics, organ failures, and cumulative incidence were compared. The predictive performance of prognostic scores and cytokine-augmented models was assessed using AUC, Brier score, and cross-validation, with comparisons performed using the DeLong test. AH and infection status were defined by the treating physician; biomarker analyses are therefore exploratory. **Results:** In addition to EASL-CLIF definition, we also applied the A-TANGO definition to assess AH-ACLF, identifying 239 and 316 patients, respectively. AH-ACLF was associated with a high incidence of liver (61.1%) and coagulation (42.7%) failure. Concomitant infections were present in 46% of patients and, compared with AH-ACLF without infection, were associated with higher creatinine (1.2 vs 1.7 mg/dL; $p = 0.01$) and CRP levels (31 vs 47 mg/L; $p < 0.001$). These patients also had higher rates of circulatory (9 vs 25%; $p = 0.001$) and cerebral failure (16 vs 27%; $p = 0.026$). Overall 28-day mortality was 42.2%, it was significantly higher in patients with concomitant infection than in those without infection (53.6% vs. 33.4%; $p = 0.002$) in EASL-CLIF-defined ACLF. Competing-risk multivariate regression analyses identified TNF-α as an independent predictor of mortality. Addition of TNF-α to established prognostic scores (e.g., CLIF-C OF and ACLF) significantly increased the AUC across all models; for example, the AUC of the CLIF-C ACLF + TNF-α + albumin model increased from 0.699 to 0.778 ($p = 0.007$). In patients without infection, TNF-α resulted in a substantially greater improvement across all models, for example from 0.747 to 0.899 for CLIF-C ACLF + TNF-α + albumin ($p = 0.003$). Additionally, these findings were confirmed in patients with ACLF according to the A-TANGO definition. **Conclusion:** Incorporation of TNF-α improves prognostic discrimination in AH-ACLF, particularly in patients without infection. TNF-α should be validated in independent cohorts as a biomarker for risk stratification in AH-ACLF. These findings require external validation before clinical use and support phenotype-specific approaches in future trial design.

2016 | ◆ RISK STRATIFICATION AND MORTALITY OF ACUTE-ON-CHRONIC LIVER FAILURE ACROSS DIFFERENT DIAGNOSTIC CRITERIA: A MULTICENTER COHORT STUDY

Wenling Wang[1] Manman Xu[1] Yu Chen[1], [1]Beijing youan hospital, capital medical university

Background: Acute-on-chronic liver failure (ACLF) is a heterogeneous syndrome with high short-term mortality. Despite multiple proposed definitions, universally accepted and standardized diagnostic criteria are lacking. The Chinese Medical Association (CMA) has released the new China Guidelines for the Diagnosis and Treatment of ACLF (2025), and this study aims to evaluate the compatibility and comprehensiveness of these guidelines. **Methods:** In this prospective, multicenter study, clinical data were collected between September 2023 and May 2025 across multiple centers in China within the CGSLD consortium. Eligible patients were those with acute decompensation of cirrhosis or severe liver injury who met predefined thresholds (total bilirubin [TB] $\geq$ 5 mg/dL and international normalized ratio [INR] $\geq$ 1.5). Organ failure is defined according to the consensus criteria from *Defining Organ Failures in Patients with Cirrhosis: Consensus Statements*. Baseline characteristics, clinical course, and outcomes were analyzed to compare existing diagnostic frameworks (APASL-, COSSH-, EASL-ACLF). **Results:** Among 1,038 patients, all met APASL-ACLF criteria (28-/90-day mortality: 22.9%/35.5%), while 83.1% and 35.5% met COSSH- and EASL-ACLF criteria, with higher mortality rates of 26.8%/41.4% and 36.3%/53.7%, respectively, indicating heterogeneity in patient identification.To harmonize definitions, patients were reclassified according to the CMA-aligned CGSLD-ACLF criteria.CGSLD-ACLF I was defined as acute severe liver injury on chronic liver disease with TB $\geq$ 12 mg/dL and INR $\geq$ 1.5, accounting for 67.7of patients, with 28-/90-day mortality of 20.7%/35.2%. Stratification by INR (1.5–<2.0, 2.0–<2.5, $\geq$2.5) demonstrated a clear stepwise increase in mortality (8.1%/19.7%, 22.1%/33.7%, and 40.0%/58.2%).CGSLD-ACLF II was defined as TB $\geq$7.5mg/dL with INR $\geq$1.5, complicated by renal dysfunction or extrahepatic organ failure within 1 week, accounting for 16.8% of patients. This group showed significantly higher mortality (49.3%/63.6%), with further stratification (renal dysfunction, single, and multiple organ failure) yielding mortality rates of 25.7%/37.1%, 58.0%/66.7%, and 70.8%/91.7%, respectively. Patients not meeting CGSLD criteria (15.6%) had low mortality (5.5%/8.6%), indicating improved specificity. **Conclusion:** The CGSLD-ACLF classification demonstrated improved risk stratification compared with existing criteria, with clearer separation of mortality across stages.

2017 | ◆ DEVELOPMENT AND EXTERNAL VALIDATION OF THE READ SCORE: A MACHINE LEARNING TOOL FOR ACUTE DECOMPENSATION PREDICTION IN COMPENSATED ADVANCED CHRONIC LIVER DISEASE.

Marco Vicardi[1] Lorenz Balcar[2] Filippo Cattazzo[1] Leonardo Natola[1] Manuele Bicego[1] Vincenzo Di Maria[1] Michele Bevilacqua[3] Anna Mantovani[1] Laura Alaimo[1] Georg Semmler[2] David Poulakos[2] Adrina Wunderbaldinger[2] Lucie Simonis[2] Jan Embacher[2] Veronica Paon[1] Donatella Ieluzzi[1] Nicola Zeni[4] Roberta Gagliardi[4] Rosa Lombardi[5] David Sacerdoti[1] Mattias Mandorfer[2] Salvatore Piano[4] Andrea Dalbeni[1], [1]University of Verona, [2]Medical University of Vienna, [3]Universiy of Verona, [4]University of Padova, [5]University of the Study of Milan

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Patients with compensated advanced chronic liver disease (cACLD) face significant risk of acute decompensation (AD), including acute-on-chronic liver failure (ACLF), with increased mortality. Most established prognostic tools include substantial non-acute decompensation (NAD) components, making accurate short-term AD prediction challenging. We aimed to develop and externally validate the Risk Estimation of Acute Decompensation (RE-AD) score using machine learning models for predicting AD within 12 months in cACLD patients. **Methods:** This multicenter retrospective cohort study enrolled consecutive cACLD patients from Verona and Vienna University Hospitals between January 2017 and December 2024. Patients were followed-up for 12 months, or until AD occurred. The combined cohort (n = 1440) was used for model development using regularized ML techniques with LOOCV and LASSO feature selection. External validation was performed in an independent cohort of 110 patients from Padua University Hospital. Model performance was assessed in terms of discrimination, calibration, and clinical utility. The RE-AD score was compared with established prognostic scores, including FIB-4, APRI, MELD, Child–Pugh, ALBI, RESIST-HCV, ANTICIPATE ± NASH, Baveno VII criteria, SAVE. Post-hoc recalibration using Platt scaling was applied in the external cohort to account for differences in baseline risk. **Results:** Overall, 81 of 1,550 patients (5.2%) developed AD within 12 months. The RE-AD score included age, number of elective and non-elective hospital admissions and infection episodes requiring antibiotic treatment in the preceding 12 months, serum albumin, and INR. In internal validation, RE-AD demonstrated good discrimination (AUC 0.818, 95% CI 0.78–0.85), acceptable calibration, and a high negative predictive value (99.1%). RE-AD showed numerically higher discrimination than most established prognostic scores, while it did not outperform ALBI and SAVE. In external validation, RE-AD maintained excellent discrimination (AUC 0.910, 95% CI 0.84–0.98), ranking higher than all comparator scores. Initial calibration improved substantially after Platt scaling (Brier score reduction from 0.070 to 0.054). The score retained high sensitivity (90.0%) and negative predictive value (98.9%), supporting its role as a rule-out tool. **Conclusion:** RE-AD is a clinically interpretable ML-based score designed to predict short-term acute decompensation in cACLD, addressing a clinical gap not fully covered by existing tools. The score demonstrated preserved discrimination across internal and external cohorts and relies exclusively on routinely available clinical variables, unlike some established scores (e.g. SAVE) requiring less frequently assessed information such as varices. These features support the use of RE-AD for individualized risk stratification and rule-out strategies in cACLD.

transcriptomics may offer a minimally invasive readout of systemic immune dysregulation. We aimed to develop and internally evaluate a PBMC transcriptomic machine-learning model for predicting 90-day adverse outcomes, defined as death or liver transplantation. **Methods:** We enrolled 219 patients with HBV-related acutely decompensated cirrhosis and collected admission PBMC samples for bulk RNA sequencing. Forty-six patients met ACLF criteria at admission, and the 90-day adverse outcome rate was 22.8%. Three transcriptomic input spaces were evaluated: a Tier A 25-gene panel, a Tier A+B 100-gene panel, and 24 transcriptomic module features. Five feature representations, including gene-only, module-only, and gene–module fusion spaces, were benchmarked across six classifiers: logistic regression, elastic-net logistic regression, linear discriminant analysis, linear support vector machine, random forest, and gradient boosting. Performance was assessed by repeated nested cross-validation, with outer 5-fold cross-validation repeated 20 times and inner 5-fold tuning. All preprocessing steps were confined to training folds. Metrics included AUROC, AUPRC, Matthews correlation coefficient, and Brier score. **Results:** The Tier A+B 100-gene panel combined with logistic regression performed best, achieving AUROC 0.949 ± 0.037, AUPRC 0.876 ± 0.078, MCC 0.721 ± 0.102, and Brier score 0.081 across repeated outer test folds. A sensitivity strategy integrating Tier A+B genes with transcriptomic modules showed similar but slightly lower performance, with AUROC 0.945, AUPRC 0.870, MCC 0.702, and Brier score 0.084. Compared with the Tier A 25-gene panel, the 100-gene panel improved logistic model performance, with mean gains of ΔAUROC +0.037, ΔAUPRC +0.093, and ΔMCC +0.113. Module-only models were less predictive than gene-level feature spaces. The strongest module-only model achieved AUROC 0.874, AUPRC 0.711, and MCC 0.461. Key genes and modules mapped to disease-relevant immune programs, including myeloid activation, complement-associated inflammatory injury, and adaptive T-cell signaling. **Conclusion:** A 100-gene PBMC transcriptomic logistic model showed strong internal discrimination, favorable prediction error, and biological interpretability for 90-day adverse outcome prediction in HBV-related acutely decompensated cirrhosis. Transcriptomic modules aided biological interpretation but did not improve prediction. Independent multicenter validation, calibration assessment, threshold robustness testing, and model simplification are needed before clinical implementation.

2019 | ◆ VALIDATION OF THE 2025 GLOBAL EXPERT PANEL CONSENSUS ON ACUTE-ON-CHRONIC LIVER FAILURE IN AN ASIAN POPULATION

Jingjing Chen[1] Wenling Wang[1] Yu Wu[1] Yanrong Yang[1] Xiao Che[2] Rui Zhao[2] Manman Xu[2] Yu Chen[2], [1]Beijing You'an Hospital, Capital Medical University, [2]Beijing Youan Hospital, Capital Medical University

Background: The 2025 Global Expert Panel Consensus (GEC) for acute-on-chronic liver failure (ACLF) redefined organ failure (OF) thresholds and integrated gastrointestinal (GI) failure. We evaluated GEC criteria in an Asian cohort and compared its performance with European Association for the Study of the Liver-Chronic Liver Failure (EASL-CLIF) criteria. **Methods:** Cirrhotic patients with acute hepatic insult were retrospectively enrolled. Primary endpoints were 28/90-day transplant-free survival (TFS). Independent predictors were identified via Cox regression. Performance was assessed using area under the receiver operating characteristic curve (AUROC), C-index, and Net Reclassification Index (NRI). **Results:** Among 410 patients, 181 (44.1%) fulfilled GEC-ACLF criteria. GI failure was the most prevalent OF (79.0%). The 28/90-

day TFS rates were significantly lower in GEC-ACLF versus non-ACLF (28/90-day: 44.2%/59.7% vs. 8.7%/13.1%, $P < 0.001$). GEC identified 91 high-risk patients (50.3% of GEC-ACLF) categorized as non-ACLF by EASL-CLIF, who exhibited a 49.5% 90-day event rate (death or transplantation). Compared to EASL-CLIF, GEC demonstrated superior 90-day AUROC (0.759 vs. 0.678, $P = 0.010$), C-index (0.706 vs. 0.653, $P = 0.019$), and reclassification improvement (NRI: 26.7%, $P < 0.001$). Multivariate Cox analysis confirmed GEC-ACLF as a potent independent predictor (90-day adjusted HR 6.06, $P < 0.001$), with liver (aHR 6.58) and GI failure (aHR 3.01) identified as the strongest organ-specific predictors (both $P < 0.01$). Subgroup analyses confirmed GEC's reliability across etiologies, infection status, and cirrhosis stages (all $P < 0.001$). **Conclusion:** GEC criteria enhance prognostic stratification by capturing previously under-recognized high-risk individuals. The substantial prognostic weight of GI failure supports its clinical relevance, providing evidence for global ACLF standardization.

2020 | ◆ ANGIOPOETIN-1/WNT AXIS PROTECTS FROM SEPSIS-INDUCED ACUTE-ON-CHRONIC LIVER FAILURE BY PRESERVING HEPATOCYTE DIFFERENTIATION

Michael Schonfeld[1] Samson Mah[1] Kruti Nataraj[1] Steven Weinman[2] Irina Tikhanovich[1], [1]The University of Kansas Medical Center, [2]University of Kansas Medical Center

Background: Sepsis is a common precipitating factor for acute-on-chronic liver failure (ACLF). In our previous work we identified angiopoietin-1/angiopoietin-2 imbalance as a key mechanism of sepsis-induced ACLF. However, the mechanism of angiopoietin-mediated changes in the liver were not fully understood. **Methods:** 8 weeks old male C57Black6/J mice were fed high fat western diet with 20% alcohol in the drinking water (WDA model of liver disease) for 16 weeks followed by 4 weeks recovery. Sepsis was induced with a cecal ligation and puncture (CLP). To test the role of *Angpt1* in the liver, we overexpressed *Angpt1* gene under the control of TBG promoter using an AAV vector. The role of WNT ligand expression was assessed by AAV-mediated *Wnt2* and *Rspo3* overexpression. The mechanism of angiopoietin-mediated changes was assessed by a combination of scATAC-seq analysis and spatial transcriptomics (5k Xenium panel, 10x Genomics). **Results:** Mice treated with WDA followed by sepsis induction (WDA-CLP) showed elevated liver injury (ALT), reduced liver function (increased bilirubin, prothrombin time), and markers of kidney dysfunction (BUN and serum creatinine). *Angpt1* overexpression protected mice from ACLF by reducing liver injury, inflammation, and preserving liver function. Kidney dysfunction was similarly ameliorated. To assess the mechanism of *Angpt1*-mediated protection, we used a combination of scATAC-seq analysis and spatial transcriptomics (5k gene panel, Xenium). We found that *Angpt1* overexpression resulted in an increase of *Wnt2* and *Rspo3* expressing endothelial cells and an increase in *Lrp5* expressing hepatocytes, suggesting that WNT signaling mediates *Angpt1* overexpression effects. WNT activation correlated with increased hepatocyte differentiation, reestablished liver zonation, and a dramatically reduced number of immature SOX9-positive progenitor-like cells. *In vitro* analysis confirmed that ANG-1 treatment promoted endothelial cell *Wnt2* expression under inflammatory conditions and promoted the ability of endothelial cells to preserve hepatocyte differentiation in an LRP5-dependent way. *In vivo* AAV-mediated *Wnt2* or *Rspo3* overexpression mimicked the effects of *Angpt1* overexpression in preserving hepatocyte differentiation in an ACLF model. **Conclusion:** Angiopoietin 1 protects from sepsis-induced ACLF via WNT signaling activation.

2021 | ◆ PROGNOSTIC ANALYSIS OF ARTIFICIAL LIVER SUPPORT SYSTEM THERAPY GUIDED BY THE SYSTEMIC INFLAMMATION RESPONSE INDEX FOR ACUTE-ON-CHRONIC LIVER FAILURE

Xiao Che[1] Rui Zhao[2] Manman Xu[2] Yu Chen[2], [1]Beijing You'an Hospital, Capital Medical University, [2]Fourth Department of Liver Disease, Beijing You'An Hospital, Capital Medical University

Background: The Artificial Liver Support System (ALSS) effectively removes circulating toxins and

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

inflammatory mediators and has been widely utilized in the clinical management of Acute-on-Chronic Liver Failure (ACLF). However, due to the substantial heterogeneity in patients' baseline conditions, the survival benefits of ALSS exhibit significant inter-individual variability in clinical practice, highlighting an urgent need for reliable biomarkers to guide precise patient stratification. This study aims to investigate the impact of ALSS therapy—specifically, the Double Plasma Molecular Adsorption System combined with Plasma Exchange (DPMAS+PE)—on the prognosis of patients with ACLF across different levels of the Systemic Inflammation Response Index (SIRI). **Methods:** A total of 788 patients with ACLF were enrolled in this prospective cohort study and followed up for 28-day and 90-day clinical outcomes. Patients were divided into the ALSS group and the control group (receiving standard medical therapy) based on their treatment modalities, and Cox regression analysis was performed to identify independent prognostic factors. Patients were further stratified by SIRI to investigate the specific therapeutic efficacy of ALSS under varying systemic inflammatory statuses. **Results:** Multivariate analysis demonstrated that ALSS was an independent protective factor for 28-day (HR = 0.71, 95% CI: 0.52–0.97) and 90-day (HR = 0.79, 95% CI: 0.63–0.99) outcomes, whereas an elevated SIRI significantly increased the risk of mortality at 28 days (HR = 1.02, 95% CI: 1.01–1.04) and 90 days (HR = 1.01, 95% CI: 1.00–1.03) (all $P < 0.05$). Restricted Cubic Spline (RCS) analysis revealed a significant non-linear relationship between SIRI and mortality ($P < 0.05$), identifying SIRI = 3 as the optimal stratification threshold. Subgroup analysis confirmed that among patients with high inflammation levels (SIRI $\geq$ 3), the survival rates were significantly higher in the ALSS group compared with the Control group (28-day: 78.0% vs. 63.6%; 90-day: 55.3% vs. 43.2%, $P < 0.05$), Furthermore, within this high-inflammation stratum, ALSS intervention significantly reduced the risk of 28-day (HR = 0.62, 95% CI: 0.41–0.93) and 90-day (HR = 0.74, 95% CI: 0.54–1.00) mortality. **Conclusion:** Both SIRI and ALSS (DPMAS+PE) are independent prognostic factors for patients with ACLF. The SIRI serves as a valuable clinical stratification indicator to identify ideal candidates who will benefit from ALSS therapy. For ACLF patients presenting with a high systemic inflammatory response (SIRI $\geq$ 3), ALSS therapy significantly improves survival rates and effectively mitigates the risk of both short-term (28-day) and mid-term (90-day) mortality.

Background: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome with high short-term mortality, and effective treatment options remain limited beyond liver transplantation. We previously generated hepatocyte-derived liver progenitor-like cells (HepLPCs) through small molecule-based reprogramming. Although our preliminary studies suggested that HepLPCs exert immunomodulatory effects, the mechanisms by which HepLPCs alleviate systemic inflammation in ACLF remain unclear. **Methods:** A concanavalin A (ConA)-induced mouse model was used to recapitulate the systemic inflammatory features of ACLF. HepLPCs were administered via tail vein injection (8×10^6 cells/kg). Single-cell RNA sequencing (scRNA-seq) and flow cytometry were performed to evaluate changes in hepatic immune cell composition after treatment. scRNA-seq data were analyzed using t-SNE, followed by subclustering, differential gene expression, and GO/KEGG pathway enrichment analyses. Bulk RNA sequencing and secretome proteomic analysis of HepLPCs were performed to identify potential immunomodulatory factors. In vitro, HepLPC-conditioned medium was incubated with PMA-stimulated primary mouse bone marrow-derived neutrophils, and neutrophil extracellular trap formation was assessed. **Results:** Following HepLPC administration, ConA-treated mice showed improved liver function and increased survival. scRNA-seq of liver tissues and flow cytometry demonstrated a marked reduction in hepatic neutrophil infiltration after HepLPC treatment. Further dimensional reduction and subclustering of neutrophils identified a CCl4-expressing inflammatory neutrophil subset, which was decreased following HepLPCs administration. GO enrichment analysis revealed that HepLPC treatment alleviated endoplasmic reticulum stress in $CCl4^+$ inflammatory neutrophils. In addition, the expression of key glycolysis-related genes was reduced after treatment, suggesting that HepLPCs may improve neutrophil status by modulating neutrophil metabolism, thereby limiting the recruitment of inflammatory neutrophils.In vitro, HepLPC-conditioned medium suppressed PMA-induced neutrophil extracellular trap formation in primary mouse bone marrow-derived neutrophils, as measured by SYTOX Green staining. **Conclusion:** Our study highlights the therapeutic potential of HepLPCs in alleviating neutrophil-driven liver inflammation in acute-on-chronic liver failure. HepLPCs reduce $CCl4^+$ inflammatory neutrophil infiltration and suppress NETs formation, suggesting that HepLPC-based therapy may represent a promising strategy for the treatment of ACLF.

2023 | CIRRHOTIC CARDIOMYOPATHY INCREASES THE RISK FOR ACUTE-ON-CHRONIC LIVER FAILURE, PARTICULARLY CIRCULATORY FAILURE, IN WAITLISTED PATIENTS.

Murray Coetzee[1] Andre Hall[2] Rawia Aburumman[1] James Slaughter[1] Ashley Spann[1] Deepak Gupta[1] Manhal Izzy[1], [1]Vanderbilt University Medical Center, [2]Vanderbilt University School of Medicine

Background: Cirrhotic cardiomyopathy (CCM) is cardiac dysfunction in patients with advanced cirrhosis without primary cardiac disease . While CCM has been shown to influence post-transplant cardiac outcomes, its impact on acute on chronic liver failure and hepatorenal syndrome-acute kidney injury is less defined. **Methods:** We performed a retrospective cohort study of adults with cirrhosis waitlisted for liver transplantation at a large academic center in North America between 1 Nov 2020 and 1 Apr 2025. Outcomes of interest were acute-on-chronic liver failure (ACLF), its components (circulatory, renal, cerebral or pulmonary failure) and hepatorenal syndrome–acute kidney injury (HRS-AKI). ACLF outcomes were analysed using multivariable logistic regression. HRS-AKI was analysed with Fine–Gray competing-risk regression treating transplantation as the competing event. ACLF analyses incorporated inverse probability weighting using prespecified demographic and liver disease covariates, whereas circulatory failure models were adjusted for age and MELD 3.0 and HRS-AKI models for MELD 3.0. **Results:** Among 453 candidates with sufficient echocardiographic data to define CCM, 81 had CCM and 372 did not (prevalence 18%). CCM was independently associated with higher odds of ACLF (30.9 % vs 19.4 %; aOR 1.75, 95 % CI 1.02–3.01). Among ACLF components, the strongest association with CCCM was for circulatory failure (17.3 % vs 7.3 %; aOR 2.47, 95 % CI 1.22–4.99). Renal failure, as part of ACLF, was more frequent in CCM but was not significant after adjustment (11.1 % vs 5.1 %; aOR 2.15, 95 % CI 0.93–4.99). CCM was not associated with HRS-AKI (19 total events; adjusted sHR 0.85, 95 % CI 0.25–2.94). **Conclusion:** Among liver transplant waitlist candidates, CCM was associated with increased risk of ACLF, particularly circulatory failure, but not with increases in HRS-AKI. These findings suggest hemodynamic consequences for CCM in patients with ACLF; the HRS-AKI estimates should be interpreted cautiously because of limited event counts.

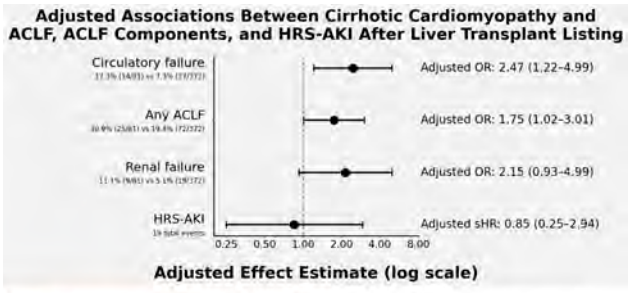

Figure 1: Adjusted associations between cirrhotic cardiomyopathy and ACLF, its components, and HRS in waitlisted patients. Points represent adjusted odds ratios for ACLF outcomes and adjusted subdistribution hazard ratio for HRS-AKI; horizontal lines represent 95

2024 | VISCO-ELASTIC TESTING GUIDED RESTRICTIVE TRANSFUSION REDUCES BLOOD PRODUCT UTILIZATION WITHOUT INCREASING PROCEDURE-RELATED COMPLICATIONS IN PATIENTS OF ACLF-INTERIM RESULTS OF A RANDOMIZED CONTROLLED TRIAL. (NCT06831565)

Sanda Kavitha[1] Manoj Sharma[2] Ashok Choudhury[1] Satender Pal[1] Satender Pal[1] Sugunasree Aakula[1] Chitranshu Vashishtha[1] Sarthak Chanana[1] Ananthu Naryanan[1] ShivKumar Sarin[1], [1]Institute Liver and Biliary Sciences, [2]Institute of Liver and Biliary Sciences

Background: Patients with acute-on-chronic liver failure (ACLF) had a state of balanced coagulation despite systemic inflammation, infection, multiorgan dysfunction and severe coagulopathy. Invasive procedure in these patient and the transfusion strategy is not known, leading to frequent transfusion and associated complications. The aim of the current prospective randomised study is to evaluate the safety of the transfusion of the blood products and the procedure-related outcomes of ROTEM-guided versus standard transfusion strategies in ACLF patients undergoing invasive procedures **Methods:** In this prospective randomized controlled trial, 158 patients fulfilling APASL ACLF criteria and requiring invasive procedures were randomized into three transfusion strategy arms: High-demand (minimal transfusion threshold), Low-demand (standard liver transplant-based transfusion strategy), and On-demand (no prophylactic transfusion, only used when clinically indicated). Outcome evaluated in relation to blood product utilization, procedure-related complications, requirement for procedure-related interventions, and procedure-related mortality **Results:** A total of 158 ACLF patients undergoing invasive procedures were randomized to the High-demand (n = 53), Low-demand (n = 51), and On-demand (n = 54) arms, with mean CTP score of 12.36 ± 1.70, MELD score of 31.04 ± 6.95, AARC ACLF score of 10.27 ± 2.11, CLIF-C ACLF score of 54.06 ± 12.87. The majority were male (91.8%). ACLF grades were distributed as Grade 1 (38.3%), Grade 2 (25.2%), and Grade 3 (23.4%). Paracentesis was the most frequently performed procedure (46.8%), followed by central venous/haemodialysis catheter insertion

(32.9%). Fresh frozen plasma transfusion rates were 1.9%, 17.0%, and 19.4% in the High-demand, Low-demand, and On-demand groups, respectively ($p = 0.012$). Cryoprecipitate transfusion rates were 1.9%, 34.0%, and 27.0%, respectively ($p < 0.001$). Despite significant differences in transfusion exposure, procedure-related adverse outcomes were uncommon. Procedure-related complications and mortality occurred in only two patients (1.3%), both in the On-demand arm, with no statistically significant difference between groups ($p = 0.142$). **Conclusion:** Among ACLF patients undergoing invasive procedures, restrictive ROTEM-guided transfusion strategies substantially reduced blood product utilization without increasing procedure-related complications, intervention requirements, or mortality. These interim findings support the safety and clinical feasibility of individualized, restrictive transfusion approaches guided by viscoelastic testing in patients with ACLF undergoing invasive procedures

2025 | LIPOPROTEIN Z IS A BIOMARKER OF LIVER DECOMPENSATION ASSOCIATED WITH HIGH MORTALITY

Shanshan Su[1] Sebastian Niezen[2] Michelle Lai[2] Zachary Fricker[2] Alan Bonder[2] Vilas Patwardhan[2] Margery A. Connelly[3] Z. Gordon Jiang[2], [1]1. Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medic, [2]Division of Gastroenterology and Hepatology, Beth Israel Deaconess Medical Center, Harvard Medica, [3]Labcorp, Morrisville, NC 27560

Background: Lipoprotein metabolism is a core hepatic function that is frequently disrupted in liver failure and decompensated cirrhosis. We previously identified elevated levels of lipoprotein X (LP-X) and lipoprotein Z (LP-Z), abnormal low-density lipoprotein (LDL)-like particles enriched with free cholesterol (FC) and triglycerides (TG) in patients with severe alcohol-associated hepatitis (AH). In this study, we investigate whether LP-Z is present across other liver diseases, identify clinical factors associated with LP-Z levels, and evaluate its utility in predicting patient outcomes. **Methods:** A total of 896 patients were identified from five registries at Beth Israel Deaconess Medical Center, comprising 364 patients with various liver disease diagnoses and 532 with cirrhosis. Nuclear magnetic resonance (NMR) lipoprotein profiling was performed to quantify lipoprotein subclass concentrations, including LP-X and LP-Z. A Z-index was defined as the ratio of LP-Z to the sum of very low-density lipoprotein (VLDL), LDL, and LP-Z, representing total apolipoprotein B-containing lipoproteins. **Results:** All patients with detectable LP-X also had detectable LP-Z, confirming that these particles co-exist, while LP-X alone was frequently unreliable when quantified from frozen samples. LP-Z was found in 70 patients, almost exclusively in patients with cirrhosis. Although most prevalent in AH and alcohol-associated cirrhosis (AC), these abnormal lipoproteins were also detected in patients with cirrhosis due to metabolic dysfunction-associated steatotic liver disease (MASLD), hepatitis C, autoimmune hepatitis, and primary sclerosing cholangitis. LP-Z levels correlated strongly with MELD score, with total bilirubin showing the strongest individual association. Notably, every patient with a bilirubin level exceeding 15 mg/dL had detectable LP-Z. Patients with circulating LP-Z had significantly lower LDL and HDL levels compared to those with cirrhosis but without LP-Z. While the Z-index demonstrated prognostic value comparable to MELD-Na for overall mortality prediction (Fig. 1A), a Z-index threshold of 0.6 offered significant additional predictive value for 90-day mortality in patients with severe liver decompensation (MELD $\geq$ 28) (Fig. 1B). **Conclusion:** LP-Z is a late-stage biomarker of liver failure or decompensation in cirrhosis, reflecting the breakdownof lipoprotein metabolism. A Z-index cutoff of 0.6 independently risk-stratifies patients at high risk of mortality beyond MELD-Na and may serve as a valuable tool in clinical decision-making.

2026 | VITAL SIGNS OUTPERFORM MELD 3.0 AND CLIF-C AD IN DYNAMICALLY PREDICTING DETERIORATION AMONGST INPATIENTS WITH DECOMPENSATED CIRRHOSIS

Jason Hearn[1] Surain Roberts[2] Matthew Wankiewicz[2] Sahar Saeed[1] Wei Tu[1] Lauren Lapointe-Shaw[3] Siddhartha Srivastava[1] Amol Verma[3] Fahad Razak[3] Florence Wong[3] Gideon Hirschfield[4] Jennifer Flemming[5] Kristel Leung[1], [1]Queen's University, [2]Unity Health, [3]University of Toronto, [4]Toronto General Hospital, [5]Queen's University Cancer Research Institute

Background: Predicting rapid deterioration of decompensated cirrhosis inpatients remains one of the most elusive problems in hepatology. Existing prognostic scores (e.g. MELD 3.0, CLIF-C AD) have focused on bloodwork and clinical features, without consideration of vital signs. We sought to develop supervised machine learning models incorporating vital signs to predict deterioration amongst decompensated cirrhosis inpatients, and to compare model performance with existing clinical scores. **Methods:** We included patients with decompensated cirrhosis admitted to medicine wards across 7 hospitals in Ontario, Canada (Apr. 2016 to Oct. 2021). Demographic, vital sign and lab data were extracted and cleaned (e.g. values outside predefined limits were removed). The primary outcome of deterioration was defined as admission to the intensive care unit or death. Admissions less than 84 hours were excluded. The final 12 hours of data prior to the outcome or discharge (if outcome was not met) were removed. Each encounter was divided into one or more 72-hour windows, with each window assigned a binary indicator denoting whether the outcome occurred at 12 hours post-window. In each window, features were calculated for vital sign data, and the most recent lab values were extracted. The MELD 3.0 and CLIF-C AD scores were calculated for windows containing their respective required components. Three random forest models were generated using features derived from: (1) vital signs, (2) labs, and (3) combined vital signs and labs. Generalized linear models were created using the MELD 3.0 and CLIF-C AD scores to serve as comparators. All models were trained and assessed using a 100-iteration Monte Carlo cross-validation. Performance was quantified using area under the precision-recall curve (AUPRC), which measures the trade-off between sensitivity and positive predictive value across all probability thresholds. **Results:** A total of 8,744 windows were derived from 3,722 hospital admissions. Of the generated windows, 631 (7.2%) were followed by deterioration at 12 hours post-window. The random forest models outperformed the traditional scores, with mean AUPRCs of 0.33 for the vital signs model and 0.38 for the combined vital signs and labs model (compared to 0.21 [CLIF-C AD] and 0.22 [MELD 3.0]). The combined vital signs and labs model achieved a mean accuracy of 0.81, sensitivity of 0.73, specificity of 0.81, positive predictive value of 0.24 and negative predictive value of 0.98, based on probability thresholds optimized using Youden's method (Figure 1). **Conclusion:** Models incorporating vital signs outperformed existing clinical scores in predicting deterioration in 12 hours amongst patients admitted with decompensated cirrhosis. Integrating such models with existing clinical workflows may improve our ability to identify patients at risk for deterioration in real-time, allowing for timely intervention and improved patient outcomes.

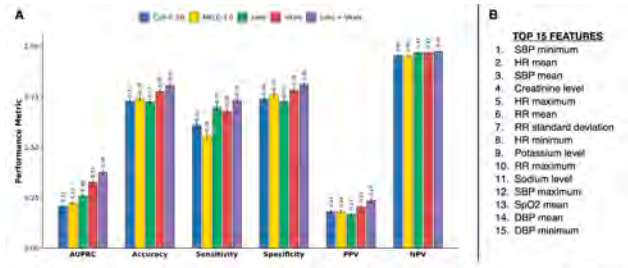

Figure 1. A) Performance metrics (mean ± 95% confidence interval) achieved by the assessed models based on probability thresholds optimized using Youden's method, where AUPRC = area under the precision-recall curve, CLIF-C AD = Chronic Liver Failure Consortium Acute Decompensation, MELD = Model for End-Stage Liver Disease, NPV = negative predictive value, and PPV = positive predictive value. **B)** Most predictive features (as per permutation importance) in the combined vital signs and labs model, where DBP = diastolic blood pressure, HR = heart rate, RR = respiratory rate, SBP = systolic blood pressure, and SpO2 = peripheral oxygen saturation.

2027 | ACUTE HEMODYNAMIC RESPONSE TO CARVEDILOL PREDICTS 28-DAY TRANSPLANT-FREE SURVIVAL IN ACUTE-ON-CHRONIC LIVER FAILURE: THE ACT-C ACLF STUDY.

Garvit Mundra[1] Ishank Johri[2] Chitranshu Vashishtha[3] Shiv Kumar Sarin[4], [1]Institute of liver and billiary sciences ILBS, [2]Institute of liver and billiary sciences, [3]ILBS, [4]ILBS Newdelhi

Background: Elevated hepatic venous pressure gradient (HVPG) drives outcomes in acute-on-chronic liver failure (ACLF). In cirrhotic patients, ≥20% reduction in HVPG with non-selective beta blockers improves survival. However, the prognostic significance of acute HVPG reduction and the optimal cutoff to define response in ACLF remain unknown. We evaluated whether acute hemodynamic response (AHR) to a single oral dose of carvedilol predicts short-term transplant-free survival in ACLF **Methods:** In this prospective interventional cohort study, consecutive patients fulfilling APASL ACLF criteria undergoing HVPG assessment were enrolled. HVPG was repeated 1 hour after oral carvedilol 12.5 mg administration. The primary and secondary outcomes were 28-day and 90-day transplant-free survival, respectively. AHR was defined using percentage reduction in HVPG among 28-day survivors by receiver operating characteristic (ROC) analysis and Youden's Index. **Results:** Eighty-eight patients were analysed and 65 (73.9%) achieved 28-day transplant-free survival. Baseline demographic and disease severity variables including age, gender, etiology, Child–Turcotte–Pugh (CTP), MELD, AARC score, lactate, TNF-α, IL-6 and CRP were evaluated. Baseline HVPG was comparable between 28-day survivors and non-survivors (18.52 ± 4.35 vs 19.43 ± 5.81 mmHg; p = 0.497). However, survivors demonstrated significantly greater acute portal pressure reduction with lower post-dose HVPG (13.03 ± 4.22 vs 16.52 ± 5.35 mmHg; p = 0.008) and greater percentage HVPG reduction (31.16% vs 14.73%; p = 0.001). ROC analysis identified an optimal AHR cutoff of ≥20.7% to predict 28-day survival (AUC 0.764; sensitivity 73.9%; specificity 70.5%). Kaplan–Meier analysis demonstrated significantly superior transplant-free survival among responders (≥20% HVPG reduction) compared with non-responders at both 28 days (85.2% vs 55.9%; log-rank p = 0.0027) and 90 days (79.6% vs 47.1%; log-rank p = 0.0014). Multivariable Cox proportional hazards regression confirmed acute HVPG response (adjusted HR 0.198, 95% CI 0.045–0.865; p = 0.031) and serum lactate (adjusted HR 3.095, 95% CI 1.157–8.282; p = 0.024) as independent mortality predictors. **Conclusion:** Acute HVPG reduction following carvedilol predicts 28-day and 90-day transplant-free survival in ACLF. An acute HVPG reduction of approximately 20% identifies hemodynamic responders and may serve as an early functional biomarker for individualized beta-blocker therapy in ACLF.

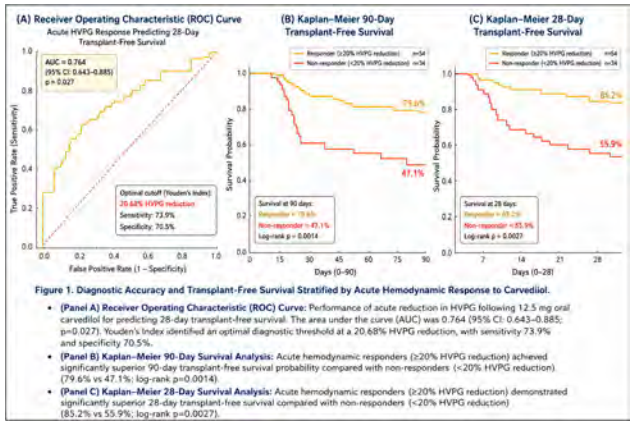

Figure 1. Diagnostic Accuracy and Transplant-Free Survival Stratified by Acute Hemodynamic Response to Carvedilol.

- **(Panel A) Receiver Operating Characteristic (ROC) Curve:** Performance of acute reduction in HVPG following 12.5 mg oral carvedilol for predicting 28-day transplant-free survival. The area under the curve (AUC) was 0.764 (95% CI: 0.643–0.885; p=0.027). Youden's Index identified an optimal diagnostic threshold at a 20.68% HVPG reduction, with sensitivity 73.9% and specificity 70.5%.
- **(Panel B) Kaplan–Meier 90-Day Survival Analysis:** Acute hemodynamic responders (≥20% HVPG reduction) achieved significantly superior 90-day transplant-free survival probability compared with non-responders (<20% HVPG reduction) (79.6% vs 47.1%; log-rank p=0.0014).
- **(Panel C) Kaplan–Meier 28-Day Survival Analysis:** Acute hemodynamic responders (≥20% HVPG reduction) demonstrated significantly superior 28-day transplant-free survival compared with non-responders (<20% HVPG reduction) (85.2% vs 55.9%; log-rank p=0.0027).

Background: Very severe alcohol-associated hepatitis (V-SAH) [SS1] with Maddrey's discriminant function (mDF) > 120 is extremely sick cohort of patient and is associated with extremely high short-term mortality. Therapeutic plasma exchange (PLEX) may improve inflammatory burden and organ dysfunction, potentially providing a bridge-to-transplant (LT) window in carefully selected patients. We evaluated temporal mortality patterns, organ failure burden, renal recovery, bilirubin kinetics, sepsis, and the impact of PLEX intensity in severe AH. **Methods:** Retrospective analysis was done; 532 patients were evaluated with AH and very high (mDF > 120) and underwent PLEX (atleast 1 session). Primary endpoint was mortality at 7, 28, and 90 days. Secondary endpoints were longitudinal reduction in severity scores (mDF, MELD) and inflammatory markers (WBC) by Day 7, incidence and impact of new-onset sepsis, and stratification of Day 7 bilirubin response into rapid decliners vs low decliners and non-decliners; 28- and 90-day mortality. **Results:** The cohort (86.8% male, mean age 45.1 ± 12.0 years) was very sick with mean mDF 163.2 ± 49.9; MELD 31.7 ± 8.2; SOFA 9.1 ± 2.5; CLIF-SOFA 12.8 ± 6.0 and baseline OF noted in 68.4% . Baseline number of organ failure was 2.5 ± 1.2. Renal failure was present in 309/532 (58.1%), hepatic encephalopathy in 330/532 (62.0%), circulatory failure in 207/532 (38.9%), respiratory failure in 96/532 (18.0%), and coagulation failure in 378/532 (71.1%). PLEX limited 7-day mortality to 10.2% (54/532) and facilitated successful LT in 4.5% (n = 24) of this highly unstable cohort, Renal recovery post-PLEX by day 7 occurred in 132 patients (24.8%). Greater early bilirubin decline after PLEX, reflected by both higher mean reduction (14.8 ± 8.2 vs 6.1 ± 5.4 mg/dL) and median reduction [12.6 (IQR 8.4–18.2) vs 4.3 mg/dL (IQR 1.9–8.1)], strongly correlated with improved 28-day and 90-day [SS1] survival, renal recovery, and reduced progression of organ failure. Most notably, the mean mDF demonstrated a sharp decline to 106.2 ± 64.8, alongside parallel reductions in MELD (to 28.3 ± 8.3) and total WBC (17.2 to 15.6 × 10^3/mm^3),

reflecting robust SIRS attenuation. Patients with greater Day-7 bilirubin reduction demonstrated lower 28-day mortality (18%, n = 48/267 vs 46%, n = 123/265) and lower 90-day mortality (32%, n = 85/267 vs 61%, n = 162/265) [SS2] compared with poor biochemical responders. New-onset sepsis within 7 days post-PLEX occurred in 10.0% (n = 53), and in led to high 90-day mortality. Overall 28-day and 90-day mortality were 37.0% and 63.9%, respectively. **Conclusion:** In verysevere alcoholic hepatitis, PLEX helps to improve organ failure and reduces 7-day mortality and increases transplant window Post-PLEX sepsis mandates rigorous infection surveillance.

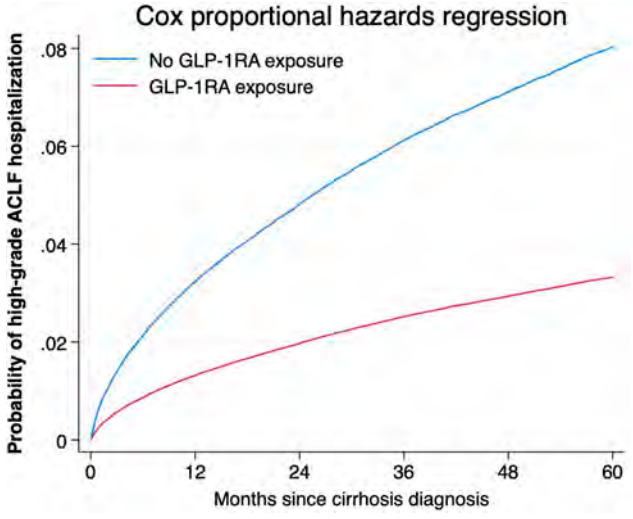
2029 | GLP-1 RECEPTOR AGONIST INITIATION AND RISK OF ACUTE-ON-CHRONIC LIVER FAILURE IN PATIENTS WITH CIRRHOSIS



Snehitha Talugula[1] David Kaplan[1] Nadim Mahmud[2], [1]University of Pennsylvania, [2]Hospital of the University of Pennsylvania

Background: Acute-on-chronic liver failure (ACLF) is a major complication of cirrhosis associated with high short-term mortality. Few therapies reduce the risk of ACLF or modify disease progression. Glucagon-like peptide-1 receptor agonists (GLP-1RAs) have demonstrated cardiometabolic benefits, including reduced cardiovascular risk, with emerging evidence suggesting additional anti-inflammatory and metabolic effects beneficial in chronic liver disease. However, data evaluating the impact of GLP-1RA therapy on clinically significant outcomes in cirrhosis remain limited. We aimed to evaluate the association between GLP-1RA initiation and risk of incident high-grade ACLF hospitalization in patients with cirrhosis. **Methods:** We performed a retrospective cohort study using data from

VOCAL, a national Veterans Health Administration cohort of patients with incident diagnoses of cirrhosis. Patients with prior GLP-1RA exposure were excluded. Data regarding demographics, comorbidities, etiology of liver disease, and MELD-Na were obtained. The primary exposure was GLP1-RA initiation identified from VHA pharmacy records and modeled as a time-updated variable. Major cardiometabolic comorbidities were also modeled as time-updated variables. The primary outcome was incident hospitalization with high-grade ACLF (grade 2 to 3), defined per EASL criteria using a previously validated VHA algorithm. Follow-up was censored at death, liver transplantation, or 5 years. Multivariable Cox proportional hazards models with clustered standard errors were used to evaluate the association between GLP-1RA exposure and ACLF hospitalization. **Results:** Among 158,571 patients with cirrhosis, 6,859 (4.3%) initiated GLP-1RA therapy during follow-up. Compared with patients without GLP-1RA exposure, GLP-1RA initiators were younger (mean 61.7 vs. 63.9 years, $p < 0.001$), had higher BMI (34.7 vs. 28.3, $p < 0.001$), and were more likely to have MASLD or MetALD etiologies and metabolic comorbidities (e.g., diabetes 96.0% vs. 47.8%, $p < 0.001$). Over 5 years of follow-up, time-updated GLP-1RA exposure was associated with significantly lower risk of incident high-grade ACLF hospitalization (adjusted hazard ratio [aHR] 0.54, 95%CI 0.44 to 0.65, $p < 0.001$). Adjusted cumulative incidence curves demonstrated substantially lower probability of high-grade ACLF hospitalization among GLP-1RA-exposed patients over time (approximately 3.2% vs. 8.0% at 60 months; **Figure**). **Conclusion:** In this national cohort study of patients with cirrhosis, GLP-1RA initiation was associated with significantly lower risk of incident high-grade ACLF hospitalization. These findings suggest that GLP-1RA therapy may be beneficial in cirrhosis. Further prospective longitudinal studies are needed to determine whether these associations are causal, evaluate effects across cirrhosis etiologies, and assess impacts on mortality and other liver-related outcomes.

2030 | DEFINING THE GOLDEN WINDOW FOR LIVER TRANSPLANTATION IN ACUTE-ON-CHRONIC LIVER FAILURE: A SYSTEMATIC REVIEW

Roy Khalaf[1] Daljeet Chahal[2], [1]University of Calgary, [2]University of British Columbia

Background: Acute-on-chronic liver failure (ACLF) is characterized by rapid clinical deterioration, multiorgan failure, and high short-term mortality. Liver transplantation (LT) remains the only definitive treatment for many patients with severe ACLF; however, the optimal timing of transplantation remains poorly defined. We performed a systematic review and meta-analysis evaluating timing-related outcomes in ACLF patients undergoing LT. **Methods:** A systematic review was conducted according to PRISMA guidelines. MEDLINE and Embase were searched from inception to February 2026 for studies evaluating LT timing, waitlist mortality, post-transplant survival, or allocation-related outcomes in adult ACLF patients. Thirteen studies met inclusion criteria. Studies with overlapping registry populations were excluded from pooled analyses. Random-effects meta-analysis using logit-transformed proportions was performed for 1-year post-transplant survival outcomes. **Results:** Across included studies, earlier transplantation was consistently associated with improved outcomes, particularly among patients with ACLF-3. In a large UNOS registry analysis of 7,607 ACLF-3 patients, transplantation within 7 days of listing was associated with improved 1-year survival compared with transplantation between days 8–28 (87.1% vs 83.6%). Multiple studies demonstrated rapid clinical deterioration in the absence of transplantation, with mortality frequently occurring within days of hospitalization or urgent listing. Prospective cohorts identified the first week following hospitalization or listing as a critical period associated with substantial waitlist mortality. Increasing ACLF severity was associated with a progressively narrower transplant window, with median time-to-transplant decreasing from 20 days in ACLF-1 to 5 days in ACLF-3 in the ECLIS cohort. Significant heterogeneity

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

was observed in timing definitions across studies, including transplantation timing measured from hospital admission, ACLF diagnosis, or waitlist registration. Pooled analysis of non-overlapping cohorts demonstrated a 1-year post-transplant survival of 83.8% (95% CI 80.6–86.5%; $I^2 = 72.4\%$). **Conclusion:** The available literature supports LT as a highly time-sensitive intervention in severe ACLF, with delayed transplantation associated with rapid clinical deterioration and substantial waitlist mortality. The transplant window appears to narrow with increasing ACLF severity, particularly in ACLF-3. However, substantial heterogeneity in timing definitions limits direct comparison across studies. Future prospective studies using standardized and clinically meaningful timing frameworks are needed to better define the optimal timing of LT in ACLF.

Background: Whether amplified maladaptive emergency myelopoiesis (MEM) that occurs in patients with ADC contributes to or correlates with 90-day mortality is unclear. This study aimed to address this question. **Methods:** Both "bulk" whole blood RNA-seq data (which capture RNA features from myeloid cells) obtained on nonelective admission (baseline) of 694 ADC patients (including 164 ACLF) and from 25 matched healthy subjects and single-cell whole blood RNA-seq data obtained in 10 additional patients were used to compute metrics assessing low, average and high baseline MEM intensity relative to healthy status. The risk of death by 90 days was assessed with semiparametric Fine–Gray competing-risk models with liver transplantation (LT) treated as a competing risk of death. After handling missing data using multiple imputation by chained equations, univariable and multivariable regression models were fitted in the imputed datasets. The overall contribution of MEM intensity was assessed using pooled type III Wald tests based on the D1 method (two-sided) comparing full models with nested models excluding MEM intensity. **Results:** As compared with healthy subjects, ADC patients exhibited amplified MEM at baseline, i.e., they had neutrophilia and monocytosis developed at the expense of lymphoid lineages, and blood enrichment with RNA features indicating increases in bone marrow outputs of immature and mature myeloid cells exhibiting actuated immunosuppressive gene programs. Of the 694 patients, 47 (7%) received a LT by 90 days; of the 647 nontransplanted patients 193 (30%) died by 90 days. Patients with low or average MEM intensity at baseline had significantly lower risks of 90-day transplant-free death than those with high MEM intensity (low versus high intensity: subdistribution hazard ratio [sHR], 0.30; 95% CI, 0.20-0.46; average versus high: sHR, 0.45; 95% CI, 0.33-0.61; type III $P < 0.0001$). All associations were preserved after adjustments that included age, CLIF-C

organ failure score, blood cytokine levels, differential neutrophil counts, and recent use of immunosuppressants. Then, analyzing MEM intensity according to patients' phenotypes determined by the presence or absence of ACLF at baseline, we found that average or low MEM intensity was associated with significantly lower risk of death for each phenotype, as compared with high MEM intensity (both type III $P < 0.05$). Notably, among patients without ACLF, those with low MEM intensity had a 64% lower risk of death, compared with those who had high MEM intensity. **Conclusion:** Our findings identify the intensity of baseline MEM as an unrecognized determinant of 90-day transplant-free mortality among ADC patients, with and without ACLF, highlighting potential implications for patient stratification and the development of therapeutic strategies that dampen MEM intensity.

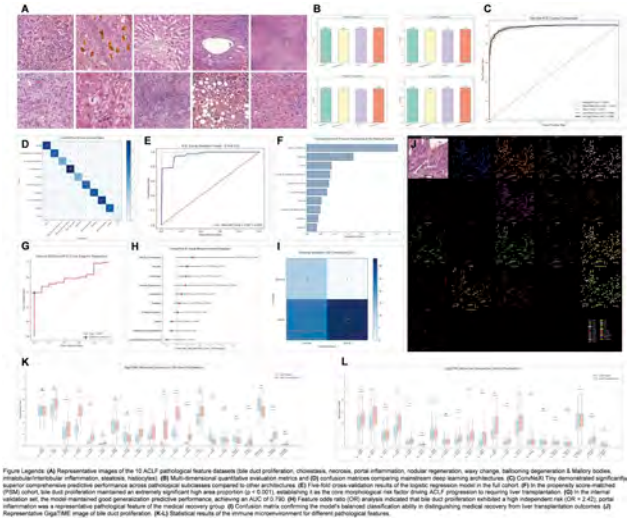
2032 | CANDIDATE BIOMARKERS IDENTIFIED BY MULTIMODAL ARTIFICIAL INTELLIGENT INFORM LIVER TRANSPLANTATION DECISIONS IN ACUTE-ON-CHRONIC LIVER FAILURE (ACLF)



Rui Zhao[1] Jingran Jiao[1] Xiao Che[1] Manman Xu[1] Wenling Wang[1] Pengfei Yu[1] Yu Chen[1], [1]Fourth Department of Liver Disease, Beijing You'An Hospital, Capital Medical University

Background: Liver transplantation (LT) is a key treatment for ACLF, requiring refined patient classification to guide rational clinical decisions. Recent advances in Artificial intelligent (AI) make it possible to re-assess digital pathology for candidate biomarker discovery. **Methods:** 117 ACLF patients was conducted (source of pathological specimens: medical recovery group (LT-free): liver biopsy, $n = 36$; LT group: explant, $n = 81$). A patch-level dataset of 1,469 patches covering 10 ACLF pathological features (bile duct proliferation, cholestasis, necrosis, et al) was built by liver pathology diagnostic physicians through manual annotation. A ConvNeXt-Tiny model was trained with 5-fold cross-validation (AdamW optimizer, learning rate 1e-4, data augmentation) and achieved high accuracy for feature classification. Tissue ratios were computed. Logistic regression identified features associated with LT in full and matched cohorts. Recently reported virtual spatial proteomics technology GigaTIME converted key regions into virtual 21-marker multiplex immunofluorescence (mIF) with patient-level equal sampling. Mean intensities were compared. Mann-Whitney U test was used (two-sided, $p < 0.05$). **Results:** ConvNeXt-Tiny achieved a mean AUC of 0.984 for 10 histological features, outperforming ResNet50, EfficientNet-v2-s, and Swin-T. In the full cohort, LR coefficients highlighted bile duct proliferation (2.26), portal inflammation, ballooning/Mallory, and steatosis as top contributors to LT. After propensity score matching (age, MELD score), bile duct proliferation remained the dominant risk factor (coefficient 1.33, $p < 0.001$), while portal inflammation showed protective effect. In internal validation, multivariate LR model had AUC 0.790; bile duct proliferation OR was 2.42, and SHAP analysis confirmed the protective role of portal inflammation. GigaTIME revealed that in portal inflammation areas, Transgelin was significantly higher in LT-free patients. In bile duct proliferation regions, LT patients exhibited upregulation of T-bet, CD11c, PD-L1, and PHH3-B, and decreased CK and Caspase3-D, indicating inflammatory storm and immune exhaustion with disordered proliferation. Tryptase emerged as a candidate secreted biomarker for LT decision-making, elevated in LT cases. These findings suggest that AI-based pathology combined with spatial proteomics can refine LT candidate selection. **Conclusion:** This study applies AI based multi omics to ACLF pathology, offering a new perspective to refine LT decision making in ACLF. We emphasize that our findings are intended to assist LT decisions rather than replace them—according to recent insights,ignoring this distinction would overlook the subgroup of patients who

2033 | PLASMA PROTEOMICS STRATIFIES HIDDEN MORTALITY RISK IN THE MELD HIGH-RISK GREY ZONE OF HBV-RELATED ACUTE-ON-CHRONIC LIVER FAILURE

Fuxia Ta[1] Jinwen Feng[2] Bingyao Wang[1] Mengmeng Wang[1] Mengqi Zhu[3] Yilei Cao[4] Jian-Ming Zheng[5], [1]Huashan Hospital, Fudan University, [2]Human Phenome Institute, Fudan University, Shanghai, China, [3]Huashan Hospital, Fudan University, Shanghai, China, [4]Shanghai Medical College, Fudan University, Shanghai, China, [5]Huashan Hospital Fudan University

Background: Prognostication remains challenging in patients with HBV-related acute-on-chronic liver failure (HBV-ACLF), particularly once conventional clinical scores already indicate high risk. We aimed to determine whether baseline plasma proteomics could further stratify mortality risk within the MELD high-risk grey zone. **Methods:** We profiled baseline plasma from 55 patients with HBV-ACLF using data-independent acquisition mass spectrometry (DIA-MS). The primary outcome was 180-day mortality. Patients with MELD ≥25 were analyzed as the high-risk grey-zone subgroup. Mortality-associated proteins were prioritized using differential abundance analysis, pathway and protein-interaction context, low-dimensional protein-only model benchmarking, Cox analysis, and Kaplan-Meier risk stratification. **Results:** Overall, 18 of 55 patients died by 180 days. Within the MELD ≥25 subgroup, MELD did not distinguish 180-day survivors from non-survivors (P = 0.395), indicating limited prognostic resolution among clinically severe patients. Death-associated plasma proteins were enriched for extracellular matrix (ECM)/adhesion, membrane-trafficking and stress-related programs. STRING contextualization identified complementary mortality-associated biology represented by CHMP5, linked to ESCRT and vesicle sorting; ZC3H4, linked to RNA and nuclear regulation; and NID2, linked to basement membrane and extracellular matrix remodeling (**Figure 1A**). In repeated cross-validation, the three-protein CHMP5/ZC3H4/NID2 model achieved an internal cross-validated AUC of 0.902 and outperformed the best single- and two-protein models, while adding a fourth protein produced minimal incremental gain (**Figure 1B**). This supported the three-protein panel as the parsimonious model. Each protein was associated with increased 180-day mortality risk in Cox analysis (**Figure 1C**). A three-protein risk score sharply separated outcomes: no deaths occurred in the low-risk group, whereas 15 of 19 high-risk patients died by 180 days (Kaplan-Meier P < 0.001, **Figure 1D**). **Conclusion:** Plasma proteomics revealed a parsimonious CHMP5/ZC3H4/NID2 mortality signature that identifies hidden risk within the MELD high-risk grey zone of HBV-ACLF. These findings suggest that cellular stress, membrane-trafficking, and ECM/basement-membrane remodeling programs may capture mortality biology not resolved by conventional severity scoring, supporting further validation of this candidate risk-stratification strategy for clinically severe HBV-ACLF.

2034 | *EX VIVO* BLOOD ASSAYS DEMONSTRATE SYSTEMIC ANTI-INFLAMMATORY ACTIVITY OF G1090N, A NOVEL FORMULATION OF NITAZOXANIDE; AND SUPPORT FURTHER CLINICAL EVALUATION IN ACUTE-ON-CHRONIC LIVER FAILURE (ACLF)

Debaecker Simon[1] Marie Bobowski-Gerard[1] Alexandra Pruvost[1] Manon Clarisse[1] Virginie Galoseau[1] Anthony Rabat[1] Jérémy Magnanensi[1] Camille Vanbésien[1] Jean-Marie Brusq[1] Jonel Trebicka[2] Bart Staels[3] Zouher Majd[1] Sakina Sayah Jeanne[4], [1]GENFIT SA, [2]University Hospital Münster, Münster, Germany, [3]Univ. Lille, Institut Pasteur de Lille, CHU Lille, Inserm U1011, Lille, France, [4]Genfit

Background: G1090N, a novel formulation of nitazoxanide (NTZ), is an investigational drug under development for the treatment of ACLF, a severe complication of acutely decompensated cirrhosis characterized by organ failures and high-short term mortality. Systemic inflammation, triggered by bacteria or pathogen-associated molecular patterns such as lipopolysaccharide (LPS), is a key driver of ACLF. Oral NTZ has been shown to protect against systemic inflammation and organ damage in animal models of ACLF. This study aimed to confirm the anti-inflammatory activity of NTZ using human peripheral blood mononuclear Cells (PBMCs) from subjects enrolled in a G1090N Phase 1 study and blood samples from cirrhosis patients. **Methods:** In the NCT07110441 Phase 1 clinical trial, healthy participants received 300 mg (n = 12) or 600 mg (n = 11) G1090N twice daily for 7 days. PBMCs and plasma were isolated from blood samples collected at baseline (D-1, before treatment), after a single dose (D1, T+6h), and after repeated doses (D7, T+6h). PBMCs were cultured in the presence of 50% of their autologous plasma for 1h before stimulation with LPS (100 ng/mL) for 6h (Figure).*Ex vivo* assays were also performed using whole blood obtained from healthy (n = 13 pool) and cirrhotic (n = 5) donors collected at EFS and Cerba laboratories, respectively. Blood samples were incubated with 60-120 µM tizoxanide (TZ), the active metabolite of NTZ for 1h prior to stimulation with LPS (50 ng/mL) for 4h.Homogenous Time-Resolved Fluorescence (HTRF) quantified cytokines levels in supernatants. **Results:** In clinical trial *ex vivo* assays, PBMCs and plasma from healthy subjects treated with 300 mg G1090N exhibited reduced LPS-induced cytokine secretion, compared with LPS-stimulated samples at baseline (D-1, untreated): by 62% ($p = 0.03$) and 74% ($p < 0.001$) for IL-6, and by 53% ($p = 0.03$) and 65% ($p < 0.001$) for TNFα, after a single dose (D1) or repeated doses (D7), respectively. Similar effects were observed with the 600 mg dose of G1090N, with IL-6 reductions of 46% at D1 and 43% at D7 (both $p < 0.001$), and TNFα reductions of 19% at D1 ($p = 0.002$) and 20% at D7 ($p = 0.001$).In *ex vivo* assays from cirrhotic and healthy blood, TZ treatment attenuated LPS-induced cytokine secretion in a dose dependent manner, with maximal inhibition of 68% and 63% for TNFα, and 85% and 84% for IL-6, respectively ($p < 0.001$). Notably, we observed greater anti-inflammatory activity in the cirrhotic group at low and intermediate doses compared to the healthy group. **Conclusion:** Single or repeated G1090N doses used in the first-in-human study were sufficient to achieve robust ex-vivo anti-inflammatory activity. These findings were confirmed in cirrhotic blood, indicating NTZ's potential in conditions associated with heightened systemic inflammation. Together with previously reported organ-protective properties of NTZ in disease models, these data support phase 2 clinical investigation of G1090N in patients with ACLF.

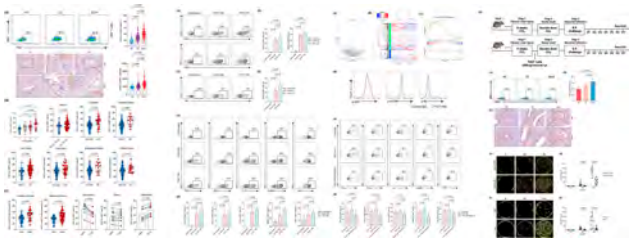
2036 | TIGIT EXACERBATES ACUTE-ON-CHRONIC LIVER FAILURE INFECTION AND MORTALITY THROUGH CD8⁺ T CELL EXHAUSTION



Yidi Jia[1] Yao Zhang[2] Xueyun Zhang[2] Yan Wang[2] Yuxian Huang[2] Jiming Zhang[2], [1]Fudan University, [2]Huashan Hospital

Background: Overwhelming infection caused by immunity deficiency contributes to the high short-term mortality in acute-on-chronic liver failure (ACLF). T-cell Immunoreceptor with Ig and ITIM domains (TIGIT) regulates T cell function in oncology, but its role in anti-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

infection immunity in ACLF remains unclear. We aimed to investigate the pathogenic role and therapeutic potential of TIGIT in ACLF. **Methods:** TIGIT expression and function on $CD8^+$ T cells was examined in blood and liver samples from ACLF patients, cirrhosis (LC), and healthy controls (HCs). RNA-seq was employed to investigate the pathways, which was verified by phosphoflow cytometry. To model ACLF conditions, we established an ACLF mouse model involving chronic liver injury (CCl4 injection for 8 weeks), acute insult (double-dose CCl4 injection), and Klebsiella pneumoniae (K.P.) challenge, according to Xiang et al. Two groups of ACLF mice were developed: TIGIT-knockout ($TIGIT^{-/-}$) versus wild-type (WT) ACLF mice and anti-TIGIT mAb treated versus control-IgG treated ACLF mice. **Results:** TIGIT expression on $CD8^+$ T cells was significantly increased in ACLF patients compared to HCs and LC patients. Immunohistochemical analysis of liver tissue corroborated these findings. Higher TIGIT expression on $CD8^+$ T cells correlated with worse prognostic scores, organ failure, infections and 28-/90-day non-survival status in ACLF patients. During hospitalization, TIGIT expression increased in deterioration, decreased in improvement, and unchanged in stable patients. Blockade with anti-TIGIT monoclonal antibody (mAb) improved activation (CD25, CD69), proliferation (Ki67) and cytokine production (IFN-γ, IL-2, TNF-α, Granzyme B, Perforin) in $CD8^+$ T cells isolated from ACLF PBMCs. RNA-seq-based gene expression profiling of anti-TIGIT mAb-treated $CD8^+$ T cells, followed by GSEA analysis, identified the PI3K-AKT-mTOR pathway as a key mediator. Anti-TIGIT mAb increased p-AKT, p-mTOR, and p-S6 in $CD8^+$ T cells. Rapamycin (mTOR inhibitor) intervention abolished elevated $CD8^+$ T cell function mediated by anti-TIGIT mAb. In a mouse model of ACLF, treatment with anti-TIGIT mAb upregulated CD25, CD69, IFN-γ, TNF-α, and Granzyme B in $CD8^+$ T cells, significantly improved survival rates, and reduced Klebsiella pneumoniae (K.P.) loads at 24 and 48 hours post-bacterial challenge. Similarly, $TIGIT^{-/-}$ ACLF mice exhibited higher expression of these cytokines, better survival, and lower K.P. burdens. **Conclusion:** Blockade of TIGIT leads to improvement of $CD8^+$ T cell function and anti-infection immunity in ACLF. The findings clarify ACLF pathogensis and nominate TIGIT as a promising therapeutic target.

2037 | TYPE A AND TYPE B ACLF BY KYOTO CLASSIFICATION CLEARLY CHARTERS NATURAL DISEASE COURSE AT BASELINE AND GUIDES THERAPEUTIC INTERVENTIONS -A COHORT STUDY

Rakhi Maiwall[1] Samba Siva Rao Pasupuleti[2] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences, [2]Pachhunga University College Mizoram University (A Central University)

Background: Systemic inflammation is a key driver of organ failures in acute on chronic liver failure (ACLF). The Kyoto Consensus classified ACLF into Type A and Type B, emphasizing a liver-centric paradigm with hepatic failure as primary and excluding patients with prior episodes of decompensation to define ACLF. This could be relevant as immune dysregulation in the critically ill are specific to the host maladaptation to cytokine amplification during sepsis. **Methods:** Retrospective cohort of consecutive patients admitted to the liver intensive care unit (n = 600) with ACLF defined according to Kyoto consensus, [Type A, n = 148 (25.7%); Type B, n = 452 (75.3%)] were evaluated. Patients who succumbed in first 72 hours were excluded. **Results:** Type B ACLF were more prevalent (75.3% vs. 25.7%),being older [(49.9 ± 10.9) vs. (43.8 ± 11.2); $p < 0.001$] with higher prevalence diabetes [(15.5% vs.7.4%); $p = 0.013$], hypertension [(9.1% vs. 2%);$p = 0.004$] and higher incidence of acute variceal bleed [(23% vs. 12.8%); $p = 0.008$] and refractory ascites [(20% vs.10.8%);$p = 0.009$] respectively. A similar prevalence of sepsis and alcohol as the dominant etiology [(71.7% vs. 71.6%)] was noted. Type A had deep jaundice [(22.3 (11.3) vs. 8.2(8.7); $p < 0.001$], coagulopathy [4.1(2.9) vs. 3.2(2.5); $p < 0.001$] and severe SIRS (1: 2: > 2 components) (50% vs. 32.4%) vs. (35% vs. 41.2%) vs. (14.2% vs. 25.7%) than type B. The need of mechanical ventilation (39.2% vs. 32.5%), with lower PaO2/FiO2 ratio [284 (161.4) vs. 311.6(169.4)], comparable grades of hepatic encephalopathy 1: 2: 3: 4 [(10.1 vs 5.8%) vs. (18.9% vs 17.5%) vs. (16.2% vs. 21.2%) vs. (23.6% vs.22.3%), arterial lactate [3.49(3.1) vs. 3.4(2.65) umol/L] with similar proportion of patients on vasopressors. More severe kidney involvement with significantly higher serum creatinine [2.3(1.7) vs. 1.94(1.51) mg/dl], lower urine output [39.7(34.7) vs. 53.7(65.7)], higher KDIGO stage 3(43.2% vs. 35.2%) stage 2(31.8% vs.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

21.8%) vs. stage 1(8% vs. 17.9%),need of dialysis (2.7% vs.0.7%), higher uNGAL [1446.1(904.4) vs. 1073 (546.5) ng/ml] and Cystatin C [2.49(0.76) vs. 2.18 (0.67)] was seen in Type A ACLF. On multivariable Cox-regression analysis, Type A patients had higher 30-day mortality [37.2%vs.23%; 1.37, (1.09-1.71); $p < 0.001$] alongside higher arterial lactate, need of mechanical ventilation and sepsis. **Conclusion:** ACLF type A patients are younger with more severe liver failure, intense systemic inflammation, kidney failure, and significantly higher mortality possibly needing bridging therapies ameliorating hepatic inflammation. Type B patients have more frequent portal-hypertension driven complications and more comorbid diseases signifying distinct systemic inflammation and immunometabolic phenotypes. The segregation into Type A and B is relevant for developing therapeutic strategies and selection for an early liver transplant for patients with cirrhosis and organ failures.

APASL ACLF research consortium (AARC) database from 2020 to 2025. Out of 3498 patients of ACLF, alcohol and MASLD were etiology of chronic liver diseases in 2534 (73%) and 128 (3.6%) patients respectively. Propensity score matching (PSM) was performed to minimize baseline differences between the study groups and reduce selection bias. Patients were matched using relevant demographic and clinical variables bilirubin, INR, creatinine, albumin, HE, ascites, hemoglobin, TLC and platelet counts with nearest-neighbor matching and a predefined caliper width. Finally, 125 patients in each ALD ACLF and MASLD ACLF groups were analyzed. **Results:** In ALD-ACLF, patients were younger and majority were male as compared to MASLD-ACLF (45 vs 48 years, P = 0.04 and 83% vs 64%, P = 0.001) respectively. In comparison to ALD-ACLF, MASLD-ACLF had significantly more female patients (17% vs 36%, P = 0.001) respectively. ALD-ACLF had significantly lower platelets than MASLD-ACLF (131 vs 150, P = 0.02). MASLD-ACLF had higher prevalence of jaundice than ALD-ACLF (94% VS 77%, P = < 0.05). Liver failure and acute variceal bleed (AVB) was present in (32% vs 28%, P = 0.49 and 4% vs 7%, P = 0.27) patients in ALD-ACLF and MASLD-ACLF respectively. There was no significant difference in 90-day mortality between ALD-ACLFand MASLD-ACLF.The multivariable Cox proportional hazards regression analysis was performed to evaluate the impact of different parameters in whole cohort on 90-day mortality. Controlling for other covariates like age, sex and different groups, liver failure and acute variceal bleed (AVB) were predictors of 90-day mortality with HR = 1.785 (95% CI 1.196-2.663, P = 0.005) and HR = 1.810 (95%CI 1.020-3.213, P = 0.043) respectively. Further, cox regression analysis of different parameters of ALD-ACLF revealed that serum bilirubin was predictor of increased 90-day mortality with HR = 1.037[95%CI 1.002-1.074, P = 0.040]. In MASLD-ACLF, liver failure, INR and AVB were predictors of increased 90-day mortality with HR 3.015 [95%CI 1.553-5.852, P = 0.001], HR 2.477 [95%CI 1.198-5.122, P = 0.014] and HR 1.491 [955CI 1.057-2.103, P = 0.023] respectively. On the other hand, male sex was associated with decreased risk of 90-day mortality with HR 0.565 [95% CI 0.335-0.953, P = 0.032] **Conclusion:** MASLD is involving more female patients with worst outcomes as compared to ALD. Presence of liver failure, deranged INR and AVB in these patients predict increased 90-day mortality in this group. We need prospective studies to further evaluate this subgroup for presence of comorbidities and their impact on outcomes.

2039 | LIVER TRANSPLANT OUTCOMES IN ACLF PATIENTS MANAGED IN A DEDICATED LIVER ICU

Kathryn Thompson[1] Jake MacDonald[1] Nishita Sunkara[1] Naveena Murugan[1] Michael Yu[2] Hima Veeramachaneni[2] Ram Subramanian[3] Vignesh Jayaraman Muralidharan[4] Nader Dbouk[5], [1]Department of Internal Medicine, Emory University School of Medicine, [2]Emory Transplant Center, [3]Emory University, [4]Department of Surgery/Grady, Emory School of Medicin, [5]Emory University School of Medicine

Background: Dedicated liver intensive care units (LICU) may improve outcomes in critically ill liver patients, though their role remains controversial. We analyzed outcomes among Acute-on-Chronic Liver Failure (ACLF) patients managed in a dedicated LICU at a single tertiary care center who underwent liver transplantation (LT) over an 11-year period. **Methods:** We conducted a retrospective study evaluating outcomes among 816 LT recipients managed in Emory University's dedicated LICU between 2014 and 2025, including 244 patients with ACLF. Primary outcomes included 1-, 3-, and 5-year patient and graft survival comparing ACLF versus non-ACLF patients and stratified by ACLF grade (1-3). Secondary outcomes included total hospital length of stay, post-LT ICU length of stay, discharge disposition, and 30-day readmission rates. ChatGPT (OpenAI) was used solely to assist with language refinement and improve readability of the abstract. **Results:** Patients without ACLF demonstrated significantly better patient and graft survival compared to patients with ACLF. The presence of ACLF was associated with a 67% higher risk of mortality (HR 1.67, 95% CI 1.17–2.39, p = 0.005) and a 65% higher risk of graft loss (HR 1.65, 95% CI 1.16–2.35, p = 0.005). These differences were driven by poorer outcomes among patients with ACLF grade 3, whereas patients with ACLF grades 1 and 2 had survival rates comparable to those without ACLF (Figure 1). Both patient survival (log-rank p = 0.001) and graft survival (log-rank p = 0.0004) differed significantly across ACLF grades, with each incremental increase in ACLF grade associated with a 30% higher risk of mortality and graft loss (HR 1.30 for both, p < 0.001). Patients with ACLF grade 3 had a 2.32-fold higher risk of death (HR 2.32, 95% CI 1.48–3.65, p = 0.0003) and a 2.44-fold higher risk of graft loss (HR 2.44, 95% CI 1.56–3.81, p < 0.0001) compared to non-ACLF and ACLF grade 1 and 2 patients. ACLF was also associated with substantially greater healthcare utilization, particularly among ACLF grade 3 patients, who experienced significantly longer total hospital length of stay (median 35 vs 9 days, p < 0.001), longer ICU stay following transplant (median 8 vs 3 days, p < 0.001), and longer post-transplant length of stay (median 18 vs 8 days, p < 0.001) compared to non-ACLF patients. ACLF grade 3 patients were also significantly more likely to require inpatient rehabilitation (49% vs 4.4%, p < 0.001) and less likely to be discharged home (37% vs 93%, p < 0.001). **Conclusion:** Patients with ACLF Grades 1 and 2 managed in a dedicated LICU achieved post-liver transplant outcomes comparable to patients without ACLF. Although ACLF Grade 3 patients had worse outcomes, their 1-year survival still approached 80%, consistent with published literature despite the severity of illness in this population. Prospective multicenter studies are needed to further evaluate the impact of dedicated LICU care on post-transplant outcomes in ACLF patients.

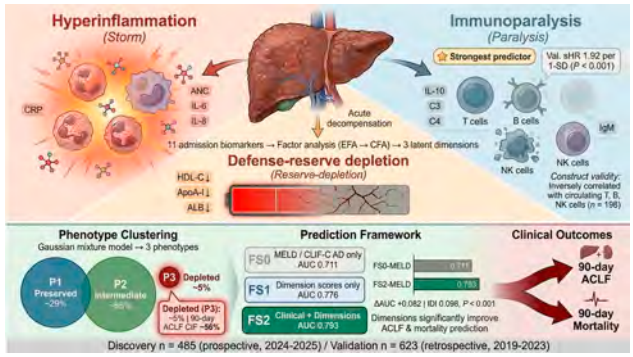
2040 | THREE DATA-DRIVEN IMMUNOLOGICAL DIMENSIONS IMPROVE ACLF PREDICTION BEYOND MELD IN ACUTELY DECOMPENSATED CIRRHOSIS: AN AMBISPECTIVE COHORT STUDY



Ruiqi Li[1] Hao Ren[2] Jiale Shen[2] Jun Guo[2] Xiaoying Dong[2] Shū Jí Chén[2] Hongli Liu[2] Caiyun Zhang[2]

Changhua Yi[2] Wei Chen[2] Qingfang Xiong[2] Xixuan Wang[2] Yongfeng Yang[2], [1]The Second Hospital of Nanjing, Southeast University, [2]The Second Hospital of Nanjing

Background: Immune dysregulation drives progression from acute decompensation of cirrhosis (ADC) to acute-on-chronic liver failure (ACLF), yet conventional clinical scores (MELD, CLIF-C AD) do not capture the underlying immunological heterogeneity. We aimed to discover and externally validate data-driven immunological dimensions from routine biomarkers, identify immunological phenotypes, and assess their incremental predictive value for ACLF and mortality beyond established clinical scores. **Methods:** In a prospective discovery cohort (n = 485) of hospitalized ADC patients, exploratory and confirmatory factor analysis (EFA/CFA) identified three latent dimensions from 11 routine biomarkers: hyperinflammation (CRP, ANC, IL-6, IL-8), immunoparalysis (IL-10, C3, C4, IgM), and defense-reserve depletion (HDL-C, ApoA-I, albumin). Gaussian mixture modeling on dimension scores classified patients into three phenotypes. Fine-Gray competing-risks models assessed 90-day ACLF risk (subdistribution hazard ratio [sHR]; death/transplantation as competing events), and Cox models assessed 90-day mortality. Prediction frameworks were compared: FS0 (clinical score alone), FS1 (dimension scores alone), and FS2 (clinical score + dimension scores). A retrospective validation cohort (n = 623) from the same center underwent one-shot frozen evaluation with no parameter modification. **Results:** The CFA model showed acceptable-to-good fit (discovery CFI = 0.954; validation CFI = 0.974, RMSEA = 0.050). Three phenotypes were identified: Preserved (P1, 28.7%), Intermediate (P2, 66.2%), and Depleted (P3, 5.2%). Compared with P1, P3 had markedly higher 90-day ACLF risk (sHR 5.94, 95% CI 2.90-12.20 in discovery; 11.93, 5.86-24.29 in validation; both P < 0.001) and 90-day mortality (HR 24.41, 8.77-67.95 and 6.59, 2.72-15.98, respectively). 90-day restricted mean survival time was 87.1, 79.2, and 50.9 days for P1, P2, P3, respectively. All three dimensions independently predicted ACLF and mortality after mutual adjustment (all P < 0.01). Adding dimension scores to MELD improved validation AUC for 90-day ACLF (FS2 0.793, 0.748-0.832 vs FS0 0.711, 0.661-0.756; delta-AUC = +0.082) and 90-day mortality (FS2 0.824, 0.777-0.863 vs FS0 0.754, 0.701-0.805; delta-AUC = +0.070). Construct validity was confirmed through immune cell correlations in a cytological subgroup (n = 196). Results were robust across CLIF-C AD-based models and five sensitivity analyses. **Conclusion:** Three data-driven immunological dimensions capturing hyperinflammation, immunoparalysis, and defense-reserve depletion significantly improve ACLF and mortality prediction beyond conventional clinical scores in ADC patients. This routine-biomarker-based framework enables mechanistically informed risk stratification at hospital admission and may guide phenotype-targeted management strategies.

2041 | SERUM GALECTIN-3 IS ASSOCIATED WITH ORGAN FAILURE BURDEN AND IMPROVES MORTALITY RISK STRATIFICATION IN ACUTE-ON-CHRONIC LIVER FAILURE

Osvely Méndez-Guerrero[1] Claudia Daniela López-López[2] Anaisa Carranza-Carrasco[2] Yesica Meraz Arredondo[2] Rodrigo Guerrero-Guerrero[2] Alfonso Rodriguez-Espada[3] Alma Estanes-Hernández[2] Aldo Torre[4] Ignacio Garcia Juarez[5] Graciela Castro-Narro[6] Ashuin Kammar García[7] Nalu Navarro-Alvarez[8], [1]Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubiran, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, [3]Panamerican University School of Medicine, [4]Medical Center ABC. Mexico City., [5]The National Institute of Medical Science and Nutrition, [6]Hospital Médica Sur, Ciudad de México. Instituto Nacional de Ciencias Médicas y Nutrición, [7]Instituto Nacional de Geriatría, [8]University of Colorado Anschutz Medical Campus/Instituto Nacional de Ciencias Médicas y Nutrición

Background: Short-term mortality in acute-on-chronic liver failure (ACLF) is driven by the interaction between hepatic decompensation, systemic inflammation, and extrahepatic organ failure. Although MELD, Child-Pugh, and CLIF-C ACLF are widely used for prognostic assessment, biomarkers that reflect inflammatory and tissue-remodeling pathways may improve early risk stratification. Galectin-3 (Gal-3), a macrophage-derived lectin involved in fibrosis, inflammation, and tissue injury, has been associated with

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

cirrhosis severity and adverse outcomes. Despite its biological relevance in cirrhosis, Gal-3 has received limited attention in ACLF, a syndrome defined by acute inflammation, organ failure, and early mortality. We evaluated admission Gal-3 in relation to ACLF severity, organ failure burden, short-term mortality, and prognostic performance beyond CLIF-C ACLF. **Methods:** In this prospective cohort study, patients admitted with acute decompensation were screened for ACLF according to EASL-CLIF criteria within the first 7 days of hospitalization. Serum Gal-3 levels were measured at admission by ELISA, and patients were categorized according to Gal-3 tertiles. The primary outcome was all-cause mortality at 7, 28, and 90 days. Prognostic performance was evaluated using Harrell's C-index. **Results:** A total of 131 patients with ACLF were included. Median age of 54 years and mean MELD score of 28 ± 7. Patients were stratified by serum Gal-3 tertiles: T1 < 14.6 ng/mL, T2 14.6–27.1 ng/mL, T3 > 27.1 ng/mL. Higher Gal-3 levels were associated with greater disease severity, with progressively higher MELD scores across T1, T2, and T3 (26 ± 5 vs. 29 ± 7 vs. 30 ± 8; p = 0.019), CLIF-C ACLF scores (49 ± 7 vs. 52 ± 11 vs. 56 ± 11; p = 0.006), and CLIF-OF scores [11 (10–12) vs. 11 (10–13) vs. 12 (11–14); p = 0.004]. The proportion of patients with ACLF grade 3 also increased across Gal-3 tertiles (20.5% vs. 34.1% vs. 48.8%; p = 0.013). Among individual organ failures, liver failure (34.1% vs. 52.3% vs. 69.8%; p = 0.001) and renal failure (27.3% vs. 47.7% vs. 53.5%; p = 0.033) increased significantly with higher Gal-3 levels, whereas other organ failures did not differ across tertiles. Adding Gal3 to the CLIF-C ACLF model improved discrimination for 7, 28, and 90-day mortality, with C-index values of 0.801, 0.766, and 0.718 compared with 0.782, 0.731, and 0.681 for CLIF-C ACLF alone. During 90-day follow-up, mortality increased stepwise across T1, T2, and T3 (48.8% vs. 72.1% vs. 79%; log-rank p < 0.001), with significantly reduced survival among patients with higher Gal-3 levels (Figure 1). **Conclusion:** Elevated serum Gal-3 levels identify patients with ACLF who have greater disease severity, higher liver and renal failure burden, and worse short-term survival. The addition of Gal-3 improved mortality discrimination beyond CLIF-C ACLF alone, supporting its potential role as an admission biomarker for prognostic stratification in ACLF.

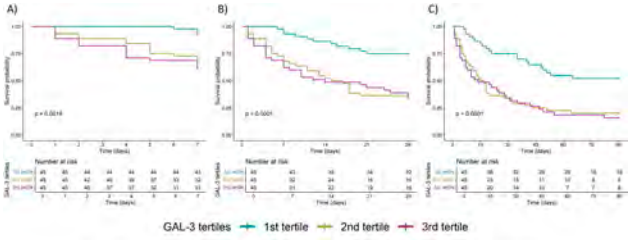

Figure 1. Kaplan–Meier survival analysis at 7, 28, and 90 days according to serum Gal-3 tertiles.

2043 | OMENTIN-1 DERIVED FROM M2-LIKE MACROPHAGES IN THE FIBROTIC LIVER MEDIATES THE HEPATOPROTECTION AGAINST ACUTE INSULT IN ACUTE-ON-CHRONIC LIVER FAILURE BY INHIBITING FERROPTOSIS SIGNALING

Yanrong Yang[1] Huixin Tang[2] Qi Yang[1] Xiaoxuan Liu[1] Li Bai[1] Yu Chen[1], [1]Beijing You'an Hospital, Capital Medical University, [2]Jining No.1 People's Hospital

Background: Acute-on-chronic liver failure (ACLF) is a life-threating clinical syndrome characterized by acute onset of hepatic dysfunction superimposed on underlying chronic liver disease, with high short-term mortality and limited effective therapeutic strategies. Omentin-1 is an adipokine predominantly secreted by visceral adipose tissue, which has been reported to exert protective effects against metabolic disorders and inflammatory responses. However, its specific role and underlying mechanism in the progression of ACLF remain to be elucidated. **Methods:** Control and fibrotic mice were challenged with D-GalN/LPS, omentin-1 levels were detected by WB, IHC and qPCR. Gain-of-function experiment (recombinant omentin-1) was conducted in ALF mice, and hepatic damage was assessed. The correlation between omentin-1 and M2 macrophage markers was analyzed. Macrophage depletion was performed in fibrotic mice, and omentin-1 expression was evaluated. Fibrotic mice upon macrophage depletion were treated with recombinant omentin-1, and hepatic injury was assessed. Ferroptosis levels were evaluated in fibrotic mice or ALF mice upon omentin-1 treatment. **Results:** The gene and protein expression of omentin-1 was significantly up-regulated in fibrotic mice compared to ALF mice, regardless of acute insult. Recombinant omentin-1 conferred mice enhanced resistance upon acute insult, as manifested by elevated survival rate, improved hepatic histopathology, and reduced levels of serum aminotransferases. Omentin-1 was co-localied with CD206, a representative M2 macrophage activation marker. Moreover, the expression of omentin-1 was positively correlated with the levels of M2 markers TGF-β and Arg-1. In addition, the administration of recombinant omentin-1 led to the reduced expression of M1 markers

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and elevated M2/M1 ratios. When we depleted M2-like macrophages in fibrotic livers, the gene and protein expression of omentin-1 was obviously decreased. Macrophage depletion in the fibrotic mice resulted in aggravated hepatic damage, however, the administration of recombinant omentin-1 restored hepatic function, as shown by decreased levels of aminotransferases. Ferroptosis levels assessed by MDA and GSH were remarkably reduced in the fibrotic livers compared with those in ALF mice, regardless of acute insult. On the other hand, recombinant omentin-1 also brought about the evident reduction in ferroptosis levels. Interestingly, the administration of ferroptosis inducer erastin destroyed the hepatoprotection mediated by recombinant omentin-1 against acute insult. **Conclusion:** Omentin-1 derived from M2-like macrophages in the fibrotic liver mediates the hepatoprotection against acute insult in ACLF by inhibiting ferroptosis signaling. Our work provides novel insights into the pathogenesis and treatment of ACLF.

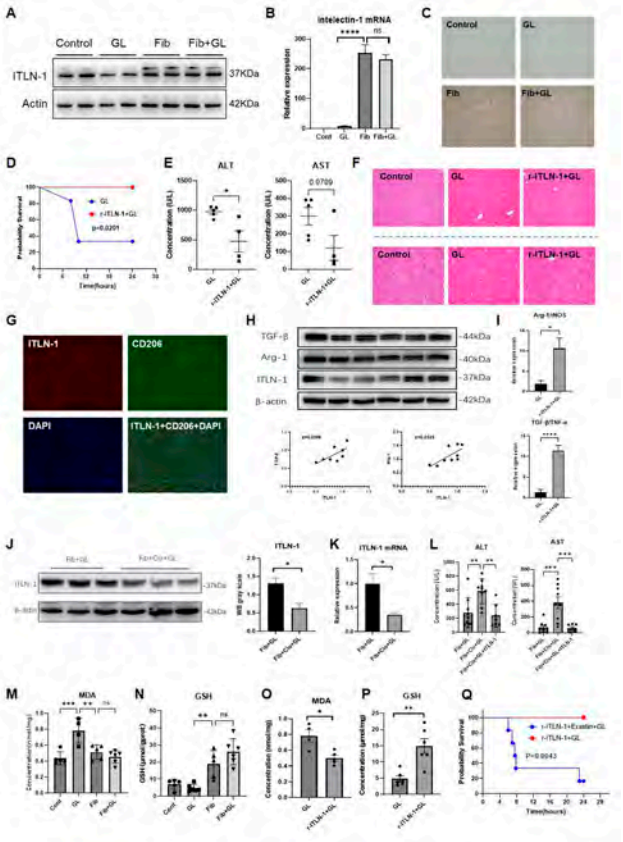

Figure: Omentin-1 (ITLN1) protects against ferroptosis-mediated liver injury by promoting M2 macrophage polarization in acute-on-chronic liver failur (ACLF). (A, B, C) Gene and protein expression of omentin-1 (ITLN1) was upregulated in fibrotic livers compared to acute liver failure (ALF) mice. (D, E, F) Administration of recombinant omentin-1 (r-ITLN1) conferred enhanced resistance to acute insult in ALF mice. (G, H, I) Immunofluorescence showed that ITLN1 co-localized with the M2 macrophage marker CD206. Western blot analysis revealed positive correlations between ITLN1 and M2 markers (TGF-β and Arg-1). Furthermore, r-ITLN1 treatment reduced M1 marker expression while increasing the M2/M1 ratio. (J, K, L) Depletion of M2 macrophages reduced ITLN1 expression and aggravated liver injury, whereas r-ITLN1 administration restored hepatic function. (M, N) Ferroptosis levels, assessed by MDA and GSH, were significantly lower in fibrotic livers compared with those in ALF mice, regardless of acute insult. (O, P) Administration of r-ITLN1 led to a significant reduction in ferroptosis levels. (Q) Erastin destroyed r-ITLN1-mediated hepatoprotection.

2044 | FLUX-CENTRIC COARSE-GRAINING OF HEPATIC METABOLISM CAPTURES ACUTE-ON-CHRONIC DYNAMICS IN ALCOHOL-ASSOCIATED LIVER DISEASE

Madison Shoraka[1] Rajanikanth Vadigepalli[2],
[1]University of New Mexico Health Sciences Campus,
[2]University of New Mexico School of Medicine

Background: Alcohol-associated liver disease (ALD) and its most severe manifestation, alcohol-induced hepatitis (AH), carry short-term mortality rates of 30–50%, yet therapeutic options remain limited. A central barrier is an incomplete understanding of the metabolic mechanisms driving hepatic failure. Existing frameworks largely focus on isolated pathway defects, but metabolic dysfunction in AH likely reflects coordinated dysregulation across interconnected subsystems. We propose that hyperammonemia, a hallmark of severe AH, arises not as a direct product of ethanol metabolism, but as an emergent property of resource competition between the glutathione, methionine, urea, and fatty acid biosynthesis cycles under oxidative stress. **Methods:** We developed a reduced-order, flux-centric model coarse-graining hepatic metabolism into four interacting metabolic modules (glutathione, methionine, urea, and fatty acid biosynthesis cycles) derived from the Human1 genome-scale metabolic network. Module interactions were encoded via a biochemically derived adjacency matrix. Patient-specific initial velocities were estimated from RNA sequencing data of 90 human liver biopsies spanning seven disease states using the Pheflux entropy-maximization algorithm. Ethanol was introduced as an external forcing term driving oxidative and metabolic burden, with resource reallocation governed by a priority-weighted allocation rule. Uncertainty quantification was performed over physiologically constrained parameter ranges using variance-based sensitivity analysis. **Results:** Across a broad parameter space, the model reproduced key features of ethanol-induced metabolic dysfunction: decreased methylation capacity, impaired nitrogen metabolism, mitochondrial glutathione depletion, and increased fatty acid biosynthesis. GSH depletion matched mouse experimental data within 5% at 2 and 6 hours post-ethanol exposure. Further, simulated corticosteroid response rates (70–76%) bracketed a published clinical benchmark of 75% without calibration. The trajectory space partitioned into four mechanistically distinct failure regimes defined by oxidative failure and metabolic

decompensation. Sensitivity analysis revealed that repeated ethanol exposure shifts system behavior from parameter-driven to interaction-dominated dynamics, consistent with loss of compensatory capacity. **Conclusion:** This coarse-grained, resource-allocation framework reproduces emergent features of ALD progression and identifies bifurcation-like stability thresholds separating recoverable from non-recoverable metabolic states. The results support a network-level view of ALD in which disease severity reflects coordinated subsystem dysregulation rather than isolated pathway failure, offering a mechanistically interpretable and computationally tractable tool for studying metabolic resilience and therapeutic response.

2045 | HEPATIC DECOMPENSATION AS A MORTALITY MULTIPLIER IN INFLAMMATORY BOWEL DISEASE HOSPITALIZATIONS: TRANSFER BURDEN, SEVERE INPATIENT OUTCOMES, AND RESOURCE USE IN A CONTEMPORARY NATIONAL ANALYSIS

Anas Al Mardini[1] Sabah Kulsum[2] Harika Dadigiri[2] Prathuima Guntipalli[2] Edward Barbarito[3], [1]NYMC, [2]NYMC-St Clare/St Mary hospital, [3]St Clare hospital

Background: Inflammatory bowel disease (IBD) is associated with hepatobiliary comorbidity, yet the inpatient impact of hepatic decompensation among IBD hospitalizations is not well defined. We evaluated whether compensated cirrhosis and hepatic decompensation were associated with mortality, transfer burden, severe inpatient outcomes, and resource use among U.S. IBD hospitalizations. **Methods:** We performed a retrospective cross sectional analysis of adult IBD hospitalizations in the 2020-2022 National Inpatient Sample. Crohn's disease and ulcerative colitis were identified using ICD-10-CM codes. Hospitalizations were categorized as IBD without cirrhosis/decompensation, IBD with compensated cirrhosis, or IBD with hepatic decompensation, defined by ascites, hepatic encephalopathy, variceal bleeding, spontaneous bacterial peritonitis, or hepatorenal syndrome. Outcomes included in-hospital mortality, acute-care transfer-in, sepsis, acute kidney injury (AKI), mechanical ventilation, discharge to facility, length of stay (LOS), and total hospital charges. Survey-weighted models adjusted for age, race/ethnicity, payer, and ZIP-code income quartile. **Results:** Among 929,629 weighted adult IBD hospitalizations, 2.08% had compensated cirrhosis and 3.34% had hepatic decompensation. Weighted mortality increased from 1.91% in IBD without cirrhosis/decompensation to 3.59% with compensated cirrhosis and 10.21% with hepatic decompensation. Compared with IBD without cirrhosis/decompensation, compensated cirrhosis was associated with increased adjusted odds of mortality (aOR 1.85, 95% CI 1.54-2.22), while hepatic decompensation was associated with a sixfold increase (aOR 6.24, 95% CI 5.67-6.88; both $P < 0.001$). Hepatic decompensation was also associated with higher odds of acute transfer-in (aOR 1.76, 95% CI 1.61-1.91), sepsis (aOR 2.68, 95% CI 2.52-2.84), AKI (aOR 2.58, 95% CI 2.43-2.75), mechanical ventilation (aOR 4.80, 95% CI 4.38-5.25), and discharge to facility (aOR 1.96, 95% CI 1.84-2.09). Resource use was markedly higher with hepatic decompensation, with mean LOS of 10.58 versus 5.49 days and mean charges of $150,476 versus $68,779. **Conclusion:** In this contemporary national analysis, hepatic decompensation was a powerful mortality multiplier among IBD hospitalizations and was associated with greater transfer burden, organ failure, mechanical ventilation, non-home discharge, and resource use. These findings support early recognition of hepatic decompensation as a high-risk inpatient phenotype in IBD and may inform triage, transfer, and multidisciplinary management strategies.

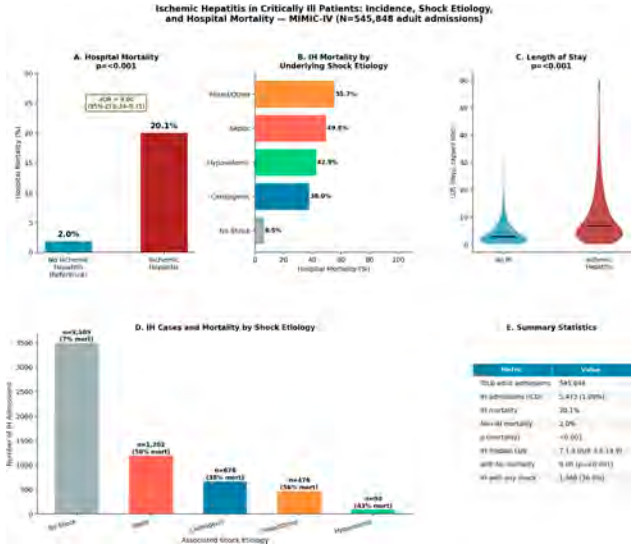
2046 | ISCHEMIC HEPATITIS CARRIES A 9-FOLD INCREASED ICU MORTALITY RISK: A POPULATION-LEVEL ANALYSIS OF 5,473 CASES



Innocent Lutaya[1] Vicki Oladoyin[1] Brian Xu[1] Emmanuel Marfo[1] Shanelle Brodeur[1] Abisola Ajayi[1] Shaikhoon Mohammed[1] Chima Amadi[1] Nicolas Bakinde[1] Henok Tafasse[1], [1]Morehouse School of Medicine

Background: Ischemic hepatitis (IH), or hypoxic hepatitis, arises from acute hepatocellular hypoperfusion and is encountered across diverse ICU populations. Despite its clinical significance, population-level incidence, shock-type-specific associations, and independent contribution to its mortality in a large unselected hospital cohort remain poorly characterized. **Methods:** We performed a retrospective cohort study using MIMIC-IV v3.1 comprising of 545,848 adult hospital admissions (2008-2022). IH was defined by ICD-10/ICD-9 codes for ischemic hepatitis, toxic liver disease, or acute hepatic failure (K76.89, K76.00, K72.00-11, K72.90-91, K76.2; ICD-9: 570.9, 573.0,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

573.1). Shock was classified by ICD codes into cardiogenic, septic, hypovolemic, and mixed/other subtypes. Primary outcome was in-hospital mortality. Logistic regression provided adjusted odds ratios (aOR) for IH-associated mortality; Mann-Whitney U test compared length of stay. **Results:** IH was identified in 5,473 admissions (1.00%; 58.7% male, median age 59). In-hospital mortality was 20.1% in IH vs. 2.0% in non-IH patients ($p < 0.001$; aOR 9.00, 95% CI 8.34-9.71). Median hospital LOS was 7.1 days (IQR 3.5-14.9) in IH vs. 2.8 days (IQR 1.1-5.6) in non-IH patients ($p < 0.001$). Shock was present in 36.0% of IH patients vs. 11.3% of non-IH patients ($p < 0.001$). Septic shock conferred the highest IH-associated mortality (49.8%), followed by cardiogenic shock (38.0%), hypovolemic shock (32.7%), and mixed/other shock (30.9%). IH without any shock carried 10.6% mortality, which suggested a 5-fold higher than non-IH controls. **Conclusion:** Ischemic hepatitis affects 1% of hospital admissions in a large tertiary-care database and independently carries a 9-fold increase in mortality risk. Shock is present in one-third of IH cases, with septic shock associated with highest mortality. IH without identifiable shock still carries substantial excess mortality, highlighting the importance of IH recognition across the full spectrum of hemodynamic instability.

2047 | IS PRIORITIZING ACLF-3 FOR LIVER TRANSPLANTATION COST-EFFECTIVE? A COST-EFFECTIVENESS ANALYSIS

Tomohiro Tanaka[1] Dan Shane[2], [1]University of Iowa, [2]University of Iowa College of Public Health

Background: Acute-on-chronic liver failure grade 3 (ACLF-3) carries 28-day transplant-free mortality approaching 80%, yet MELD-based liver transplant (LT) allocation does not account for this short-term acuity. Although expedited allocation for ACLF-3 has gained clinical interest, the economic implications of such a policy have not been formally evaluated. **Methods:** A state-transition (Markov) model was constructed from the US healthcare payer perspective to compare two allocation strategies for a simulated cohort of 10,000 adult LT candidates listed with ACLF-3: (1) standard MELD-based allocation and (2) a top-priority strategy analogous to Status 1A designation. Pre-transplant probabilities were derived from US registry data. Post-transplant outcomes for the priority arm were based on counterfactual survival estimates from a previously published marginal structural model applied to OPTN data. The model incorporated three post-transplant health states (Stable, Deteriorated, Death) over a 20-year horizon, with monthly Markov cycles. The primary outcome was the incremental cost-effectiveness ratio (ICER) at a contemporary willingness-to-pay threshold of $150,000/QALY. One-way deterministic and probabilistic sensitivity analyses (10,000 Monte Carlo iterations) were performed. **Results:** Under the priority strategy, 93% of candidates received transplantation compared with 75.6% under MELD-based allocation, with the difference attributable to averted waitlist deaths. Over 20 years, the priority strategy generated 74,208 QALYs at a total cost of $6.80 billion versus 62,558 QALYs at $5.43 billion for the MELD strategy. The incremental gain was 1.2 QALYs per patient at an additional cost of $137,015 per patient (ICER: $117,608/QALY), below the $150,000/QALY threshold. In one-way sensitivity analyses, the ICER remained below $150,000/QALY in most scenarios. > Probabilistic sensitivity analysis demonstrated a 95% probability of cost-effectiveness at $150,000/QALY, with the majority of simulations falling within the cost-effective region of the cost-effectiveness plane (**Figure**). **Conclusion:** Granting top-priority LT allocation to ACLF-3 candidates is likely cost-effective over a 20-year horizon in the US. These findings provide economic support for ACLF-specific allocation reform and warrant prospective validation.

2048 | PROGNOSTIC VALUE OF IMMUNITY, INFLAMMATION AND NUTRITION-RELATED BIOMARKERS FOR 28-DAY MORTALITY IN SEPSIS PATIENTS WITH CIRRHOSIS: A RETROSPECTIVE STUDY FROM MIMIC IV AND EICU

Yunhan Zhao[1] Jiamiao Shi[1] Kai Lu[1], [1]Xian Jiaotong University

Background: Sepsis in patients with cirrhosis is associated with markedly high short-term mortality, driven by a complex interplay of immune dysfunction, systemic inflammation, and hepatic decompensation. Reliable, readily available biomarkers for early risk stratification remain limited in this vulnerable population. This study aimed to identify and validate a robust immune-inflammatory-nutritional index for predicting 28-day mortality in cirrhotic patients with sepsis. **Methods:** Adult patients with a diagnosis of sepsis and cirrhosis were retrospectively enrolled from the MIMIC-IV database. Key candidate biomarkers were selected using the Boruta algorithm and LASSO regression. The independent prognostic value of selected indices was assessed by Cox proportional hazards regression, Kaplan–Meier survival analysis, and SHAP analysis. The primary index (PALBI) was further validated in an internal training/validation split and an external eICU cohort. Restricted cubic spline and segmented regression analyses were performed to explore dose-response and threshold effects, and subgroup analyses were conducted to assess effect modification. **Results:** Four indices (NPR, NMAR, BAR, and PALBI) were identified as candidate predictors, among which PALBI emerged as the most important. PALBI showed significant and consistent associations with 28-day mortality across internal and external validation cohorts. Restricted cubic spline and threshold analyses revealed a nonlinear relationship, with a critical inflection point at PALBI = -2.66, above which the risk of mortality increased sharply. The prognostic effect of PALBI remained stable across most subgroups, with a significantly stronger association observed in female patients. **Conclusion:** PALBI is a robust, externally validated biomarker for predicting short-term mortality in cirrhotic patients with sepsis. Its threshold-dependent association with mortality supports its use in early risk stratification, and may help guide individualized management strategies in this highrisk population.

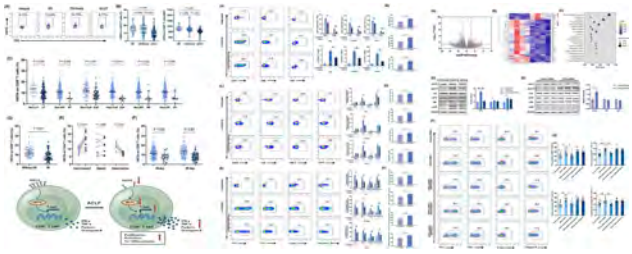
2049 | VISTA DEFICIENCY EXACERBATES THE DEVELOPMENT OF ACUTE-ON-CHRONIC LIVER FAILURE BY PROMOTING TC1 DIFFERENTIATION



Yao Zhang[1] Yidi Jia[2] Xueyun Zhang[2] Jiming Zhang[2], [1]Huashan Hospital, Fudan University, [2]Huashan Hospital

Background: Acute-on-chronic liver failure (ACLF) has a high early mortality, and there is abundant evidence that persistent inflammatory response and immune activation are the core pathogenesis of ACLF. However, the mechanism of immune disorder has not been fully clarified. Previous studies have shown that deficiency of V-type immunoglobulin domain-containing suppressor of T-cell activation (VISTA) exacerbates the progression of inflammatory diseases. Moreover, the immune response mediated by CD8+T cells can directly cause liver damage and is closely related to the dysregulation of inflammatory response in ACLF patients. Our study was designed to investigate the role of VISTA expression on CD8+T cells in the pathogenesis of ACLF. **Methods:** We assessed the expression and function of VISTA on CD8+ T cells in blood samples from healthy controls, patients with stable cirrhosis, and ACLF patients. Transcriptome sequencing was performed to determine the relevant pathways, which was then verified by Western blot. Inhibitors of relevant signaling pathways were added to the CD8+ T cells to explore the key signal mechanism. **Results:** In ACLF patients, the expression of VISTA was significantly reduced in the CD8+ T cells compared with healthy subjects and stable cirrhosis patients, especially in the effector memory and terminally differentiated effector memory cells with high CD45RA

expression subsets. The expression of VISTA on CD8+ T cells was associated with disease severity and prognosis. VISTA downregulation contributed to the activation and proliferation of CD8+ T cells, and enhanced the differentiation of type 1 cytotoxic T cells (Tc1), as well as heightened inflammatory cytokine secretion. This effect was mediated through the activation of the extracellular signal-regulated kinase 1 and 2 (Erk1/2) signaling pathway. **Conclusion:** Our study reveals that VISTA downregulation drives ACLF progression by amplifying Tc1-mediated inflammation. This insight not only advances the mechanistic understanding of ACLF pathogenesis but also nominates VISTA as a potential candidate for therapeutic intervention.

2050 | MAM-LOCALIZED SEC62 DRIVES APAP-INDUCED HEPATOTOXICITY THROUGH INTEGRATED STRESS RESPONSE AND MACROPHAGE RECRUITMENT

Junchao Lin[1], [1]Zhongshan Hospital Affiliated to Fudan University

Background: Acetaminophen (APAP) overdose causes acute liver failure (ALF) through endoplasmic reticulum (ER) stress and mitochondrial dysfunction, which trigger the Integrated Stress Response (ISR) and hepatocyte death. The upstream regulators of ISR activation remain unclear. We previously established that SEC62, localized at mitochondria-associated endoplasmic reticulum membranes (MAMs), regulates organelle homeostasis. This study investigates the spatiotemporal role of MAM-localized SEC62 in ISR activation and immune microenvironment remodeling during APAP-induced hepatotoxicity. **Methods:** Wild-type (WT), hepatocyte-specific SEC62 knockout (SEC62-HKO), and AAV-SEC62 overexpression mice received APAP. Liver tissues were collected across a 0-72h time course. We assessed histological severity and lipid accumulation at 24h using H&E and Oil Red O staining. We performed single-cell RNA sequencing (scRNA-seq) and spatial transcriptomics on liver tissues to evaluate transcriptional kinetics. Cell-cell communication analysis mapped ligand-receptor interactions and hepatocyte-macrophage crosstalk. **Results:** Combined scRNA-seq and spatial transcriptomics over a 0-72h APAP time-course showed a spatiotemporal positive correlation between hepatic SEC62 expression and ISR activation. *In vivo*, histological assessment at 24h showed SEC62-HKO attenuated, while AAV-SEC62 overexpression aggravated, APAP-induced liver necrosis and lipid accumulation, confirming SEC62 mediates injury severity. ScRNA-seq interactome analysis demonstrated that during peak SEC62 expression, hepatocytes promote macrophage infiltration via the Fn1-Cd44 axis, contributing to immune-mediated liver injury. **Conclusion:** MAM-localized SEC62 regulates APAP-induced ALF progression. Intracellularly, SEC62 upregulation mediates hepatotoxicity by activating the ISR. Extracellularly, SEC62 promotes macrophage recruitment via the Fn1-Cd44 axis. Our multi-omics and *in vivo* data show hepatocellular SEC62 drives APAP hepatotoxicity through intracellular stress and immune infiltration, identifying it as a potential therapeutic target.

2051 | MYELOID 5-LIPOXYGENASE ACTIVATION DRIVES SYSTEMIC INFLAMMATION AND LIVER INJURY IN ACUTE-ON-CHRONIC LIVER FAILURE

Huilan Tu[1] Jing Guo[2] Ruoqi Zhou[1], [1]The First Affiliated Hospital of Zhejiang University, [2]Stanford University School of Medicine

Background: Acute-on-chronic liver failure (ACLF) is characterized by systemic inflammation, immune dysregulation, and high short-term mortality. However, the lipid inflammatory circuits that sustain myeloid activation and propagate liver injury remain incompletely defined. We investigated whether myeloid 5-lipoxygenase (5-LOX) activation contributes to inflammatory amplification in ACLF. **Methods:** We integrated single-cell RNA sequencing, bulk transcriptomics, targeted plasma oxylipid metabolomics, synchronized peripheral-portal-hepatic venous sampling, liver tissue validation, hepatocyte assays, and pharmacologic intervention in murine acute liver failure and acute-on-chronic liver injury models. 5-LOX pathway activity was assessed across immune compartments, disease stages, circulating lipid mediators, liver tissues, and experimental injury models. Hepatocyte responses to 5-oxo-ETE were evaluated under subthreshold ferroptotic stress. **Results:** 5-LOX pathway activity was predominantly enriched in monocytes/macrophages and neutrophils and increased with disease severity. In ACLF, neutrophils shifted from an interferon-high state toward an IL1R2^{+} inflammatory amplification state, while cell-cell communication analysis supported a leukotriene-centered myeloid-to-neutrophil signaling circuit. Circulating 5-LOX-derived oxylipins, including 5-HETE, 5-oxo-ETE, and LTB4, were elevated in ACLF. Tri-venous profiling demonstrated consistent peripheral enrichment of 5-oxo-ETE compared with portal and hepatic venous compartments, supporting extrahepatic generation. In liver tissues, 5-LOX expression was associated with infiltrating inflammatory myeloid cells. Functionally, 5-oxo-ETE increased hepatocyte susceptibility to subthreshold ferroptotic stress and induced rapid ERK activation. Across multiple murine liver injury models, 5-LOX inhibition with zileuton attenuated systemic inflammation, liver injury, and ferroptosis-related injury signatures. **Conclusion:** ACLF is characterized by a compartmentalized myeloid 5-LOX axis that links inflammatory oxylipid production to neutrophil activation, systemic inflammation, and liver injury. These findings identify 5-LOX as a mechanistically relevant and potentially targetable inflammatory pathway in ACLF.

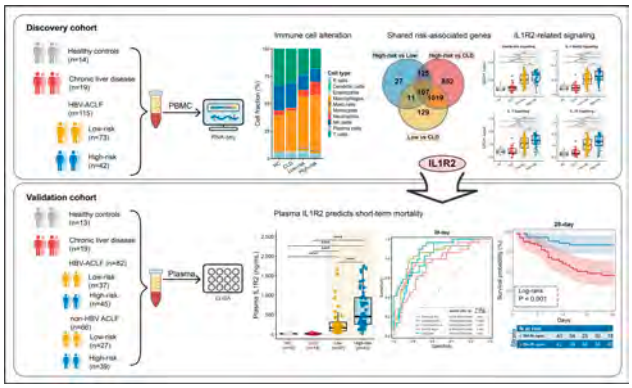
2052 | PBMC TRANSCRIPTOMICS REVEALS RISK-STRATIFIED MYELOID ACTIVATION AND IL1R2-ASSOCIATED INFLAMMATION IN HBV-ACLF



Jun Li[1] Xiao Wu[1] Xi Liang[1] Jiaojiao Xin[1] Dongyan Shi[1] Jing Jiang[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: Acute-on-chronic liver failure (ACLF) carries high short-term mortality, and risk stratification is clinically used to identify patients at increased risk of early death. This study aimed to characterize PBMC transcriptomic profiles across COSSH-ACLF II risk strata and evaluate plasma IL1R2 associated with risk and outcome in HBV-related ACLF. **Methods:** PBMC transcriptomes were profiled in healthy controls (n = 14), chronic liver disease (n = 19), low-risk HBV-ACLF (n = 73), and high-risk HBV-ACLF (n = 42), according to COSSH-ACLF II stratification. Representative immune genes were examined in experimental models, and plasma IL1R2 was measured by ELISA in independent HBV-related and non-HBV ACLF validation cohorts. **Results:** COSSH-ACLF II risk groups differed significantly in 28-day survival, with poorer survival in high-risk than low-risk HBV-ACLF (log-rank $P < 0.001$). High-risk ACLF showed increased monocyte, macrophage, and neutrophil signatures, together with reduced NK-cell and T-cell signatures, consistent with myeloid activation. Across risk-stratified comparisons, 107 shared risk-associated genes were identified, and leading immune pathways involved immune recognition, cytokine signaling, and innate effector responses. IL1R2 ranked among the top 10 shared risk-associated genes and was represented in four interleukin-related cytokine pathways, particularly IL-1 family signaling and IL-1 signaling. After immune-cell adjustment, IL1R2 remained associated with inflammatory signatures, whereas its inverse association with NK/T-cell signatures was largely attenuated. Representative genes from these immune categories were concordantly induced in acute liver failure mouse liver and LPS-stimulated RAW264.7 macrophages. Metabolic pathway alterations involved mitochondrial energy and carbohydrate metabolism, lipid and bile acid metabolism, amino-acid stress responses, and glycan remodeling, and were associated with IL1R2 and representative immune pathways. Plasma IL1R2 increased in high-risk patients, ACLF-2/3, and non-survivors with HBV-related ACLF. Plasma IL1R2 showed moderate discrimination for 28-day and 90-day mortality, with AUROCs of 0.738 and 0.723, and patients with plasma IL1R2 $\geq$304.58 ng/mL had poorer short-term survival. **Conclusion:** PBMC profiling revealed risk-associated myeloid activation and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

metabolic pathway alterations in HBV-related ACLF. IL1R2 represents a plasma-detectable candidate marker associated with higher risk, disease severity, and poor short-term outcome.

2053 | SINGLE-CELL MAPPING REVEALS CXCR2⁺ NEUTROPHIL–NETS AXIS DRIVING HEPATOCYTE NECROPTOSIS ACROSS ACLF ETIOLOGIES

Jun Li[1] Jinjin Luo[1] Xi Liang[1] Qian Zhou[1] Jiaojiao Xin[1] Jing Jiang[1] Meiqian Hu[1] Wei Qiang[1] Dongyan Shi[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: Acute-on-chronic liver failure (ACLF) is a life-threatening syndrome driven by dysfunction of multiple immune cell types and can arise from various etiologies. This study aims to comprehensively characterize the immune landscapes of ACLF across different etiologies and identify potential therapeutic targets. **Methods:** Single-cell sequencing was performed on peripheral blood mononuclear cells (49 samples) and hepatic non-parenchymal cells (12 samples) from ACLF, cirrhosis, chronic liver disease and healthy controls. Findings were validated by bulk transcriptomics, immunostaining, in vitro assays and murine ACLF models. **Results:** Single cell transcriptomic profiling of 594,255 cells revealed etiology dependent differences in the intrahepatic immune landscape. Hepatitis B virus (HBV)-ACLF was characterized by preserved but functionally exhausted lymphocytes, whereas non-HBV-ACLF showed enrichment of activated neutrophils and monocyte macrophage populations, while peripheral immune trajectories converged toward a terminal phenotype marked by aberrant myeloid expansion and amplified inflammatory cascades. CXCR2⁺ mature neutrophil was identified as an expanded subset in both the circulation and the liver of ACLF patients. Bulk liver transcriptomics and immunostaining from human and mouse samples confirmed enhanced neutrophil infiltration and widespread formation of neutrophil extracellular traps (NETs) in ACLF, which positively correlated with necroptosis pathways. In murine ACLF models, blockade of CXCR2 or inhibition of PADI4-dependent NET formation reduced NET generation, alleviated hepatic inflammatory injury, suppressed hepatocyte necroptosis, and improved survival outcomes. Clinically, plasma CXCR2 levels in ACLF patients correlated with liver injury, ACLF severity scores, and short-term mortality. **Conclusion:** CXCR2⁺ neutrophils represent a distinct subset driving hyperinflammation and immune exhaustion in ACLF, a syndrome that exhibits intrahepatic immune heterogeneity but peripheral convergence across different etiologies. Targeting the CXCR2–NETs axis may provide a promising immunomodulatory strategy for ACLF treatment.

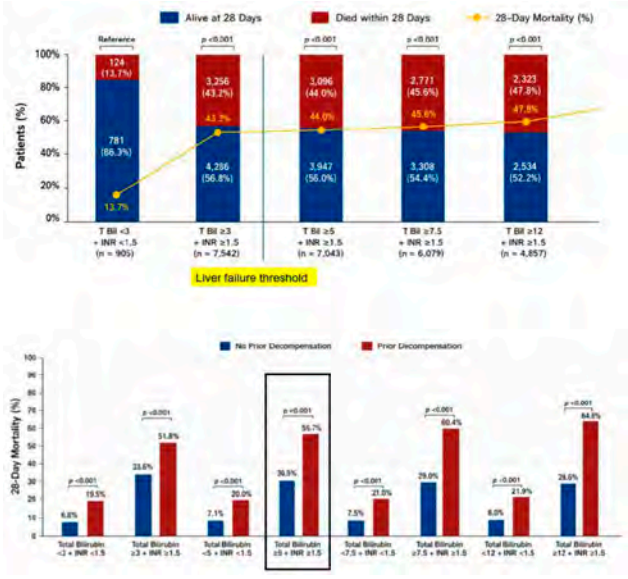
2054 | DEFINING THE LIVER FAILURE CUT-OFF FOR SERUM TOTAL BILIRUBIN AND PT-INR AND IMPACT OF PRIOR DECOMPENSATION IN A COHORT OF 10,058 PATIENTS WITH CIRRHOSIS REQUIRING NON-ELECTIVE HOSPITALISATION.



Ashok Kumar Choudhury[1] Garima Singhal[2] Shruti Reddy[3] Satender Pal Singh[1] Sanda Kavitha[2] Amanjot Kaur[2] Vinod Arora[2] Manoj Sharma[1] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences, [2]Institute of Liver and Biliary Science, [3]Institute of Liver Biliary Sciences

Background: Liver failure in patients with cirrhosis is associated with poor survival and the impact of prior decompensation is not well characterised among them. We aimed to identify bilirubin and INR thresholds associated with 28-day mortality in patients of cirrhosis with non-elective hospitalisation. **Methods:** This retrospective observational study included consecutive patients with cirrhosis admitted non-electively to the hospital. Clinical and laboratory parameters were retrieved from hospital medical records and analysed for 28-day survival outcomes. Previously established bilirubin and INR cut-offs were evaluated and compared according to index presentation and also correlated with index decompensation versus

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

prior decompensation status. **Results:** A total of 10,058 patients with chronic liver disease [SS1] were included. The mean age was 46.0 ± 11.5 years, and 86.0% were male. Alcohol-related liver disease was the commonest etiology (58.4%), followed by viral liver disease (17.6%). The cohort represented a relatively sick population, with mean serum total bilirubin of 14.83 mg/dL, mean INR of 2.24, and anoverall 28-day mortality of 36.4%. Using the cut-off of total bilirubin <3 mg/dL with INR <1.5, 905 patients were categorised into a low-risk group, with a 28-day mortality of 13.7%.Increasing the bilirubin threshold to ≥ 5 mg/dL with INR ≥ 1.5 was associated with a significant rise in mortality to 44.0%. Further escalation of bilirubin thresholds to ≥ 7.5 mg/dL or ≥ 12mg/dL with INR ≥ 1.5 did not significantly improve sensitivity, specificity, PPV, or NPV for predicting 28-day mortality (Figure). Among patients with prior decompensation,mortality was consistently higher across all categories ($p < 0.01$). Mortality increased to 55.7% for the bilirubin ≥ 5 mg/dL with INR ≥ 1.5 category, to 60.4% for bilirubin ≥ 7.5 mg/dL with INR ≥ 1.5, and from 21.9% to 64.6% for bilirubin ≥ 12 mg/dL with INR ≥ 1.5 in presence of prior decompensation. **Conclusion:** Increasing total bilirubin thresholds with elevated INR and history of prior decompensation identifies the group with high mortality. A cut-off of serum total bilirubin ≥ 5 mg/dL with INR ≥ 1.5 identifies high-risk patients early and represents a data driven and clinically relevant definition of 'liver failure' associated with adverse short-term outcomes in cirrhosis.

★ 2055 | ROLE OF PLASMA EXCHANGE IN ACUTE-ON-CHRONIC LIVER FAILURE DUE TO HEPATITIS B REACTIVATION

Jayashree Biswas[1] Shiv Kumar Sarin[1] Ankur Jindal[1] Ankit Bhardwaj[1], [1]Institute Of Liver And Biliary Sciences, New Delhi, India

Background: Hepatitis B virus reactivation is an important cause of acute-on-chronic liver failure, particularly in Asia. Plasma exchange has been used to reduce serum bilirubin, bile acids, inflammatory mediators, and circulating toxins in patients with acute liver failure as a bridge to liver transplantation. However, its benefit in HBV-related ACLF remains variable across studies. **Methods:** Records of 200 patients with ACLF due to hepatitis B reactivation observed over the past 10 years were reviewed; 8 were excluded due to incomplete baseline data. 39 of 192 (20%) underwent therapeutic plasma exchange (PLEX) based on clinical deterioration, worsening LFTs and coagulopathy. All patients received standard medical treatment (SMT) in the ICU, including nutrition, diuretics and protocol based antibiotics and antifungals. Propensity score matching was performed to select 68 patients; 34 each in the PLEX plus SMT and SMT alone group. HBV reactivation was defined by serum HBV DNA $>20{,}000$ IU/mL, reappearance of HBsAg and/or HBV DNA, or a two-log increase in HBV DNA from baseline with ALT flare >5 times ULN. All patients received potent antiviral therapy; tenofovir alafenamide or entecavir. Outcomes included changes in MELD, bilirubin, albumin, ALBI, creatinine, INR, and predictors of mortality. **Results:** The baseline demographics were comparable between PLEX and SMT groups, with 76.5% being male. The mean age of the entire cohort was 50.72 ± 14.07, and baseline MELD score was 28.95 ± 7.2. Both PLEX and SMT groups had low albumin level (2.78 ± 0.5 vs 2.8 ± 0.76; p = 0.82) and high creatinine levels (1.27 ± 1.35 vs 1.7 ± 1.59; p = 0.23), with AKI in 50% and 64.7% respectively. In the PLEX group, compared to baseline, the post-PLEX serum bilirubin decreased from 24.87 ± 11.15 mg/dL

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

to 20.89 ± 13.12 mg/dL and serum albumin increased from 2.86 ± 0.55 g/dL to 3.21 ± 0.55 g/dl (p 0.003). ALBI score improved from −0.73 ± 0.45 to −1.11 ± 0.51(p 0.001), serum albumin increased from 2.86 ± 0.55 g/dL to 3.21 ± 0.55 g/dl (p 0.003). However, the MELD score post-PLEX did not improve [29.15 ± 6.59 to 31.03 ± 11.56 (p = 0.23)], and it correlated with mortality(29.4%).Univariate analysis of predictors for mortality at baseline included MELD, creatinine, and haemoglobin. Multivariate analysis showed baseline creatinine [OR 1.57, 95% CI 1.03–2.4; p value 0.037] contributed to mortality at baseline. MELD was not an independent predictor of mortality (OR 0.97, 95% CI 0.88–1.07; p = 0.53). **Conclusion:** Plasma exchange in hepatitis B reactivation-related acute-on-chronic liver failure was associated with improvements in bilirubin and albumin levels, indicating short-term laboratory improvements. However, the MELD score did not improve significantly, and mortality was attributed to baseline disease severity, especially MELD score, and creatinine. Larger prospective studies are needed to determine whether plasma exchange offers a survival benefit in this high-risk population.

2056 | PRE-TRANSPLANT ICU LENGTH OF STAY IS A STRONG PREDICTOR OF MORTALITY AFTER LIVER TRANSPLANT IN ACLF PATIENTS

Nishita Sunkara[1] Jake MacDonald[1] Kathryn Thompson[1] Naveena Murugan[1] Vignesh Jayaraman Muralidharan[2] Michael Yu[1] Hima Veeramachaneni[1] Ram Subramanian[2] Nader Dbouk[1], [1]Emory University School of Medicine, [2]Emory University

Background: Acute-on-chronic liver failure (ACLF) is characterized by multiorgan dysfunction and high mortality rates. Although post-liver transplant (LT) survival is significantly better than transplant-free survival, outcomes remain worse compared to patients without ACLF. Identifying predictors of post-LT mortality is important to optimize candidate selection given the scarcity of liver allografts. We evaluated the impact of pre-transplant ICU length of stay on survival post-LT in ACLF patients managed in a dedicated Liver ICU (LICU). **Methods:** We conducted a retrospective study to evaluate the impact of pre-transplant ICU length of stay on post-liver transplant survival in 244 patients with ACLF compared to 572 patients without ACLF who underwent liver transplantation between 2014 and 2025 at Emory University. ChatGPT (OpenAI) was used solely to assist with language refinement and improve readability of the abstract. **Results:** Compared to non-ACLF patients, ACLF patients undergoing liver transplantation were younger (median age 54 vs 58 years, p < 0.001) and had significantly greater illness severity at transplant, including higher MELD (33 vs 17) (p < 0.001). Alcohol-associated liver disease was more common among ACLF patients (45% vs 26%) (p < 0.001). ACLF patients also had substantially higher rates of CKD/ESRD (48% vs 22%), vasopressor use (24% vs 1.1%), pre-transplant intubation (14% vs 0.7%), infection prior to transplant (44% vs 4.4%), and hemodialysis/CRRT use (55% vs 1.0%) (all p < 0.001). ACLF patients demonstrated significantly inferior patient survival on Kaplan-Meier analysis (both log-rank p = 0.004) with 1-, 3-, and 5-year patient survival rates of 84.8%, 82.7%, and 77.7% in ACLF patients versus 91.0%, 88.2%, and 85.6% in non-ACLF patients, respectively. ACLF patients also had significantly greater healthcare utilization, including longer total hospital length of stay (LOS) (median 26 vs 9 days, p < 0.001) and longer post-transplant ICU LOS (median 5 vs 2 days, p < 0.001). Pre-transplant ICU LOS was a strong predictor of outcomes, with each additional ICU day associated with a 5% increased risk of mortality (HR 1.05, 95% CI 1.03–1.07, p < 0.001) and graft loss (HR 1.05, 95% CI 1.03–1.07, p < 0.001). Post-transplant ICU LOS was also associated with worse patient survival (HR 1.01, 95% CI 1.00–1.03, p = 0.034) and graft survival (HR 1.01, 95% CI 1.00–1.03, p = 0.030). Patients with prolonged post-transplant ICU stays (≥ 3 days) had significantly worse patient survival on Kaplan-Meier analysis (log-rank p = 0.02). **Conclusion:** In a cohort of 244 ACLF patients who received LT, pre-transplant ICU LOS had a significant impact on post-transplant survival, with each additional ICU day associated with a 5% increase in mortality risk. These findings suggest that prolonged pre-transplant ICU stay may be an important consideration when evaluating transplant candidacy in this high-risk patient population.

2057 | CURRENT UTILISATION AND IMPACT OF PLASMA EXCHANGE TO TREAT ACUTE-ON-CHRONIC LIVER FAILURE PATIENTS IN USA: A NATIONAL INPATIENT SAMPLE ANALYSIS

Santhosh Kumar[1] Dylan Nunn[2] Anand Kulkarni[3] Ashish Goel[1] C Eapen[4] Ashwani Singal[2], [1]Christian Medical College, Vellore, India, [2]University of Louisville School of Medicine, [3]Asian Institute of Gastroenterology, [4]Christian Medical College

Background: Plasma exchange (PLEX) is a frequently used bridging therapy for patients with acute-on-chronic liver failure (ACLF) with studies reporting improved survival in patients with APASL and EASL defined ACLF (with no sepsis and shock). However, there is no data regarding utilisation of PLEX and its effect on in-hospital mortality in NACSELD defined ACLF which we aimed to assess. **Methods:** Using the National Inpatient Sample (NIS) database (2017–2023), we identified hospitalizations for ACLF based on NACSELD criteria. ICD-10 diagnosis and procedure codes were used. Patients with pre-existing neurologic or autoimmune conditions were excluded. PLEX-treated ACLF patients were matched to ACLF patients not receiving PLEX using propensity score matching (PSM). Matching variables included age, sex, liver disease etiology, comorbidities, and the need for invasive mechanical ventilation, vasopressors (shock), or renal replacement therapy (dialysis). Logistic regression was performed to identify independent predictors of in-hospital mortality. **Results:** Of 1,546,499 hospitalizations with cirrhosis, 207,362 (13.6%) met NACSELD ACLF criteria: Grade 1 (n = 163,217; 10.7%), Grade 2 (n = 38,965; 2.6%), and Grade 3 (n = 5,180; 0.3%). Only 267 (0.13%) patients underwent PLEX (Grade 1: 177, Grade 2: 80, Grade 3: 10). In a 1: 10 PSM cohort of ACLF grades 2 and 3 (42 PLEX vs. 420 SMT), in-hospital mortality was similar comparing the two groups (38% vs. 49.5%, p = 0.16). In a 1: 5 PSM cohort of Grade 1 ACLF (170 PLEX vs. 850 SMT), the PLEX group was younger and had lower rates of alcoholic cirrhosis, hepatic encephalopathy, and diabetes. However, the PLEX group had a higher prevalence of sepsis and required higher rates of mechanical ventilation and hemodialysis (Table 1). In-hospital mortality, total hospital charges, and length of stay were higher in the PLEX group. Among

Grade 1, after adjusting for confounders, in-hospital mortality was similar in PLEX vs. SMT groups (OR 0.92; 95% CI, 0.56–1.5). Independent predictors of mortality among Grade 1 were invasive ventilation (OR 4.7; 95% CI, 3.3–6.6), shock (OR 4.3; 95% CI, 2.1–8.6), and hemodialysis (OR 2.5; 95% CI, 1.7–3.7). **Conclusion:** PLEX is rarely utilized for patients with NACSELD defined ACLF in the US and is not associated with reduced in-hospital mortality. Prospective studies are needed to examine the benefit of PLEX in patients with ACLF in US before multiorgan failure sets in.

Table 1: Comparison between PLEX and SMT treated PS matched ACLF grade 1 patients from National In-patient Sample 2017-2023 cohort

Parameters	PLEX (N=170)	SMT(N=850)	P value
Age (Mean±SD)	51.1±18.8	58.1±12.3	<0.001
Sex (female)	78 (45.9%)	327 (38.4%)	0.08
Etiology			
Alcohol associated cirrhosis	51 (30%)	388 (45.6%)	<0.001
HCV cirrhosis	10 (5.8%)	43 (5%)	0.66

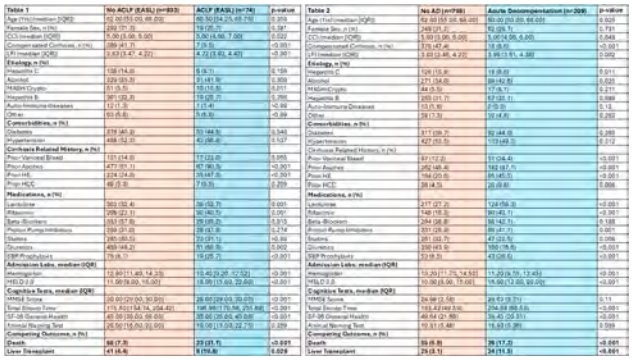
2058 | PREDICTION OF ACLF DEVELOPMENT IN A MULTI-CENTER OUTPATIENT CIRRHOSIS COHORT ACROSS NORTH AMERICA



Jasmohan Bajaj[1] Jacqueline O'Leary[2] Jennifer Lai[3] Puneeta Tandon[4] Patrick Kamath[5] Hugo Vargas[6] Philip Vutien[7] Guadalupe Garcia-Tsao[8] Scott Biggins[9] Daniela Goyes[8] Jawaid Shaw[10] Dorothea Kent[3] Tahira Shaikh[11] Katharina Staufer[12] Haley Obolewicz[13] Stephanie Tsai[14] Kaitlyn Wethey[15] Brian Bush[10] Florence Wong[16] Scott Silvey[10] K Rajender Reddy[17], [1]Virginia Commonwealth University, [2]Dallas VAMC, [3]UCSF, [4]University of Alberta, [5]Mayo Clinic Rochester, [6]Mayo Clinic Arizona, [7]University of Washington, [8]Yale University, [9]University of Pittsburgh, [10]VCU, [11]U Alberta, [12]VCU and Genfit, [13]Richmond VAMC, [14]UTSW, [15]U Penn, [16]University of Toronto, [17]University of Pennsylvania

Background: ACLF is variously defined worldwide using EASL, NACSELD and APASL definitions. Most ACLF diagnoses are made in inpatients, which is often too late to intervene. Predicting ACLF development in stable outpatients could improve prognostication & preventive strategies. **Aim**: Define determinants of ACLF development in a prospective multi-center outpatient etiology-controlled cirrhosis cohort. **Methods:** NACSELD-3 (North American Consortium for the Study of End-Stage Liver Disease) is a consortium that enrolls a compensated/decompensated outpatient cirrhosis cohort from 11 centers. Pts are etiology-controlled (no active alcohol/HCV/HBV) and followed systematically over 12 mths for hospitalizations. We excluded hospitalizations that were < 1 day, elective, or those when pt received LT. At baseline pts underwent frailty and cognitive testing and laboratory/medication evaluations. Determinants of time to ACLF by EASL, APASL, & NACSELD criteria and acute decompensation (AD) during hospitalizations were evaluated. Survival analysis for time-to-first ACLF & AD was performed accounting for the competing risks of death/LT. **Results:** Cohort : 1007 pts were included (Age 62 yrs, 69% men, 36% alcohol). 342 (33.9%) were hospitalized, of which 74 (22%) developed EASL-ACLF (Grade 1: 51, Grade 2: 22, Grade 3: 1), 15 (4.4%) developed NACSELD-ACLF & 11 (3.2%) developed APASL-ACLF. AD was seen in 209 (21%) patients. 9.0% died & 4.9% got LT.Baseline comparisons: EASL-ACLF pts had higher CCI , frailty index, were more likely to have decompensated cirrhosis/prior ascites/HE & related medications at baseline, had lower hemoglobin, higher MELD3.0, and worse cognition (Table 1). AD patients showed similar trends (Table 2).Time to event : Due to small N for others, we only did this for EASL-ACLF: ascites (adj. sHR: 3.28 [1.36-7.90], p = 0.008) & baseline MELD3.0 (adj. sHR: 1.14 [1.08-1.21], p < 0.001) were associated. Within hospitalized patients only, these associations persisted. Using AUC, the optimal MELD3.0 cutoff was 14 (AUC: 0.753, sHR: 3.93 [2.95-5.25], p < 0.001).*For time-to-AD*, ascites (adj. sHR: 2.79 [1.32-5.90], p = 0.007), HCC (adj. sHR: 2.18 [1.15-4.15], p = 0.017), PPI (adj. sHR: 2.54 [1.07-2.19], p = 0.019), & hemoglobin (adj. sHR: 0.81 [0.74-0.90], p < 0.001) were associated, which persisted on analysis of hospitalized patients only.

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Conclusion: Despite enrolling stable and etiology-controlled outpatients with cirrhosis, 34% required hospitalizations for acute decompensation over 12 months. 22% of these hospitalizations resulted in EASL-defined ACLF development. NACSELD and APASL-defined ACLF development were significantly lower. The presence of ascites tripled the risk, and each MELD3.0 point increased the risk by 14% of EASL-CLIF ACLF development. Even in stable outpatients, there is a substantial risk for ACLF development over one year, which can help early prognostication.

2059 | EXTERNAL VALIDATION OF THE SALT-M SCORE IN LIVING DONOR LIVER TRANSPLANTATION FOR ACUTE-ON-CHRONIC LIVER FAILURE

Bandar Aljudaibi[1] Saleh Alqahtani[2] Saad Alghamdi[3] Abdullah AlFhaid[4] Ehab Abu-Farhaneh[5] Khalid Bzeizi[4] LDLT registery.org[4], [1]King Faisal Specialist Hospital and Research Centre, [2]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [3]King Faisal Specialist Hospital and Research Center, [4]KFSH, [5]University of Toronto

Background: The Sundaram Acute-on-Chronic Liver Failure–Liver Transplant Mortality (SALT-M) score predicts 1-year post-transplant mortality in patients with severe ACLF undergoing deceased donor liver transplant (DDLT). Its performance in living donor liver transplantation (LDLT) remains unknown **Methods:** We conducted an external validation of SALT-M in two independent ACLF cohorts undergoing LDLT: one from King Faisal Specialist Hospital and Research Centre (KFSHRC), Riyadh, Saudi Arabia (n = 121) and 57 patients that represent a global cohort from the International LDLT Registry. Model performance was assessed by predicted mortality distribution, association with observed outcomes, and comparison with MELD-based scores **Results:** One-year mortality was 14.9% in the KFSHRC cohort and 21.1% in the global cohort. Thirty-day and 90-day mortality were 4.1% and 8.3% in the KFSHRC cohort and 14.0% and 21.1% in the global cohort. SALT-M–predicted mortality was $\leq$ 30% in 95.9% and 98.2% of patients, respectively. In the KFSHRC cohort, median predicted mortality was 11.4% (IQR 6.5) and did not differ between survivors and non-survivors ($p = 0.435$). SALT-M predictions were not associated with observed 1-year mortality (OR 1.005, 95% CI 0.930–1.087; $p = 0.889$). In contrast, MELD-Na and MELD 3.0 were significantly higher in non-survivors in the global cohort ($p = 0.027$ and $p = 0.015$). White blood cell count was associated with mortality in the KFSHRC cohort ($p < 0.001$). **Conclusion:** In LDLT-dominant ACLF cohorts characterized by stringent candidate selection and restricted risk distributions, SALT-M demonstrates limited standalone discrimination for post-transplant mortality. These findings indicate the importance of case-mix–aware external validation and suggest that SALT-M should be applied cautiously as an adjunctive risk stratification

2060 | PROTON PUMP INHIBITOR PROMOTES GUT–LIVER AXIS DISRUPTION AND IMPAIR LIVER REGENERATION DURING ACUTE-ON-CHRONIC LIVER FAILURE

Hitoshi Mori[1] Kosuke Kaji[1] Norihisa Nishimura[1] Yui Osaki[1] Tomihiro Iwata[1] Hiroki Kachi[2] Yuki Motokawa[1] Akihiko Shibamoto[1] Yuki Tsuji[1] Shinya Sato[1] Koh Kitagawa[1] Tadashi Namisaki[1] Hitoshi Yoshiji[1], [1]Nara Medical University, [2]Nara Medical Univesity

Background: Proton pump inhibitors (PPIs) are widely prescribed in patients with cirrhosis and have been associated with gut dysbiosis, bacterial translocation, and adverse clinical outcomes. However, their impact on the development and progression of acute-on-chronic liver failure (ACLF) remains unclear. This study investigated whether PPI administration aggravates ACLF and explored the underlying mechanisms, with a particular focus on disruption of the gut–liver axis. **Methods:** ACLF was induced in cirrhotic mice established by chronic carbon tetrachloride (CCl4) administration, followed by acute double-dose CCl4 and lipopolysaccharide (LPS) exposure. Esomeprazole was administered before and during ACLF induction. Liver injury, inflammation, hepatic regeneration, renal dysfunction, intestinal barrier integrity, and gut microbiota alterations were evaluated using histological and molecular analyses, microcirculatory blood flow assessment, intestinal permeability assays, and 16S rRNA sequencing. **Results:** Esomeprazole significantly reduced survival and aggravated liver injury in ACLF mice, accompanied by enhanced hepatic macrophage infiltration and upregulation of proinflammatory cytokines. PPI treatment increased portal LPS levels, impaired intestinal barrier function, and induced gut dysbiosis characterized by reduced microbial diversity and depletion of barrier-protective taxa. Hepatic regeneration was markedly suppressed, as evidenced by decreased hepatocyte proliferation and reduced HNF4α expression, along with a shift toward aberrant progenitor cell–driven repair associated with impaired angiogenic maturation. Furthermore, esomeprazole exacerbated acute kidney injury, renal inflammation, microcirculatory dysfunction, and intrarenal microthrombosis. **Conclusion:** PPI administration worsens ACLF by disrupting the gut–liver axis, amplifying endotoxin-driven inflammation, impairing effective hepatic regeneration, and exacerbating renal injury. These findings suggest that cautious use of PPIs may be warranted in patients with ACLF.

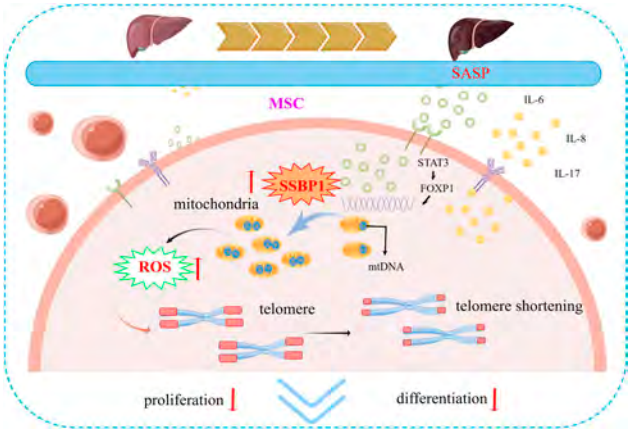
2061 | SENESCENT HEPATOCYTES HINDER UCMSCS PROLIFERATION BY UPREGULATING SSBP1 THROUGH THE IL-17 PATHWAY



Min Qiu[1] Jiaqi Pan[1] Ka Zhang[1], [1]the Third Affiliated Hospital of Sun Yat-Sen University

Background: End-stage liver disease (ESLD) is prevalent and has a poor outlook. Mesenchymal stem cells (MSCs) are promising for ESLD treatment, but their effectiveness varies among individuals, possibly due to a senescent microenvironment with chronic inflammation and mitochondrial dysfunction. Single-stranded DNA-binding protein 1 (SSBP1) is key in mitochondrial biogenesis and repair, but it's unclear if this environment impacts MSC proliferation via SSBP1 expression. **Methods:** Doxorubicin (DOX) induced senescence in THLE-2 cells, and we used a Transwell co-culture system to study the effects of senescent hepatocytes on UCMSCs, measuring SSBP1 expression, cell viability, and apoptosis. We confirmed IL-17 role in regulating SSBP1 after screening inflammatory factors. Mitochondrial structure and function were evaluated in UCMSCs with SSBP1 overexpression or knockdown using CCK-8, flow cytometry, TEM, and western blotting. **Results:** DOX triggered dose-dependent senescence in THLE-2 cells. Senescent hepatocytes paracrinally upregulated SSBP1 in UCMSCs, accompanied by impaired cell viability and enhanced apoptosis. Persistently high IL-17 induced SSBP1expression time dependently. Either SSBP1 overexpression or knockdown inhibited UCMSC proliferation. SSBP1 overexpression increased morphologically abnormal mitochondria without altering membrane potential and ROS. SSBP1 knockdown reduced mitochondrial number, disrupted structure and raised

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

membrane potential and ROS. COX IV was upregulated under both interventions. **Conclusion:** Senescent hepatocytes promote the upregulation of SSBP1 in UCMSCs via IL-17 signaling, thereby impairing the proliferative capacity of UCMSCs. Both the overexpression and knockdown of SSBP1 lead to the suppression of UCMSC proliferation. Thus, maintaining a balanced expression of SSBP1 is essential for preserving mitochondrial homeostasis and facilitating the proliferation of UCMSCs.

2062 | RACIAL DISPARITIES IN OUTCOMES OF ACUTE ON CHRONIC LIVER FAILURE IN THE UNITED STATES.

Ifelunwa Osanakpo[1] Cindy Onumajuru[1] Ihunanya Kanu[2] Cherechi Nwabueze[3] Emeka Stanley Obi[4] Chimezirim Ezeano[5], [1]Carle Foundation Hospital, [2]Baptist Memorial Hospital- Golden Triangle, [3]John H. Stroger Jr. Hospital of Cook County, [4]Brookdale University Hospital and Medical Center, [5]Advocate Aurora Healthcare

Background: Acute-on-chronic liver failure (ACLF) is characterized by multi-organ failure and is associated with worse outcomes. Few studies have assessed the impact of race on outcomes in patients with ACLF. We sought to determine whether racial and ethnic disparities affect outcomes in patients with ACLF. **Methods:** The study conducted a retrospective analysis of the National Inpatient Sample (NIS) Database from 2016 to 2022 to identify hospitalized patients with liver cirrhosis. ACLF was defined as two or more extrahepatic organ failures in patients with cirrhosis. The study population was divided into four major racial/ethnic groups: Non-Hispanic White (NHW), non-Hispanic Black (NHB), Hispanic, and Asian. The primary outcomes were in-hospital mortality, palliative referrals, liver transplantation, endoscopic therapy, and bleeding requiring transfusion. We conducted a weighted multivariate logistic regression to evaluate in-hospital outcomes. **Results:** Of 714,358 admissions for cirrhosis (2016 – 2022), 497,914 (69.7%) were NHW, 73,195 (10.2%) were NHB, 128,551 (18.0%) were Hispanic, and 14,698 (2.1%) were Asian. Hispanics were more likely to be younger (56.3 years vs. Asians 60.3, vs. NHB 58.1, vs. NHW 59.2 years). NHB were more likely to be female (NHB 40.0%; NHW 38.4%; Asians 36.1%; Hispanics 31.1%). Hispanics were more likely to be Medicaid-insured (38.1% vs. NHB 32.6% vs. Asians 27.4% vs. NHW 23.2%). NHB were in the lowest-income quartile and had a higher prevalence of comorbidities. ACLF severity was higher among NHB and Asians. Compared with NHW patients, in-hospital mortality was significantly higher in Black patients (aOR 1.11, 95% CI 1.07-1.45) and in Asian patients (aOR 1.23, 95% CI 1.15-1.31), and lower in Hispanics (aOR 0.92, 95% CI 0.89-0.95). Palliative referrals were similar among NHW, NHB, and Asian patients but were significantly lower among Hispanics than among NHW (aOR 0.78, 95% CI 0.67-0.85). The rates of liver transplantation were significantly lower among NHB (aOR 0.76, 95% CI 0.67-0.85) but higher among Asians (aOR 1.26, 95% CI 1.08-1.47). The rates of endoscopy were similar among NHB and Hispanics but significantly higher among Asians (aOR 1.09, 95% CI 1.04-1.15). The rates of bleeding requiring transfusion were significantly higher in all three racial/ethnic groups compared with NHW (NHB: aOR 1.12, 95% CI 1.08-1.16; Hispanic: aOR 1.25, 95% CI 1.21-1.29; Asians: aOR 1.39, 95% CI 1.30-1.48). **Conclusion:** Racial disparities in outcomes are observed among patients hospitalized with cirrhosis, highlighting the need for healthcare strategies stratified by race to mitigate the increased risk of adverse outcomes. Further research into the possible causes and social determinants of health that contribute to worse outcomes in Black and Hispanic patients is imperative.

2063 | DETERMINANTS OF PERSISTENT EARLY ACUTE KIDNEY INJURY AFTER LIVER TRANSPLANTATION: DISTINCT ROLES OF FRAILTY, RENAL RESERVE, AND PERIOPERATIVE INJURY

Ahmed Aboseria[1] Tasmia Promi[1] Michael Attanasi[1] Jade Pace[1] Justin Lin[1] Anwesha Satapathy[1] William Han[1] James Park[2] Nazia Qazi[2] Nabil Dagher[2] Sanjaya Satapathy[3], [1]North Shore University Hospital/Long Island Jewish Medical Center, [2]Northwell Health, [3]Northshore University Hospital/Northwell Health

Background: Frailty is increasingly recognized as an important determinant of outcomes in cirrhosis and liver transplantation (LT), but its relationship with postoperative acute kidney injury (AKI) remains unclear. We evaluated the association of frailty with persistent early postoperative AKI, renal recovery, and perioperative outcomes after LT. **Methods:** We performed a retrospective study of 208 adult LT recipients with pretransplant frailty assessment and postoperative renal data. Frailty was defined by Liver Frailty Index (LFI) ≥ 4.5. Persistent postoperative AKI was defined using KDIGO-based renal trajectory phenotypes with sustained AKI through postoperative day 7. Renal recovery was assessed by an estimated glomerular filtration rate (eGFR) at days 14, 30, and 90. Multivariable Firth logistic regression identified predictors of persistent postoperative AKI. **Results:** Among 208 recipients, 87 (41.8%) were frail and 100 (48.1%) developed persistent postoperative AKI. Frail recipients had lower baseline eGFR (63 vs 88 mL/min/1.73m², $p = 0.021$), higher prevalence of baseline eGFR < 60 mL/min/1.73m² (44.8% vs 28.9%, $p = 0.018$), greater perioperative transfusion requirements (22 vs 18 units, $p = 0.032$), and longer hospital stay (26 vs 19 days, $p = 0.0002$). However, frailty was not associated with persistent AKI, severe AKI, or renal recovery at 14, 30, or 90 days. In multivariable analysis, baseline eGFR < 60 mL/min/1.73m² was independently associated with lower odds of persistent AKI (OR 0.30, 95% CI 0.15–0.60, $p = 0.001$), while transfusion burden independently predicted persistent AKI (OR 1.017 per unit, 95% CI 1.002–1.033, $p = 0.033$). Frailty was not independently associated with persistent AKI (OR 0.72, 95% CI 0.38–1.34, $p = 0.31$). **Conclusion:** Frailty was associated with impaired baseline renal reserve, increased perioperative transfusion requirements, and prolonged hospitalization, but was not independently associated with persistent early postoperative AKI or renal recovery following LT. Persistent postoperative AKI appears to be driven predominantly by perioperative injury burden and renal adaptive physiology rather than frailty status alone. These findings suggest that frailty, renal reserve, and perioperative injury represent distinct but interconnected determinants of postoperative recovery after LT.

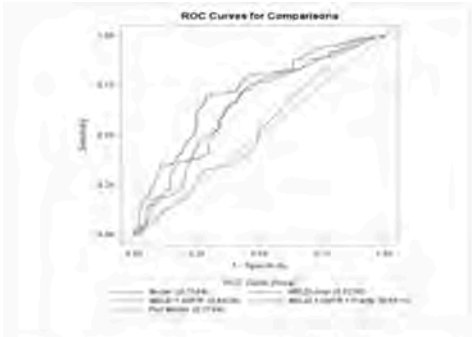

Figure 1. Receiver operating characteristic (ROC) curve analysis for prediction of persistent early postoperative acute kidney injury after liver transplantation. Receiver operating characteristic (ROC) curves demonstrating the discriminative performance of sequential predictive models for persistent early postoperative acute kidney injury (AKI). The MELD-only model demonstrated poor predictive ability (AUC 0.523). Addition of baseline renal reserve using pre-transplant eGFR improved discrimination (AUC 0.643), while inclusion of frailty provided minimal incremental improvement (AUC 0.652). The final multivariable model, incorporating frailty, baseline renal reserve, perioperative transfusion burden, and additional clinical covariates, demonstrated the highest predictive performance (AUC 0.718). These findings suggest that baseline renal physiology and perioperative injury burden contribute more substantially to persistent postoperative AKI risk than frailty status alone.

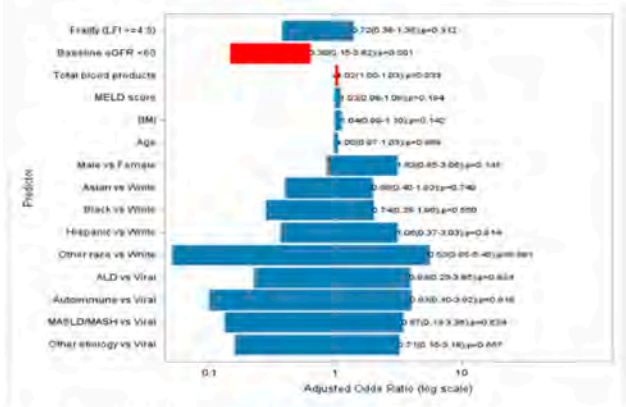

Figure 2. Multivariable predictors of persistent early postoperative AKI. Forest plot showing adjusted odds ratios and 95% confidence intervals from the missing-adjusted Firth penalized logistic regression model. Persistent postoperative AKI was defined using KDIGO-based early postoperative renal trajectory phenotypes. Red markers indicate predictors with $p<0.05$. Baseline eGFR <60 mL/min/1.73m² and total blood product utilization were independently associated with persistent AKI, while frailty was not independently associated.

2064 | PALLIATIVE CARE CONSULTATION MODIFIES MORTALITY IN PATIENTS WITH RENAL REPLACEMENT THERAPY UNDERGOING INPATIENT LIVER TRANSPLANT EVALUATION

Katherine Cooper[1] Kathy Nguyen[2] Adil Fazir[3] VanAnh Pham[3] Navine Nasser-Ghodsi[4], [1]Massachusetts General Hospital, Harvard Medical School, [2]University of Massachusetts School of Medicine, [3]University of Massachusetts Chan Medical School, [4]University of Massachusetts Memorial Health Care

Background: Inpatient liver transplant evaluation (iLTE) is usually reserved for the subset of patients with acute on chronic liver failure (ACLF) who are too ill for routine outpatient evaluation. Outcomes for those who do not undergo liver transplant (LT) during iLTE are not well described, particularly for patients initiated on renal replacement therapy (RRT). **Methods:** This is a retrospective analysis of iLTEs at our center from 2019–2023. Patients were categorized based on need for RRT during iLTE (RRT vs. no RRT). Inpatient mortality was assessed in the full cohort and in the subgroup of patients who did not undergo LT during the index admission. Logistic regression was used to examine the association between RRT, palliative care (PC) consultation, and their interaction with inpatient mortality. Estimated probabilities of mortality were calculated and reported as percentages. **Results:** One in three patients (35%, n = 94) required RRT during iLTE. The RRT group was younger (50 vs. 54, p = 0.01) but did not differ in race (p = 0.52), sex (p = 0.27), or liver disease etiology (p = 0.24) compared to no RRT. During iLTE, RRT patients had increased ICU admission (79% vs. 30%, < 0.01), vasopressor initiation (68% vs. 12%, p < 0.01), and PC consultation (16% vs. 9%, p = 0.01); they were also more likely to be approved for LT during index admission (59% vs. 39%, p < 0.01). Among those not transplanted (n = 197), inpatient mortality was significantly higher in the RRT group (71% vs. 11%, p < 0.01). On logistic regression, both RRT (OR 27.3, 95% CI 11.5-64.90) and PC consult (OR 3.5, 95% CI 0.8-15.0) were associated with increased mortality; there was also a significant interaction between RRT and PC consult (OR 0.12, 95% CI 0.02-0.85, p = 0.034), indicating attenuated mortality risk when both were present. The interaction variable remained significant after adjustment for age, sex, and MELD (aOR 0.08, 95% CI 0.01-0.72, p = 0.02). Estimated probability of inpatient mortality was 20% lower in RRT patients with a PC consult compared to no PC consult. In contrast, estimated probability of death was 18% higher in non-RRT patients with a PC consult compared to no PC consult. Among patients discharged without LT, RRT was associated with increased post-discharge 30-day mortality (Figure 1); post-discharge death was numerically lower in RRT patients with compared to without PC consult (16.7% vs. 40.0%). **Conclusion:** These results demonstrate RRT as a dominant risk factor for short-term mortality among patients undergoing expedited, inpatient evaluation for LT. PC consultation was associated with different mortality patterns according to RRT status, with lower predicted mortality among non-transplanted patients requiring RRT who received PC consultation. These findings support timely PC integration for patients requiring RRT during iLTE, particularly when LT candidacy is uncertain or transplantation is not achieved.

Group	All patients: Probability of Death	Patients without LT: Probability of Death
No RRT + No Palliative	7.7 (4.4-13.1)	9.7 (5.6-16.3)
No RRT + Palliative	20.0 (6.6-47.0)	27.3 (9.0-58.6)
RRT + No Palliative	48.1 (37.3-59.0)	74.5 (60.9-84.6)
RRT + Palliative	40.0 (19.2-65.2)	54.5 (26.8-79.7)

Figure 1: Survival following discharge from inpatient liver transplant evaluation without receiving a LT in patients with RRT (Yellow, n=20) vs. No RRT (Blue, n=124). Mortality was significantly greater in patients with RRT .

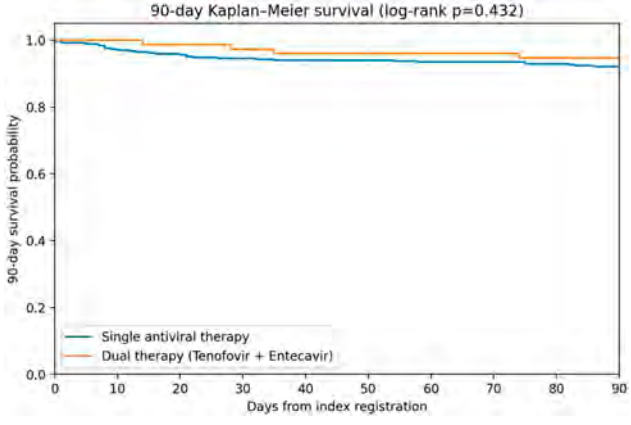
2065 | DUAL VERSUS SINGLE ANTIVIRAL THERAPY IN HBV-RELATED ACUTE-ON-CHRONIC LIVER FAILURE PATIENTS



Shreya Singh[1], [1]Institute of Liver and Biliary Sciences

Background: HBV-related acute-on-chronic liver failure (HBV-ACLF) carries high short-term mortality despite antiviral therapy. Data comparing dual antiviral therapy with potent single antiviral therapy remain limited. We compared survival, virological response, and clinical outcomes between the two strategies in HBV-ACLF patients. **Methods:** This retrospective observational cohort study included consecutive HBV-

ACLF patients admitted to ILBS, New Delhi over 17 years. Patients receiving single antiviral therapy (Tenofovir or Entecavir) between 2009–2017 were compared with those receiving dual antiviral therapy (Tenofovir + Entecavir) between 2018–2026. Baseline demographic, biochemical, virological, and clinical parameters including MELD, MELD-Na, CTP, AARC score, HE, ascites, AKI/HRS, and sepsis were analyzed. Primary outcomes included overall and 28-day mortality. Secondary outcomes included HBV DNA decline, MELD improvement, 90-day mortality, LT-free survival, and organ failure progression. Kaplan–Meier survival analysis and Cox regression were performed. **Results:** A total of 442 patients were included (single therapy: n = 367; dual therapy: n = 75). Baseline MELD (27.48 ± 7.28 vs 27.45 ± 7.62; p = 0.78) and HBV DNA levels (7.28 ± 1.12 vs 7.05 ± 1.01 log10 IU/mL; p = 0.28) were comparable between groups. Overall mortality (10.35% vs 9.33%; p = 0.81), 28-day mortality (5.45% vs 2.67%; p = 0.29), 90-day mortality (7.9% vs 5.3%; p = 0.47), LT-free survival (87.7% vs 88.0%; p = 0.94), ICU requirement, AKI/HRS development, and MELD improvement were similar between groups. A ≥2-log HBV DNA decline was numerically higher with dual therapy (28.4% vs 19.9%) but was not significant. HBV DNA decline modestly correlated with MELD improvement (r = 0.285; p < 0.001). Kaplan–Meier analysis showed no survival difference (log-rank p = 0.432). On multivariate Cox regression, increasing age (HR 1.04; p = 0.0049) and higher baseline MELD (HR 1.06; p = 0.0107) independently predicted mortality. **Conclusion:** HBV DNA decline correlated with MELD improvement. However, dual antiviral therapy did not demonstrate more rapid virological decline or survival benefit over potent single antiviral therapy in HBV-ACLF. Baseline liver disease severity and age remained the major predictors of mortality. Larger prospective studies are required to define the role of combination antiviral therapy in HBV-ACLF.

2066 | THERAPEUTIC PLASMA EXCHANGE (TPE) AS AN ADJUNCT TO STANDARD MEDICAL THERAPY IN ACUTE-ON-CHRONIC LIVER FAILURE: A PROSPECTIVE COHORT STUDY FROM INDIA

Apalak Garg[1] Virendra Singh[1] Bisman Khurana[2] Shweta Aghi[3] Nitesh Bassi[4] Tanvi Sood[1] Amandeep Singh[1] Narayana Yaddanapudi[1] Jahnvi Dhar[1] Sayan Malakar[1] Mehakdeep Kaur[1] Swapnil /[1] Kandagaddala Raja Sekhar[1], [1]Punjab Institute of Liver and Biliary Sciences Mohali Punjab India, [2]Punjab Institute of Liver and Biliary Sciences, Mohali Punjab India, [3]Punjab Institute Of Liver and Biliary Sciences, Mohali, Punjab, [4]Punjab Institute of Liver and Biliary Sciences, Mohali, Punjab India

Background: Acute-on-chronic liver failure (ACLF) is characterised by severe systemic inflammation, multi-organ dysfunction, and high short-term mortality. Therapeutic plasma exchange (TPE) has emerged as a potential adjunctive therapy because of its ability to remove inflammatory mediators and circulating toxins, particularly in developing countries where immediate liver transplantation is often unavailable. **Methods:** A study was conducted at a tertiary care liver institute. Ninety-two patients diagnosed with ACLF were enrolled and divided into SMT (n = 46) and SMT+TPE (n = 46) groups. Baseline demographic, clinical, laboratory, prognostic, and organ failure parameters were analysed. The primary outcomes were 28-day and 90-day mortality.Standard-volume TPE was performed using a centrifugal apheresis technique with exchange of 1.5 times the estimated plasma volume per session. Univariate and multivariate logistic regression analyses were performed to identify predictors of mortality. Absolute risk reduction (ARR), relative risk (RR), and relative risk reduction (RRR) were calculated to assess survival benefit. The incidence of sepsis and other TPE-related complications was also evaluated **Results:** A total of 92 patients with ACLF were included in the study. Alcohol was the predominant etiology in both groups (91.3% in SMT vs 93.5% in SMT+TPE). The SMT+TPE group had significant baseline disease severity, higher MELD (34.1 ± 6.5 vs 28.9 ± 5.7, p < 0.001), serum bilirubin (26.6 ± 9.2 vs 12.8 ± 6.1 mg/dL, p < 0.001), and INR (2.3 ± 0.6 vs 1.8 ± 0.4, p < 0.001). Serum creatinine (2.4 ± 1.3 vs 1.8 ± 1.0 mg/dL, p = 0.006) and prevalence of acute kidney injury (63.0% vs 43.5%, p = 0.048) were higher in the SMT +TPE group.Despite baseline severity the SMT+TPE group demonstrated lower mortality at 28 days (21.7% vs 30.4%) and 90 days (37.0% vs 47.8%). Survival benefit analysis showed an ARR of 4.3%, RR of 0.87, and RRR of 13.3%.Univariate analysis, elevated serum creatinine (OR 1.83, p = 0.005) and systemic

inflammatory response syndrome (SIRS) (OR 5.29, p = 0.005) were significant predictors of mortality. Multivariate analysis, SIRS emerged as the strongest independent predictor of mortality (adjusted OR 8.04, 95% CI 2.11–30.62, p = 0.002).TPE-related adverse events were generally mild and manageable, with fever, shivering, and electrolyte abnormalities being the most common complications. Sepsis is a major concern with extracorporeal therapies, including TPE; however, the incidence of sepsis in our cohort was relatively low (15%), which may be attributed to strict adherence to aseptic precautions and meticulous infection-control practices **Conclusion:** Therapeutic plasma exchange demonstrated a favourable trend toward improved short-term survival in patients with ACLF despite significantly greater baseline hepatic and renal dysfunction in the TPE cohort. Systemic inflammation was the strongest independent determinant of mortality.

Table 1: Comparison of study participants from the SMT and SMT plus TPE cohorts

Variables	Overall cohort (N=92)	SMT (n=46)	SMT plus TPE (n=46)
Age (years)	48.8 ± 12.9	56.0 ± 11.8	40.1 ± 12.7
Male	85 (92.4%)	42 (91.3%)	43 (93.5%)
Female	7 (7.6%)	4 (8.7%)	3 (6.5%)
Etiology			
Alcohol	85 (92.4%)	42 (91.3%)	43 (93.5%)
HCV	76 (82.6%)	40 (87.0%)	36 (78.3%)
Hematological and Biochemical Parameters			
Hemoglobin (g/dL)	9.1 ± 1.8	8.9 ± 1.9	9.3 ± 1.6
TLC (×10³/L)	11.2 ± 5.8	8.7 ± 4.2	13.6 ± 6.3
Platelets (×10³/mm³)	148.2 ± 74.5	112.4 ± 61.8	184.1 ± 72.6
Bilirubin (mg/dL)	19.7 ± 10.3	12.8 ± 6.5	26.6 ± 9.2
INR	2.1 ± 0.6	1.8 ± 0.4	2.3 ± 0.6
Creatinine (mg/dL)	2.1 ± 1.2	1.6 ± 1.0	2.4 ± 1.1
CRP (mg/L)	39.8 ± 21.5	34.2 ± 18.4	45.4 ± 23.1
Procalcitonin (ng/mL)	0.93 ± 0.54	0.76 ± 0.41	1.08 ± 0.61
Sodium (mEq/L)	130.8 ± 5.9	131.6 ± 5.3	129.9 ± 6.2
Prognostic Scores			
MELD score	31.5 ± 6.8	28.9 ± 5.7	34.1 ± 6.5
CLIF-C ACLF score	47.9 ± 8.1	46.3 ± 7.2	49.5 ± 8.6
AARC score	10.7 ± 2.1	9.8 ± 1.8	11.6 ± 2.0
Child–Pugh score	11.2 ± 1.5	10.6 ± 1.3	11.8 ± 1.4
Grade of ACLF			
Grade 1	14 (15.2%)	9 (19.6%)	5 (10.9%)

2067 | HISTOPATHOLOGICAL HETEROGENEITY AND ITS CLINICAL RELEVANCE IN ACUTE-ON-CHRONIC LIVER FAILURE

Jingran Jiao[1] Rui Zhao[1] Man Lai[2] Manman Xu[1] Hui Liu[3] Yu Chen[1], [1]Fourth Department of Liver Disease, Beijing You'an Hospital, Capital Medical University, [2]Department of Critical Care Medicine, Beijing You'an Hospital, Capital Medical University, [3]Department of Pathology, Beijing You'an Hospital, Capital Medical University

Background: Acute-on-chronic liver failure (ACLF) exhibits marked histopathological heterogeneity, while the clinical significance of different pathological injury patterns remains unclear. This study aimed to systematically evaluate the histopathological features of ACLF and analyze their associations with clinical disease severity. **Methods:** This single-center retrospective study included 78 ACLF patients who underwent liver transplantation for various etiologies. Histological assessments were performed by experienced pathologists. Semi-quantitative analyses were conducted for histopathological features including hepatocellular necrosis, cholestasis, portal inflammation, and steatosis. Patients were stratified according to the presence or absence of cirrhosis to evaluate histopathological heterogeneity in ACLF. Clinical parameters were further compared across different grades of pathological injury, and disease severity scores were applied to assess liver dysfunction and organ failure, in order to analyze the relationship between histopathological alterations and clinical severity. **Results:** Among the 78 ACLF patients who underwent liver transplantation, 52 (66.7%) had cirrhosis. Comparisons between cirrhotic and non-cirrhotic patients demonstrated significant differences in histopathological features, including hepatocellular necrosis (p = 0.009), bile duct proliferation (p = 0.041), liver progenitor cell-derived regeneration (p = 0.050), and ductular cholestasis (p = 0.047). With increasing grades of hepatocellular necrosis, ALT, AST, and serum sodium levels progressively increased. ALT levels in grades 1, 2, and 3 hepatocellular necrosis were 144 U/L, 285 U/L, and 713 U/L, respectively, while AST levels were 183 U/L, 271 U/L, and 541 U/L, respectively. Analysis by ductular cholestasis grades showed progressive increases in both TBiL (p = 0.006) and DBiL (p = 0.004). TBiL levels were 322 μmol/L in patients without ductular cholestasis and 488 μmol/L in those with severe ductular cholestasis, while DBiL levels were 209 μmol/L and 311 μmol/L, respectively. ALT and INR levels also increased with higher grades of portal inflammation. These findings indicate that more severe histopathological injury is associated with greater clinical severity, and that hepatocellular necrosis,

cholestatic injury, and portal inflammation may be associated with disease progression in ACLF. **Conclusion:** Patients with ACLF exhibit significant histopathological heterogeneity, with a certain correlation between different pathological damage patterns and clinical disease severity. Among these, pathological changes such as necrosis, cholestasis, and portal inflammation may be significant in reflecting disease activity and clinical deterioration, providing histological evidence for further understanding the pathological features and progression of ACLF.

2068 | DYNAMIC IMMUNE CELL INTERACTIONS IN LIVER FAILURE: MULTI-OMICS ANALYSES UNCOVER A HYPERINFLAMMATORY CD40+ MONOCYTE SUBSET ASSOCIATED WITH DISEASE PROGRESSION

YuanKang Luo[1] Dazhi Zhang[1] Qiongfang Zhang[1] Chang Shu[1] Zhiling Zhou[1] HuiMin Fan[1] ZhiHan Zhang[1] Yang Lv[1], [1]Chongqing Medical University

Background: Liver failure is a clinical syndrome associated with extremely high mortality. Its core pathological mechanism involves massive hepatocyte necrosis or apoptosis, ultimately leading to multi-organ dysfunction and failure. Increasing evidence demonstrates that immune dysregulation plays a pivotal role throughout the onset and progression of liver failure. Therefore, elucidating the dynamic alterations and interaction networks of specific immune cell subsets during liver failure development is of great significance for understanding disease pathogenesis. **Methods:** Randomization analysis, single-cell transcriptomic analysis, and composite machine-learning models were used to explore the associations between immune cell phenotypes and liver failure. Flow cytometry was constructed to confirm the abnormal distribution of immune cell subsets in patients with liver failure. **Results:** Mendelian randomization revealed a causal link between CD40 on CD14+CD16+ monocytes and liver failure. Single-cell transcriptomics and flow cytometry confirmed this monocyte subset upregulation in liver failure patients compared with healthy controls. Pseudotime trajectory analysis clarified the differentiation path from classical to intermediate (CD40 −→CD40+) and then to non-classical monocytes, with the CD40 state representing a specialized intermediate stage characterized by increased expression of genes such as HLA-DRB1, indicating enhanced inflammatory activity. Cell-cell communication analysis showed that overall immune interactions were weakened in ACLF, but CD40 intermediate monocytes exhibited enhanced interactions with immune cells such as B cells and NK cells through signaling axes including TNFSF14. Transcriptome profiling revealed a 'high inflammation–high metabolism' dual activation phenotype, with pathway enrichment in antigen processing, phagosome formation, and related pathways. WeIdentified differentially expressed genes and used machine learning methods to construct a prediction model. **Conclusion:** This study comprehensively delineates the interaction network between intermediate monocytes and liver failure, offering potential directions for early intervention strategies.

[3]Mahatma Gandhi Hospital Jaipur,, [4]Asian Institute of Gastroenterology, Hyderabad, [5]Amrita Hospitals, Kochi, [6]Mahatma Gandhi Hospital Jaipur, [7]Apollo Multispeciality Hospitals, Kolkata

Background: Biochemical liver-failure definitions for ACLF do not distinguish first-presentation from prior decompensation, despite their differing clinical trajectories. We evaluated whether prior decompensation defines a distinct acute decompensation (AD) phenotype and whether APASL, CLEARED and EASL-CLIF liver-failure thresholds retain consistent prognostic performance across phenotypes. **Methods:** In this multicentre cohort, 966 adults hospitalized with acute decompensation across four Indian centres were stratified as first-presentation (n = 364) or prior-decompensation (n = 602). Biochemical liver-failure thresholds were assessed using APASL criteria: bilirubin ≥ 5 mg/dL and INR ≥ 1.5; CLEARED criteria: bilirubin ≥ 7.5 mg/dL and INR ≥ 1.5; and the EASL-CLIF liver component: bilirubin ≥ 12 mg/dL. The primary outcome was 30-day mortality **Results:** Patients with prior decompensation were older, more often had MASLD-related cirrhosis (21.3% vs 10.7%), and had greater extra-hepatic organ failure. Thirty-day mortality was higher after prior decompensation than at first presentation (40.5% vs 30.5%; adjusted RR 1.31, 95% CI 1.10–1.56; p = 0.003) after adjustment for MELD and baseline infection, but was attenuated after additional adjustment for hepatic encephalopathy. In the overall cohort, APASL and CLEARED criteria modestly predicted 30-day mortality (OR 1.36 and 1.41), whereas the EASL-CLIF bilirubin threshold did not. Stratified analysis showed phenotype-dependent performance: biochemical thresholds predicted mortality better in prior-decompensation patients (APASL OR 1.57; CLEARED OR 1.67; EASL-CLIF OR 1.71). The bilirubin-only EASL-CLIF liver component captured the fewest deaths and showed significant phenotype-dependent prognostic behaviour. Those without biochemical liver failure thresholds are predominantly MASLD, have high baseline infection (57.1%) and predominantly extrahepatic organ failures driving mortality (33.6%). **Conclusion:** Prior decompensation identifies a clinically distinct, high-risk acute decompensation phenotype, with excess mortality partly mediated by hepatic encephalopathy. Established biochemical liver-failure thresholds show discordant prognostic performance across decompensation phenotypes. ACLF liver-failure definitions may require decompensation phenotype-aware recalibration

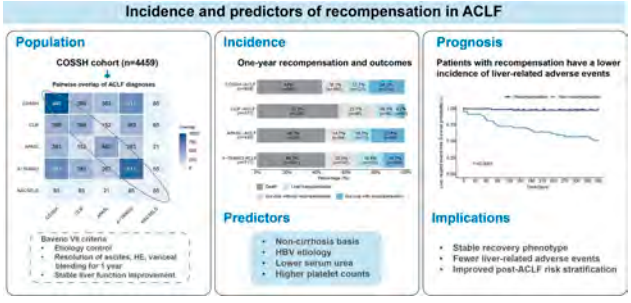
2070 | INCIDENCE AND PREDICTORS OF RECOMPENSATION IN ACUTE-ON-CHRONIC LIVER FAILURE



Jun Li[1] Wei Qiang[1] Jinjin Luo[1] Xi Liang[1] Jiaojiao Xin[1] Dongyan Shi[1] Jing Jiang[1], [1]The First Affiliated Hospital, Zhejiang University School of Medicine

Background: Acute-on-chronic liver failure (ACLF) is a complicated syndrome with high short-term mortality. However, the long-term trajectory remains unclear. We aimed to evaluate the incidence and predictors of recompensation in ACLF patients. **Methods:** A total of 4,459 enrolled patients with acute deterioration of chronic liver disease from the Chinese Group on the Study of Severe Hepatitis B (COSSH) prospective open cohort were assessed for recompensation at 1 year using Baveno VII criteria. **Results:** ACLF was identified in 948 patients by COSSH criteria (28/90/360-day liver transplant (LT)-free mortality: 30.2%/44.6%/53.7%), 398 by CLIF (45.3%/59.4%/72.4%), 480 by APASL (31.6%/45.8%/54.2%), 65 by NACSELD (52.8%/61.5%/75.5%), and 811 by A-TANGO (29.9%/45.8%/58.1%). The COSSH-ACLF II score

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

showed the highest discriminative ability for 28/90/360-day mortality among six prognostic scores. One-year recompensation rates among LT-free survivors eligible for assessment were 66.9% (97/145) under COSSH, 12.1% (4/33) under CLIF, 65.0% (39/60) under APASL, 14.3% (1/7) under NACSELD criteria, and 36.8% (35/95) under A-TANGO. After inverse probability weighting, one-year estimated recompensation rates in the whole ACLF populations were 24.2%, 4.7%, 22.8% and 14.7% under COSSH, CLIF, APASL and A-TANGO criteria, respectively. Recompensation was lower in patients with cirrhotic basis than those without (16.2% vs. 58.1%), in non-HBV-related ACLF than HBV-related ACLF (6.4% vs. 33.1%), and in ACLF grade 2/3 than grade 1 (8.2% vs. 33.3%). Cirrhotic basis, HBV etiology, serum urea level, and platelet count were major predictors among 37 candidate variables. During the second year after enrollment, recompensated patients had a lower incidence of liver-related adverse events than non-recompensated patients (3.0% vs. 57.9%). **Conclusion:** Recompensation is achievable in ACLF patients. Major predictors include cirrhotic basis, HBV etiology, serum urea, and platelet count.

2071 | THE ACLF RESCUE GAP: HIGH-INTENSITY DEATH WITHOUT PALLIATIVE CARE AND DISPARITIES AMONG HOSPITALIZATIONS WITH ACUTE-ON-CHRONIC LIVER FAILURE

Anas Al Mardini[1] Harika Dadigiri[2] Aatman Shah[2] Edward Barbarito[2], [1]NYMC, [2]NYMC-St Clare/St Mary hospital

Background: Acute-on-chronic liver failure (ACLF) carries high inpatient mortality, yet mortality alone does not capture the intensity or quality of end-of-life care. Whether patients with severe ACLF experience disparities in palliative care and high-intensity death without palliative support is poorly understood. We evaluated high-intensity death without palliative care as a national rescue-gap phenotype among U.S. ACLF hospitalizations. **Methods:** We performed a retrospective cross sectional analysis of adult cirrhosis hospitalizations in the 2020-2022 National Inpatient Sample. ACLF grade was defined by organ failure burden across kidney, respiratory, circulatory, neurologic, infectious, and bleeding/coagulation domains and categorized as cirrhosis without ACLF, ACLF-1, ACLF-2, and ACLF-3+. High-intensity care was defined as mechanical ventilation, dialysis, vasopressor use, or cardiopulmonary resuscitation. The primary outcome was high-intensity in-hospital death without a palliative care encounter. Secondary outcomes included mortality, palliative care, and high-intensity care. Survey-weighted models adjusted for age, sex, race/ethnicity, payer, and ZIP-code income quartile. A prespecified ACLF-3+ subgroup analysis evaluated disparities among the sickest hospitalizations. **Results:** Among 2,480,109 weighted adult cirrhosis hospitalizations, 34.8% had ACLF-1, 17.9% ACLF-2, and 13.3% ACLF-3+. Mortality increased stepwise from 0.57% without ACLF to 2.08% in ACLF-1, 7.31% in ACLF-2, and 34.54% in ACLF-3+. Palliative care use also increased with severity but remained limited, occurring in 2.89%, 5.82%, 11.96%, and 26.81%, respectively. High-intensity death without palliative care occurred in 0.22% of ACLF-1, 1.47% of ACLF-2, and 13.84% of ACLF-3+ hospitalizations. Among ACLF-3+ hospitalizations, Black (aOR 0.91), Hispanic (aOR 0.70), Asian/Pacific Islander (aOR 0.76), and Other race/ethnicity (aOR 0.85) patients had lower adjusted odds of palliative care. Conversely, these groups had higher adjusted odds of high-intensity death without palliative care: Black aOR 1.61, Hispanic aOR 1.31, Asian/Pacific Islander aOR 1.39, and Other race/ethnicity aOR 1.56. Medicaid and self-pay status were also associated with higher odds of high-intensity death without palliative care, while residence in the highest ZIP-income quartile was protective (aOR 0.76). **Conclusion:** In this contemporary national analysis, ACLF severity was associated with escalating mortality and high-intensity death without palliative care. Among ACLF-3+ hospitalizations, racial/ethnic minority and socioeconomically vulnerable patients had lower palliative care use and higher odds of high-intensity death without palliative support. These findings identify a measurable ACLF rescue gap and support earlier, equitable integration of hepatology palliative care for patients with severe ACLF.

2072 | FEMALE GENDER AND ALD PREDICT SUPERIOR PATIENT SURVIVAL AFTER LIVER TRANSPLANTATION IN ACLF

Jake MacDonald[1] Nishita Sunkara[1] Kathryn Thompson[1] Naveena Murugan[1] Vignesh Jayaraman Muralidharan[1] Hima Veeramachaneni[1] Andrew Yu[1] Ram Subramanian[2] Nader Dbouk[1], [1]Emory University School of Medicine, [2]Emory University

Background: Acute-on-chronic liver failure (ACLF) is characterized by multiorgan dysfunction and very high mortality rates. Although liver transplantation (LT) significantly improves survival, outcomes remain worse than in patients without ACLF. Identifying predictors of post-LT mortality is important to optimize candidate selection. We therefore evaluated the impact of demographic, clinical, and transplant-related variables—including age, gender, race, BMI, primary etiology, CAD, DM, CKD, PVT, and MELD score—on post-LT outcomes in ACLF versus non-ACLF patients. **Methods:** We conducted a retrospective study evaluating the impact of multiple clinical and demographic variables on post-liver transplant survival among 244 patients with ACLF and 572 patients without ACLF who underwent liver transplantation at Emory University between 2014 and 2025. ChatGPT (OpenAI) was used solely to assist with language refinement and improve readability of the abstract. **Results:** Female ACLF patients demonstrated significantly superior patient and graft survival compared to males (log-rank $p = 0.006$ and $p = 0.002$, respectively), with the survival advantage increasing over time. Five-year patient survival was 88.6% in females versus 71.4% in males, and this disparity was even more pronounced in ACLF Grade 3 patients, where 5-year survival was 83.5% in females compared to 57.8% in males ($p = 0.047$). Primary etiology was also highly predictive of outcomes in ACLF patients ($p < 0.0001$). Patients with alcohol-associated liver disease (ALD) had the best outcomes, with 1-, 3-, and 5-year survival rates of 92.4%, 92.4%, and 86.7%, respectively, compared to lower 5-year survival in MASH/metabolic liver disease (81.2%) and markedly worse outcomes in HCV-related ACLF (54.2%). In ACLF Grade 3 patients, ALD maintained stable survival of 86.8% at 1, 3, and 5 years, compared to 61.9% for MASH/metabolic disease and 50.0% for HCV at 5 years. Older age was not a significant predictor of survival in the overall ACLF cohort; however, among ACLF Grade 3 patients, age >55 years was associated with a clinically meaningful trend towards reduction in 5-year survival (55.9% vs 76.7%) ($p = 0.145$). Obesity (BMI ≥ 30) and diabetes mellitus were also associated with significantly inferior outcomes in ACLF patients at all time points, particularly in Grade 3 disease, where obese patients had a 5-year survival of 54.8% compared to 82.4% in non-obese patients ($p = 0.005$), and diabetic patients had markedly lower 5-year survival compared to non-diabetics (50% vs 70.2%, $p = 0.032$). Race, CAD, and portal vein thrombosis were not significant predictors of survival. **Conclusion:** Female sex and ALD as the primary etiology emerged as strong predictors of improved post-liver transplant survival in ACLF patients, whereas these associations were not observed in non-ACLF patients. These findings may help inform transplant candidate selection in this high-risk population

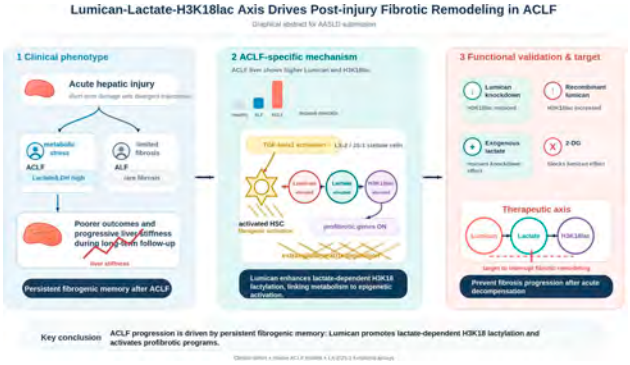
2073 | LUMICAN IS PROGRESSIVELY ACTIVATED DURING ACLF-ASSOCIATED FIBROGENIC REMODELING AND PROMOTES HEPATIC FIBROSIS THROUGH H3K18 LACTYLATION



Lingxiao Zhu[1] Qi Jiang[2] Yan Lv[3] Xiaowei Xu[3], [1]The First Affiliated Hospital of Zhejiang University, [2]Institute of Pathogen Biology, Chinese Academy of Medical Sciences & Peking Union Medical College, [3]he First Affiliated Hospital, Zhejiang University School of Medicine

Background: ALF and ACLF can both be precipitated by acute hepatic insults, but they differ in disease context and long-term trajectory. ALF usually occurs without pre-existing chronic liver disease and rarely progresses to sustained fibrosis after a single acute injury. In contrast, ACLF develops on a chronically injured liver, where acute decompensation may amplify inflammation, extracellular matrix deposition, and aberrant repair, promoting fibrosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

during recovery. However, mechanisms driving post-injury fibrotic progression in ACLF remain poorly understood. Lumican, an extracellular matrix proteoglycan implicated in fibrotic diseases, may regulate matrix remodeling and fibrogenic activation. We investigated whether lumican promotes ACLF-associated fibrosis through H3K18 lactylation. **Methods:** Clinical information from ACLF, ALF, and healthy controls was retrospectively collected from the First Affiliated Hospital, Zhejiang University School of Medicine; no human biospecimens were used. C57BL/6 mice were used to establish ACLF, ALF, chronic fibrosis, and healthy control models. Mouse liver tissues were analyzed by single-nucleus RNA sequencing and bulk RNA sequencing to define cell-type-specific and global transcriptional programs related to lumican expression and fibrotic remodeling. Liver injury and collagen deposition were assessed by hematoxylin and eosin staining and Sirius Red staining. qPCR and western blotting were performed to validate lumican expression, fibrogenic markers, and H3K18 lactylation. **Results:** During acute injury, ACLF patients showed elevated serum lactate and LDH levels, which were associated with poorer outcomes and progressive liver stiffness during long-term follow-up, whereas ALF patients rarely developed post-injury fibrosis. In mouse models, ACLF livers exhibited increased lumican mRNA and protein expression and enhanced H3K18 lactylation compared with healthy and ALF controls. TGF-β1-induced fibrogenic activation increased lumican protein expression in LX-2 and JS-1 cells. Functionally, lumican knockdown reduced H3K18 lactylation, whereas recombinant lumican increased H3K18 lactylation. Exogenous lactate rescued the inhibitory effect of lumican knockdown, while 2-DG blocked lumican-induced H3K18 lactylation, supporting a lactate-dependent lumican–H3K18lac axis in ACLF-associated fibrotic remodeling. **Conclusion:** ACLF progression involves a persistent fibrogenic memory after acute hepatic injury. Lumican promotes post-injury fibrotic remodeling by enhancing lactate-dependent H3K18 lactylation, linking metabolic dysregulation to epigenetic activation of profibrotic programs. The lumican–lactate–H3K18lac axis may represent a novel therapeutic target for preventing fibrosis progression after acute decompensation.

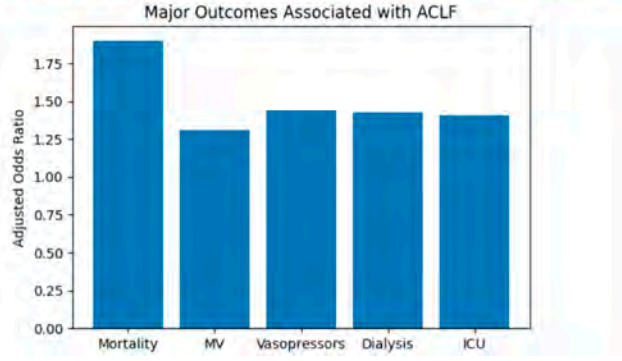
2074 | ACUTE-ON-CHRONIC LIVER FAILURE IN SEPSIS: NATIONAL TRENDS, PREDICTORS, AND OUTCOMES IN THE UNITED STATES

Eunice Omeludike[1] Cherechi Nwabueze[2] Obinna Orji[1] Eunice Aregbesola[3] Nzubechukwu Okeke[4] Sarpong Boateng[5] Ihunanya Kanu[6] Yetunde Akande[2], [1]Piedmont Athens Regional Medical Centre, [2]John H. Stroger Jr. Hospital of Cook County, [3]University of Missouri, Columbia, [4]Zucker school of medicine at Hofstra/Northwell at Vassar Brothers Medical Center, [5]Yale New Haven Health, Bridgeport Hospital, [6]Baptist Memorial Hospital- Golden Triangle

Background: Acute-on-chronic liver failure (ACLF) in the setting of sepsis is associated with high mortality, but its national burden, predictors, and outcomes remain incompletely defined. We evaluated trends, predictors, and outcomes of ACLF among septic hospitalizations in the United States using a nationally representative database. **Methods:** We conducted a retrospective cohort study of adult hospitalizations in the National Inpatient Sample (2016–2022). Sepsis was identified using ICD-10-CM codes. ACLF was defined as the coexistence of chronic liver disease (alcohol-associated liver disease, chronic hepatitis, fibrosis/cirrhosis, portal hypertension, or hepatorenal syndrome) and acute organ failure (hepatic failure, acute kidney injury, respiratory failure, or shock). Survey-weighted regression models assessed temporal trends, predictors of ACLF among septic patients with chronic liver disease, and outcomes associated with ACLF in the full sepsis cohort, adjusting for demographics, comorbidities, insurance, socioeconomic status, and hospital factors. **Results:** Among 41,015,057 adult hospitalizations, 3,900,437 (9.5%) involved sepsis. Chronic liver disease was present in 4.4% of septic admissions. ACLF occurred in 3.3% of all septic hospitalizations (approximately 1 in 30) and in 74.6% of septic patients with underlying chronic liver disease. The prevalence of ACLF among septic hospitalizations increased from 3.1% in 2016 to 3.6% in 2022 (adjusted OR per year 1.034, 95% CI 1.029–1.040; $P < 0.001$). Among septic patients with chronic liver disease, older age, higher comorbidity burden, chronic kidney disease, COPD, non-private insurance, and admission to large urban teaching hospitals were independently associated with ACLF. In the full sepsis cohort, ACLF was associated with significantly higher in-hospital mortality (aOR 1.90,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient



© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

95% CI 1.86–1.94), increased use of mechanical ventilation (aOR 1.31), vasopressors (aOR 1.44), and dialysis (aOR 1.43), and greater ICU-level intervention (aOR 1.41). ACLF was also strongly associated with gastrointestinal bleeding (aOR 33.1), hepatic encephalopathy (aOR 24.1), coagulopathy/DIC (aOR 1.83), and procedural interventions including paracentesis (aOR 17.7). Overall, ACLF was associated with higher complication burden (aOR 1.37) and increased palliative care consultation (aOR 1.70). **Conclusion:** ACLF complicates approximately 1 in 30 septic hospitalizations in the United States, and its prevalence is increasing. Among septic patients with chronic liver disease, nearly three-quarters develop ACLF. Its presence is associated with substantially higher mortality, organ support requirements, and healthcare utilization. These findings highlight the need for early recognition and risk stratification of ACLF in septic patients with chronic liver disease.

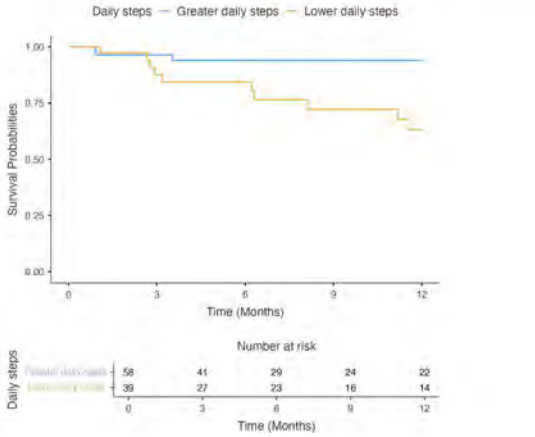
2075 | DAILY STEP COUNT AS A PROGNOSTIC INDICATOR OF SURVIVAL IN ADULTS WITH LIVER CIRRHOSIS



Araceli López Nepomuceno[1] Orfanel Sebastian Pineda-Arzate[2] Alondra Rosales-Padrón[2] Luis Fernando Rubio-Acosta[2] Claudia Daniela López-López[2] Osvely Méndez-Guerrero[2] Ignacio García-Juárez[2], [1]National Institute of Medical Sciences and Nutrition Salvado, [2]National Institute of Medical Sciences and Nutrition Salvador Zubirán

Background: Liver cirrhosis is a major cause of morbidity and mortality worldwide. Although several prognostic tools are available, the role of objective physical performance measures in predicting clinical outcomes remains unclear. For the above, the objective this study was to evaluate the prognostic impact of daily step count on survival, acute-on-chronic liver failure (ACLF), and liver transplantation in adults with cirrhosis. **Methods:** This prospective cohort study included 98 outpatients with liver cirrhosis in Mexico City. Functional status was assessed using the ECOG, Karnofsky Performance Status, and 6-minute walk distance. Daily step count was measured using pedometry (Garmin Vivosmart 5) as a 3-day average. Patients were followed for 12 months to evaluate hospitalization, ACLF, liver transplantation, and mortality. Statistical analyses included ROC curves, Cox regression, and Kaplan-Meier survival analysis. **Results:** Among 98 patients, 48 had decompensated cirrhosis. ROC analysis identified <3750 daily steps as the optimal cutoff for reduced physical performance. Lower daily step count was associated with older age ($p=0.018$) and lower Karnofsky scores ($p<0.001$), but not with Child-Pugh or MELD scores. Reduced daily step count was independently associated with higher risk of ACLF (HR 3.07, $p=0.048$), mortality (HR 3.02, $p=0.021$), and lower likelihood of liver transplantation (HR 0.52, $p=0.022$). Daily step count demonstrated greater prognostic performance than Karnofsky score and 6-meter walking speed. **Conclusion:** Lower daily step count was associated with ACLF and mortality independently of conventional liver severity scores, supporting its use as a simple and objective prognostic tool in cirrhosis.

2076 | CLINICAL PROFILE, ORGAN FAILURE PATTERN, AND PROGNOSTIC UTILITY OF SERIAL SCORING SYSTEMS IN ACUTE-ON-CHRONIC LIVER FAILURE

Anubhavsingh Pawar[1] Sumit Rungta[2], [1]king gerorge medical univeristy, [2]KGMU

Background: Acute-on-chronic liver failure (ACLF) is a rapidly progressive syndrome characterized by acute hepatic decompensation, systemic inflammation, multi-organ failure, and high short-term mortality in patients with underlying chronic liver disease. Owing to its highly dynamic clinical course, static prognostic scores assessed only at admission may inadequately predict outcomes. Serial reassessment of prognostic scores may provide superior prognostic accuracy; however, prospective data evaluating this approach in Indian populations remain limited. **Methods:** This prospective observational study included 130 patients diagnosed with ACLF according to APASL criteria at a tertiary care center in North India. Demographic, clinical, laboratory, microbiological, and organ failure profiles were recorded at admission. AARC, CLIF-C ACLF, MELD-Na, and Child–Turcotte–Pugh (CTP) scores were assessed serially on day 1, day 4, and day 7.The primary outcome was 28-day in-hospital mortality. ROC analysis was performed to compare prognostic accuracy of different scoring systems using AUROC, sensitivity, specificity, and optimal cutoff values. **Results:** A total of 130 ACLF patients were enrolled, predominantly middle-aged males with alcohol-related liver disease as the most common etiology and precipitating insult. The 28-day mortality rate was 33.1%, with most deaths occurring between day 7 and day 14. Jaundice, ascites, hepatic encephalopathy, coagulopathy, and renal dysfunction were the predominant clinical manifestations. Non-survivors had significantly higher bilirubin, INR, creatinine, leukocyte count, serum lactate, circulatory dysfunction, and ICU requirement.Liver failure was the most common organ failure followed by coagulation and renal failure. Mortality increased progressively with increasing organ failures, with no survival in patients with six organ failures. Grade III hepatic encephalopathy strongly predicted mortality with 62.8% sensitivity and 94.3% specificity.Among prognostic models, AARC showed the best baseline predictive accuracy on day 1 (AUROC 0.788). Serial monitoring significantly improved prognostic performance, with AARC AUROC increasing to 0.955 on day 4 and 0.965 on day 7. Persistently elevated day 7 AARC scores (>12) were strongly associated with mortality and need for urgent liver transplantation evaluation. **Conclusion:** ACLF is associated with high short-term mortality, particularly in patients with advanced hepatic encephalopathy and multiple organ failures. Serial AARC assessment demonstrated superior prognostic accuracy compared with single baseline evaluation. Daily score monitoring during the first week may help identify high-risk patients requiring aggressive organ support and early liver transplantation evaluation.

Table 30: Summary Table for Comparison efficiency of different prognostic scores at different days of assessment for prediction of in-hospital mortality as per Receiver Operator Characteristic Curve

SN	Type of score	AUC±SE	95% CI	'p' value	Sensitivity	Specificity	Cut-off value	J-Index
Day 1								
1.	MELD-Na	0.639± 0.054	0.539-0.744	0.010	39.5%	88.5%	37.50	0.280
2.	CLIF-ACLF	0.765± 0.047	0.672-0.857	<0.001	62.8%	88.5%	52.50	0.513
3.	CTP	0.738± 0.048	0.644-0.833	<0.001	65.0%	73.6%	12.50	0.387
4.	AARC	0.788± 0.046	0.697-0.879	<0.001	81.4%	70.1%	10.50	0.515

2077 | INVESTIGATING THE ASSOCIATION OF STATIN INTENSITY WITH REDUCTION IN RISK FOR HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC LIVER DISEASE

Pranav Jayakumar[1] Naveen Raj[1] Yash Gupta[1] Resham Ramkissoon[2], [1]NEOMED, [2]University Hospitals

Background: Statins have demonstrated chemopreventive potential against hepatocellular carcinoma (HCC) in chronic liver disease (CLD), with meta-analyses showing a 40–50% risk reduction. However, no study has evaluated whether the ACC/AHA-defined statin intensity classification (high, moderate, low) differentially affects HCC risk. The objective of this study is to evaluate the association between statin intensity and incident HCC across hepatitis C virus (HCV), alcohol-associated liver disease (ALD), and metabolic dysfunction-associated steatotic liver disease (MASLD). **Methods:** This retrospective cohort study utilized the TriNetX federated research network. Adults with CLD attributable to HCV, ALD, or MASLD were stratified into high-, moderate-, and low-intensity statin groups per 2026 ACC/AHA guideline classifications. Sustained statin use was confirmed by requiring prescriptions within 1 year, 1 to 2 years, and 2 to 3 years of diagnosis. Within each etiology, pairwise propensity score-matched cohorts were constructed. Cox proportional hazards regression was used to compare time to HCC. **Results:** No statistically significant differences in HCC risk by statin intensity were observed within any etiology after applying sustained-use criteria. In MASLD, hazard ratios were 0.966 (95% CI 0.714–1.308, p = 0.53) for high vs. moderate, 0.844 (0.45–1.586, p = 0.29) for high vs. low, and 0.798 (0.431–1.479, p = 0.42) for moderate vs. low. In HCV, high vs. moderate showed an HR of 0.91 (0.677–1.223, p = 0.91), high vs. low 0.969 (0.47–1.998, p = 0.66), and moderate vs. low 0.93 (0.453–1.909, p = 0.41). In ALD, only the high vs. moderate comparison was analyzed, as the low-intensity group had insufficient sample size for reliable analysis; this comparison yielded an HR of 0.673 (0.419–1.083, p = 0.62). Despite the absence of individual significance, point estimates in ALD suggested a trend favoring higher-intensity therapy. **Conclusion:** In this large retrospective cohort requiring sustained statin use, statin intensity was not significantly associated with differential HCC risk across HCV, ALD, or MASLD. However, a trend toward greater HCC risk reduction with higher-intensity statins was observed in ALD, suggesting this etiology may warrant further investigation in prospective studies. The lack of significance may reflect reduced statistical power after applying strict sustained-use exposure definitions, and future studies with larger sample sizes may be needed to clarify these associations.

Background: Acute-on-Chronic Liver Failure (ACLF) Type A is a liver centric definition by APASL which is characterized by high short term mortality. A liver transplantation (LT) vis required early in the course of ACLF in non-responding patients. Often LT is not feasible in view of extrahepatic organ failure, donor fitness/unavailability, or non-availability of LT. **Methods:** The study was done to determine the percentage of patients with ACLF, who could undergo LT, and determinants of conversion to LT. This study included 1043 patients from the APASL ACLF Research Consortium (AARC) database, in year 2025. **Results:** The study population aged 44.5 ± 11.4 years, 85% of the patients were male. The jaundice to hospital admission interval was 18.3 ± 7.8 days. Alcohol was the most common acute etiology (n = 475, 45.54%), followed by hepatitis B (n = 143, 13.71%). Alcohol was the chronic etiology in 67.1% patients. A total of 80 (7.6%) patients underwent LT. Overall mortality was 48%, which was significantly more in the non-LT group (50.4%), versus 25% in the LT group, p < 0.001. The MELD and AARC scores were not significantly different at baseline (MELD 29.9 ± 5.4 and 29.2 ± 6.7, AARC 9.04 ± 1.8 vs 9.1 ± 1.4). The MELD score at day 7 was significantly higher in the non-LT group (26.8 ± 8.6 vs 22.1 ± 2.6, p 0.017). The following parameters were significantly different between the non-LT and LT groups: a delayed presentation (duration from jaundice to admission, 18 ± 7 vs 15 ± 5 days, p < 0.001), circulatory failure (63% vs 22%, p < 0.001). The presence of renal failure at presentation was higher (26% vs 16%) but not statistically significant (p 0.062) in the non-LT group. Patients who underwent LT had higher bilirubin (21.8 ± 19.9 m/dl vs 19.1 ± 9.4, p 0.022), lower total leucocyte count (9.4 ± 6.7 vs 15.5 ± 15 x 10^3, p < 0.001), higher hemoglobin (11.5 ± 1.6 vs 10.3 ± 2.6, p 0.003), lower platelet count (100.9 ± 63.6 vs 143.2 ± 86.9 x 10^3, p < 0.001) and higher INR (2.5 ± 0.5 vs 2.3 ± 0.5, p < 0.001). **Conclusion:** The mortality of patients with ACLF was 50.5% in the non-LT group. Only 7.6% patients with ACLF could have an LT. It represents a big unmet need. Extrahepatic organ failure appears to be significant barrier to LT.

2079 | ◆ ADVANCED-PRACTICE-NURSE-LED LIFESTYLE INTERVENTION AFTER AUTOMATED MASLD CASE-FINDING IN PRIMARY CARE: 24-WEEK OUTCOMES FROM LIVERSEEK

Laura Suárez[1] Carmen Corps[2] María Sasía[1] María Teresa Hernando[2] Susana Sanchez Berdial[2] Andres Conthe[2] Sonia Irisarri[2] Eduardo Montenegro[2] Zhanhui Wang Jiang[2] Jacobo Caride[1] Carmen Lorenzo[2] Rafael Bañares[3] Magdalena Salcedo[2] Luis Ibáñez Samaniego[2], [1]Hospital General Universitario Gregorio Marañon, [2]Hospital General Universitario Gregorio Marañón, [3]Universidad Complutense de Madrid

Background: Lifestyle modification remains the foundation of MASLD management, including in patients with significant fibrosis or steatohepatitis, but scalable primary-care (PC) delivery models are limited. LiverSeek is a laboratory-driven, passive case-finding program that identifies PC patients with metabolic risk and elevated FIB-4. We assessed 24-week changes in liver and metabolic parameters after a structured advanced-practice-nurse (APN)-led intervention in LiverSeek-identified patients with abnormal non-invasive tests (NITs). **Methods:** Patients identified through LiverSeek at 11 PC centres in Madrid (serving ~350,000 residents) with elevated FIB-4 underwent reflex second-line NITs. Those with ≥ 1 positive NIT (VCTE ≥ 8 kPa, ELF ≥ 9.8 or MASEF ≥ 0.33) were referred to an APN visit including baseline anthropometry/BIA, Mediterranean-diet and physical-activity assessment and structured barrier review. Personalised SMART intervention included brief Mediterranean-diet counselling, progressive physical-activity prescription and weekly self-weighing. Reassessment at 24 weeks included VCTE (LSM, CAP), liver biochemistry, HbA1c and FIB-4. Paired changes were tested with Wilcoxon signed-rank using available paired data; responder analyses used prespecified thresholds. **Results:** 146 patients with ≥ 1 positive baseline NIT completed paired 24-week assessment (age 61.5 ± 6.0y, 32% female, BMI 32.0 ± 4.8, T2D 67%, hypertension 62%). Significant improvements were observed: LSM 9.8→9.0 kPa (Δ−0.86; $p = 0.0001$), CAP 301.5→283.4 dB/m (Δ −18.1; $p < 0.0001$), ALT 67.0→46.9 U/L (Δ−20.1; $p < 0.0001$), AST 51.2→38.4 U/L (Δ−12.9; $p < 0.0001$), GGT 107.6→77.3 U/L (Δ−30.4; $p < 0.0001$), HbA1c 7.01→6.50% (Δ−0.51; $p < 0.0001$) and FIB-4 2.11→1.86 (Δ−0.25; $p < 0.0001$). Responder rates were: LSM reduction $\geq 20\%$, 25%; CAP reduction ≥ 30 dB/m, 37%; among patients with baseline LSM ≥ 10 kPa, 33% migrated to < 10 kPa; elevated baseline ALT normalized in 43%; HbA1c decreased $\geq 0.5\%$ in 35%. **Conclusion:** In LiverSeek-identified PC patients with abnormal NITs, a structured 24-week APN-led lifestyle intervention was associated with clinically meaningful improvements in LSM, CAP, liver enzymes, glycaemic control and FIB-4. These findings support nurse-led lifestyle care as a scalable first-line pathway after automated MASLD case-finding and a practical bridge to selecting patients who may require MASLD-targeted pharmacotherapy.

2080 | PHARMACIST-LED IMPLEMENTATION OF AASLD RESMETIROM PRACTICE GUIDANCE: A REAL-WORLD EXPERIENCE AT A HEPATOLOGY CLINIC IN ACADEMIC MEDICAL CENTER

Jane Giang[1] Madison Owen[2] Brianna Wagoner[2], [1]University of North Carolina Health, [2]UNC Health

Background: Resmetirom is the first FDA-approved therapy for metabolic dysfunction–associated steatohepatitis (MASH) with moderate to advanced fibrosis. Following approval, the American Association for the Study of Liver Diseases (AASLD) published practice guidance on patient selection and safety monitoring. Implementation of these recommendations requires substantial longitudinal coordination among patients and clinical staff. At this academic medical center, a Clinical Pharmacist Practitioner (CPP) is embedded within the hepatology clinic to support medication management, patient education, and therapy monitoring processes. This study evaluated CPP-supported follow-up among patients receiving resmetirom. . **Methods:** A retrospective, single-center chart review was conducted among adults prescribed resmetirom between March 2024 and August 2025 at an academic hepatology clinic. Patients were stratified into pre-guidance and post-guidance cohorts. Outcomes included time to first liver function test (LFT), completion of LFT monitoring at 3, 6, and 12 months, documentation of laboratory reminder outreach, hepatotoxicity events, and discontinuation rates. The embedded CPP supported implementation of guidance recommendations through laboratory coordination, patient outreach, reminder documentation, and longitudinal monitoring follow-up. **Results:** Ninety-nine patients were included (pre-guidance n = 28; post-guidance n = 70). Median time to first LFT was similar between cohorts (102 days [IQR 67–117] vs 90 days [IQR 78–102]; p = 0.12). Completion of 3-month LFT monitoring occurred in 71.4% versus 81.7% (p = 0.26), while 6-month monitoring occurred in 50% versus 73.7% (p = 0.055) in the pre- and post-guidance cohorts, respectively. CPP-documented laboratory reminder outreach increased substantially following guidance publication (3.6% vs 43.7%; p < 0.001). Hepatotoxicity events were uncommon (0% vs 4.3%; p = 0.57). Resmetirom discontinuation occurred less frequently in the post-guidance cohort (42.9% vs 15.5%; p = 0.055). **Conclusion:** In this academic hepatology clinic, safety monitoring for resmetirom was frequently performed even prior to AASLD guidance publication. However, integration of CPP-supported workflows improved longitudinal laboratory monitoring and increased documentation of patient outreach. Lower treatment discontinuation rates were observed with pharmacist-led implementation of AASLD guidance which may warrant further investigation in future. These findings highlight the important role of embedded hepatology pharmacists in monitoring patients receiving novel MASH therapies while reducing the burdent of hepatology providers.

Table 1. Baseline Characteristics and Results

	Pre-Guidance (n=28)	Post-Guidance (n=70)
Age, years	56.7	53.5
Female – no. (%)	14 (50.0%)	37 (52.1%)
BMI, kg/m^2	34.2	33.6
Fibrosis Stage II – no. (%)	7 (25.0%)	26 (36.6%)	
Fibrosis Stage III – no. (%)	16 (57.1%)	41 (57.7%)
Median time to first LFT, days	102.5	90
3-month LFT completion – no. (%)	20 (71.4%)	58 (81.7%)
6-month LFT completion – no. (%)*	14 (50.0%)	42 (73.7%)
12-month LFT completion – no. (%)†	12 (42.9%)	15 (53.6%)
Documented laboratory reminders – no. (%)	1 (3.6%)	31 (43.7%)
Hepatotoxicity events – no. (%)	0 (0.0%)	3 (4.3%)
Resmetirom discontinuation – no. (%)	12 (42.9%)	13 (18.8%)

*6-month monitoring assessed only among patients eligible for 6-month follow-up at time of chart review.
†12-month monitoring assessed only among patients eligible for 12-month follow-up at time of chart review.

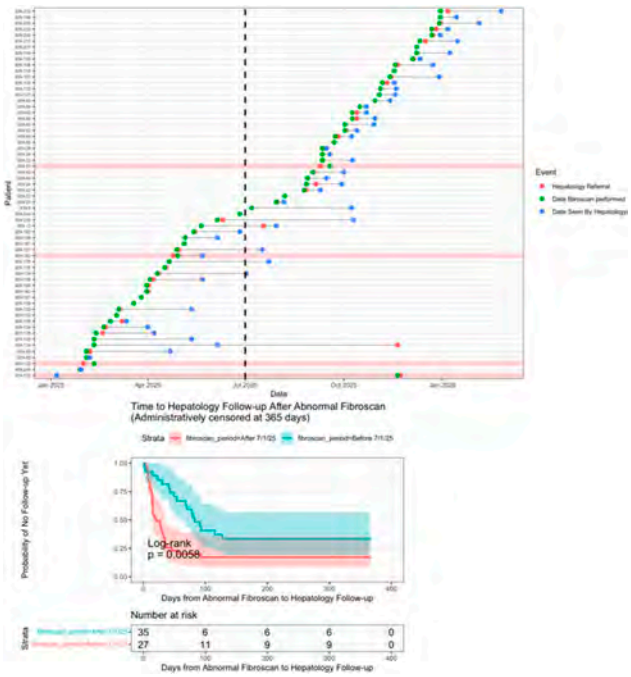
2081 | IMPLEMENTATION OF A NURSE PRACTITIONER–LED FIBROSCAN REFERRAL PATHWAY IMPROVES HEPATOLOGY LINKAGE TO CARE IN A MASLD SCREENING PROGRAM



Amanda Cheung[1] Andres Castillo[2] Kenny Chen[1], [1]Northwestern University, [2]Northwestern Memorial Hospital

Background: FibroScan-based liver stiffness measurement (LSM) is increasingly incorporated into metabolic dysfunction–associated steatotic liver disease (MASLD) screening programs. However, abnormal screening results do not consistently result in timely hepatology evaluation. Delays in specialty referral and fragmented care coordination remain major implementation barriers within MASLD screening programs. To address this gap, we implemented a nurse practitioner (NP)–led FibroScan-triggered referral pathway on July 1, 2025, to facilitate expedited hepatology consultation after abnormal fibrosis screening and evaluated the impact of this pathway on time to hepatology follow-up and identified clinical factors associated with abnormal FibroScan findings. **Methods:** We conducted a prospective quality improvement study of 253 adults undergoing FibroScan assessment in 2025 within a MASLD screening pathway. Abnormal FibroScan was defined as LSM > 8 kPa. Demographic, metabolic, and social determinant variables were collected, including age,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

sex, race/ethnicity, language, insurance status, obesity, diabetes, hypertension, and dyslipidemia. Among patients with abnormal FibroScan results, time to hepatology follow-up was defined as days from FibroScan completion and first hepatology encounter. Patients without follow-up were censored at 365 days. Kaplan-Meier and multivariable Cox proportional hazards analyses compared patients undergoing FibroScan for 6 months before versus after July 1, 2025, when the FibroScan-triggered hepatology referral protocol was implemented. **Results:** The cohort had a median age of 63 years, 56% were male, and median BMI was 30.1 kg/m². Diabetes and hypertension were present in 41% and 47% of patients, respectively. Overall, 25% of patients had elevated LSM. Patients with abnormal FibroScan LSM had significantly higher BMI (32.5 vs 29.3 kg/m², $p < 0.001$) and higher prevalence of obesity (66% vs 44%, $p = 0.004$) and diabetes (61% vs 34%, $p < 0.001$). In multivariable logistic regression, morbid obesity (OR 8.92, 95% CI 1.67–71.4, $p = 0.018$) and diabetes (OR 3.11, 95% CI 1.62–6.10, $p < 0.001$) were independently associated with abnormal FibroScan findings. Implementation of the NP-led referral pathway was associated with significantly faster hepatology consultation (HR 3.68, 95% CI 1.66–8.16, $p = 0.001$) with median time to hepatology evaluation decreasing from 61 days before implementation to 15 days after implementation [see Figure]. **Conclusion:** Implementation of a structured NP-led FibroScan-triggered referral pathway significantly improved linkage to hepatology care within a MASLD fibrosis screening program, reducing median follow-up time from 61 to 15 days. This NP-led care coordination pathway represents an effective and scalable implementation strategy to improve specialty access and longitudinal liver care within MASLD screening programs.

★ 2082 | ASSESSING THE EFFECT OF SEMAGLUTIDE IN PATIENTS WITH MASLD: REAL-WORLD EXPERIENCE FROM A PHARMACIST-LED SUB-CLINIC

Ngan Nguyen[1] Erica Kohen[1] Martin Gozar[1] Sanjaya Satapathy[1], [1]Northwell Health - North Shore University Hospital

Background: Semaglutide has demonstrated efficacy in improving histologic and metabolic outcomes in metabolic dysfunction-associated steatohepatitis (MASH). To expand access to glucagon-like peptide-1 receptor agonist (GLP-1RA) therapy in patients with metabolic dysfunction-associated steatotic liver disease (MASLD), our institution developed a pharmacist (PharmD)-led sub-clinic focused on GLP-1 initiation, titration, and longitudinal monitoring. We evaluated the real-world effectiveness and implementation outcomes of this multidisciplinary care model. **Methods:** We performed a retrospective cohort study of adults with MASLD referred to a PharmD-led GLP-1 sub-clinic at a tertiary hepatology center between January 2022 and March 2024. Patients underwent structured medication counseling, monthly telehealth follow-up, dose titration, and lifestyle education. Baseline demographics, fibrosis stage, cardiometabolic parameters, insurance outcomes, and treatment-related adverse events were collected. The primary outcome was achievement of $\geq 10\%$ weight loss within 12 months of injectable semaglutide therapy. Secondary outcomes included changes in elastography parameters, glycemic indices, treatment persistence, and medication tolerability. **Results:** A total of 118 patients were included. Mean age was 54.3 years, 55.1% were female, and mean body mass index was 35.6 kg/m². Comorbid diabetes and dyslipidemia were present in 40.7% and 66.9% of patients, respectively. Fibrosis stages ranged from F0–F4, with 14.4% demonstrating advanced fibrosis (F4). PharmD involvement resulted in 100% insurance approval, with treatment initiation occurring within a median of 5 days. Maximum tolerated dose was achieved within a median of 119 days, and 42.4% of patients reached semaglutide doses ≥ 2 mg/week. Weight reduction thresholds of $\geq 5\%$, $\geq 7\%$, and $\geq 10\%$ were achieved in 41%, 31%, and 20% of patients, respectively. Median weight loss at 12 months was -8%. Among 22 patients with paired elastography data, median liver stiffness decreased by 1.0 kPa ($p = 0.009$) and controlled

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

attenuation parameter decreased by 31 dB/m (p = 0.027). Hemoglobin A1c decreased by a median of 0.4%. Nausea was the most common adverse event, reported in 44.9% of patients, with 21% discontinuing therapy because of intolerance. **Conclusion:** A PharmD-led GLP-1 sub-clinic facilitated rapid semaglutide initiation, equitable medication access, and clinically meaningful weight loss in patients with MASLD in a real-world setting. Improvements in steatosis, liver stiffness, and cardiometabolic parameters were also observed. Although weight loss outcomes were lower than those reported in randomized trials, likely reflecting real-world barriers including medication supply limitations, copay burden, and less intensive lifestyle supervision, this multidisciplinary model represents a scalable strategy to improve MASLD care delivery.

2084 | REBUILDING RESILIENCE: ADDRESSING PROVIDER BURNOUT TO ENHANCE PROFESSIONAL FULFILLMENT

Sarah Johnson[1] Andrea Benton[2], [1]The Ohio State University, [2]The Ohio State University Wexner Medical Center

Background: The purpose of this descriptive study is to identify the levels of burnout in APP's within the outpatient arm of a major medical center, and to identify factors that may be contributing to or mitigating burnout. The study included a survey that will be distributed to APP's employed by the outpatient arm of a major medical center. By completing this research, we hope that institutions and individuals can implement interventions that may mitigate burnout, thus increasing job satisfaction, provider retention, and long-term productivity. **Methods:** A common tool identified within the literature to assess occupational burnout is the Maslach Burnout Inventory Human Services Survey for Medical Personal (MBI). The MBI– the gold standard for evaluating provider burnout—is a brief 22 statement survey that is accessed online. Upon completion of individual surveys, participants were provided with an individual analysis report, and we were provided a group report of the emotional exhaustion, depersonalization and personal accomplishment scores. The group scores were compared to 11,000+ people in the human services profession who also completed this survey. The MBI survey was distributed electronically in 2024 and again in 2025 via email to all APPs within the GHN Division prior to interventions. 13 APPs were included with a 100% response rate for ongoing evaluation. 11 APPs were retained from initial survey and 2 APPs were new hires. Statistical analysis was not performed due to small sample size. **Results:** The research supports that addressing burnout through individualized targeted interventions positively influences job satisfaction and retention amongst healthcare providers. Furthermore, early identification provides the institution with clear goals to individualize and support providers who are experiencing different levels of burnout. Common factors among engaged APPs included: having an average of six years of experience in their role and a patient care schedule limited to four days per week. These APPs also reported taking personal time at least once a month and expressed intentions to maintain their current FTE status moving forward. **Conclusion:** Organizations must prioritize system-level changes over individual responsibility by using tools like the MBI survey to identify and address the structural causes of stress. Building resilience requires a long-term, integrated approach that combines employee support with organizational responsibility, using updated data to continuously adapt policies and create environments that promote psychological safety and sustainable performance.While the challenges of provider burnout are significant, the growing awareness, innovation, and commitment to change leaves hope that the next chapter in healthcare will be one where Advanced Practice Providers can thrive. **Disclosures:** Sarah Johnson: Nothing to Disclose, Andrea Benton: Nothing to Disclose.

2085 | ◆ TRENDS AND PREDICTORS OF NON-PHARMACOLOGIC MANAGEMENT OF PAIN AMONG VETERANS WITH CIRRHOSIS

Prajwal Gowda[1] Rebecca Loeb[2] Sophie Phillips[3] Hui Shen[4] Katherine Hoggatt[5] Jennifer Lai[2] Jessica Rubin[2],

[1]Department of Medicine, University of California San Francisco, San Francisco, California, USA., [2]Division of Gastroenterology and Hepatology, University of California, San Francisco, California, [3]NCIRE / Northern California Institute for Research and Education, San Francisco, CA, [4]VA Medical Center, San Francisco Veterans Affairs Healthcare System, San Francisco, California, [5]Center for Data to Discovery and Delivery Innovation, SFVA Health Care System, San Francisco, CA

Background: Up to 80% of patients with cirrhosis experience chronic pain, yet nearly every analgesic class carries elevated risk of hepatotoxicity, renal impairment, or hepatic encephalopathy in this population. Non-pharmacologic modalities (NPM) are therefore an attractive alternative. The Veterans Health Administration (VHA) expanded NPM access following the 2013 Opioid Safety Initiative and through its Whole Health System transformation, yet NPM utilization among veterans with cirrhosis remains poorly characterized. **Methods:** Using national VHA Corporate Data Warehouse and linked CMS data, we identified veterans with cirrhosis who were in care between 2010 and 2024. We defined annual NPM use as ≥ 1 CPT/HCPCS/CHAR code within following pain-focused modalities: acupuncture, massage, chiropractic care, osteopathic manipulation, biofeedback, clinical hypnosis, and mind-body interventions (yoga/tai chi/mindfulness). Physical therapy, occupational therapy, psychotherapy, exercise therapy, and education-based interventions were categorized separately, given their non-specificity for analgesia. Trends in NPM use were examined annually. Baseline demographics, medical and psychiatric comorbidities, substance use, and cirrhosis complications were compared between ever-users and non-users of NPM using Wilcoxon rank-sum and chi-square tests. **Results:** Of 344,443 Veterans with cirrhosis, 77,561 (22.5%) ever used a pain-focused NPM. Annual NPM use more than doubled from 5.3% in 2010 to 12.1% in 2024, with growth across all modalities (**Figure 1**). Acupuncture (0.3% to 3.0%), chiropractic care (2.0% to 3.9%), and massage (3.3% to 8.7%) experienced the most significant growth. A pandemic-related dip was observed in 2020. Compared to never-users, NPM users were younger (median age 64.8 vs. 66.4 yrs) and more likely to be married (49.0% vs. 42.0%). They had higher rates of depression (31.0% vs. 26.6%), anxiety (23.8% vs. 20.2%), and PTSD (11.0% vs. 7.9%), but lower rates of alcohol use disorder (32.7% vs. 37.8%), illicit drug use (23.8% vs. 25.5%), and current tobacco use (33.1% vs. 41.3%). NPM users also demonstrated lower rates of decompensated cirrhosis (40.6% vs. 56.2%), including ascites (31.6% vs. 47.3%) and hepatic encephalopathy (10.1% vs. 16.2%) ($p < 0.001$ for all comparisons). Among Veterans with a documented chronic pain diagnosis (n = 194,688), only 26% had ever received any NPM over the study period. **Conclusion:** Despite a more than two-fold increase in annual NPM use over 15 years, fewer than 1 in 8 Veterans with cirrhosis receive these therapies in any given year, and 3 in 4 of those with a documented chronic pain diagnosis have never received any NPM. Uptake is lowest among Veterans with decompensated disease and active substance use, the populations with the fewest safe pharmacologic options. These findings reveal substantial equity gaps in NPM access for the highest-risk segment of the cirrhosis population.

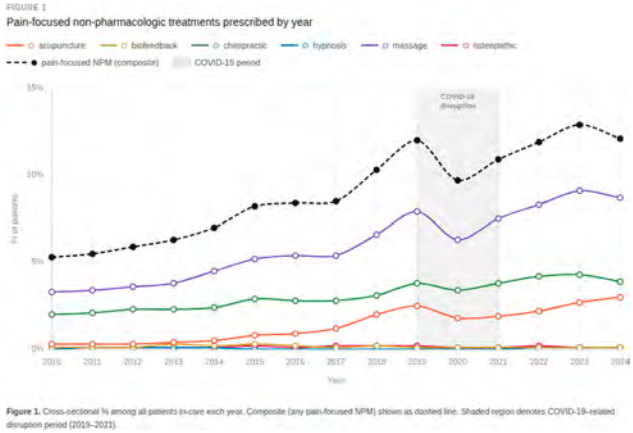

Figure 1. Cross-sectional % among all patients in-care each year. Composite (any pain-focused NPM) shown as dashed line. Shaded region denotes COVID-19–related disruption period (2019–2021).

2086 | ◆ UNLOCKING THE POWER OF LIVED EXPERIENCE: A QUALITATIVE STUDY EXPLORING THE ROLE OF PEER NAVIGATORS IN A MOBILE HEPATITIS C CLINIC

Bharathi Selvan[1] Zainab Fatima[1] Meghan Morris[1] Pauli Gray[1] Cecilia Rivas Alfaro[1] Rosaura Camberos[1] Yesenia Laguardia[1] Sophie Stern[1] Jennifer Price[1], [1]University of California San Francisco

Background: Disparities in linkage to hepatitis C virus (HCV) treatment impact marginalized populations,

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

including people who use drugs and those experiencing housing instability. Peer interventions have shown promise in improving care linkage, but how these interventions succeed and what experiences constitute a successful peer navigator are unclear. We conducted a qualitative study of the Lived Experience Alliance (LEA) peer navigation program in an urban mobile HCV clinic. **Methods:** The UCSF DeLIVER van is a mobile liver care unit offering free HCV screening and on-site treatment. We implemented a peer navigator program to assist clients navigating HCV treatment. We conducted semi-structured interviews with 4 peer navigators (referred to as LEAs), 6 clients who were partnered with a LEA, and 2 mobile clinic staff, using purposeful convenience sampling. An interview guide elicited 1) participants' background and introduction to the LEA program 2) perception of peer role 3) support provided 4) barriers and challenges and 5) sustainability and next steps. Transcripts were coded deductively, and data analysis began after 9 interviews were conducted. **Results:** Three major themes emerged (Table). First, clients and LEAs felt they shared common lived experiences. HCV was the primary unifying lived experience- three out of four LEAs had been cured of HCV. LEAs' lived experiences with HCV promoted self-confidence in clients and normalized experiences related to treatment (e.g., side effects, challenges with daily pills). Other shared social identities like current or prior substance use and housing instability contributed to peer relatability and allowed LEAs to support clients during their treatment. Secondly, LEAs facilitated treatment by meeting and walking with people where they were, often literally. For many clients, HCV cure was attributed to their LEAs meeting them where they resided multiple times a week to provide reminders to pick up or take their medications. LEAs would also walk with them to the mobile clinic for medication pickup or appointments. Third, LEAs' professional identities were characterized by a strong commitment to give back to their community, shaped largely by their prior experiences with street homelessness and HCV. **Conclusion:** Peer navigators have a unique role in HCV linkage to care, particularly for patients who face barriers to receiving traditional HCV care. Our study highlights that peer navigators enhance treatment success by building a relationship, based on a shared lived experience with HCV or other salient social identities. They lower barriers for clients with competing factors by meeting them where they are at and guiding them. Our findings underscore that patient and peer experiences are improved through the integration of a peer navigator program within a mobile HCV clinic. Recognizing the role of lived experience and replicating similar programs elsewhere may support HCV elimination goals.

Theme	Illustrative Quotes
Role of lived experience	"We had a lot in common in that aspect, like, we both, used the needle at one time in our lives, you know, like, we both did stuff like that, so it was really helpful to have somebody that had experience the same experiences that I did to do, you know?" "He's completed it (HCV treatment), though you know what I mean? Like, that just shows, like, it could be done." "He's done the hep C treatment before, too, so… you know what I mean? He knows exactly, what it's like, what the side effects are, and, you know what I'm saying? Like, how you could fall off, and all the things necessary that you would want to know."
Supporting clients by meeting them where they are	"The most helpful? Him coming and picking me up every week. Coming to the door to tell me to take my pills. Like, everything he did was helpful, like, walking me down there" "He just walked up and would get me every week, and then we'd walk down together."
Sense of contributing to community	"I'd had Hep C myself, and was cured, and… in a way for me to… to get further involved in my community, and to help wipe out… hopefully wipe out Hep C completely." "Just because, the people we're trying to reach, it's not always easy for them to remember things, and I've been in their, the exact position before, so I know how hard it is, and it's really rewarding being able to give back where it's needed most, in my opinion."

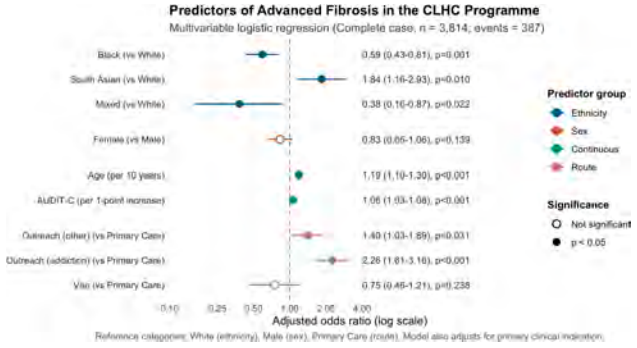
2087 | ◆ ETHNIC AND SOCIOECONOMIC DISPARITIES IN FIBROSIS DETECTION AND OUTCOMES FROM A DIVERSE UK COMMUNITY LIVER SCREENING PROGRAMME



Thomas McKane[1] Kaushik Agarwal[1] Neha Mehta[1] María Guerra veloz[1], [1]Institute of Liver Studies, King's College Hospital

Background: The Community Liver Health Check (CLHC) is a National Health Service England pilot using transient elastography (TE FibroScan) for early detection of chronic liver disease (CLD) in poorly engaged populations at high risk (alcohol excess, metabolic risk or viral hepatitis). Ethnic disparities in ALD/MASLD are reported globally but ethnicity is poorly characterised as risk factor for CLD in UK data. The aim of this project was to assess risk factors associated with advanced fibrosis detection and clinical outcomes in a deprived, multiethnic South East London cohort. **Methods:** Patients meeting CLHC eligibility criteria were enrolled prospectively via community

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

outreach, primary care and a mobile unit from March 2022 to March 2026. Advanced fibrosis was defined as TE LSM ≥8.5 kPa (as per national guidance). Demographics, AUDIT-C score, deprivation decile and housing status were collected. Retrospective electronic record review for engagement rate, diagnosis confirmation and adverse outcomes was performed in those with advanced fibrosis. Adjusted logistic regression was performed to assess risk factors associated with advanced fibrosis. **Results:** 5,175 valid scans were performed. The population was 52.3% White, 25.1% Black, 4.0% South Asian, 3.0% Asian (other), 7.2% Mixed/Other and 8.5% Not Stated. 73% with a recorded address lived in the more deprived half of England and 19.4% of patients were homeless. The prevalence of advanced fibrosis was 10.4%, highest in South Asian patients (16.4%). After adjustment, South Asian ethnicity was an independent predictor of advanced fibrosis (aOR 1.84, 95% CI 1.16–2.93), strengthening to aOR 2.29 (1.30–4.04) for LSM ≥11.5 kPa. Black ethnicity had lower adjusted odds (aOR 0.59, 0.43–0.81). The South Asian finding was robust across multiple sensitivity analyses. Other significant predictors were Outreach (addiction services) (aOR 2.26, 1.61-3.16), AUDIT-C (per point, aOR 1.06, 1.03-1.08) and age (per 10 years, aOR 1.19, 1.09-1.31). 98.7% of those with advanced fibrosis had an accessible health record. 71.6% were linked to secondary care, 68.9% of whom attended hepatology appointment. Attendance did not differ by ethnicity, but in those with a confirmed outcome, was lower in homeless patients (70.6% vs 85.3%, p = 0.015). The predominant diagnoses were ALD (53%) and MASLD (34%). Rates of all-cause mortality & decompensation events in patients with advanced fibrosis were 5.8% & 7.7%. These were higher in homeless patients (12.7%, p = 0.015; 13.9%, p = 0.037) despite similar baseline LSM. **Conclusion:** The CLHC programme achieved high-yield fibrosis detection and engaged an ethnically and socioeconomically diverse cohort. South Asian ethnicity emerged as an independent risk factor for advanced fibrosis and may warrant inclusion in screening criteria. Targeted strategies may be needed to improve engagement and reduce adverse outcomes in at-risk groups, particularly homeless patients.

2088 | ◆ TEN YEAR TRENDS IN HEPATOCELLULAR CARCINOMA SURVEILLANCE AND STAGE AT DIAGNOSIS

Richard O'Halloran[1] Weiyuan Fan[2] Thisuri Jayawardena[3] Phoebe Sun[3] Andrea Jasareno[3] Wei Ling Teh[3] Andrew Chin[2] Kazuya Miyamoto[4] Wesley Billingham[5] Tim Mitchell[1] Simon Hazeldine[3] Chloe Attree[1] George Garas[6] Angus Jeffrey[1] Gary Jeffrey[1] Gerry MacQuillan[1] Briohny Smith[1] Michael Wallace[1] Leon Adams[6], [1]Sir Charles Gairdner Hospital, [2]Royal Perth Hospital, [3]Fiona Stanley Hospital, [4]The University of Western Australia, [5]The Kids Institute, Perth WA, Australia, [6]University of Western Australia

Background: Hepatocellular carcinoma (HCC) is a low survival cancer with a rising incidence in Australia. Ultrasound surveillance enables earlier diagnosis and improved outcomes. We aimed to describe trends and risk factors for non-surveillance and cancer stage in patients with a new diagnosis of HCC over a ten year period. **Methods:** Patients with newly diagnosed HCC at three tertiary hospitals in Western Australia between 2015-2024 were retrospectively identified. Patient variables at diagnosis, including demographics, underlying liver disease, participation in surveillance and Barcelona Clinic Cancer (BCLC) stage were ascertained from prospective databases and electronic records. Multivariate logistic regression was used to identify factors associated with non-surveillance and HCC stage at diagnosis. Variables were included in multivariate analysis if there was a strong epidemiological basis or they were statistically significant on univariate analysis. **Results:** Overall, 1,168 individuals with a new diagnosis of HCC were identified with 81.5% being male, 73.3% cirrhotic and an average age 66.8 years. Of these, 437 (37.4%) were not known to have liver disease prior to HCC diagnosis. The proportion of patients not in a surveillance program at diagnosis was 59.2% (691/1168), which did not change over the decade (p = 0.43). Patients not in surveillance were more likely to present with late-stage HCC (BCLC C or D) (OR 4.28, 95%CI 3.13-5.94). Risk factors for a non-surveillance HCC diagnosis among patients with cirrhosis included rural residence (OR 1.74, 1.25-2.45) and alcohol-related liver disease (OR 1.45, 1.05-2.01), while hepatitis C was associated with lower odds (OR 0.58, 0.40-0.84). The proportion of late-stage HCC cases was 27.7% and did not change over 10 years (p = 0.52). No factors were associated with a higher odds for late-stage HCC, but there were lower odds among patients with metabolic dysfunction-associated steatotic liver disease (MASLD) (OR 0.47, 0.33-0.66). Early-stage HCC (BCLC 0 or A) was less likely to be

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

diagnosed in rural patients (OR 0.62, 0.46-0.83) and more likely to be diagnosed in patients with MASLD (OR 1.68, 1.24-2.29), hepatitis B (OR 1.65, 1.10-2.49) and hepatitis C (OR 1.39, 1.01-1.91). **Conclusion:** Most HCC cases are not detected through surveillance and a significant proportion have unrecognized chronic liver disease at diagnosis. Surveillance and early diagnosis rates have not improved over the past decade, with rural residence and alcohol-related liver disease associated with non-surveillance diagnosis, while rural residence is associated with a lower likelihood of early-stage HCC.

Table 1. Multivariate logistic regression showing association between demographics, cirrhosis, site and etiology with non-surveillance diagnosis and HCC stage.

2089 | BEYOND COVERAGE: STRUCTURAL BARRIERS AND COST-RELATED MEDICATION NON-ADHERENCE FOR INDIVIDUALS WITH HBV IN THE US

Xiaohan Ying[1] Jacky Choi[2] Himel Mallick[2] Tatyana Kushner[2], [1]NewYork Presbyterian/Weill Cornell, [2]Weill Cornell Medicine

Background: Medication adherence is essential for effective treatment of chronic hepatitis B (HBV), yet cost-related medication non-adherence (CRN) remains poorly characterized. Using the All of Us Research Program, we evaluated socioeconomic and structural factors associated with CRN in a nationally representative, diverse cohort. **Methods:** Adults with HBV were identified in the All of Us Database. CRN was defined as affirmative responses to any of the four cost-related medication behaviors in the past 12 months: not obtaining medications, skipping doses, taking less than prescribed, and delaying refills. Sociodemographic characteristics, insurance coverage, and healthcare access were compared by CRN status using Chi-square and Wilcoxon rank-sum tests. Inverse probability weighting (IPW) was applied to address potential selection bias from missing data. Multivariable logistic regression was adjusted for age, sex, race, ethnicity, income, and insurance type to identify factors independently associated with CRN. **Results:** Of 2,323 individuals with HBV, 838 individuals answered cost-related medication behavior questions, and 167 (20%) experienced CRN. Individuals who experienced CRN were more likely to have lower income ($\leq$\$50K: 76% vs 48%, $p < 0.001$), lower education ($p = 0.021$), and be younger (62 vs 66 years, $p < 0.001$). Despite majority having insurance coverage, those with CRN were less frequently covered (92% vs 96%, $p = 0.026$), although with similar insurance types ($p = 0.09$). Individuals with CRN more commonly reported inability to afford emergency (16% vs 1.3%), mental health (22% vs 2.2%), dental (54% vs 10%), and specialist care (34% vs 5.6%), $p < 0.001$. They also more frequently delayed care due to rural residence (12% vs 2.8%), lack of transportation (31% vs 7.6%), and inability to take time off work (15% vs 5.2%), $p < 0.001$. Individuals who experience CRN had lower perceived respect in healthcare interactions (21% vs 45%) and worse self-rated health (46% vs 28%), $p < 0.001$.On multivariable analysis, older age and higher income were associated with lower odds of CRN, while Hispanic and multiracial identity were associated with higher odds. Compared to uninsured individuals, patients covered by Medicaid had lower odds of CRN. **Table 1 Conclusion:** One in five individuals with HBV experienced CRN, and many experienced other structural barriers, including socioeconomic disadvantages, access constraints, and differences in healthcare experiences. These patterns persist despite high overall insurance coverage, suggesting coverage alone does not ensure

2090 | FASTER NATIONAL DEVELOPMENT AMPLIFIES MASLD BUT NOT VIRAL HEPATITIS OR ALCOHOL-ASSOCIATED LIVER DISEASE

James Paik[1] Eliabe Abreu[2] Annette Paik[3] Khalid AlNaamani[3] Mohamed El-Kassas[4] Cristiane Villela-Nogueira[3] Saleh Alqahtani[3] Zobair Younossi[3], [1]Global NASH/MASH Council, [2]Mayo Clinic Rochester, [3]The Global NASH/MASH Council, [4]Capital University

Background: The global burden of MASLD is rising, yet whether development velocity (the rate of national development improvement) independently amplifies this burden, and whether this effect is disease-specific, remains unknown. This study examined whether development velocity amplifies MASLD burden relative to viral hepatitis and ALD. **Methods:** A multinational country level analysis was conducted using GBD and WHO Global Health Observatory data for 204 countries. A 2-dimensional framework combining baseline Socio-demographic Index (SDI, 2005 to 2007; median 0.60) and development velocity (SDI change, 2006 to 2023; median 8.1%) classified countries into 4 groups: Rapid Risers (low SDI, fast velocity; n = 75), Late Accelerators (high SDI, fast velocity; n = 27), Stalled (low SDI, slow velocity; n = 27), and Plateaued (high SDI, slow velocity; n = 75). Outcomes were age-standardized MASLD prevalence (2019 to 2021) and liver mortality for MASLD, ALD, HBV, and HCV (2023). Dominant liver disease per country was defined as the disease with the highest age-standardized mortality rate. Interaction regression models, adjusted for urbanization, healthcare quality, and political stability, were used to test whether velocity modified each liver outcome. **Results:** While MASLD prevalence differed significantly across 4 groups ($p = 0.002$), highest in Late Accelerators, followed by Rapid Risers, Stalled, and Plateaued countries, MASLD mortality did not differ significantly ($p = 0.199$; Table 1). Despite high MASLD prevalence, MASLD did not emerge as the leading cause of liver death in any group. HBV predominated in Rapid Risers and Stalled countries, whereas ALD led in Plateaued countries, which demonstrated the highest per capita alcohol supply (Table 1). Notably, Late Accelerators showed the narrowest gap between MASLD and viral hepatitis mortality (Table 1), indicating an approaching disease transition. Loess regression identified a crossover point at SDI 0.60, where MASLD mortality converges with HBV. Velocity-SDI interaction analysis revealed that development velocity significantly amplifies the relationship between SDI and MASLD for both prevalence ($\beta = +299.1$, $p < .001$, $\Delta R^2 = 0.074$) and liver mortality ($\beta = +34.3$, $p = 0.049$), whereas velocity showed no effect for HBV ($p = 0.626$), HCV ($p = 0.532$), or ALD ($p = 0.533$), establishing MASLD as the only velocity-sensitive liver disease. **Conclusion:** The rising burden of liver disease linked to development velocity requires dual, concurrent strategies. Currently, we must prioritize viral hepatitis control in Rapid Risers and Stalled nations and ALD reduction in Plateaued countries. Simultaneously, we must establish MASLD prevention infrastructure, especially in Late Accelerator and Rapid Riser countries to prevent disease transition before MASLD becomes the dominant cause of liver mortality.

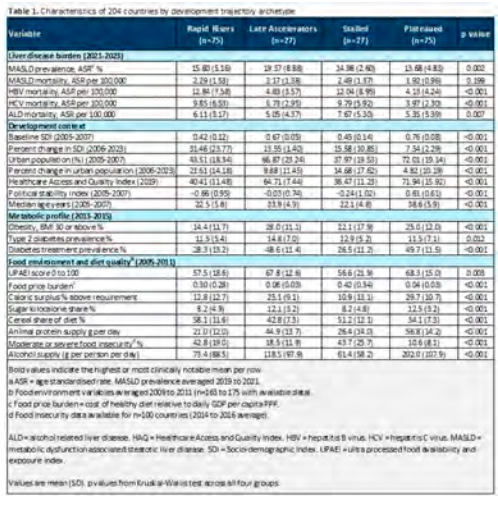

Table 1. Characteristics of 204 countries by development trajectory archetype

Variable	Rapid Risers (n=75)	Late Accelerators (n=27)	Stalled (n=27)	Plateaued (n=75)	p value
Liver disease burden (2021-2023)					
MASLD prevalence, ASR[a] %	15.80 (1.59)	19.57 (8.88)	14.98 (2.40)	13.68 (4.83)	0.002
MASLD mortality, ASR per 100,000	2.29 (1.58)	3.17 (1.33)	2.49 (1.37)	1.92 (0.99)	0.199
HBV mortality, ASR per 100,000	12.84 (7.58)	4.83 (3.57)	12.04 (8.99)	4.13 (4.24)	<0.001
HCV mortality, ASR per 100,000	9.85 (5.53)	5.73 (2.95)	9.79 (5.92)	3.97 (2.30)	<0.001
ALD mortality, ASR per 100,000	6.11 (5.17)	5.05 (4.37)	7.67 (5.30)	5.35 (5.39)	0.007
Development context					
Baseline SDI (2005-2007)	0.42 (0.12)	0.67 (0.05)	0.45 (0.14)	0.76 (0.08)	<0.001
Percent change in SDI (2006-2023)	31.46 (23.77)	13.55 (1.40)	15.58 (10.85)	7.34 (3.29)	<0.001
Urban population (%) (2005-2007)	43.51 (18.54)	66.87 (20.24)	37.97 (19.51)	72.01 (19.14)	<0.001
Percent change in urban population (2006-2023)	23.61 (14.18)	9.88 (11.45)	14.68 (7.62)	4.82 (10.19)	<0.001
Healthcare Access and Quality Index (2019)	40.41 (11.48)	64.71 (7.44)	36.47 (11.28)	71.94 (15.92)	<0.001
Political stability index (2005-2007)	-0.66 (0.95)	-0.03 (0.74)	-0.24 (1.02)	0.61 (0.61)	<0.001
Median age (years) (2005-2007)	32.5 (5.6)	33.9 (4.9)	22.1 (4.6)	38.6 (5.9)	<0.001
Metabolic profile (2015-2015)					
Obesity, BMI 30 or above %	14.4 (11.7)	28.0 (11.1)	12.1 (17.9)	25.0 (12.0)	<0.001
Type 2 diabetes prevalence %	11.3 (5.4)	14.8 (7.0)	12.9 (5.2)	11.5 (7.1)	0.053
Diabetes treatment prevalence %	28.3 (13.2)	48.6 (11.4)	26.5 (11.2)	49.7 (11.5)	<0.001
Food environment and diet quality[b] (2005-2011)					
UPAE[c] score 0 to 100	57.5 (18.6)	67.8 (12.8)	56.6 (21.9)	68.3 (15.0)	0.008
Food price burden[c]	0.30 (0.28)	0.06 (0.03)	0.40 (0.34)	0.04 (0.03)	<0.001
Caloric surplus % above requirement	12.8 (12.7)	25.1 (9.1)	10.9 (11.1)	28.7 (10.7)	<0.001
Sugar calorie share %	8 (2.9)	12.1 (3.2)	8.2 (4.8)	12.5 (3.2)	<0.001
Cereal share of diet %	58.1 (11.9)	42.8 (7.3)	51.2 (12.1)	34.1 (7.3)	<0.001
Animal protein supply g per day	21.0 (12.0)	44.9 (13.7)	26.4 (14.0)	58.8 (14.2)	<0.001
Moderate or severe food insecurity[d] %	42.8 (19.0)	18.5 (11.9)	43.7 (25.7)	10.6 (8.1)	<0.001
Alcohol supply (g per person per day)	78.4 (68.5)	118.5 (97.9)	61.4 (58.2)	202.0 (107.9)	<0.001

Bold values indicate the highest or most clinically notable mean per row.
a ASR = age-standardised rate. MASLD prevalence averaged 2019 to 2021.
b Food environment variables averaged 2005 to 2011 (n=161 to 175 with available data).
c Food price burden = cost of healthy diet relative to daily GDP per capita PPP.
d Food insecurity data available for n=100 countries (2014 to 2016 average).

ALD = alcohol-related liver disease. HAQ = Healthcare Access and Quality Index. HBV = hepatitis B virus. HCV = hepatitis C virus. MASLD = metabolic dysfunction-associated steatotic liver disease. SDI = Socio-demographic Index. UPAE = ultra-processed food availability and exposure index.

Values are mean (SD). p values from Kruskal-Wallis test across all four groups.

2091 | LIVERLINK LOUNGE: FEASIBILITY AND ACCEPTABILITY OF A MULTISITE VIRTUAL PEER SUPPORT INTERVENTION FOR PATIENTS WITH HEPATOCELLULAR CARCINOMA

Lauren Nephew[1] Samantha Ky[1] Courtney Moore[2] Lisa Parks[2] Allison McKay[2] Sebastian Abad[1] Susan Rawl[3] Joshua Sumner[4] Juliette Dixon[5] Kathy Liu[6] Alexandra Strauss[6], [1]Division of Gastroenterology and Hepatology, Department of Medicine, Indiana University, [2]Research Jam, Community Health Partnerships, Clinical and Translational Sciences Institute, [3]Indiana University School of Nursing, Simon Cancer Center, [4]Indiana University Health, [5]Johns Hopkins Medicine, [6]Division of Gastroenterology and Hepatology, Department of Medicine, Johns Hopkins University

Background: Patients with hepatocellular carcinoma (HCC) experience substantial psychosocial burden, including isolation, uncertainty, and difficulty navigating complex care pathways. Despite these challenges, scalable psychosocial interventions are not routinely integrated into HCC care. LiverLink Lounge is a live, virtual peer support intervention developed through iterative Explore, Create, and Test human-centered design (HCD) phases. We evaluated the feasibility and acceptability of cross-site implementation across two academic transplant centers. **Methods:** LiverLink Lounge were virtual peer support groups led by transplant social workers from Indiana University and Johns Hopkins. Participants were patients with HCC froom both centers enrolled from a prospective LiverLink cohort focused on individuals experiencing barriers to care, including adverse social determinants of health. Session content was informed by prior HCD work with this popuation identifying needs related to communication, emotional support, medical mistrust, and coping. Sessions were conducted monthly via video platform with phone participation available. Feasibility was assessed through successful session delivery and multisite participation. Acceptability was evaluated using post-session Likert-scale surveys and qualitative feedback. **Results:** Eight sessions were conducted between July 2025 and March 2026, with simultaneous participation from both institutions in most sessions. Attendance ranged from 1–4 participants per session. Among survey respondents (n = 14), 93% agreed or strongly agreed that participation positively impacted emotional well-being (Figure 1). Qualitative analysis demonstrated three major themes: reduced isolation through emotionally safe peer connection, improved coping and communication skills, and strong desire for continued participation. Participants valued structured facilitation and opportunities to share experiences across institutions and disease stages. Representative comments included: “Being able to talk freely and be vulnerable without being judged was so helpful” and “I got a lot of good ideas on how to communicate with my doctors and advocate for myself". **Conclusion:** A multi-institution, live, and virtual peer support intervention for patients with HCC is feasible and highly acceptable. Integration of patient-informed content derived from iterative HCD phases and multi-site implementation support scalability and inform future trials integrating psychosocial and educational interventions into HCC care.

Figure 1. Impact and Patient Experience of Virtual Peer Support Intervention
A. Impact on Emotional Well-Being (n=14 responses)

Theme	Representative Quote
Emotional Support & Reduced Isolation	Being able to talk freely and be vulnerable without being judged was so helpful.
Improved Coping & Communication	I got a lot of good ideas on how to communicate with my doctors and advocate for myself.
High Acceptability & Desire for Continuity	I want to continue attending sessions if I can... the group helps me feel better.

2092 | RACIAL AND ETHNIC DISPARITIES IN LIVER TRANSPLANT EVALUATION, WAITLISTING, AND OUTCOMES IN THE POST-ACUITY CIRCLE ERA: A NATIONWIDE MULTI-INSTITUTIONAL COHORT STUDY

Noor Albusta[1] Sara Isa[2] Mohamed Abdulla[2], [1]Lahey Hospital and Medical Center, [2]Royal College of Surgeons in Ireland

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Racial disparities in liver transplant (LT) access are well-documented, yet most studies rely on UNOS registry data capturing only waitlisted patients — missing the referral-to-evaluation gap where the largest disparities likely exist. The 2020 acuity circle (AC) policy aimed to improve geographic equity but has not demonstrably reduced racial disparities. No multi-institutional study has examined the full LT care cascade across all racial/ethnic groups using EHR data with pre- vs. post-AC and etiology-specific stratification. **Methods:** Using the TriNetX Global Collaborative Network (>120 healthcare organizations), we conducted a retrospective cohort study of adults (≥18 y) with cirrhosis and either MELD-Na ≥15 or ≥1 hepatic decompensation event from Jan 2016–Dec 2024. Patients were stratified by race/ethnicity (NHW, NHB, Hispanic, Asian, AI/AN) and era (pre-AC: 2016–2020; post-AC: 2020–2024). Primary outcomes were LT evaluation probability, waitlisting, and all-cause mortality at 1 and 3 years. Propensity score matching (1: 1) was performed between each minority group and NHW on 38 covariates including age, sex, cirrhosis etiology, MELD-Na components, insurance type, Elixhauser comorbidity index, and HCC status. Subgroup analyses were performed by etiology, insurance type, and AC era. Cox and Fine-Gray competing risk models estimated adjusted HRs with 95% CIs. **Results:** Among 87,342 adults (NHW 60%, NHB 17%, Hispanic 15%, Asian 5%, AI/AN 3%), mean age was 59.7 ± 10.4 y, 43.8% female, with leading etiologies of ALD (38.2%), MASLD (31.4%), and viral hepatitis (18.6%). NHB patients had higher Medicaid/uninsured rates (52.3% vs. 31.6% NHW, p < 0.001) despite similar MELD-Na scores. After matching, NHB and AI/AN patients had 33% and 44% lower odds of LT evaluation, respectively (Table 1). Median time from decompensation to evaluation was 14.2 months (NHB) and 16.7 months (AI/AN) vs. 9.6 months (NHW; p < 0.001). Three-year mortality was highest among AI/AN (48.2%) and NHB (44.6%) vs. NHW (36.8%). Among LT recipients (n = 4,218), NHB patients had lower 1-year post-LT survival (86.4% vs. 91.2%; HR 1.42, p < 0.001). The AC policy increased overall evaluation rates (16.8% to 20.2%, p < 0.001) but did not attenuate racial gaps (NHB-NHW gap: 5.4% pre vs. 5.8% post, p-interaction = 0.62). Disparities were most pronounced in ALD and among Medicaid/uninsured patients (Table 2; p-interaction < 0.001). **Conclusion:** Significant racial and ethnic disparities persist across the full LT care cascade, greatest at the evaluation stage — upstream of allocation. Black and AI/AN patients face 33–44% lower odds of evaluation and 24–38% higher mortality vs. White patients, unmitigated by the AC policy. Disparities were most severe in ALD and among publicly insured patients, identifying modifiable targets for equity-focused interventions at the referral and evaluation stages.

Table 1. Liver Transplant Care Cascade Outcomes by Race/Ethnicity After Propensity Score Matching

Outcome	NHW (ref)	NHB	Hispanic	Asian	AI/AN

2093 | SOCIOECONOMIC DISPARITIES IN SURGICAL RESECTION AND SURVIVAL AMONG PATIENTS WITH INTRAHEPATIC CHOLANGIOCARCINOMA DESPITE SIMILAR STAGE AT PRESENTATION: A POPULATION-BASED SEER ANALYSIS

Hamza Khan[1] Ritu Yadav[1] Mansha Gupta[1], [1]Northern Arizona Healthcare

Background: Intrahepatic cholangiocarcinoma (ICC) is an aggressive hepatobiliary malignancy for which surgical resection remains the primary potentially curative therapy. The impact of socioeconomic status (SES) on treatment utilization and survival outcomes in ICC remains incompletely characterized. This study aimed to evaluate socioeconomic and racial disparities in stage at diagnosis, receipt of surgical resection, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

overall survival among patients with ICC. **Methods:** A retrospective cohort study was performed using the Surveillance, Epidemiology, and End Results (SEER) database, including adults diagnosed with ICC between 2004 and 2022. Patients were categorized into low-, middle-, and high-income groups based on county-level median household income. Multivariable logistic regression identified factors associated with advanced stage at diagnosis and receipt of surgical resection. Cox proportional hazards models evaluated overall survival after adjustment for demographic, socioeconomic, and clinical variables. **Results:** Among 16,235 patients with ICC, 17.98% underwent surgical resection. Resection rates differed significantly by income level ($p = 0.006$). In a subgroup analysis restricted to localized or regional disease, middle-income patients had higher odds of resection compared with low-income patients (OR 1.28, 95% CI 1.09–1.50, $p = 0.003$), while high-income patients demonstrated 48% greater odds of undergoing surgery (OR 1.48, 95% CI 1.25–1.75, $p < 0.001$). Income was not associated with advanced stage at diagnosis. In adjusted survival analyses, middle-income (HR 0.89, 95% CI 0.84–0.95, $p < 0.001$) and high-income patients (HR 0.86, 95% CI 0.81–0.92, $p < 0.001$) experienced significantly improved survival compared with low-income patients. American Indian/Alaska Native patients had increased mortality (HR 1.32, 95% CI 1.05–1.67, $p = 0.017$). Surgical resection was independently associated with markedly improved survival (HR 0.32, 95% CI 0.30–0.34, $p < 0.001$). Kaplan-Meier analysis demonstrated significant survival differences across income strata (log-rank $p < 0.001$). **Conclusion:** Significant socioeconomic disparities exist in access to potentially curative surgery and survival among patients with ICC. Despite presenting at similar stages, higher-income patients were substantially more likely to undergo surgical resection and experienced superior survival outcomes. These findings suggest that socioeconomic barriers may influence access to definitive hepatobiliary cancer care and contribute to outcome disparities in ICC.

Table 1. Multivariable Predictors of Surgical Resection Among Patients with Localized/Regional ICC

Variable	Adjusted OR	95% CI	P value
Middle Income vs Low	1.28	1.09–1.50	0.003
High Income vs Low	1.48	1.25–1.75	<0.001
NH Asian/API vs Reference	1.38	1.13–1.67	0.001
Male Sex	0.86	0.78–0.96	0.006
Regional vs Localized Disease	0.43	0.39–0.48	<0.001
Age (per year)	0.96	0.96–0.97	<0.001

Background: Cirrhosis care varies worldwide due to differing etiologies, and access to care & interventions. Prior analyses have focused on either regional or country income-based evaluations. **Aim** : Determine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

individual patient-level access to important interventions and it's impact on inpatient cirrhosis outcomes. **Methods:** CLEARED Consortium recruits cirrhosis inpatients globally and follows them for inpatient mortality or liver transplant (LT). Data collected included demographics, cirrhosis details, medications, inpatient course data and country-level income according to the World Bank. Centers were divided into those belongng to high (HIC), upper middle (UMIC) & low/low-middle (LIC) income countries. We collected availability, affordability, and clinical need for important drugs (IV albumin, rifaximin, octreotide, somatostatin, terlipressin), interventions (LT, TIPS) & services (ICU, microbiology cultures, palliative care). For each, we asked whether it was clinically indicated or not. If indicated, we collected % receiving, % not receiving due to unavailability or unaffordability deemed lack of access. Logistic regression models using either lack of access or country income for inpatient mortality prediction were created using variables significantly different on crude analysis and compared using AUC. **Results:** 1612 patients (57 yrs, 61% men, 38% alcohol) were recruited from 53 centers. 27% were from HIC, 42% from UMIC) & 31% LICs. 167 (10%) died during the admission and were more likely to be from LICs, with more advanced cirrhosis (Fig A). Lack of access: Was highest in LIC: LT (28.5%), followed by terlipressin (8.5%), Palliative care (8.5%), TIPS (7.2%), somatostatin (6.8%), Octreotide (5.9%), ICU (5.6%), rifaximin (5.1%), Cultures (4.2%), & albumin (3.8%). LT access was also not easily accessible in UMICs (24.1%). Lack of access was linked with higher inpatient mortality (Fig A/B), with the largest differences for ICU, LT, rifaximin, cultures & TIPS. Regression Models: Model with access variables showed lack of LT (adj OR 4.5, 1.8-13, $p = 0.003$ vs access), ICU (adj. OR: 2.8,1.4-5.7, $p = 0.003$) & rifaximin access (adj. OR: 2.7,1.0-7.1, $p = 0.048$) were significant for increased mortality in addition to prior HE (2.1, 1.2-3.6, $p = 0.009$) & MELD-Na (1.06, 1.02-1.09, $p < 0.001$). Comparison of multivariable models containing access versus country income showed superiority of access model for inpatient mortality prediction (Fig C). **Conclusion:** Individual patient access to lifesaving interventions such as LT, ICU care, rifaximin, blood cultures are major determinants of inpatient mortality in a global cirrhosis cohort. Using patient-level access is significantly more predictive than crude country-level income level metrics and should be used to enhance prognostication and identify patients who will benefit from improving access.

2095 | MULTILEVEL DETERMINANTS OF LIVER TRANSPLANT EVALUATION CLOSURE AT A LARGE TEXAS TRANSPLANT CENTER

Kishore Botla[1] Olgert Bardhi[1] Amy Hughes[1] Alaina Beauchamp[2] Rutu Rathod[3] Alvaro Noriega Ramirez[1] Dyanna Gregory[1] Lisa VanWagner[1] Amit Singal[1] Sarah Lieber[1], [1]University of Texas Southwestern Medical Center, [2]University of Kansas Medical Center, [3]University of Arkansas for Medical Sciences

Background: Liver transplant evaluation (LTE) is critical to accessing transplantation, yet many patients who begin LTE are never listed. LTE closure (i.e., decline to place a patient on the waitlist), occurs for medical and psychosocial reasons. Identifying individual and neighborhood-level factors associated with LTE closure may reveal modifiable barriers to liver transplant (LT) access. **Methods:** This retrospective cohort study of adults undergoing LTE from 2014-2023 matched patients with LTE closure to those waitlisted/transplanted by date, age, sex, and alcohol-related versus non-alcohol-related LT indication. Sociodemographic, clinical, and psychosocial factors were manually abstracted from the electronic health record. Primary reasons for closure and incomplete LTE components were abstracted from selection committee documentation. Patient addresses were geocoded to census tracts to characterize neighborhood socioeconomic context including social deprivation, ethnic enclave status, alcohol outlet density, retail food environment, walkability, transit access, and rurality. Multivariable logistic regression estimated adjusted odds ratios (aORs) for LTE closure. **Results:** Among 885 patients, 466 (52.7%) had LTE closure and 419 (47.3%) were waitlisted/transplanted. LTE closure was most often due to medical/physical (67.5%), followed by psychosocial/financial (27.5%) reasons and personal choice (4.9%). Medical closures were most commonly due to non-liver comorbidities (46.9%) or clinical improvement (26.1%); psychosocial/financial closures were due to ongoing/relapsed substance use (40.6%) or inadequate social support (26.6%). More than one-third of patients (34.9%) did not complete all LTE components, most commonly cardiac (23.6%) and preventative health clearance (21.9%). In multivariable analysis, any psychiatric history was associated with higher odds of closure (aOR 1.68, 95% CI 1.16-2.44). Non-liver comorbidity burden showed a graded association with closure: mild (aOR 1.90, 95% CI 1.23-2.99), moderate (aOR 2.91, 95% CI 1.78-4.83), and severe (aOR 7.28, 95% CI 2.79-21.6) compared to none. Neighborhood mapping suggests spatial overlap between area deprivation and Hispanic enclave status, with broadly low walkability and healthy retail food access across Texas (**Figure 1**). **Conclusion:** More than half of evaluated patients were closed due to medical and potentially modifiable psychosocial factors. Psychiatric history and non-liver comorbidity burden were independently associated with closure, supporting earlier behavioral health integration and targeted evaluation support to improve transplant access, particularly around the completion of required pre-transplant clearance testing. Neighborhood-level mapping provides a structural context for these barriers and may help identify communities where pre-evaluation outreach and resource navigation are most needed.

MULTIVARIABLE REGRESSION: PREDICTORS OF LTE CLOSURE

Variable		aOR[1]	95% CI[1]	p-value[1]
Race/Ethnicity				0.8
	White	Referent	Referent

2096 | THE DEVELOPMENT DIVIDE: HOW FOOD SYSTEMS DRIVE METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) THROUGH DIFFERENT STRUCTURAL PATHWAYS ACROSS 204 COUNTRIES

James Paik[1] Markos Kalligeros[2] Shira Zelber-Sagi[3] Annette Paik[2] Carina Kugelmas[4] Saleh Alqahtani[2] Zobair Younossi[2], [1]Global NASH/MASH Council, [2]The Global NASH/MASH Council, [3]The University of Haifa, [4]Denver Health

Background: Food systems shape metabolic diseases globally, yet their causal pathways to MASLD remain unmapped across each country's economic contexts. We applied structural equation modeling to elucidate how food-system characteristics, mediated through obesity and type 2 diabetes (T2D), drive MASLD prevalence and mortality across 204 countries stratified by development level. **Methods:** Cross-national ecological study harmonizing Global Burden of Disease, NCD Risk Factor Collaboration, Food and Agriculture Organization of the United Nations Statistics Database (FAOSTAT), and World Bank data. Food-system exposures (2005–2011), metabolic mediators (2013–2015), and liver outcomes (2019–2023) were analyzed separately for low-SDI (n = 101) and high-SDI (n = 103) countries. **Results:** Despite similar age-standardized MASLD prevalence (low-SDI: 15.58% vs. high-SDI: 15.19%, p = 0.055), causal pathways diverged fundamentally. In low-SDI countries, urbanization-driven ultra-processed food (UPF) expansion increased the prevalence of obesity and MASLD while political stability independently reduced MASLD risk **(Figure)** . In high-SDI countries, UPF drove dietary sugar consumption, which drove obesity and T2D, the dominant MASLD correlate (β = +0.80). A healthcare detection paradox emerged: greater healthcare access increased MASLD detection (β = +0.28) but reduced mortality (β = −0.33) **(Figure)** . **Conclusion:** MASLD prevention requires development-stratified structural interventions: UPF regulation and governance strengthening in low-SDI nations while T2D prevention in high-SDI nations.

hospital of northwestern university, [6]Northwestern Memorial Hospital, [7]Surgeon

Background: Hispanic patients face persistent disparities in liver transplantation (LT). In 2010, a HispanicLiver Transplant Program (HLTP) was implemented to provide culturally and linguistically competent care through bilingual staff, Spanish-language education, and navigation support. We evaluated whether HLTP implementation was associated with improved Hispanic access to LT care. **Methods:** OPTN (Organ Procurement & Transplantation Network(OPTN)/UNOS (United Network for Organ Sharing) data were used to compare LT access metrics at Northwestern Medicine (NM),Illinois (IL), and the United States across three eras: pre-HLTP (2000-2009), post-HLTP (2011-2020), and recent era (2021-2025). The implementation year, 2010, was excluded. Outcomesincluded waitlist additions, overall LT, and living donor liver transplantation (LDLT). Waitlistadditions were used as a metric for access to transplant care. To account for volume changes, wecalculated a Hispanic-to-non-Hispanic White (NHW) equity ratio: [Hispanic outcome/totaloutcome]/[NHW outcome/total outcome]. Higher ratios indicate movement toward parity andreduced disparity. **Results:** A culturally competent HLTP was associated with improved Hispanic accessacross the LT pathway, including waitlist additions, overall LT, and LDLT. The observedimprovement in Hispanic/NHW equity ratios suggests narrowing disparities in LT. These findings parallel prior kidney transplant experience, supporting that culturally competent transplant care is not organ-specific. At NM, mean annual Hispanic waitlist additions increased from 13.4 to 21.7 (+62%), while the Hispanic/NHW waitlist equity ratio increased from 0.10 to 0.21 (+114%). Mean annual Hispanic LT increased from 8.5 to 15.6 (+84%), with the LT equity ratio increasing from 0.11 to 0.20 (+76%). During the same period, the LT equity ratio increased by 20% in IL and 18% nationally. Hispanic LDLT at NM increased from 0.8 to 1.6/year (+100%), while the LDLT equity ratio increased from 0.07 to 0.17 (+146%), compared with +26% in IL and +0.7% nationally. NM's mean annual NHW LT volume remained stable (74.9 to 77.9). By 2021-2025, Hispanic LT reached 24.2/year and the Hispanic/NHW LT equity ratio rose to 0.27, suggesting sustained improvement in access and continued narrowing of the LT disparity. **Conclusion:** Implementation of a culturally competent HLTP was associated with improved Hispanic accessacross the LT pathway, including waitlist additions, overall LT, and LDLT. The observedimprovement in Hispanic/NHW equity ratios suggests narrowing disparities in livertransplantation. The HLTP was modeled after a renal transplant program within the same instutionon that demonstrated a similar reduction in disparities. These findings parallel prior kidney transplant experience, supporting thatculturally competent transplant care is not organ-specific; it is an access design strategy acrossorgan systems.

HLTP Impact Compared With Illinois and U.S. Benchmarks

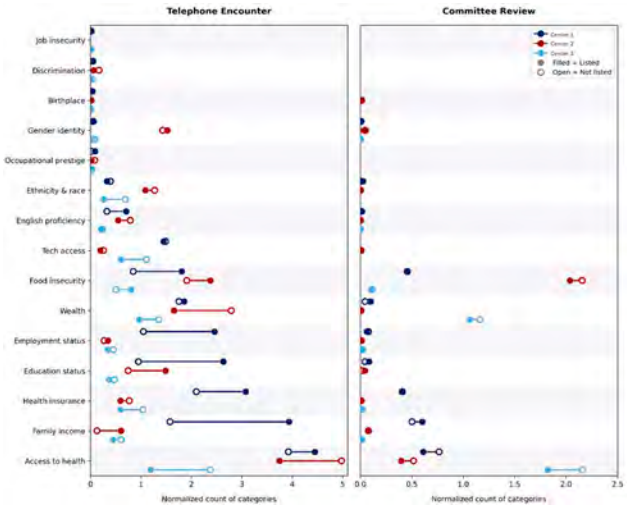
2098 | USING NATURAL LANGUAGE PROCESSING TO EXTRACT SOCIAL DETERMINANTS OF HEALTH DATA FROM TRANSPLANT NOTES: A MULTI-CENTER FEASIBILITY STUDY



Alexandra Strauss[1] Hamed Zaribafzadeh[2] Mia Grayson[2] Jennifer Gagnon[2] Tyrus Vong[3] Sue Hyon Kim[4] Marina Serper[5] Ricardo Henao[2] Lisa McElroy[6], [1]Johns Hopkins University, [2]Duke, [3]Johns Hopkins, [4]U of pennsylvania, [5]University of Pennsylvania Health System, [6]Duke University

Background: Disparities in liver transplant access are well documented, but rigorous study of modifiable social determinants of health (SDOH) is limited by sparse and inconsistently captured structured data. Because SDOH are often documented in free-text transplant notes, natural language processing (NLP) may augment missing structured data and improve inference. Our prior single-center work showed that rule-based NLP can identify SDOH terms in transplant notes at one institution. Here, we sought to assess the feasibility of this approach across centers with different note formats and documentation practices and to assess similarities and differences in SDOH documentation. **Methods:** We applied a rule-based spaCy NLP pipeline to telephone encounter and committee review notes from transplant patients at 3 centers from 2016-2025. Token-based rules were used to identify and count the SDOH terms per patient. Term and category

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

counts were stratified by transplant listing status and normalized by the number of patients in each group. **Results:** We analyzed notes from 9,509 referred patients. Figure 1 showed marked between-site variation in SDOH documentation, but similar broad patterns across centers. Telephone Encounters contained substantially higher and more diverse SDOH content than sparse committee review notes (eg, access to health, financial factors, family support, education). Center 1 had higher normalized counts for employment, education, insurance, and family income. Conversely, Center 2 shows pronounced spikes in areas such as wealth and food insecurity. Center 3 demonstrates lower but more stable counts. In Telephone Encounters, the listed vs unlisted "dumbbell" gaps suggested pre-listing differences in documentation density for several domains, including family income (Center 1) and wealth (Center 2). **Conclusion:** Rule-based NLP successfully extracted SDOH content from transplant notes across 3 centers, with consistent finding of greater SDOH density in telephone encounters than committee review notes. Although the frequency and mix of SDOH categories varied by center, the same broad domains were detectable across institutions and waitlist status, supporting the feasibility of multi-center SDOH extraction from free text. These findings suggest that NLP can help overcome missingness in structured SDOH data and enable future multi-center work focused on causal inference, disparities, and center-level variation in transplant evaluation and listing.

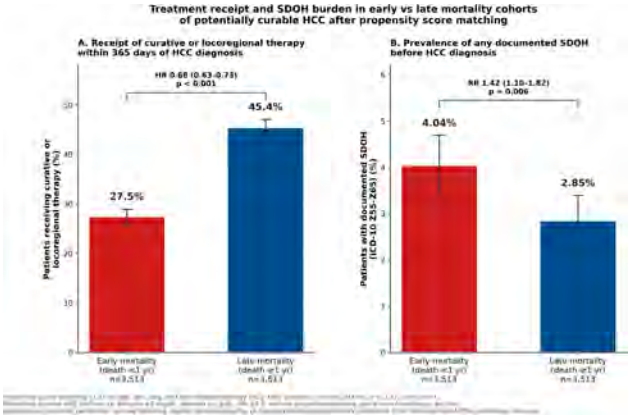
2099 | EARLY MORTALITY IN POTENTIALLY CURABLE HEPATOCELLULAR CARCINOMA IS ASSOCIATED WITH HIGHER POOR SOCIAL DETERMINANTS OF HEALTH BURDEN



Ali Emre Bardak[1] Nazli Begum Ozturk[2] Okan Cetin[1] Kamran Qureshi[2], [1]Boston Medical Center - Brighton, [2]Saint Louis University School of Medicine

Background: Despite advances in curative therapies for hepatocellular carcinoma (HCC), substantial variation in outcomes persists. Social determinants of health (SDOH) – non-medical factors such as housing stability, food security, financial resources, and social support that influence access to care – may drive disparities in treatment access and survival, but evidence in potentially curable cancer populations is limited. We examined whether early mortality among potentially curable HCC patients is associated with higher SDOH burden after control for demographic and etiologic confounders. **Methods:** We performed a retrospective cohort study using the TriNetX US Collaborative Network (66 healthcare organizations, 113.9 million patients). Adults with HCC (ICD-10 C22.0) diagnosed between 2010 and 2025 were eligible if: total bilirubin ≤ 3 mg/dL, albumin ≥ 3 g/dL, INR ≤ 1.5 at the time of HCC diagnosis, without distant metastases, portal vein thrombosis, ascites, spontaneous bacterial peritonitis, variceal bleeding, hepatic encephalopathy, or hepatorenal/hepatopulmonary syndrome. Among patients with documented mortality, two cohorts were defined: early mortality (death within 1 year of HCC diagnosis) and late mortality (death ≥ 1 year after HCC diagnosis). Cohorts were 1: 1 propensity score matched on age, sex, race, and liver disease etiology (HCV, HBV, alcoholic cirrhosis, MASH). Outcomes included receipt of any SDOH documentation (ICD-10 Z55–Z65) before HCC diagnosis, and curative-intent or locoregional therapy (liver transplant, resection, ablation, TACE, TARE) within 365 days post-diagnosis. Kaplan-Meier analysis was performed. **Results:** Of 13,224 potentially curable HCC patients with documented mortality identified, 3,513 per cohort remained after matching. Despite matching on demographic and etiologic factors, early-mortality patients had significantly higher prevalence of any documented SDOH (4.04% vs 2.85%; RR 1.42, 95% CI 1.10–1.82; $p = 0.006$). Compared with late-mortality patients, those who died within 1 year had significantly lower

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

receipt of curative-intent or locoregional therapy (27.5% vs 45.4%; HR 0.68, 95% CI 0.63–0.73; p < 0.001). **Conclusion:** Among potentially curable HCC patients matched on demographic and etiologic factors, early mortality is independently associated with higher documented SDOH burden and reduced receipt of curative therapy, when compared with patients who survived at least 1 year after the HCC diagnosis. These findings suggest SDOH influences access to curative care beyond tumor biology and hepatic reserve. Targeted SDOH screening and intervention may improve treatment access and survival in potentially curable HCC.

2100 | CUMULATIVE SOCIAL DETERMINANTS OF HEALTH BURDEN IDENTIFIES SEVERE PRESENTATION AND IMPAIRED BIOCHEMICAL RESPONSE IN PRIMARY BILIARY CHOLANGITIS: RESULTS FROM THE ELLA-PBC COHORT

Paul Yoon[1] Isabel Obias[1] Sade Brown[1] Jennifer Dodge[1] Ani Kardashian[1] Jeffrey Kahn[1] Saro Khemichian[1] Lily Dara[1], [1]University of Southern California Keck School of Medicine

Background: Social determinants of health (SDOH) may contribute to delayed recognition and incomplete biochemical response in primary biliary cholangitis (PBC), but data in underrepresented populations are limited. We examined whether cumulative SDOH burden was associated with baseline disease severity and 1-year alkaline phosphatase (ALP) normalization after ursodeoxycholic acid (UDCA) initiation. **Methods:** The East Los Angeles Latinx PBC (ELLA-PBC) cohort includes predominantly Hispanic patients (≥18 years) with PBC treated at the University of Southern California Medical Centers (2006-2022). SDOH domains were measured using validated PhenX Toolkit surveys. A 5-component SDOH score included insurance status, discrimination burden, health literacy, educational attainment, and access to health services. The composite score was categorized as none (0), moderate (1-2), or high (≥3). The primary outcome was severe baseline presentation, defined as the presence of ≥1 of the following: cirrhosis, decompensation, hepatocellular carcinoma, ALP >2x the upper limit of normal (ULN), or bilirubin >ULN. Logistic regression models estimated odds ratios (OR), adjusting for age and sex. Secondary analyses examined 1-year ALP normalization among UDCA-naive patients. **Results:** Among 95 patients, median age was 54 years, 94% were female, and 73% were Hispanic. SDOH burden was none in 27 (28%), moderate in 58 (61%), and high in 10 (11%) patients. Median baseline ALP was 271 U/L (IQR 159-436) overall and increased across SDOH burden: 181 vs. 304 vs. 405 for none, moderate, and high burden, respectively (p = 0.01). Severe presentation occurred in 79% patients and increased with SDOH burden (63% for none vs. 85% for moderate vs. 90% for high, p = 0.05). In adjusted models, moderate SDOH burden had 3-fold higher odds of severe presentation compared with no SDOH burden (OR 3.06, 95% CI 1.05-8.94, p = 0.04), while high SDOH burden had nearly 5-fold higher odds (OR 4.89, 95% CI 0.53-45.0, p = 0.16). Each 1-point increase in SDOH burden corresponded to 77% higher odds of severe presentation (OR 1.77, 95% CI 0.99-3.14, p = 0.05). Among 47 UDCA-naive patients with 1-year follow-up data, ALP normalization was achieved by 11 (23%) and was lower with SDOH burden: 7 (70%) with no burden, 3 (10%) with moderate burden, and 1 (17%) with high burden (p < 0.001). **Conclusion:** Cumulative SDOH burden was associated with a higher baseline ALP, higher odds of severe presentation, and lower ALP normalization after UDCA initiation. These findings support integrating structured SDOH screening into PBC care to guide risk stratification and targeted interventions to improve early diagnosis, monitoring, and treatment optimization.

2101 | THE PATH TO THE LIST: PROVIDERS&RSQUO; PERSPECTIVES ON EQUITY GAPS IN LIVER TRANSPLANT EVALUATIONS

Zamzam Ismail Artan Ali[1] Mohamed Addani[1] David Chascsa[2] Denise Harnois[3] Blanca Lizaola-Mayo[2] Kasey Boehmer[4] Lewis Roberts[5], [1]Mayo Clinic, [2]Mayo Clinic Arizona, [3]Mayo Clinic Florida, [4]Mayo Clinic, Rochester, [5]Mayo Clinic Rochester

Background: End Stage Liver Disease (ESLD) is an emerging public health concern with more than 15,000 hospitalizations each year in the United States. Together with cirrhosis, it is considered the 14th leading cause of death in the world. Liver transplantation (LT) is considered the only curative treatment for ESLD. More than 10,000 patients are currently awaiting LT in the USA. Unfortunately, about 20% of people will die while waiting for LT. Disparities in access to LT outcomes are influenced by a complex interplay of social determinants of health. The LT evaluation process is susceptible to structural inequities, but these effects are often masked by its clinical, logistical, and ethical complexities. Moreover, a recent scoping review found that female patients, Black race, and patients with Medicare insurance were less likely to be referred and evaluated for LT. Therefore, there is a need to investigate and identify mechanisms between social determinants of health and inequities in access to LT. **Methods:** This qualitative study is part of a mixed methods project examining disparities in access to LT. It is a multicenter study including Mayo Clinic LT centers in Minnesota, Florida, and Arizona. It utilizes 1: 1 in depth interviews with both healthcare providers and LT patients, aiming to understand upstream barriers to LT access for underrepresented communities. 23 interviews were conducted between Nov 2024-March 2026 with healthcare providers[figure1]. **Results:** Five main themes emerged from this study,[Figure1].Theme 1 explores language barriers and how it impacts care through time constraints, limitations in technology used and available resources to navigate this challenge. Many participants discussed socioeconomic and financial barriers in Theme 2. They highlighted insurance, lifelong medication costs, and distance from healthcare centers as factors limiting equal access to LT evaluation. Theme 3 discussed subjectivity of psychosocial assessment and how personality, social support and history of substance abuse can impact decision-making. Teamwork and power dynamics were emerging areas discussed by participants in Theme 4 stating the importance of shared leadership across disciplines and collective accountability. Final theme discussed patient empowerment and awareness of rights within the system. This included cultural differences in self-advocacy, medical literacy and disconnect between available resources and patients' knowledge. Overall, providers believed it's critical to establish partnerships and transparent relations with patients, to optimize equitable access to LT **Conclusion:** Mitigating LT barriers requires patient empowerment and effective language and system navigation. Providers identified critical gaps in care that require innovative and patient's involve solutions. Next phase of this project will collect patients' input, allowing them to share their voices, needs and lived experiences

2102 | NATIONAL MORTALITY TRENDS IN ALCOHOLIC LIVER DISEASE (1999–2024) AND FORECAST TO 2034: A CDC WONDER-BASED ARIMA ANALYSIS

Simran Joshi[1] Muhammad Umar[2] Faizan Faisal[2] Hannan Sharif[2] Hadia Arshad[2] Humna sohail[2] Ali Shan Hafeez[3] Hamza Sajid[4] Cheng-Hung Tai[1] Mohammad Aatiq Islam[1], [1]Yale New Haven Health, [2]Akhtar Saeed Medical and Dental College Lahore, Pakistan, [3]CMH Multan Institute of Medical Sciences, [4]Allama Iqbal Medical College, Lahore, Pakistan

Background: Alcoholic liver disease (ALD) is a leading driver of morbidity and mortality in the United States accounting for roughly one quarter of cirrhosis deaths. ALD is also the principal indication for liver transplantation reflecting a growing clinical and an economic burden. In this study, we aim to evaluate and predict alcoholic liver disease mortality trends among US individuals aged ≥15 from 1999-2034. **Methods:** Mortality data was extracted from the CDC WONDER database for individuals aged ≥15 years with alcoholic liver disease (ICD: K70). We assessed age-adjusted mortality rates (AAMRs) per 100,000 population as stratified by sex, age, race/ethnicity, U.S. Census regions, and 2013 urbanization categories. Annual Percent Change (APC) with 95% confidence intervals (CI) was estimated using Joinpoint regression; $p < 0.05$ was considered statistically significant. Future AAMRs through 2034 were forecasted using Autoregressive Integrated Moving Average (ARIMA) models with model selection based on corrected Akaike Information Criterion (AICc). **Results:** From 1999 to 2024, 606,023 deaths occurred among U.S individuals aged ≥15 years. The overall AAMR rose from 5.11 to 11.77. The trend increased non-linearly through 2021, then showed a modest decline from 2021 to 2024 (APC -6.48%, $p < 0.001$). AAMRs were consistently higher in men (13.29) than in women (5.04). Racial and ethnic disparities were evident with, Hispanic or Latinos bearing the most burden (11.20), followed by non-Hispanic Whites (8.47), non-Hispanic Others (6.58), and non-Hispanic Blacks or African Americans (6.12). The burden was the greatest in the Western region (13.85) and in non-metropolitan areas compared to metropolitan areas (8.43 vs 7.39). ARIMA forecasting indicates that mortality will continue to remain elevated through 2034. The overall AAMR is projected to be 11.75 in 2034, with a sustained sex-specific gap of 16.46 in men and 7.41 in women. By age, the highest projected rates are in adults aged 65-74 years (30.21) and 55-64 years (27.63), whereas adults aged 25-34 years remain lowest (2.94). Among racial/ethnic groups, Hispanic or Latino adults remain highest in 2034 (13.45), followed by White adults (12.73) and Black or African American adults (7.25). The West continues to show the highest projected regional rate (16.91), emphasising ongoing and widening inequities. **Conclusion:** Despite a modest decline in mortality from 2021 onwards, the overall burden remains markedly elevated with persistent disparities in alcoholic liver disease mortality projected for all stratifications through 2034. These projections provide insight into the growing burden of alcoholic liver disease as a contributor of mortality while highlighting inequities across various groups. These findings can guide targeted prevention strategies, early diagnosis and treatment efforts for this preventable cause of liver failure.

2103 | RAPID INCREASES IN POPULATION-BASED ACCESS TO LIVER TRANSPLANT FOR ALCOHOL-ASSOCIATED HEPATITIS COMPARED TO OTHER STEATOTIC LIVER DISEASES

Sharmitha Yerneni[1] Russell Rosenblatt[2] Eytan Palte[1] Giuseppe Cullaro[1] Elizabeth Verna[3] Gene Im[1], [1]NYP - Columbia University Irving Medical Center, [2]Weill Cornell Medicine, [3]NYP - Columbia University Medical Center

Background: Population-based measures of liver transplant (LT) access that incorporate disease-attributable mortality can help identify disparities in care across disease etiologies and geographic regions. We used this framework to evaluate temporal and regional

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

trends in population-based LT access for steatotic liver diseases (SLD), including metabolic dysfunction-associated liver disease (MASLD), alcohol-associated cirrhosis (AC), and alcohol-associated hepatitis (AH). **Methods:** We conducted a retrospective study of the UNOS and CDC WONDER databases from 2011 to 2024. Adults waitlisted for LT with MASLD, AC, or AH, along with deaths attributed to these conditions, were included. The primary outcome was the listing-to-death ratio (LDR), calculated as the ratio of LT waitlist registrations to disease-attributable deaths. LDR provides a population-based measure of LT access. Secondary outcomes included transplant-to-death ratio (TDR). Ratios were calculated nationally and stratified by state to assess temporal and geographic variations in LT access. **Results:** Over the 13-year study period, MASLD consistently had the highest LDR, remaining stable between 2011 and 2019 with LDR 0.36-0.42 before declining after 2020 to 0.20 by 2024 (Figure 1a). In contrast, LDR for AC increased by 73% from 0.11 in 2011 to 0.19 in 2024. AH demonstrated the most dramatic increase in LDR over the study period. AH waitlist registrations were initially very low, below 0.05 through 2016, but increased substantially after 2017. The LDR for AH surpassed AC (0.19 vs. 0.15) by 2021 and MASLD (0.62 vs. 0.30) by 2023. The most notable increase occurred between 2022 to 2024, during which LDR for AH rose from 0.25 to nearly 0.70, a 180% increase that temporally aligned with the new UNOS AH diagnosis codes. Trends in TDR were similar. In 2024, AH waitlist registrations were predominantly concentrated in the Southern and Northeastern United States (Figure 1b). Texas accounted for the largest proportion of listings (153; 16.5%), followed by New York (85; 9.2%), Florida (68; 7.3%), and Pennsylvania (66; 7.1%). **Conclusion:** Among patients with SLD, MASLD had the highest access to LT relative to disease-attributable mortality until 2023, when it was surpassed by AH. While new UNOS diagnosis codes for AH can partially explain this rapid rise in LDR, our findings also support the growing evidence that LT for AH may be underreported as AC, the MELD advantage in AH, and increasing adoption of LT for AH particularly in Texas and the Northeast.

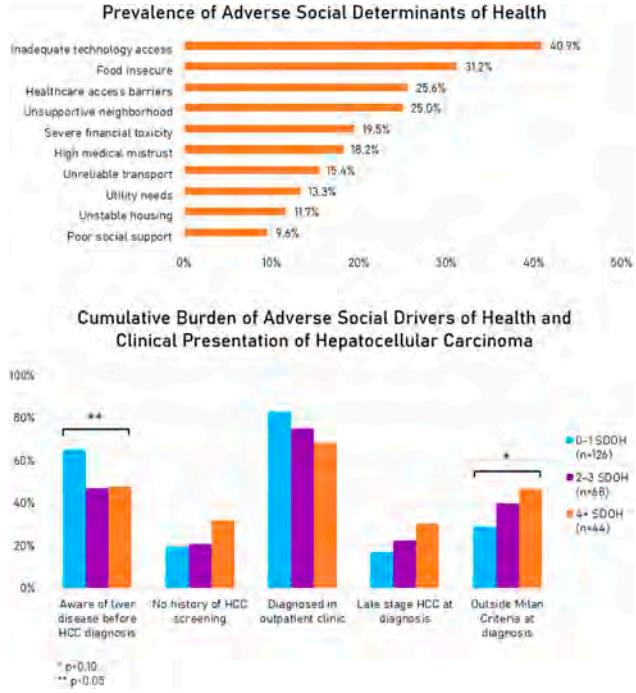
2104 | THE LIVER CANCER EQUITY PROJECT: CHARACTERIZING ADVERSE SOCIAL DETERMINANTS OF HEALTH IN A PROSPECTIVE COHORT OF PATIENTS WITH HEPATOCELLULAR CARCINOMA



Alison Ly[1] Jennifer Tsui[2] Myles Cockburn[2] Norah Terrault[3] Kali Zhou[3], [1]Keck School of Medicine at USC, Los Angeles General Medical Center, [2]Keck School of Medicine at USC, USC Norris Comprehensive Cancer Center, [3]Keck School of Medicine of USC

Background: Social determinants of health (SDOH) are key contributors to differential screening rates and cancer stage for individuals with hepatocellular carcinoma (HCC), though reported associations usually employ macro-level proxies such as area-level indices, race/ethnicity, and insurance. To address this gap, we developed the Liver Cancer Equity Project, a unique prospective cohort of HCC patients that links clinical history with a robust characterization of patient-level social needs through a multi-lingual survey. **Methods:** Adults with a diagnosis of HCC were surveyed from Hepatology and Oncology clinics at an academic transplant center and safety net hospital between 6/2024-3/2026. The 63-item survey of demographics, social needs, and liver disease knowledge/history was adapted from multiple validated questionnaires and offered in six languages. We examined ten adverse SDOH: unstable housing, utility needs, food insecurity, unreliable transportation, low neighborhood/social support, inadequate technology access, severe financial toxicity, high medical mistrust, and healthcare access barriers. Patients were grouped by total number of adverse SDOH: 0-1, 2-3, and >4. Clinical outcomes of liver disease awareness, HCC screening, and stage at diagnosis were compared by SDOH category. **Results:** The survey response rate was 82.6%, with 238 patients included (49% non-English surveys; 34% safety-net). The cohort's median age was 66 years (IQR 60-72), 71.8% were male, and 72.9% Hispanic/15.7% Asian/8.3% White/1.7% Black, with 69.0% reporting high school or less education. 38.2% had metabolic liver disease, 33.6% alcohol, and 22.7% viral hepatitis; 72.3% were ECOG

0, 67.5% CPT-A and 79.1% BCLC 0-A. Individual prevalence of adverse SDOH ranged from 9.6-40.9% (see Figure), with inadequate technology access defined by lack of a computer or stable internet and food insecurity the most frequently reported and unstable housing and insufficient social support least reported (see Figure). The median number of adverse SDOH per participant was 1 (IQR 1-3) with 52.9%, 28.6%, and 18.5% having 0-1, 2-3, and >4 SDOH factors, respectively. Compared to 0-1, patients with ≥2 SDOH were significantly less likely to be aware of their liver disease prior to HCC diagnosis ($p = 0.03$; see Figure). Higher SDOH groups were also more likely to report no HCC screening, be diagnosed in an acute care setting, have late-stage HCC, and fall outside of Milan Criteria, though these differences were not statistically significant. **Conclusion:** In the Liver Cancer Equity Project prospective cohort, 77% reported at least one adverse SDOH, with nearly one in five reporting greater than four. Higher adverse SDOH burden was linked to lower liver disease awareness, an essential first step to early detection of HCC, highlighting the need for targeted interventions to increase cirrhosis detection in socially at-risk populations.

2105 | SOCIODEMOGRAPHIC DISPARITIES IN DIETARY QUALITY AMONG PATIENTS WITH CIRRHOSIS: A MULTICENTER SURVEY STUDY

Nicole Rich[1] Mohammed Al-Hasan[2] Yan Liu[3] Jennifer Kramer[3] Juana Campos[3] Lisa Quirk[1] Diya Kar[1] Janha Anyanwu[3] Amanda Gibbons[3] Valeria Londono[3] Gabriela Morales Pielago[3] Aaron Nguyen[3] Dalal Youssef[3] Fasiha Kanwal[4] Amit Singal[1], [1]UT Southwestern Medical Center, [2]University of Texas Southwestern Medical Center, [3]Baylor College of Medicine, [4]Michael E. DeBakey VA Medical Center

Background: Nutritional health is an important modifiable factor in cirrhosis management, yet real-world dietary behaviors among patients with cirrhosis remain poorly characterized. We evaluated diet quality across sociodemographic and clinical subgroups in a multicenter cohort of patients with cirrhosis. **Methods:** We conducted a prospective survey study of adults with cirrhosis across four U.S. health systems. Diet behaviors were assessed using the 13-item Latino Dietary Behaviors Questionnaire (LDBQ), a validated dietary behavior instrument with scores ranging from 13-47, where higher scores indicate a healthier diet. Total scores and individual dietary behaviors were compared across sex, household income, race/ethnicity, liver disease etiology and cirrhosis severity. **Results:** Among 1,319 patients with cirrhosis (mean age 60.0 ± 10.6 years; 58.9% men), 42.1% were non-Hispanic White, 21.5% Black, 34.0% Hispanic. Most patients reported annual household income < $50,000 (69.0%), and 25.5% reported limited health literacy. The most common liver disease etiologies were HCV (29.5%), ALD (27.2%) and MASLD (27.1%). Mean LDBQ score was 23.4 ± 6.0, consistent with suboptimal diet behaviors. Patients with annual household income < $50,000 reported poorer diet quality, including more frequent consumption of fast food, fried food, and sugar-sweetened beverages (all $p < 0.05$). Women demonstrated healthier diet behaviors than men across several domains, including lower intake of soft drinks and more frequent portion control (both $p < 0.001$). Dietary quality also varied across racial/ethnic groups and liver disease etiologies. Less healthy diet behaviors were more commonly observed among patients with ALD and MASLD compared to those with HCV, while differences by Child Pugh score were less pronounced. **Conclusion:** Substantial sociodemographic disparities in diet quality exist among patients with cirrhosis. Less healthy dietary behaviors were more commonly observed among patients with lower household income, men, and those with MASLD or ALD, highlighting the importance of incorporating social and behavioral determinants into nutrition-focused interventions for chronic liver disease.

2106 | EVALUATING LARGE LANGUAGE MODELS FOR REPRODUCING DIRECTIONALITY OF EPIDEMIOLOGIC ASSOCIATIONS IN HEPATITIS C RISK AMONG PEOPLE WHO INJECT DRUGS

Sophia Mao[1] Alexander Gutfraind[1] Keshav Gandhi[1], [1]University of Illinois Chicago

Background: People who inject drugs (PWID) account for most new Hepatitis C virus (HCV) infections in the United States. Large language models (LLMs) are increasingly being explored for synthetic data generation and epidemiologic modeling, but it remains unclear whether LLM-generated outputs preserve epidemiologic relationships relevant to HCV transmission. We evaluated whether

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

contemporary LLMs reproduce literature-supported directional associations between housing status and HCV-related risk behaviors among PWID. **Methods:** We conducted a controlled simulation study using three LLMs (Claude Sonnet 4.5, Amazon Nova 2 Lite, and OpenAI GPT-OSS-120B). PWID profiles informed by longitudinal Chicago cohort and surveillance data were evaluated under two hypothetical housing conditions (homeless versus stable; N = 224 per condition per model). Prompts were standardized across conditions. Selected LLMs generated structured outputs describing injection and alternative drug use practices, syringe sharing, withdrawal frequency, treatment engagement, social network characteristics, and HCV outcomes in a fentanyl-era context. Paired effect sizes, bootstrap confidence intervals, subgroup analyses, and pairwise correlations were used to assess directional consistency and cross-model agreement. **Results:** Across selected LLMs, homelessness was consistently associated with greater public/shelter-based injecting behaviors (Cohen's d: 1.12–3.94) and higher likelihood of positive HCV status (d: 0.13–0.42), consistent with prior epidemiologic evidence. However, several expected associations varied in direction across LLMs, including injection frequency (d: −0.24–0.02), withdrawal frequency (d: −0.15–0.29), and proportion of injection partners with HCV (d: −0.13–0.20). Baseline profile characteristics such as injection frequency and syringe-sharing behaviors also showed minimal variation relative to corresponding LLM-generated outputs. **Conclusion:** Current LLMs partially reproduce established epidemiologic relationships relevant to HCV transmission, but inconsistencies in association direction, effect sizes, subgroup differences, and correlation structures suggest that behavioral outputs may reflect model-specific representations rather than stable epidemiologic patterns. This reinforces the importance of empirical validation and cross-model evaluation before applying LLM-generated behavioral outputs in transmission or policy modeling.

Cohen's d (homeless minus stable housing) with 95% confidence intervals across models (N = 224 per condition per model)

Variable	Expected Direction	GPT-OSS-120B	Claude Sonnet 4.5	Nova 2 Lite
Public or Shelter Use	↑	3.94 (3.52, 4.47)	3.64 (3.13, 4.30)	1.12 (1.00, 1.26)
Positive HCV status	↑	0.23 (0.15, 0.29)	0.42 (0.31, 0.52)	0.13 (-0.07, 0.20)
Partner Count	↑	0.15 (0.02, 0.28)	0.19 (0.08, 0.29)	-0.06 (-0.18, 0.07)
Partners with HCV	↑	-0.13 (-0.19, -0.07)	0.20 (0.08, 0.32)	
Withdrawals	↑	-0.15 (-0.30, -0.02)	0.30 (0.17, 0.42)	-0.08 (-0.17, 0.06)
Injection Frequency	↑	-0.24 (-0.36, -0.13)	-0.07 (-0.21, 0.05)	0.02 (-0.12, 0.12)
Receptive Sharing	↑	0.13 (0.02, 0.22)	0.08 (-0.06, 0.18)	0.02 (-0.03, 0.04)
Distributive Sharing	↔	-0.05 (-0.14, 0.10)	-0.02 (-0.20, 0.12)	-0.07 (-0.62, 0.39)
Treatment	↓	-0.31 (-0.41, -0.20)	-0.74 (-0.85, -0.64)	
Alternative Routes	↓	-0.26 (-0.41, -0.11)	-0.53 (-0.62, -0.45)	

↑, ↓, and ↔ indicate expected positive, negative, or no clear direction of association between homelessness and each variable, based on prior literature. "-" indicates no variation in model outputs across conditions.

2107 | WHEN LOW SOCIAL STATUS MEETS LIVER DISEASE, OUTCOMES ARE WORSE: INTERIM ANALYSIS FROM THE ITALIAN MASLD COHORT

Andrea Vaiano[1] Luigina Ferrigno[1] Stefano Rosato[1] Benedetta Mattioli[2] Maria Giovanna Quaranta[1] Lucia Craxì[3] Loreta A Kondili[1], [1]Istituto Superiore di Sanità, Rome, Italy, [2]Istituto Superiore di Sanità, [3]University of Palermo, Palermo, Italy

Background: Social Determinants of Health (SDoH) are non-clinical factors that drive unequal exposure to health risks and inequalities in health outcomes. This interim analysis evaluates their role in liver disease severity in Italian patients in care recently enrolled in the ITA-MASLD (Italian Metabolic Dysfunction-Associated Steatotic Liver Disease) cohort. Currently over 30 clinical centers have put clinical and SDoH data of the consecutively enrolled patients. This interim analysis focused on the evaluation of the association of SDoH (when available) with the fibrosis progression (Metavir classification) as a proxy of liver cancer risk. **Methods:** Data on SDoH (available for 169 patients) were assessed using standardised questionnaires across domains including education, social context, environment, and financial stability. A composite indicator of economic insecurity was derived from individual items. These metrics were integrated with anthropometric data to explore associations with clinical risk factors. **Results:** As shown in Table 1, better socioeconomic conditions were associated with milder liver disease. A significantly higher prevalence of advanced fibrosis was observed among economically insecure patients (55.6% vs. 35.4%, p = 0.020) and those with lower educational attainment (57.8% vs. 34.0%, p = 0.004).Multivariable analysis included adjustments for BMI overweight/obesity, because a significant relationship between overweight/obesity (versus underweight/ normal) and economic insecurity (p = 0.034) was observed whereas other factors correlated with MASLD (diabetes, hypertension or dyslipidemia) were not included as no associations were found with SDoH indicators. According to the multivariable analysis, economic insecurity (OR = 2.48, 95% CI 1.12 to 5.70) and age (OR = 1.07/year, 95% CI 1.02 to 1.12) were associated with F3-F4 fibrosis stage. Conversely, occupational status (OR = 2.11, 95% CI 0.79 to 5.95), low education (OR = 2.13, 95% CI 0.99 to 4.75), overweight/obesity (OR = 1.01, 95% CI 0.22 to 4.04) and sex (OR = 0.50, 95% CI 0.21 to 1.15) were not significantly associated with F3-F4 fibrosis stage (Table 1). **Conclusion:** Social disadvantage is a key determinant of liver disease severity across etiologies. These findings support the integration of SDoH assessment into clinical risk

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

stratification, allowing social vulnerability to be translated into actionable information. Collecting SDoH data may help design more targeted care pathways and reduce inequalities in advanced liver disease and liver cancer risk. Tailored public health interventions and integrated clinical care pathways will prove essential to mitigate health disparities and improve long-term prognostic outcomes.

Table. Factors associated with severe fibrosis in the MASLD cohort: baseline characteristics and multivariable analyses

Variable	No severe fibrosis N = 53[1]	Severe fibrosis N = 116[1]	p-value[2]
Epidemiological features			
Age	61 (51, 67)	64 (56, 71)	**0.017**
Sex			0.061

2108 | ETHNICITY MODIFIES THE ASSOCIATION OF DIET AND INSURANCE WITH LIVER STIFFNESS IN A DIVERSE URBAN MASLD POPULATION

Maryfe Coronel Novoa[1] Adeeba Tak[1] Julia Napoli[1] Yulu He[1] Kamileh Rivera[1] Mark Miller[1] Victor Llanes[1] Asher Leviton[1] Megan Miller[1] Frances Lee[1] Ryan Walker[1] Dania Valvi[1] Emanuela Taioli[1] Scott Friedman[1] Meena Bansal[2] Xiaotao Zhang[1], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: MASLD disproportionately affects Hispanic individuals, who have higher US prevalence, advanced fibrosis, and liver-related mortality than non-Hispanic counterparts. Genetic susceptibility may contribute, but the role of social determinants of health (SDOH) including neighborhood disadvantage, diet quality, and healthcare access in ethnicity-specific fibrosis outcomes remains understudied. **Methods:** We analyzed 125 patients from the Mount Sinai MASLD/MASH Registry, including 54 Hispanic and 71 non-Hispanic patients. Liver stiffness measurement (LSM) was assessed by FibroScan. Significant fibrosis, advanced fibrosis, and cirrhosis were defined as LSM $\geq$8, $\geq$12, and $\geq$14 kPa, respectively. SDOH measures included 2023 Area Deprivation Index (ADI), diet quality by NCI Dietary Screener Questionnaire composite z-score, insurance type, and language preference. Multivariable linear regression tested ethnicity interactions for SDOH predictors of log-LSM, adjusting for age, sex, BMI, and diabetes. Exploratory Hispanic subgroup analyses compared Caribbean, Mexican/Central American, and South American patients. **Results:** Hispanic and non-Hispanic patients were similar in age, sex, diabetes, and diet quality. Hispanic patients had significantly higher obesity prevalence (61% vs. 41%, p = 0.039), higher ADI (13.5 vs. 9.0, p = 0.054), more Medicaid coverage (30% vs. 13%, p = 0.033), and greater fibrosis burden, including significant fibrosis (30% vs. 20%), advanced fibrosis (20% vs. 9.9%), and cirrhosis (17% vs. 4.2%). ADI was not associated with LSM. A significant diet-by-ethnicity interaction was observed (p = 0.003): each 1-SD higher diet-quality score was associated with 19% lower LSM in Hispanic patients (95% CI, 5.9%–30.3%; p = 0.008), but not in non-Hispanic patients. Medicare coverage, versus commercial insurance, was associated with 99.8% higher LSM in Hispanic patients (95% CI, 26.3%–216.1%; p = 0.004), but not non-Hispanic patients. Language preference was not associated with LSM. Among Hispanic subgroups, diet quality differed by region of origin, with highest scores among Caribbean patients (p = 0.020). **Conclusion:** In this diverse urban MASLD cohort, ethnicity modified the associations of diet quality and insurance type with liver stiffness. Higher diet quality was associated with lower LSM only among Hispanic patients, despite similar diet quality by ethnicity, supporting further study of diet–genetic susceptibility interactions, especially *PNPLA3*. Medicare coverage was associated with higher LSM only among Hispanic patients, suggesting possible cumulative access barriers or residual clinical complexity. These findings support culturally tailored dietary interventions, equitable access strategies, and larger studies with *PNPLA3* genotyping and Hispanic subgroup oversampling.

2109 | LOST IN TRANSLATION: MACHINE TRANSLATION SIGNIFICANTLY IMPACTS READABILITY OF LLM-GENERATED PATIENT EDUCATION MATERIALS FOR CHRONIC LIVER DISEASE IN ENGLISH AND SPANISH

Husayn Ramji[1] Aishwarya Gatiganti[1] Luis Morales[1] Shaquille Lewis[1] Sharan Poonja[2] Devika Dixit[1] Molly Delk[1] Peng-Sheng Ting[1], [1]Tulane University School of Medicine, [2]Tulane University

Background: Health literacy is a critical social determinant of health, with lower health literacy being associated with poor clinical outcomes and healthcare disparities. Although the Agency for Healthcare Research and Quality (AHRQ) recommends that all patient educational materials (PEMs) be written at a 6th -grade reading level or below, a large percentage of PEMs in English and Spanish do not reach this standard, including those written for patients with chronic liver conditions, contributing to a health literacy gap. Tools like large-language models (LLMs) with certain prompt engineering techniques have shown promise in addressing this in English, but the extent to which this benchmark can be achieved in other languages remains undertested. Furthermore, for providers in resource-limited settings, machine translation is often the most widely available tool in creating PEMs, but the effects of translation on readability is also understudied. This study seeks to address this by testing various prompt engineering techniques in English and Spanish, and assessing the readability of the outputs, pre- and post-translation. **Methods:** Three prompt engineering techniques (Zero-Shot, Constrained, Contextualized) were asked to ChatGPT 5.5 Instant, Gemini 3.5 Flash, and Claude Sonnet 4.6 in English and in Spanish to explain hepatitis, MASLD, MASH, cirrhosis, and hepatocellular carcinoma. Google Translate was then utilized to translate the outputs from one language to the other. The readability of the outputs and translations was assessed with the Python texstat library, which yielded language-appropriate metrics – SMOG for English, and SOL for Spanish, which both report a grade level metric. Readability was compared by prompt, and data underwent a One-Way ANOVA followed by a Post-Hoc analysis. The comparison between Original and Translated readability was conducted with a Student's t-test, with $p < 0.05$ deemed significant. **Results:** No prompt in English or Spanish averaged at or below a 6th grade reading level. The Contextualized prompt came close in Spanish (6.45 ± 0.62). The effects of machine translation, however, varied. The Spanish-to-English translation was significantly less complex than the Native English outputs (-0.5 to -1.36 grades, $p < 0.05$) while the English-to-Spanish translation was significantly more complex than the Native Spanish outputs (+1.53 to +2.22 grades, $p < 0.01$). **Conclusion:** Modern LLM and prompt engineering techniques continue to struggle to meet AHRQ recommendation regarding PEMs. In addition, machine translation can significantly worsen the readability of LLM-generated patient materials for liver conditions, particularly when going from English-to-Spanish. For physicians in resource-limited settings using LLMs, we recommend prompting in the native or target language, in order to continue to strive to reach patients where they are in terms of health literacy.

2110 | SOCIAL DETERMINANTS OF HEALTH PREDICT FRAILTY AMONG LIVER TRANSPLANT CANDIDATES AT A SAFETY-NET MEDICAL CENTER

Pei-Lun Kuo[1] Wyatt Nice[2] Cameron Amini[2] Sarina Maini[3] Teresa Eder[4] Neha Jakhete[5] Chandra Bhati[6] Kirti Shetty[6], [1]University of Maryland Medical Center - Midtown Campus, [2]University of Maryland School of Medicine, [3]University of Virginia Medical Centre, [4]University of Maryland Medical Center Downtown

Campus, [5]University of Maryland, [6]University of Maryland, Baltimore

Background: Frailty is a strong predictor of poor outcomes among patients awaiting liver transplantation (LT) and is associated with increased post-LT mortality and greater post-LT healthcare utilization. However, the association between neighborhood-level social determinants of health (SDoH) and pre-LT frailty remains poorly characterized. **Methods:** All adult liver transplant (LT) candidates undergoing LT evaluation (January 2025 – April 2026) at an academic liver transplant center serving as a safety-net provider were included. Pre-LT frailty was assessed in either the ambulatory or inpatient setting using the Liver Frailty Index (LFI) (http://liverfrailtyindex.ucsf.edu), with robust defined as LFI <3.2, prefrail as $3.2–<4.5$, and frail as ≥ 4.5. Neighborhood social determinants of health (SDoH) were measured by the Social Vulnerability Index (SVI), a CDC tool that assesses community resilience based on 16 US Census variables grouped into four themes: socioeconomic status (SES), household composition, minority status, and housing & transport; higher scores indicate greater social vulnerability (https: //www.atsdr.cdc.gov/placeandhealth/svi/index.html). Logistic regression was used to examine the association between neighborhood SDoH and pre-LT frailty (prefrail/frail vs. robust), adjusting for age, sex, and insurance type as a surrogate for individual-level socioeconomic status. In the logistic regressio, each SDoH indicator was dichotomized at the 25th percentile, with the bottom quartile (least vulnerable) serving as the reference group. **Results:** Among 106 LT candidates, 18 (17.0%) were robust, 42 (39.6%) were prefrail, and 46 (43.4%) were frail (Table 1). Fifty-one (48.1%) were female, with a median age of 57 years (IQR 46–66). After adjusting for age, sex, and insurance type, higher SVI minority status (Q2–Q4 vs. Q1) was significantly associated with increased odds of being prefrail or frail (OR 3.39, 95% CI 1.13–10.21, $p = 0.030$), and a borderline association was observed for SVI housing & transport (OR 2.72, 95% CI 0.86–8.54, $p = 0.087$) (Table 2). SVI overall, SVI SES, and SVI household composition also showed positive associations with the odds of being prefrail or frail, though these did not reach statistical significance. **Conclusion:** The prevalence of frailty in this safety-net medical center cohort undergoing evaluation for LT was 43.4%, nearly double the 21% reported in the Multi-Center Functional Assessment in Liver Transplantation (FrAILT) Study. Neighborhood-level SDoH, particularly minority status vulnerability, was associated with pre-LT frailty. These findings lay the groundwork for future studies investigating whether targeted prehabilitation interventions among LT candidates residing in high social vulnerability neighborhoods can improve post-LT outcomes and reduce healthcare resource utilization.

Table 1 - Baseline Characteristics of Liver Transplant Candidates (n = 106)

Group[1]	Robust (n=18)	Prefrail (n=42)	Frail (n=46)	Overall (n=106)

Continuous variables: median [IQR]. Categorical variables: n (%).
[1] Liver Frailty Index (LFI): a validated measure of physical frailty in patients with chronic liver disease, calculated from grip strength, balance, and chair stand performance. Available at: [redacted] LFI was used to categorize patients as robust (LFI <3.2), prefrail (LFI 3.2–<4.5), or frail (LFI >=4.5).
[2] Social Vulnerability Index (SVI): a CDC measure of community resilience based on 16 US Census variables grouped into four themes – socioeconomic status, household composition & disability, minority status & language, and housing type & transportation. Scores range from 0 (least vulnerable) to 1 (most vulnerable). Available at: [redacted]

Table 2 - Association between Higher Social Vulnerability and Odds of Being Prefrail/frail (n = 106)

Variable[1]	Adjusted OR (95% CI)[2]	p-value
SVI Overall	2.52 (0.82, 7.71)	0.105
SVI – SES	2.54 (0.81, 7.92)	0.108
SVI – Household	2.33 (0.78, 6.94)	0.130
SVI – Minority	3.39 (1.13, 10.21)	0.030 *
SVI – Housing & Transport	2.72 (0.86, 8.54)	0.087 †

* p<0.05 † p<0.10
[1] Social Vulnerability Index (SVI): a CDC measure of community resilience based on 16 US Census variables grouped into four themes – socioeconomic status, household composition & disability, minority status & language, and housing type & transportation. Scores range from 0 (least vulnerable) to 1 (most vulnerable). Available at: [redacted]
[2] Logistic regression with adjustment for age, sex, and insurance type was used to examine the association between neighborhood SDoH and liver frailty (binary outcome, prefrail/frail vs robust, with robust group as the reference). Liver Frailty Index (LFI) was used to categorize patients as robust (LFI <3.2), prefrail (LFI 3.2-<4.5), or frail (LFI >=4.5). The main exposure variables (SVI) were dichotomized into two groups, with the lowest quartile indicating the least socially vulnerable group and treated as the reference group. Therefore, the adjusted odds ratio (aOR) shows the association between higher social vulnerability and odds of being Prefrail/Frail.

2111 | HEALTH RELATED SOCIAL NEEDS SCREENING AND COMMUNITY RESOURCE REFERRALS WITHIN GENERAL AND TRANSPLANT HEPATOLOGY CLINICS

Rebecca Kim[1] April Ballantyne[1] Gregory Stoddard[1] Jiawen Guo[1] Bob Wong[1] John Inadomi[1] Molly Conroy[1] Jennifer Price[2] Andrea Wallace[1], [1]University of Utah, [2]University of California San Francisco

Background: Health related social needs (HRSN) contribute to worse outcomes in chronic liver disease

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(CLD). HRSN screening and resource referral programs have led to improved health outcomes among patients with chronic diseases, yet routine HRSN screening remains uncommon in hepatology practice. To address this gap, we aimed to identify HRSN and refer patients to community resources by implementing HRSN screening and resource referrals in hepatology clinic. **Methods:** From 12/2024-03/2026, a 10-item HRSN screener was integrated into hepatology care through electronic health record-based workflows. Screening was completed via MyChart or during visit check-in. Patients requesting assistance were referred to available resources including transportation services, food pantries, utility assistance, etc. Descriptive analyses included mean and frequency. Comparative analyses were performed using Chi-Square and Fisher's exact tests. **Results:** Among 3,480 unique liver clinic patients screened, 54% were female, 74% White, 11% Hispanic (**Table A**). Most (96%) spoke English; commercial insurance was most common (54%). Most (85%) were seen in general hepatology clinic, and 3,141 (90%) had CLD. Overall, 1,348 (39%) patients reported 1 or more need within the 16-month period. Reported needs included limited finances for household items (16%), food insecurity (14%), and as listed in **Table A** .No significant differences in HRSN were found by gender, language, or clinic visit type. However, statistically significant differences by race and insurance provider were identified ($p < 0.02$). Several HRSN were more often reported among American Indian/Alaska Native (AI/AN), Black, Hispanic and Native Hawaiian/Pacific Islander (NH/PI) populations, and among patients with Medicaid. Additionally, those with CLD compared to without, reported a higher prevalence of food insecurity (15% vs 10%, $p = 0.045$), utility insecurity (12% vs 9%, $p = 0.04$), and housing costs (11% vs 6%, $p = 0.01$).Overall, 171 patients (5%) requested a referral to resources, including 142 patients (11%) who reported HRSN. Among them, 54% female, 61% White, 20% Hispanic, and 98% with CLD (**Table B**). A larger proportion of AI/AN, Black, Hispanic, and NH/PI patients were referred to resources than White patients ($p < 0.001$); as well as 12% of Spanish-speaking patients and 13% with Medicaid. The most common HRSN among those requesting resources were food insecurity, limited funds for home items, and utility insecurity (**Table B**). **Conclusion:** HRSN screening and community resource referrals were successfully integrated into hepatology clinics. HRSN are prevalent within our hepatology patient population, particularly among racial minority groups. People interested in resources can be referred to community programs through healthcare-based referrals, though our referral rate was low. The impact of this intervention on CLD outcomes requires ongoing longitudinal follow up.

2112 | UNEQUAL BURDEN: INCOME-RELATED DISPARITIES IN CIRRHOSIS

Arti Patel[1] Sujay Singh[1] Homan Abdollahzadeh[1],
[1]Eisenhower Medical Center

Background: Cirrhosis disproportionately affects socioeconomically disadvantaged populations, with substantial morbidity and mortality. Income-related disparities may influence disease severity, healthcare access, and outcomes. This study evaluates the association between income level and demographics, comorbidities, healthcare utilization, and inpatient outcomes in hospitalized patients with cirrhosis. **Methods:** This retrospective cohort study used the National Inpatient Sample (NIS) database to identify adults with cirrhosis between 2019 and 2022. Patients were stratified by income into the lowest (first) quartile versus higher quartiles to compare their demographics, comorbidities, hospital characteristics, and inpatient outcomes. Statistical analyses were performed using STATA software. **Results:** A total of 3,229,299 patients with cirrhosis were included; 32.8% were in the first income quartile and were younger (59.8 vs 61.0 years, $P < 0.05$). Racial distribution differed by income, with White (OR 0.564, 95% CI 0.545-0.584) and Asian (OR 0.350, 95% CI 0.323-0.380) patients less likely to be in the first income quartile,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

while Black (OR 2.601, 95% CI 2.505-2.701), Hispanic (OR 1.399, 95% CI 1.332-1.469), and Native American (OR 2.166, 95% CI 1.981-2.368) patients more likely to be in the first income quartile. Charlson Comorbidity Index (CCI) differed, with higher intermediate comorbidity burden (CCI 4-6, $P < 0.05$) in the first income quartile. These patients were more likely to be treated in the South and at large hospitals, and less likely in the Northeast and West ($P < 0.05$), with no difference in the Midwest ($P \geq 0.05$). They also had higher Medicaid use (OR 1.325, 95% CI 1.296-1.355) and lower private insurance use (OR 0.639, 95% CI 0.622-0.656). Patients in the first income quartile had lower rates of ascites, spontaneous bacterial peritonitis (SBP), variceal bleeding, hepatocellular carcinoma (HCC), liver transplantation, and hospitalization charges, but higher ICU admission and mortality ($P < 0.05$). There were no significant differences in rates of hepatic encephalopathy, acute liver failure, length of stay, or discharge disposition to home ($P \geq 0.05$). **Conclusion:** Patients with cirrhosis in the first income quartile were predominantly Black, Hispanic, and Native American. Their care was more often provided in large hospitals and had higher rates of ICU admission and mortality. However, there was a lower rate of ascites, SBP, variceal bleeding, and HCC. This may reflect less severe disease in these patients or possibly ascertainment bias from limited healthcare in this population.

Table 1: Demographics

	First Income Quartile (n = 1,060,480)	Higher Income Quartile (n = 2,168,819)	p value	Odds Ratio (95% CI)

2113 | HEALTH RELATED SOCIAL NEEDS SCREENING IN HEPATOLOGY CLINICS MAY UNDERESTIMATE SOCIAL NEEDS PREVALENCE, PARTICULARLY AMONG VULNERABLE POPULATIONS

Rebecca Kim[1] April Ballantyne[1] Gregory Stoddard[1] Jiawen Guo[1] Bob Wong[1] John Inadomi[1] Molly Conroy[1] Jennifer Price[2] Andrea Wallace[1], [1]University of Utah, [2]University of California San Francisco

Background: Vulnerable populations are disproportionately impacted by liver disease, and patients with health related social needs (HRSN) suffer from worse health outcomes. To systematically identify and reduce HRSN within our hepatology patient population, HRSN screening and resource referrals were incorporated into hepatology clinic. While we previously confirmed screening acceptability using mixed methods analyses, we aimed to re-evaluate patients' response rate after HRSN screening was integrated into clinical practice. **Methods:** From 12/2024-03/2026, HRSN screening was completed during routine hepatology care through electronic health record-based workflows. The HRSN screener includes 10 yes/no questions, with the option "prefer not to answer". Screening was completed via MyChart or during pre-visit check-in. Patients reporting HRSN and/or interest in assistance were referred to resources. Descriptive analyses included mean and frequency. Comparative analyses were performed using Chi-Square and Fisher's exact tests. **Results:** Among 3,480 unique liver clinic patients screened, 87% of patients answered all 10 questions with a yes or no response. The rate of "prefer not to answer" (PNA) responses for each question were similar, ranging from 3% (n = 97) for question 1, transportation needs, to 6% (n = 210) for question 7, housing costs, and 5% for most other questions. The sub-population who selected PNA for ≥ 1 question, when compared to the majority who answered all with yes or no, had a higher prevalence of Hispanic patients (19% vs 10%), non-English speaking patients (9% vs 3%), patients with Medicaid (21% vs 9%), and had a ≥ 2x prevalence of all HRSN ($p < 0.001$), (**Table**). There were no differences by gender or clinic type.If PNA responses are considered missing data and are excluded from analysis, then 448 patients with disproportionately higher HRSN prevalence are dropped. Alternatively, if PNA is interpreted as a "yes", the increase in each HRSN is notable: transportation needs increase from 4% to 7%, utility insecurity 12% to

17%, housing costs 10% to 16%, medical expenses 7% to 11%, medication expenses 5% to 9%, food insecurity 14% to 19%, limited funds for home items 16% to 21%, unstable housing 2% to 5%, unemployment 10% to 15%, and caregiving interference 2% to 5%. **Conclusion:** Most patients seen in hepatology clinics answered all HRSN screening questions. However, Hispanic patients, non-English speaking patients, and those with Medicaid were more likely to select PNA. Moreover, among the yes/no responses provided by those who selected PNA for ≥1 question, HRSN were twice as common. These findings may suggest patients from vulnerable populations experience more discomfort answering HRSN screening questions resulting in an underestimation of their needs. A response of PNA, similar to a "yes," should be explored by the healthcare team to better understand if HRSN may be present and if resources may be of interest to that patient.

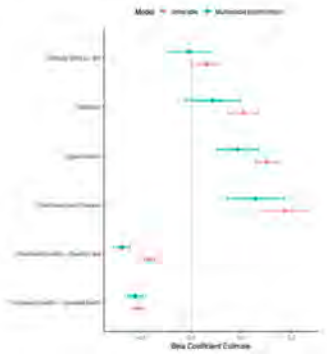
2114 | DIGITAL HEALTH LITERACY AND CARDIOMETABOLIC DISEASE BURDEN IN U.S. ADULTS: A NATIONAL SURVEY ANALYSIS

Somaya Albhaisi[1] Sevan Esaian[2] Payal Shah[3] Jennifer Dodge[1] Norah Terrault[1], [1]University of Southern California, [2]Department of Pediatrics, CHLA, Los Angeles; Southern California Center for Chronic Disease Research, [3]Department of Pediatrics, Children's Hospital Los Angeles



Background: Metabolic-associated steatotic liver disease (MASLD) and its cardiometabolic comorbidities, including obesity, type 2 diabetes, hypertension (HTN), and cardiovascular disease (CVD), represent a growing public health burden. Digital health tools have emerged as promising platforms for chronic disease self-management, yet inequities in digital health literacy (DHL) may limit their benefit to those most at risk. We examined DHL as a modifiable determinant of cardiometabolic disease burden and health perception in a nationally representative U.S. adult population. **Methods:** We analyzed cross-sectional 2024 Health Information National Trends Survey 7 data of U.S. adults aged ≥18 years, excluding respondents with ≥15% missing data. Survey-weighted methods with JK1 jackknife variance estimation over 50 replicate weights generated nationally representative estimates. Factor Analysis of Mixed Data across >240 variables identified two latent dimensions of digital health variation: 1) Healthcare Interaction Quality/Telehealth Engagement, 2) DHL/Technology Adoption. Associations with obesity (BMI ≥30), diabetes, HTN, CVD, and perceived quality of care and general health scores (range 1-5) were tested by survey-weighted regression adjusted for demographic, socioeconomic, and clinical covariates. **Results:** Of 5,203 included respondents (mean age 55 years, 48.7% female, 75.2% non-Hispanic White, 94.0% insured), frequent internet use was reported by 86.8% and electronic physician messaging ranged from 53.1% to 86.2% across income groups. Cardiometabolic outcomes were prevalent (37.9% with obesity, 21.8% diabetes, 41.6% HTN, 10.2% CVD) with mean perceived quality of care and general health scores of 3.83 and 3.32, respectively. The Healthcare Interaction Quality/Telehealth Engagement axis had a median score of -5.61 (range −8.10 to 49.66) and the DHL/Technology Adoption axis had a median score of 0.07 (range −7.54 to 15.77). Healthcare Interaction Quality/Telehealth Engagement axis was not significantly associated with cardiometabolic outcomes. In contrast,

poorer DHL/Technology Adoption was significantly associated with obesity (OR 1.03, 95% CI 1.00–1.06), diabetes (OR 1.11, 95% CI 1.08–1.15), HTN (OR 1.16, 95% CI 1.14–1.19), CVD (OR 1.21, 95% CI 1.15–1.26), and lower perceived quality of care (β −0.08, 95% CI −0.09 to −0.07) and general health (β −0.11, 95% CI −0.12 to −0.10). After adjustment, the association with obesity and diabetes was attenuated whereas the other outcomes remained statistically significant (Figure 1). **Conclusion:** Lower DHL and technology adoption are associated with greater cardiometabolic disease burden and poorer perceived health. Given the role of these comorbidities in MASLD progression, these findings highlight DHL as a potential intervention target for reducing metabolic and liver disease disparities.

Figure 1. Univariable and Multivariable Associations Between Axis 2 (Digital Health Literacy / Technology Adoption) and Cardiometabolic Outcomes.

2115 | SOCIAL DISADVANTAGE IS ASSOCIATED WITH FIBROSIS SEVERITY AND GLP-1 RECEPTOR AGONIST UTILIZATION IN MASLD

Ridhi Chaudhary[1] Hwi Young Kim[1] Yeongjin Gwon[1] Holland Stevenson[1] Avry Logeman[1], [1]University of Nebraska Medical Center

Background: Glucagon-like peptide-1 receptor agonists (GLP-1RAs) are increasingly used for metabolic diseases including MASLD, whereas treatment discontinuation and differential access may limit their long-term impact on the outcomes. Because social

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

determinants of health (SDoH) may influence both MASLD burden and medication utilization, the aims were to evaluate the association of overlapping SDoH domains with MASLD presence and severity and GLP-1RA utilization. **Methods:** Using the National Health and Nutrition Examination Surveys (NHANES) and Medical Expenditure Panel Survey (MEPS) data (2017–2023), we conducted two retrospective analyses as independent cohorts. SDoH scores were stratified into three levels (low, medium, high). GLP-1RA utilization was identified through prescription medication records. Survey-weighted multivariable logistic regression models were used separately for each cohort to examine associations between SDoH and the following outcomes: 1) GLP-1RA utilization; 2) MASLD prevalence; and 3) significant fibrosis (liver stiffness > 8kPa) among individuals with MASLD. The models were adjusted for age, sex, and geographic region (in MEPS). Sensitivity analyses were conducted to examine the impact of individual SDoH variables. **Results:** In NHANES, MASLD prevalence was 36.4% in 2017–2020 and 33.9% in 2021–2023. Among participants with MASLD, the prevalence of significant fibrosis was 17.2% in 2017–2020 and 19.4% in 2021–2023. Higher SDoH burden was associated with greater fibrosis severity (OR 1.994, 95% CI 1.302–3.054), while its association with MASLD prevalence was less consistent across survey periods (OR 1.018, 95% CI 0.818–1.265 in 2017–2020; OR 1.263, 95% CI 0.999–1.596 in 2021–2023). In the sensitivity analysis, high food security was associated with lower fibrosis burden in 2021–2023 (OR 0.544, 95% CI 0.386–0.765), while higher educational attainment was associated with lower odds of MASLD prevalence (OR 0.637, 95% CI 0.457–0.886). In MEPS, individuals with medium and high SDoH burden had lower odds of GLP-1 RA use than those with low SDoH burden (OR 0.559, 95% CI 0.470–0.664 [medium] and OR 0.482, 95% CI 0.391–0.594 [high] in 2021–2023; OR 0.586, 95% CI 0.449–0.764 [high] in 2017–2020). In the sensitivity analysis of individual SDoH domains, high food security was associated with lower GLP-1RA use in both 2017–2020 (OR 0.597, 95% CI 0.381–0.934) and 2021–2023 (OR 0.722, 95% CI 0.524–0.995), while improved healthcare access (OR 3.691, 95% CI 2.480–5.493) and higher educational attainment (OR 1.882, 95% CI 1.253–2.825) were associated with higher GLP-1RA utilization in 2021–2023. **Conclusion:** Social disadvantage may be linked to treatment access and utilization as well as disease severity among individuals with MASLD, suggesting the importance of incorporating SDoH into assessment of disease progression and access to newer therapies.

2116 | AN EXPLORATION OF STRUCTURAL AND CONTEXTUAL BARRIERS TO LIVER CANCER SCREENING IN THE HEPATOLOGY CLINIC AT MONTEFIORE MEDICAL CENTER

Kristen Gotsis[1] Cyrus Mowdawalla[2] Lydia Bioh[1] Kush Desai[1] Kylie Heering[1] Iman Siddiqui[1] Courtney Balgobin[2] Andrew Takchi[3] Adebola Adedimeji[4] David Lounsbury[4] Bahar Laderian[5] Clara Tow[6] Yvonne Saenger[7], [1]Albert Einstein College of Medicine, Bronx, NY, USA, [2]Department of Medicine, Montefiore Medical Center, Bronx, NY, USA, [3]Department of Medicine, Jacobi Medical Center, Bronx, NY, USA, [4]Dept. of Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx, NY, USA, [5]Department of Oncology, Montefiore Medical Center, Bronx, NY, USA, [6]Department of Medicine, Division of Transplant Hepatology, Montefiore Medical Center, Bronx, NY, USA, [7]Montefiore Einstein Comprehensive Cancer Center, Bronx, NY, USA

Background: Hepatocellular carcinoma (HCC) is the fourth leading cause of cancer-related mortality worldwide and the most common primary liver cancer. Prognosis is highly dependent on the stage at diagnosis. Montefiore Medical Center (MMC) serves a diverse population with a high proportion of socioeconomically disadvantaged patients. HCC screening rates, patient understanding of liver cancer, and the role of socioeconomic and structural barriers to liver cancer screening have not been well characterized in this population. **Methods:** Patients receiving care at MMC hepatology clinics were recruited. Eligible participants included adults over the age of 18 who met criteria for HCC screening: those with advanced fibrosis, cirrhosis, and/or chronic hepatitis B infection. Patients with a history of HCC or undergoing surveillance of other liver lesions were excluded. Participants completed a questionnaire-based survey assessing HCC screening history, understanding of liver cancer, and barriers to screening. EMR review was performed to verify true screening frequency with screening defined as abdominal ultrasound, MRI, or CT evaluating the liver. **Results:** A total of 157 patients completed the survey, with demographics summarized in Table 1. 57.3% of patients reported undergoing liver cancer screening within the last 7 months, 1.3% reported screening within 7 months to 1 year, 27.4% reported no screening within the past 12 months, and 14% of patients could not remember. EMR review demonstrated higher than reported screening rates, with 66.2% of patients screened within the last 7 months, 9.6% screened between 7 months to 1 year, and 24.2% receiving no screening within 12 months. Knowledge gaps

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

regarding liver cancer were substantial. Over half of patients were unable to identify any symptoms of liver cancer, and 28.6% were unable to identify any risk factors for liver cancer. Regarding barriers to screening, 55.4% of patients reported no barriers, 29.3% reported one, and 15.3% reported two or more. Commonly reported barriers included unreliable transportation, scheduling and work conflicts, high copays, and anxiety surrounding testing. **Conclusion:** Despite receiving specialty hepatology care, many patients demonstrated limited understanding of liver cancer risk and surveillance, with gaps in knowledge regarding symptoms and risk factors for HCC. Patients often underestimated the extent of screening they had undergone, suggesting poor understanding of screening practices and the purpose of screening. Structural barriers also remained prevalent within this population. These findings suggest that access to specialty care alone may be insufficient to optimize HCC surveillance adherence. Targeted patient education initiatives and system-level interventions addressing socioeconomic barriers may be necessary to improve surveillance engagement and reduce disparities in HCC outcomes among vulnerable populations.

2117 | CLOSING THE HCC SCREENING GAP: AN ADVOCACY DRIVEN MULTIDISCIPLINARY WORKGROUP TO DEVELOP EQUITY-CENTERED IMPLEMENTATION RECOMMENDATIONS

Sandra Ponce[1] Amit Singal[2] Jesse Powell[3] Lily Benig[4], [1]Global Liver Institute, [2]UT Southwestern Medical Center, [3]Hennepin Healthcare, [4]Consultant

Background: Hepatocellular carcinoma is a leading cause of cancer-related death in the United States, with most cases diagnosed at advanced stages due to underuse of guideline-recommended surveillance. While early-stage diagnosis is associated with >70% five-year survival, advanced-stage survival remains below 20%. System, provider, and patient-level barriers, including fragmented EHR systems, limited provider awareness, and structural inequities, continue to limit effective surveillance implementation. This workgroup developed practical, equity-centered recommendations to improve HCC screening implementation. **Methods:** Global Liver Institute convened the HCC Screening Guidelines Workgroup, a multidisciplinary panel of 15 stakeholders including hepatologists, oncologists, primary care physicians, advanced practice providers, radiologists, and two patient advocates with lived HCC experience. Participants were selected based on clinical expertise, geographic diversity, and representation of high-burden communities. Using a structured consensus-based process across three meetings, the workgroup reviewed clinical guidelines, peer-reviewed literature, and health systems data. Pre- and post-session surveys assessed barriers, feasibility, and intervention priorities. Recommendations were refined through iterative discussion and consensus prioritization. **Results:** Phase I workgroup discussions identified interconnected system, provider, and patient-level barriers limiting consistent semiannual HCC surveillance. System barriers included fragmented care pathways, limited specialist and imaging capacity, inconsistent radiology quality, and EHR limitations

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

affecting identification and tracking of high-risk patients. Provider barriers included variable awareness of surveillance guidelines, limited primary care support, time constraints, and unclear ownership of surveillance. Patient barriers included low awareness of liver cancer risk, stigma, mistrust of health systems, language and cultural discordance, transportation, and insurance-related challenges.In response, the workgroup developed four consensus recommendations: (1) a simplified, one-page primary care roadmap translating HCC surveillance guidelines into actionable steps for non-specialist providers; (2) automated EHR-based identification of at-risk patients; (3) standardized EHR-embedded care pathways defining referral and follow-up responsibilities; and (4) expansion of culturally responsive patient navigation programs to address barriers to surveillance adherence. **Conclusion:** Phase I produced actionable, equity-centered recommendations emphasizing system-level change, provider support, and patient navigation to improve HCC surveillance uptake. Phase II will pilot these strategies in high-burden communities to evaluate scalability and implementation effectiveness.

2118 | INCOME DISPARITIES IN HEPATOCELLULAR CARCINOMA OUTCOMES: IMPACT OF COVID 19 PANDEMIC AND INSIGHT FROM TREATMENT MEDIATION ANALYSIS

Neil Sundaram[1] Hyunseok Kim[1] Michael Luu[1] Paul Martin[1] Alexander Kuo[2] Walid Ayoub[2] Yun Wang[1] Aarshi Vipani[2] Nicole Rich[3] Neehar Parikh[4] Kambiz Kosari[1] Nicholas Nissen[1] Cristina Ferrone[1] Amit Singal[3] Ju Dong Yang[2], [1]Cedars Sinai Medical Center, [2]Cedars-Sinai Medical Center, [3]University of Texas Southwestern Medical Center, [4]University of Michigan Medical Center

Background: In the United States, HCC disproportionally affects persons from racial and ethnic minority groups and those from low socioeconomic status (SES) neighborhoods. While recent large studies have documented a clear relationship between SES and HCC mortality, the exact contributions of treatment and the recent COVID-era years (2020 – 2023) to existing disparities have yet to be described. **Methods:** Using data from the National Cancer Center Database (NCDB), we examined the relationship between income and HCC mortality at the national level and conducted a treatment-mediation analysis. Data on 247,192 patients with a diagnosis of HCC and neighborhood-level income were collected from 2004 through 2023. Survival outcomes were assessed using Kaplan-Meier methods and Cox proportional hazards regression models estimated hazard ratios (HR). Multivariate models were controlled for age, sex, race, geographic region, disease stage, and insurance status. Treatment mediation analysis was conducted by calculating the HR attenuation after stratifying by curative or non-curative treatment. Results were further stratified by pre-COVID (2004 – 2019) and COVID (2020-2023) eras. **Results:** The cohort had a mean age of 64.7 years and was predominantly male (76%), White (60%), Medicare-insured (49%), stage I disease (30.6%), and located in the South (39%). Approximately 26% received curative surgical treatment (resection, ablation, liver transplantation) and 44% received non-curative (locoregional, systemic therapy) HCC treatment. Lower income quartile (Q1 vs. Q4) was independently associated with increased HCC mortality HR 1.20 (95% CI 1.19 – 1.22, $P < 0.001$). Subgroup analyses demonstrated the greatest income-related mortality disparities among patients who were age < 50 years, Black, privately insured, had stage I HCC, or resided in the Midwest (all $p < 0.001$) (Figure). Treatment mediation analysis revealed that 25% of the income-related mortality disparities may be attributable to HCC treatment receipt (curative or non-curative) with an absolute HR reduction from 1.20 (95% CI 1.19 – 1.22) to 1.15 (95% CI 1.14 – 1.17). During the COVID-era, Asian and Black Americans experienced the largest worsening income-related HCC mortality disparities by 2.9 fold (from HR 1.16 to 1.46, $p < 0.001$) and 1.5 fold (1.20 to 1.29, $p < 0.001$) increases, respectively. **Conclusion:** Neighborhood-level income independently predicts HCC mortality beyond insurance status, cancer stage, and geographic region. Variations in treatment receipt explain only 25% of the income-related disparity in HCC mortality. These findings highlight the need for interventions that not only promote equitable access to treatment but also address social determinants of health to mitigate income-based disparities among patients with HCC.

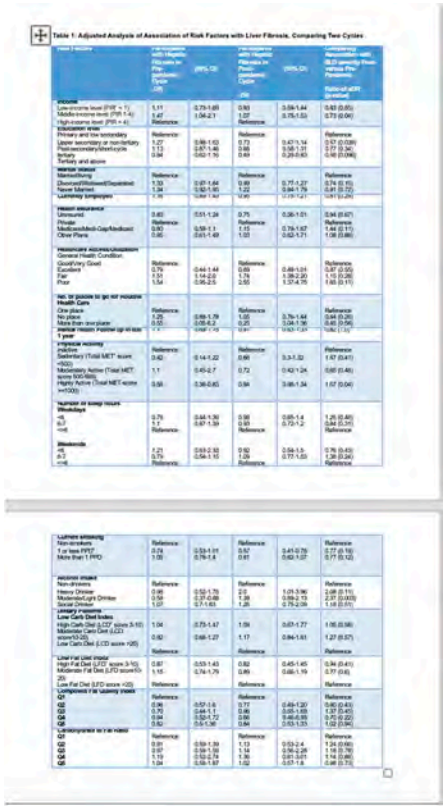
2119 | COMPARING ASSOCIATIONS OF SOCIAL, BEHAVIORAL AND DIETARY RISK FACTORS WITH HEPATIC FIBROSIS AMONG US ADULTS IN POST-PANDEMIC ERA, ARE TRENDS CHANGING?



Iqra Arshad[1] Xinyuan Zhang[2], [1]Saint Louis University Hospital, [2]Brigham and Women's Hospital and Harvard Medical School

Background: In addition to known cardiometabolic risk factors, e.g., morbid obesity, type 2 diabetes; social, behavioral and dietary factors serve as key players in shaping risk of developing fatty liver disease and advanced fibrosis. Despite stable reported prevalence of steatotic liver disease (SLD)[1-2] since pandemic, data to assess associations of these risk categories with liver fibrosis seems limited. Current study aims to evaluate whether associations of these risk categories with liver fibrosis are changing since pandemic. **Methods:** Using National Health and Nutrition Examination Survey (NHANES) data, we performed a cross-sectional observational study. Data on sociodemographic, behavioral and dietary factors were extracted from pre-pandemic(2017-2020) and post-pandemic (2021-2023) cycles. Outcome was the presence of liver fibrosis, defined as liver stiffness measure (LSM) score $\geq$8.0 kPa. Missing data on key predictors were handled using Multiple Imputations Chain Equation method. Univariate regression models were used to assess prevalence, and multivariate models to evaluate associations with outcome in each cycle. Associations between cycles were compared as a ratio of adjusted odds ratio and effect modification by time was used for statistical significance. A two-tailed p-value $<$0.05 was set as significant. **Results:** In both cycles, SLD participants with liver fibrosis (11.2% in pre- and 12.9% in post-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

pandemic) showed similar trends, i.e., were less likely to have higher education and mental health follow-ups, more likely to belonging to middle-income group, having obesity, medical comorbidities and being in higher quintiles of poor fat and low fiber diets intake compared to their controls. In the adjusted analysis, among social factors, increasing trends of associations of liver fibrosis with being covered by non-private payers, and in overall fair to poorer health conditions were observed, but findings were non-significant (p-value >0.05). Among lifestyle factors, higher levels of physical activity were significantly associated with lower odds of fibrosis ($_a$OR; 0.56 [0.38-0.83]) in pre-pandemic and non-significantly associated with fibrosis ($_a$OR; 0.94 [0.66-1.34]) in post-pandemic era. The associations remained statistically stronger (ratio; 1.67 [p 0.04]) comparing the cycles. Moderate drinking was not significantly associated with higher odds of fibrosis ($_a$OR;1.38,[0.89-2.13]) in post-pandemic era, although overall association seems significantly stronger (ratio; 2.37 [p 0.003]) over time.Among dietary habits, a low fiber diet was associated with a higher risk of fibrosis, although findings did not reach statistical significance in each cycle and over time. [Table 1]. **Conclusion:** Study supports evidence on protective role of higher physical activities and high fiber in diet in reducing risk of liver fibrosis and reinforces their integration through education and policy since pandemic.

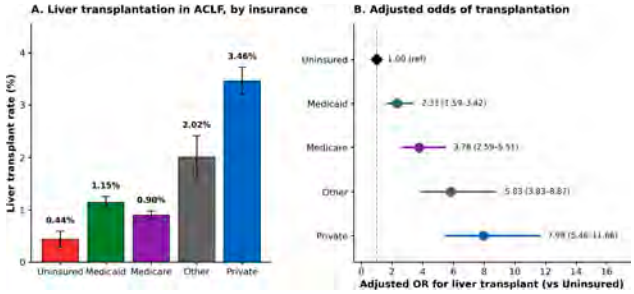
2120 | NATIONAL TRENDS AND INSURANCE-BASED DISPARITIES IN LIVER TRANSPLANTATION, TIPS, AND OUTCOMES AMONG HOSPITALIZED PATIENTS WITH ACUTE-ON-CHRONIC LIVER FAILURE



Gedion Yilma Amdetsion[1] Amir Sultan[2] Chun-Wei Pan[3] Fnu Vikash[4] Hiwot Tebeje[5] Emeka Stanley Obi[6] Yonas Fetie[7] Yetunde Akande[8] Edgar Arza Basualdo[8] Ayokunle Abegunde[8], [1]John H Stroger Hospital, [2]Mayo clinic, Rochester, [3]U Mass Chan, [4]Cleveland Clinic, [5]WASHU, [6]Brookdale University Hospital and Medical Center, [7]Marshall University, [8]John H Stroger Hospital of Cook County

Background: Acute-on-chronic liver failure (ACLF) carries the highest short-term mortality in hepatology, and rescue depends on two procedures with sharply different resource footprints: TIPS for portal decompression and liver transplantation. Whether a decade of national expansion in these procedures has narrowed insurance-based access gaps is unknown. **Methods:** We analyzed 1,924,619 weighted ACLF hospitalizations in the National Inpatient Sample (2016–2022), defining ACLF by ≥1 extrahepatic organ failure (renal, circulatory, respiratory, cerebral, coagulation) using EASL-CLIF–adapted ICD-10-CM/PCS codes, graded 1–3. This coding algorithm was adapted from previously validated ICD-10 ACLF definitions in administrative data. Survey-weighted logistic and Poisson models compared in-hospital mortality (primary outcome), liver transplantation, TIPS, palliative care, and discharge against medical advice (AMA) across payers (Uninsured = reference), adjusting for demographics, all five organ failures, decompensation features, ACLF grade, and hospital characteristics. Findings were independently verified using entropy balancing on covariate means and IPWRA. Sensitivity analyses restricted to strict ACLF, and transplant-eligible patients (defined by absence of absolute contraindications per ICD-10 coding). **Results:** Uninsured patients (5.1%) were younger (mean 51.0 vs 68.6 yrs Medicare) yet carried equivalent organ failure burden (mean 1.84 vs 1.82). Liver transplantation showed the steepest disparity: 0.44% of uninsured underwent transplant versus 3.46% of privately-insured patients (aOR 7.98, 95% CI 5.46–11.66). TIPS use among ACLF hospitalizations rose ≍20-fold nationally from 2016 to 2022, yet insurance-based differences in TIPS receipt remained unchanged across the decade (Private vs Uninsured aOR 1.51, 1.29–1.77). Uninsured patients were 2.8-fold more likely to leave AMA (aOR Private 0.40, 0.36–0.44) and were less likely to receive palliative care (aOR 0.62 vs insured, adjusted for mortality risk). Adjusted in-hospital mortality was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

modestly but consistently lower among insured patients (Private aOR 0.78, 0.74–0.82), with a widening payer-related mortality disparity at ACLF-3 (interaction $p < 0.05$; aOR grade 3 vs grade 1: 13.6). **Conclusion:** A decade of dramatic national expansion in ACLF procedural care has not narrowed insurance-based disparities. Uninsured patients, equally sick, often younger, remain systematically diverted away from rescue therapies and toward AMA discharge. The transplant access gap may represent the most consequential and actionable disparity in modern hepatology.

2121 | POPULATION SCREENING FOR LIVER DISEASE USING EXISTING BLOOD TESTS DOES NOT EXCLUDE CORE20 DEPRIVED POPULATIONS: RESULTS FROM THE LIVEWELL STUDY

Timothy Jobson[1] Katie Denver[2] Christina Owen[1] Neil Stevens[2] Axelle Caudrillier[3] Yasmin Hamadache[3] Heath O'Brien[3] Louise Campbell[4] Patrick Short[3] Jamie Webb[3] Katie Barnes[3], [1]Somerset NHS Foundation Trust, [2]Predictive Health Intelligence, [3]Sanogenetics, [4]Tawazun Health

Background: The LiveWell study evaluated whether combining longitudinal blood test results with a polygenic risk score supports population-level liver disease screening. Hospital admissions for advanced liver disease are 3-fold higher in the most deprived populations compared to the least. We present the results of the analysis of the impact of deprivation on invitation and uptake of screening in a research context. hepatoSIGHT, an NHS-adopted tool, was used to risk stratify the Somerset population. Eligible individuals were invited by letter, linked to an e-enrolment platform and underwent saliva based genetic analysis and transient elastography. **Methods:** Index of Multiple Deprivation (IMD) decile distributions were compared across: 1) general Somerset population; 2) hepatoSIGHT-identified cohort (n = 61,116; aged 25-35 or 45-55, with at least one liver function test in five years, with no ALT > 500) 3) high-risk active subgroup, (highest 7% of the population, based on cumulative ALT) 4) the consented cohort (n = 996, cases plus controls). Analyses used Pearson chi-squared, standardised residuals, and odds ratios (OR) with Wilson 95% confidence intervals (CI). CORE20 was defined as IMD deciles 1-2. **Results:** The hepatoSIGHT-identified cohort contained more CORE20 individuals than predicted (IMD 1-2 12.12% vs Somerset 8.91%; OR 1.41, 95% CI 1.36-1.46; $p < 0.0001$), with excess in IMD 1-5 and deficit in 7-10, indicating deprived populations had more blood tests. Risk stratification pronounced this difference (active group IMD 1-2 13.53%, OR 1.60 vs Somerset; active vs control OR 1.15, 95% CI 1.05-1.26, $p = 0.002$). The recruitment step reduced deprivation weighting: study recruited IMD 1-2 9.72%; no different from Somerset population ($p = 0.37$) but lower than the eligible-pool (eligible vs recruited OR 1.28, 95% CI 1.04-1.58, $p = 0.025$; active vs recruited OR 1.45, 95% CI 1.16-1.82, $p = 0.001$).Data-driven liver disease screening does not systematically exclude deprived populations. CORE20 patients are over-represented at the cohort generation and risk-stratification stages, reflecting higher disease prevalence and historic blood test availability. In LiveWell, the enrollment rate was lower in CORE20 patients, but in line with population baseline, showinf data-driven recruitment may recruit individuals from deprived areas more effectively than traditional encounter based recruitment. **Conclusion:** Data-driven liver disease screening does not systematically exclude deprived populations. CORE20 patients are over-represented at the cohort generation and risk-stratification stages, reflecting higher disease prevalence and greater historic blood test availability. In LiveWell, the enrollment rate was lower in CORE20 patients, but still in line with population baseline, demonstrating data-driven recruitment may recruit individuals from deprived areas more effectively than traditional encounter based recruitment.

2122 | BARRIERS TO EFFECTIVE CIRRHOSIS CARE IN CAMEROON: PERSPECTIVES FROM FRONTLINE PHYSICIANS

Maitri Patel[1] Ikechukwu Eze[1] Kasopefoluwa Oguntuyo[1] Abdoulaye Epse Mohamadou Balkissou[2] Tidang Tchinda Carinele[2] Baiye William Abange[2] Mathurin Kowo[2] Sofia Jakab[1], [1]Yale University, [2]University Teaching Hospital of Yaounde

Background: There is limited systematic data on cirrhosis healthcare delivery in sub-Saharan Africa. The Pathways to Cirrhosis Care in Cameroon Project seeks to characterize access patterns and barriers amongst patients presenting with cirrhosis at a large tertiary care center in Yaoundé, Cameroon. **Methods:** As part of our project, we conducted a cross-sectional physician survey amongst internal medicine and gastroenterologist trainees and attendings, evaluating perceived barriers to chronic liver disease management within their tertiary care, academic hospital. Survey domains were based on the World Health Organization (WHO) health systems framework and included leadership and governance, service delivery, workforce and health systems, access to medicines and technologies, and patient-related factors. Due to low sample size, this study focused on descriptive analyses. **Results:** A total of 19 (82.6%) survey responses were collected amongst 23 eligible physicians. 18 (95%) of these responses were from physician trainees. No survey responders reported any experience at a liver transplant center. Within leadership and governance, most respondents felt strongest about deficiencies in referral pathways (74%), while liver disease stigma (37%) and national policy availability (32%) were ranked as lowest concerns. Service delivery barriers included geographic distance from care (74%), chronic disease management infrastructure (79%), and management of cirrhosis complications (74%). Inadequate healthcare worker availability (84%), insufficient provider education (67%), and poor data management capabilities (74%) were ranked highest among workforce and infrastructure limitations. Within medicine and technology domains, endoscopy access was the primary barrier (79%). Key patient-related challenges included affordability concerns (84%), transportation limitations (72%), and confidentiality issues (42%). Patient literacy was universally identified as a barrier by all respondents (100%). Interestingly, "traditional medicine" was commonly noted in the free-text section of the survey inquiring about additional barriers. **Conclusion:** This study identified multilevel barriers to cirrhosis care in Cameroon, including endoscopy access, chronic disease infrastructure, data management, and low patient health literacy. These findings highlight opportunities for targeted interventions including expansion of endoscopy services, implementation of standardized cirrhosis documentation templates, and data management strategies to strengthen longitudinal liver disease care.

2123 | ECONOMIC VALUE WITHOUT EQUITY? A SYSTEMATIC REVIEW OF TRIAL-LINKED COST-EFFECTIVENESS, HEALTHCARE DELIVERY, AND PATIENT FINANCIAL BURDEN STUDIES IN LIVER DISEASE

Rubab Fatimaa[1] Rida Fatima[2], [1]Fatima Jinnah Medical University, [2]Shaukat Khanum Hospital

Background: Cost-effectiveness evidence guides liver care, but average value may not translate into equitable value when studies omit access barriers, patient-borne costs, and underserved populations. We mapped value conclusions, patient financial burden, and equity reporting across liver economic and delivery studies. **Methods:** PubMed/Embase were searched from January 2015 to May 2025 for adult liver disease studies linked to RCTs, pragmatic trials, or trial-derived models reporting costs, ICERs, QALYs, utilisation, linkage-to-care efficiency, or financial burden. Two reviewers screened studies following PRISMA 2020. Studies

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

were classified into five domains; equity domains were race/ethnicity, insurance, income/education, language, safety-net setting, rurality, and patient-borne costs. **Results:** Twenty-three studies were included: HCC systemic therapy (n = 10), MASH therapeutics (n = 2), transplant/infectious prophylaxis (n = 3), surgery/procedural care (n = 3), and surveillance/delivery/patient burden (n = 5). Equity reporting was critically limited: among 20 CEA studies, only 2 (10%) reported equity stratification and 18 (90%) reported none. HCC systemic therapy had the broadest ICER range ($26,477-$782,105/QALY; median $135,789 across 14 estimates); 8/14 (57%) were below the $150,000/QALY US threshold, though value was highly sensitive to comparator, setting, and pricing. Second-line agents were unfavourable: regorafenib ($201,797-$268,506/QALY) and ramucirumab ($782,105/QALY) exceeded thresholds. Resmetirom for MASH was estimated cost-effective at list price but with substantial projected budget impact. Procedural and delivery interventions more consistently generated dominant or favourable value: preemptive CMV therapy reduced disease (9% vs 19%) and saved $8,707/patient; laparoscopic hemihepatectomy yielded €36,677/QALY; ERAS reduced costs and morbidity; and mailed HCC outreach cost $32.45/patient in year 1 while generating 300 additional QALYs per 10,000 patients. Patient financial burden was substantial: 21.8% of screened cirrhosis patients reported moderate-to-severe burden, and Medicare HCC patients incurred median first-year payments of $66,338 and patient liabilities of $10,008, exceeding cirrhosis-only comparators by $50,110 and $7,166, respectively. **Conclusion:** Liver economic evidence estimates average population value without determining who accesses benefit or bears disproportionate financial harm. Procedural and delivery interventions deliver consistent value, whereas HCC systemic therapy cost-effectiveness is price- and setting-dependent. Future liver health technology assessments should disaggregate ICERs by insurance, race/ethnicity, and treatment access, and incorporate patient-borne costs, so cost-effective liver care is also equitable liver care.

Disclosures: Rubab Fatimaa: Nothing to Disclose, Rida Fatima: Nothing to Disclose.

2124 | RACIAL VARIATION IN MORTALITY, SEPSIS, AND ORGAN FAILURE AFTER TIPS: A CONTEMPORARY NATIONAL INPATIENT SAMPLE ANALYSIS (2019–2022)

Amna Naveed Butt[1] Anjum Dhamani[1] Maher Taha[1] Bryce Mays[1] Scott Keeney[1], [1]Texas Health Resources

Background: Racial disparities in outcomes of end-stage liver disease remain a continuing concern, yet contemporary national data on transjugular intrahepatic portosystemic shunt(TIPS) outcomes are limited. We evaluated racial differences in in-hospital mortality and clinical outcomes using the 2019-2022 National Inpatient Sample (NIS). **Methods:** Adult hospitalizations undergoing TIPS were identified using ICD-10 -PCS procedure code 06183J9 from the NIS 2019-2022. Survey weights were applied to generate national estimates. Race was categorized as White, Black, Hispanic, Asian/Pacific Islander, Native American, and Other. The primary outcome was in-hospital mortality. Secondary outcomes included acute kidney injury (AKI), sepsis, shock, hepatic encephalopathy, discharge disposition, and hospital characteristics. Weighted chi-square tests and t-tests compared baseline characteristics. Survey-weighted logistic regression estimated crude and adjusted odds ratios (ORs) for mortality. **Results:** A weighted total of 26,064 TIPS procedures were identified. The cohort was 70.9% White, 4.7% Black, 16.9% Hispanic, 2% Asian/Pacific Islander, 1.9% Natie American, and 3.5% Other. Overall, the in-hospital rate was 9 %. Mortality differed significantly by race ($p < 0.001$): White 8.1%, Black 18%, Hispanic 7.2%, Asian/Pacific Islander 12%, Native American 16.7%, and Other 13.4%. AKI occurred in 32.4% of cases, sepsis in 10 %, and shock in 22.9%, each displaying significant racial variation. Crude mortality associations included race (OR 1.11; 95% CI 1.03-1.19), age (OR 0.99; $p = 0.001$), and Elixhauser score (OR 1.18; $p < 0.001$). Race-stratified mortality odds were highest among Black patients (OR 7.88; 95% CI 5.63-11.02). In the fully adjusted model, significant predictors of mortality included Black race (OR 1.97; 95% CI 1.12-3.47), AKI (OR 4.46; $p < 0.001$), shock (OR 2.31; $p < 0.001$), sepsis (OR 2.58; $p < 0.001$), and mechanical ventilation (OR 7.54; $p < 0.001$). Hospital region, teaching status, and bed size were not independently associated with mortality. **Conclusion:** In this contemporary national cohort, racial disparities in TIPS outcomes persist. Black patients experienced nearly double the in-hospital mortality compared with White patients, even after adjustments for co-morbidities and organ failure. These findings highlight ongoing inequities in liver disease care and underscore the need for targeted interventions to address pre-procedure optimization, access to specialty care, and system-wide barriers.

2125 | HEALTH LITERACY IS AN IMPORTANT DETERMINANT OF HEALTH OUTCOMES IN HEPATOCELLULAR CARCINOMA

Hannah Lee[1] Alana Saddic[1] Beomchang Kim[1] Priyam Das[1] Deborah DiazGranados[2] Grant Chin[1] Mary Kate Lantzy[1] Spencer Rice[1] Antara Sarkar[1] Richard Sterling[1], [1]Virginia Commonwealth University, [2]Virginia Commonwealth Universty

Background: Health literacy (HL), defined as the ability to access, understand, appraise, and apply health information to manage one's health, is important in addressing cancer care and chronic disease. Hepatocellular cancer (HCC) is a major cause of liver related morbidity/ mortality with suboptimal outcomes. The HL status of HCC patients and its relationship to disease status is unknown. We hypothesize that lower HL is associated with decreased HCC surveillance and greater disease burden at presentation. Our aims were: (1) to asses the HL status of HCC patients and (2) to evaluate the relationship of HL measures to HCC disease status. **Methods:** In a single center prospective study, the Health Literacy Questionnaire (HLQ), a globally validated instrument, was administered to HCC patients. Demographic, laboratory, imaging data were obtained from medical records. UNOS TNM and Barcelona Clinic Liver Cancer (BCLC) staging were used to assess disease status. Quality of life (QOL) was assessed by the Edmonton Symptoms Assessment System (ESAS). Logistic ordinal and linear regression were performed to determine the relationship between HL and HCC status, screening and QOL. Significance was set at $p < 0.05$. **Results:** 100 patients (mean age: 66 yrs, males 77%, White 72%, Black 18%, Latino 5%, other 5%, 38% ALD, 27% MASLD, 11% MetALD, 41% HCV, 12% other, 95% cirrhosis (CTP 77% A,15% B, 8% C) were studied. TNM stage 1 was 10%, 2 51%, 3 21%, and 4 18%. BCLC stage 0 was 7%, A 59%, B 13%, C 14%, and D 7%. Mean MELD was 12. Education was 53% =/< high school, 37% college,10% > college. For HLQ part 1 (response scale 1-4/ mean ± SD), scores for "Feeling understood/ supported by healthcare providers (HCP)" (3.46 ± 0.49) were the highest. "Appraisal of health information" (3.09 ± 0.53) were the lowest. For part 2 of the HLQ (response scale 1-5), scores for "Ability to actively engage with HCP" (4.29 ± 0.55) were the highest. "Ability to find good health information" (3.96 ± 0.65) were the lowest. Lower HL scores for "Having sufficient information to manage my health" (OR = 0.103; 95% CI [0.016,0.665]), $p = 0.0169$), and "Navigating the health care system" (OR = 0.091,95% CI [0.009,0.913]),$p = 0.0416$) were more likely to have higher TNM stage. Lower HL scores for "Ability to actively engage with HCP" (b = -22.6098, 95% CI [-42.0702, -3.1494], $p = 0.0237$) had higher ESAS scores. Higher HL scores for "Ability to actively engage with HCP" (OR = 51.516; 95% CI [1.213, 2186.593], $p = 0.0393$) were more likely diagnosed with HCC during screening. Higher HL scores for "Having sufficient information to manage my health" (OR = 15.812; 95% CI [1.150, 217.369], $p = 0.0390$] were more likely in surveillance. **Conclusion:** Lower HL was associated with more advanced HCC and poorer QOL. Higher HL was associated with diagnosis of HCC by screening and were in routine surveillance. This novel data provides opportunities for targeted interventions to address areas of poor HL that could improve HCC screening, outcomes and QOL.

2126 | HETEROGENEOUS PATTERNS OF HEPATIC DECOMPENSATION ACROSS RACIAL AND ETHNIC GROUPS: A PROPENSITY SCORE-MATCHED ANALYSIS OF U.S. ADULTS WITH CIRRHOSIS

Rowan Bandaranaike[1] Samuel Tarwater[2] Travis Rutland[2] Adam Edwards[2] George Nelson[3], [1]Southeast

Health Hospital, [2]Digestive Health Specialists of the Southeast, [3]University of Alabama at Birmingham

Background: Racial and ethnic disparities in chronic liver disease are well described; however, the relative burden of portal hypertensive and decompensation-related outcomes across racial groups after adjustment for comorbidities remains incompletely defined. Prior studies suggest differences in decompensation risk across racial groups, but large propensity score-matched analyses in diverse U.S. populations, including Hispanic and Asian patients, are limited. **Methods:** We performed a retrospective cohort study using a federated electronic health record network (TriNetX). Adults ($\geq$18 years) with cirrhosis were stratified by race/ethnicity (White, Black, Hispanic, Asian). Three pairwise 1: 1 propensity score-matched analyses were conducted (White vs each comparator), adjusting for age and baseline comorbidities including hypertension (I10), type 2 diabetes (E11), chronic hepatitis C (B18.2), obesity (E66), alcohol-associated liver disease (K70.1), and insurance insufficiency (Z59.71). The primary outcome was a composite of portal hypertensive and decompensation-related events within one year. Time-to-event analyses were performed using Kaplan-Meier methods and Cox proportional hazards models. **Results:** A total of 563,625 adults with cirrhosis were identified. After matching, cohorts included White vs Black (n = 62,973/arm), White vs Hispanic (n = 55,720/arm), and White vs Asian (n = 32,828/arm), with good covariate balance. A heterogeneous pattern in outcomes was observed. White patients had higher risk compared with Black (22.4% vs 17.1%; HR 1.38, 95% CI 1.34-1.42; $p < 0.0001$) and Asian patients (37.0% vs 22.5%; HR 2.09, 95% CI 2.02-2.16; $p < 0.0001$), but lower risk compared with Hispanic patients (23.3% vs 25.4%; HR 0.88, 95% CI 0.85-0.90; $p < 0.0001$). Observed differences in outcome rates across comparisons partly reflect cohort-specific matching and exclusion of patients with prevalent decompensation at baseline. Baseline prevalence of decompensation-related diagnoses was higher among White compared with Asian patients (38.6% vs 20.5%), suggesting differences in disease stage at diagnosis. One-year decompensation-free survival was 80.6% (Black), 77.5% (White), 74.5% (Hispanic), and 63.0% (Asian) in matched cohorts. **Conclusion:** In this large propensity score-matched analysis, cirrhosis outcomes varied substantially across racial and ethnic groups without a uniform direction of risk. These findings suggest that factors beyond race alone including differences in disease phenotype, stage at presentation, and underlying etiology, may contribute to these observed disparities. Further studies incorporating detailed etiologic and severity measures are needed to clarify the mechanisms underlying these differences. Race-stratified risk models for cirrhosis decompensation may require etiology-specific calibration.

2127 | BEYOND SOCIOECONOMIC STATUS: PERSISTENT RACIAL AND ETHNIC DISPARITIES IN CARE ESCALATION AMONG HOSPITALIZED PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS

Hassan Sinan[1] Jazmin Mexia Cabrales[1] Philip Juliano[1] Frances Lee[2], [1]Icahn School of Medicine at Mount Sinai / Elmhurst, [2]Icahn School of Medicine at Mount Sinai

Background: Alcohol-associated hepatitis (AH) is a severe manifestation of alcohol-associated liver disease associated with high morbidity, frequent hospitalizations and substantial healthcare utilization. Racial, ethnic, and socioeconomic disparities have been increasingly recognized as key determinants of outcomes in chronic liver disease and alcohol-related conditions, but these disparities remain incompletely characterized. We aim to evaluate the association of race/ethnicity and socioeconomic status (SES) with short and medium-term outcomes among patients hospitalized with AH. **Methods:** We performed a retrospective cohort study of adults hospitalized with AH between January 2022 and January 2026 at a large urban safety-net hospital in a major metropolitan area. Patients with other chronic liver diseases were excluded. Patients were stratified by race/ethnicity and SES, defined by insurance type and ZIP code–based deprivation indices. Demographic, clinical, and laboratory variables reflecting disease severity were extracted at index admission. Primary outcomes included in-hospital and post-discharge clinical events, disease progression, and mortality. **Results:** 740 patients with AH were included. Most were male (91.1%), Hispanic (73.6%), and median age 44 years [IQR 37–52]). 10.1% identified as White, 87% Other and 2.9% Black. Most were insured through Medicaid (75.8%) in the middle-income group (75.3%). 25.8% had cirrhosis with 29.5% severe AH (Maddrey DF

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

≥32). Hispanics had higher rates of 30-day readmission (16.7% vs. 10.3%, p = 0.041), ascites (34.7% vs. 25.6%, p = 0.025), esophageal varices (9.9% vs. 4.6%, p = 0.033), and more inpatient (p = 0.003) and ED visits (p < 0.01) in the prior 12 months vs non-Hispanics. No differences in prednisone/prednisolone use were noted. No differences were observed for portal hypertension complications among races. On multivariable logistic regression, Hispanic patients had significantly higher odds of 30-day readmission in the unadjusted model (OR 1.75, 95% CI 1.07–3.01, p = 0.032), but this association was attenuated after adjustment for SES (OR 1.55, 95% CI 0.87–2.87, p = 0.148). No racial differences were noted for 30-day readmission or 90-day mortality. Hispanics had lower odds of ICU admission even after adjustment for SES and clinical factors (OR 0.60, 95% CI 0.40–0.90, p = 0.014). Similarly, Black patients had significantly lower odds of ICU admission compared to non-black even after adjustment for SES (OR 0.17, 95% CI 0.04–0.76, p = 0.02). **Conclusion:** While SES partially explains disparities in healthcare access among Hispanic patients with higher rates of readmissions, disparities in ICU admissions in both Hispanic and black patients persist despite adjusting for SES, suggesting disparities in care escalation. Further studies are needed to better understand the structural and healthcare-system factors contributing to these observed differences.

Table: Baseline characteristics and clinical outcomes in patients with alcohol-associated hepatitis stratified by ethnicity.

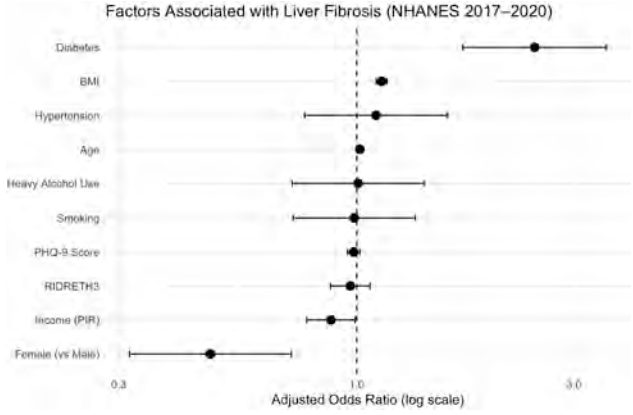
2128 | DEPRESSIVE SYMPTOM SEVERITY IS NOT INDEPENDENTLY ASSOCIATED WITH LIVER FIBROSIS AFTER ADJUSTMENT FOR METABOLIC, BEHAVIORAL, AND SOCIOECONOMIC FACTORS



Matthew Solway[1] Nazli Begum Ozturk[2] Ahmet Gurakar[3], [1]Henry Ford Hospital, [2]St. Louis University, [3]Johns Hopkins University

Background: Depression has been proposed to contribute to chronic liver disease through behavioral and metabolic pathways; however, its independent association with liver fibrosis remains uncertain. We evaluated the relationship between depressive symptom severity and liver fibrosis in a nationally representative U.S. cohort, accounting for metabolic, behavioral, and socioeconomic confounders. **Methods:** We performed a cross-sectional analysis of 8318 adults from the NHANES 2017–2020 cycle with available vibration-controlled transient elastography (VCTE) data. Depressive symptoms were assessed using the PHQ-9 as a continuous variable. Liver fibrosis was defined using VCTE-derived liver stiffness (≥8 kPa). Survey-weighted multivariable logistic regression was performed using MEC exam weights, adjusting for age, sex, race/ethnicity, body mass index (BMI), diabetes, hypertension, alcohol use, smoking status, income-to-poverty ratio, and education. A secondary analysis was performed using survey-weighted linear regression to assess the association between depressive symptom severity and continuous fibrosis stage. **Results:** In survey-weighted multivariable logistic regression analysis, depressive symptom severity was not associated with liver fibrosis (OR per 1-point increase in PHQ-9: 0.98, 95% CI 0.95–1.02, p = 0.29). Increasing age was independently associated with higher odds of fibrosis (OR 1.02 per year, 95% CI 1.00–1.03, p = 0.009), while female sex was associated with lower odds compared to males (OR 0.48, 95% CI 0.32–0.72, p = 0.002). Among metabolic factors, higher BMI was strongly associated with fibrosis (OR 1.13 per unit increase, 95% CI 1.10–1.16, p < 0.001), and diabetes was associated with more than two-fold increased odds (OR 2.46, 95% CI 1.71–3.54, p < 0.001). Hypertension was not significantly associated with fibrosis (OR 1.10, 95% CI 0.77–1.58, p = 0.56). Behavioral factors including heavy alcohol use (OR 1.01, 95% CI 0.72–1.41, p = 0.96) and smoking (OR 0.99, 95% CI 0.72–1.34, p = 0.93) were not significantly associated with fibrosis. Higher income-to-poverty ratio was independently associated with lower odds of fibrosis (OR 0.88, 95% CI 0.78–0.99, p = 0.038), while education level was not significantly associated. In complementary linear regression models evaluating fibrosis severity, depressive symptom severity was not associated with fibrosis

stage (β = −0.0004, SE 0.0011, p = 0.74). Consistent with the primary analysis, higher BMI (β = 0.019, p < 0.001) and diabetes (β = 0.165, p < 0.001) were independently associated with greater fibrosis severity, while female sex was associated with lower fibrosis stage (β = −0.064, p = 0.001). **Conclusion:** In a nationally representative cohort of U.S. adults, depressive symptom severity was not independently associated with liver fibrosis after comprehensive adjustment for metabolic, behavioral, and socioeconomic factors. Fibrosis risk appears to be driven primarily by metabolic disease and social determinants of health rather than depressive symptom burden. These findings suggest that previously observed associations between depression and liver disease may reflect confounding by metabolic and socioeconomic factors rather than a direct effect.

2129 | BURDEN AND DETERMINANTS OF STIGMATIZATION IN PATIENTS WITH CHRONIC LIVER DISEASE: A CROSS-SECTIONAL STUDY FROM PERU

Daniel Chacón[1] Pedro Montes[2] Hector Pastrana[1] Yadhira Requena[1] Kevin Gutierrez[1] Gunther Coronado[2] Stalin Yance[2] Diego Rosales[2] Alissa Garcia-Reyes[1], [1]Universidad Nacional Mayor de San Marcos, [2]Hospital Nacional Daniel A. Carrión

Background: Stigmatization is increasingly recognized as a major psychosocial burden in patients with chronic liver disease (CLD), negatively impacting quality of life, social functioning, and healthcare engagement. However, data from Latin America remain scarce. We aimed to evaluate the prevalence, domains, and determinants of stigmatization among patients with cirrhosis and chronic liver disease in a tertiary referral center in Peru. **Methods:** We conducted a cross-sectional study including 97 adult patients with chronic liver disease attending a tertiary hospital in Lima, Peru. Demographic and clinical data, including cirrhosis stage, Child-Pugh class, MELD score, and liver disease etiology, were collected. Stigmatization was assessed using a structured questionnaire evaluating multiple domains of perceived and internalized stigma. Positive stigma responses were defined as agreement or strong agreement with questionnaire items. The total stigma burden was calculated as the number of positive responses. Univariate and multivariate analyses were performed to identify factors associated with higher stigma scores **Results:** Mean age was 64.3 ± 9.6 years, and 55.7% had decompensated cirrhosis. The predominant etiology was MASLD (60.8%), followed by alcohol-related liver disease (18.6%). Overall, 95.9% of patients reported at least one stigma-related experience, and the mean stigma score was 6.8 ± 3.8 items.The most frequent stigma-related perceptions were assumptions of prior alcohol misuse (61.9%), perceived personal responsibility for liver disease (53.6%), and negative impact on work capacity (50.5%).The predominant stigma domains included: Patient-blaming perceptions (“people assume I must have been a drinker,” “I am partially responsible for my disease”);Self-stigma and shame (“I feel less competent,” “defective or incomplete”); Social isolation and concealment (“I avoid telling others,” “I avoid public activities”); andOccupational and functional impairment.These findings suggest a substantial burden of both social stigma and internalized stigma, particularly related to alcohol-associated perceptions and functional deterioration.Stigma burden increased according to liver disease severity: Child A: 6.3 ± 4.1Child B: 7.1 ± 4.0Child C: 10.1 ± 4.3 (p = 0.037) Patients with alcohol-related etiologies demonstrated the highest stigma scores (mean 9.0). In multivariate linear regression analysis, alcohol-related liver disease remained independently associated with higher stigma burden (β = 2.39, p = 0.027), whereas MELD score and decompensation status were not independently significant. **Conclusion:** These findings from a Latin American cohort underscore the need for culturally adapted psychosocial interventions and stigma-reduction strategies in hepatology care, particularly for patients with alcohol-associated liver disease and advanced cirrhosis.

2130 | BURDEN OF DECOMPENSATED CIRRHOSIS IN A TERTIARY REFERRAL CENTER IN CAMEROON

Maitri Patel[1] Ikechukwu Eze[1] Mathurin Kowo[2] Claudia Suiru[2] Kasopefoluwa Oguntuyo[1] Sofia Jakab[1], [1]Yale University, [2]University Teaching Hospital of Yaounde

Background: There is limited systematic assessment of cirrhosis healthcare delivery in sub-Saharan Africa. The Pathways to Cirrhosis Care in Cameroon Project seeks to characterize barriers, facilitators, and access patterns for patients presenting with cirrhosis at a large tertiary care center in Yaoundé, Cameroon. **Methods:** We performed a retrospective analysis of all adult hepatology hospitalizations from 2023-2025. We collected data from handwritten charts on demographics, presenting symptoms, liver disease etiology, decompensation, recommended interventions, and medications. Due to extensive missing data, this study was not powered to conduct hypothesis testing and focused on descriptive assessment of current practices. **Results:** Of the 138 patients identified in the hospital registry as admissions for cirrhosis management, only 68 (49%) charts could be physically located for data extraction. Most patients were male (51, 75%), and traveled greater than 30 minutes to reach care (38, 58%). Viral hepatitis and alcohol-associated liver disease were found in most patients: hepatitis B (38, 56%), hepatitis C (23, 34%), alcohol (27, 40%), and mixed (25, 37%). Cirrhosis diagnosis was based on clinical criteria (exam, laboratory, and ultrasound data). Cirrhosis decompensation was present in almost all patients: ascites (66, 97%), jaundice (50, 74%), hepatic encephalopathy (33, 49%), variceal bleeding (18, 28%). There was more than one decompensation in 38 patients (56%). Hepatocellular carcinoma was suspected by ultrasound and elevated alpha-fetoprotein in 41 patients (60%), with confirmatory contrast study performed in 7 patients. Within one year from presentation, 37 patients died (54%).Standardized liver disease severity metrics were inconsistently collected: Child-Turcotte-Pugh (CTP) score could be calculated in 31 (46%), and MELD 3.0 score in 11 (16%) patients. Endoscopy was completed in 14 of 25 (56%) of patients referred; 9 of 18 (50%) patients with known or suspected varices were prescribed a beta-blocker. Anti-viral therapy was prescribed in 20 of 38 HBV patients (53%). No patients underwent liver transplantation (which would entail international travel). **Conclusion:** Patients with cirrhosis admitted for tertiary care in Cameroon frequently presented with multiple cirrhosis decompensations or liver cancer and had high mortality, highlighting the need for earlier linkage to hepatology care especially given low transplant availability. Gaps in documentation and evaluation limited standardized disease assessment and stratification. Low follow-through with recommended care reflected barriers in care coordination, patient retention, and treatment access. These findings identify areas of improvement across the cirrhosis care continuum, including medical record infrastructure, management pathways, and access to treatment.

Disclosures: Maitri Patel: Nothing to Disclose, Ikechukwu Eze: Nothing to Disclose, Mathurin Kowo: Nothing to Disclose, Claudia Suiru: Nothing to Disclose, Kasopefoluwa Oguntuyo: Nothing to Disclose, Sofia Jakab: Nothing to Disclose.

2131 | DIFFERENCES IN TIPS VS TRANSPLANT: THE IMPACT OF SOCIAL FACTORS ON TREATMENT PATHWAYS IN PATIENTS WITH ESLD

Urania Argueta[1] Diana Jimenez-Briseno[2] Jessica Menjivar Cruz[2] Arzoo Manandhar[2] Shenise Gilyard[2], [1]David Geffen School of Medicine, UCLA, [2]Ronald Reagan UCLA Medical Center, Interventional Radiology

Background: Liver transplantation (LT) is one of the mainstays of treatment for advanced chronic liver disease. Bridging therapies, like placement of a transjugular intrahepatic portosystemic shunt (TIPS), are used to control sequelae of portal hypertension such as ascites and varices. However, health disparities affect disease management, particularly among racial minorities. Studies show that Black and Latino patients are less likely to undergo TIPS placement and LT compared to white patients. Our study aims to characterize the clinical outcomes of patients with ESLD in the US and assess the effect of social determinants of health on treatment pathways. **Methods:** This is a retrospective cross-sectional study analyzing data from the National Inpatient Sample (NIS) from 2018-2022. The NIS is an all-payer US inpatient database representing 20% of US

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hospitalizations. For all years, each individual hospitalization is deidentified and carries demographic details, including age, sex, race/ethnicity, insurance provider, and zip code-based income quartile. Our study selected patients across these years admitted with cirrhosis and/or sequelae of portal hypertension, and further stratified clinical outcomes per each cohort according to year. Admissions were included if they contained at least 1 cirrhosis-related International Statistical Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) code and/or at least 1 ICD-10-CM code related to ascites or varices. Variables were analyzed using Odds Ratio. **Results:** Among 155,413 hospitalizations analyzed between 2018-2022, patients were further stratified by ethnicity, zip code-based income quartile, insurance provider. 64% identified as QWhite, 7.7% as Black, 18.5% as Latino, 1.9% as Asian or Pacific Islander, 1.9% as Native American and 3.3% as Other. Most White patients presented with Medi-Care as their primary health insurance, while most Black, Latino, and Asian patients presented with Medicaid as their primary health insurance. By 2022, Black patients were had an increased risk of in-hospital mortality compared to White patients (OR, 1.72; 95% CI, 1.44-2.04) while Latino patients had a decreased risk of in-hospital mortality (OR, 0.79; 95% CI, 0.68-0.92). Black patients are also less likely to undergo TIPS placement compared to White patients (OR, 0.52; 95% CI, 0.37-0.73). Our study suggests there is additional work to be done to ameliorate disparities in healthcare outcomes. **Conclusion:** Black patients were less likely to receive care for decompensated cirrhosis. Many prior studies have suggested healthcare access as a driver for poor health outcomes, however, a majority of patients were on Medicaid or Medi-Care which suggests there may be other social factors driving disparities.

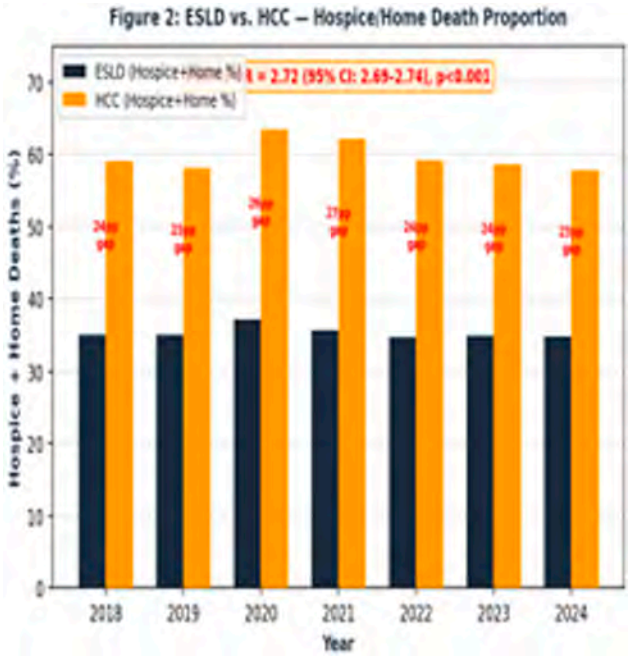
2132 | STAGNANT HOSPICE AND HOME-BASED END-OF-LIFE CARE UTILIZATION AMONG PATIENTS WITH END-STAGE LIVER DISEASE IN THE UNITED STATES, 2018–2024: A POPULATION-BASED ANALYSIS



Saba Irfan[1] Javeria Sana[2], [1]University of Texas Rio Grande Valley, [2]Rawalpindi Medical University

Background: End-stage liver disease (ESLD) carries high symptom burden and poor prognosis comparable to many cancers, yet palliative and hospice care utilization remains understudied at the population level. Nationally, ESLD-related deaths increased 28.5% from 85,026 in 2018 to a peak of 109,245 in 2021, accumulating 697,580 deaths over the 7-year study period.Recent ACG guidelines recommend goals-of-care discussions for patients with acute-on-chronic liver failure, yet the extent to which ESLD patients access hospice services nationally is unknown. We aimed to characterize temporal trends in place of death for ESLD, identify racial/ethnic and demographic disparities, and compare hospice utilization with hepatocellular carcinoma (HCC). **Methods:** We conducted a retrospective cross-sectional analysis of 697,580 adults ($\geq$ 25 years) who died from ESLD (ICD-10: K70.3, K72.0-K72.9, K74.0-K74.6, K76.6-K76.7) between 2018 and 2024 using the CDC WONDER Multiple Cause of Death database. HCC deaths (C22.0-C22.9; N = 226,380) served as comparators. Primary outcome was proportion of deaths occurring in hospice facilities or decedent's home. Cochran-Armitage trend tests, chi-square analyses, and odds ratios with 95% CIs were calculated. **Results:** ESLD mortality increased 28.5% from 2018 (85,026) to 2021 (109,245), stabilizing at 103,923 by 2024. Only 35.3% of ESLD deaths occurred in home-based settings (home or hospice facility) compared with 59.7% of HCC deaths (OR = 2.72; 95% CI: 2.69–2.74; $p < 0.001$). The hospice +home proportion remained unchanged over seven years (35.0% in 2018 vs. 34.8% in 2024; $p = 0.514$ for linear trend), while hospital inpatient deaths dominated at 50.1%. Significant disparities were observed: Black patients had the lowest home-based death proportion (26.1% vs. White 36.7%; $\chi^2 = 849.12$; $p < 0.001$); Hispanic patients showed a declining trend (32.9%→30.8%); females were lower than males (33.6% vs. 36.4%; $\chi^2 = 581.92$; $p < 0.001$); younger patients aged 25–34 had half the rate of those $\geq$ 85 years (22.9% vs. 42.1%); and the Northeast (29.2%) significantly lagged behind the South (38.3%; $\chi^2 = 2,948.83$; $p < 0.001$). **Conclusion: :** ESLD mortality increased 28.5% from 2018 (85,026) to 2021 (109,245), stabilizing at 103,923 by 2024. Only 35.3% of ESLD deaths occurred in home-based settings (home or hospice facility) compared with 59.7% of HCC deaths (OR = 2.72; 95% CI: 2.69–2.74; $p < 0.001$). 2133 | ◆ RISING U.S. MORTALITY FROM LIVER DISEASE WITH PSYCHOACTIVE SUBSTANCE USE AS A CONTRIBUTING CAUSE, 1999–2020: GEOGRAPHIC, RURAL–URBAN, AND DEMOGRAPHIC DISPARITIES

Mounika Kotte[1] Jagadish Koyi[2] Serene Sara John[3] Sri Ram Charan Gundapaneni[4] Nayanika Tummala[5] Digantkumar Patel[6] Pragathi Munnangi[7] Hardik Dineshbhai Desai[8], [1]Prime south consortium, [2]Integris Health, Oklahoma City, Oklahoma. USA. 73112, [3]Detroit medical center, Detroit, Michigan, 48201, [4]UCF/HCA Florida Ocala Hospital, Ocala, Florida, United States, 34471, [5]NYMC St Mary's and St Clare's, [6]Springfield Clinic, Springfield, IL, USA, [7]BronxCare Health System , Bronx , New York - 10457, [8]AB Plus Multispecialty Hospital, Ahmedabad, Gujarat, India

Background: Mortality involving liver disease with psychoactive substance use as a contributing cause is an emerging intersection of hepatology, addiction medicine, and population health, but its long-term U.S. patterns across geography, urbanicity, and sociodemographic groups remain insufficiently defined. **Methods:** Using CDC WONDER Multiple Cause of Death data, we analyzed U.S. deaths from 1999–2020 with liver disease as the underlying cause and psychoactive substance use as a contributing cause. Outcomes included deaths, crude rates, and age-standardized rates per 100,000. Annualized percentage change (APC) from 1999–2020 was calculated as compounded yearly change for overall burden, census region, state, 2013 urbanization category, 10-year age group, sex, race, and Hispanic origin. **Results:** National deaths increased from 3,550 in 1999 to 8,098 in 2020, a 128% increase and APC of +4.0%/year. The crude rate rose from 1.3 to 2.5 per 100,000, and the age-standardized rate increased from 1.3 to 2.1 per 100,000 (APC +2.3%/year), indicating that growth was not explained only by population aging. Regional APC in deaths was highest in the South (+6.2%/year; 865 to 3,057 deaths) and Midwest (+5.8%/year; 638 to 2,095), followed by the Northeast (+3.2%/year) and West (+1.1%/year). State-level APC ranged from −4.1%/year in California to +10.9%/year in Indiana, +10.4%/year in Tennessee, +9.8%/year in Minnesota and Kansas, and +9.2%/year in Nebraska and Georgia. By urbanization, increases were greatest in noncore nonmetro (+6.7%/year; 211 to 823 deaths), small metro (+6.2%/year), and micropolitan areas (+6.2%/year), compared with +0.6%/year in large central metros. By age, APC was highest in adults 55–64 years (+6.3%/year; 817 to 2,950 deaths), 65–74 years (+5.6%/year), and 25–34 years (+5.3%/year). Female deaths increased faster than male deaths (+5.0% vs +3.6%/year), although 2020 deaths remained higher in males (5,467 vs 2,631). Among racial groups, APC was highest in Asian or Pacific Islander (+6.1%/year) and American Indian/Alaska Native populations (+5.2%/year); non-Hispanic deaths increased faster than Hispanic deaths (+4.3% vs +2.0%/year). **Conclusion:** U.S. mortality involving liver disease and psychoactive substance use rose markedly from 1999–2020, with disproportionate growth in the South, Midwest, rural/nonmetro communities, mid-to-older adulthood, females, and selected racial groups. These findings support targeted prevention, earlier substance-use treatment integration into liver care, and regionally tailored public health strategies.

2134 | ◆ BEYOND MASLD: PREVALENCE AND INDEPENDENT PREDICTORS OF ADVANCED FIBROSIS BY HISPANIC ETHNICITY ACROSS THE FULL STEATOTIC LIVER DISEASE SPECTRUM IN ADULTS WITH OVERWEIGHT AND OBESITY

Monica Tincopa[1] Ricki Bettencourt[2] Seema Singh[2] Egbert Madamba[2] Lisa Richards[1] Rohit Loomba[1], [1]University of California, San Diego, [2]UCSD

Background: Hispanic/Latinx adults are disproportionately affected by metabolic dysfunction-associated steatotic liver disease (MASLD), yet the full spectrum of steatotic liver disease (SLD) — including MetALD and alcohol-associated liver disease (ALD) — remains poorly characterized in this population. Critically, whether Hispanic ethnicity is independently associated with advanced fibrosis (AF) across SLD after accounting for metabolic and socioeconomic risk factors is an important knowledge gap. We determined SLD prevalence, fibrosis burden and predictors of AF by Hispanic ethnicity in a prospective cohort of adults with overweight and obesity undergoing MRI phenotyping. **Methods:** This is a cross-sectional analysis of prospectively enrolled adults with overweight and obesity [body mass index (BMI) ≥ 25 kg/m^2]) from primary care and community settings. Participants underwent laboratory testing, vibration controlled transient elastography (VCTE) and MR elastography (MRE) with proton density fat fraction (PDFF). Alcohol use was assessed with AUDIT-C, Skinner Lifetime Drinking History and phosphatidylethanol (PEth).Participants were placed in SLD subcategories based on validated self-reported alcohol measures and AASLD definitions. At risk-MASH was defined among those with liver biopsy (N = 106). AF was defined as liver stiffness measurement (LSM) on MRE ≥ 3.63 kPa or ≥ 12 kPa on VCTE. Multivariate logistic regression identified independent predictors of AF in those with SLD. **Results:** The cohort included 989 individuals with a median (IQR) age of 53 yrs (19), 52% female, 38.5% Hispanic (N = 381), 23% had diabetes with a mean (± SD) BMI of 32.3 kg/m^2 (± 5.8). Compared to non-Hispanic participants, Hispanic participants: were younger, had higher BMI, MRI-PDFF, and triglycerides; lower alcohol consumption, income and formal education. Prevalence in Hispanic compared to non-Hispanic adults was 75% vs 67.5% for SLD, 68% vs 59.1% for MASLD, 48.9% vs 44.1% for at risk MASH, 4.5% vs 5.3% for MetALD, and 2.1% vs 3.1% for ALD, respectively. AF was significantly more prevalent among Hispanic vs non-Hispanic adults (8.7% vs. 4.4%, p < 0.01) (**Figure**). AF was independently associated with age, Hispanic ethnicity (OR 2.19, p = 0.04), diabetes, and ALT (**Table**). **Conclusion:** In a large, prospective cohort of adults with overweight and obesity who underwent MRI phenotyping, SLD was significantly more prevalent and severe in Hispanic compared to non-Hispanic adults. Despite lower alcohol consumption, Hispanic adults had twice the prevalence of AF compared to non-Hispanic adults. Hispanic ethnicity remained an independent predictor of AF after adjustment for metabolic and socioeconomic factors. These findings highlight the urgent need for targeted, real-world SLD screening and risk stratification strategies in Hispanic adults.

Figure. Prevalence and Staging of SLD by Hispanic Ethnicity

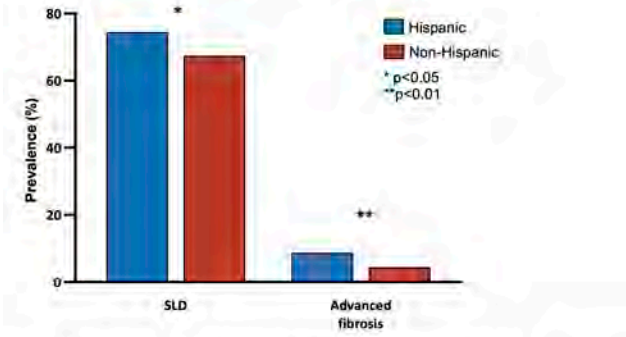

Table. Logistic regression for predictors of advanced fibrosis in those with SLD

Variable	Univariate OR (95% CI)	p-value	Multivariate OR (95% CI)	p-value

2135 | ◆ ESTRADIOL THERAPY IS ASSOCIATED WITH REDUCED RISK OF LIVER DISEASE AND CARDIOVASCULAR EVENTS IN TRANSGENDER AND GENDER DIVERSE INDIVIDUALS: A PROPENSITY-MATCHED COHORT STUDY

Ximena Parraga[1] Kaanthi Rama[1] Hyundam (Dami) Gu[1] Omar Albhaisi[1] Juan Pablo Arab[1] Hanna Blaney[1],
[1]Virginia Commonwealth University

Background: Sex hormones are known modulators of hepatic metabolism, inflammation, and fibrosis pathways, but their role in liver disease progression remains largely unexplored. Yet the long-term hepatic effects of estradiol-based gender-affirming hormone therapy in transgender and gender diverse (TGD) individuals remain poorly characterized, representing a critical gap in clinical practice. We aimed to evaluate the impact of estradiol therapy on hepatic and cardiometabolic outcomes in this population. **Methods:** A retrospective cohort study was conducted using the TriNetX Global Collaborative Network between January 2010 and January 2020, with outcomes followed over 5 years. TGD individuals were identified using ICD-10 F64 codes (gender incongruence); patients with viral hepatitis, autoimmune hepatitis, and other competing chronic liver diseases were excluded. Individual gender identity could not be further characterized within the dataset. The exposure cohort included TGD patients on estradiol (n = 10,441) and the comparator cohort TGD patients not receiving estradiol (n = 10,441). The comparator cohort was not restricted to exclude individuals receiving testosterone or other gender-affirming therapies. Outcomes included SLD, MASLD, ALD, fibrosis/cirrhosis, MALOs, ascites, and MACE.Kaplan-Meier survival analyses with HRs and log-rank p-values were reported. **Results:** After 1: 1 propensity score matching, both cohorts comprised 10,441 well-balanced TGD individuals. Estradiol therapy was associated with statistically significant risk reductions across most hepatic and cardiovascular outcomes over 5 years. The strongest effect was observed for MACE (214 vs. 342 events; HR 0.596, 95% CI 0.503–0.708, p < 0.001), followed by ALD (11 vs. 24 events; HR 0.439, p = 0.020), MALO (51 vs. 81 events; HR 0.601, p = 0.004), ascites (45 vs 70 events; HR 0.614, p = 0.010), MASLD (221 vs. 268 events; HR 0.785, p = 0.008), and SLD (231 vs. 238 events; HR 0.777, p = 0.004). Absolute risk differences were small, reflecting the young median age of the cohort. Fibrosis and cirrhosis showed a protective but non-significant trend (29 vs. 41 events; HR 0.678, p = 0.107). **Conclusion:** Estradiol therapy demonstrated a consistent hepatoprotective and cardiometabolic signal in TGD individuals across 5 years. These preliminary real-world findings warrant further investigation in older populations with established metabolic risk factors.

Figure 1. Hazard Ratios for Hepatic and Cardiovascular Outcomes Among TGD Individuals Receiving Estradiol Therapy vs. No Estradiol (5-Year Follow-Up).

2136 | CHRONIC LIVER DISEASE IN SEXUAL AND GENDER-DIVERSE MINORITY POPULATIONS: A GLOBAL SCOPING REVIEW AND META-ANALYSIS HIGHLIGTHING CRITICAL EVIDENCE GAPS BEYOND VIRAL HEPATITIS

Felice Cinque[1] Carlos Myers-Ascencio[2] Sahar Saeed[3] Carla Coffin[4] Radin Pakseresht[5] Duy Dinh[3] Genevieve Gore[2] Jihoon Lim[6] Rosa Lombardi[7] Bertrand Lebouche[8] Giovanni Guaraldi[9] Keyur Patel[10] Tzu-Hao Lee[11] Giada Sebastiani[2], [1]University of Milan, [2]McGill University, [3]Queen's University, [4]University of Calgary, [5]University of Western Ontario, [6]Research Institute of the McGill University Health Centre, [7]University of the Study of Milan, [8]McGill University Health Centre, [9]University of Modena and Reggio Emilia, [10]University of Toronto, [11]Baylor College of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) and other non-communicable chronic liver diseases (CLDs) are major global health challenges, yet their burden among sexual and gender minority populations remains poorly characterized. These populations disproportionately experience adverse social and structural determinants of health—including stigma, barriers to inclusive healthcare, mental health disorders, and substance use—which may amplify liver disease risk. Existing data focus on viral hepatitis among men who have sex with men (MSM), with limited representation of transgender, lesbian, and non-binary populations. We conducted a global scoping review and meta-analysis to characterize the epidemiology of non-communicable and viral CLDs across sexual and gender minority populations. **Methods:** This scoping review and meta-analysis was conducted in accordance with PRISMA guidelines. Six electronic databases (MEDLINE, Embase, CENTRAL, Web of Science, Global Health, and Global Index Medicus) were systematically searched from inception through May 31, 2025. Two reviewers independently screened titles, abstracts and full texts, and performed standardized data extraction. Pooled prevalence estimates were calculated using random effects models. **Results:** Among 6,459 records screened for non-communicable CLDs and viral hepatitis in sexual and gender minority populations, 117 studies met inclusion criteria. No study reported prevalence data on MASLD or other non-communicable CLDs. In addition, lesbian and non-binary populations were almost entirely absent from the literature. Across 63 studies, pooled hepatitis B virus (HBV) prevalence was 6.0% (95% CI 4.2–8.4), with the highest observed in Africa (8.4%; 95% CI 4.8–14.1) and the lowest in Asia/Pacific (3.2%; 95% CI 1.4-7.1). HBV prevalence was significantly higher among MSM (7.3%) than transgender individuals (2.2%). Across 88 studies, pooled hepatitis C virus (HCV) prevalence was 3.6% (95% CI 2.6–5.2), with comparable estimates across geographic regions and between MSM and transgender populations (Figure). Meta-regression analyses showed a gradual decline in HBV and HCV prevalence since the 1980s. Funnel plot asymmetry showed possible small-study effects for HBV, whereas no evidence of publication bias was observed for HCV. **Conclusion:** There is a profound global evidence gap regarding MASLD and other non-communicable CLDs in sexual and gender minority populations, especially in lesbian and non-binary individuals. Despite declining viral hepatitis prevalence over time, HBV and HCV continue to disproportionately affect MSM and transgender populations. These findings highlight an urgent need for inclusive liver disease research and equitable prevention, screening, and care strategies for MASLD and non-communicable CLDs in historically underserved sexual and gender minority populations.

2137 | RACE AND ETHNICITY REPORTING AND REPRESENTATION IN CONTEMPORARY LIVER DISEASE CLINICAL TRIALS: A SYSTEMATIC REVIEW AND BENCHMARKING ANALYSIS

Meena Tadros[1] Yiwei Hang[1] Nicol Tugarinov[1] Claudio Salinas[1] Anna Goebel[1] Nadim Mahmud[2], [1]University of Pennsylvania, [2]Hospital of the University of Pennsylvania

Background: Racial and ethnic disparities are well established in chronic liver disease (CLD). Representation within clinical trials remains poorly characterized. Prior studies have focused primarily on whether race or ethnicity was reported, without evaluating if enrolled populations reflect underlying disease epidemiology. We performed a systematic review of contemporary liver disease clinical trials to assess trends in race/ethnicity reporting and quantify representation relative to disease-specific population benchmarks. **Methods:** We utilized Medical Subject Headings (MeSH) to search PubMed for English language randomized controlled trials (RCTs) published from 2013 to 2024 across major categories including metabolic dysfunction-steatotic associated liver disease (MASLD), cirrhosis/transplant, hepatocellular carcinoma (HCC), and non-MASLD CLD. Sample size, racial and ethnic reporting and composition, study location, and funding source were extracted. Race and ethnicity reporting rates were evaluated over time via linear regression and stratified by US versus non-US studies. Among US studies with race/ethnicity data, representation was assessed using participation-to-prevalence ratios (PPRs), defined as the observed trial proportion divided by disease-specific epidemiologic benchmarks. PPR < 0.8 was considered underrepresentation. **Results:** A total of 1,593 RCTs were included, of which 415 (26.1%) reported race and 225 (14.1%) reported ethnicity. Studies reporting race were larger (median 150 vs. 80 participants, $p < 0.001$), more often US-based (48.4% vs. 4.6%, $p < 0.001$), and more commonly industry-funded (72.3% vs. 24.2%, $p < 0.001$). Race reporting was higher in US versus non-US studies over time (**Panel A**); ethnicity reporting increased modestly over time only among US studies (β 0.019/year, 95% CI 0.002-0.036; $p = 0.025$). Among US studies, Black participants were consistently underrepresented across disease categories, with median PPRs often below 0.8. Hispanic underrepresentation was most pronounced in HCC trials (**Panel B**). White participants were generally proportionally represented or overrepresented, while Asian representation varied greatly by disease category. Temporal analyses showed persistent underrepresentation of Black participants over time despite modest improvements in reporting practices (**Panel C**). **Conclusion:** Contemporary CLD trials often do not report participant race/ethnicity. Among studies reporting race and ethnicity, participants do not reflect disease burden. Our benchmarking analysis using CLD-specific epidemiology shows that Black participants are underrepresented in CLD trials relative to their disease burden. Asian participants are underrepresented most in cirrhosis/transplant trials, while Hispanic participants are often underrepresented in HCC trials. This disease burden-specific analysis highlights critical inequities.

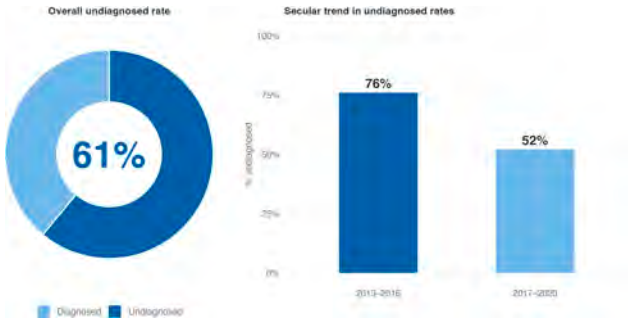
2138 | HEPATITIS B SCREENING GAPS AMONG FOREIGN-BORN ADULTS IN THE UNITED STATES: A NATIONALLY REPRESENTATIVE PRE-GUIDELINE BASELINE USING A NATIONAL NUTRITION SURVEY, 2013–2020



Rakshana Ravichandran[1] Ravi Patel[1] Aditya Kohli[1] Keeranmayee Mishra[2] Sonu Dhillon[3], [1]Trinity Health

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Oakland/wayne State School Of Medicine, [2]Trinity Health,Oakland/Wayne State University Program, [3]University of Illinois College of Medicine Peoria

Background: Hepatitis B virus (HBV) infection disproportionately affects foreign-born individuals from high-endemicity regions, yet the proportion living with undiagnosed infection in the United States remains unknown. In March 2020, the U.S. Preventive Services Task Force (USPSTF) expanded HBV screening to adults at increased risk, including foreign-born persons from countries with hepatitis B surface antigen (HBsAg) prevalence ≥2%. Nationally representative estimates of undiagnosed HBV in this population prior to guideline expansion are lacking. **Methods:** We analyzed National Health and Nutrition Examination Survey (NHANES) 2013–March 2020 pre-pandemic cycles. Adults ≥18 years were stratified by nativity (DMDBORN4). HBV infection was defined as HBsAg positivity (LBDHBG), consistent with chronic infection at the population level though acute infection cannot be excluded. Undiagnosed infection was defined as HBsAg positivity without self-reported prior diagnosis (HEQ010). Secular trends were examined across 2013–2016 and 2017–2020. Univariable logistic regression was used to explore predictors of undiagnosed status. All analyses incorporated complex survey design weights to account for NHANES sampling methodology. **Results:** Among 20,624 adults, 6,108 (30%) were foreign-born; 393 lacked HBsAg data and were excluded. Of 88 HBsAg-positive foreign-born adults, 87 comprised the final analytic sample. HBsAg prevalence was 1.24% (SE 0.0017). Of HBsAg-positive participants, 61% were undiagnosed, representing an estimated 313,000 undiagnosed individuals nationally (95% CI 202,000–425,000). Undiagnosed rates declined from 76% (2013–2016) to 52% (2017–2020), predating the USPSTF update and likely reflecting secular community awareness trends. Absence of insurance (OR 1.75), lack of usual care (OR 1.85), and non-Asian race/ethnicity (OR 2.22) showed trends toward higher odds of undiagnosed infection; no predictor reached statistical significance (n = 52 events). **Conclusion:** Prior to the 2020 USPSTF expansion, 61% of HBsAg-positive foreign-born adults were undiagnosed — 313,000 individuals at risk for cirrhosis and hepatocellular carcinoma (HCC) without access to antiviral therapy or surveillance. The decline from 76% to 52% reflects encouraging progress with potential for further gains through systematic guideline implementation. Limitations include cross-sectional design, HBsAg subsample missingness, and recall bias. These findings establish a pre-guideline baseline for evaluating future guideline impact. Targeted screening addressing insurance and primary care gaps is urgently needed to support WHO 2030 HBV elimination targets.

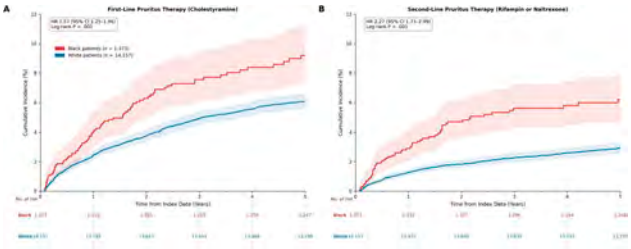
2139 | RACIAL DIFFERENCES IN SYMPTOMATIC PRURITUS BURDEN AMONG BLACK AND WHITE PATIENTS WITH PRIMARY BILIARY CHOLANGITIS



Basil Jalamneh[1] Dian Chiang[1] Omar Sims[1], [1]Cleveland Clinic Foundation

Background: Pruritus is the predominant symptomatic burden in primary biliary cholangitis (PBC), adversely affecting quality of life, sleep, and daily functioning. Despite growing recognition of racial disparities in chronic liver disease, whether the pruritus burden differs by race remains undefined. We evaluated racial differences in antipruritic treatment patterns as real-world proxies of symptom severity among Ursodeoxycholic acid (UDCA)-treated patients with PBC. **Methods:** Using the TriNetX Research Network — a federated electronic health record platform spanning 110 U.S. healthcare organizations — we conducted a retrospective cohort study of adults (≥18 years) with PBC (ICD-10: K74.3) initiated on UDCA. Patients were stratified into two mutually exclusive cohorts by documented race (Black or White). Exclusions included prior liver transplantation, primary sclerosing cholangitis, intrahepatic bile duct carcinoma, and digestive organ malignancy. The index date was defined as the first concurrent documentation of PBC diagnosis and UDCA prescription. Outcomes were assessed from 30 days through 5 years post-index. Pruritus burden was operationalized via time to initiation of first-line therapy (cholestyramine) and second-line therapy (rifampin or naltrexone). Kaplan–Meier analysis and multivariable Cox proportional hazards regression were used for between-group comparisons. **Results:** Of 15,530 eligible patients, 1,373 were Black and 14,157 were White. Black patients were younger (mean age 64.8 vs. 68.5 years) and demonstrated greater baseline disease severity, including higher alkaline phosphatase, total bilirubin, ascites, jaundice,

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

abdominal pain, and malnutrition. At 5-year follow-up, Black patients were significantly more likely to initiate first-line antipruritic therapy (cholestyramine: 6.4% vs. 4.3%; HR 1.57, 95% CI 1.25–1.96; P < .001) and second-line therapy (rifampin or naltrexone: 4.5% vs. 2.1%; HR 2.27, 95% CI 1.73–2.99; P < .001). Figure-1. **Conclusion:** In this large real-world cohort of UDCA-treated patients with PBC, Black patients faced a disproportionately higher antipruritic treatment burden, with more than twice the hazard of requiring second-line therapy compared to White patients. These findings highlight the need for earlier symptom recognition, equitable access to emerging antipruritic therapies, and further investigation into biologic and healthcare factors driving racial differences in symptom experience among patients with PBC.

2140 | IMPROVING MASLD RISK AWARENESS IN AN UNDERSERVED POPULATION USING AN AI-VIDEO AS AN INNOVATIVE EDUCATIONAL TOOL: ANALYZING THE IMPACT OF ETHNICITY AND EDUCATION LEVEL

David Weinstein[1] Mitchelle Zolotarevsky[1] Keon Karimabady[1] Raza Muhammad[1] Athanasios Kondilis[1] Madhav Patel[1] Ruxandra Dane[1] Elizabeth Ward[1], [1]Endeavor Health

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is widely prevalent yet underdiagnosed, with low screening rates in primary care contributing to poor patient awareness. Patient education remains a critical and underutilized tool in bridging this gap. Educational videos have improved patient comprehension in various clinical settings. Our goal was to determine whether ethnicity or education level influenced patients' accurate perception of their MASLD risk and whether an AI-driven, multilingual educational video improved patient understanding and self-identification of risk status. **Methods:** We conducted a single-blind prospective study of 200 underserved adult patients in a resident clinic at risk for, or diagnosed with, MASLD based on 2022 AASLD–AACE criteria. Participants completed the validated Public Awareness of Non-Alcoholic Fatty Liver Disease (PAN-AFLD) survey assessing baseline MASLD knowledge and perceived risk. Participants then viewed an original AI-generated video, in English and validated in Spanish, discussing MASLD pathophysiology, complications, and lifestyle strategies, followed by a post-intervention PAN-AFLD survey. Ethnicity was categorized as: Caucasian, Hispanic, Asian/Pacific Islander, African-American, or Other, and education level as Elementary School, High School, College, Postgraduate, or None. **Results:** Of the 200 patients enrolled, 5 were excluded due to incomplete questionnaires. The cohort was predominantly Hispanic (45.6%, n = 89). In terms of education, 17.4% had elementary school education (n = 34), and 10.3% had postgraduate education (n = 20). Among ethnic groups, Hispanic patients had the highest post-video risk awareness (87.6%, n = 78), up from 66.3% (n = 59), a 1.32-fold increase. Among education groups, patients with elementary school education showed a 1.48-fold increase, from 61.8% (n = 21) to 91.2% (n = 31). Postgraduate patients demonstrated the greatest relative improvement at 1.86-fold, increasing from 35% (n = 7) to 65% (n = 13). **Conclusion:** Our preliminary data show that perceived MASLD risk increased across all ethnicity and education groups. Notably, Hispanic patients, who bear the highest burden of MASLD compared to non-Hispanics, comprised the largest proportion of our cohort and had the highest absolute post-video risk awareness. Among education groups, postgraduate patients showed the greatest relative improvement despite having the lowest baseline awareness, which may reflect that higher educational attainment enhances receptiveness to new health information. These findings suggest that AI-driven multilingual education may be particularly effective in diverse, underserved populations where language and educational barriers have historically limited health literacy. Correct risk perception is a critical first step toward lifestyle modification and, hopefully, decreased MASLD risk and progression.

Limsui[9] Priyanka Kanth[7], [1]University of California Los Angeles (UCLA), [2]Georgetown University School of Medicine, [3]Colorado University, [4]Kentucky College of Osteopathic Medicine, [5]MedStar Georgetown University, [6]Georgetown University Hospital, [7]MedStar Georgetown University Hospital, [8]Johns Hopkins University, [9]Stanford University

Background: Publication leadership influences promotion and visibility, yet contemporary authorship equity across gastroenterology and hepatology journals is incompletely characterized. We evaluated women's lead and senior authorship and first–last author concordance across selected specialty journals. **Methods:** We analyzed PubMed-indexed publications from 14 prespecified gastroenterology/hepatology journals from 2013 through 2025. First and last individual authors were proxies for lead and senior authorship. Gender was inferred from first names using Genderize.io with manual adjudication of missing/ambiguous cases; temporal trends, journal heterogeneity, and first–last gender concordance were assessed. **Results:** Among 60,453 publications, women represented 19,045/60,453 first authors (31.5%) and 12,579/60,453 last authors (20.8%), yielding a 10.7 percentage-point seniority gap and last- to-first leadership ratio of 0.66. Women's first authorship ranged from 18.7% to 43.8% across journals and last authorship from 11.5% to 31.3% ($p < 0.001$ for both). From 2013 to 2025, women's first authorship rose from 29.5% to 34.6% (+0.53 percentage points/year; 95% CI 0.34-0.72), and last authorship rose from 17.0% to 24.8% (+0.76 percentage points/year; 95% CI 0.66-0.87). Articles with women first authors were more likely to have women last authors than articles with men first authors (29.0% vs 17.0%; OR 1.99, 95% CI 1.91-2.07). **Conclusion:** Women's authorship increased across selected GI/hepatology journals, but senior authorship remained substantially lower than lead authorship. Journal-level heterogeneity and first–last author concordance suggest that equitable sponsorship, editorial representation, and research leadership pathways remain priority targets.

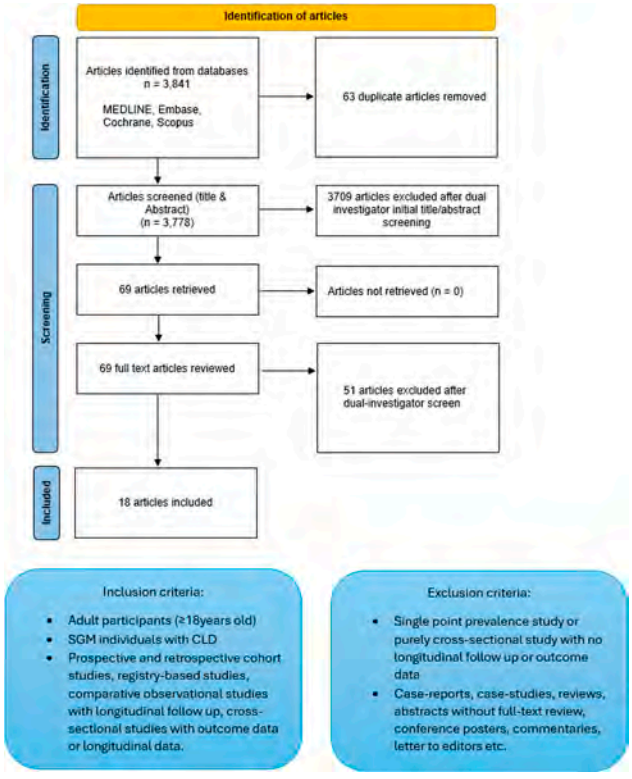
2142 | HEALTH OUTCOMES IN SEXUAL AND GENDER MINORITY POPULATIONS WITH CHRONIC LIVER DISEASE: A SYSTEMATIC REVIEW



Kamalpreet S. Hara[1] Tulio Correa[2] Alberto Calleri[1] Sonali Paul[3] Alexandra Strauss[4] Nikki Duong[5] Victor Chedid[1] Douglas Simonetto[1], [1]Mayo Clinic Rochester, [2]University of Pittsburgh, [3]University of Chicago Medical Center, [4]Johns Hopkins School of Medicine, [5]Stanford University

Background: Sexual and gender minority (SGM) individuals face persistent disparities in healthcare access, utilization and outcomes driven by stigma, discrimination, and barriers to care. While these inequities are increasingly recognized, no systematic review has examined chronic liver disease (CLD) outcomes among SGM populations. **Methods:** A comprehensive search of MEDLINE, Cochrane, Embase and Scopus databases was performed through April 15, 2025, using controlled vocabulary supplemented with keywords. Studies including adult SGM individuals (≥ 18 years) with CLD reporting longitudinal follow-up or outcome data were included. Study designs were substantially heterogeneous across SGM ascertainment, outcome definitions, among others, which precluded a meta-analysis, hence our findings were synthesized narratively. Review was prospectively registered on PROSPERO (CRD420251033801). **Results:** Our search yielded 3,841 studies, of which 18 were included in the final synthesis (Figure 1). Included studies were primarily observational cohort and database studies across 10 countries, predominantly in Europe. Of note, SGM populations were predominantly represented through behavioral transmission risk categories, particularly men who have sex with men (MSM), with substantial underrepresentation of broader SGM community and identities. One study used self-reported gender identity but was limited to 60 transgender participants, another captured transgender adults at national scale but relied on diagnostic coding rather than self-reporting. Majority

of evidence focused on viral hepatitis, HBV (n = 9) and HCV (n = 8) deriving primarily from HIV-coinfected cohorts. Among HIV-positive MSM with HCV, significant fibrosis (METAVIR ≥ F2) developed in 39.4% and cirrhosis in 11.6%; however, successful antiviral therapy drove substantial regression, with 78.3% maintaining FIB-4 < 1.45 at 3.5-year follow-up. Among HIV/HBV coinfected MSM, liver-related mortality was highest (14.2 per 1,000 person-years) which declined markedly after tenofovir-containing ART introduction (aHR 0.29; 95%CI 0.11–0.75) reflecting the hepatoprotective impact of modern antiretroviral therapy. Transgender adults carried more than double the age-standardized cirrhosis prevalence of cisgender adults (1,285 vs 561 per 100,000) with disproportionate psychosocial comorbidity. In MASLD-focused data, steatosis burden was numerically higher in transgender women versus cisgender comparators (54% TW vs 44%CM vs 49%CW) despite being younger, while transgender women receiving gender-affirming hormone therapy demonstrated slightly lower steatosis burden. **Conclusion:** CLD outcomes across the broader SGM spectrum remain critically understudied. The systematic review underscores the unmet need of standardized SOGI data collection and prospective SGM-focused hepatology cohorts to better understand outcomes of CLD in this population.

2143 | HIGH ACCEPTABILITY OF COMMUNITY-BASED LIVER DISEASE SCREENING AMONG PEOPLE EXPERIENCING HOMELESSNESS AND HOUSING INSECURITY

Roshawn Jamasi[1] George Tadros[2] Yeabsera Ephrem[1] Kathan Pathak[1] AJ Tran[1] Henry Huynh Nguyen[2],
[1]Alberta Homeless Foundation, [2]Liver Health Connect

Background: People experiencing homelessness face elevated risks for viral hepatitis, alcohol-associated and metabolic liver disease, cirrhosis, and barriers to preventive and longitudinal care. Low-barrier community screening may improve detection and linkage to care. We aimed to characterize liver disease history, healthcare access, barriers, and acceptability of liver testing among people experiencing homelessness or housing insecurity in Calgary, Alberta to further refine education and outreach efforts. **Methods:** Alberta Homeless Foundation and Liver Health Connect conducted a cross-sectional survey of people experiencing homelessness or housing insecurity in Calgary. Participants were recruited from downtown service-adjacent areas, public spaces, and all public transit stations. Surveys assessed healthcare sources, recent physician/nurse contact, sleeping location, liver disease history, interest in testing, willingness to attend a free liver clinic, and barriers to care. Percentages used non-missing denominators. Totals may exceed 100% because respondents could select multiple options. Associations were assessed using Pearson's chi-square or Fisher's exact tests when expected counts were < 5. AI statement: ChatGPT 5.4 was used to improve grammar and readability. **Results:** Of 112 respondents, 17/109 (15.6%) reported being told they had a liver problem, and 18/107 (16.8%) reported a named liver diagnosis, including hepatitis C (10, 9.3%), cirrhosis (5, 4.7%), hepatitis B (2, 1.9%), and fatty liver (1, 0.9%). 90/110 (81.8%) would want testing if it could prevent serious illness, and 96/109 (88.1%) would attend or try a free liver clinic offering food, hygiene essentials, and snacks. Among those with a named diagnosis, 18/18 (100.0%) were willing to attend a free liver clinic. Testing interest was associated with willingness to attend compared with those not interested or unsure (86/90, 95.6% vs. 10/19, 52.6%; p < 0.001). Healthcare access gaps were common. Of 111 responses, 42 (37.8%) reported regular emergency or urgent care use, while 33 (29.7%) reported no regular care site or not

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

seeking care. Barriers to care were reported by 78 respondents (76.5%), including judgment or disrespect (21, 20.6%), lack of transit fare (19, 18.6%), lack of ID/health card (12, 11.8%), and mental health/substance use concerns (10, 9.8%). Respondents reporting any barrier were more likely to endorse willingness to attend a liver clinic than those reporting none (74/78, 94.9% vs. 19/24, 79.2%; p = 0.031). **Conclusion:** In this community-based survey of people experiencing homelessness or housing insecurity, self-reported liver disease and interest in testing were high. Most respondents were willing to attend a free liver clinic, especially those with barriers. Findings suggest barriers reflect unmet need rather than lack of interest and support low-barrier community liver screening to improve detection and linkage to care.

2144 | DIFFERENCES IN METABOLIC PROFILE AND FIBROSIS SEVERITY AMONG PATIENTS UNDERGOING VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY IN A SAFETY-NET HOSPITAL

Dominique Mosley[1] Kathryn Thompson[2] Lesley Miller[2], [1]Emory University, Internal Medicine Residency Program, [2]Emory University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) disproportionately affects racial and ethnic minority populations in the United States. Hispanic/Latino populations experience the highest prevalence of MASLD and are at increased risk for progression to advanced fibrosis and cirrhosis, while Black patients, despite lower overall prevalence, remain at risk for severe liver-related complications once diagnosed. We aimed to evaluate differences in metabolic characteristics and vibration-controlled transient elastography (VCTE) findings among patients with MASLD in a large urban safety-net health system. **Methods:** We performed a retrospective cohort study of 305 adults with MASLD who underwent VCTE at Grady Memorial Hospital between January 2018 and March 2024. Demographic data, metabolic comorbidities, laboratory data, and VCTE findings were collected. Individual two-sample t-tests were conducted among three different racial/ethnic groups (Hispanic/Latino, Black/African American (AA), White/Caucasian) to identify differences in metabolic risk factors and VCTE findings among groups. **Results:** Of 305 patients with MASLD undergoing VCTE, 46.9% were Hispanic/Latino, 41% were Black/AA, and 8.9% were White/Caucasian. Hispanic patients underwent VCTE at a younger age compared to AA patients (48.2 vs. 55.5 years, p < 0.001). Hispanic patients demonstrated lower mean liver stiffness measurements compared to AA patients (7.1 vs 9.0 kPa, p = 0.009), while controlled attenuation parameter (CAP) scores were similar between groups (305.7 vs 292.0 dB/m, p = 0.051). Hispanic patients had higher ALT (60.5 vs 37.0 U/L, p < 0.001) and triglyceride levels (213.5 vs 128.7 mg/dL, p < 0.001), along with lower HDL levels (46.1 vs 52.4 mg/dL, p = 0.002) compared to AA patients. Rates of diabetes and hyperlipidemia were similar between groups. AA patients had significantly higher rates of hypertension (80.0% vs 42.7%, p < 0.001). **Conclusion:** Significant racial/ethnic differences were observed in screening patterns, metabolic risk factors, and fibrosis severity among patients with MASLD undergoing VCTE in a safety-net health system. Hispanic/Latino patients underwent screening at younger ages and demonstrated greater steatotic and metabolic lab abnormalities, whereas Black patients had higher liver stiffness measurements and greater cardiometabolic comorbidity burden. These findings may help inform targeted screening strategies and risk stratification in underserved populations.

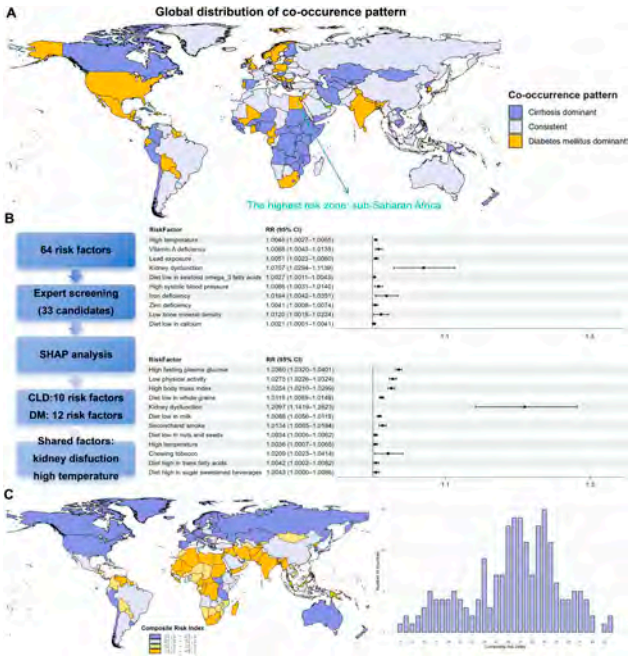
2145 | CO-OCCURRENCE PATTERNS AND SHARED RISK FACTORS OF CHRONIC LIVER DISEASES AND DIABETES: A SYSTEMATIC ANALYSIS BASED ON SPATIAL EPIDEMIOLOGY



Yujiao Deng[1] Xubing Zhou[1] Xiao Yuan[1] Qiaoman Fei[1] Zhanpeng Yang[1] Yixin Guo[1] Jingyue Tan[1] Meijuan Han[1] Haidan Shi[1] Bowen Qin[1] Si Yang[2] Yuan Wang[1] Fanpu Ji[1], [1]The Second Affiliated Hospital of Xi'an Jiaotong University, [2]Air Force Medical University

Background: Chronic liver diseases (CLD) and diabetes mellitus (DM) are major public health concerns. Previous studies have addressed them separately, leaving their co-occurrence underexplored. We aimed to characterize the global co-occurrence pattern of CLD and DM and identify shared risk factors. **Methods:** Using GBD 2023 data, we extracted age-standardized incidence rates (ASIRs, per 100,000 persons) for both diseases and exposure data for 64 risk factors across 204 countries. According to the quartiles of global incidence rates for both diseases, countries were categorized into three co-occurrence regions: consistent, CLD-dominant, and DM-dominant

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

areas. Employing machine learning algorithms alongside negative binomial regression models, we identified and quantified the impact of relevant risk factors. The population-attributable fraction and a composite risk index were subsequently calculated to assess the disease burden associated with CLD and DM. **Results:** Matched concurrence occurred in 67 countries, CLD-predominant in 69, and DM-predominant in 68. Twenty risk factors were classified into common and specific features. Kidney dysfunction and high temperature were identified as the two common risk factors shared by both conditions. Kidney dysfunction exerted the strongest effect on both CLD (RR = 1.07, 95% CI 1.03–1.11) and DM (RR = 1.21, 95% CI 1.14–1.28). The composite risk index exhibited a pronounced right-skewed distribution. Geographically, sub-Saharan Africa emerged as the primary cluster of high-risk zones (35.0–46.0), whereas Europe, North America, and northern Russia were predominantly characterized by low-risk areas (11.0–25.0). This spatial pattern closely mirrors the incidence burden distribution of CLD and DM. Among the eight specific risk factors that affect CLD, iron deficiency has the greatest impact. For diabetes, among the ten specific risk factors, high fasting plasma glucose has the greatest influence. The spatial distribution characteristics of common risk factors reveal significant regional disparities in kidney dysfunction and high temperature exposure (Figure 1). **Conclusion:** The co-occurrence of CLD and DM is a growing global health challenge. Kidney dysfunction and high temperature were identified as the two common risk factors. Targeting these shared determinants through integrated interventions could substantially reduce the global burden of both diseases.

2146 | FEASIBILITY AND ACCEPTABILITY OF A BRIEF INTERVENTION TARGETING SUGAR-SWEETENED BEVERAGE CONSUMPTION IN LATINO PATIENTS WITH CIRRHOSIS

Vanessa Torres[1] Arleth Escoto[1] Jailene Cruz[1] Paulina Monteon-Garcia[1] Liana Gutierrez[1] Edward Mena[2], [1]Cedars-Sinai, [2]California Liver Reasearch Institiute

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality among U.S. patients with cirrhosis, with Latino adults disproportionately affected due to higher rates of chronic liver disease. High sugar-sweetened beverage (SSB) consumption, along with chronic disease and dietary management challenges, contributes to poorer liver cancer outcomes among Latinos. Brief interventions are recognized as effective strategies for targeting modifiable behaviors, yet few have been adapted among this population. In this study, we assessed the feasibility and acceptability of a contextually tailored brief intervention to reduce SSB consumption among Latino patients with cirrhosis. **Methods:** We developed and pilot tested a brief intervention to reduce SSB consumption among Latino patients with cirrhosis. Eligibility criteria included being 18 years or older, fluency in English or Spanish, and diagnosed with cirrhosis (Child Pugh A or B). Participants received a 25-minute intervention delivered by trained bilingual research staff. Participants completed baseline and 4–8-week follow-up semi-structured interviews. Descriptive statistics were used to summarize participant characteristics, SSB intake, and feasibility outcomes (e.g., recruitment and retention). Interviews assessing intervention acceptability were analyzed using direct content analysis guided by the Theoretical Framework of Acceptability. **Results:** Of the 32 eligible patients screened, 20 were enrolled (63% recruitment) and all participants completed follow-up interviews (100% retention). Participants had a mean age of 66 years, and most were women (80%), born in Mexico (60%), Spanish-speaking (60%), and had less than a high school education (55%). SSB intake was low to moderate at baseline. Qualitative findings demonstrated high acceptability of the intervention. Participants described the “Rethink Your Drink” sugar demonstration as the most impactful component, increasing awareness of hidden sugars and motivating healthier beverage choices. The intervention was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

perceived easy to follow and integrate into daily routines, with few reported barriers. Participants reported difficulties identifying hidden sugars in culturally familiar foods and drinks, managing hydration and protein intake, accessing nutrition support, and coping with hepatic encephalopathy, while emphasizing the importance of family support for healthy behavior change. **Conclusion:** A brief intervention targeting SSB consumption among Latino patients with cirrhosis was feasible and acceptable. Future interventions should address nutrition-related challenges, hepatic encephalopathy related to cognitive barriers, and family support to improve behavior change. Future contextually tailored interventions may help address modifiable behavioral risk factors relevant to liver disease progression and HCC risk among Latinos with cirrhosis.

2147 | UNDERSTANDING DISPARITIES: IDENTIFYING REASONS FOR LIVER TRANSPLANTATION DEFERRAL OR DENIAL AMONG AMERICAN INDIAN PATIENTS

Brett Chy[1] Stephen Xie[1] Meghan Fuller[1] Chloe Raygoza[1] Yunzhe Hu[1] Elena Dreisbach[1] Sandra Elmasry[2] David Chascsa[2], [1]Mayo Clinic Alix School of Medicine, [2]Mayo Clinic Arizona

Background: American Indians (AI) experience the highest liver disease mortality in the USA yet remain among the least likely to receive liver transplantation (LT). Prior studies show AI patients face greater psychosocial barriers to LT than non-White Hispanic (NHW) patients, but the barriers remain poorly characterized. A better understanding of reasons for deferral and denial may identify modifiable drivers of disparities in LT access. **Methods:** We performed a retrospective, single-center, matched cohort study including all AI patients who were deferred or denied LT between 2017 and 2022. A NHW cohort was matched by age, sex, and transplant indication. For patients who underwent transplant selection committee review, "explicit" committee-documented reasons for deferral or denial were collected and coded using a hierarchical coding scheme. Additional "implicit" concerns documented by hepatology, psychiatry, or social work throughout evaluation were collected and coded using the same scheme. For patients who did not reach committee review, reasons for attrition were collected as implicit barriers. **Results:** A total of 118 patients were included in the analysis, including 56 AI and 62 NHW patients.Among explicit committee-documented reasons, AI patients were more frequently deferred or denied for inadequate caregiver planning (14.3% vs 4.8%), need for psychiatric clearance (12.5% vs 4.8%), and inability to follow a complex care plan (10.7% vs 3.2%) than NHW.When considering both explicit reasons and implicit concerns, AI patients more frequently had documented substance use within their social environment (10.7% vs 1.6%), inadequate financial planning (16.1% vs 8.1%), and inability to follow a complex care plan (17.9% vs 6.5%) than NHW patients.Among patients who reached selection committee review, AI patients had a higher median number of uniquely coded barriers, both implicit and explicit, than NHW patients (5 vs 3). (Figure 1) **Conclusion:** AI patients deferred or denied LT were more likely to have psychosocial barriers documented throughout the evaluation process than matched NHW patients, reflected in both explicit reasons and implicit concerns. Disparities were particularly evident in caregiver planning, financial planning, psychiatric clearance, substance use related concerns, and inability to follow a complex care plan. A higher overall number of barriers were documented for AI patients during evaluation than for NHW patients, suggesting a more complex pathway to LT candidacy. Overall, these findings highlight the need for earlier, targeted interventions aimed at reducing psychosocial and structural barriers to LT among AI patients. Potential strategies include implementation of culturally appropriate caregiver programs, expanded financial assistance, and improved access to addiction services both for patients and members of their social circles.

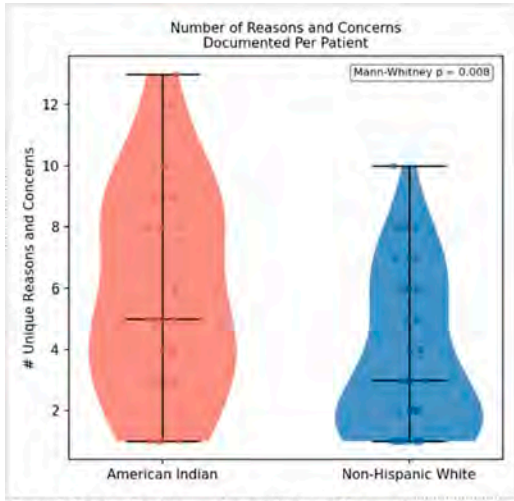

Figure 1. Violin plot showing the distribution of the number of uniquely coded explicit reasons and implicit concerns documented per patient. AI patients demonstrated a higher median number of barriers than NHW patients (5 vs 3, Mann-Whitney p=0.008).

2148 | METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) IN ASIAN AMERICAN CHILDREN

Jaden Ruffy[1] Johanna Ferreira[2] Christine Sethna[1],
[1]Cohen Children's Medical Center, Northwell,
[2]University of Miami Miller School of Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease in children. In the United States, MASLD affects up to 38% of children with obesity. MASLD is a silent disorder that is underdiagnosed, particularly in individuals with a normal body mass index (BMI). Asian adults are known to be at higher metabolic risk at a lower BMI. However, it remains unknown whether Asian American children are similarly at higher risk for MASLD at a lower BMI. Racial and ethnic differences in the prevalence of MASLD among children remain underexplored. The objective of this study was to compare the prevalence of MASLD between Asian American and non-Hispanic White (NHW) children and to determine the association of Asian race with MASLD. **Methods:** This cross-sectional study analyzed nationally representative pooled data from the 2017–2022 National Health and Nutrition Examination Survey (NHANES) on US children aged 12–17 years who underwent liver ultrasound transient elastography (FibroScan) with controlled attenuation parameter (CAP) scoring. Children who self-identified as Asian American or non-Hispanic White were included. MASLD was defined as steatotic liver disease on FibroScan (CAP >237 dB/m) in the absence of other causes, with evidence of at least one cardiometabolic risk factor: BMI z-score ≥1 or WC ≥ over 95%, fasting glucose ≥100 mg/dL or prediabetes/type 2 diabetes mellitus, blood pressure ≥95th percentile or ≥130/80 mmHg for children <13 years and ≥130/85 mmHg or specific antihypertensive drug treatment for ≥ 13 years, triglycerides ≥150 mg/dL, or HDL <40 mg/dL. The prevalence of MASLD was compared between Asian American and NHW children using the chi-square test. Regression models adjusted for age, sex, poverty income ratio (PIR), and BMI z-score examined the association of Asian American race (NHW as reference) with CAP score, liver stiffness, and MASLD. Complex survey design procedures were applied throughout. **Results:** Among 234 Asian American children (mean age 14.45 ± SE 0.12 years) and 2,541 NHW children (mean age 14.41 ± SE 0.14 years), Asian American children had significantly lower BMI z-scores, lower rates of obesity, and higher PIR compared to NHW children (Table 1). The prevalence of MASLD was significantly lower in Asian American children (1.1% ± SE 1.1%) compared to NHW children (8.3% ± 1.1%; p = 0.03). In adjusted regression analysis, Asian American race was independently associated with a greater CAP score (β = 17.67, 95% CI: 2.99–32.35; p = 0.02). Race was not independently associated with liver stiffness (p = 0.1) or MASLD (p = 0.43) in adjusted models (Table 2). **Conclusion:** This study demonstrates a lower prevalence of MASLD in Asian American children compared to NHW children using the current 2023 revised criteria diagnostic criteria. However, in regression analysis which adjusted for BMI, Asian American race was not associated with MASLD. The observed disparity in prevalence may reflect the fact that Asian American children have significantly lower BMI values and therefore may not meet the current BMI-dependent diagnostic thresholds for MASLD, potentially underestimating their true disease burden. Notably, despite significantly lower BMI, Asian American children tended toward higher CAP scores compared to their NHW counterparts, suggesting heightened hepatic fat accumulation at lower body weights: a pattern consistent with "lean" MASLD described in Asian American adults. These findings underscore the potential accuracy of current diagnostic criteria when applied to Asian American pediatric populations and support future investigation into ethnicity-specific BMI thresholds for MASLD diagnosis in children.

Table 1: Demographic and Clinical Characteristics of Study Population

N= 2775 Mean (SE) or %	Asian American n=234	Non-Hispanic White n=2541	P-Value
Age (years)	14.45(0.12)	14.41(0.14)	0.83
Male	43.2% (5.2%)	52.5% (3.2%)	0.12
Poverty Income Ratio	3.69 (0.30)	3.10 (0.14)	0.07
BMI Z-score	-0.01 (0.25)	0.61 (0.10)	0.04
Obesity	5% (2.8%)	13.8% (2%)	0.08
Systolic Blood Pressure Index	0.78 (0.03)	0.81 (0.01)	0.37
Diastolic Blood Pressure Index	0.75(0.03)	0.76(0.01)	0.59
Hypertensive Blood Pressure	2.2% (1.3%)	2.6% (0.7%)	0.812
Triglycerides (mg/dl)	66.2 (4.4)	70.3 (1.96)	0.14
HDL (mg/dl)	54.4 (1.1)	51.8 (0.47)	0.05
Fasting Glucose (mg/d)	93.37 (1.03)	94.86 (0.52)	0.3
Diabetes	0% (0)	0.2% (0.1)	0.06
CAP Score	212.64(6.77)	208.81(3.11)	0.57
Liver Stiffness E	5.30 (0.41)	4.92 (0.10)	0.40

Table 2: Regression analysis of Asian American race (reference non-Hispanic White) predicting liver tests

OR or ß (95% confidence interval)	Crude	Adjusted
CAP	3.82(-10.21-17.85) P=0.57	ß 17.67(2.99-32.35) P=0.02
Liver Stiffness E	0.38(-0.56-1.31) P=0.40	ß 0.85(-0.22-1.9) P=0.1
MASLD	OR 0.24 (0.07, 0.8) P=0.02	OR 0.613(0.17, 2.22) P=0.43

TOOL: ANALYZING THE IMPACT OF LOW VERSUS ELEVATED FIB-4 SCORES

David Weinstein[1] Mitchelle Zolotarevsky[1] Keon Karimabady[1] Raza Muhammad[1] Athanasios Kondilis[1] Madhav Patel[1] Ruxandra Dane[1] Elizabeth Ward[1], [1]Endeavor Health

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is widely prevalent yet underdiagnosed, with low screening rates in primary care contributing to poor patient awareness. Patient education remains a critical and underutilized tool in bridging this gap. Educational videos have improved patient comprehension in various clinical settings. Our goal was to determine whether patients with low or elevated FIB-4 scores accurately perceived their MASLD risk and whether an AI-driven, multilingual educational video improved patient understanding and self-identification of risk status. **Methods:** We conducted a single-blind prospective study of 200 underserved adult patients in a resident clinic at risk for, or diagnosed with, MASLD based on 2022 AASLD–AACE criteria and the Fibrosis-4 (FIB-4) index. At a routine visit, participants completed the validated Public Awareness of Non-Alcoholic Fatty Liver Disease (PANAFLD) survey assessing baseline MASLD knowledge, perceived risk, alcohol use (AUDIT-C), dietary habits (MINI-EAT), and physical activity using the International Physical Activity Questionnaire (IPAQ). FIB-4 scores were calculated retrospectively using age-adjusted cutoffs to classify patients as low or elevated risk. Participants then viewed an original AI-generated video, in English and validated in Spanish, using Synthesia software discussing MASLD pathophysiology, complications, and lifestyle strategies, followed by a post-intervention PANAFLD survey. **Results:** Of the 200 patients, 5 were excluded due to incomplete questionnaires. Among these, 75.9% (n = 148) had a low FIB-4 score, while 24.1% (n = 47) had an elevated FIB-4 score. Overall, perceived MASLD risk increased from 52.3% (n = 102) to 76.4% (n = 149) following the video. In the low FIB-4 group, perceived risk increased from 47.3% (n = 70) to 78.4% (n = 116). In the elevated FIB-4 group, perceived risk increased from 68.1% (n = 32) to 70.2% (n = 33). Notably, among the 36.9% (n = 72) of patients whose doctor had previously mentioned fatty liver, perceived risk increased from 38.9% (n = 28) to 80.6% (n = 58). **Conclusion:** Our preliminary data show that patient perception of risk for MASLD in the low FIB-4 group increased by 66% after the video. Most patients with elevated FIB-4 scores already understood their risk for MASLD, which modestly improved post-video. Interestingly, among patients whose doctor had previously mentioned fatty liver, risk perception increased by 107%, suggesting that prior clinical priming enhances receptiveness to targeted education. These findings indicate that AI-driven patient education can meaningfully improve patients' awareness of MASLD in an underserved primary-care resident clinic setting. Correct risk perception is a critical first step toward lifestyle modification and, hopefully, decreased MASLD risk and progression.

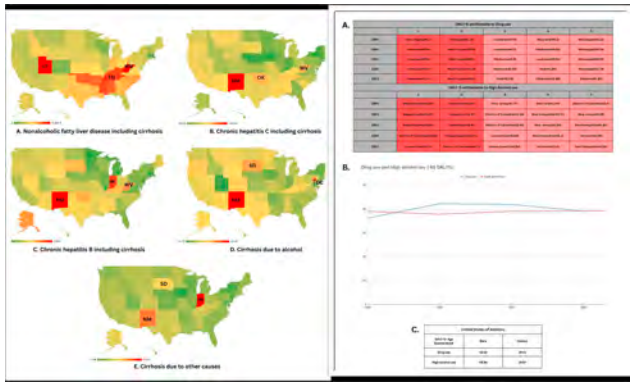
2150 | LIVER HEALTH CONNECT: A COMMUNITY-FIRST APPROACH TO ADVANCING LIVER HEALTH AWARENESS AND ENGAGEMENT

George Tadros[1] Henry Nguyen[2], [1]University of Calgary, [2]University of Calgary Cumming School of Medicine

Background: Liver Health Connect (LHC) is a newly established, community-first non-profit organization in Calgary, Alberta, dedicated to promoting liver health, reducing stigma surrounding chronic liver disease, and improving public awareness through education. LHC engages directly with diverse populations by participating in cultural festivals, community outreach events, and health fairs, and by providing accessible liver health resources via its website and social media. The purpose of this organization is to identify existing gaps in public knowledge and perceptions of liver health, and to assess community interest and willingness to participate in liver health education and outreach activities. **Methods:** All members of the public who directly interacted with LHC volunteers at festivals and community seminars (July-December 2025) were given the option to fill out an anonymous survey via an online secure platform. LHC utilizes these surveys to tailor its content and better serve its community partners based on identified needs. Surveys collected participant demographics, liver health knowledge, current engagement with liver testing, as well as their perception of the importance of liver health and need for further information and education in the community. **Results:** 459 participants were surveyed across the events, with 306 being female (66.7%), with a mean age of 38 years (SD = 16). Participants came from a variety of ethnicities with East Asian (135, 29.4%) and Caucasian (129, 28.1%) being most represented and Indigenous (3, 0.7%) and Southeast Asian (8, 1.7%) being least represented. Participants came from all 4 quadrants of the city (NW: 27%, NE: 19.8%, SW:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



30.5%, SE: 14.2%). Importantly, only 280 (61%) of participants reported having a regular healthcare provider that they can talk to about liver health, and only 123 (26.8%) reported ever having their liver health tested. A total of 294 participants (64.1%) reported having little to no familiarity with liver health topics. However, 301 (65.6%) participants reported that liver health was extremely or very important to them and their family, and 290 (63.2%) expressed a need for more information about liver testing and education in the community, with a further 107 (23.3%) expressing interest in receiving such information **Conclusion:** Preliminary findings indicate a significant gap in both liver health awareness and access to liver testing in the community, despite widespread acknowledgment of the liver's importance to overall health. Survey responses show strong public interest in accessible, free educational opportunities, highlighting an appetite for community-based learning and engagement. These findings demonstrate a clear need for inclusive, culturally responsive liver health education, which remains the core mission of Liver Health Connect (LHC)

2151 | GEOGRAPHIC, SEX AND AGE DISPARITIES IN CIRRHOSIS AND OTHER CHRONIC LIVER DISEASES: INSIGHTS FROM GBD 2023

Sri Ram Charan Gundapaneni[1] Sameer Kumar Majety[2] Praneeth Koushik Sriramaneni[3] Madhu Babu Adusumilli[1] Moksha Prasoona Avvaru[4] Ashwin Rumalla[1], [1]UCF/HCA Florida Ocala, [2]Xiamen University School of Medicine, [3]Kamineni Academy of Medical Sciences and Research Center, [4]Harnett Health

Background: Cirrhosis and chronic liver disease (CLD) remain major causes of morbidity in the United States. Using Global Burden of Disease (GBD) 2023 estimates, we described national and state level patterns, age and gender differences, and temporal trends. **Methods:** Age standardized incidence, prevalence, mortality, and DALY rates were obtained from the Institute for Health Metrics and Evaluation Global Burden of Disease 2023 study using the IHME GBD Results Tool. Burden was assessed for NAFLD including cirrhosis, chronic hepatitis C, chronic hepatitis B, alcohol related cirrhosis, and other causes. Age specific, gender specific, and state patterns were evaluated. Estimated annual percent change (EAPC) with 95 percent confidence intervals was calculated. **Results:** NAFLD had the highest national burden (9543.63 per 100000), followed by chronic hepatitis C (1035.29), chronic hepatitis B (259.25), alcohol related cirrhosis (67.23), and other causes (41.86). NAFLD burden was highest in West Virginia (11527.80), Utah (11514.18), and Tennessee (11041.05) and lowest in Massachusetts (8064.12), the District of Columbia (8419.89), and Colorado (8554.98). Hepatitis C burden peaked in New Mexico (1426.52) and West Virginia (1201.30). Alcohol related cirrhosis was highest in New Mexico (101.51). Other cause cirrhosis peaked in Indiana (77.45).Age patterns showed very low burden in children with sharp increases through adulthood. Prevalence peaked at 36367.89 in males aged 80 to 84 years and 32658.30 in females aged 85 years and older. Mortality was highest at 76.20 in males aged 65 to 69 years and 53.74 in females aged 85 years and older. DALY rates peaked at 2107.60 in males and 1153.48 in females aged 60 to 64 years. Case counts were highest in adults aged 15 to 49 years, with 10551156.24 cases in males and 7041155.24 in females.Gender differences were largest in New Hampshire and Oregon and smallest in Hawaii and West Virginia, with no reversed patterns.Temporal trends showed rising burden. Incidence increased with an ASIR EAPC of 0.58 (95 percent CI 0.54 to 0.62). Prevalence rose with an ASPR EAPC of 0.60 (95 percent CI 0.56 to 0.64). DALYs increased with an ASDALYR EAPC of 0.55 (95 percent CI 0.46 to 0.63). Mortality increased with an ASDR EAPC of 0.69 (95 percent CI 0.61 to 0.78). **Conclusion:** Cirrhosis and CLD show wide geographic variation, with the highest burden in West Virginia, New Mexico, and surrounding regions. NAFLD accounts for most disease. Rising EAPC values across all indicators highlight growing national impact and the need for state targeted strategies focusing on metabolic risk, alcohol use, and timely CLD management.

2152 | ACCULTURATION AND LIVER HEALTH INEQUITIES: NATIONAL PATTERNS IN STEATOSIS AND FIBROSIS SEVERITY AMONG U.S. IMMIGRANTS

Michelle Zhao[1] Yunxi Pu[2] Xiaotao Zhang[3] Frances Lee[4], [1]Department of Medicine, Icahn School of Medicine at Mount Sinai, [2]New York University School of Global Public Health, [3]Institute for Translational Epidemiology, Icahn School of Medicine at Mount Sinai, [4]Division of Liver Diseases, Icahn School of Medicine at Mount Sinai

Background: Steatotic liver disease (SLD) disproportionally affects minority and immigrant populations, a disparity largely driven by inequities in social determinants of health and higher metabolic risk factors. Acculturation—the process by which immigrants adapt to the cultural, social, behavioral, and linguistic norms of a new country—may be an important mediator of social determinants of health by impacting health behaviors, healthcare access, and health outcomes. This study aims to address this gap by investigating the association between acculturation and SLD severity among U.S. immigrants using nationally representative data. **Methods:** Patients (n = 676) with MASLD, metALD, ALD, hepatitis B, and hepatitis C were identified from the NHANES 2017-2020 dataset with acculturation data. Acculturation scores were generated based on interview language, language spoken at home, and length of residence in the U.S. We utilized Fibrosis-4 (FIB-4) Index as well as Controlled Attenuation Parameter (CAP) and Liver Stiffness Measurement (LSM) from vibration controlled transient elastography. Weighted analyses, multivariate analysis, and linear regression explored relationships between acculturation scores and measures of liver severity by SLD type. **Results:** Of the 676 patients, there were 624 MASLD patients, 23 metALD patients, 15 ALD patients, and 14 hepatitis B or C patients. Participants were predominantly Hispanic White (36.6%) and non-White Hispanic (26.0%). Acculturation scores were similar across different SLD types. More acculturated individuals had a higher cardiometabolic burden ($p = 0.009$), higher prevalence of diabetes ($p = 0.005$), and higher FIB-4 score ($p < 0.001$). In adjusted linear models, composite acculturation independently predicted higher FIB-4 ($p < 0.001$) and CAP scores ($p = 0.023$) but not LSM. Single proxy variables of acculturation like interview language and length of residence in the United States were also associated with higher FIB-4 and CAP scores. Higher acculturation is associated with three times greater odds of high-risk fibrosis based on FIB-4 independent of metabolic risk factors or etiology of liver disease (adjusted OR = 3.00; 95% CI 1.01-8.96). The single hepatitis patient with high acculturation also had high FIB-4 and LSM, but we were unable to do a full regression analysis due to low sample size. **Conclusion:** This study demonstrates that acculturation may contribute a meaningful role in markers of liver fibrosis and steatosis. Continued investigation is needed to clarify how acculturation shapes SLD severity. Expanding sample size through further iterations of NHANES and exploring how acculturation mediates lifestyle and diet will be critical to fully define this relationship and strengthen its implications for liver disease risk stratification.

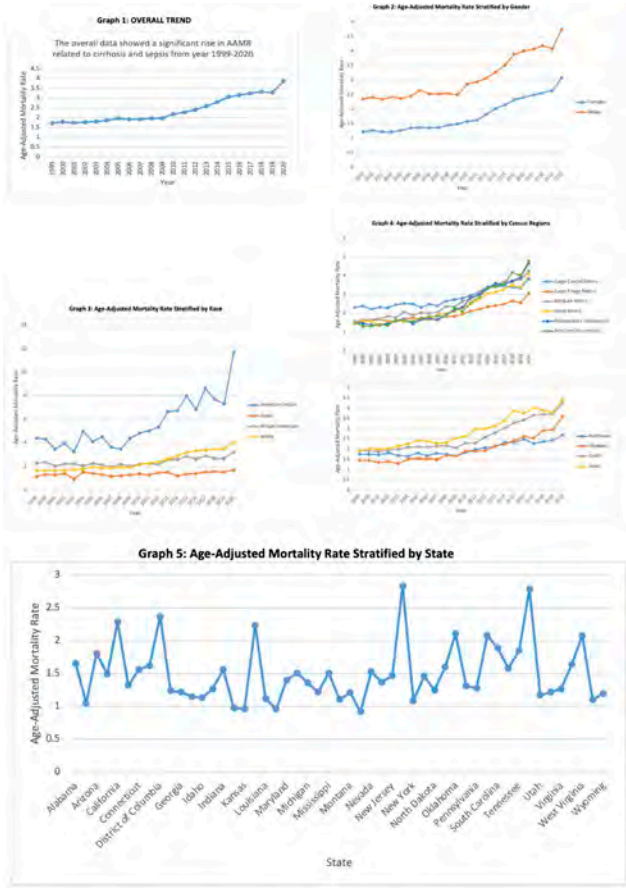
2153 | TRENDS AND DISPARITIES IN SEPSIS AND LIVER CIRRHOSIS IN UNITED STATES FROM 1999-2020: A CDC-WONDER DATABASE STUDY



Simran Joshi[1] Syed Irtiza Imam[2] Hania Haque[2] Laiba Tanveer[2] Sufyan Raza Khan[2] Preeti Advani[2] Marium Jawaid[2] Marium Jawaid[2] Muhammad Owais[3] Jeevin Singh Sandhu[4] Corrine Caissie[1] Mohammed Aatiqul Islam[1], [1]Yale New Haven Health, [2]Jinnah Sindh Medical University, Karachi, Pakistan, [3]Liaqut University of Medical and Health Sciences, Jamshoro, [4]Methodist Dallas Medical Center

Background: Sepsis and liver cirrhosis are major causes of morbidity & mortality worldwide. Patients with cirrhosis are vulnerable to infections and sepsis due to cirrhosis-associated immune dysfunction,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

leading to worse clinical outcomes. However, limited data exist on mortality trends among patients with both sepsis and cirrhosis.Therefore, this study aimed to evaluate temporal trends and demographic disparities in mortality among adults with sepsis and cirrhosis in the United States from 1999 to 2020. **Methods:** Individuals aged 25 and older who died from sepsis and cirrhosis were identified in the CDC WONDER database using ICD codes A40.0-A40.3, A40.8-A40.9, A41.0-A41.9 (sepsis) and K70.3, K74.0-K74.6 (cirrhosis) for the years 1999–2020. Mortality patterns were analyzed using the Age-Adjusted Mortality Rate (AAMR) per 100,000 population. Join point Regression 5.0 was applied to calculate the Average Annual Percent Change (AAPC), with p-values assessing statistical significance. Age-adjusted mortality rates were standardized to the 2000 U.S. Standard Population. The urban-rural stratification was based on the 2013 NCHS Urban–Rural Classification Scheme. Trends were examined by stratifying data by gender, race, urbanization, census region and state. **Results:** From 1999 to 2020, a total of 120,124 sepsis and cirrhosis related deaths were reported in the United States, with age-adjusted mortality rates (AAMR) increasing from 1.73 to 3.87 per 100,000. Mortality rose modestly from 1999–2008 (APC 1.45) followed by a significant increase from 2008–2020 (APC 5.61, $p < 0.05$). Males consistently exhibited higher mortality than females, with AAMR reaching 4.75 (4.88-4.63) vs 3.09 (3.19-2.99) in 2020. American Indian/Alaska Native populations had the highest mortality with AAMR 11.69 (12.96-10.42) in 2020, followed by Whites AAMR: 4.03 (4.12-3.95) and Blacks 3.19 (3.39-2.99), while Asians had the lowest rates 1.74 (1.96-1.53). Mortality increased across all racial groups, with the highest rise among American Indian/Alaska Native populations. Non-metropolitan areas demonstrated higher mortality than metropolitan regions, particularly in non-core areas AAMR 4.79 (5.15-4.43). Regionally, the West AAMR 4.42 (4.6-4.25) and South 4.23 (4.36-4.1) exhibited higher mortality compared to the Midwest 3.60 (3.76-3.43) and Northeast 2.68 (2.83-2.53). At the state level, New Mexico (2.84) and Texas (2.79) had the highest AAMRs, while Nebraska (0.92) and Kansas (0.96) had the lowest. **Conclusion:** Mortality related to sepsis and cirrhosis has steadily increased in the United States. Notable differences across sex, race, region, and rural versus urban areas highlight important gaps that warrant focused attention. These findings emphasize the need for targeted prevention strategies, improved resource allocation and further research to understand the causes and risk factors of rising trends in sepsis and cirrhosis related deaths.

2154 | REDUCING HEALTH DISPARITIES IN CROATIAN WAR VETERANS: MOBILE LIVER SCREENING, TRUST-BASED OUTREACH, AND LINKAGE-TO-CARE OUTCOMES (2024–2025)

Tatjana Reic[1] Anna Mrzljak[2] Magda Pletikosa Pavic[3] Diana Nonkovic[3] Ivona Reic[4] Ana Visic[1] Viktor Domislovic[2], [1]Croatian Society for the Liver Diseases "Hepatos", [2]University Hospital Center Zagreb, [3]Teaching Institute for Public Health Split -Dalmatia County, [4]Croatian society for Liver Diseases Hepatos

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: War veterans represent a vulnerable population with increased cardiometabolic burden and lifestyle-related risk factors contributing to metabolic-associated steatotic liver disease (MASLD) and progressive liver fibrosis. Croatia, with one of the largest veteran populations in the European Union (≍11%), provides an important setting for evaluating long-term health disparities. We aimed to assess the prevalence and severity of hepatic steatosis and fibrosis in Croatian war veterans using transient elastography and to promote a mobile, community-based liver screening model. **Methods:** During 2024–2025, the Society Hepatos implemented a nationwide outreach program using a mobile clinic in collaboration with the Ministry of Veterans' Affairs, public health institutions, hospitals/hepatologists, and veterans' organizations. Participants underwent non-invasive liver assessment using FibroScan® with liver stiffness measurement (LSM) and controlled attenuation parameter (CAP). Clinically significant fibrosis was defined as ≥F2 and advanced fibrosis as F3–F4. Significant steatosis was defined as CAP ≥238 dB/m. Demographic, anthropometric, and clinical variables were collected, and multivariable logistic regression analyses identified factors associated with liver disease severity. **Results:** Among 448 participants, 72.0% were male, with a mean age of 51.3 ± 23.4 years. Mean BMI was 29.7 ± 10.1 kg/m² and waist circumference 100.9 ± 16.0 cm. Clinically significant fibrosis (≥F2) was identified in 18.1% and advanced fibrosis (F3–F4) in 6.5% of participants. Significant steatosis (≥S2) was detected in 63.8%, while severe steatosis (S3) was present in 44.5%. Arterial hypertension was present in 52.2%, dyslipidemia in 42.2%, active smoking in 23.9%, and ongoing alcohol consumption in 2.9%. Significant fibrosis was independently associated with alcohol consumption (OR 5.73, p = 0.006), arterial hypertension (OR 2.40, p = 0.008), and higher CAP values (OR 1.016, p < 0.001). Advanced fibrosis was associated with alcohol consumption (OR 11.29, p = 0.001) and higher CAP values (OR 1.021, p < 0.001). Significant steatosis was independently associated with higher BMI (OR 1.12, p = 0.008). **Conclusion:** Croatian war veterans carry a substantial burden of steatosis and liver fibrosis accompanied by high rates of metabolic comorbidities, highlighting important health disparities. Mobile, community-based liver screening provided linkage-to-care, increased participation, and facilitated earlier identification of individuals at risk for progressive liver disease. This scalable model may help reduce healthcare inequities and improve liver-related outcomes in growing veteran populations across Europe.

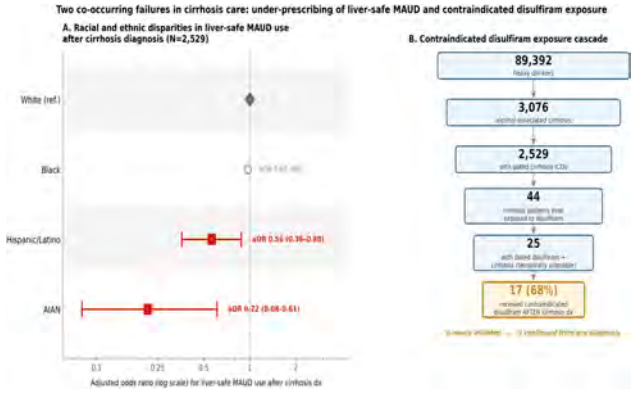
2155 | PERSISTENT RACIAL AND ETHNIC DISPARITIES AND CONTRAINDICATED DISULFIRAM EXPOSURE IN 3,076 PATIENTS WITH ALCOHOL-ASSOCIATED CIRRHOSIS: A TEMPORALLY-ANCHORED ANALYSIS IN THE ALL OF US RESEARCH PROGRAM



Sophia Yang[1] Walid Ayoub[2] Alexander Kuo[1] Paul Martin[1] Aarshi Vipani[1] Yun Wang[1] Yee Hui Yeo[1] JuDong Yang[1] Hyunseok Kim[2], [1]Cedars Sinai Medical Center, [2]Cedars-Sinai Medical Center

Background: Medications for alcohol use disorder (MAUD) reduce mortality and hepatic complications in alcohol-associated cirrhosis but are persistently underprescribed. Whether population-level prescribing disparities persist in cirrhotic patients, and whether contraindicated disulfiram exposure continues or initiates after cirrhosis is documented, has not been characterized in a diverse, temporally-anchored cohort. **Methods:** From 89,392 heavy drinkers in the All of Us Research Program, we identified 3,076 with alcohol-associated cirrhosis (2,529 with dated cirrhosis ICD codes enabling temporal alignment). Post-cirrhosis prescribing rates were calculated requiring ≥3 prescriptions per ingredient initiated or continued after the documented cirrhosis diagnosis. Multivariable logistic regression adjusted for demographic and metabolic risk factors. Disulfiram, hepatotoxic and contraindicated in cirrhosis, was temporally aligned with cirrhosis diagnosis dates to distinguish historical pre-diagnosis exposure from continued or de novo prescribing afterward. **Results:** Among 2,529 cirrhotic patients with dated cirrhosis, only 11.3% received any AUD-specific MAUD after diagnosis; 8.1% received liver-safe MAUD (baclofen or acamprosate); 4.8% received naltrexone. Racial and ethnic disparities observed at the population level among heavy drinkers persisted in this cirrhotic cohort with similar magnitude, even when treatment indication was strongest. For liver-safe MAUD after cirrhosis diagnosis (vs White non-Hispanic): Hispanic/Latino aOR 0.564 (95% CI 0.36-0.88, p = 0.011); American Indian and Alaska Native (AIAN) aOR 0.216 (0.08-0.61, p = 0.004), a 78% relative reduction; Black-White equivalence (aOR 0.974, p = 0.89). Among 44 cirrhotic patients exposed to disulfiram, 25 had dated diagnoses enabling temporal alignment. 17 (68%) received contraindicated disulfiram after cirrhosis was documented: 8 newly initiated and 9 continuing from pre-diagnosis

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

prescriptions. Median continued post-diagnosis exposure was 1,110 days (~3 years). **Conclusion:** Among patients with established alcohol-associated cirrhosis, evidence-based MAUD prescribing remains low overall (8.1% liver-safe), with substantial Hispanic and AIAN disparities that persist even at the highest level of clinical need. Concurrently, contraindicated disulfiram exposure occurred in 68% of disulfiram-exposed cirrhotic patients with multi-year continued prescribing after diagnosis. These two co-occurring failures, under-prescribing of safe MAUD and persistent disulfiram exposure despite documented cirrhosis, are potential targets for hepatology-led quality improvement.

2156 | SOCIAL RISK AND RACIAL DISPARITIES IN EHR-DOCUMENTED MASLD AMONG ADULTS WITH METABOLIC SYNDROME

Ihunanya Kanu[1] Bolaji Ayinde[2] Ankita Verma[3] Yetunde Akande[4] Yousef Ebrahim[3] Richard Heard[3], [1]Baptist Memorial Hospital- Golden Triangle, [2]Northeast Georgia Medical Center, [3]Baptist Memorial Hospital - Golden Triangle, [4]John H Stroger Jr. hospital of cook county

Background: MASLD is the hepatic manifestation of metabolic dysfunction and is strongly associated with obesity, type 2 diabetes, hypertension, and dyslipidemia. Population-based studies show racial/ethnic differences in MASLD burden, with higher prevalence among Hispanic adults and lower documented prevalence among non-Hispanic Black adults. Social risks, including food insecurity and difficulty affording healthcare, may influence MASLD screening and EHR documentation. We examined whether these factors were associated with EHR-documented MASLD/MASH among adults with metabolic syndrome and whether associations differed by race/ethnicity. **Methods:** We conducted a cross-sectional analysis of adults $\geq$18 years with EHR data in the All of Us Controlled Tier Dataset v8. Metabolic syndrome was defined as $\geq$3 of 5 components: BMI $\geq$30 kg/m², type 2 diabetes, hypertension, triglycerides $\geq$150 mg/dL, and low HDL cholesterol using sex-specific cutoffs. EHR-documented MASLD/MASH was identified using diagnosis concepts for nonalcoholic fatty liver disease, nonalcoholic steatohepatitis, and NASH-related cirrhosis, excluding alcoholic fatty liver and acute fatty liver of pregnancy. Food insecurity was defined as worrying that food would run out before money was available to buy more. Healthcare access barrier was defined as inability to afford a healthcare provider. Multivariable logistic regression assessed associations with MASLD/MASH, adjusting for age, BMI, sex at birth, race/ethnicity, diabetes, and SDOH variables. Interaction terms tested effect modification by race/ethnicity. Analyses used Python in Jupyter Notebook. **Results:** Among 388,424 adults with EHR data, 63,659 met criteria for metabolic syndrome. EHR-documented MASLD/MASH was identified in 2,114 participants (3.32%) and increased with metabolic syndrome burden: 2.89% with 3 components, 3.93% with 4, and 5.13% with 5. Among 18,966 participants with complete SDOH data, 4,111 (21.7%) reported food insecurity and 1,316 (6.9%) reported a healthcare access barrier. MASLD/MASH prevalence was 3.38% in food-secure versus 3.92% in food-insecure participants and varied by race/ethnicity: Hispanic 4.94%, non-Hispanic White 3.82%, Unknown 3.14%, and non-Hispanic Black 1.75%. After adjustment, food insecurity (aOR 1.06, 95% CI 0.87–1.28) and healthcare access barriers (aOR 1.03, 95% CI 0.77–1.40) were not independently associated with MASLD/MASH. Non-Hispanic Black participants had lower adjusted odds of MASLD/MASH than Hispanic participants (aOR 0.31, 95% CI 0.22–0.46) **Conclusion:** Food insecurity and healthcare affordability barriers were common but not independently associated with EHR-documented MASLD/MASH after adjustment. Persistent racial/ethnic differences, including lower documentation among non-Hispanic Black participants, suggest possible gaps in recognition and support equitable MASLD screening in high-risk populations.

2157 | EXCESS ECONOMIC AND HEALTHCARE UTILIZATION BURDEN OF MASLD VERSUS NON-MASLD CONTROLS: A NATIONWIDE LONGITUDINAL STUDY

Xiaonan Su[1] Xianhua Mao[2] Hong Fan[2] Rui Huang[3] Bowu Chen[4] Danfeng Ren[5] Ramsey Cheung[2] Mindie Nguyen[2], [1]The First Affiliated Hospital, Zhejiang University School of Medicine, [2]Stanford University Medical Center, [3]Nanjing Drum Tower Hospital, [4]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [5]The First Affiliated Hospital of Xi'an Jiaotong University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of chronic liver disease globally, incurring substantial economic and healthcare utilization burden. We aimed to quantify the excess burden attributable to MASLD. **Methods:** Using data from the Merative™ MarketScan® databases (2007–2023), patients with MASLD and non-MASLD controls with at least a 2-year look-back period prior to baseline were matched 1: 1 to non-MASLD controls via a sequential matching strategy of exact matching on index year and sociodemographic characteristics followed by stratified propensity score matching on smoking, obesity, T2D, hyperlipidemia, hypertension, CVD, CKD, non-liver cancer, co-hepatic diseases, cirrhosis, HCC, CCI score and historical health care costs and resource utilization (HCRU). To estimate the excess 10-year cumulative health care costs and HCRU attributable to MASLD, we calculated the difference between these cohorts using a Horvitz–Thompson estimator with monthly updated inverse probability of censoring weighting (IPCW). **Results:** From the initial populations of 272,087 patients with MASLD and 62,444,397 patients without MASLD, 71,018 pairs of MASLD and non-MASLD patients were identified following the two-staged matching strategy. The 10-year cumulative all-cause excess cost in MASLD (vs non-MASLD controls) was $52,886 (95% CI, $46,054-$59,173) per patient with an associated cost ratio (CR) of 1.41 (95% CI, 1.35-1.46) (Figure 1). Outpatient services constituted the largest component of the excess cost ($24,340; CR, 1.37), followed by pharmacy ($15,822; CR, 1.47), inpatient ($10,767; CR, 1.40), and emergency department care cost ($2,035; CR, 1.47), and with excess cost by facility fees ($23,163; CR, 1.39) more than double those of physician fees ($10,065; CR, 1.35). In subgroup analyses, CRs remained consistently and significantly higher than those of controls across all strata defined by sex, age, insurance type, and specific metabolic comorbidities. In the secondary exact-matched cohort without adjustment for differences in patient background comorbidities, excess costs were substantially larger ($162,883; CR, 2.34). **Conclusion:** Newly diagnosed MASLD incurs substantial long-term excess healthcare cost across care settings and domains, especially without statistical adjustment for comorbidities, many of which are associated with MASLD.

2158 | CIRRHOSIS HEALTHCARE COSTS TRIPLED IN MANITOBA FROM 2010–2022: VOLUME, NOT INTENSITY, DRIVES THE BURDEN

Nabiha Faisal[1] Harminder Singh[1] Randy Walld[1], [1]University of Manitoba

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Cirrhosis is a major contributor to healthcare spending, U.S. direct costs reached $32.5 billion in 2016, with over 65% from inpatient and emergency department (ED) care yet longitudinal Canadian data across cirrhosis etiologies are limited. We evaluated temporal trends in etiology-specific healthcare utilization and direct medical costs among adults with cirrhosis in Manitoba, 2010–2022. **Methods:** We conducted a population-based cohort study using Manitoba Centre for Health Policy (MCHP) linked administrative databases (hospital discharges, physician claims, outpatient prescription dispensings, and ED visits), 2010–2022. Adults (≥18 years) with cirrhosis were identified using a validated case-finding algorithm and classified hierarchically into mutually exclusive etiologies: alcohol-associated liver disease (ALD); metabolic dysfunction-associated steatotic liver disease (MASLD); autoimmune liver disease (AIH, PBC, PSC); and viral hepatitis (HBV/HCV). Direct costs were estimated using standardized MCHP methodologies; hospitalization from resource intensity weights and provincial cost estimates, physician services from claims, prescriptions from dispensing records, and ED from Canadian Institute of Health Information (CIHI) Manitoba average cost per visit × visit frequency. Total, annual aggregate, and per-person annual costs were calculated using a one-year active denominator in Canadian dollars and compared across etiologies and over time. **Results:** The prevalent cirrhosis population in Manitoba nearly tripled between 2010 and 2022 (4,625 to 13,839), and total annual healthcare expenditures rose 2.6-fold ($56.7M to $147.3M). Per-person annual cost declined modestly ($12,270 to $10,645), indicating that rising aggregate cost reflected case-volume growth rather than per-patient cost intensity. Hospitalizations dominated spending across all etiologies ($95.7M, 65% of 2022 expenditures). By 2022, autoimmune liver disease was the most expensive etiology per patient ($16,486), overtaking ALD ($13,444), a reversal from 2010 when ALD was highest ($15,076). This shift was driven by autoimmune inpatient cost, which reached $11,332/person in 2022, the highest of any etiology. Viral hepatitis prescription costs peaked at $11,421 per person in 2015 with HCV direct-acting antiviral rollout before declining to $2,892 by 2022. MASLD had the lowest per-person cost ($7,755) but, with 8,006 patients (58% of cohort), contributed $62.1M (42%) of total spending, the largest population-level burden. **Conclusion:** Rising cirrhosis costs in Manitoba reflect case-volume growth rather than per-patient cost intensity, with hospitalizations dominant across all etiologies. Etiology-specific prevention, particularly for MASLD and ALD and strategies to reduce avoidable hospitalizations are the key policy levers to decrease direct healthcare costs associated with cirrhosis.

2159 | COST-EFFECTIVENESS OF SEQUENTIAL NON-INVASIVE TESTING (NIT) FOR DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) RISK STRATIFICATION IN US PRIMARY CARE: A LIFETIME MARKOV ANALYSIS

Zobair Younossi[1] Khalid AlNaamani[1] Cristiane Villela-Nogueira[2] Fatema Nader[1] Saleh Alqahtani[3] Laurent Castera[4] James Paik[5], [1]The Global NASH/MASH Council, [2]Universidade Federal do Rio de Janeiro, [3]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [4]Hopital Beaujon, [5]Global NASH/MASH Council

Background: To identify at risk MASLD patients, current guidelines recommend sequential NIT algorithms using FIB-4 followed by vibration-controlled transient elastography (VCTE) or FIB-4 followed by enhanced liver fibrosis (ELF) score in patients with type 2 diabetes (T2D) or medically complicated obesity (MCO). We evaluated the cost-effectiveness of this sequential testing strategy in the US primary care setting. **Methods:** We developed a 14-state lifetime Markov model (US healthcare payer perspective; 3% discount rate; 2025 US dollars). Populations comprised 36.4 million adults with T2D and 56.8 million with MCO derived from NHANES 2017-2020. Prevalence of advanced fibrosis among patients with T2D (9.7%) and MCO (6.0%), fibrosis stage distribution, and the diagnostic performance of NITs were further characterized using Global MASLD Project (≥21,000 biopsy-confirmed cases) and adjusted for referral and spectrum bias. Four strategies were compared: 1) current standard of care (comparator), 2) FIB-4 followed by VCTE, 3) FIB-4 followed by ELF and 4) FIB-4 followed by either VCTE (70%) or ELF (30%) based on available modality. Patients were stratified into 3 risk groups: (1) Low risk [1st NIT: FIB-4 (<1.3) or 2nd NIT: VCTE/ELF (<8 kPa/<9.2)], (2) Treatment-eligible (F2-F3),

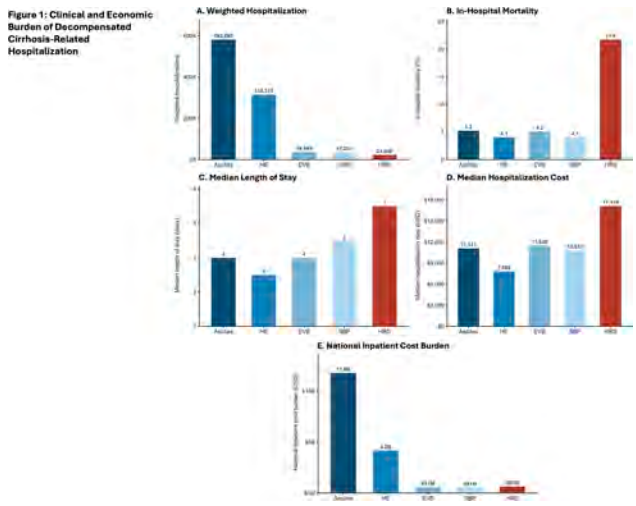
(3) Cirrhosis. Fibrosis stage distributions were estimated using Bayesian analysis combining NIT test performance (Global MASLD Project) with NHANES population prevalence priors, yielding posterior probabilities reflecting primary care populations. These distributions served as Markov model starting states for each group. Treatments included resmetirom, semaglutide, and lifestyle intervention with real-world adherence, persistence, and price erosion. **Results:** Across the combined target population of 93.2 million US adults, the base case yielded a combined incremental cost-effectiveness ratio (ICER) of $27,523 per quality-adjusted life-year (QALY) gained versus standard of care. Individual cohort ICERs were $49,852/QALY (T2D) and $16,870/QALY (MCO). Results were consistent across NIT strategies (combined: $27,497 to $27,583/QALY). Over lifetime horizon, this strategy substantially reduced the risk of complications by preventing cirrhosis, DCC and liver-related deaths (Table). **Conclusion:** Sequential NIT-based MASLD risk stratification is cost-effective in US primary care patients with T2D and MCO. This supports systematic implementation in primary care to identify at-risk patients.

Table. Lifetime Clinical Impact of Sequential NIT-Based MASLD Risk Stratification Versus Standard of Care in High-Risk Primary Care Populations

Outcome	Type 2 Diabetes			Medically Complicated Obesity		
	Cases prevented	Reduction	NNS	Cases prevented	Reduction	NNS
Compensated cirrhosis	1,107,806	22%	33	2,050,563	20%	28
Decompensated cirrhosis	846,094	24%	43	1,567,566	25%	36
Liver-related deaths	166,488	16%	219	287,705	18%	197



- Lifetime cumulative events prevented by the base case strategy (FIB-4 followed by VCTE in 70% or ELF in 30% of patients) versus current standard of care across 93.4 million adults with type 2 diabetes and 56.8 million with medically complicated obesity.
- Percentage reduction represents relative risk reduction versus standard of care.
- NNS, number needed to screen to prevent one outcome event over a lifetime horizon.

2160 | INPATIENT HEALTHCARE UTILIZATION AND ECONOMIC BURDEN OF DECOMPENSATED CIRRHOSIS IN THE UNITED STATES

Kartik Dapke[1] Spencer Goble[2] Timothy Davie[3] Jesse Fletcher[3] Anna Strauss[3] Serena Brosten[3] Giovanni Roldan[2] Prowpanga Udompap[4], [1]Department of Medicine, Saint Vincent Hospital, Worcester, MA, [2]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, [3]Department of Medicine, University of Minnesota, [4]Division of Gastroenterology, Minneapolis VA Health System

Background: The prevalence of decompensated cirrhosis has tripled in the United States since 1990, and it now ranks among the costliest inpatient conditions. Although its per-patient costs exceed those of heart failure and chronic obstructive pulmonary disease, subtype-specific data on clinical outcomes and national cost burden is lacking. **Methods:** We conducted a retrospective analysis using the National Inpatient Sample (NIS) database from January 1, 2016, to December 31, 2022 and identified adult hospitalizations with cirrhosis-related decompensation using ICD-10-CM codes. Decompensation was stratified by subtype: ascites, hepatic encephalopathy (HE), esophageal variceal bleeding (EVB), spontaneous bacterial peritonitis (SBP), and hepatorenal syndrome (HRS). Outcomes included in-hospital mortality, length of stay, total hospitalization cost, and discharge disposition. Weighted national estimates were derived and clinical outcomes were compared across subtypes. **Results:** Decompensated cirrhosis accounted for approximately 1,000,085 hospitalizations and $17.8 billion in national costs. Ascites was the most common subtype (583,885 admissions; national burden $11.8 billion (B); median cost $11,141), followed by HE (316,375 admissions; $4.2B; median cost $7,869). HRS, though least common (24,000 admissions), had the highest in-hospital mortality (21.8%), longest median LOS (7 days; IQR 4-12), and highest median per-admission cost ($17,139; IQR $9,592-$30,455) (Figure 1). HRS also had the highest rates of renal replacement therapy (17.8%), vasopressor use (6.0%), and sepsis (9.7%). Among survivors, 58.8% of HRS patients were discharged home versus 85.3% for EVB. **Conclusion:** Decompensated cirrhosis contributes about $17.8 billion to the total inpatient costs in the United States. HRS carries the highest per-admission mortality, resource use, and cost despite its low prevalence. Ascites has the largest share of national expenditure due to its high volume.

2161 | THE GLOBAL MACROECONOMIC CONSEQUENCES OF MASLD: GLOBAL VALUE-OF-LOST-WELFARE LOSSES AND REGIONAL INEQUITIES ACROSS 193 COUNTRIES

Jagadish Koyi[1] Hardik Dineshbhai Desai[2] Digantkumar Patel[3] Mounika Kotte[4] Sri Ram Charan Gundapaneni[5] Serene Sara John[6] Pragathi Munnangi[7], [1]Integris Health, Oklahoma City, Oklahoma. USA. 73112, [2]AB Plus Multispecialty Hospital, Ahmedabad, Gujarat, India, [3]Springfield Clinic, Springfield, IL, USA, [4]Prime south consortium, Weslaco, Texas, USA,78596, [5]UCF/HCA Florida Ocala Hospital, Ocala, Florida, United States, 34471, [6]Detroit medical center, Detroit, Michigan, 48201, [7]BronxCare Health System , Bronx , New York - 10457

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is now a dominant driver of chronic liver disease, yet its macroeconomic burden remains poorly quantified. We estimated global, regional, and national welfare losses attributable to MASLD-related disability-adjusted life years (DALYs). **Methods:** We used Global Burden of Disease 2023 estimates for MASLD-related burden, and World Bank 2023 gross domestic product (GDP), GDP per capita, and population data. Value of lost welfare (VLW) was estimated as DALYs multiplied by GDP per capita adjusted for purchasing power parity (PPP). VLW/GDP (%) quantified macroeconomic loss relative to national economic output. **Results:** Across 193 countries, MASLD accounted for 2.52 million DALYs in 2023. Global MASLD-attributable value of lost welfare was $81.56 billion, equivalent to 0.044% of global GDP. The largest absolute welfare losses occurred in the United States ($13.91 billion; 0.050% of GDP), Russian Federation ($8.66 billion; 0.134%), Mexico ($6.65 billion; 0.206%), Germany ($6.50 billion; 0.113%), and the United Kingdom ($5.08 billion; 0.128%). The highest VLW/GDP was observed in Republic of Moldova (0.310%), followed by Mexico (0.206%), Puerto Rico (0.204%), Ecuador (0.154%), Peru (0.152%), Guyana (0.151%), United States Virgin Islands (0.146%), Bolivia (0.137%), Ukraine (0.136%), and El Salvador (0.136%). By GBD super-region, High-income countries had the largest absolute VLW ($39.95 billion; 52.5% of global VLW), followed by Latin America and Caribbean ($12.29 billion; 16.2%), Central Europe, Eastern Europe, and Central Asia ($11.37 billion; 14.9%), and Southeast Asia, East Asia, and Oceania ($7.63 billion; 10.0%). However, VLW/GDP was highest in Central Europe, Eastern Europe, and Central Asia (0.165%), followed by Latin America and Caribbean (0.099%) and High-income countries (0.045%). From 1990 to 2023, MASLD DALYs increased in all GBD super-regions. The largest proportional increases occurred in Latin America and Caribbean (+208.1%), Central Europe, Eastern Europe, and Central Asia (+185.7%), Sub-Saharan Africa (+162.9%), and North Africa and Middle East (+157.9%). VLW/GDP increased most prominently in Central Europe, Eastern Europe, and Central Asia (+0.096 percentage points) and Latin America and Caribbean (+0.051 percentage points), indicating worsening relative macroeconomic strain in these regions. **Conclusion:** MASLD imposes a measurable global macroeconomic burden exceeding $81 billion annually, with disproportionate relative losses in Eastern Europe/Central Asia and Latin America. These findings support prioritizing MASLD prevention, early fibrosis detection, and metabolic-risk control as economic as well as hepatologic imperatives.

2162 | CONTEMPORARY TRENDS IN CHRONIC LIVER DISEASE AMONG HOSPITALIZED PATIENTS IN THE UNITED STATES: A NATIONWIDE ANALYSIS (2016-2023)

Aalam Sohal[1] Mariam Alamgir[1] Carol Singh[2] Kris Kowdley[1], [1]Liver Institute Northwest, [2]Dayanand Medical College and Hospital

Background: The epidemiologic landscape of chronic liver disease (CLD) in the United States is rapidly evolving, with metabolic-associated steatotic liver disease (MASLD) emerging as the most common cause of CLD. During the COVID-19 pandemic, there has been an increase in the rates of both MASLD and alcohol use. The study examines recent national trends in the burden and cost of CLD-related hospitalizations between 2016 and 2023. **Methods:** Adult hospitalizations with CLD were identified using the National Inpatient Sample from 2016 to 2023. Patient demographics, liver disease etiology, cirrhosis, decompensated cirrhosis and acute-on-chronic liver failure (ACLF) were identified among patients with CLD. The total healthcare cost was estimated using the cost-to-charge ratio and adjusted for inflation to 2023 dollars. Multivariate logistic regression was used to evaluate temporal trends in hospitalizations for chronic liver disease. **Results:** A total of 16.7 million hospitalizations with CLD were identified. Total CLD hospitalizations increased from 1.9 million in 2016 to 2.3 million in 2023 (aOR 1.04, $p < 0.001$) (Fig 1). Total hospitalization costs in patients with CLD increased from $37.8 billion in 2016 to $55.1 billion in 2023. The total hospitalization cost among patients with CLD during the study period was $383 billion dollars. The proportion of hospitalizations with cirrhosis and decompensated cirrhosis increased from 40.8% to 45.9%, and 19.6% to 26.3%, respectively. The costs for patients with cirrhosis and decompensated cirrhosis increased from $16 billion to $27 billion and from $9.9 billion to $17.5 billion. The proportion of ACLF hospitalizations increased from 3.4% to 7.7% during the study period. Costs for ACLF increased from $3.9 billion to $8.7 billion, a 126% increase. MASLD was the most common CLD, increasing from 618,535 in 2016 to 1.04 million in 2023 (aOR 1.09, $p < 0.001$). Costs of MASLD hospitalizations increased from $12 billion in 2016 to $23.7 billion in 2023, a 100% increase during the study period. An increase in alcohol-related liver disease (ALD) hospitalizations from 467,515 in 2016 to 617,775 in 2023 (aOR: 1.05, $p < 0.001$) was also observed. Costs for ALD hospitalizations increased from $8.8 billion in 2016 to $13.6 billion in 2023. Hospitalizations for hepatitis C (aOR 0.93, $p < 0.001$) and hepatitis B (aOR 0.98, $p < 0.001$) decreased during the study period. The in-hospital mortality rate increased from 4.4% in 2016 to 5.6% in 2021, then decreased to 4.7% in 2023. **Conclusion:** Our study reports an alarming increase in CLD hospitalizations, driven by a striking increase in hospitalizations for MASLD and ALD. This represents the changing landscape as well as the rising healthcare and economic burden of CLD hospitalizations at a national level. Public health interventions aimed at reducing alcohol use, lifestyle modifications, and new pharmacologic therapies will be beneficial in curbing the healthcare burden.

2163 | THE IMPACT OF CARDIOMETABOLIC RISK FACTORS ON HEALTH CARE RESOURCE USE IN ADULT PATIENTS LIVING WITH STEATOTIC LIVER DISEASE

Guanghao Zhang[1] Abdalla Aly[1] Andres Quintero[1] David Shi[1] Aidan McGovern[1] Hashem El-Serag[2], [1]Novo Nordisk, [2]Baylor College of Medicine

Background: Steatotic liver disease (SLD), including alcohol-related liver disease (ALD) and metabolic dysfunction–associated steatotic liver disease (MASLD) poses a growing healthcare burden in the US. Studies have shown that the number of cardiometabolic risk factors (CMRFs) is associated with advanced hepatic fibrosis and mortality, but limited data exist on their impact on health care resource use (HCRU). The objective of this analysis was to estimate the burden of SLD by subtype and compare the impact of CMRFs (number and type) on HCRU and costs in patients living with SLD by subtype. **Methods:** This retrospective study used Komodo data from Jan 2017-Nov 2023. Adults with ≥ 2 outpatient or ≥ 1 inpatient diagnosis for ALD or MASLD (index was the first qualifying diagnosis) and ≥ 12 months of pre- and post-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

index enrollment were included. Patients with other liver diseases or decompensation were excluded. Outcomes were per patient per year (PPPY) total costs and all-cause HCRU (outpatient [OP], inpatient [IP], emergency room [ER], intensive care unit [ICU]). Negative binomial and gamma models estimated adjusted rate ratios (RRs) and cost ratios (CRs) for the association between number and type of CMRFs (hypertension, dyslipidemia, overweight/obesity, type 2 diabetes using ICD-10 codes) on HCRU and costs by SLD subtype, using interaction terms, controlling for demographics, comorbidities, and baseline HCRU. **Results:** The study included 995,114 SLD patients (MASLD: 92.7%, ALD: 7.3%). Almost all patients with ALD had $\geq$1 CMRF (97%). Compared to the MASLD group, the ALD group had greater proportions of patients who were male (68% vs 40%), had Medicaid insurance (37% vs 24%), 3+ Quan Comorbidity Index (45% vs 25%). Compared to the MASLD group, the PPPY adjusted total medical costs were 73% higher in the ALD group (CR: 1.73, 95% CI 1.68-1.77) and the PPPY adjusted HCRU was also higher in the ALD group (RR for OP: 1.10 (1.08-1.11), INP: 2.44 (2.35-2.52), ER: 1.57 (1.53-1.61), ICU: 3.59 (3.39-3.80). In the MASLD group, patients with 4 CMRFs were associated with 46% higher costs (CR: 1.46, 95% CI 1.45-1.47) than patients with only 1 CMRF. A similar, yet smaller in magnitude, association was observed in the ALD group (CR: 1.13, 95% CI 1.10-1.16). The highest effect sizes were for hypertension and type 2 diabetes (Figure). **Conclusion:** ALD was associated with substantially higher economic burden per patient than MASLD. The number of CMRFs significantly adds more burden to patients living with SLD, especially in MASLD.

2164 | POPULATION-LEVEL TRENDS IN CIRRHOSIS-RELATED HOSPITAL ENCOUNTERS AND RELATED HEALTHCARE COSTS IN ALBERTA

Puneeta Tandon[1] Ting Wang[2] Kinjal Patel[1] Samina Khan[1] Mayur Brahmania[2], [1]University of Alberta, [2]University of Calgary

Background: Cirrhosis-related hospitalizations are increasing globally, driven largely by alcohol-associated liver disease and metabolic dysfunction-associated steatotic liver disease. This has implications for healthcare utilization, mortality, and expenditures. We evaluated temporal trends in cirrhosis-related hospital burden and associated healthcare costs across Alberta. **Methods:** We performed a retrospective population-based study of adult patients with cirrhosis-related hospital encounters in Alberta between 2024 and 2025 using validated ICD-10 coding algorithms derived from administrative and electronic medical record data. Cirrhosis-related encounters included emergency department visits and inpatient hospitalizations. Outcomes of interest included hospitalization frequency, readmission within 7 and 30 days, mortality rates within 30 and 90 days, and total healthcare costs. Temporal trends across the study period were stratified by provincial zone and hospital. **Results:** Alcohol-related cirrhosis of the liver and mental/behavioural disorders associated with alcohol use and withdrawal were the two most frequent primary diagnoses among cirrhosis-related hospital encounters. Most patients were admitted to General Medicine units, accounting for 81% of total admissions. Patients aged 59-61 accounted for the highest proportion of these encounters. In 2024 and 2025, there were 3,301 and 3,090 cirrhosis-related hospital visits, respectively, involving 1,966 and 1,905 distinct patients. 7-day readmission rates were 28.65% and 28.39%, and 30-day readmission rates were 50.14% and 50.20%. 30-day mortality rates were 13.61% and 8.01%, and 90-day mortality rates were 18.42% and 10.26%. Concurrently, total healthcare costs were $243.5 million in 2024 and $236.6 million in 2025, highlighting the substantial healthcare burden associated with cirrhosis in Alberta. **Conclusion:** Cirrhosis-related healthcare utilization and associated costs remain high across Alberta, reflecting the substantial burden of cirrhosis and the need for targeted preventative and resource-allocation strategies. These findings emphasize the need for upstream interventions to mitigate the determinants of health and disease associated with cirrhosis.

2165 | ◆ HEPATOLOGIST-LED POINT-OF-CARE ELASTOGRAPHY (H-POCE): IMPLEMENTATION AND DELIVERED QUALITY OF A BEDSIDE LIVER ASSESSMENT SERVICE

Akash Roy[1] Suhita Dutta[1] Shardhya Chakroborty[1] Shruti Keyal[1] Surabhi Jajodia[1] Mahesh Goenka[1], [1]Apollo Multispeciality Hospitals

Background: Liver elastography is central to risk stratification in hepatology, yet access is frequently rate-limited by dependence on radiology or technician-led services, creating referral delays and fragmented, multi-visit pathways. A hepatologist-led, point-of-care (POC) model in which the treating clinician acquires and interprets elastography within the same clinical encounter could improve access and consolidate assessment, However, its real-world feasibility and delivered quality remains poorly characterised **Methods:** We established a hepatologist led , point-of-care 2D shear-wave elastography (h-POCE) service and prospectively enrolled consecutive patients with hepatologist acquiring and interpreting all examinations at the POC, generating liver stiffness (LSM), liver attenuation metrics and per-examination quality indices (interquartile-range-to-median ratio [IQR/M]; reliability measurement index [RMI]) Implementation was characterised by throughput (patients per scan day), referral case-mix, and proportion receiving a complete assessment in one encounter. Delivered technical quality was assessed against pre-specified IQR/M thresholds (accepted $\leq$30%; stringent $<$15%), including in patients in whom acquisition is conventionally difficult **Results:** Within the first six weeks the service assessed 140 consecutive patients across 32 scan days (4.4 patients/day; median age 48 years; 59% male; median BMI 25.5 Kg/m^2). The case-mix was weighted toward early case-finding: 62% (87/140) were MASLD screening referrals, 16% were serial LSM monitoring and 16% were chronic viral hepatitis. A complete LSM result was delivered at the point of care in 140/140 patients (100%) and a full multiparametric assessment (stiffness, attenuation and fat) in 108 (77%), all within a single clinician encounter **.** Delivered quality met accepted standards : all 140 examinations satisfied the IQR/M $\leq$30% criterion (100%; 95% CI 97.3–100) and 95.7% (134/140; 95% CI 91.0–98.0) met the stringent $<$15% criterion. Reliability was preserved in groups conventionally considered difficult to image (100% obese patients and 100% of operator-rated difficult scans). RMI tracked an acquisition-quality gradient (median 0.84 easy/moderate vs 0.72 difficult). Clinically, the single-encounter pathway reclassified 21% of FIB-4 low-risk patients toward possible significant fibrosis **Conclusion:** A h-POCE service was rapidly implementable and delivered a complete, reliable liver assessment within a single clinical encounter consolidating a pathway that conventionally requires separate referral. Delivered quality met accepted reliability standards in all patients, including the obese and technically difficult, and actionable risk reclassification was available at the bedside. This care-delivery model offers a scalable route to expand hepatology led POC elastography.

Table. Implementation and delivered-quality metrics of a hepatologist-led point-of-care elastography service.

Metric	n / value	IQR/M ≤30%	IQR/M <15%	Median RMI
Patients assessed	**140**	**100%**	**95.7%**	**0.82**
Throughput (patients/scan day)	4.4	—	—	—
Screening referrals	87 (62%)	—	—	—
Complete result, single encounter	140/140	—	—	—
Full multiparametric, single encounter	108 (77%)	—	—	—
Delivered technical quality, by acquisition difficulty				
Skin-capsule ≤2.0 cm	82	100%	99%	0.83
Skin-capsule 2.0–2.5 cm	30	100%	90%	0.81
Skin-capsule >2.5 cm (deep)	13	100%	92%	0.82
Obese (BMI ≥30)	22	100%	95%	0.82
Operator-rated difficult [1]	38	100%	84%	0.72
Easy / moderate [2]	100	100%	100%	0.84

IQR/M, interquartile-range-to-median ratio; RMI, reliability measurement index (0–1, higher = better). [1] Operator-rated difficulty prospectively recorded with documented reasons (impaired breath-hold n=24, obesity n=13, narrow intercostal window n=11, ascites n=3, other n=5). [2] Easy n=90 and moderate n=10 combined.

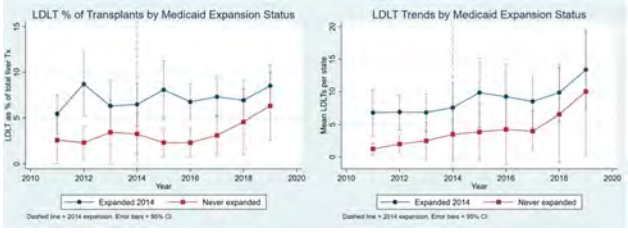
2166 | ◆ THE EFFECT OF MEDICAID EXPANSION ON LIVING DONOR LIVER TRANSPLANT RATES



Christopher McLaughlin[1] Yael Nobel[1] Russell Rosenblatt[2], [1]Columbia University Irving Medical Center, [2]Weill Cornell Medicine

Background: Living donor transplantation (LDLT) is one tool to overcome the longstanding issue of organ shortage. LDLT represents only 6% of liver transplants, a figure that remains largely unchanged over the past decade. Financial costs are a significant barrier to LDLT, and insurance status is a potentially modifiable input. Medicaid coverage rose from 13% to 19% of liver transplants from 2013 to 2023, likely reflecting increased Medicaid enrollment following the 2014 Medicaid expansion under the Affordable Care Act. We examined whether Medicaid expansion is associated with differential increases in LDLT utilization among Medicaid-insured patients in expansion versus non-expansion states. **Methods:** We included

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

patients in the UNOS STAR file from 2011-2019 residing in states that expanded Medicaid eligibility in 2014 (n = 20) or did not (n = 10). States with fewer than 10 total LDLTs per year were excluded. The primary outcome was change in LDLT volume per state-year from pre-expansion (2011–2013) to post-expansion (2014–2019). DDLT volume, which requires less support and resources, was a secondary outcome. Medicare and private insurance cohorts were also analyzed. A difference in difference (DiD) analysis was performed with fixed effects for state and year. **Results:** Mean LDLT per state-year increased overall (4.8 to 7.6) but did not significantly differ between expanding (6.5 to 9.2) and nonexpanding (1.5 to 4.3) states (DiD -0.47, $p > 0.10$) (**Figure**). LDLT as a proportion of total LTs also increased (4.1% to 5.0%), with no significant group difference (expanding: 5.6% to 6.3%; nonexpanding: 1.3% to 2.7%; DiD -0.52, $p > 0.10$). Similarly, no significant treatment effect on LDLT volume was seen for patients with Medicare (DiD 0.13, $p > 0.10$) or private insurance (DiD -0.82, $p > 0.10$). In contrast, DDLT volume for Medicaid patients significantly increased in expanding states (18.9 to 30.6) but not non-expanding states (16.3 to 16.1; DiD 10.97, $p < 0.01$), representing a 54% relative increase (DiD log+1 0.44, $p < 0.01$), with divergence beginning in 2016. **Conclusion:** Following Medicaid expansion, total volume and percentage of LDLT increased similarly in states, irrespective of Medicaid expansion or patient insurance. DDLT volume for Medicaid patients increased significantly more in states that expanded Medicaid eligibility. While LDLT trends beyond 2019 were not assessed, our findings suggest that while increasing access to health insurance increases access to DDLT, it may not be sufficient to increase utilization of LDLT due to the potential need for additional support and other direct or indirect costs.

2167 | ◆ GLOBAL VARIABILITY IN HEPATOLOGY TRAINING: RESULTS OF THINK COLLABORATIVE INTERNATIONAL MULTINATIONAL SURVEY

Sanjaya Satapathy[1] Tiffany Sahadeo[2] Kenan Moral[3] Zita Galvin[4] Marta Tejedor[5] Kymberly Watt[6], [1]Northshore University Hospital/Northwell Health, [2]Northwell Health, [3]Lokman Hekim University, [4]St. Vincent's Private Hospital, [5]James A. Clifton Digestive Health Center, University of Iowa Health Care, [6]Mayo Clinic, Rochester, Minnesota

Background: Hepatology training pathways vary considerably worldwide, with limited contemporary data evaluating differences in curriculum structure, procedural competency expectations, transplant exposure, and competency-based educational frameworks across regions. We conducted an international multinational survey to characterize current hepatology training models and identify areas of global convergence and variability. **Methods:** A cross-sectional international survey assessing hepatology training structure, curriculum content, procedural competencies, teaching methodologies, transplant exposure, research requirements, and competency-based curriculum implementation was distributed globally. Survey responses underwent quality assessment, and low-quality responses were excluded prior to analysis. Descriptive analyses were performed, and regional comparisons were evaluated using chi-square and Fisher exact tests where appropriate. **Results:** Ninety respondents from more than 30 countries across North America, Europe, Asia-Pacific, Latin America, and the Middle East/Africa were included. Hepatology was a standalone specialty in 31.1% of programs, a gastroenterology subspecialty in 24.4%, and integrated within gastroenterology training in 5.6%. Core topics—including chronic liver disease, viral hepatitis, cholestatic and autoimmune liver disease, MASLD/MASH, and drug-induced liver injury—were included in over 94% of curricula. Alcohol-associated liver disease, fibrosis assessment, and radiology/imaging training were less common (75.6%, 76.7%, and 58.9%, respectively). Procedural competency expectations varied considerably. Therapeutic upper endoscopy, upper GI bleeding management, and paracentesis were included in over 80% of programs, whereas liver biopsy (46.7%), liver ultrasound (36.7%), ultrasound-guided procedures (35.6%), and transjugular liver biopsy (3.3%) were less frequently required. Regional differences were significant. Standalone hepatology training ranged from 81.8% in North America to 5.1% in Asia-Pacific ($p < 0.0001$).

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Mandatory transplant rotations varied from 75% in Europe to 0% in North America ($p < 0.0001$), and research requirements also differed by region ($p = 0.0007$). Overall, 68.9% supported a unified global hepatology curriculum. **Conclusion:** Global hepatology training demonstrates substantial heterogeneity in specialty structure, transplant exposure, procedural competency expectations, and educational frameworks despite broad consensus regarding core hepatology curriculum content. Important gaps were identified in radiology/imaging training and advanced procedural exposure. These findings support the need for increased international collaboration and consideration of harmonized competency-based hepatology training standards worldwide.

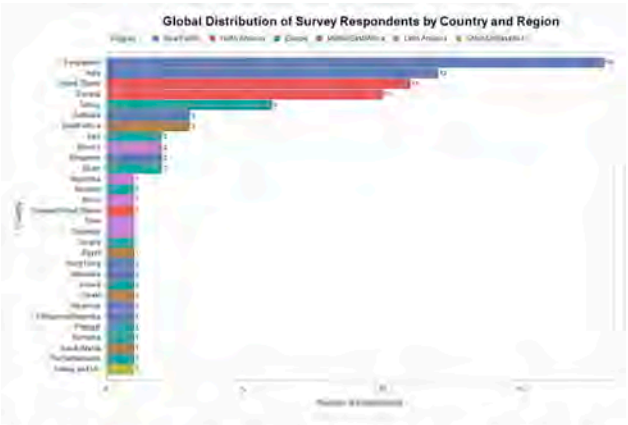

Figure 1. Geographic distribution of respondents participating in the international multinational hepatology training survey. Respondents represented more than 30 countries across North America, Europe, Asia-Pacific, Latin America, and the Middle East/Africa regions. Countries with at least two respondents are shown in the primary figure display.

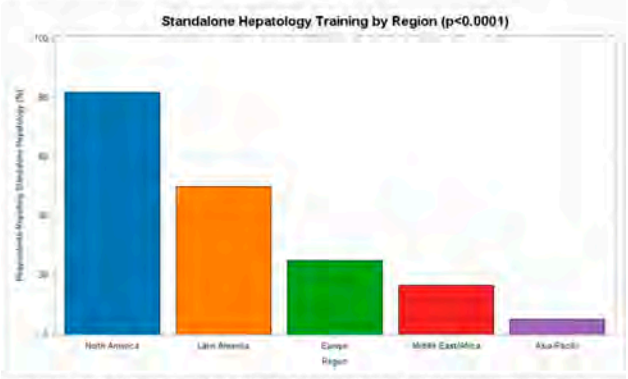

Figure 2. Regional variability in standalone hepatology training models. Bars represent the percentage of respondents within each geographic region reporting hepatology as a standalone specialty. Significant regional differences were observed, with the highest prevalence reported in North America and the lowest in the Asia-Pacific region (p<0.0001).

2168 | ◆ DEVELOPMENT OF THE PORPHYRIA BURDEN ASSESSMENT, A PATIENT-REPORTED OUTCOMES MEASURE TO ASSESS THE BURDEN OF CHRONIC SYMPTOMS OF ACUTE HEPATIC PORPHYRIA

Teresa Kauf[1] Hetanshi Naik[2] Francesca Granata[3] Liz Gill[4] Rebecca Leaf[5] Susana Monroy-Santoyo[6] Eliane Sardh[7] Michael Scott[8] Paulo Sgobbi de Souza[9] Ulrich Stölzel[10] Brittany Klooster[11] Ben Banderas[11] Ilaria Olivetti[1] Sabina Wiekhorst[1], [1]Alnylam Pharmaceuticals, Cambridge, MA, USA, [2]Stanford University, Palo Alto, CA, USA, [3]S.C Medicina ad Indirizzo Metabolico, Milano, Italy, [4]British Porphyria Association, Durham, UK, [5]Center for Hematology, Mass General Brigham Cancer Institute, Boston, MA, USA, [6]Centro Médico ABC, Mexico City, Mexico, [7]Centre for Inherited Metabolic Diseases, Karolinska University Hospital, Stockholm, Sweden, [8]Department of Medicine, University of Toronto and Unity Health Toronto, Toronto, ON, Canada, [9]Federal University of São Paulo (UNIFESP), São Paulo, Brazil, [10]Department of Internal Medicine II, Porphyria Centre, Klinikum Chemnitz, Chemnitz, Germany, [11]Adelphi Values, Boston, MA, USA

Background: Acute hepatic porphyrias (AHPs) are rare diseases characterized by acute attacks and chronic symptoms between attacks, resulting in diminished health-related quality of life (HRQoL). Owing to the heterogeneous presentation of AHP, generic patient-reported outcome measures (PROMs) may not sufficiently assess disease burden from the patient perspective. To support a clearer understanding of the full burden of AHP, we developed the Porphyria Burden Assessment (PBA): an AHP-specific PROM that assesses the cardinal symptoms and HRQoL impacts of AHP outside of attacks. **Methods:** A systematic literature review was conducted to identify the key signs, symptoms, and HRQoL impacts of AHP. Utilizing

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

FDA guidance and best practices for questionnaire development, findings were used to develop a conceptual disease model and an initial draft (version 0.1) of the PBA. Draft versions of the PBA underwent iterative review by AHP clinical experts and patients with AHP (**Figure**).The PBA was reviewed by patients who were ≥15 years old, had experienced ≥1 self-reported AHP attack in the past 2 years, were not receiving hemin prophylaxis, and had not received givosiran within 6 months before the date of informed consent. Patients completed a demographic and health information questionnaire and a two-part, semi-structured, qualitative 90-minute interview by telephone or virtually. During the first part of the interview, patients spontaneously described their experience of AHP-related signs, symptoms, and HRQoL impacts; researchers asked targeted questions to further explore specific symptom concepts. In the second part of the interview, patients completed the draft PBA using a 'think-aloud' approach to assess its readability, comprehensibility, relevance, and comprehensiveness. Six interview waves, each including approximately five participants, informed iterative refinements to the draft PBA. **Results:** The conceptual disease model identified six symptom concepts and four HRQoL impact domains for inclusion in version 0.1 of the PBA. Following expert review, two additional symptom concepts were added. A total of 30 participants completed the interviews; concepts were further refined following patient interviews and review of the draft PBA. The final PBA (version 1.0) comprises 14 items which generate domain-level scores for symptom severity and HRQoL impact, as well as a total score. Testing of the final PBA confirmed questions were relevant to and understandable for patients. The full PBA will be presented. **Conclusion:** The PBA is a content valid tool designed to assess the burden and disease-specific impacts of AHP, including chronic symptoms and how these affect patients' lives. This tool may empower patients to fully communicate their needs, support shared/patient-centered decision-making with their healthcare professionals, and facilitate a comprehensive understanding of the disease burden associated with AHP.

2169 | LINKAGE TO CARE AMONG HEPATITIS B AND C PATIENTS FOLLOWING PATIENT NAVIGATION IN A FEDERALLY QUALIFIED HEALTH CENTER IN SAN DIEGO COUNTY

Sydney Sharp[1] Monica Vidaurrazaga[1], [1]Family Health Centers of San Diego

Background: San Diego County has large populations at increased risk for chronic hepatitis B (HBV) and hepatitis C (HCV) including people who inject drugs, people who are unhoused, and foreign-born individuals. Barriers to care include lack of insurance, treatment costs, limited access for vulnerable populations, and low awareness of disease and treatment options. Family Health Centers of San Diego (FHCSD), a federally qualified health center, adapted established HIV linkage-to-care models to implement a patient navigation program aimed at improving reengagement in HBV/HCV care among patients not currently receiving treatment. **Methods:** The program was funded by the Center for Disease Analysis Foundation Relink Initiative and operated from March 2024 to June 2025. Eligible FHCSD patients met one of the following criteria: (1) positive quantitative viral load laboratory results for HBV and/or HCV, or (2) reactive antibody or antigen laboratory results for HBV and/or HCV without a documented viral load test. Outreach was conducted in English, Spanish, and Haitian Creole through phone calls, text messages, and email. Navigators performed standardized chart reviews to assess care status and patients received up to four contact attempts. Transportation assistance through Uber Health was available but rarely used. Data were analyzed using univariate logistic regression with HCV as the reference group. **Results:** Over 15 months, patient navigators attempted outreach to 3,678 patients: 731 with HBV, 2,935 with HCV, and 12 with both infections. Table 1 shows patient demographics. The HBV population demonstrated greater demographic diversity, including a more balanced sex distribution (58.0% male, 42.0% female), more evenly distributed employment status (26.8% employed, 39.7% unemployed, 21.9% unknown), and greater racial diversity

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

(30.9% White, 25.7% Black/African American, and 24.6% Asian/Pacific Islander). Additionally, 25.7% of HBV patients reported a preferred language other than English or Spanish.HBV patients had significantly greater odds of successful contact compared with HCV patients (OR = 5.33, 95% CI: 3.93-7.25; p < 0.001). HBV patients also had four times the odds of appointment completion (OR = 4.05, 95% CI: 2.23-7.45; p < 0.001). **Conclusion:** Despite using various contact methods, successful contact was achieved for only 10% of patients. HBV patients had higher odds of successful contact and appointment completion, potentially reflecting greater awareness of HBV diagnosis and treatment due to the longstanding emphasis on HBV vaccination and education. Low appointment completion may also reflect structural barriers. Limitations of this study included no in-person or mail outreach and underutilization of transportation assistance. Overall, low rates of successful contact and appointment completion underscore the persistent barriers to hepatitis care engagement among underserved populations.

2170 | IMPACT OF THE SURREY COMMUNITY LIVER HEALTH CHECK PROGRAMME ON EARLY DETECTION OF CIRRHOSIS AND HEPATOCELLULAR CARCINOMA: A 4-YEAR REGIONAL EVALUATION

Janani Ragavan[1] Romanie Westwood[1] Regelien Ariola[1] Charish Pria[1] Paul Obeney[1] Maisie Gadsby[1] Adam Nigh[1] Tina Zackova[1] Kusum Gurung[1] Philippa Cobb[1] Michelle Gallagher[1], [1]Royal Surrey Hospital

Background: Hepatocellular cancer (HCC) is one of the fastest growing causes of cancer mortality in the UK, with approximately 7000 cases per year anticipated to rise by 40% by 2040. Whilst HCC is associated with deprivation it does not exclusively affect people living with health inequalities. Surrey, a relatively affluent region, was one of the first ten NHSE funded community liver health check (CLHC) operational delivery networks (ODNs). The aim of the CLHC was to use transient elastography (FibroScans) to identify liver disease early in at-risk populations. **Methods:** Targeted screening was offered to individuals with liver disease risk factors – hazardous alcohol consumption, risk of current or previous Hepatits B/C virus and metabolic disease (Type 2 diabetes/obesity/hepatic steatosis). To improve accesibility FibroScans were delivered in clinics and on a mobile screening van across multiple locations within the community such as drug and alcohol services and homeless shelters. The team also partnered with GP practices in deprived areas to identify patients with risk factors and invite them to book appointments in CLHC clinics.Liver stiffness measurements (LSM) were categorised as negative (<8.5 kPa), moderate (8.5–11.4 kPa), or positive (>11.5 kPa). All participants received lifestyle advice. Secondary care hepatology referrals were made for people with positive scans; moderate fibrosis patients were recalled at 2 years. **Results:** A total of 11,275 FibroScans were performed over the four-year period (Table 1). 504 individuals were referred for specialist assessment: 322 remain in active HCC surveillance. 42 patients were discharged following clinical review, 54 moved away, 42 refused to engage and 41 are deceased.To date, 4 surveillance patients have been diagnosed with HCC, all of which were early stage (BCLC Stage A) and one other is on intensive surveillance due to an indeterminent (LI-RADS 3) lesion.Moderate LSM values were identified in 653 (6%) of initial scans. 96 patients, out of 272 recalled at the 2 year mark, had a repeat scan ; 81% demonstrated improvement with lower LSM on follow-up, while 16% showed an increase in LSM. All patients progressing to advanced disease had evidence of severe hepatic steatosis at baseline.Drug and alcohol services achieved the highest yield, despite accounting for only

12% of patients scanned. **Conclusion:** The Surrey ODN has delivered 5% conversion to specialist referral. Linkage to specialist care was high, resulting in the identification of four early-stage HCCs. The majority of those with moderate fibrosis rescanned had improved LSM at 2 years demonstrating the benefits of early lifestyle intervention and education given at the initial scan. Targeted screening optimised the finding of cases while also improving access to healthcare. Outcomes within the Surrey ODN compare favourably to programmes with similar demographics such as Bristol and Severn and North London.

Table 1: Indications, demographics and diagnostic yield of 11,275 scans in Surrey (June 2022 to May 2026)

Catergory	Subgroup	Result	Percentage (%)	Positive yield (%)	Moderate yield (%)
Scan results	Positive (>11.5 kPa)	504	5%		
	Moderate (8.5–11.4 kPa)	653	6%		
	Negative (<8.5 kPa)	10118	89%		
Indication	Risk of / previous Hep B/C	1543	14%		
	Excess alcohol	2553	23%		
	Metabolic RF (T2DM, High BMI, NAFLD)	5855	52%		
	Two or more risk factors	1324	11%		
Location	GP	3223	28%	4%	6%
	Drug & Alcohol Service	1346	12%	6%	7%
	Events	2142	19%	2%	4%
	Clinics (eg: Bariatric, Diabetes)	4301	38%	6%	6%
	Homeless shelters	263	3%	6%	4%
Gender	Male	6380	57%		
	Female	4895	43%		
Ethnicity	White British	6638	59%		
	White – Other	1047	9%		
	Black	361	3%		
	Asian	1314	12%		
	Other/Mixed	1915	17%		
Country of Birth	UK	8244	73%		
	Non-UK	3031	27%		

81% of Surrey residents are UK born white British. Targeted screening engaged non-UK birth cohorts with risk factors

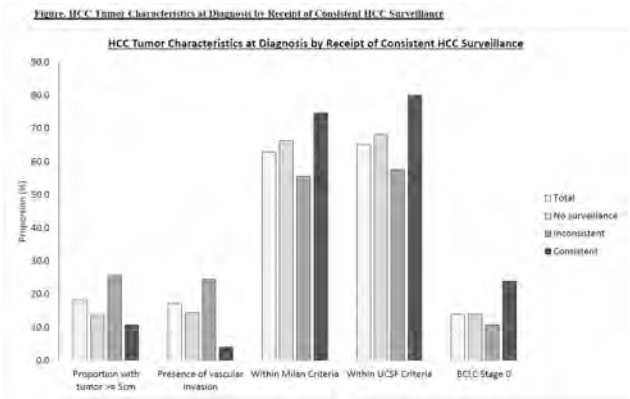
2171 | GAPS AND INCONSISTENCIES IN HEPATOCELLULAR CARCINOMA SURVEILLANCE ARE ASSOCIATED WITH MORE ADVANCED TUMOR STAGE AT DIAGNOSIS AMONG U.S. SAFETY-NET POPULATIONS



Robert Wong[1] Patricia Denise Jones[2] Bolin Niu[3] Paulo Pinheiro[4] Mae Thamer[5] Onkar Kshirsagar[6] Yi Zhang[6] Ronnie Fass[3] Jasmine Davis[4] Lisa Quirk[7] George Therapondos[8] Amit Singal[7] Mandana Khalili[9],

[1]Stanford/VA Palo Alto Healthcare System, [2]University of Miami School of Medicine, [3]MetroHealth Medical Center, [4]University of Miami, [5]Medical Technology and Practice Patterns Institute, [6]Medical Technology and Pratice Patterns Institute, [7]University of Texas Southwestern, [8]Ochsner Health System, [9]University of California, San Francisco

Background: Current practice guidelines recommend semiannual hepatocellular carcinoma (HCC) surveillance in patients with cirrhosis. However, consistent HCC surveillance remains suboptimal in real-world practice. We aim to evaluate gaps in guideline-concordant HCC surveillance and its impact on tumor stage at diagnosis among U.S. adults. **Methods:** Adults with cirrhosis who were diagnosed with HCC from 3/1/2018 – 2/29/2024 across four U.S. safety-net health systems were evaluated. Surveillance in the 12 months prior to HCC diagnosis was categorized as consistent (semiannual HCC surveillance), inconsistent (annual HCC surveillance), and no surveillance. HCC surveillance was determined by CPT codes for imaging type and associated ICD-9/10-CM codes for indication. HCC characteristics at diagnosis included number and size of tumors, presence of vascular invasion (VascInv), Barcelona Clinic Liver Cancer (BCLC) stage, and whether HCC was within Milan criteria. **Results:** Among 622 adults with HCC (mean age 61.8y, 74.6% men, 46.0% Hispanic, 28.8% non-Hispanic white, 16.1% African American, 1.0% Asian, 33.3% Medicare, 25.4% Medicaid, 23.3% commercial, 12.2% uninsured/indigent care), etiology of cirrhosis was 45% chronic hepatitis C, 42% alcohol-associated liver disease, 7% chronic hepatitis B, and 7% metabolic dysfunction-associated steatohepatitis. At HCC diagnosis, 18.3% had HCC $\geq$ 5cm, 17.3% had VascInv, 14% had very early stage (BCLC stage 0), and 62.9% was within Milan criteria. In the 12 months prior to HCC diagnosis, 12.5% had consistent surveillance, 41.8% inconsistent, and 45.7% no surveillance. Consistent surveillance was associated with greater proportion of HCC within Milan criteria, and with BCLC stage 0, and lower proportion with HCC $\geq$5cm or with VascInv compared to inconsistent or no surveillance (Figure). For example, compared to no surveillance, patients who received consistent surveillance had lower proportion with VascInv (4.1% vs. 14.4%) and greater proportion within Milan criteria (74.7% vs. 66.3%), and BCLC stage 0 (24.0% vs. 14.1%), all $p < 0.05$. **Conclusion:** Among a multi-center safety-net cohort of patients with cirrhosis who developed HCC, only 1 in 8 received guideline-concordant semiannual surveillance prior to HCC diagnosis. This is particularly alarming given that consistent surveillance was associated with earlier tumor stage and more favorable tumor characteristics at diagnosis, which ultimately leads to improved options for HCC treatment.

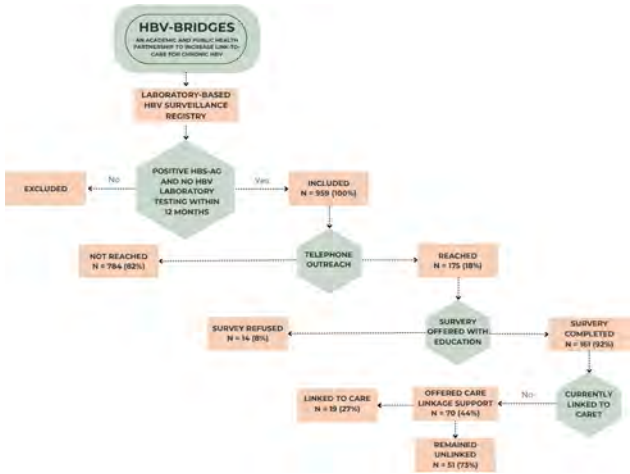
2172 | RATES, TIMING, AND CONTENT OF DOCUMENTED GOALS OF CARE DISCUSSIONS IN DECOMPENSATED CIRRHOSIS

Raina Saxena[1] Hillary Ta[1] Saul Euceda[2] Amber Phung[2] Brian Horwich[1] Jasleen Singh[1] Alissa Ulanday[2] Jessica Kaltman[1] Moira Inkelas[3] Anne Walling[1] Neil Wenger[1] Arpan Patel[1], [1]David Geffen School of Medicine at UCLA, Los Angeles, CA, [2]UCLA Health, Los Angeles, CA, [3]UCLA Fielding School of Public Health, Los Angeles, CA

Background: Patients with decompensated cirrhosis experience high symptom burden, mortality, and exposure to life-sustaining treatments. Goals of care discussions are an important component of high-quality care. To identify opportunities for improvement, we aimed to describe patterns and content of documented GOC discussions in hospitalized adults with decompensated cirrhosis. **Methods:** We identified adults with decompensated cirrhosis who had $\geq$ 1 hospitalization within our health system between 1/1/2025–4/4/2026 using validated ICD-10 codes. During this timeframe, we captured demographics, mortality, transplant status (ever evaluated, listed, transplanted), presence of any palliative care consultation, and any hospice referral. Any GOC discussions ever documented using a long-standing electronic health record (EHR) template were captured. Logistic regression examined factors associated with documented GOC discussions. To contextualize discussions, we performed content analysis of first GOC discussions recorded from 38 decedent charts using maximum variation sampling, stratified by timing before death, palliative care involvement, and transplant status. A hybrid inductive-deductive approach was used. **Results:** Among 516 patients across 730 hospitalizations, mean age was 63 years (SD: 17), 38% were White, 39% Latino, 7% Asian, 5% Black, and 5% Other Race. Half underwent liver transplant evaluation; 25% died during the study period. Palliative care consultations (17%) and hospice referrals (4%) were uncommon. Thirty percent had any documented GOC discussion. In fully adjusted analyses, palliative care consultation (OR 32.1, 95% CI 14.1–73.1), death (OR 9.78, 95% CI 5.47–17.5), and Other versus White race (OR 3.38, 95% CI: 1.24–9.20) were associated with GOC documentation. Of 384 documented discussions, 89% occurred inpatient; hospital medicine (34%) and palliative care (33%) providers documented most conversations. Median time from first GOC discussion to death or hospice was 4 (IQR 1–23) days. Content analysis identified 4 patterns: 1) conversations were often crisis-triggered and focused on prognosis and treatment limits; 2) family decision-making often predominated due to patient incapacity; 3) transplant candidacy strongly shaped timing and content despite

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



limited gastroenterology/transplant team involvement; and 4) outpatient discussions addressed broader serious illness communication domains. **Conclusion:** Among hospitalized adults with decompensated cirrhosis, fewer than one-third had any documented GOC discussion and among decedents, first documented discussions occurred shortly before death. Content analysis suggested that earlier discussions before acute clinical deterioration may improve patient participation and anticipatory communication around evolving transplant status and serious illness outcomes.

2173 | HBV-BRIDGES: AN ACADEMIC-PUBLIC HEALTH PARTNERSHIP TO INCREASE LINKAGE TO CARE AMONG RESIDENTS WITH CHRONIC HEPATITIS B IN LOS ANGELES COUNTY

Kevin Sun[1] Cierra LeBlanc[2] Mark Wang[1] Ariel Lee[1] Justin Ong[1] Anusha Koka[1] Nikhilesh Kumar[1] Alison Ly[1] Sophia Paik[1] Sabrina Zhang[1] Prabhu Gounder[2] Kali Zhou[1], [1]University of Southern California, [2]Los Angeles County Department of Health Services

Background: Chronic hepatitis B virus (HBV) infection disproportionately affects Los Angeles County (LAC) residents, where one in three are foreign-born. Prior studies have shown that many chronic HBV-infected are unaware of their diagnosis and/or not linked to care, leading to liver-related complications. University of Southern California (USC) researchers in collaboration with the LAC Department of Public Health (LADPH) developed the HBV-BRIDGES Program, a county-wide population-based multilingual initiative, to directly address this problem. **Methods:** The HBV-BRIDGES Program utilized the LADPH laboratory-based HBV surveillance registry to identify potentially out of care LAC residents 18 years or older with a positive hepatitis B surface antigen test after January 2025. “Out of care” was defined as no HBV-related laboratory testing within 12 months after initial positive HBsAg. Patient navigators from USC made up to three telephone attempts per resident, conducted a brief voluntary survey assessing linkage-to-care/treatment status and barriers to each, and delivered targeted HBV education to promote linkage. Calls were conducted in the resident's preferred language with professional interpreter assistance when needed. Linkage-to-care was defined as any HBV-related laboratory test reported to LADPH after initial contact. **Results:** To date, 959 individuals have been contacted, of which 175 (18%) were reached (82% on first attempt). Those who were reached were more likely to be aged 40-60 (50% vs 39%; $p < 0.05$), with no difference in sex (52% vs 53% female). Of the 175 residents reached, 161 (92%) completed the survey and education (see flowchart in Figure). Survey respondents were predominantly Asian (66%), followed by Hispanic (19%) and White (6%). 21%, 44%, and 27% of respondents were < 40, 40-60, and 60+ years, respectively, with 47% female sex. Of survey respondents, 54 (34%) reported being unaware of their HBV diagnosis. A total of 70 (44%) residents reported no linkage-to-care. Asians were much more likely to have already been linked than Hispanics (71% vs 20%, $p < 0.01$). The most common barrier to linkage was being unaware of HBV diagnosis (64%), followed by not knowing ongoing follow-up was necessary (13%), and no primary care provider (6%). 91 individuals (65%) were not currently receiving HBV treatment; of these, 46 (52%) expressed interest in starting treatment if eligible. Lastly, 19 (27%) residents had subsequent linkage-to-care, with a median of 6.2 months (IQR: 4.9-8.7) from initial contact to HBV laboratory testing. **Conclusion:** The HBV-BRIDGES Program reached approximately 20% of eligible LAC residents, of which nearly half were unlinked, and one-third had objective evidence of linkage to care at 6 months. This academic-public health partnership leveraging telephone outreach through a laboratory-based surveillance registry is a promising, replicable model for other counties.

2174 | STAKEHOLDER-DRIVEN DEVELOPMENT OF A HEPATOLOGY QI DASHBOARD: A HUMAN-CENTERED DESIGN STUDY

Julia Gips[1] Tyrus Vong[1] Danielle Piccinini-Black[2] Vedant Jain[3] Valerie Thompson[1] Carolina Lopez-Silva[1] Lynette Sequeira[4] Kathy Liu[3] Alexandra Strauss[1], [1]Johns Hopkins School of Medicine, [2]Johns Hopkins Carey Business School, [3]Johns Hopkins Department of Gastroenterology, [4]Johns Hopkins Hospital

Background: Hepatology providers lack systematic access to individualized feedback on patient outcomes. Clinician educator frameworks emphasize that physicians require structured, outcomes-based feedback to sustain reflective practice and drive continous improvement, yet no mechanism currently exists to deliver this data. Existing QI dashboards typically present aggregate, department-level metrics rather than individualized data, limiting clinical relevance. Additionally, dashboards built without end-user input are frequently underutilized: when tools do not reflect user priorities and workflows, adoption fails. We applied human-centered design (HCD) to develop a provider-facing QI dashboard grounded in end-user needs, ensuring clinical relevance and sustained engagement. **Methods:** Using a multi-phase HCD approach, we engaged multi-disciplinary stakeholders. Phase 1 comprised a needs assessment survey distributed to hepatology faculty (n = 12) to identify the highest-priority quality metrics for dashboard inclusion. Phase 2 comprised an in-person group session (n = 9; attendings, fellows, pharmacist; 1–34 years of experience) employing established HCD methods: "headline from the future," journey mapping, rose–bud–thorn analysis, and prioritization of pre-surveyed care metrics. Phase 3 consisted of semi-structured individual interviews (n = 14) exploring metric prioritization, data visualization preferences, and workflow integration. Qualitative thematic analysis was performed on transcripts and artifacts to identify consensus priorities and usability requirements that informed iterative dashboard prototypes. **Results:** Across all phases, providers consistently prioritized guideline-concordant, actionable metrics over administrative data. Top-ranked metrics included: timely diagnostic paracentesis (within 24 hours of admission), transplant evaluation phase and rationale for listing decisions, 30-day readmission rates, and inpatient mortality. Key design requirements included interactive, color-coded benchmarking against AASLD guidelines and historical data, drill-down functionality to individual patient data, and longitudinal filtering by time window. Providers expressed concerns about data accuracy, the display of metrics without clear reference benchmarks, and the potential for metrics to feel punitive rather than educational. **Conclusion:** HCD methodology produced a provider-informed hepatology QI dashboard aligned with clinical workflows, educational goals, and AASLD quality benchmarks. This iterative, stakeholder-driven approach revealed design requirements, particularly around data quality, benchmarking, and interactivity, that would not have emerged from administrator-driven development alone. This model offers a blueprint for participatory QI tool development in complex clinical environments and is scalable across institutions and specialties.

2175 | TRENDS IN HEPATOCELLULAR CARCINOMA DIAGNOSIS OVER A 10 YEAR PERIOD: A MULTI-CENTRE COHORT STUDY

Richard O'Halloran[1] Thisuri Jayawardena[1] Weiyuan Fan[2] Andrea Jasareno[3] Phoebe Sun[3] Wei Ling Teh[3] Andrew Chin[2] Wesley Billingham[4] Kazuya Miyamoto[5] Tim Mitchell[2] Simon Hazeldine[3] Chloe Attree[1] George Garas[6] Gary Jeffrey[1] Angus Jeffrey[1] Gerry MacQuillan[1] Briohny Smith[1] Michael Wallace[1] Leon Adams[6], [1]Sir Charles Gairdner Hospital, [2]Royal Perth Hospital, [3]Fiona Stanley Hospital, [4]The Kids Institute, [5]The University of Western Australia, [6]University of Western Australia

Background: Hepatocellular carcinoma (HCC) is a low survival cancer with a rising incidence in Australia. We aimed to describe temporal changes in underlying liver disease aetiology and patient characteristics in in patients with a new diagnosis of HCC over a 10-year period. **Methods:** Patients with newly diagnosed HCC at three tertiary hospitals in Western Australia between 2015-2024 were retrospectively identified. Patient variables at cancer diagnosis, including demographics, underlying liver disease, Barcelona Clinic Liver Cancer (BCLC) staging and functional status, were ascertained from prospective databases and electronic records. Trends in case numbers over time were analysed using Poisson regression. The change in relative proportion over time was analysed for underlying liver disease,

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

sex, cirrhosis or late-stage HCC using logistic regression, with linear regression used for age and Eastern Cooperative Oncology Group (ECOG) status at diagnosis. **Results:** Overall, 1,168 new diagnoses of HCC were identified [81.5% male, 73.3% cirrhotic]. HCC cases increased 8.7% per year from 83 in 2015 to 163 in 2024 ($p < 0.001$). Alcohol was the commonest aetiology (33.9%) followed by hepatitis C (24%), metabolic dysfunction-associated steatotic liver disease (MASLD) (22%) and hepatitis B (9.1%). All aetiological sub-groups increased in case numbers over time, including MASLD (12.3%/year, $p < 0.001$), alcohol (8.4%/year, $p < 0.001$), hepatitis B (6.1%/year, $p = 0.042$) and hepatitis C (4.4%/year, $p = 0.015$). However, the proportion related to hepatitis C decreased (OR 0.94, 95% CI 0.90-0.98), whereas the proportion related to MASLD (OR 1.05, 1.00-1.09) increased. There was also an increase in the proportion of HCC diagnoses in both those with unrecognized chronic liver disease at diagnosis (OR 1.05, 1.01-1.10), and those with no known risk factors for liver disease even on further review (OR 1.10, 1.02-1.19). The proportion of HCC due to alcohol and hepatitis B remained constant over the decade. The average age at diagnosis increased from 62.8 years in 2015-16 to 69.6 years in 2023-24 (coefficient = 0.82/ year; $p < 0.001$). Mean ECOG score at diagnosis increased significantly over time (coefficient = 0.02/year; $p = 0.002$). The proportion of cases with male sex, cirrhosis, late-stage disease (BCLC C or D) or diagnosed in a surveillance program did not change over time. **Conclusion:** In Western Australia, HCC case numbers are increasing with the proportion related to MASLD and in those without known liver disease increasing, whilst decreasing for hepatitis C. Patients with newly diagnosed HCC are becoming older and have an increasingly poorer performance status.

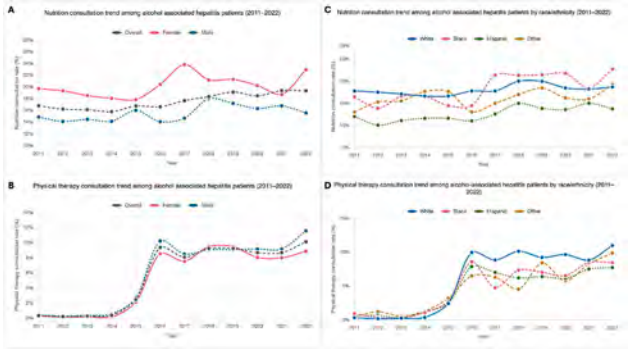
2176 | UNMET NEED FOR NUTRITION AND PHYSICAL THERAPY CONSULTATION AMONG HOSPITALIZED PATIENTS WITH ALCOHOL-ASSOCIATED HEPATITIS: A NATIONWIDE ANALYSIS, 2011–2022



Yee Hui Yeo[1] Lingyu Bao[2] Sheng-Yin Chen[3] Hanyou Loh[4] Peng-Sheng Ting[5] Ju Dong Yang[1] Hyunseok Kim[6] Karn Wijarnpreecha[7] Dian Chiang[8] Wei Zhang[3] Whitney Jackson[9] Fanpu Ji[10] Chun-Ying Wu[11], [1]Cedars-Sinai Medical Center, [2]Children's Hospital at Montefiore, [3]Massachusetts General Hospital, [4]Canton Medical Education Foundation, [5]Tulane University School of Medicine, [6]Cedars Sinai Medical Center, [7]University of Arizona College of Medicine-Phoenix, [8]Cleveland Clinic, [9]University of Colorado Denver, [10]Xi'an Jiaotong University, [11]National Yang MIng Chiao Tung University, Taiwan

Background: Alcohol-associated hepatitis (AH) is associated with high morbidity, functional decline, and complex supportive care needs. Nutrition consultation (NC) and physical therapy consultation (PT) may address modifiable risks, including poor intake, muscle wasting, frailty, and deconditioning. Nationwide patterns and predictors of NC and PT use in patients hospitalized with AH remain poorly characterized. **Methods:** We performed a retrospective study of the National Inpatient Sample (NIS) from 2011 to 2022. Adult hospitalizations with a primary diagnosis of AH (ICD-9: 571.1; ICD-10: K70.10/K70.11) were identified. NC and PT were identified using ICD diagnosis and procedure codes. Multivariable survey-weighted logistic regression was performed, adjusting for age, sex, race/ethnicity, income quartile, insurance type, Charlson Comorbidity Index (CCI), hospital region, teaching status, and bed size. **Results:** A total of 72,240 weighted AH hospitalizations were identified (mean

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

age 46.5 years; 40.2% female). In 2022, NC and PT utilization rates were 19.3% and 10%, respectively. NC rates showed no significant temporal improvement overall or across any subgroup. PT utilization increased sharply after 2015, coinciding with the ICD-9 to ICD-10 transition, with rates remaining relatively stable before and after. On multivariable analysis, female sex (vs. male, OR 1.37, 95% CI 1.22–1.54), CCI ≥ 3 (vs. CCI = 1, OR 2.26, 95% CI 1.94–2.63), South/Midwest/West region (vs. Northeast region, OR 1.62–1.89), and older age (vs. younger age, OR 1.01, 95% CI 1.00–1.02) were associated with higher odds of NC. Hispanic ethnicity was associated with lower NC odds (vs. non-Hispanic, OR 0.68, 95% CI 0.55–0.85). For PT, compared to non-Hispanic white, non-Hispanic Black (OR 2.61, 95% CI 1.00–6.78), Hispanic (OR 2.55, 95% CI 1.02–6.35), and other race (OR 3.41, 95% CI 1.37–8.53) patients demonstrated higher odds. In contrast, urban teaching hospitals were associated with lower PT odds (vs. urban non-teaching, OR 0.14, 95% CI 0.03–0.61). **Conclusion:** Utilization of NC and PT in AH remain persistently low nationwide with no improvement over 12 years, representing a critical unmet need. Observed sociodemographic differences suggest potential inequities in multidisciplinary supportive care for AH. Systematic approaches to nutrition assessment and functional evaluation may help address modifiable risks during AH hospitalization.

2177 | RECENT TRENDS IN ALCOHOL CONSUMPTION ACROSS LARGE UNITED STATES POPULATION-BASED SURVEY

Olajide Adekunle[1] Katharine Bradley[2] Lidia Rodriguez[3] Thanh Bui[4] Daniel Jonas[5] Sudie Back[6] Ha Tran[1] Phuc Le[1], [1]Cleveland Clinic, [2]Kaiser Permanente Washington Health Research Institute, [3]Case Western Reserve University, [4]The University of Oklahoma Health Sciences, [5]Ohio State University, [6]Medical University of South Carolina

Background: To assess the comparability of alcohol consumption estimates across population-based surveys and how changes in survey design and administration may affect temporal trends, we compared the average daily consumption (ADC) and prevalence of WHO-drinking risk levels in US adults across five major surveys. **Methods:** A repeated cross-sectional analysis was conducted using data from Population Assessment of Tobacco and Health Study (PATH), Behavioral Risk Factor Surveillance System (BRFSS), National Health Interview Survey (NHIS), National Health and Nutrition Examination Survey (NHANES), and National Survey on Drug Use and Health (NSDUH) from 2015 to 2024 or the most recent year available. ADC in grams per day (g/d) and the prevalence of drinking risk levels were estimated overall and stratified by age, sex, and race and ethnicity. Drinking risk levels were defined as abstinence (< 1 g/d), low-risk drinking (1-20 g/d among women and 1-40 g/d among men), and moderate-to-very-high-risk drinking (≥ 21 g/d among women and ≥ 41 g/d among men). All analyses accounted for complex survey design and were age- and sex-standardized. **Results:** Sample sizes ranged from 9,254 to 486,303 participants. ADC increased during COVID-19 pandemic across surveys and, in 2023, was lowest in NHIS (6.7 g/d) and highest in NSDUH (11.9 g/d). Although ADC decreased with increasing age, it remained stable or increased over time in older adults. In 2023, the prevalence of abstinence was lowest in NHIS (47.9%) and highest in BRFSS (58.2%), whereas the prevalence of low-risk drinking was highest in NHIS (47.9%) and lowest in BRFSS (37.5%). Over time, low-risk drinking increased in adults ≥ 50 years and women. In 2023, the prevalence of moderate-to-very-high risk drinking ranged from 3.9% in BRFSS to 7.2% in NHANES, which increased over time in most surveys except NSDUH and PATH. In NHANES, moderate-to-very-high-risk drinking increased among men, non-

Hispanic White and Hispanic individuals, and adults >25 years. **Conclusion:** Alcohol consumption estimates varied across major US population-based surveys, with greater divergence after the COVID-19 pandemic. Differences in survey design and administration should be considered when interpreting temporal trends in alcohol consumption.

2178 | UNMASKING MASH AND MASLD: INSIGHTS FROM AN ONLINE EDUCATIONAL PROGRAM

Laura Shelters[1] Deborah Talamonti[2] Steven Folstein[1] Leah Eberhardt[3] Lyndsey Aspaas[4] Patrice Lazure[2] Stephen Legault[4] Cara Orr[5] Sarah Repking[6] Hillary Lois[7] Niharika Samala[8] Suzanne Murray[2] Robert Fontana[9], [1]AASLD, [2]AXDEV Group Inc., [3]American Academy of PAs, [4]American College of Osteopathic Family Physicians, [5]Temple University Health System, [6]Rush University Medical Center, [7]VCOM-Virginia Campus, [8]Indiana University, [9]University of Michigan Hospitals and Health Centers

Background: Recent changes in the nomenclature and practice guidance of steatotic liver disease (SLD) called for educational efforts to disseminate the new terminologies. This study evaluates an educational program designed to enhance healthcare professionals' (HCPs') competence in screening, assessing, and managing patients with, or at risk of, SLD. **Methods:** An accredited educational program comprised of four 15-minute online modules (two didactic (1, 3), two skill-based (2,4)) was launched October 2025, targeting physicians, physician associates/nurse practitioners (PA/NP), and medical students/residents in primary care, general or internal medicine (primary audience) or gastroenterology, endocrinology, or hepatology (secondary audience). Each module included pre-/post-tests and evaluations. Knowledge-based multiple-choice questions were paired with confidence ratings to derive confidence-based learning (in which mastery corresponds to a good response provided with high confidence) before and after the education. Perceived skills and confidence in performing tasks related to patient management were assessed using Likert-type scales. Statistical analyses included Wilcoxon signed-rank tests (pre/post comparisons), Kruskal-Wallis tests (subgroup analyses), chi-square tests (categorical data), and thematic analysis (open-ended questions). **Results:** At month 3 of 12, 875 total learners accessed the program, with 735 modules completed. Participants were categorized as primary (36%); secondary (18%); and non-targeted audience (46%).Significant gains were observed for all modules (Figure 1) in confidence-based learning (% of completers who achieved mastery increased by 38.5% on average across 14 SLD-related knowledge questions, $p < .001$), skills and confidence (26% average gains respectively, across 9 questions, $p < .05$). Compared to the secondary audience, the primary and non-targeted groups gained greater knowledge across 7 SLD management-related items ($p < .05$), and increased their confidence in using primary assessment tools ($n = 274$, $\chi2 = 8.79$, $p = .012$) and in determining appropriate referral pathways ($n = 274$, $\chi2 = 9.70$, $p = .008$).Moreover, learners from the primary audience reported greater intention to improve screening of at-risk patients ($n = 334$ $\chi2 = 63.74$, $p < .001$) and patient referral ($n = 334$, $\chi2 = 15.06$, $p < .001$), whereas learners from the secondary audience reported wanting to improve patient education on lifestyle changes ($n = 281$ $\chi2 = 23.12$, $p < .001$). **Conclusion:** This 1-hour online educational program had a positive impact on HCPs' competence and intention to change clinical practice for patients with, or at risk of, SLD. Insights from this evaluation informed the adaptation of content for live educational activities, expanding the reach and potential impact of the program.

2179 | HUMAN AUDITS IMPROVE EHR-BASED HCV PATIENT RE-ENGAGEMENT: RESULTS FROM A US PROGRAM

Helen Nde[1] Natalie Spicyn[2] Peyton Thompson[3] Tasnim Bhuiyan[4] Jared Coe[5] Mariana Gomez De La Espriella[6] Tuesdae Stainbrook[7] Brandon Eurich[1] Susan Ford[7] Daemena Leocadio[4] Hannah Manley[5] Shivakumar Shivakumar[2] Corinne Spencer[3] Mandy Swann[6] Jasmine Jackson-Akers[6] Nicolette Fitzgibbon[8] Jihae Jeon[4] Stephen Ohakanu[2] Matthew Akiyama[5] Francina Collado[4] Kate McCormack[3] Lauryn Ursery[9] Donald Salami[2] Mariana Salamoun[6] Anna Mageras[10] Medha Thummala[3] Daryin Hummel[4] Lismeiry Paulino[4] Christopher Kim[4] Andrea Branch[11] Douglas Dieterich[4] Lisa Abuogi[12] Kim Arispe[13] Sandra Marrero-Ashford[14] Tiffany Austin[13] Victoria Awe[15] Marguerite Beiser[16] Nikita Bhatnagar[16] Erin Bredenberg[17] Robin Bricker-Ford[18] Ruth Brogden[19] Leigh Brooks[20] Edward Brown Jr[21] Nandanie Budhoo[19] Chooson Byambaa[15] Amie Cook[22] Benjamin Coy[23] Morgan Davis[24] Sarah Deans[21] Rebecca Dillingham[25] Ricardo Fonseca Franco[26] Brittany Freeman[13] Kelly Furr[23] Jennifer Galdamez[15] Sara Garcia[27] David Gonzalez[28] Ryan Gould[16] Samantha Hall[1] Meron Haile[29] Cassidy Hernandez-Tamayo[30] Lisa Holtzworth[25] Inzali Htut[15] Arlis "Jenkins "[31] Kevin Kamis[29] Saisreeram Kandula[26] Terry Kemp Knick[25] Jeffrey Klausner[30] Carolyn Knoll[32] Jay Kostman[32] Elizabeth Lewis[16] Cameron Lincoln[28] Alain Litwin[24] Claudia Lopez[16] Camille Lupianez-Merly[33] Lora Magaldi[32] Stefanie Mayorga[29] Elizabeth (Biz) Mcchesney[34] Jaymie Yango[19] Jennifer Moor[35] James Moore[23] Aaron Murray[16] Khadija Muse[16] Betty Nakitende[36] Hope Nalls[37] Liz Ramseur[38] Lillie Reder[39] Annabel Reyes[26] April Rideout[31] Jose Rodriguez[40] Janet Seabrook[37] Arsalan Shah[39] Sydney Sharp[41] Lindsey Sheehan[42] Marina Shestakova[26] Morgan Stacey[23] Chrysovalantis Stafylis[30] Lauren Stemboroski[33] Scott Strobel[27] Aryana Velez[19] Monica Vidaurrazaga[41] Su Wang[43] Andrea Washington[25] Brandi Wells[33] David Wyles[29] Lisa Yarber-Cambron[21] Yanxue You[28] Matthew Zeltner[23] Wendy Zou[15] Homie Razavi[1], [1]Center for Disease Analysis Foundation, [2]University of Maryland, Baltimore, [3]UNC Chapel Hill, [4]Icahn School of Medicine at Mount Sinai, [5]Albert Einstein College of Medicine & Montefiore Medical Center, [6]Carilion Clinic, [7]TruCare Internal Medicine & Infectious Diseases, [8]Montefiore Medical Center, [9]Gillings School of Global Public Health, [10]anna.mageras@mssm.edu, [11]Icahn School of Medicine at Mount Sinai (ISMMS), [12]University of Colorado, Anschutz Medical Campus, [13]First Choice Primary Care, Federally Qualified Health Center, [14]SandraAshford@hbi-dc.org, [15]Health Betterment Initiative, [16]Boston Health Care for the Homeless Program, [17]University of Colorado School of Medicine, [18]UCHealth, [19]Cooperman Barnabas Medical Center, RWJBarnabas Health, [20]Bluestone Primary Care, [21]Norton Healthcare, [22]Kansas Dept of Health & Environment, [23]University of Kentucky HealthCare, [24]Prisma Health, [25]Sentara Martha Jefferson Medical Group, [26]University of Miami, [27]Kansas Dept. of Health & Environment, [28]Asian Health Services, [29]Denver Health Medical Center, [30]Keck School of Medicine, University of Southern California, [31]Arizona Department of Health Services, [32]Philadelphia FIGHT, [33]University of Florida- Jacksonville, [34]Iowa Department of Health and Human Services, [35]University of Colorado, Denver CHIP Prevention, [36]bnakitende@chn-indiana.org, [37]Community HealthNet, Inc., [38]AIDS Leadership Foothills-area Alliance, [39]Central City Concern, [40]First Choice Primary Care, [41]Family Health Centers of San Diego, [42]lindsey.porter@uky.edu, [43]Cooperman Barnabas Medical Center, RWJBH

Background: Re-engaging patients who are lost to follow-up (LTFU) aids hepatitis C virus (HCV) elimination. The Relink grant funds US programs that re-engage LTFU HCV patients. Electronic health records (EHRs) connect patient data across health institutions, however, the completeness and usability of EHR data for LTFU HCV patient case-finding and re-engagement is underexplored. **Methods:** We examined factors linked to successful contact and re-engagement of LTFU HCV patients from Epic EHR-using and non-using organizations. Data came from 29 sites in diverse clinical and geographic settings. Pre-contact investigation (PCI), defined as human effort to verify LTFU status beyond EHR output, was encouraged. Exclusion criteria were standardized across sites. Re-engagement was defined as post-outreach laboratory or treatment provider visit. Fisher's Exact test, Chi-square tests, and Firth (penalized) logistic regression were performed for effects and significance. Regression variables included demographic and system-level factors. Results were analyzed in R v4.6.0. Copilot was used to troubleshoot R code. **Results:** 24,245 cases contacted from January 2024 to December 2025 were analyzed. Table 1 shows patient characteristics and outcomes. In-person contact (IPC) was used in 8% of cases and accounted for 22% of contact successes. Large registries (n > 5,000) had high odds of Epic use, and low odds of PCI, IPC and successful re-engagement. PCI alone weakly improved contact but with Epic

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

use, contact odds rose by 62%. IPC alone led to a 9-fold and 3-fold higher odds of contact and re-engagement respectively. In the multivariable models, Epic use was associated with extremely low contact (OR 0.06 CI: 0.05 – 0.07) and re-engagement (OR 0.02 CI: 0.01 – 0.03) odds. PCI overwhelmingly reversed Epic-use odds for both contact (OR 33.8 CI: 28.4 – 40.2) and re-engagement (OR 39.6 CI: 22.0 – 73.0). Adding IPC to the model dampened but did not negate PCI's effect on contact (OR 10.4 CI: 8.5 – 12.8) or re-engagement (OR 24.4 CI: 13.3 – 45.4). All effects were significant, and estimates were well-defined despite large test statistics. **Conclusion:** PCI remains linked to dramatically improved odds of contact and re-engagement in the multivariable models, even after adjusting for Epic use and IPC. This indicates human-mediated audits mitigate EHR data entry and resultant quality issues upstream of outreach. This supports better contact and re-engagement outcomes.

Table 1: Patient characteristics and re-engagement outcomes

Category	Contact Failure	Contact Success	Enrolled	Linked	% of Successful Contacts	% Linked of Successful Contacts	% Linked of All Contacts

2180 | TRENDS IN DIRECT-ACTING ANTIVIRAL PRESCRIPTIONS AMONG MEDICARE BENEFICIARIES: EXPANDING ROLE OF ADVANCED PRACTICE PROVIDERS AND REGIONAL DISPARITIES IN HEPATITIS C CARE

Kimberly Ho[1] Xiaohan Ying[2] Arun Jesudian[2] Paige McLean Diaz[3], [1]Brown University, [2]Weill Cornell Medicine, [3]Brown Medicine/Brown University Health

Background: Hepatitis C virus (HCV) infection affects approximately 2.4 million US adults. Yet despite direct-acting antivirals (DAAs) that achieve sustained virologic response (SVR) in >95% of cases, only 30% of Medicare beneficiaries with HCV receive timely, curative treatment within 12 months. Advanced practice providers (APP) have been proposed as key contributors to expanding DAA access, yet national prescribing patterns and regional distribution of DAA use remain incompletely characterized. We examined trends in provider type and regional variability in DAA prescribing among Medicare beneficiaries. **Methods:** We performed a retrospective, cross-sectional analysis of publicly available Medicare part D data from 2014-2021. Seven medications were included in this study: Harvoni®, Sovaldi®, Epclusa®, Mavyret®, Vosevi®, generic ledipasvir-sofosbuvir, generic sofosbuvir-velpatasvir. Outcomes included annual 30-day DAA prescriptions, number of beneficiaries receiving treatment, prescriber specialty (APP, gastroenterology [GI], primary care, infectious disease [ID], and other), and US Census region. Joinpoint regression was performed using R to evaluate temporal trends and annual percent change (APC) with 95% confidence intervals (CI). **Results:** From 2015 to 2021, the annual number of Medicare beneficiaries receiving DAAs declined despite increasing HCV rates among Medicare-eligible populations. APP involvement in DAA prescribing increased substantially, accounting for 27.1% of prescriptions in 2014 and 47.2% in 2021 (APC 9.52; 95% CI 7.5–11.5; $p < 0.001$). In contrast, GI specialists demonstrated the greatest decline in prescribing share among physician specialties (APC −7.53; 95% CI −8.99 to −6.05; $p < 0.0001$), with comparatively smaller contributions from ID and primary care providers. Regional analysis demonstrated declining DAA prescriptions across all US Census regions after 2015. The South accounted for the largest and increasing proportion of prescriptions over time (APC 4.05; 95% CI 2.89–5.23; $p < 0.001$), whereas prescribing shares declined in the Northeast and remained relatively stable in the West and Midwest. **Conclusion:** Although APPs now account for an increasing share of DAA prescribing among Medicare beneficiaries, overall DAA utilization has declined since 2015. Furthermore, the areas of highest HCV prevalence showed relative limited access to APP support, which may make progress towards HCV elimination difficult. Thus, persistent regional variation in treatment patterns highlights the need for targeted strategies to improve treatment access and delivery.

Figure 1. Share of HCV prescriptions by (a) prescriber specialty and (b) region.

2181 | CLINICAL SPECTRUM AND DISEASE BURDEN OF SYMPTOMATIC POLYCYSTIC LIVER DISEASE: A NATIONWIDE STUDY IN JAPAN

Kota Tsuruya[1] Satoko Ohfuji[2] Yusuke Mishima[1] Yoshitaka Arase[1] Shunji Hirose[1] Atsushi Tanaka[3] Tatehiro Kagawa[1], [1]Tokai University School of Medicine, [2]Osaka Metropolitan University, [3]Teikyo University School of Medicine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Polycystic liver disease (PLD) is often asymptomatic, but some patients develop clinically relevant symptoms or complications requiring specialized and multidisciplinary care. However, the nationwide burden, clinical spectrum, and healthcare needs of symptomatic PLD remain unclear. **Methods:** We conducted a two-stage nationwide epidemiological survey in Japan. In the first-stage survey, 3,127 of 10,270 institutions were selected by stratified random sampling and asked to report patients with symptomatic PLD treated or followed between 2021 and 2023. Symptomatic PLD was defined as ≥ 10 hepatic cysts with hepatic cyst-related symptoms or complications. In the second-stage survey, patient-level data were collected from institutions reporting symptomatic patients in 2023. **Results:** In the first-stage survey, 1,608 institutions responded (51.4%), and 2,684 patients were reported during 2021–2023. The estimated number of patients with symptomatic PLD was 6,500 (95% confidence interval [CI], 4,990–8,020) during 2021–2023 and 3,570 (95% CI, 2,780–4,360) in 2023, corresponding to period prevalences of 52.0 and 28.6 per million, respectively. In the second-stage survey, 557 patients were analyzed. The mean age was 63.7 years, and 344 of 555 patients (62.0%) were female. The median maximum hepatic cyst diameter was 8.1 cm; 218 patients (40.9%) had cysts ≥ 10 cm; and Gigot type III disease was observed in 121 of 543 patients (22.3%). Renal cysts were present in 453 of 547 patients (82.8%), and 368 (67.3%) fulfilled the definition of polycystic kidney disease. Older age was significantly associated with larger maximum cyst diameter (Spearman's $\rho = 0.33$, $P < 0.0001$). Patients with Gigot type III disease were younger and had higher frequencies of polycystic kidney disease and a higher proportion of deaths. The most frequent symptoms or complications were abdominal distension (39.7%), abdominal pain (21.0%), and cyst infection (18.3%). Larger maximum cyst diameter was associated with higher frequencies of mass-related symptoms, including abdominal distension, abdominal pain, loss of appetite, exercise limitation, and dyspnea. A history of hepatic cyst treatment was reported in 308 of 555 patients (55.5%). Cyst fenestration was reported as effective in 59 of 77 treatments (76.6%). Multidisciplinary consultation or inter-institutional referral was reported in 335 of 555 patients (60.4%), and 22 patients (3.9%) died. **Conclusion:** This nationwide survey estimated the burden of symptomatic PLD in Japan and identified clinically relevant patterns of disease severity, including age-related cyst enlargement and the association of Gigot type III disease with polycystic kidney disease and mortality. These findings provide baseline data for developing severity classification criteria, treatment strategies, and healthcare support systems for symptomatic PLD.

2182 | TARGETED HEPATITIS C TESTING AND LINKAGE AMONG UNHOUSED POPULATION IN SOUTHERN NEVADA THROUGH COMMUNITY-BASED OUTREACH AND CROSS-SECTOR COLLABORATION, 2024-2025

Shannon Pickering[1] Lourdes Yapjoco[1], [1]Southern Nevada Health District

Background: Southern Nevada Health District's Sexual Health Clinic and Sexual Health Outreach and Prevention Programs (SHOPP) have systematically increased the number of Hepatitis C (HCV) screenings conducted annually, aligning with the goals of the Viral Hepatitis National Strategic Plan. This national framework emphasizes testing and awareness, specifically among affected populations. Recognizing the elevated vulnerability of unhoused populations due to factors such as injection drug use, shared personal hygiene items, incarceration history, mental illness, and decreased access to healthcare, SHOPP intensified targeted HCV testing efforts among this group in 2025 as well as maximizing team resources to focus on increasing linkage to first provider visits. **Methods:** Data from 2024 and 2025 were compared, including testing volume, positivity rates, housing status, and linkage to care. In 2025, SHOPP expanded outreach partnerships with SNHD's Division of Disease Surveillance and Control, Help of Southern Nevada, and Nevada Homeless Alliance. Multidisciplinary teams (nurses, community health workers, and disease investigators) conducted testing in non-clinical settings. Staff also increased engagement through a whole person approach with unhoused clients, often providing transportation to first provider visits. **Results:** In 2024, 3,478 HCV tests identified 30 RNA-positive clients (0.86%), including 3 unhoused. Outreach accounted for 50 tests and 4 positives. Of all positives, 16 (53.3%) were linked to care; none of the unhoused clients were linked.In 2025, 4,626 tests identified 43 positives (0.93%), including 15 unhoused. Expanded outreach accounted for 130 tests and 16 positives. Of the 43 positives, 22 (51.2%) were linked to first provider visits, including 7 of 15 unhoused clients (46.7%).The proportion of positive clients who were unhoused increased from 10% to 34.9%, reflecting targeted outreach rather than increased prevalence. Linkage to care among unhoused individuals improved from 0% to 46.7%. **Conclusion:** The 2025 expansion of

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

targeted HCV testing among unhoused individuals by SHOPP demonstrates an effective strategy for improving identification in high-risk groups. By shifting clinic-based staff to street outreach and strengthening partnerships, SNHD increased testing and detection while addressing social determinants of health. Overall, linkage to first provider visits for Hepatitis C positive clients remain a significant challenge and even more so for the unhoused. However, with a whole person approach to linkage to care a significant improvement was made in 2025 linking unhoused clients . Expanding mobile, field-based care is critical to close gaps and advance HCV elimination goals. **Disclosures:** Shannon Pickering: Nothing to Disclose, Lourdes Yapjoco: Nothing to Disclose.

2183 | "IT NEVER GETS EASIER": EXPLORING BEREAVEMENT PRACTICES AMONG ADULT LIVER TRANSPLANT CLINICIANS

William Munroe[1] Anushka Dalvi[2] Grace Bizup[1] Malia Armstrong[3] Bailey Marshall[1] Abigail Scherrer[1] Ana Ivkovic[1] Kerry O'Brien[1] Laura Sterritt[1] Jane Lavallee[1] Nancy Mason[1] Sara Kenimer[1] Kirsten Engel[1] Michelle Diop[1] Karen O'Brien[1] Chengbo Zeng[4] Rennie Bimman[5] Nneka Ufere[1], [1]Massachusetts General Hospital, [2]Wayne State, [3]Duke University, [4]Brigham and Women's Hospital, [5]McGill University

Background: Advanced liver disease (AdvLD) is the 9th leading cause of death in the United States. Processing patient death is an inevitable part of the job of clinicians providing care to patients with AdvLD and their families. However, little is known about grief and bereavement practices among adult liver transplant (LT) clinicians. **Methods:** We conducted a mixed-methods study at a large academic LT center. Between 5/2025-6/2025, we surveyed adult LT clinicians to characterize their current bereavement practices and explore what resources could help clinicians process loss following patient death. Clinicians who completed the survey were invited to participate in individual semi-structured interviews conducted between 9/2025-5/2026 to further explore systemic and cultural barriers and facilitators to: 1) clinician outreach to bereaved caregivers and 2) opportunities for clinicians to emotionally process patient loss. We conducted a team-based qualitative thematic analysis of interview data to identify grief-related perspectives and processes. **Results:** In total, 73/114 (64%) clinicians completed the survey (20 hepatologists, 4 surgeons,16 fellows, 6 social workers, 11 APPs, 5 transplant coordinators, 5 nurses, 4 psychiatrists, 1 dietitian, 1 anesthesiologist). Following patient death, 61/73 (84%) clinicians reported contacting the primary caregiver or family to acknowledge the loss. However, only 17/61 (28%) reported providing material support to grieving families, which most commonly included social work follow-up, one-on-one psychological support, and referral to bereavement support groups. A majority of respondents expressed interest in expanding support for both grieving families and staff-facing bereavement through recurring remembrance ceremonies(n = 62, 85%), a standardized bereavement packet for families (n = 56; 77%), and formal bereavement training (n = 40, 55%). We conducted semi-structured interviews with 18 clinicians (4 hepatologists, 2 surgeons, 3 transplant coordinators, 1 fellow, 2 APPs, 2 nurses, 2 psychiatrists, 2 social workers). Qualitative analysis revealed four core themes: 1) Inconsistent and delayed death notification resulting in clinician distress and guilt; 2) Professional role ambiguity regarding ownership of outreach to bereaved families; 3) Cultural resistance to specialty palliative care integration in LT care; and 4) Lack of desired formal opportunities for peer-driven processing and bereavement resulting in compounded emotional burden and professional burnout. **Conclusion:** Although most LT clinicians identified bereavement outreach as a professional responsibility, inconsistent death notification, cultural resistance to palliative care, and role ambiguity were reported as barriers to engagement. Enhancing bereavement support in LT is crucial to improve clinicians' emotional processing after patient loss and mitigate professional burnout.

2184 | IMPROVING VIRAL HEPATITIS CARE ENGAGEMENT AND SHARED DECISION-MAKING THROUGH A GLOBAL PATIENT AND PROVIDER EDUCATION INITIATIVE

Mark Sulkowski[1] Tanyaporn Wansom[2] Kosh Agarwal[3] Leah Molloy[4] Laura Simone[4] Jenniffer Meza Jimenez[4] Jeffrey Carter[4] Cherilyn Heggen[4] Kelly Pillinger[4],
[1]Johns Hopkins Medicine, [2]Thai Red Cross AIDS and Infectious Diseases Research Centre, [3]King's College, [4]PRIME Education

Background: Despite advances in antiviral therapies and updated guideline recommendations, including treatment simplification, major gaps in viral hepatitis awareness, diagnosis, linkage to care, and treatment persist among vulnerable populations worldwide. **Methods:** From September 2025 – February 2026, a global initiative across the U.S., Europe, and Asia was conducted to improve HBV, HCV, and HDV screening, engagement, and treatment through (1) Community Care Forums (CCFs) for patients and vulnerable populations and (2) Clinical Practicums (CPs) for healthcare professionals (HCPs). CPs incorporated real-world patient perspectives and case-based learning tailored to regional needs. Pre- and post- surveys were administered for all sessions. **Results:** A total of 253 individuals participated in the CCFs (Table 1). Following the sessions, participants were more likely to perceive themselves at risk for HBV/HDV and HCV exposure in the next 6 months (HBV/HDV: 17% vs. 37%, p = 0.002; HCV: 30% vs. 63%, p < 0.001). The patient-reported likelihood of hepatitis testing within the next 30 days also increased significantly (HBV/HDV: 53% vs. 67%; p = 0.021; HCV: 45% to 71%, p = 0.005). Participants in the HCV CCFs gained confidence in their ability to protect themselves from HCV (67% vs. 92%, p < 0.001). In the HBV CCFs, while only 38% had completed HBV vaccination prior to the session, 77% of those who were unvaccinated reported they were somewhat or very likely to get vaccinated after the session.The initiative identified critical gaps in shared decision-making (SDM). Among patients, key barriers were difficulty understanding medical terminology (36%) and insufficient information from HCPs (35%), whereas 87% of HCPs reported lack of time during appointments as their primary barrier. Although 56% of all participants desired to be very involved in their own care, only 18% of participants with viral hepatitis (n = 38) reported being very involved. The most cited facilitator of follow-up care among those with hepatitis was a supportive HCP who clearly explained the benefits of regular monitoring.There were 102 HCPs who participated in the CPs with significant gains in HCP knowledge and confidence, including recognition of the burden of undiagnosed viral hepatitis (40% vs. 89%, p < 0.001), confidence in culturally competent communication (54% vs. 82%, p < 0.001), and commitment to incorporating SDM into hepatitis care (76% vs. 100%, p < 0.001). **Conclusion:** This viral hepatitis educational initiative improved perceived risk, screening intent, and engagement in care among vulnerable populations globally. Additionally, it improved HCP confidence in and commitment to incorporating shared decision-making in their care of individuals with viral hepatitis. Multi-platform educational strategies for both patients and HCPs remain essential to equip providers to deliver optimal care and achieve WHO hepatitis elimination targets.

2185 | INCREASING HEPATITIS C TREATMENT INITIATION AND LINKAGE TO CARE AMONGST PATIENTS HOSPITALIZED IN A SAFETY-NET ACUTE CARE SETTING: A RESIDENT-LED QUALITY IMPROVEMENT PROJECT

Bharathi Selvan[1] Chelsea Pan[2] Emma McCune[1] Joanna Krupp[1] Katie Leiner[1] Austin Peer[1] Madeline Stewart[1] Hannah Tierney[1] Lou Xie[1] Alexandra Moss[3] Lisa Winston[1] Anne Luetkemeyer[1], [1]University of California San Francisco, [2]University of California, San Francisco, [3]San Francisco Department of Health

Background: Despite curative direct-acting antivirals, HCV treatment uptake remains low in high-prevalence populations including people who use drugs and underserved groups. Hospitalization offers an opportunity to identify and treat patients not engaged in outpatient care. At our safety-net teaching hospital, patients hospitalized for >7 days and eligible per AASLD/IDSA guidelines for simplified HCV treatment can initiate treatment inpatient. However, fewer than 10% of eligible patients were started on treatment from Nov 2023- Nov 2024. **Methods:** We conducted a resident-led quality improvement project from July 1, 2025 to April 30, 2026 to improve inpatient HCV treatment initiation. Stakeholder interviews and a root cause analysis identified the lack of a standardized workflow and clinician knowledge of HCV treatment as core issues. A workflow was created, including treatment initiation criteria and instructions for medication approval (glecaprevir/ pibrentasvir or sofosbuvir/velpatasvir) and coordination with the specialty pharmacy. This was coupled with a shared tool in the electronic health record (EHR) that provided guidance regarding baseline labs, fibrosis scoring, and treatment plan options for use in progress notes and discharge summaries. For patients unable to start treatment inpatient, we recommended referrals to low barrier outpatient care and patient navigation. The initiative was presented to IM residents during didactics and reinforced with flyers, and monthly reminder emails. The percentage of admitted patients who were started on HCV treatment or discharged with an outpatient referral was tracked via a report in the EHR. **Results:** During this 10-month period, 168 patients with untreated HCV were admitted to our safety-net hospital of which 79 patients (47%) were cared for by an IM resident service. Of these, 21 patients were eligible for inpatient treatment initiation per project guidelines, and 4 patients (19% of those eligible) were started on inpatient treatment, which is double the historic 10% baseline. A majority, 43 patients (54%) were discharged with a low barrier outpatient HCV treatment referral, including to walk-in clinics, street medicine, treatment navigation, and primary care, ID, or hepatology follow up. Referral rates increased over the project period. **Conclusion:** Implementation of EHR-based tools and targeted education increased inpatient HCV treatment initiation above baseline and improved linkage to care, reinforcing the opportunity that hospital admissions provide for engaging patients in HCV care. Despite availability of robust low barrier resources, discharge referrals were only provided to half of patients, underscoring the need for further recognition of untreated HCV as well as innovation in HCV care delivery.

2186 | UNDERSTANDING PATIENT PERSPECTIVES ON RISK-STRATIFIED APPROACHES TO HCC SURVEILLANCE

Thomas Hunold[1] Rachel Bergmans[1] Neehar Parikh[1], [1]University of Michigan Medical Center

Background: Surveillance for hepatocellular carcinoma is associated with early tumor detection and improved survival; however, adherence to HCC surveillance is poor with only one quarter of patients receiving recommended testing. Risk-stratification for HCC risk is one novel approach to improve benefits and adherence to HCC surveillance in high-risk patients while minimizing harms to low-risk patients. We aimed to characterize patient Preferences surrounding HCC surveillance and attitudes toward risk-based surveillance paradigms. **Methods:** Patients with cirrhosis eligible for liver cancer screening were identified through the electronic health record. We performed a purposeful sampling with a balance of ages, genders, etiologies of liver disease, and adherence to surveillance recommendations. We conducted semi-structured interviews using a prespecified guide to allow the interviewer to explore patient understanding of liver

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

disease, current surveillance recommendations, experiences completing HCC surveillance recommendations, and perspectives on transitioning to a risk-stratified surveillance approach. Interviews were completed via Zoom video calls (or audio, if video unavailable), recorded, and transcribed. Thematic analysis was performed using rapid analysis techniques allowing for reflexive thematic analysis to develop preliminary themes. **Results:** A total of 3,119 patients were identified for potential inclusion. 419 charts were screened and 237 patients were contacted to enroll a total of 30 patients whose characteristics are shown in the Table 1. Four core themes emerged from the interviews: 1) a lack of information related to their liver disease (ie: severity of disease, implications of liver disease, and relationship to liver cancer), 2) scheduling of imaging tests became harder after this was no longer done at check-out from clinic visits, 3) transportation to imaging tests limited the ability of patients to complete their screening, 4) patients would be amenable to a risk-based screening approach as long as their physician had the ability to use clinical judgement outside of a strict surveillance protocol. Additionally, many patients were unable to provide a HCC risk level at which they would be willing to skip their next screening noting that they would rather have a false positive than skip a screening test if they were determined to be low risk for HCC. **Conclusion:** Patients in this study identified several barriers to completing HCC surveillance including a lack of information, trouble scheduling tests, and lack of transportation. While patients said they would be amenable to a risk-based surveillance approach, patients could not identify a threshold for de-escalation of surveillance, potentially limiting the implementation of risk-based surveillance in clinical practice.

Table 1. Characteristics of Included Patients

Characteristic	N = 30

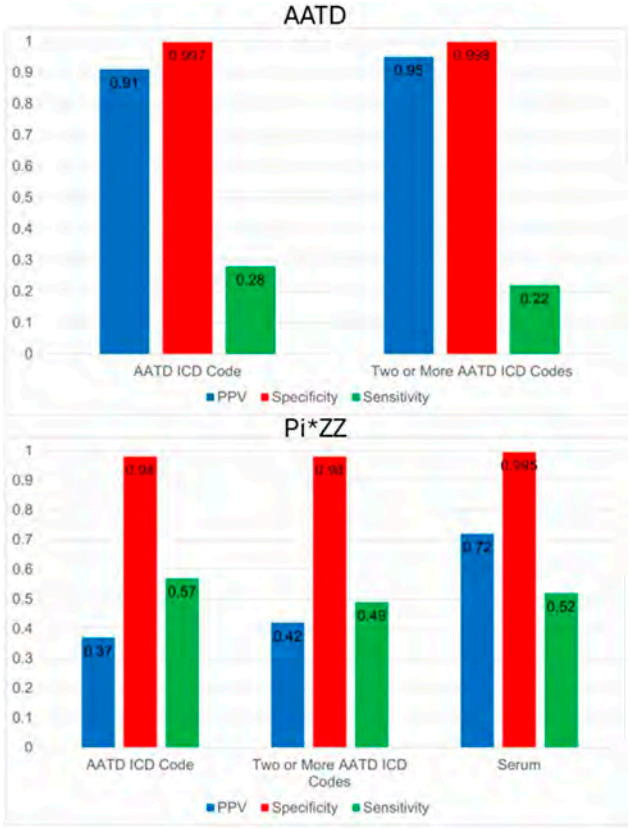
2187 | A MULTI-MODAL APPROACH TO IDENTIFYING ALPHA-1 ANTITRYPSIN DEFICIENCY ASSOCIATED LIVER DISEASE IN LARGE ADMINISTRATIVE DATABASES USING NATURAL LANGUAGE PROCESSING, DIAGNOSTIC CODES, AND SERUM BIOMARKERS



Dustin Bastaich[1] Bassam Dahman[1] Austen Hentschel[2] Chitra Karki[3] Tami Nussbaum[3] Suna Park[3] Seth Spector[4] Gregory Bigford[5] Brian Garnet[4] Michael Campos[4] John Binu[4], [1]Virginia Commonwealth University and Miami VA, [2]Florida International University and Miami VA, [3]Takeda, [4]University of Miami and Miami VA, [5]Miami VA

Background: Alpha-1 antitrypsin deficiency (AATD) increases susceptibility to chronic liver disease but remains underdiagnosed and insufficiently documented. Underdiagnosis occurs due to infrequent testing of both AAT levels and genotypes in patients with liver disease, while insufficient documentation is attributable to systematic under coding practices where providers fail to document and assign appropriate internal classification of diseases (ICD) codes. These issues may introduce bias in outcome studies. This study evaluated the diagnostic performance ICD9/10 codes for identifying AATD among patients with liver disease and assessed whether alpha-1 antitrypsin (AAT) serum levels < 50 mg/dl accurately identify patients with protease inhibitor (Pi)*ZZ genotype. **Methods:** This was a retrospective cohort study using Veterans Health Administration (VHA) database from January 2000 to April 2025. Veterans were included if they had a classifiable genotype at any time during the study period. Genotypes were ascertained using previously validated natural language processing (NLP) applied on medical records and lab comments, with high agreement with manual chart review (Kappa = 0.89). AATD was identified using ICD codes of 273.4 and E88.01, respectively. **Results:** There were 782 participants with an ICD code for AATD, and 2,540 participants with AATD genotypes (Pi* MZ, SZ or ZZ) identified by NLP-however, only 28.1% (n = 714) of participants with AATD had a corresponding ICD code. Coding prevalence varied by genotype: 17.2% among Pi*MZ,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

41.0% among Pi*SZ, and 57.3% among Pi*ZZ. Of 782 participants with an ICD code for AATD, 714 had genotype-confirmed AATD (PPV = 0.91) with a specificity of 0.997 and sensitivity of 0.28. Restricting the definition of AATD to ≥2 ICD codes (n = 584) resulted in only a marginal increase in PPV to 0.95 and specificity to 0.998, but reduced sensitivity to 0.22. For identifying Pi*ZZ genotype specifically, ICD 9/10 codes had lower performance (PPV = 0.37, specificity = 0.98, and sensitivity = 0.57). Restricting to ≥2 ICD codes modestly increased PPV to 0.42, while reducing sensitivity to 0.49 (specificity = 0.98).Of 290 participants with AAT serum level < 50 mg/dL (a surrogate for Pi*ZZ), 209 had Pi*ZZ genotype (PPV = 0.72). However, misclassification remained: 10.0% Pi*MM, 10.3% Pi*SZ, and 7.6% Pi*MZ, corresponding to specificity of 0.995 and sensitivity of 0.52 for identifying Pi*ZZ using AAT < 50 mg/dl **Conclusion:** While ICD codes for AATD demonstrate high specificity, they capture fewer than one-third of genotype-confirmed cases and perform poorly for identifying Pi*ZZ specifically. In contrast, an AAT serum level threshold of < 50 mg/dL offers a pragmatic surrogate for Pi*ZZ identification, outperforming ICD-based approaches. However, an NLP based approach identifying AATD genotype outperforms both ICD and AAT level-based approach to study AATD outcomes in administrative databases.

2188 | TRENDS IN AND DETERMINANTS OF HCC SURVEILLANCE ADHERENCE: A NATIONWIDE COHORT STUDY

Mohamed Moussa[1] Dave Sprengers[1] Willem Pieter Brouwer[1] Raoel Maan[1] Harry Janssen[1] Adriaan Van der Meer[1] Milan Sonneveld[1], [1]Erasmus University Medical Center

Background: Current guidelines recommend bi-annual liver imaging in patients with cirrhosis as it facilitates early diagnosis and potentially curative treatment. Previous studies in highly selected patient populations suggest suboptimal adherence to surveillance. However, real-world data on longitudinal adherence and contemporary disparities remain limited. We aimed to study time-trends in and determinants of HCC surveillance adherence in a nationwide sample. **Methods:** We identified patients receiving hospital-based care for cirrhosis in the Netherlands from 2015 to 2023 through a search of the Dutch Central Bureau of Statistics (CBS) database. Information on diagnostic procedures was obtained through cross-referencing with insurance claims databases. Adherence was assessed in 14-month intervals, with optimal adherence defined as ≥ 2 abdominal imaging studies within that timeframe. Longitudinal trends in adherence were analyzed using Generalized Estimating Equations (GEE), while a multivariable logistic regression model was fit adjusted for sex, etiology of cirrhosis (viral/non-viral), cirrhosis status (compensated/decompensated), hospital type (academic/general), socioeconomic status, and country of birth (Netherlands/elsewhere) to identify contemporary determinants of non-adherence in the most recent year (2023-2024). **Results:** We identified 23,467 individuals with cirrhosis (63% compensated), the majority of whom were male (60%). Mean age was 62.1 years (SD ± 12.4) and non-viral etiology predominated (85%). Between 2015 and 2023, the number of patients increased by 65% (from 5,521 to 9,133). The rate of optimal adherence increased from 17% to 40% (Annual percentage change [APC]: 11.3% [95% CI: 10.6–12.1]; p < 0.001), while the proportion of patients who underwent no surveillance at all declined from 24% to 14%. Multivariable GEE models identified management in an academic hospital (aOR: 1.44 [95% CI: 1.37–1.52]; p < 0.001) and decompensated cirrhosis (aOR: 1.08 [95% CI: 1.04–1.13]; p < 0.001) as independent predictors of optimal adherence. Among

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

patients in care in 2023 (n = 9,133), management in an academic hospital remained associated with a higher likelihood of optimal adherence (aOR: 1.40 [95% CI: 1.23–1.58]; p < 0.001), while lower socioeconomic status was associated with a reduced likelihood of optimal surveillance (aOR: 0.90 [95% CI: 0.82–1.00]; p = 0.04). **Conclusion:** Although HCC surveillance adherence appears to be improving over time, biannual imaging rates remain suboptimal. As we observed disparities across hospitals and socioeconomic statuses, our findings call for initiatives to ensure the equitable delivery of this life-saving preventative care.

2189 | MACHINE LEARNING IDENTIFIES SURVEILLANCE ENTRY AS THE OPTIMAL WINDOW FOR HEPATOCELLULAR CARCINOMA SURVEILLANCE INTERVENTION IN A SAFETY-NET POPULATION

Leila Taj[1] Kang Wang[2] Violet Wolfe[1] Hailey Choi[2] Mandana Khalili[1], [1]University of California San Francisco, Division of Gastroenterology and Hepatology, [2]University of California San Francisco

Background: Hepatocellular carcinoma (HCC) surveillance adherence is suboptimal in safety-net populations, yet clinicians lack pragmatic tools to identify patients at high risk for surveillance dropout early enough to target intervention. We aimed to develop a model using clinical characteristics to predict surveillance non-adherence and assessed how long these baseline risk factors retain utility relative to dynamic factors on follow-up. **Methods:** We used data from 1,004 adults (mean age 60 years; 56% male) undergoing ultrasound-based HCC surveillance at an urban safety-net health system between June 2020 and December 2024 (median follow-up 50 months; up to 6 visits). HCC surveillance adherence was categorized as full, partial, or non-adherent based on AASLD guidelines. Twenty-three prespecified baseline demographic, clinical, behavioral, and access-related variables were used to fit logistic regression (LR) and two tree-based models (random forest and XGBoost) to predict non-adherence. We then applied the baseline model to visits 2–6 to evaluate the persistence of the predictive utility of risk factors identified at baseline over time. Separately, we developed a visit-level model that included the following dynamic variables on follow-up: US findings (US LI-RADS categories and visualization scores), time since the prior ultrasound, and surveillance adherence at the prior visit to predict full adherence at the next visit. **Results:** At baseline, the LR model matched or outperformed tree-based models in predicting adherence, suggesting a predominantly linear relationship between risk factors associated with non-adherence. The model predicted future non-adherence with an AUC of 0.76 and conversely, full adherence with an AUC of 0.75. The strongest baseline predictors included older age, BMI, prior ultrasound completion, hepatology clinic attendance, and current smoking or alcohol use. Performance was highest at baseline and remained modest through visit 4 (AUC 0.59–0.70), with attenuation at later visits as the non-adherent subgroup declined from 331 patients at visit 1 to 11 at visit 6, leaving an increasingly homogeneous adherent cohort. In the visit-level model, time since prior ultrasound was the strongest predictor of next-visit adherence and outperformed baseline characteristics. **Conclusion:** A pragmatic risk score predicts HCC surveillance non-adherence, with peak performance at baseline, supporting surveillance entry as the optimal time for targeted equity-focused adherence interventions in the safety-net population. The length of time between surveillance visits, on the other hand, provides a simple real-time signal for outreach to enhance adherence once surveillance is underway.

2190 | CLINICAL PRACTICE PATTERNS IN THE ASSESSMENT AND TREATMENT OF METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Sonal Kumar[1] Naim Alkhouri[2] Ibiagbani Max-Harry[3] Jeffrey Carter[3] Chelsie Anderson Chadha[3] Emily Zyborowicz[3] Leah Molloy[3] Laura Simone[3] Jennifer Balmer[3], [1]Weill Cornell Medicine, [2]Summit Clinical Research, [3]PRIME Education

Background: Management of metabolic dysfunction-associated steatohepatitis (MASH) is rapidly evolving with increasing validation of noninvasive liver disease assessments (NILDAs) and recent FDA-approval of two treatment options for patients with stage F2–F3 fibrosis; however, real-world practice patterns remain unclear. We sought to evaluate current practices for MASH assessment and treatment and identify opportunities to improve care. **Methods:** A nationwide survey was disseminated in March 2025 via email to hepatology and gastroenterology providers as part of an educational initiative. Survey items assessed approaches to fibrosis staging, use of NILDAs, treatment practices, and barriers to care. **Results:** A total of 100 healthcare professionals completed the survey, including gastroenterologists (80%), hepatologists (5%), advanced practice providers (10%) and other providers (5%) practicing across private (57%), academic (18%), hospital outpatient (16%), and specialty (7%) settings. Most providers reported using NILDAs for fibrosis assessment, including the FIB-4 index (76%), vibration-controlled transient elastography (VCTE; 83%), Enhanced Liver Fibrosis (ELF) test (49%), and magnetic resonance elastography (MRE) (20%), while 21% reported use of liver biopsy. Although 82% reported liver biopsy is not routinely required prior to treatment, 55% cited uncertainty regarding NILDA selection and sequencing as a key challenge. Treatment of patients with F2–F3 MASH varied substantially; 36% reported fewer than half of eligible patients were receiving FDA-approved therapy (resmetirom and/or semaglutide). Among lower adopters, top barriers were lack of institutional protocols (50%), uncertainty identifying treatment candidates (31%), and referral of patients at advanced fibrosis stages (31%), whereas higher adopters more frequently cited prior authorization burden (70%) and safety/tolerability concerns (47%) (Figure). **Conclusion:** Although noninvasive tests are widely replacing biopsy for fibrosis assessment and treatment decision-making, uncertainty persists in their application. Use of FDA-approved therapies for eligible patients varies substantially, with lower adopters more frequently citing foundational knowledge gaps and lack of protocols as key barriers. These findings suggest a need for targeted education and practical tools to support consistent, evidence-based integration of noninvasive assessment strategies and new therapies into clinical practice.

Clínicas Norberto Quirno "CEMIC, [4]Liver Unit, Hospital R.A. Calderón Guardia

Background: Scientific production reflects research capacity, innovation, and healthcare priorities within hepatology systems. However, contemporary analyses evaluating scientific asymmetries and thematic transition across Latin American hepatology are limited. **Methods:** We performed a scientometric analysis of 191 abstracts submitted to ALEH 2025. Abstracts were categorized according to thematic area, methodological design, country of origin, and multinational collaboration. Scientific productivity was normalized per million inhabitants, and countries were grouped into exploratory research ecosystem clusters according to production volume and thematic diversification. **Results:** MASLD was the leading research topic (21.5%), followed by cirrhosis/portal hypertension (18.3%), HCC (14.1%), and viral hepatitis (13.1%), reflecting the evolving regional liver disease burden. Scientific production was highly concentrated, with Mexico (n = 44), Brazil (n = 41), and Colombia (n = 23) accounting for most submissions. However, normalization by population revealed disproportionately high productivity in Uruguay (1.71 abstracts/million inhabitants), Costa Rica (1.13), and Chile (0.85). Observational studies represented 76.4% of submissions, whereas clinical trials (1.6%) and AI/big-data studies (3.1%) were uncommon, suggesting limited interventional and technological research capacity. Only 19 abstracts involved multinational collaborations. **Conclusion:** Latin American hepatology demonstrates increasing thematic diversification but persistent scientific concentration, low interventional research density, and limited technological innovation. Scientometric ecosystem analysis may help identify strategic opportunities for regional collaboration, research prioritization, and capacity development in emerging hepatology systems.

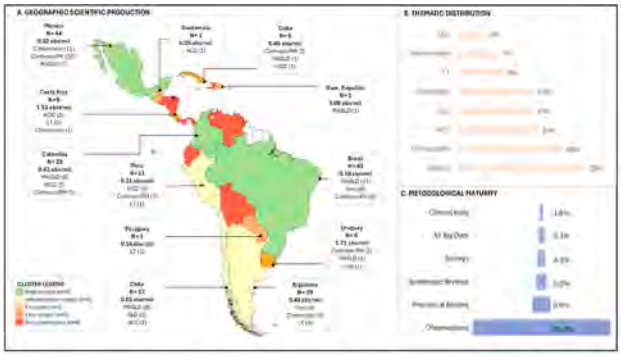

Figure 1. Geographic scientific production, thematic specialization patterns, and methodological composition of hepatology research across Latin America based on ALEH 2025 abstract submissions. Countries were categorized into exploratory research ecosystem clusters according to abstract volume and thematic diversification. Boxes summarize total scientific production, abstracts normalized per million inhabitants (abs/million), and dominant thematic areas. Panel B displays the overall thematic distribution of submitted abstracts, whereas Panel C illustrates methodological composition and research maturity across the region.

2192 | GENERAL POPULATION CIRRHOSIS SCREENING - LONGITUDINAL FERRITIN DATA COMBINED WITH A CUMULATIVE LIVER DAMAGE INDEX ENHANCES POPULATION-LEVEL DETECTION OF CIRRHOSIS: SECONDARY ANALYSIS OF THE LIVEWELL TRIAL.

Katie Denver[1] Christina Owen[2] Neil Stevens[1] Axelle Caudrillier[3] Yasmin Hamadache[3] Heath O'Brien[3] Louise Campbell[4] Patrick Short[3] Jamie Webb[3] Katie Barnes[3], [1]Predictive Health Intelligence, [2]Somerset NHS Foundation Trust, [3]Sano Genetics, [4]Tawazun Health

Background: We have previously demonstrated that the Cumulative Liver Damage Index (CLDI), integrating longitudinal routine alanine aminotransferase (ALT) data from patient records, identifies clinically significant fibrosis (F2+) with receiver operator characteristic area under the curve (ROC-AUC) 0.884, outperforming published FIB-4 population benchmarks (LiveWell study; presented EASL 2026). CLDI independently predicted cirrhosis (F4; OR 5.02, $p < 0.01$). Ferritin, a marker of hepatic inflammation and metabolic dysfunction, may provide a discriminatory signal for advanced fibrosis. We hypothesised that mean longitudinal ferritin would enhance F4 prediction using routinely available blood test results. **Methods:** Secondary analysis of LiveWell study data (994 participants, aged 25-55, Somerset, United Kingdom). The cohort with complete transient elastography (TE) data (N = 627) included 51 F2+ cases (TE ≥ 8kPa) and 18 F4 cases (TE ≥ 12kPa). Logistic regression models (age, sex, BMI, log-CLDI, mean platelets) were evaluated with and without mean ferritin (60-month window) for both F2+ and F4 outcomes. Blood-test-only models (substituting BMI with platelet minimum and HbA1c mean) were assessed. The impact of mean red blood cell volume (MCV) was analysed as a potential marker of alcohol use. Performance was quantified by 5-fold cross-validated AUC (CV-AUC) and DeLong comparison. F4 analyses are exploratory given low event rate. **Results:** The F2+ base model achieved CV-AUC 0.879. Adding ferritin produced no significant improvement on DeLong comparison ($p = 0.37$), confirming no additional benefit of using ferritin for moderate fibrosis. For F4, the base model achieved apparent ROC-AUC

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

0.904. Ferritin was independently associated with cirrhosis (p = 0.008) and improved apparent ROC-AUC from 0.904 to 0.924; DeLong comparison did not reach significance (p = 0.25), consistent with insufficient power at 18 events. Blood-test-only models demonstrated consistent directionality (apparent ROC-AUC 0.870; +ferritin 0.891; DeLong p = 0.052). The ferritin association was specific to F4 across all model variants. MCV had no effect on the performance of any of these models **Conclusion:** Longitudinal ferritin adds a consistent signal for cirrhosis detection, but no significant improvement on DeLong comparison for F2+ fibrosis (p = 0.37), supporting a potentially distinct role in advanced liver disease. The lack of signal for MCV would suggest this is mediated via metabolic hyperferritinaemia rather than alcohol. These preliminary findings require validation in a larger cohort. Routine identification of previously undiagnosed cirrhosis would define patients requiring enrolment in hepatocellular carcinoma (HCC) surveillance programmes and recruitment to emerging cirrhosis-specific therapeutic trials, representing a high-value application of population-level longitudinal data.

2193 | CLINICALLY SIGNIFICANT LIVER STIFFNESS AND ROUTINE DETECTION GAPS IN YOUNG ADULTS IN THE U.S.

Ariana Bockstahler[1] Megan Roach[1] Jeffrey Schwimmer[1], [1]University of California, San Diego

Background: Liver disease presenting clinically in young adulthood is increasing, yet fibrosis risk assessment is oriented toward selected high-risk groups which may not adequately capture young adults. Vibration-controlled transient elastography (VCTE) can identify clinically concerning liver stiffness before overt clinical recognition. We estimated the national prevalence of elevated liver stiffness and clinically significant liver stiffness among young adults in the U.S. and assessed how often these findings occurred in the absence of potential clinical triggers for further fibrosis evaluation. **Methods:** We analyzed adults aged 18–34 years in the 2017–March 2020 National Health and Nutrition Examination Survey with valid VCTE. Liver stiffness measurement (LSM) was categorized as <8, ≥ 8, and ≥ 12 kPa. LSM ≥ 8 kPa was defined as elevated liver stiffness in a fibrosis range. LSM ≥ 12 kPa was defined as clinically significant liver stiffness. We assessed whether elevated liver stiffness occurred in young adults without potential clinical triggers for further fibrosis evaluation. The potential clinical triggers were defined as ALT > laboratory reference range, clinical or laboratory evidence of diabetes, class 2 or 3 obesity (BMI $\geq$ 35 kg/m²), and elevated FIB-4 (≥ 1.3). Survey-weighted prevalence estimates, 95% confidence intervals, and U.S. population counts were calculated using NHANES examination weights and design variables. **Results:** The analytic sample included 2,175 young adults, representing 68.4 million young adults in the U.S. aged 18–34 years. LSM ≥ 8 kPa was present in 6.1% (95% CI, 4.7%–8.0%), corresponding to 4.19 million young adults. LSM ≥ 12 kPa was present in 1.8% (95% CI, 1.1%–3.0%), corresponding to 1.25 million young adults. Among young adults with LSM ≥ 8 kPa, 64.6% had ALT within the laboratory reference range, 97.7% had no clinical or laboratory evidence of diabetes, 43.1% had BMI <35 kg/m², and 99.2% had FIB-4 <1.3. Among those with LSM ≥ 12 kPa, 62.5% had ALT within the laboratory reference range, 99.0% had no clinical or laboratory evidence of diabetes, 26.1% had BMI <35 kg/m², and 99.0% had FIB-4 <1.3. **Conclusion:** In a nationally representative sample, approximately 4.2 million young adults in the U.S. had elevated liver stiffness and 1.25 million had clinically significant liver stiffness. Most young adults with clinically significant liver stiffness had ALT within the laboratory reference range, no clinical or laboratory evidence of diabetes, and FIB-4 <1.3. These findings identify a young-adult detection gap in liver fibrosis risk assessment and support development of age-appropriate strategies to recognize clinically important liver stiffness earlier in adulthood.

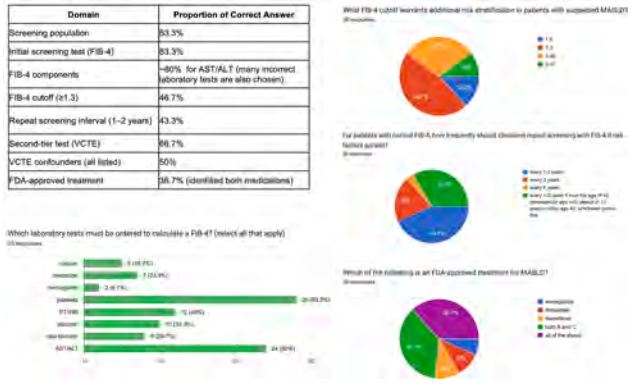
2194 | MASLD SCREENING KNOWLEDGE ASSESSMENT: A QUALITY IMPROVEMENT SURVEY AT A RESIDENT PRIMARY CARE CLINIC

Kimberly Ho[1] Alex Chang[1] Rebekah Gardner[1] Paige McLean Diaz[2], [1]Brown University, [2]Brown Medicine/ Brown University Health



Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) remains largely underdiagnosed in the routine clinical care of patients outside hepatology clinics. The 2025 American Diabetes Association (ADA) consensus recommends systematic fibrosis screening in high-risk patients using the Fibrosis-4 (FIB-4) index in primary care settings. We assessed baseline knowledge of MASLD screening and management among clinicians at our resident primary care clinic as part of a QI initiative to improve FIB-4 screening rates. **Methods:** We administered an 8-question survey to residents and attendings who practice at an internal medicine residency-affiliated primary care clinic. Questions assessed knowledge in three domains: (1) target population and screening interval, (2) FIB-4 interpretation and ordering, and (3) management of abnormal results. We identified questions in which more than half of responses were incorrect as representing a significant knowledge gap. Respondent demographics and self-reported guideline familiarity were also collected. **Results:** Among the 30 respondents, half were attendings (53.3%) and the remainder were PGY-3 residents (6.7%), PGY-2 residents (30.0%), and PGY-1 residents (10.0%). 90% of respondents had not yet read the ADA guidelines on MASLD screening, and 83.3% reported being "not at all" or only "slightly" familiar with them. Correct response rates varied substantially across domains, with an average score of 4.33/8 points. 83.3% correctly identified FIB-4 as the initial screening test, and 66.7% identified transient elastography (VCTE) as the appropriate second-tier test for MASLD. While 80% recognized AST/ALT as required FIB-4 components, 40% also incorrectly included PT/INR. Fewer than half of respondents selected the guideline-recommended FIB-4 cutoff of $\geq$1.3 for further risk stratification (46.7%) and the recommended 1-2 year rescreening interval (43.3%). Only a third (36.7%) correctly identified both FDA-approved treatments for MASH. **Conclusion:** This baseline survey revealed knowledge gaps in MASLD screening and management among primary care clinicians, particularly regarding FIB-4 components, the $\geq$1.3 cutoff threshold, and current FDA-approved pharmacotherapy. These findings, in the context of very low self-reported guideline familiarity, identify high-yield targets for educational intervention as part of our QI initiative to implement systematic FIB-4 screening in clinic. Planned interventions for this QI project include clinician education sessions, increase uptake of FIB-4 calculation into the electronic health record, and development of a clinical decision support algorithm based on the two-tier FIB-4/VCTE screening pathway.

Figure 1. Survey results and frequently missed questions.

Domain	Proportion of Correct Answer
Screening population	53.3%
Initial screening test (FIB-4)	83.3%
FIB-4 components	~80% for AST/ALT (many incorrect laboratory tests are also chosen)
FIB-4 cutoff (≥1.3)	46.7%
Repeat screening interval (1–2 years)	43.3%
Second-tier test (VCTE)	66.7%
VCTE confounders (all listed)	50%
FDA-approved treatment	36.7% (identified both medications)

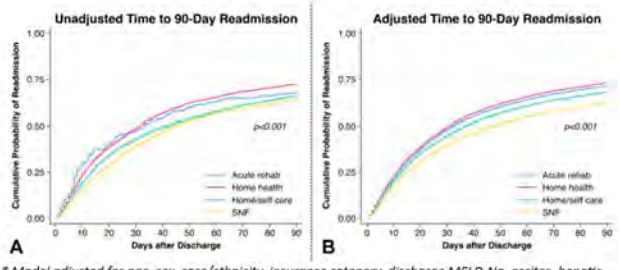
2195 | DISCHARGE DISPOSITION IS INDEPENDENTLY ASSOCIATED WITH 90-DAY READMISSION FOLLOWING CIRRHOSIS HOSPITALIZATION

Yiwei Hang[1] Jonathan Heintz[2] Nadim Mahmud[1], [1]Hospital of the University of Pennsylvania, [2]University of Pennsylvania



Background: Cirrhosis is associated with high rates of hospitalization, readmission, and mortality, making transitions of care a critical target to improve outcomes and to reduce healthcare utilization. Discharge disposition, defined as the level and location of care after hospitalization, may influence post-discharge outcomes in patients with cirrhosis. We aimed to evaluate the association between discharge disposition after an index hospitalization for cirrhosis and subsequent hospital readmission. **Methods:** We conducted a retrospective cohort study of patients with a first cirrhosis-related hospitalization within the University of Pennsylvania Health System from 1/1/2016 to 1/1/2026, excluding those who did not survive to discharge. Eligible patients were identified through The Center for Data, Outcomes, & Team Science (CDOTS) registry. Demographics, cirrhosis decompensations, comorbidities, insurance status, and hospitalization data were obtained. The primary exposure was discharge disposition, classified as skilled nursing facility (SNF), home health (HH), home/self-care, and acute rehabilitation. The primary outcome was time to hospital readmission within 90 days, using Kaplan-Meier and multivariable Cox proportional hazards models for unadjusted and adjusted analyses, respectively, with censoring at death or end of follow-up. **Results:** A total of 6,331 first hospitalizations for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

cirrhosis were included. The most common discharge disposition was home/self-care (44.7%), followed by HH (35.7%), SNF (16.9%), and acute rehabilitation (2.8%). Patients discharged to SNF were older (median age 67.3) and more likely to have Medicare (65.7%), whereas those discharged to home were more likely to have Medicaid (22.6%) or commercial insurance (39.2%). Comorbid conditions such as ascites, hepatic encephalopathy, diabetes, congestive heart failure, chronic kidney disease, and chronic obstructive pulmonary disease differed significantly across discharge disposition groups. Time to hospital readmission differed by discharge disposition in Kaplan-Meier analysis (log-rank $p < 0.001$; **Figure 1A**). In adjusted Cox regression analyses, discharge with HH was associated with increased hazard of 90-day readmission compared with home/self-care (HR 1.15, $p < 0.001$), whereas discharge to SNF was associated with lower risk (HR 0.85, $p = 0.003$; **Figure 1B**). **Conclusion:** Among patients surviving a first cirrhosis-related hospitalization, discharge disposition was independently associated with 90-day readmission risk. The lower observed readmission risk among patients discharged to SNF, despite greater baseline clinical vulnerability, highlights the complexity of using readmission as a post-discharge quality metric in this population. These findings support further evaluation of how discharge setting, patient severity, and post-discharge care structure interact to shape outcomes in cirrhosis.

Figure 1: Time to Post-Discharge Readmission in (A) Unadjusted Kaplan-Meier and (B) Adjusted Cox Regression Models*

* Model adjusted for age, sex, race/ethnicity, insurance category, discharge MELD-Na, ascites, hepatic encephalopathy, diabetes mellitus, heart failure, CKD, COPD, mechanical ventilation, and length of stay

2196 | HOW LIVER CIRRHOSIS AFFECTS CLINICAL OUTCOMES OF ACUTE PANCREATITIS: A NATIONWIDE ANALYSIS

Ahmed Ali Aziz[1] Sara Rahman[2] Muhammad Ali Aziz[3] Taseen Ahmed Syed[1] Rehan Shah[4] Muhammad Amir[1] Ijlal Akbar Ali[5], [1]INTEGRIS Health Baptist Medical Center, Oklahoma City, Oklahoma, [2]Services Institute of Medical Sciences, Lahore, Pakistan, [3]University of Kentucky School of Medicine, Lexington, Kentucky, [4]Bayonne Medical Center, Bayonne, New Jersey, [5]University of Pennsylvania, Philadelphia, Pennsylvania

Background: Acute pancreatitis (AP) is a leading cause of gastrointestinal-related hospitalizations in the United States and is associated with significant morbidity, mortality, and healthcare expenditures. Patients with liver cirrhosis (LC) exhibit immune dysregulation, portal hypertension, altered hemostasis, and reduced physiologic reserve, which may adversely affect outcomes during acute inflammatory illnesses. We aimed to evaluate the impact of concomitant liver cirrhosis on hospitalization outcomes among patients admitted with acute pancreatitis.
Methods: We conducted a retrospective cohort study using the Nationwide Inpatient Sample (NIS) database from 2020–2022. Adult hospitalizations with a primary discharge diagnosis of acute pancreatitis were identified using ICD-10-CM codes. Patients were stratified by the presence or absence of a secondary diagnosis of liver cirrhosis. The study included 14,179 hospitalizations with cirrhosis and 723,959 without cirrhosis. Multivariable regression analyses adjusted for demographics, hospital characteristics, and relevant comorbidities. Outcomes included in-hospital mortality, shock, acute renal failure (ARF), venous thromboembolism (VTE), intensive care unit (ICU) admission, length of stay (LOS), and total hospitalization costs adjusted to 2022 U.S. dollars.
Results: Patients with cirrhosis experienced significantly worse outcomes compared with those without cirrhosis. Liver cirrhosis was independently associated with increased odds of in-hospital mortality (aOR 1.72, 95% CI 1.22–2.42, $p = 0.002$), shock (aOR 1.87, 95% CI 1.42–2.46, $p < 0.001$), ARF (aOR 1.44, 95% CI 1.30–1.49, $p < 0.001$), ICU admission (aOR 1.62, 95% CI 1.38–1.91, $p < 0.001$), and VTE (aOR 1.65, 95% CI 1.29–2.11, $p < 0.001$). Cirrhosis was also associated with longer LOS (β +0.46 days, 95% CI 0.25–0.66, $p < 0.001$) and higher hospitalization costs (β +$4,163.48, 95% CI $1,530.94–$6,796.02, $p = 0.002$). **Conclusion:** Among patients hospitalized with acute pancreatitis, concomitant liver cirrhosis is associated with significantly higher mortality, greater risk of shock, renal failure, VTE, and ICU utilization, as well as prolonged hospitalization and increased healthcare costs. These findings suggest that cirrhosis is an important prognostic marker in acute pancreatitis and may identify a high-risk population that could benefit from closer monitoring, early recognition of complications, and more intensive multidisciplinary management.

2197 | LEVERAGING A SYSTEM-LEVEL PROVIDER-FACING FIBROSIS SCREENING DASHBOARD: SIGNALING THE NEED FOR A MASH QUALITY MEASURE

Anna Mageras[1] Arshad Rahim[2] Alexandra Ingber[2] Kristie Heiden[2] Christopher Pae[2] David Lam[1] Xiaotao Zhang[3] Francis Lobo[4] Suneil Hosmane[4] Grace Kiernan[5] Meena Bansal[6], [1]Icahn School of Medicine at Mount Sinai, New York, NY, USA, [2]Mount Sinai Health System, New York, NY, USA, [3]Icahn School of Medicine at Mount Sinai, [4]Madrigal Pharmaceuticals, Conshohocken, PA, USA, [5]MASHNET (Liver Health Leaders Network), New York, NY, USA, [6]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: With the underdiagnosis of MASH with significant fibrosis, there is a growing need for tools that will support health system–level screening. To this end, we developed a primary care (PC) and endocrinology (endo)–facing fibrosis dashboard in the electronic health record (EHR) for patients living with diabetes (PWD) as a demonstration project for health systems to automate reporting and streamline adherence to a MASH Care Pathway (CP). **Methods:** Stakeholders including internal Epic IT team, population health leaders, and front-line providers were convened to build a provider-facing dashboard using a screening algorithm. For adult patients in the Mount Sinai Diabetes Registry, the algorithm calculates a FIB-4 score for each patient based on their most recent lab results. Patients are sorted into a) Intermediate Risk (age 18-64: FIB-4 1.3-2.67, 65-84: FIB-4 2.0-2.67), and b) High Risk (FIB-4 > 2.67). Quarterly metrics with a 36-month lookback include the number and percentage of patients who have a FIB-4 score, and who have received referrals and completed secondary testing based on FIB-4 values. Patients age 85+ and those in care with hospice or palliative care were excluded. The dashboard enables specialty, clinic, and provider-level reporting, as well as lists of patients who still need labs or referrals. The dashboard also has built-in bulk orders for FIB-4 labs, bulk referrals for secondary testing, and bulk personalized patient messaging in the patient-facing portal. Baseline metrics and cohort characteristics were extracted for primary care and endocrinology and compared using Chi-square tests in SAS. **Results:** The baseline population included 57,196 PWD across endo and PC who were eligible for fibrosis screening. Demographics, FIB-4 scores, and HbA1c levels were similar across clinic types. Among 10,223 PWD seen by both PC and endo, 92% had a calculatable FIB-4, versus 63% of 13,965 seen in endo only, versus 91% of 33,008 seen in PC only. Platelets in endocrinology were the most frequently missing lab (35%). Of those with intermediate or high FIB-4 scores, 15% of those seen in PC and endo had received a referral, versus 11% in endo, versus 10% in PC ($p < 0.001$). Ten percent seen in both had completed their referral, versus 8% in endo, and 7% in PC ($p < 0.001$). (Table 1). **Conclusion:** A system-level provider-facing dashboard that automates FIB-4 fibrosis screening provides a robust, cross-sectional, and longitudinal reporting tool. At baseline, patients seen by both PC and endo had the highest rates of FIB-4 labs, while endo-only patients had the lowest. FIB-4-score distribution was similar across populations, and most patients did not see both types of providers, reinforcing the need to screen in both endo and PC. Referral and completion rates were low but similar across departments. These findings indicate the ability to build and quantify a quality measure using automated FIB-4 scoring to screen for fibrosis due to MASH in PWD.

Table 1: MASH Care Pathway Outcomes and Patient Characteristics by Clinic Type, Reported in the Fibrosis Dashboard

	Both		Endocrinology Only		Primary Care Only		Total		Chi-square p-value
	N	% of Prior Milestone	N	% of Prior Milestone	N	% of Prior Milestone	N	% of Prior Milestone	
Eligible	10,223		13,965		33,008		57,196		
Screened	9,441	92.4%	8,782	62.9%	30,159	91.4%	48,382	84.6%	<0.001
Low Risk	7,847	77.8%	6,586	75.0%	23,269	77.2%	37,202	76.9%	<0.001
Intermediate Risk	1,572	16.7%	1,668	19.0%	5,225	17.3%	8,465	17.5%	
High Risk	522	5.5%	528	6.0%	1,665	5.5%	2,715	5.6%

2198 | CAREGIVER PERSPECTIVES ON END-OF-LIFE CARE FOR VETERANS WITH CIRRHOSIS: A QUALITATIVE ANALYSIS OF THE VA BEREAVED FAMILY SURVEY

Kanika Malani[1] Tulio Correa[2] Olivia Belliveau[3] Ramsey Cheung[4] Neha Jakhete[5] Sofia Jakab[6] Catherine Mezzacappa[3] Anna Nobbe[7] Jacqueline O'Leary[8] Shari Rogal[2] Anne Walling[9] Karleen Giannitrapani[10] Tamar Taddei[6] Arpan Patel[9], [1]Yale New Haven Hospital, [2]University of Pittsburgh, [3]Yale School of Medicine, [4]Stanford University Medical Center, [5]University of Maryland, [6]VA Connecticut Healthcare System, [7]VA Cincinnati Healthcare System, [8]VA North Texas Healthcare System, [9]VA Greater Los Angeles Healthcare System, [10]VA Palo Alto Healthcare System

Background: The end of life (EOL) experience for adults with cirrhosis includes repeated hospitalizations and a high frequency of life-sustaining treatments. While caregivers face significant burden throughout the illness trajectory, their specific experiences in navigating EOL care have not been reported. Our aim is to identify major themes of their experience through qualitative analysis of the Veterans Affairs Bereaved Family Survey (VA BFS). **Methods:** The VA BFS is a validated, national post-death survey used to assess the quality of EOL care delivered to Veterans who die in VA settings. In addition to standardized quantitative measures, the BFS includes 2 open-ended items ("Is there anything else that you would like to share about the Veteran's care during his/her last month of life?; Is there anything else that you would like to share about how the care could have been improved for the Veteran?") that provide insight into caregiver experiences, unmet needs, perceived strengths, and gaps in EOL care delivery. We randomly selected 100 Veterans with cirrhosis out of 1,330 whose caregivers completed the BFS from 2023-2025. Open coding of free-text responses was conducted by 9 hepatology clinicians (physicians, advance practice practitioners, residents). All responses were compiled, summarized, and analyzed by 3 coders (2 residents, 1 hepatologist), who applied a hybrid inductive/deductive approach to identify domains and themes, which were modified iteratively until content was non-overlapping. **Results:** Of 100 caregiver survey responses, 85 included substantive comments that yielded 22 distinct themes organized within 6 domains: Patient Needs, Family Needs-Communication, Family Needs-Administrative and Logistical, Family Needs-Emotional Support, Facility and Organizational Characteristics, and Clinical Teams and Personnel **(Table)** . The most frequent themes were: clear communication about the patient's condition and treatment options (n = 17), smoother transfer between facilities (n = 8), alerting family of the patient's final hours (n = 7), and improved care team collaboration (n = 7). In a sub-analysis of responses coded within the Family Needs-Communication domain (n = 19), the majority reflected low-quality communication experiences (n = 17), most commonly pertaining to staff not keeping family members informed of the patient's condition or planned procedures (n = 11). **Conclusion:** Clear communication emerged as the dominant theme among bereaved caregivers of decedent Veterans with cirrhosis. The majority described low-quality interactions in regard to prognosis and decision making. Teams invested in caring for this population should consider strategies to meet such informational needs proactively in order to improve the EOL experience for caregivers.

Table. Domains, Themes, and Representative Quotes for Major End of Life Experiences for Caregivers of Veterans with Cirrhosis

2199 | EVALUATING ASCITES CARE IN HOSPITALIZED PATIENTS WITH DECOMPENSATED CIRRHOSIS IN ONTARIO, CANADA: INSIGHTS AND LIMITATIONS OF HEALTH RECORD DATA

Shadia Adekunte[1] Matthew Wankiewicz[2] Surain Roberts[2] Lauren Lapointe-Shaw[3] Siddhartha Srivastava[1] Sahar Saeed[1] Michelle Ricci[1] Florence Wong[4] Gideon Hirschfield[4] Fahad Razak[4] Amol Verma[4] Jennifer Flemming[1] Kristel Leung[1], [1]Queen's University, Kingston, Ontario, Canada, [2]Li Ka Shing Knowledge Institute, Unity Health, Toronto, Ontario, Canada, [3]Institute of Health Policy, Management and Evaluation, Toronto, Ontario, Canada, [4]University of Toronto, Toronto, Ontario, Canada

Background: There is growing interest in evaluating care quality across hospitals using structured data. We aimed to evaluate whether adherence to ascites-related evidence-based quality indicators and outcomes could be assessed using health record data in Ontario. **Methods:** Using electronic health record (EHR) and administrative data from >60% of medicine/ICU admissions in Ontario (April 2016-June 2023), decompensated cirrhosis admissions were identified using validated algorithms. Decompensation events and procedures were determined using ICD-10-CA and CCI codes; diuretics (furosemide and spironolactone) and albumin transfusions were retrieved. Quality indicators assessed included paracentesis, combination diuretics use, and albumin use amongst coded ascites encounters. Outcomes explored included in-hospital mortality, ICU use, 7-day, and 30-day readmission to GEMINI hospitals. Associations were assessed with logistic regression adjusted for age and sex. **Results:** A total of 43,428 decompensated cirrhosis admissions were identified (25,426 individuals, median 63y, 59% male; MASLD 60%, ALD 33%). Admissions with coded ascites (n = 19,745, 45%) had less frequent concurrent variceal bleeding (12 vs. 22%) and HE (16 vs. 37%) codes, but more HRS (6.4 vs. 4.7%) and AKI (33 vs. 28%) than admissions without coded ascites (all $p < 0.001$). These admissions also had reduced in-hospital mortality (aOR 0.85, 95%CI 0.81-0.90) and ICU use (aOR 0.70, 95%CI 0.67-0.73), but higher readmission (7 days: aOR 1.14, 95%CI 1.06-1.23; 30 days: aOR 1.28, 95%CI 1.22-1.34). Of note, 9,705 admissions had 1+ recorded paracentesis or both diuretics prescribed, but no ascites code. Among coded ascites admissions, paracentesis (n = 12,490, 63%) was not significantly associated with in-hospital mortality but was associated with reduced ICU use (aOR 0.85, 95%CI 0.79-0.92), increased 7-day (aOR 1.14, 95%CI 1.02-1.28), and 30-day readmission (aOR 1.23, 95%CI 1.15-1.32). Albumin use with coded ascites and 1+ paracentesis (n = 4,727, 38%) was associated with in-hospital mortality (aOR 1.81, 95%CI 1.65-1.99) and ICU use (aOR 2.05, 95%CI 1.87-2.25) but not associated with 7-day or 30-day readmission. Diuretics use with coded ascites admissions had reduced in-hospital mortality (aOR 0.49, 95%CI 0.45-0.53) and ICU entry (aOR 0.82, 95%CI 0.76-0.88); however, 30-day readmission (but not 7-day readmission) was increased (aOR 1.31, 95%CI 1.22-1.40). **Conclusion:** Ascites codes were associated with less concomitant decompensation complications, which may explain lower in-hospital mortality/ICU use, higher readmission rates, and variably associated quality metrics (i.e. paracentesis, diuretics, albumin transfusion) with outcomes. Further validation of codes and objective clinical severity parameters are required prior to using such data to inform targeted quality improvement strategies and reduce practice variability across hospitals.

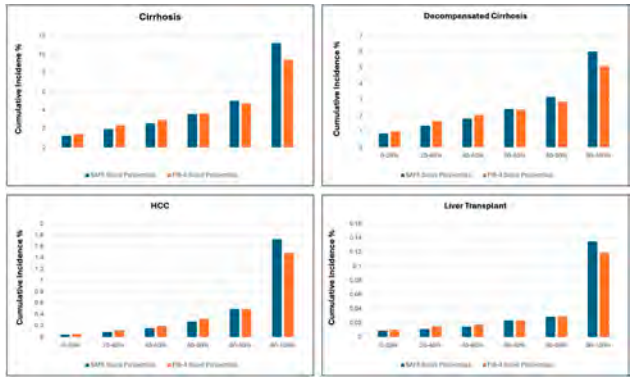
2200 | RISK STRATIFICATION FOR MAJOR ADVERSE LIVER OUTCOMES IN THE VETERANS HEALTH ADMINISTRATION SYSTEM USING FIB-4 VERSUS SAFE SCORES



George Ioannou[1] Shari Rogal[2] Prowpanga Udompap[3] Heather Patton[4] Sumedha Chhatre[5] Patrick Spoutz[6] W. Ray Kim[7] Timothy Morgan[8], [1]University of Washington, [2]University of Pittsburgh, [3]Minneapolis VA Medical Center, [4]VA San Diego Healthcare, [5]University of Pennsylvania, [6]Boise VA Medical Center, [7]Mayo Clinic Arizona, [8]VA Long Beach Healthcare System

Background: Major adverse liver outcomes (MALOs), including cirrhosis, decompensation (DC), and hepatocellular carcinoma (HCC), are a major source of morbidity and mortality in the Veterans Health Administration (VHA) system. Scalable tools for population-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

level risk stratification are needed to enable early detection and intervention. In this work, we compared 10-year risk prediction of MALOs in a national VHA cohort using the FIB-4 index versus and the Steatosis-Associated Fibrosis Estimator (SAFE) score. **Methods:** Starting with 6.15 million VHA enrollees with at least one encounter in 2013-14, we excluded subjects with known liver disease (e.g., hepatitis C and cirrhosis at baseline), incomplete data for FIB-4 and SAFE, or deceased as of 12/31/2014. Individuals were followed for 10 years starting on 01/01/2015 for the cumulative incidence of MALOs using diagnostic codes, with death as a competing risk. We estimated associations between baseline FIB-4 or SAFE, categorized into percentiles (0-20%, 20-40%, 40-60%, 60-80%, 80-90% and 90-100%) and 10-year risks of MALOs. **Results:** A total of 3,007,621 VHA enrollees met the eligibility criteria. The mean age was 62.3 years and 92% were male. Obesity (BMI $\geq$ 30) was present in 43%, including 17% with BMI $\geq$ 35. Diabetes was present in 27.6%. In the Figure, risks of all MALOs rose progressively with increasing FIB-4 or SAFE. For FIB-4, compared to subjects in 0-20th percentile, subjects in the 90-100th percentile category had a hazard ratio for 6.85 (95% confidence interval [CI] 6.68 - 7.01) for cirrhosis, 5.19 (95% CI: 5.04 - 5.35) for DC and 30.12 (95% CI: 26.79 - 33.86) for HCC. For SAFE, the corresponding hazard ratios were larger - 9.49 (95%CI: 9.26-9.73) for cirrhosis, 7.03 (95% CI: 6.82-7.25) for DC, and 39.97 (95% CI: 35.31 - 45.24) for HCC. Compared to these relative risks, absolute risks are more informative for potential future screening implementation. For example, if the top 10% with the highest risk were to be prioritized for the VHA system screening resources, SAFE would outperform FIB-4, identifying 19% more cirrhosis (33,822 versus [vs] 28,313), 18% more DC (18,179 vs 15,363), 17% more HCC (5,252 vs 4,497) and 13% more liver transplants (407 vs 360), given the same number of subjects tested (n = 300,762). However, even with the better performing SAFE score, the top decile only identified a relative minority of those with future MALOs (32% of cirrhosis, 27% of DC, 51% HCC and 48% liver transplant correctly detected). **Conclusion:** In this large population-based study with long term follow-up, FIB-4 and SAFE scores risk stratified the 10-year risk of MALOs. The top 10% of veterans with the highest SAFE scores suffered 13-19% more liver outcome events over 10 years than the top 10% of FIB-4 scores. These risk stratification, although imperfect, may advance systematic, evidence-based strategies to reduce the impact of liver disease in the VHA system.

2201 | LEVERAGING A COUNTYWIDE HEPATITIS B AND HEPATITIS C VIRUS REGISTRY TO LINK PERSONS WITH A HISTORY OF EXPERIENCING HOMELESSNESS TO CARE — LOS ANGELES COUNTY, JANUARY–MAY, 2025.

Prabhu Gounder[1] Jennifer Paul[2] Sophie Varma[3] Mirna Jewell[3] Heidi Behforouz[2], [1]Los Angeles County Department of Health Services, [2]LA County Department of Homeless Services and Housing, [3]LA County Department of Public Health

Background: The Los Angeles County Homeless Services and Housing (HSH) agency provides supportive housing for persons who are at-risk for or currently experiencing homelessness (PEH). The hepatitis C virus (HCV) prevalence among PEH in the Skid Row area of LAC was 27% in one study. It can be challenging to do phlebotomy and retain PEH in HBV or HCV care before addressing other social determinants of health such as housing and access to healthcare. The LAC Department of Public Health (DPH) maintains a Countywide registry of all persons reported with chronic hepatitis B virus (HBV) and HCV infection. We describe a data exchange collaboration between HSH and DPH to identify PEH with HBV or HCV and link them to care by using existing resources during January–May 2026. **Methods:** Clinical laboratories are mandated to report to DPH all positive test

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

results indicating current or past HBV or HCV infection and negative HCV polymerase chain reaction (PCR) results. All test results are related to unique persons to create a HBV and HCV registry. Persons with a positive anti-HCV or HCV PCR without a subsequent negative PCR are defined as having diagnosed but untreated (DBU) HCV. Persons without a positive hepatitis B surface antigen, HBV PCR, or hepatitis B e antigen reported in >12 months were classified as DBU per AASLD HBV disease monitoring recommendations. We cross-referenced the HBV and HCV registry with the HSH client list to identify DBU persons and their assigned HSH case managers (CMs) worked to link them to care (attending a first appointment for HBV or HCV care). **Results:** In January 2026, we cross-referenced 31,418 HSH clients against the DPH HBV and HCV registry and identified 255 (1%) HBV and 1,530 (5%) HCV DBU clients represented by CMs at 110 agencies. Among HBV DBU, 44 (17%) were successfully contacted by a CM and 7 (3%) were linked to care; 37 (14%) were not linked (6 declined care, 21 already treated or in care, relocated 2). Among HCV DBU, 236 (16%) were successfully contacted by a CM and 48 (3%) were linked to care, 52 had pending appointments as of May 22; 136 (9%) were not linked (37 declined care, 80 already treated or are in care, 19 for various other reasons). **Conclusion:** Our collaboration demonstrates 1) the potential for improved data exchange to identify persons with known HBV and HCV without the need for repeat phlebotomy, and 2) for State or Local Public Health Departments to partner and leverage available resources to link persons in hard to reach populations to HBV or HCV care. We presented preliminary results from an ongoing effort and anticipate that a greater proportion of HBV and HCV DBU will be linked to care by the end of this effort. This model could be adapted to other high prevalence settings, such as jails.

2202 | PRACTICE PATTERNS AND BARRIERS AFFECTING GOALS OF CARE COMMUNICATION AMONG HEPATOLOGY CLINICIANS WITHIN THE VETERANS HEALTH ADMINISTRATION

Likith Surendra[1] Jacqueline O'Leary[2] Sofia Jakab[3] Jasmohan Bajaj[4] Jennifer Anwar[5] Nicole Prause[6] Abbey Barnard Giustini[7] Ponni Perumalswami[8] Neha Jakhete[9] Heather Patton[10] Timothy Whitworth[11] Ashley Lane[12] Thuy-Van Hang[13] Timothy Morgan[5] Anne Walling[14] Shari Rogal[15] Arpan Patel[16], [1]Department of Medicine, University of California Los Angeles, Los Angeles, CA, USA, [2]Division of Gastroenterology, VA North Texas Healthcare System, Dallas, TX, [3]Division of Gastroenterology, VA Connecticut Healthcare System, New Haven, CT, [4]Division of Gastroenterology, VA Richmond Healthcare System, Richmond, VA, [5]Division of Gastroenterology, VA Long Beach Healthcare System, Long Beach, CA, [6]Vatche and Tamar Manoukian Division of Digestive Diseases, University of California Los Angeles, Los, [7]Division of Gastroenterology, VA Puget Sound Healthcare System, Puget Sound, WA, [8]Division of Gastroenterology, VA Ann Arbor Healthcare System, Ann Arbor, MI, [9]Division of Gastroenterology, VA Maryland Healthcare System, Baltimore, MD, [10]Division of Gastroenterology, VA San Diego Healthcare System, San Diego, CA, [11]Division of Gastroenterology, VA Illiana Healthcare System, Danville, IL, [12]Division of Gastroenterology, VA Eastern Colorado Healthcare System, Aurora, CO, [13]Division of Gastroenterology, VA Atlanta Healthcare System, Decatur, GA, [14]Division of General Internal Medicine, VA Greater Los Angeles Healthcare System, Los Angeles, CA, [15]Division of Gastroenterology, VA Pittsburgh Healthcare System, Pittsburgh, PA, [16]Division of Gastroenterology, VA Greater Los Angeles Healthcare System, Los Angeles, CA

Background: Cirrhosis is a life-limiting illness affecting nearly 100,000 Veterans each year. Goals of care communication (GOCC) helps ensure value-aligned care at the end of life. Within the Veterans Health Administration (VA), the largest integrated health system within the United States, GOCC occurs infrequently (30% of the time) and late (median of 37 days before death). Our aim was to identify practice patterns, as well as clinician and organizational factors affecting GOCC, among VA hepatology clinicians. **Methods:** We administered a brief, 26-item survey to hepatology clinicians within the VA. Items included demographics and a short-form version of the Goals of Care Communication Survey (n = 14 items), an assessment that captures clinician and organizational factors affecting GOCC: 1) *Knowledge, skills, and beliefs about capabilities*; 2) *Beliefs about consequences*, 3) *Intentions*; 4) *Social Influences*, and 5) *Organizational context*. We used 5 and 7-point Likert scales to capture responses, which were rescaled to all range from 0-100, where lower scores indicate greater barrier to GOCC. **Results:** A total of 52 out of 190 hepatology clinicians (response rate = 27%) across 35 facilities completed the survey. Most were White (58%), female (65%), physicians (60%), practicing non-transplant hepatology (58%), and with a predominantly outpatient

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

practice (median 80%). About half (48%) reported discussing prognosis with seriously ill patients 75-100% of the time, but fewer reviewed goals and values (33%) or preferences for life-sustaining treatments (23%). Median scores for *knowledge, skills and beliefs about capabilities* (80, interquartile range [IQR] = 70-90), *beliefs about consequences* (80, IQR = 80-100), *intentions* (80, IQR = 75-100), and *social influences* (80, IQR = 60-80) for GOCC were high. However, the median score for *organizational context* was lower (66, IQR = 52-72). Individual items with the lowest scores were: "My organization provides me feedback on the quality of my goals of care discussions with seriously ill patients" (40, IQR = 20-60) and "I have sufficient time for conducting goals of care discussions with seriously ill patients in the outpatient setting" (60, IQR = 40-80). Only 25% of clinicians reported receiving simulation with supervised observation and structured feedback in GOCC. **Conclusion:** We found multiple positive influences for GOCC, indicating that VA hepatology clinicians were highly invested in providing value-aligned care for seriously ill patients, but they reported that discussions on goals/values/preferences occur infrequently. They cited insufficient feedback on GOCC and limited time in the outpatient setting as the greatest barriers. Structural changes in hepatology practice, including workflow support tools, GOCC training, and collaboration with palliative care may be needed to prioritize specific and frequent GOCC.

2203 | EXPERIENCES WITH VETERANS ADMINISTRATION AND COMMUNITY-BASED TRANSPLANT CARE FOLLOWING THE MISSION ACT

Claire Durkin[1] Nicole Beyer[2] Kristina Hruska[2] Anne-Marie Sheilds[2] Maria Mor[2] Michael Fine[3] Steven Weisbord[4] Shari Rogal[1], [1]University of Pittsburgh, [2]VA Pittsburgh Healthcare System, [3]University of PIttburgh, VA Pittsburgh Healthcare System, [4]University of Pittsbugh, VA Pittsburgh Healthcare System

Background: The MISSION Act of 2018 expanded Veterans' eligibility to receive community care outside the Veterans Health Administration (VA). However, the impact of this expanded access on Veterans' transplant experiences remains unclear. This study qualitatively evaluated facilitators and barriers to kidney and liver transplant care through VA and community programs. **Methods:** We conducted semi-structured interviews with Veterans, VA transplant providers, and VA operations leaders across the U.S. from 8/2022-6/2024 to explore VA, community, and dual transplant care experiences. Purposive sampling captured perspectives across transplant type (kidney or liver), stage (waitlisted or post-transplant), and care setting (VA, community, or dual). Interviews were transcribed and analyzed using deductive and inductive approaches. Double-coding 20% of interviews ensured intercoder reliability. **Results:** We interviewed 66 Veterans (29 kidney, 37 liver; 27 waitlisted, 39 transplanted) and 52 providers/operations leaders. Most Veterans reported being offered VA-only (39%) or dual-care (44%) pathways, while fewer were offered community care alone (17%). Veterans identified patient preference (56%), lower cost (30%), transplant outcomes/reputation (21%), and travel/lodging support (20%) as key facilitators of VA transplant care. The main barrier was travel burden (35%). Liver transplant patients more commonly emphasized continuity of care, communication, and Veteran-centered support as reasons for choosing VA care than kidney patients. Facilitators of community care included trust in community programs (32%) and proximity to care (20%). Veterans offered dual care often described communication gaps and logistical complexity.Providers and operations leaders identified continuity of care and communication (75%), travel/lodging support (48%), patient preference (40%), and provider experience with VA transplant centers (39%) as major strengths of VA care. Key barriers included travel limitations (54%) and difficulty identifying support persons (54%). They viewed community care as improving geographic access (50%), but cited administrative barriers (50%), communication challenges (33%), and variable oversight (17%) as concerns. Across all groups, participants emphasized the need for improved patient education, care coordination, earlier referral, and transplant navigation support. **Conclusion:** Following the expansion of community care access for Veterans, transplant site selection was strongly influenced by patient preference, geographic access, and perceptions of quality and trust. While VA transplant centers were seen as providing strong continuity and coordinated care, maintaining these strengths was challenging within community and dual-care models. Improved education, navigation, and coordination may optimize transplant experiences and care delivery for Veterans across all settings.

2204 | IMPROVING HEPATOCELLULAR CARCINOMA (HCC) SCREENING RATES IN PATIENTS WITH CIRRHOSIS AT THE LOUISVILLE VA MEDICAL CENTER

Cristina Chiodi[1] Ashutosh Barve[1] Alicia Clum[2] Priya Krishnan[3], [1]University Of Louisville - Gastroenterology, Hepatology and Nutrition - LOUISVILLE, KY, [2]University of Louisville Internal Medicine, [3]Louisville VA Medical Center

Background: Hepatocellular carcinoma (HCC) is a leading cause of cancer-related mortality among patients with cirrhosis. Six-month surveillance with abdominal ultrasound is recommended, yet adherence at our institution remains suboptimal. At the Louisville VA Medical Center, only 38% of eligible patients were up to date with HCC screening, increasing the risk of delayed diagnosis and limited treatment options. Contributing factors included inaccurate identification of cirrhosis, lack of standardized workflows, provider knowledge gaps, and challenges in patient follow-up. The objective of this project is increase the rate of appropriate HCC screening in patients with cirrhosis at the Louisville VAMC. **Methods:** We conducted a QI initiative using iterative interventions informed by a retrospective review. Among 782 patients coded with cirrhosis, 488 lacked appropriate surveillance; chart review showed 43.1% were miscoded and 17.3% had uncertain diagnoses. A multidisciplinary team comprised of the Chief Resident, Primary Care, Nursing, and GI providers implemented interventions targeting system and provider-level barriers, including (1) refinement of the "Advanced Liver Disease" dashboard to improve cohort accuracy, (2) provider education and deployment of electronic clinical reminders, and (3) nursing education and workflow optimization. The primary outcome measure was the amount of patients with cirrhosis receiving appropriate 6-month HCC screening. Secondary measures included qualitative assessment of barriers to screening completion. **Results:** 6-month screening rates improved from 38% in Q1 2025 to 60.4% in Q4 2025. In Q1 2026, 6-month screening rates declined slightly to 57.7%. Repeat analysis revealed disparities by care setting: patients followed in GI clinic had 100% ordering rates while those managed exclusively in primary care had significantly lower rates (11.8%). Persistent barriers to screening completion included patient no-shows and refusal. Continued data review also identified ongoing misclassification, with 22% lacking confirmed cirrhosis. **Conclusion:** Targeted data validation and provider-focused interventions led to a 20% increase in HCC screening rates. Accurate cohort identification was essential to avoid both under- and over-screening. Differences between specialty and primary care highlight the need for improved care coordination for surveillance. Patient engagement remains a critical barrier, particularly in specialty settings where missed appointments reduce screening completion. Limitations include data autocorrelation and reliance on electronic health record data, which may not capture external imaging. Ongoing efforts will focus on sustaining gains through continued cohort refinement, enhanced primary care collaboration, and implementation of a nurse navigator model to address patient-level barriers and improve adherence to surveillance guidelines.

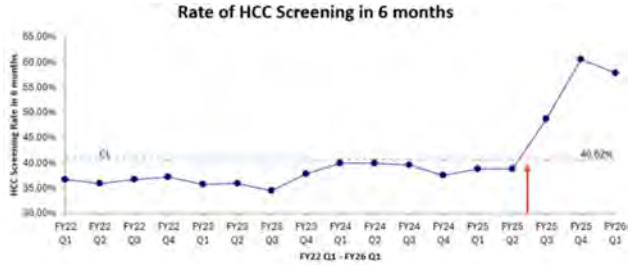

Figure 1: This run chart depicts quarterly data for HCC screening within 6 months at the Louisville VA. The red arrow denotes the initiation of the project with first intervention (database refinement).

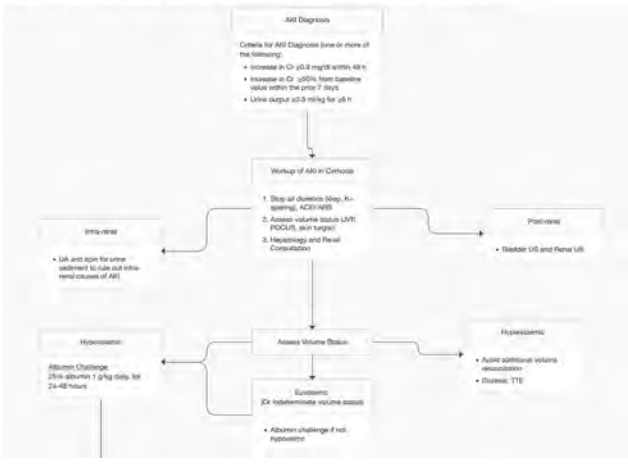
2205 | IMPROVING MANAGEMENT OF PATIENTS WITH ACUTE KIDNEY INJURY AND CIRRHOSIS ACROSS A TERTIARY CARE HEALTH SYSTEM – A QUALITY IMPROVEMENT INITIATIVE

Max Schechter[1] Sara Schwenk[1] Marina Serper[2], [1]University of Pennsylvania, [2]University of Pennsylvania Health System



Background: Acute kidney injury (AKI) is common amongst inpatients with decompensated cirrhosis and can lead to significant morbidity and mortality, especially amongst patients with hepatorenal syndrome (HRS). The management of these patients with careful volume assessment and albumin challenge has been well established however variability into the use of albumin and initiation of terlipressin exists within our healthcare system. **Methods:** Using a quality improvement framework, we interviewed relevant stakeholders and developed a process map involving the current management of patients with AKI on the inpatient liver service. We

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

developed the following goal: Increase the administration of albumin by 25% to inpatients on the general medicine floors with a goal to reduce length of stay (LOS) by 48 hours amongst patients with cirrhosis and AKI over the next 6 months. The intervention developed was a Clinical Decision Pathway to help guide the diagnosis and management of AKI in patients with cirrhosis. Pre-intervention data was obtained from Vizient and Epic SlicerDicer utilizing ICD-10 coding and included inpatients on the General Medicine service from 09/01/2023 through 10/31/2025. **Results:** A clinical decision pathway was developed, guiding the diagnosis and management of AKI in cirrhosis, stratified by volume status. The pathway included information on albumin challenge followed by prompt initiation of terlipressin in patients meeting diagnostic criteria for hepatorenal syndrome (Figure 1). Pre-intervention data consist of 785 hospital encounters with a mean age of 60.6 (STD = 13.0) and was 58% male. The data demonstrates that inpatients with a diagnosis of cirrhosis and AKI have a 30.7% ICU upgrade rate, 15.3% observed mortality rate, 9.7% 14-day readmission rate, and a mean observed LOS of 9.98 days (STD = 9.44 days). 419 (53.4%) of hospital encounters received albumin, 67 (8.5%) received a combination of albumin, midodrine, and octreotide (MAO), and 39 (5.0%) received terlipressin. **Conclusion:** Hospitalized patients with cirrhosis and AKI are particularly vulnerable to increased morbidity and mortality. Amongst our general medicine floors, only 5% of patients with a diagnosis of AKI and cirrhosis received terlipressin. A quality improvement framework was used to assess areas for improvement in caring for patients with AKI and cirrhosis and to ultimately develop a clinical decision pathway. Post-implementation data will be assessed in a future study.

2206 | IMPACT OF SERUM SEPARATOR TUBE SELECTION ON ROUTINE LIVER FUNCTION TESTING: A COMPARISON OF V-PRO® AND GREINER VACUETTE® TUBES

Somaya Alqattan[1] Safiah Almushawwah[2] Manar Sultan[2] Muzan Ismail[2], [1]Advance Medical Co, [2]Advance Medical Co.

Background: Preanalytical variability during blood collection remains a major source of laboratory error and may affect the accuracy of liver function testing and subsequent patient management. Blood collection tube composition can influence analyte stability and assay performance, potentially impacting interpretation of hepatic biomarkers. This study aimed to compare the analytical performance of V-PRO® Serum Separator Tubes (SSTs) with Greiner VACUETTE® CAT SST for routine liver function testing, including alanine aminotransferase (ALT), aspartate aminotransferase (AST), alkaline phosphatase (ALP), and gamma-glutamyl transferase (GGT), in accordance with CLSI recommendations. **Methods:** This comparative study included 20 healthy volunteers. For each participant, 10 mL of venous blood was collected and allocated between V-PRO® SST and Greiner VACUETTE® CAT SST tubes (5 mL each). Blood collection and sample processing were performed using standardized venipuncture and preanalytical procedures in accordance with CLSI GP41-Ed7 guidelines. Liver function biomarkers, including ALT, AST, ALP, and GGT, were analyzed using the Beckman Coulter DxC 700 AU chemistry analyzer. Agreement between tube types was evaluated using total allowable error, Bland–Altman analysis, Deming regression, and unpaired t-test with GraphPad Prism version 10.6.0. **Results:** No statistically significant differences were observed between V-PRO® SST and Greiner VACUETTE® CAT SST tubes for ALT, AST, ALP, or GGT measurements. Deming regression and Bland–Altman analyses demonstrated excellent agreement between tube types across all analytes, with strong correlations (r = 0.994–0.998) and minimal analytical bias. All specimens met CLIA allowable total error criteria, indicating analytical equivalence between the two serum separator tube devices. **Conclusion:** V-PRO® SST demonstrate strong analytical agreement with Greiner VACUETTE® SST for routine liver function testing, including ALT, AST, ALP, and GGT measurements. Mean bias values remained minimal and within CLIA allowable total error. Deming regression and Bland–Altman analyses confirmed excellent agreement between tube types, indicating no clinically significant differences affecting routine laboratory interpretation or

clinical decision-making. These findings support the use of V-PRO® SST as a reliable alternative blood collection system for hepatic biochemistry testing. Further studies involving larger and clinically diverse populations are warranted.

Figures

2207 | LOW NATIONWIDE UTILIZATION OF NUTRITIONAL AND PHYSICAL THERAPY CONSULTATION AMONG HOSPITALIZED PATIENTS WITH ALCOHOL-ASSOCIATED CIRRHOSIS BETWEEN 2010 AND 2022

Yee Hui Yeo[1] lingyu bao[2] Sheng-Yin Chen[3] Hanyou Loh[4], [1]Cedars-Sinai Medical Center, [2]Children's Hospital at Montefiore, [3]Massachusetts General Hospital, [4]Canton Medical Education Foundation

Background: Malnutrition and functional decline are highly prevalent in alcohol-associated cirrhosis (AC). Guidelines from professional societies recommend nutrition and physical therapy assessments, yet national patterns of use of nutritional and physical therapy consultations among hospitalized AC patients remain poorly characterized. **Methods:** We performed a retrospective study of the National Inpatient Sample from 2010 to 2022. Adult hospitalizations with a primary diagnosis of AC (ICD-9: 571.2; ICD-10: K70.30/K70.31) were identified using ICD diagnostic codes. Nutritional consultation (NC) and physical therapy consultation (PT) were identified using a combination of ICD diagnosis procedure codes. Multivariable logistic regression was performed, adjusting for age, sex, race/ethnicity, income quartile, insurance type, Charlson Comorbidity Index, hospital region, hospital teaching status, and bed size. **Results:** A total of 241,943 weighted AC hospitalizations were identified (mean age 53.7 years; 27.3% female). NC showed a modest numerical increase over time, with consistently higher rates among female and Black patients and the lowest rates among Hispanic patients. PT increased after 2015, coinciding with the ICD-9 to ICD-10 transition, with rates remaining relatively stable before and after. On multivariable analysis, female sex (OR 1.36, 95% CI 1.27–1.46), CCI $\geq$ 3 (OR 1.17, 95% CI 1.05–1.31), and non-Northeast region (OR 1.54–1.62, all 95% CI lower bounds $\geq$ 1.27) were associated with higher odds of NC. Hispanic ethnicity (OR 0.69, 95% CI 0.61–0.77), Medicaid (OR 0.86, 95% CI 0.78–0.94), and self-pay/other insurance (OR 0.83, 95% CI 0.74–0.93) were associated with lower NC odds. For PT, the highest income quartile (OR 2.21, 95% CI 1.37–3.57) and Hispanic ethnicity (OR 2.09, 95% CI 1.36–3.23) were associated with higher odds, while urban non-teaching hospital status was strongly associated with lower PT odds (OR 0.09, 95% CI 0.02–0.32). **Conclusion:** Utilization of NC and PT in AC in AH remains persistently low nationwide, representing a critical unmet need given the high burden of malnutrition, sarcopenia, and functional decline in cirrhosis. Significant sociodemographic disparities underscore the need for systematic, equitable integration of nutritional and rehabilitative care for all high-risk AC patients.

2208 | TAKING IT TO THE STREETS: A SCALABLE APPROACH TO EMBEDDING HCV SCREENING & CARE FOR HOMELESS HEALTH

Manav Patel[1] Zachary Schwartz[1] Jeanne Forrester[1] Jack Palmer[2] Amanda Rosecrans[3], [1]Decera Clinical Education, [2]Circle the City, [3]Oregon Health and Science University School of Medicine

Background: People experiencing homelessness have a high burden of hepatitis C virus (HCV) infection & face substantial barriers to health screening & care. To improve access to HCV care, Decera Clinical Education partnered with the Street Medicine Institute & Circle the City, a Federally Qualified Health Center (FQHC) with mobile clinics & street outreach teams in Maricopa County, Arizona, to embed simplified HCV screening & treatment into street medicine workflows. **Methods:** This pilot program integrated education, protocol development, mentorship, & workflow design within Circle the City's mobile & street medicine program. Components included development of a simplified guideline-aligned opt-out screening & treatment algorithm, healthcare professional (HCP) & staff training, monthly implementation mentorship from an experienced street medicine HCV HCP, & prospective collection of screening & treatment data. Primary implementation outcomes were changes in screening volume, rates of HCV test positivity, & rates of treatment initiation by the outreach team activities. Secondary observations included rate of adoption by nonspecialist HCPs. **Results:** Between 3/1/25-11/30/25, 1574 patients were screened, surpassing the program's 6-month target of 250. Compared with baseline screening of 20 patients/month before the program launch, the pilot averaged 175 patients/month, a 775% increase in screening volume. Rapid HCV antibody screening positivity was 9.7%, & confirmatory RNA testing showed a presence of active HCV disease in 7%, ultimately identifying 103 patients with active HCV infection requiring linkage to care. Of these, 34 patients (33%) initiated HCV treatment (compared to the 3 years prior to this pilot program, where Circle the City had only rare instances of treatment initiation for active HCV disease). Of the remaining patients with active HCV infection but not on treatment, most are in the process of completing linkage to care, including obtaining treatment medication from a specialty pharmacy, pending specialist consultation, or attempting to locate & follow up with the patient. Following this program's education & mentorship, all HCPs who had not previously treated HCV (i.e. MDs,PAs,NPs) began initiating therapy independently, & pharmacy collaboration helped streamline access to initial treatment & refills. **Conclusion:** Embedding simplified HCV care into an existing street medicine program through an interprofessional collaboration among a medical education provider, a street medicine network, & a homeless health FQHC was feasible, & it rapidly expanded access to HCV screening for a highly underserved population. Early treatment starts & HCP uptake suggest this model can improve delivery of HCV care outside specialty settings. This pilot offers a scalable framework for mobile & community-based programs seeking to reduce access barriers & improve quality of care for people experiencing homelessness.

2209 | TRENDS IN CHRONIC LIVER DISEASE MORTALITY IN ITALY IN THE DIRECT-ACTING ANTIVIRAL ERA: PROGRESS TOWARD WHO HEPATITIS ELIMINATION TARGETS

Stefano Rosato[1] Maria Giovanna Quaranta[1] Paola D'Errigo[1] Valerio Manno[1] Giorgia Stoppa[2] Annibale Biggeri[3] Dolores Catelan[2] Giada Minelli[1] Loreta A Kondili[1], [1]Istituto Superiore di Sanità, Rome, Italy, [2]University of Padua, Padua, Italy, [3]Univerity of Padua, Padua, Italy

Background: Viral hepatitis has represented a major public health challenge in Italy, with one of the highest burden in Europe. Expanded access to direct-acting antivirals (DAAs), with more than 280,000 patients treated to date, the highest number in Europe, has substantially changed liver disease epidemiology. This study assessed temporal trends in chronic liver disease (CLD) mortality in Italy, focusing on HCV-related mortality, and evaluated progress toward WHO elimination targets. **Methods:** ICD codes related to CLDs were extracted from multiple causes of death records (2003–2022), considering all causes reported on death certificates and selecting deaths with CLD as the underlying cause. Analyses focused on HCV-related mortality. Trends in age-standardised mortality rates were assessed by geographical macro-area using Joinpoint regression analyses. Progress toward the WHO 2030 mortality target was preliminarily estimated using age- and sex-specific Poisson models.Updated national active HCV screening program data for the key and general populations born 1969-1989, in place since 2020, were also analysed to contextualise the observed mortality trends. **Results:** A total of 375,622 CLD-related deaths were recorded among individuals aged $\geq$35 years (61.8% men); 25,418 deaths were attributable to alcohol-related liver diseases (81.8% men) and 41,416 to HCV (54.9% men). Age-standardised CLD

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

mortality rates steadily declined across all geographical areas, although Southern Italy continued to have the highest rates.HCV-related mortality peaked in 2013, followed by a marked annual decline (annual per cent change [APC] −12.5%) from 2014 onward, with a further acceleration after 2017 concurrent with unrestricted DAA access. By 2022, HCV-related mortality had declined by approximately 55% compared with 2015, and preliminary estimates suggest that Italy may achieve the WHO 2030 mortality target as early as 2025.More than 3 million individuals have been screened through the national active HCV screening program, resulting in the identification of over 20,000 with active HCV infection. However, important gaps remain. Only approximately 20% of the target birth cohort (1969–1989) has been screened to date, while older birth cohorts (1948–1968), estimated to carry the highest prevalence of active HCV infection, are not yet systematically included in national screening strategies. **Conclusion:** Italy rapidly implemented broad and equitable access to DAA treatment and national screening interventions, resulting in a substantial decline in HCV-related mortality, positioning the country most likely to achieve the WHO hepatitis elimination mortality targets. However, achieving overall HCV elimination targets in Italy will require expansion of screening and treatment strategies, particularly targeting older birth cohorts with a high residual burden of undiagnosed infection.

2210 | THE PROVIDER EXPERIENCE OF CARING FOR PATIENTS WITH MASLD

Alana Saddic[1] Jessica Mittler[1] Arun Sanyal[1] Deborah DiazGranados[1], [1]Virginia Commonwealth University

Background: MASLD is associated with multiple metabolic-dysfunction mediated end-organ diseases necessitating care from various HCPs. There are no established paradigms for integration of care across specialties in these patients. This study was undertaken to understand knowledge, attitude, and practice patterns among hepatologists and PCPs through discussing their lived experiences of caring for MASLD patients. **Methods:** HCPs completed a multisystem metabolic disease knowledge questionnaire, which was scored to evaluate group differences. Hepatology and PCPs participated in focus groups amongst other members of their specialties. Transcripts underwent inductive thematic analysis to identify and analyze core patterns. **Results:** 5 hepatologists (4 MD, 1 APP) and 2 PCPs (1 MD, 1 APP) participated. Years of practice were < 5 years (n = 3), 5-10 (n = 2), 11-20 (n = 1), > 20 years (n = 1). Overall 57.1% of the questions were answered correctly (hepatologists 58.7%, PCP 53.3%, MD 57.33%, APP 56.7%), The highest scoring question (100%) regarded Fib-4 utilization. The lowest scoring questions (14%), regarded renal dysfunction management. Hepatologists felt that they play a key role in MASLD patients care; especially those with significant fibrosis. They estimated 50% of referred patients were unaware of having MASLD. Perceived barriers to optimal MASLD care include: inadequate screening, insurance coverage, patient low health literacy, lack of time/knowledge among PCPs, lack of financial incentives, lack of supply of hepatologists and other specialists. Things that help them provide optimal care/suggested solutions include: incorporating other members of the care team (RDs, APPs, nurse navigators) and utilizing technology (embedding Fib-4 into the EMR, EMR provider communication, and providing patient education). The PCPs viewed themselves as the first-line point-person for MASLD care-including identifying/ referring patients with MASLD, providing education, and managing comorbidities. Perceived barriers to optimal MASLD care include: screening methods that do not catch MASLD early enough, lack of knowledge of liver directed therapies, patients' lack of time/knowledge. Things that help them provide optimal care/suggested solutions include: comprehensive hepatology consults, increased MASLD offerings for their professional education, e-consults with endocrinologists, EMR communication between specialists, coordinated RD/lifestyle coaching and suggested use of best practice advisories in the EMR. **Conclusion:** Both groups prioritized screening protocols for early MASLD identification. Barriers to optimal MASLD care include insufficient screening, lack of knowledge among patients and providers, lack of financial incentives, lack of sufficient specialists. They acknowledge the importance of multidisciplinary team management and both suggest the use of EMR embedded technology to aid in patient care.

2211 | ACCESS TO LIVER TRANSPLANTATION AMONG PATIENTS WITH ALCOHOL-ASSOCIATED LIVER DISEASE: A MULTISTAGE ANALYSIS

Sienna Lila[1] Daniel Huynh[1] Philip Vutien[1] Meredith Pearson[1] Meagan Alvarado[1] Lei Yu[1] Iris Liou[1] Renuka Bhattacharya[1] Anne Larson[1] Rotonya Carr[1] Erin Cleveland[1] Muyi Li[1] Nicole Kim[2], [1]University of Washington, [2]University of Washington Medical Center

Background: Despite being the most common indication for liver transplantation (LT), patients with alcohol-associated liver disease (ALD) can face various barriers to LT. We aimed to identify the sociodemographic factors associated with failure to progress through the LT evaluation process to determine which stages present the greatest barriers for patients with ALD. **Methods:** We conducted a single center, retrospective cohort study of adults (≥18 years) with ALD referred for LT in the outpatient setting from 1/1/2022 to 5/9/2024. The outcome of the first outpatient referral for each patient was considered. Medical records were queried for sociodemographic data, including age, sex, race, state of residence, primary language, and Model for End-Stage Liver Disease (MELD) score at the time of referral (MELD 3.0 when available, otherwise MELD-Na). Multivariable logistic regression was used to identify factors associated with the following outcomes: seen in liver transplant clinic, listed for transplant, and transplanted. **Results:** A total of 568 patients with ALD were referred for LT evaluation in the outpatient setting. The cohort was majority male (59%), White (61%), with a median age of 53 years (IQR 44-60) and median MELD of 19 (IQR 13-24). There was no difference in median MELD at referral between males and females. Of the patients referred, 452 (80%) were seen in transplant clinic, 126 (22%) were listed, and 88 (15%) were transplanted. In a multivariable model of patients with ALD referred for LT, a higher MELD score at referral was associated with lower odds of being seen in transplant clinic (OR 0.94, p < .001; Table). However, among those who did engage in transplant evaluation, a higher MELD score increased the likelihood of progressing to listing (OR 1.09, p < .001) and transplant (OR 1.08, p = 0.04). Once listed, female patients (vs. male) with ALD were less likely to be transplanted (OR 0.22, p < .001), while older patients (vs. younger patients) were more likely to be transplanted (OR 1.05, p = 0.03). Geography (state of residence at referral) was not associated with progression to transplant. Non-White/unknown race was independently associated with a lower likelihood of being listed for transplant (OR 0.36, p < .001). **Conclusion:** Patients with ALD experienced substantial attrition along the pathway to LT, with only 22% of all referrals and 28% of those evaluated in clinic ultimately listed for transplant. Higher MELD scores were associated with lower odds of initial transplant clinic engagement, but increased the likelihood of listing and transplant among individuals seen in clinic. Among those listed for LT, women experienced a markedly lower odds of transplantation, highlighting a potential sex-based disparity in LT access among patients with ALD. Further studies and analyses are needed to assess the factors that may contribute to this disparity.

Table. Factors associated with progression from outpatient transplant referral for patients with ALD, multivariable logistic regression

2212 | HOSPITALIZATION AS A "REACHABLE MOMENT": NURSE NAVIGATOR-DRIVEN IDENTIFICATION AND MITIGATION OF BARRIERS TO HEPATITIS C LINKAGE-TO-CARE COMBINED WITH TEST-AND-TREAT APPROACH LEADS TO HIGH RATES OF SUSTAINED VIROLOGIC RESPONSE

Patricia Werner[1] Madeline McCrary[1] Laura Marks[1] Jennifer Mullersman[1] Megan Curtis[1] Tracey Habrock-Bach[1], 1. Division of Infectious Diseases, Washington University School of Medicine, St. Louis, MO USA

Background: Hospitalization offers a "reachable moment" for Hepatitis C virus (HCV) screening, diagnosis, and treatment. We evaluated patient barriers to care and effectiveness for a hospital-based HCV treatment program. **Methods:** In 2022, we implemented a program to offer direct acting antivirals

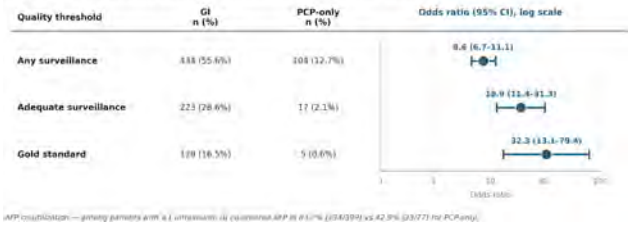
Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(DAAs) to hospitalized patients at discharge through inpatient Infectious Diseases (ID) consultation with ID pharmacy support. In March 2024, we implemented a nurse navigation program with electronic medical record-prompted HCV screening. Nurse Navigators identify HCV by running daily laboratory reports. Nurse navigators provide education, assess patient reported barriers to care and facilitate linkage to HCV DAA treatment initiation, including on hospital discharge. Delivery of DAAs is facilitated by collaboration with pharmacy staff. We assessed effectiveness using sustained virologic response (SVR) after end of therapy. **Results:** From January 2022-February 2026, 290 patients were prescribed DAAs through the "Meds to Beds" program. Of the 277 who survived SVR, 62% (171) achieved SVR. The most common patient-reported barriers to care were: not having been offered linkage to HCV treatment previously (44.8%), transportation difficulties, pharmacy or labs (23.1%), housing insecurity (10.5%), and lacking access to a phone for coordinating care (8.5%). **Conclusion:** Integration of HCV screening, diagnosis, and treatment as a bundled approach during inpatient hospitalization leverages the central role of the hospital within public healthcare and bridges the gap in care for populations who may be disconnected from outpatient healthcare systems. Dispensing HCV DAAs directly at the point of HCV testing in the hospital eliminates the need for patients to travel to a separate outpatient clinic appointment after discharge for a visit with an HCV treatment provider, resolving one of the most common patient-reported barriers to HCV treatment. By reducing multiple transitions, hospital-based HCV treatment can strengthen the HCV care continuum. Next steps include ensuring all patients can be seen by prescribers during hospital admission and improving processes to access patient assistance for DAAs for those without health insurance. **Disclosure of Interest Statement:** ***See example below:*** *L.M.M and L.R.M report funding by Gilead's Frontlines of Communities in the United States (FOCUS) program. FOCUS funding supports HIV, HCV, and hepatitis B virus screening and linkage to the first medical appointment after diagnosis; FOCUS funding does not support any activities beyond the first medical appointment and is agnostic to how FOCUS partners handle subsequent patient care and treatment.* **Disclosures:** Patricia Werner: Nothing to Disclose, Madeline McCrary: Gilead FOCUS: Grant/Research Support, Abbvie: Grant/Research Support, Laura Marks: Nothing to Disclose, Jennifer Mullersman: Nothing to Disclose, Megan Curtis: Nothing to Disclose, Tracey Habrock-Bach: Nothing to Disclose.

2213 | THE MISSED OPPORTUNITY FOR HEPATOCELLULAR CARCINOMA SURVEILLANCE BEGINS IN PRIMARY CARE

Antoine Sassine[1] Christopher Murphy[1], [1]Trinity Health Grand Rapids



Background: Hepatocellular carcinoma (HCC) surveillance rates remain suboptimal among patients with cirrhosis despite established guideline recommendations. Low surveillance rates are frequently attributed to barriers in follow-up and access to specialty care; however, surveillance patterns among patients who remain actively engaged in primary care are less well characterized. We assessed HCC surveillance ordering among patients with cirrhosis and documented primary care follow-up and examined how gastroenterology/hepatology involvement influenced surveillance rates. **Methods:** We studied 1,602 adults with cirrhosis and ≥ 1 primary care visit in 2025 within a single integrated multi-specialty health system. Using order records, HCC surveillance over 12 months was categorized on an ordinal scale as gold-standard (biannual ultrasound [US] + biannual alpha-fetoprotein [AFP]), acceptable (biannual US ± AFP or contrast-enhanced CT/MRI spanning both half-years), incomplete (imaging in only one half-year), or none. All measures reflect ordering, irrespective of completion. We recorded each patient's contact with primary care (PCP) and gastroenterology/hepatology (GI) and identified the department responsible for each surveillance order. Associations were assessed using Fisher exact tests and odds ratios (OR), with MELD-adjusted analyses where available. **Results:** All patients had at least one primary care encounter, but only 781 (49%) also had GI involvement. Adequate surveillance was ordered for just 15% of the cohort, while 66% had no surveillance ordered. Surveillance rates differed substantially according to specialty involvement: among the 821 patients (51%) without GI care, only 2% received adequate surveillance and 87% had no surveillance orders, compared with 29% adequate surveillance among patients seen by GI (OR 18.9, 95% CI 11.4–31.3; MELD-adjusted OR 17.1). The GI advantage widened with screening quality, from any imaging (OR 8.6) to gold-standard surveillance (OR 32.3; Figure 1). Among patients with at least one ultrasound order, AFP was co-ordered in 84% of GI patients versus 43% of patients without GI involvement. Analysis of ordering providers demonstrated that GI accounted for the majority of surveillance

orders, whereas primary care accounted for 21%. **Conclusion:** The missed opportunity for HCC surveillance begins at the primary care encounter. Despite universal primary care engagement in this cohort, only a minority of patients received guideline-concordant surveillance, and surveillance was strongly concentrated among those who reached gastroenterology/hepatology care. The large proportion of patients who never accessed specialty care accounted for a substantial share of missed surveillance opportunities, highlighting the need for strategies that improve surveillance delivery within primary care and facilitate access to specialty care.

Figure 1. Odds of HCC Screening Ordering — GI vs. PCP-only

2214 | FINDINGS FROM A CROSS-SECTIONAL STUDY ON THE HEALTH-RELATED QUALITY OF LIFE IN ACUTE HEPATIC PORPHYRIA

Teresa Kauf[1] Hetanshi Naik[2] Brittany Klooster[3] Roger Lamoureux[3] Rianna Leighton[4] Sabina Wiekhorst[1] Samantha Hurley[1], [1]Alnylam Pharmaceuticals, Cambridge, MA, USA, [2]Stanford University, Palo Alto, CA, USA, [3]Adelphi Values, Boston, MA, USA, [4]Alnylam Pharmaceuticals, Cambridge, MA, USA; Cytel Inc., Cambridge, MA, USA

Background: Acute hepatic porphyrias (AHPs) are characterized by acute attacks, possible chronic symptoms, and low health-related quality of life (HRQoL). This noninterventional cross-sectional HRQoL study, conducted as part of research activities to explore the lived experience of patients with AHP, utilized standard patient-reported outcome measures (PROMs) to characterize the chronic symptom burden of AHP in patients who had and had not recently experienced an AHP attack. **Methods:** Eligible patients with AHP were ≥15 years old, had experienced ≥1 self-reported attack in the past 2 years, and had not received treatment up to two weeks before completing the PROMs. Patients completed the 12-Item Short-Form Health Survey version 2 (SF-12; capturing global HRQoL and overall health status over the last 4 weeks); the Work Productivity and Activity Impairment Questionnaire (WPAI): General Health version 2 (capturing impairments over the last 7 days); and two pain severity items (capturing worst and least severity of AHP-related pain over the last 7 days). All outcomes were summarized descriptively and patients were stratified by whether they did or did not have an attack in the past 30 days, per self-reporting at the time of response to the PROMs. **Results:** Overall, 30 patients (mean age 47.4 years; 77% female; 67% with acute intermittent porphyria) were included, of whom 13 (43%) reported an attack within 30 days of the PROM (**Table**). Mean (standard deviation [SD]) SF-12 Physical Component Summary (PCS) and Mental Component Summary (MCS) scores in the overall sample were 39.30 (11.40) and 42.81 (10.33), respectively; both scores were below the population norm of 50 (SD, 10), and PCS scores were one SD below the population norm. Mean (SD) SF-12 PCS and MCS scores were lower in patients who had an attack in the past 30 days than in those who did not (**Table**). Participants in the overall sample reported WPAI impairments in all domains; the most impacted domain was activity impairment (mean [SD] impairment, 49.00% [28.93%]). Impairments in the WPAI were generally worse among patients who had an attack in the past 30 days than in patients who did not (**Table**). Mean (SD) worst pain severity score was 4.60 (2.61) in the overall sample and was greater in patients who had an attack in the past 30 days than in those who did not (**Table**). Mean (SD) least pain severity score was 2.50 (2.54) overall and was similar between patients who did and did not have an attack in the past 30 days (**Table**). **Conclusion:** Patients with AHP experience diminished HRQoL as measured by the SF-12, WPAI, and pain severity regardless of whether they have had a recent AHP attack. Similarities in least pain severity scores between groups may indicate chronic mild pain. These findings show that patients with AHP experience disease burden outside of attacks, and the development of an AHP-specific PROM designed for use in clinical and real-world practice may enable a more comprehensive assessment of the burden of AHP.

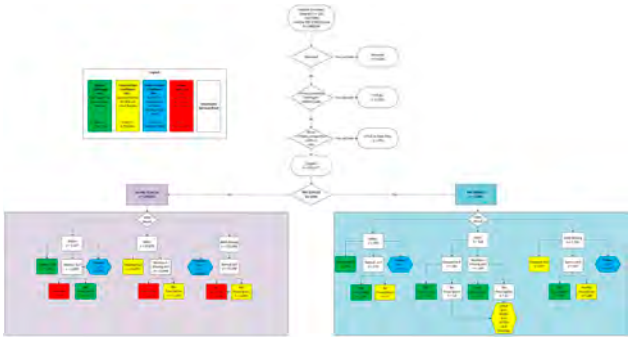
2215 | PBC CASE-FINDING LOGIC REVEALS LIMITATIONS OF STRUCTURED EMR DATA AND NEXT STEPS TOWARD IDENTIFYING TRUE AND MISSED DIAGNOSES



Anna Mageras[1] Andrea Branch[2] Christopher Kim[1] Francina Collado[1] Douglas Dieterich[1] Frances Lee[1], [1]Icahn School of Medicine at Mount Sinai, New York, NY, USA, [2]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: We used retrospective, cross-sectional electronic medical record (EMR) data to create a logic flowchart to help assess patients' likelihood of having primary biliary cholangitis (PBC) and prioritize them for care management in our large New York City health system. We aimed to a) confirm the status of patients with a PBC ICD-9/10 diagnosis (Dx) code and b) identify overlooked cases without a PBC ICD-9/10 code. **Methods:** We selected adult patients who ever had an ALP result ≥ 120, AMA result, and/or PBC dx code in their EMR (n = 268,394). We extracted most recent Dx codes; outpatient lab results (excluding inpatient, emergency, and oncology); and ursodiol, obeticholic acid, elafibranor, and seladelpar prescriptions from our EPIC EMR from 01/2000 – 1/2025. Patients with a recorded death date, a primary sclerosing cholangitis Dx code, or an isolated code for unspecified biliary cirrhosis were excluded. The likelihood of PBC was determined for the remaining patients (n = 252,677) by applying AASLD diagnostic guidance and our clinical judgement. ALP ≥ 120 U/L indicated elevation. Data were processed using pandas and NumPy in Python 3.13. Counts were summarized in Excel. The logic flowchart was created using Microsoft Visio. **Results:** The cohort with a PBC Dx code (n = 2,646) included 787 AMA+ patients (30%), 328 (12%) AMA-, and 1,531 (58%) missing AMA. According to our schema (Figure 1), 1,305 (50%) members of this cohort had highest likelihood of PBC, 750 (28%) had intermediate likelihood PBC, and 591 (22%) had indeterminate likelihood and needing follow-up testing. Among 250,031 without a PBC dx code, 1,427 (1%) were AMA+, 26,019 (10%) AMA-, and 222,585 (89%) missing AMA. We labeled 460 (0.2%) as highest likelihood PBC, 9,026 (4%) intermediate likelihood, 94,643 (38%) lowest likelihood, and 145,902 (58%) as needing follow-up testing. Manual review of 5 random charts with a PBC Dx code and missing AMA revealed testing outside our health system. This highlights the limitations of structured EMR data. Next steps are 1) extracting Anti-Sp100, Anti-GP210, and histology

results and 2) performing manual chart review to better understand the ground truth of patients in green and yellow categories. We will then review random samples from the red boxes to confirm negative logic. **Conclusion:** Structured data alone are insufficient for PBC case-finding in our system. In the future, we will aim to incorporate unstructured data obtained from the EMR using AI methods, such as natural language processing. Once we have refined and validated our schema and identified our system's true PBC cohort, we will develop a longitudinal care continuum that charts treatment response and escalation. We will aim to link undiagnosed patients to liver care. We will also engage primary care providers, hepatologists, and gastroenterologists to assess provider knowledge of PBC and encourage full diagnostic testing for patients with incomplete results.

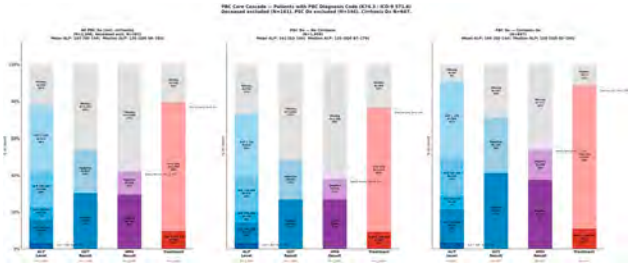
2216 | REAL-WORLD EMR DATA SHOWS HIGHER RATES OF PBC TESTING AND FIRST-LINE TREATMENT FOR PATIENTS WITH BOTH PBC AND CIRRHOSIS DIAGNOSES



Anna Mageras[1] Xiaotao Zhang[2] Francina Collado[1] Douglas Dieterich[1] Frances Lee[1], [1]Icahn School of Medicine at Mount Sinai, New York, NY, USA, [2]Icahn School of Medicine at Mount Sinai

Background: As a first step toward developing a care cascade for primary biliary cholangitis (PBC), we aimed to create a snapshot of testing and treatment received by patients with a PBC ICD-9/10 diagnosis (Dx) code in our health system.

Methods: Adult, alive patients with a PBC Dx code and no PSC Dx code were included. We extracted the following variables from our EPIC electronic medical record (EMR), selecting most recent values 01/2000–10/2025: PBC and related Dx codes; outpatient labs (excluding inpatient, emergency, and oncology); ursodiol, obeticholic acid (OCA), elafibranor, and seladelpar prescriptions (Rx); and relevant outpatient visits. Diagnostic testing and treatment rates were compared between patients with and without cirrhosis Dx using chi-square tests. Multivariable logistic regression was used to assess clinical predictors of 1) any therapy and 2) combined first line (1L) and second line (2L) therapy. Data were processed using pandas and NumPy and analyzed using statsmodels in Python 3.13. **Results:** Of 2,646 included patients, the subset with a cirrhosis Dx code (n = 647) had higher rates of testing and 1L Rx versus patients without a cirrhosis Dx; 91% vs. 73% had ALP ($p < 0.001$); 72% vs. 48% had GGT ($p < 0.001$); 58% vs. 41% had AMA ($p < 0.001$); 78% vs. 67% had one Rx ($p < 0.001$), and 11% vs. 9% had 1L plus 2L ($p = 0.23$). In multivariable regression, all ALP categories > 120 had higher odds of any Rx than ALP < 120. Positive AMA had higher odds of Rx than negative (aOR: 2.50, (1.64-3.80)). Cirrhosis Dx and osteoporosis Dx were both positively associated with any Rx. Engagement with hepatology plus primary care or hepatology alone had higher odds of any Rx compared to engagement with neither (aOR: 3.72 (2.35-5.88); aOR: 3.89 (2.94-5.16)). Low platelets had lower odds of any Rx than normal (aOR: 0.55 (0.38-0.79)). In the second model, all ALP categories > 120 had higher odds of combined 1L plus 2L, and abnormal bilirubin (total bilirubin > 1.3) had lower odds (OR: 0.56 (0.32-0.97)). **Conclusion:** High 1L rates indicate most patients with PBC Dx codes receive standard care in our health system. Our results highlight clinical markers of PBC, cirrhosis Dx, osteoporosis Dx, and engagement in hepatology as positive predictors of 1L treatment. Correlation with cirrhosis Dx may indicate higher levels of care for sicker patients or be a proxy for higher patient engagement. The inverse associations between low platelets and 1L and abnormal bilirubin and 2L may reflect gaps in care or inaccurate Dx coding. 2L rates were low relative to elevated ALP rates across groups, though cross-sectional analysis limited our ability to assess appropriate escalation. Our data also did not capture care received outside our health system. Future directions include development of a longitudinal care continuum including treatment response, escalation, and transition from OCA to newer 2L therapies.

2217 | A NOVEL CLINICAL DECISION SUPPORT INTERVENTION REDUCES AMMONIA TESTING IN CHRONIC LIVER DISEASE PATIENTS

Michael Gianarakis[1] Adam Mikolajczyk[2], [1]University of Illinois at Chicago, [2]University of Illinois Chicago

Background: Liver society guidelines in North America discourage ammonia testing in chronic liver disease (CLD) patients for diagnosing, excluding, or monitoring hepatic encephalopathy (HE). Despite this, guideline-discordant ammonia testing remains prevalent and contributes to wasteful spending. While clinical decision support (CDS) interventions have improved other aspects of liver-related care, no studies have evaluated interventions targeting ammonia overuse in patients with CLD. We evaluated the impact of a novel CDS advisory on ammonia utilization and testing behavior. **Methods:** We performed a prospective pre-post intervention study evaluating an interruptive CDS advisory implemented at a tertiary referral center in January 2026. The advisory was triggered when ammonia testing was ordered for patients with CLD and provided guideline-based recommendations on test utilization. Testing was compared across 16-week pre- and post-intervention periods. Data was extracted for inpatient, emergency department (ED) and outpatient encounters. Weekly ammonia testing trends were compared with brain natriuretic peptide testing as a control. Advisory-level characteristics were also analyzed. Multivariable logistic regression was performed to identify factors associated with alert acceptance. **Results:** Total ammonia tests decreased from 505 to 352 post-intervention, representing a 30.3% reduction and >$40,000 in cost savings ($264/test). Mean weekly testing decreased from 31.6 ± 13.7 to 22.0 ± 15.3 tests/week (p = 0.038). Reductions were observed among internal medicine (IM) (8.13 ± 4.10 vs 4.93 ± 4.80 tests/week, p = 0.020), medical critical care (CC) (12.94 ± 10.49 vs 9.67 ± 14.55, p = 0.235), and ED providers (3.64 ± 1.82 vs 2.46 ± 1.20 tests/week, p = 0.067). The number of patients undergoing repeat testing (>1 test) also declined (67 vs 47), particularly in the ED and CC department. Among 237 CDS advisories triggered, the acceptance rate was 41.4%. Among 55 patients at risk for serial testing, 25 (45.45%) of providers did not attempt to reorder and 10 (18.18%) accepted subsequent alerts. In multivariable analysis, patients with a primary diagnosis of HE (OR 0.25, 95% CI 0.06–0.97, p = 0.044) and liver transplant-related diagnoses (OR 0.17, 95% CI 0.03–0.94, p = 0.042) had lower odds of advisory acceptance. Compared with IM, there was a trend toward higher acceptance among ED providers [aOR 2.5 (95% CI 0.71–8.88), p = 0.156]. **Conclusion:** Implementation of a novel CDS advisory was associated with a significant reduction in ammonia testing and a trend toward decreased serial testing, particularly in high-utilization departments such as IM, CC, and ED. These findings support CDS tools as an effective strategy for de-implementing low-value liver care. Lower acceptance rates in patients with a primary diagnosis of HE suggests persistent reliance on ammonia testing where HE is the primary reason for presentation.

2218 | "THERE&RSQUO;S A PARADOX HERE": A QUALITATIVE EXPLORATION OF THE RESIDENT EXPERIENCE CARING FOR PATIENTS UNDER EVALUATION FOR LIVER TRANSPLANT

Annie Cravero[1] Justin Bullock[1] Mary White[2] Vandana Khungar[3] Kathleen Raskob[1], [1]University of Washington, [2]Yale-New Haven Hospital, [3]Yale University

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Studies predict a 35% shortage in hepatologists by 2033 and efforts are needed to better understand resident experiences in order to support recruitment into hepatology careers. At many transplant centers, residents are on the front lines of clinical care for patients with end stage liver disease who are under consideration for liver transplant, and these experiences shape their initial impressions of hepatology. Few studies have described how learners experience the transplant evaluation process. This exploratory study aims to understand the experiences of internal medicine residents caring for patients under evaluation for liver transplant. **Methods:** This was a multi-institutional, qualitative study. The investigators purposefully sampled internal medicine residents at the University of Washington (UW) and Yale University who had cared for at least 1 hospitalized patient under evaluation for liver transplant. Participants completed a reflective drawing exercise followed by a semi-structured interview. Methodologically, we employed phenomenology to explore the nature and meaning of these experiences for residents. During analysis, we continuously moved between discussion of the component parts of the experience and the broader whole or global themes that define this experience for residents. **Results:** Fourteen internal medicine residents were interviewed; 8 from UW and 6 from Yale. The resident experience of the liver transplant evaluation process was defined by three paradoxes, or situations that held an inherent contradiction or conflict. Paradox 1: residents worked to keep a patient stable, while knowing that the patient would have more transplant priority if they clinically worsened. Paradox 2: residents attempted to serve as the primary provider for a patient, but lacked a full understanding of or control over the clinical plan (Figure 1). Paradox 3: patients with end stage organ failure and many disease related symptoms would typically receive a palliative approach to care, but in this situation have the most potential benefit from transplant and thus receive more aggressive interventions. The extent of interventions performed in the face of uncertain transplant candidacy was challenging for residents to reconcile (Figure 2). These paradoxes resulted in residents feeling dread, frustration, and insecurity in communicating with patients. Factors that mitigated discomfort with confronted paradoxes were 1) increased experience with pre-transplant patients, 2) transparency in the purpose of transplant related processes and procedures, and 3) effective interprofessional communication with transplant hepatologists. **Conclusion:** In order to bolster trainee interest in careers in hepatology, transplant hepatologists have the opportunity to support residents in navigating key paradoxes that can contribute to disempowerment and disillusionment when caring for pre-transplant patients.

Figure 1: Drawing by Participant 10 depicting their experience caring for a patient under evaluation for liver transplant. They described their drawing with the following quote: *"...when we were taking care of him every day, there would be a lot of discussion about whether or not he would be listed. And there's so many factors that go into that that I feel like we weren't privy to, so it was a lot of questions we couldn't answer. That's why there's a cloud around us talking to the patient."*

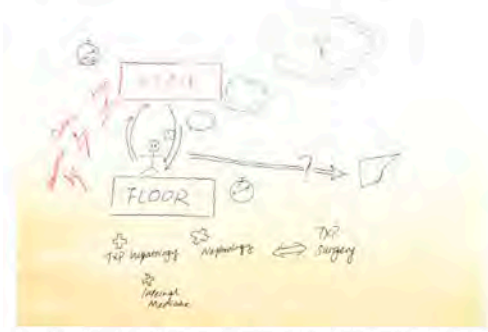

Figure 2: Drawing by Participant 6 depicting their experience caring for a patient under evaluation or liver transplant. The participant described their drawing with the following quote: *"...she was [transferred] to the ICU, and then after some stabilization, went to the [acute care] floor, and back and forth- that's what the arrows are saying. She's not happy. Then the whole team, including me, have this distant goal of, 'oh, things will just get better when she gets a transplant', but I don't really have an idea of when she's going to get the transplant or under what condition. So that's why I drew a long arrow towards this right side, towards this liver, but with a question mark saying that nobody has a crystal ball, and it very much depends on how often she goes to the ICU and for what reason. But time is ticking."*

2219 | NATIONAL TRENDS IN INFECTION RELATED HOSPITALIZATIONS AND CRITICAL CARE RECEIPT AMONG ADULTS WITH CIRRHOSIS FROM 2016-2023

Charles Marvil[1] Sarpong Boateng[2] Bahar Saberzadeh-Ardestani[3] Tamar Taddei[4] Catherine Mezzacappa[5], [1]Yale New Haven Hospital, Yale University School of Medicine, [2]Department of Medicine Yale New Haven Health, Bridgeport Hospital, [3]Department of Internal Medicine, Yale School of Medicine, [4]VA Connecticut Health Care ,Department of Internal Medicine, Digestive Diseases, Yale University, [5]Deapartment of Internal Medicine, Division of Digestive Diseases, Yale School of Medicine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Patients with cirrhosis are at increased risk of infection secondary to immune dysfunction, leading to hepatic decompensation, hospitalization, and antibiotic use. Despite this, recent estimates of infection-related hospitalizations for adults with cirrhosis in the United States are lacking. We hypothesized that infection-related hospitalizations and critical illness have increased among adults with cirrhosis in the United States. **Methods:** The Nationwide Inpatient Sample includes a representative sample of adult hospitalizations from 2016–2023. Cirrhosis was defined using a validated ICD-10 consensus code set, infections using diagnosis codes adapted from prior literature, and critical care receipt using ICD-10 codes for critical care diagnoses and procedures. Weighted annual hospitalization rates with infection or critical care were calculated per 100,000 U.S. adults stratified by cirrhosis status. Rates were normalized to 2016 to assess relative change over time, and linear regression was used to compare temporal trends. **Results:** From 2016–2023, there were an estimated 233,774,384 hospitalizations. Of these, 7,145,693 (3.06%) were for individuals with cirrhosis and 47,941,391 (20.51%) involved infection of any type. Critical care was administered in 19,178,847 (8.2%). There were 2,113,884 (0.90%) hospitalizations with cirrhosis and infection and 1,292,320 (0.55%) with cirrhosis and critical care receipt. The relative change in hospitalization rates with any infection from 2016–2023 was greater for adults with cirrhosis than those without (+27.0% vs +0.7%; $p < 0.001$) (Figure 1A). Rates increased more rapidly for bacteremia/sepsis (+47.3% vs +26.4%; $p < 0.001$), cellulitis (+22.5% vs −2.8%; $p = 0.002$), endocarditis (+67.6% vs +21.8%; $p < 0.001$), fungal infection (+71.0% vs +14.7%; $p = 0.009$), and septic arthritis (+76.1% vs +49.6%; $p = 0.041$). Pyelonephritis/UTI rates remained stable among patients with cirrhosis and declined in those without (+1.1% vs −21.5%; $p < 0.001$). Critical care receipt similarly increased faster among patients with cirrhosis (+38.3% vs +7.7%; $p < 0.001$) (Figure 1B). In patients with cirrhosis, increases in critical care receipt were similar in those with (+37.5%) and without infection (+39.2%) ($p = 0.634$). **Conclusion:** In hospitalized patients with cirrhosis, diagnosis of any infection has increased rapidly since 2016, driven by serious bacterial and fungal infections. While hospitalizations requiring critical care interventions have also increased significantly compared to those without cirrhosis, infection was not associated with this increase in critical care receipt. These findings highlight the need for ongoing research to better understand the intersection of cirrhosis, infection, and critical illness.

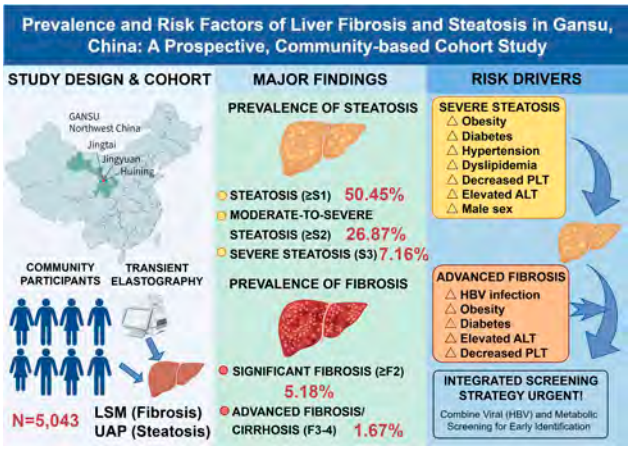
2220 | PREVALENCE AND RISK FACTORS OF LIVER FIBROSIS AND STEATOSIS IN GANSU, CHINA: A PROSPECTIVE COMMUNITY-BASED COHORT STUDY



Xueni Ma[1] Junhong Yang[2] Bin Peng[3] Min Zhang[4] Chengbo Yang[5] Yan Yang[6] Jianping Ji[7] Weidong Ren[7] Anxing Zhang[8] Xinjian Yang[9] Deqiang Luo[10] Liang Wang[1], [1]Department of Infectious Diseases, The Second Hospital of Lanzhou University, [2]Baiyin Central Hospital, Baiyin, China, [3]Department of Infectious Diseases, Jingtai County People's Hospital, Baiyin, China, [4]Department of Infectious Diseases, Huining County People's Hospital, Baiyin, China, [5]Department of Geriatrics, Jingyuan County People's Hospital, Baiyin, China, [6]Physical Examination Center, Baiyin Central Hospital, Baiyin, China, [7]Health Management Center, The First People's Hospital of Baiyin, Baiyin, China, [8]Department of Gastroenterology, Baiyin Second People's Hospital, Baiyin, China, [9]Department of Ultrasound, Baiyin Second People's Hospital, Baiyin, China, [10]Medical Affairs Department, Baiyin Central Hospital, Baiyin, China

Background: The epidemiology of chronic liver disease in China is shifting from viral hepatitis to metabolic-associated liver disease. However, population-based data from Northwest China remain scarce. This study aimed to assess the prevalence and independent risk factors of liver fibrosis and steatosis in the general population of Gansu Province, China. **Methods:** This prospective, community-based cohort study enrolled 5,043 eligible participants across three regions in Gansu (Huining, Jingtai, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Jingyuan) in 2025. All participants underwent anthropometric measurements, laboratory tests, transient elastography (TE), and a structured questionnaire. Fibrosis and steatosis were assessed via liver stiffness measurement (LSM) and ultrasound attenuation parameter (UAP). Fibrosis was staged as F0 (<7.3 kPa), F1 (7.3–7.84 kPa), F2 (7.85–9.9 kPa), and F3-4 (≥10.0 kPa). Steatosis grades S1, S2, and S3 were defined using UAP cutoffs of 244, 269, and 296 dB/m, respectively. Independent risk factors were identified using multivariate logistic regression. **Results:** Among 5,043 participants (median age 46 years; 59.8% female), significant fibrosis (≥F2) was present in 5.18% (95% CI, 4.56-5.79), while advanced fibrosis/cirrhosis (F3-4) was detected in 1.67% (95% CI, 1.31-2.02). The prevalence of steatosis (≥S1) was 50.45% (95% CI, 49.07-51.85), including 26.87% with moderate-to-severe steatosis (≥S2) and 7.16% with severe steatosis (S3). Independent predictors of advanced fibrosis included HBV infection (OR 3.19, 95% CI 1.72-5.92), obesity (OR 5.14, 95% CI 4.14-8.42), diabetes (OR 3.55, 95% CI 2.02-6.25), elevated ALT (OR 3.86, 95% CI 2.96-7.60), and decreased platelet count (OR 6.45, 95% CI 2.03-20.52). Severe steatosis was independently associated with obesity (OR 17.62, 95% CI 13.50-23.01), diabetes (OR 1.73, 95% CI 1.17-2.55), hypertension (OR 1.50, 95% CI 1.14-1.96), dyslipidemia (OR 1.36, 95% CI 1.04-1.78), decreased platelet count (OR 4.16, 95% CI 1.46-11.84), elevated ALT (OR 2.17, 95% CI 1.46-3.22), and male sex (OR 1.70, 95% CI 1.18-2.46). **Conclusion:** Liver fibrosis and steatosis are highly prevalent in the community population of Gansu Province, driven by concurrent metabolic dysfunction and chronic HBV infection. These findings highlight the urgent need for integrated metabolic and viral screening strategies to facilitate early identification and prevent progression to advanced liver disease in this region.

2221 | GENERATIVE AI IN SHAPING THE PATIENT-CLINICIAN INTERACTION IN LIVER DISEASE CARE

Mustafa Behan[1] Jutta Kurz[1] Rachma Purnama[2] Tresha Elaine Ramonal[1] Lorrinda Gray-Davis[3] Youssef Amjahdi[4] Richard Jaenisch[3] David Jaenisch[3] Michael Tunkelrott[2] Emmanuel Gorospe[5] Tarek Hassanein[6], [1]Amsety, [2]Amsety LLC, [3]None, [4]WhoFinance/Amsety, [5]Burrell College of Osteopathic Medicine, [6]Southern California Liver Centers

Background: Generative AI (Gen AI) is reshaping how patients (pts) access health information by offering personalized conversational support. With high-reaching tools such as ChatGPT, pts are increasingly turning to AI for health-related information, especially among those with chronic conditions like liver disease. With the boom in reliance on search engines and AI sources over healthcare professionals, it is critical to address questions about trust, the ability to discern information from misinformation, the evolving patient-doctor relationship as well as how Gen AI can be integrated to the benefit of pts with liver disease, including pt engagement and shared decision-making. **Methods:** The Amsety database consists of 650,000 individuals living with liver diseases in the US. We report on the results of 210 respondents surveyed about Generative AI. The survey assessed awareness and use of Gen AI, as well as its perceived usefulness, trust, accuracy, and how pts compared and integrated AI insights with advice from healthcare professionals. **Results:** 70% were recently diagnosed with liver condition (up to 3 years earlier). 32% have MASLD/MASH and 14% Alcoholic Liver Disease. 13% had cirrhosis. 53% of respondents are managed by specialists and 32% by primary care. 50% use AI for medical information, 40% have not used it but are curious, and 10% have no interest. Among users, 38% use AI several times a week, mainly ChatGPT (70%), Google Gemini (57%), and Meta AI (35%). AI is used for understanding diagnosis/disease stage (76%), explaining test results (59%), and dietary/nutrition guidance (54%). Overall experience of liver pts after using AI: 55% feel more informed about their condition, 45% are more confident speaking with their doctors, and 39% understand their treatment plan more clearly. Main concerns of use include accuracy (62%), privacy (37%), and over-reliance on AI (26%). Other sources of information include specialist/care team

(67%), health websites (50%), and hospital/clinic portals (38%). After using AI, 64% bring the information to their provider while 36% rarely or never do. 74% change diet or eating habits after AI advice, 31% request a test/referral, and 22% start or stop using a supplement. **Conclusion:** Generative AI is becoming a common tool for liver disease patients to understand their condition and well-being. It helps pts feel more informed and is frequently used as a resource to better understand clinical discussions. However, trust in AI remains dependent on alignment with professional medical advice, with ongoing concerns regarding accuracy and data privacy. There's a need to develop curated, evidence-based AI platforms to deliver trusted, high-quality pt information. This will better enable providers to integrate Gen AI into their clinical practice to support informed decision-making, enhance patient education, and ensure its safe and effective use in liver care.

2222 | A CUMULATIVE LIVER DAMAGE INDEX DERIVED FROM ROUTINE BLOOD TESTS HAS THE POTENTIAL TO TRACK POPULATION METABOLIC HEALTH AND THE RESPONSE TO POPULATION-LEVEL INTERVENTIONS

Katie Denver[1] Timothy Jobson[1] Christina Owen[1] Neil Stevens[2] Axelle Caudrillier[3] Yasmin Hamadache[3] Heath O'Brien[3] Louise Campbell[4] Patrick Short[3] Jamie Webb[3] Katie Barnes[3], [1]Somerset NHS Foundation Trust, [2]Predictive Health Intelligence, [3]Sanogenetics, [4]Tawazum Health

Background: The Cumulative Liver Damage Index (CLDI), derived from longitudinal routine alanine aminotransferase (ALT) data, identifies clinically significant hepatic fibrosis (F2+) with ROC-AUC 0.884 and number-needed-to-scan of 8 in the LiveWell study (EASL 2026). We hypothesised that CLDI risk group classification captures underlying metabolic phenotype, and that serial population-level CLDI distributions could therefore serve as a novel marker of population metabolic health to track the impact of population-level

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

interventions including NHS weight management programmes and GLP-1 prescribing, as well as longitudinal surveillance of the global trajectory of obesity and metabolic dysfunction. **Methods:** Secondary analysis of the LiveWell study (994 participants, aged 25-55, Somerset, United Kingdom). Participants were classified as control or high CLDI risk group. Four metabolic markers were compared between groups: BMI, hepatic steatosis by controlled attenuation parameter (CAP score, available in FibroScan-confirmed participants, N = 627), mean HbA1c (24-month window), and mean LDL cholesterol (24-month window). Comparisons were made across six pre-specified strata: sex (female/male) by age group (all/25-35/45-55). Wilcoxon rank-sum tests were used with rank-biserial correlation (r) as effect size. Zeros were treated as missing values for HbA1c and LDL, consistent with non-measurement in primary care records. **Results:** The high CLDI risk group had consistently higher BMI across all six sex and age strata ($p < 0.05$ in all; $r = 0.23$-0.57) and higher CAP score in five of six strata ($r = 0.30$-0.38), directly demonstrating that CLDI classification captures hepatic steatosis at a population level. HbA1c was significantly elevated in the high-risk group in female strata (all-age females $p < 0.0001$, $r = 0.21$; 45-55 females $p < 0.0001$, $r = 0.24$), with a consistent but non-significant directional trend in males, consistent with known sex differences in glycaemic risk trajectories. LDL was elevated in females (all-age $p = 0.046$) but attenuated or reversed in male strata, most plausibly reflecting differential statin prescribing in higher-risk male patients. Direction of effect was positive (higher in high-risk) for 22 of 24 comparisons across all variables and strata. **Conclusion:** CLDI risk group classification is consistently associated with higher BMI and hepatic steatosis, and with glycaemic stress particularly in women, demonstrating that CLDI functions as a metabolic health indicator rather than a liver-specific signal. Because CLDI is computable from routine blood test records, serial population-level CLDI distributions represent a novel, low-cost tool for tracking population metabolic health over time. Any health community with access to longitudinal routine ALT data — including those implementing hepatoSIGHT — can apply this approach to evaluate the impact of population health interventions.

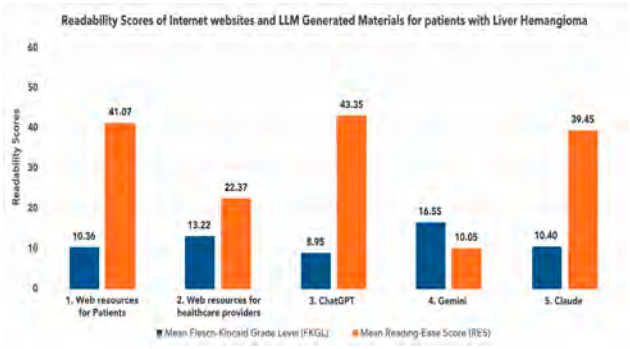
2223 | UNDERSTANDING LIVER HEMANGIOMAS IN THE ERA OF ARTIFICIAL INTELLIGENCE: A READABILITY ANALYSIS OF WEB-BASED AND LLM-GENERATED CONTENT



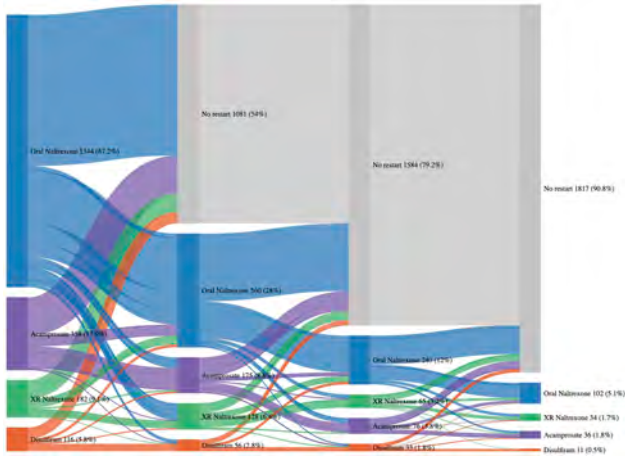
Medha Sharath[1], [1]University of South Dakota

Background: Liver hemangiomas are the most common benign liver tumors. While their exact cause and indications for surgery remain unclear, most lesions are asymptomatic and only require monitoring. Due to the uncertainty surrounding this diagnosis, many patients seek information online in addition to guidance from their physicians. With the increasing use of large language models (LLMs) such as ChatGPT, Gemini, and ClaudeAI, online medical information is becoming more accessible. Because the American Medical Association (AMA) recommends that patient education materials be written at or below a 6th-grade reading level, we evaluated and compared the readability of internet-based and LLM-generated content on liver hemangiomas. **Methods:** A Google search query for the term “liver hemangioma” was used to retrieve the top 100 results. Websites were excluded due to irrelevance, duplication, or video format. The remaining websites were categorized according to their intended audience: either patients or healthcare professionals (HCPs). In parallel, ChatGPT 5.5, Gemini 3.5 Flash, and Claude Sonnet 4.6 were each prompted with two standard questions: “What is liver hemangioma?” and “How is liver hemangioma treated?”. The readability of patient and HCP focused websites, and the 3 LLM outputs was evaluated using Flesch Reading Ease Scores (RES) and Flesch-Kincaid Grade Levels (FKGL), with categories ranging from 5th grade (90-100), 6th grade (80-90), 7th grade (70-80), 8th-9th grade (60-70), 10th-12th grade (50-60), College (30-50), to College Graduate (0-30). Statistical analysis was performed using one-way ANOVA. **Results:** Out of the 100 websites, 64 were included in the final analysis. 43 (67.2%) websites were patient directed and 21 (32.8%) were HCP directed. Mean Flesch-Kincaid Grade Level was $M = 10.36$ ($SD = 2.16$) for patient directed websites, $M = 13.22$ ($SD = 2.37$) for HCP directed websites, $M = 8.96$ ($SD = 1.45$) for ChatGPT, $M = 16.55$ ($SD = 0.05$) for Gemini, and $M = 10.40$ ($SD = 1.00$) for Claude. Mean Reading Ease Score also varied across groups: $M = 41.07$ ($SD = 12.42$) for patient directed websites, $M = 22.37$ ($SD = 11.56$) for HCP directed websites, $M = 43.35$ ($SD = 11.85$) for ChatGPT, $M = 10.05$ ($SD = 0.05$) for Gemini, and $M = 39.45$ ($SD = 10.65$) for Claude. One-way ANOVA test demonstrated a significant difference in the FKGL amongst the five groups ($F(4, 65) = 9.16$, $p < .001$, $\eta^2 = 0.36$), indicating a large effect size. There was also a

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

significant magnitude of difference in RES across the groups ($F(4, 65) = 10.37$, $p < .001$, $\eta^2 = 0.39$). **Conclusion:** Both website based and LLM generated content exceeded the 6th-grade reading level recommended by the AMA. Most patient education materials were at a college reading level. While ChatGPT performed better, it still remained at a 10th-12th grade level. These findings highlight the need for the development of more appropriate patient facing materials at suitable reading levels in order to improve understanding of liver hemangiomas.



Disclosures: Medha Sharath: Nothing to Disclose.

2224 | ALCOHOL USE DISORDER TREATMENT DISCONTINUATION AND RE-INITIATION PATTERNS AMONG ALL OF US RESEARCH PROGRAM PARTICIPANTS

Lidia Rodriguez[1] Michael Rothberg[2] Ha Tran[2] Hamlet Gasoyan[2] Katharine Bradley[3] Phuc Le[2], [1]Case Western Reserve University, [2]Cleveland Clinic, [3]Kaiser Permanente Washington Health Research Institute

Background: Despite the availability of FDA-approved medications for alcohol use disorder (AUD), real-world treatment persistence of AUD medications remains low. Understanding patterns of AUD medication discontinuation and re-initiation, and associated factors, is essential for developing interventions that support long-term treatment engagement. **Methods:** We conducted a retrospective cohort study using All of Us v8 data. Adults aged ≥ 18 with AUD diagnoses were included if they initiated AUD medications (naltrexone, acamprosate, or disulfiram) between January 1, 2018 and October 1, 2022, with follow-up through October 1, 2023. New use was defined with a 180-day medication-free washout period before the initiation (index) date, discontinuation as the first gap ≥ 60 days without medication after the index date, and re-initiation as the first new medication record after discontinuation. We estimated the probability of discontinuation within 1 year of treatment initiation and re-initiation within 1 year of discontinuation using Kaplan-Meier curves. Time to each outcome and associated patient factors were examined by Cox proportional hazards models. **Results:** Among 2000 patients initiating AUD medications (mean age 55.7 years; 58.9% male; 52.9% Non-Hispanic White), 39.5% (95% CI: 37.3%-41.7%) discontinued within one year; oral naltrexone had the lowest discontinuation rate (37.1%, 95% CI: 34.4%-39.7%). Among those who discontinued any AUD medication ($N = 919$), the median time to discontinuation was 150 days (IQR: 192), and 70.8% (95% CI: 67.8%-73.8%) re-initiated within one year. Re-initiation rates did not differ by medication ($p = 0.10$). Among those who re-initiated, median time to re-initiation was 102 days (IQR: 181). Oral naltrexone was the most common re-initiation medication (Figure). In multivariable models, alcohol-related conditions in the past year and extended-release (vs. oral) naltrexone as index medication were positively associated with discontinuation, while having less than high-school degree was negatively associated. Among patients who discontinued, those not working (vs. working) were more likely to re-initiate. **Conclusion:** Over one-third of patients discontinued AUD medications within one year of initiation, but the majority of them reinitiated within the following year. Discontinuation rate significantly differed by medication while re-initiation rate did not. Interventions to address early treatment discontinuation and support re-initiation after treatment gap in AUD care are needed.

2225 | ICD-CODED STEATOTIC LIVER DISEASE IS A MARKER OF ADVANCED DISEASE IN PATIENTS WITH CARDIOMETABOLIC RISK IN A REAL-WORLD OPPORTUNISTIC CT COHORT

Vignesh Rajasekaran[1] Asad Aali[2] Alexandria Jensen[3] Allison Kwong[4] Andrew Johnston[5] Ates Fettahoglu[2] Hye Na[5] Luyao Shen[5] Taiyo Shimizu[5] Luke Yoon[5] David Svec[6] Robert Boutin[5] Jason Hom[6] Akshay Chaudhari[2] Laura Derry[6], [1]Stanford University, Department of Internal Medicine, [2]Stanford University, Department of Biomedical Physics, [3]Stanford University, Quantitative Sciences Unit, [4]Stanford University Medical Center, [5]Stanford University, Department of Radiology, [6]Stanford University, Department of Hospital Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is highly prevalent yet frequently underrecognized until advanced disease. We previously demonstrated that opportunistic CT-based detection using Comp2Comp, a validated deep learning algorithm, identifies substantially more patients with steatotic liver disease (SLD) than standard clinical workflows. Whether formally recognized (ICD-coded) SLD represents distinct clinical risk compared with imaging-detected disease has not been directly examined. We compared all-cause mortality, cirrhosis progression, and hepatic decompensation between clinically recognized and unrecognized SLD in patients with ≥1 cardiometabolic risk factor for MASLD. **Methods:** We conducted a retrospective cohort study of adults ≥18 years old who had ≥ 1 cardiometabolic risk factor for MASLD in the 3 years preceding the qualifying contrast-enhanced or non-contrast abdominal CT at a multisite academic health system (2013–2018, 2021–2024). Patients were classified into two groups: (1) ICD-coded SLD prior to or within 30 days of the qualifying CT scan (clinically recognized [CR]) or (2) incidentally detected SLD by radiology report or Comp2Comp without ICD-coding (clinically unrecognized [CU]). Patients with ICD-9 or ICD-10 diagnosis codes for other chronic liver disease (including cirrhosis), alcohol use disorder, prior hepatic decompensation, prior hepatocellular carcinoma (HCC), liver transplant, or a cardiovascular event within 30 days of qualifying CT were excluded. All-cause mortality, incident progression to cirrhosis, and incident hepatic decompensation were modeled with modified Poisson regression and multivariable Cox analysis adjusted for demographics and comorbidities. **Results:** Among 2,361 patients with evidence of SLD on CT (CR n = 553; CU n = 1,808), median follow up was 2.2 years (IQR, 0.85, 3.41). CU was associated with lower all-cause mortality (RR 0.59; 95% CI 0.45–0.76), incident cirrhosis (n = 62 events; RR 0.20; 95% CI 0.15–0.27), and incident hepatic decompensation (n = 139 events; RR 0.44; 95% CI 0.32–0.59), all p < 0.001, compared to CR. In multivariable Cox models adjusted for demographics and comorbidities, CU patients had substantially lower hazards of death (HR 0.56; 95% CI 0.42–0.76), incident cirrhosis (HR 0.19; 95% CI 0.11–0.33), and incident hepatic decompensation (HR 0.41; 95% CI 0.29–0.58), all p < 0.001. HCC (n = 8) and liver transplant (n = 3) were too infrequent for formal modeling. **Conclusion:** Clinically recognized SLD in patients with cardiometabolic risk was associated with worse mortality and liver-related outcomes than imaging-detected but unrecognized disease, likely reflecting a sicker, more advanced cohort despite adjustments for comorbidities. Imaging-detected but unrecognized SLD may represent an earlier, still-actionable disease stage and high-yield target for FIB-4-first risk stratification pathways.

2226 | PREVALENCE OF HEPATITIS B VIRUS INFECTION, TOTAL ANTI-HBC POSITIVITY, AND ISOLATED ANTI-HBC AMONG 118,141 INDIVIDUALS UNDERGOING ROUTINE HEALTH CHECK-UPS AT MEDIC MEDICAL CENTER IN THE SOUTH OF VIETNAM

Thuy Pham[1] Dat Ho Tan[2] Nguyen Bao Toan[3] Hai Phan[3] Vi Nguyen Thi Tuong[3], [1]Medic Medical Center, Phan Chau Trinh University, [2]Medic Medical Center - Ho Chi Minh City- Viet Nam, [3]Medic Medical Center Ho Chi Minh City Vietnam

Background: This study aimed to (1) determine the prevalence of HBV serologic subgroups identified by the triple test, particularly iAHBc, among individuals in Southern Vietnam; (2) assess the associations of HBsAg positivity, anti-HBc positivity, and iAHBc with age and sex; and (3) examine the associations between HBV serologic subgroups and both liver fibrosis severity and HCC risk. **Methods:** In this cross-sectional study, at MEDIC Medical Center, HCM City (January 2023–December 2025), were simultaneously tested for HBsAg, anti-HBs, and anti-HBc; Participants were classified into five serologic groups: at risk (all negative), vaccine-induced immunity (anti-HBs only), resolved infection (anti-HBs and anti-HBc positive, HBsAg negative), iAHBc (anti-HBc only), and current infection (HBsAg positive). Liver fibrosis was staged by FibroScan (F0–F4), and HCC was ascertained from clinical records. Multivariable logistic regression estimated prevalence odds ratios (PORs) and 95% confidence intervals (CIs) for associations of serologic subgroups with age, sex, liver fibrosis, and HCC. **Results: :** Among 118,141 individuals (55.5% women, 44.5% men; mean age 44 ± 14 years), the prevalences of HBsAg, anti-HBs, and anti-HBc positivity were 6.3%, 56.1%, and 44.1%, respectively. Based on triple-test results, participants were classified as at risk (31.6%), vaccine-induced immunity (24.3%), resolved HBV infection (31.7%), iAHBc (6.2%), or current HBV infection (6.3%). At-risk and vaccine-induced immunity groups predominated among women and younger individuals, whereas resolved infection, iAHBc, and HBsAg positivity were more frequent in men. Resolved infection and iAHBc increased monotonically with age, while HBsAg positivity peaked at 40–49 years (7.5%) and declined thereafter ($p < 0.001$). In multivariable analysis, men had higher odds of HBsAg, anti-HBc, and iAHBc positivity than women (POR = 1.47, 1.39, and 1.55, respectively; $p < 0.001$). Relative to age < 20 years, HBsAg positivity peaked at 40–49 years (POR = 3.41; 95%CI 2.77-4.26), whereas anti-HBc and iAHBc increased monotonically, reaching PORs of 45.16 and 33.85, respectively, at ≥ 60 years. Compared with the at-risk group, the iAHBc group showed markedly higher advanced fibrosis prevalence (F3–F4: 21.9% vs. 9.3%) and higher odds of HCC (POR = 2.77; 95%CI 1.59-4.98), second only to current HBV infection (POR = 9.91; 95%CI 6.05-17.0). This pattern was consistent in both sexes. **Conclusion:** This is the largest study in Vietnam to apply a triple HBV serologic testing panel. Importantly, iAHBc was associated with 2.77-fold higher odds of HCC and a substantially higher prevalence of advanced fibrosis (F3–F4) compared with triple-seronegative individuals. These findings support consideration of the triple-marker panel for routine HBV screening in Vietnam.

2227 | PUBLIC DISCOURSE AND GOOGLE SEARCH PATTERNS AROUND NON-FDA-APPROVED WEIGHT LOSS COMPOUNDS: A MULTI-PLATFORM INFODEMIC ANALYSIS

Somaya Albhaisi[1] Norah Terrault[1], [1]University of Southern California

Background: Non-FDA-approved compounds, including investigational drugs (retatrutide, cagrilintide), grey-market peptides (BPC-157, ipamorelin), and research chemicals (MK-677), are increasingly discussed online as weight loss alternatives. We hypothesized that GLP-1 coverage restrictions may drive health-seeking behavior toward these alternatives. Their use remains poorly characterized at the population level. Social media platforms offer insights into emerging trends warranting clinical and research attention. **Methods:** We conducted a longitudinal digital analysis of Reddit posts (Arctic Shift archive, 30+ subreddits, January 2025–May 2026) and Google Trends data (pytrends, 72 weeks) for 48 non-FDA-approved weight loss compounds classified into three groups: investigational pharmaceuticals, grey-market peptides, and non-peptide research chemicals. Compound mentions, context themes (liver, cost, insurance, side effects, stacking, sourcing), and US state signals were extracted via keyword flagging. VADER sentiment analysis was applied to all compound-mentioning posts. Pearson correlations assessed synchrony between Reddit volume and Google search interest at compound and temporal levels. **Results:** Of 1,269 cleaned Reddit posts, 1,059 (83%) mentioned at least one compound. Retatrutide (GIP/GLP-1/glucagon agonist) dominated (920 posts, 86.9%), followed by BPC-157 (gut peptide) (111, 10.5%), MOTS-c (mitochondrial peptide)(76,

7.2%), tesamorelin (a growth hormone-releasing factor) (68, 6.4%), and ipamorelin (ghrelin mimetic)(67, 6.3%). Liver-related terms co-occurred in 474 posts (44.8%) − the single most prevalent context theme, exceeding cost (9.1%), insurance (4.2%), side effects (21.8%), and weight loss (21.3%). Sentiment was strongly positive across all compounds (68% positive, avg VADER score 0.379), including among liver-mentioning posts (74.9% positive). Google Trends showed normalized search index >10 (out of 100) for 43 of 48 compounds; sermorelin, melanotan, and retatrutide led cumulative search volume. Eight compounds showed statistically significant Reddit–Google temporal correlation, with the strongest synchrony for retatrutide ($r = +0.837$), tesamorelin ($r = +0.783$), and ipamorelin ($r = +0.756$; all $p < 0.05$). Reddit liver discussion volume remained consistently elevated (30–60% of posts monthly), while Google liver search interest rose sharply in early 2026 ($r = -0.443$, $p = 0.075$), suggesting divergent hepatic concern triggers across platforms. **Conclusion:** Online discourse around unregulated weight loss compounds rose notably in early 2026 following GLP-1 coverage restrictions. Liver-related discussions dominated, appearing in nearly half of relevant posts, yet sentiment remained persistently positive. These findings highlight an emerging infodemic with implications for hepatology practice, patient counseling, and regulatory surveillance.

Figure 1. Online Discourse Around Non-FDA-Approved Weight Loss Compounds: Platform-Specific Liver Signal Divergence (United States, January 2025–May 2026)

Monthly Reddit liver discussion versus Google liver search interest (Pearson r=−0.443, p=0.075).

2228 | EFFECTIVE STRATEGIES FOR PEOPLE WHO INJECT DRUGS TOWARD HCV ELIMINATION IN JAPAN

Ryo Sasaki[1] Taro Takami[1], [1]Department of Gastroenterology & Hepatology, Yamaguchi University Graduate School of Medicine

Background: The World Health Organization aims to eliminate hepatitis C virus (HCV) infection by 2030. In Japan, improving access to HCV testing and treatment among people who inject drugs (PWID) remains a major challenge because this population has a high prevalence of HCV infection. Since the budget for HCV treatment in prisons is limited, only a small number of incarcerated individuals can receive direct-acting antiviral (DAA) therapy. Therefore, establishing an effective care cascade linking released individuals to community-based medical care is essential. We report our institutional efforts to construct an effective HCV care cascade for PWID using Japan's unique community-based rehabilitation model and Hepatitis Medical Care Coordinator (HMCC) system. **Methods:** Following an official notification issued in February 2024 by the Correction Bureau and Rehabilitation Bureau of the Ministry of Justice encouraging collaboration between regional liver disease centers and probation services, our institution initiated cooperation with the Yamaguchi Probation Office and volunteer probation officers. Educational lectures regarding liver disease and HCV elimination among PWID were provided to probation officers, and educational materials promoting HCV testing and medical consultation were distributed. We also visited a Drug Addiction Rehabilitation Center (DARC), where lectures and questionnaire surveys were conducted to identify barriers to HCV care among PWID and explore effective intervention strategies. **Results:** More than 60 volunteer probation officers attended the educational sessions, and three probation officers were newly certified as HMCCs in fiscal year 2025. Educational sessions were also conducted for eight PWID residents at the DARC facility. Questionnaire surveys revealed insufficient knowledge regarding HCV transmission risks associated with drug use and highlighted the presence of strong social stigma toward drug users in Japan. We additionally found that many DARC residents regularly attended psychiatric hospitals for addiction treatment. Based on this finding, a collaborative liver disease care system was established with a psychiatric hospital. Consequently, two previously untreated patients with chronic HCV infection, including PWID, were promptly introduced to inpatient DAA therapy and successfully achieved sustained virological response. **Conclusion:** Collaboration among probation services, volunteer probation officers, DARC facilities, and psychiatric hospitals enabled effective outreach and reliable HCV treatment intervention for PWID. These activities may contribute to establishing a sustainable and effective HCV care cascade for PWID in Japan.

2229 | FIB-4 PERFORMANCE FOR RULING OUT ADVANCED FIBROSIS IN A PREDOMINANTLY BLACK PRIMARY CARE COHORT

Alexander Zhu[1] Meghan Cloutier[1] Melissa Bravo[1] Amera Alsalahi[1] Eliane Atallah[1] Jenna Dawson[1] Ravneet Kaur[1] Edward Tamale[1] Lan Nguyen[1] Mark Rayev[1] Inioluwa Dada[1] Brady Jensen[1] Ikjot Singh[1] Anthony Martinez[1], [1]University at Buffalo

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects roughly 25–30% of US adults, and advanced fibrosis is the strongest predictor of liver-related mortality. The 2023 American Association for the Study of Liver Diseases (AASLD) guidance endorses the Fibrosis-4 (FIB-4) index as first-line non-invasive testing for advanced fibrosis in primary care, with age-adjusted low cutoffs (<1.3 if age <65, <2.0 if ≥ 65) and a high cutoff of ≥ 2.67. Data on FIB-4 performance for ruling out advanced fibrosis in predominantly Black US primary care populations are limited. We evaluated FIB-4's performance in this setting. **Methods:** We conducted a retrospective single-center analysis of adults seen at an academic internal medicine clinic from March 2024 to December 2025. Inclusion required at least one clinic visit and a computable FIB-4. Diagnostic accuracy was evaluated in the subset who also had abdominal imaging or vibration-controlled transient elastography (VCTE). FIB-4 was stratified into low-, indeterminate-, and high-risk categories using AASLD age-adjusted cutoffs. The composite advanced-fibrosis outcome was defined as cirrhosis or portal hypertension on cross-sectional imaging, or F3–F4 fibrosis or liver stiffness ≥ 12 kPa on VCTE. Diagnostic performance at the low cutoff was assessed using Wilson 95% CIs; discrimination was assessed using area under the curve (AUC) with DeLong 95% CIs. **Results:** Of 1,906 adults meeting inclusion criteria (mean age 61 years, 50% male, 53% Black, 34% White, 17% with diabetes, 77% with hypertension), 541 (28%) had imaging or VCTE, and 39 (7.2%) met the composite advanced-fibrosis outcome. At the AASLD age-adjusted low cutoff, FIB-4 achieved sensitivity 71.8% (95% CI 56.2–83.5), NPV 96.7% (94.2–98.2), specificity 64.5% (60.3–68.6), PPV 13.6% (9.6–18.9), and AUC 0.71 (95% CI 0.611–0.802). Rate of advanced fibrosis on imaging or VCTE increased with FIB-4 risk category: 3.3% in low-risk (11/335), 9.7% in indeterminate-risk (13/134), and 20.8% in high-risk (15/72). FIB-4 correlated with age (Spearman $\rho = 0.580$, $p < 0.001$), supporting age-adjusted cutoffs. NPV exceeded 95% in all subgroups

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

except diabetes (90.4%, 95% CI 79.4–95.8). NPV was comparable between Black (96.8%, 95% CI 93.1–98.5) and White (97.2%, 95% CI 92.1–99.0) participants. **Conclusion:** In this predominantly Black primary care cohort, FIB-4 with age-adjusted cutoffs ruled out advanced fibrosis with NPV 96.7%, matching published estimates. AUC was 0.71 (95% CI 0.611–0.802), overlapping published ranges. These findings support FIB-4 as first-line testing in this underrepresented population. A lower NPV in the diabetes subgroup (90.4%) is consistent with reported reductions in FIB-4 accuracy in diabetes and suggests that additional fibrosis assessment may be warranted in these patients.

2230 | ASSESSING UTILIZATION OF HEPATOLOGY E-CONSULTS FOR MASLD IN VETERANS

Anika Mittal[1] Yolanda Rodriguez Villalvazo[1] Kyle Brown[1], [1]University of Iowa Health Care

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly prevalent among the veteran population, underscoring the need for early identification and risk stratification to prevent disease progression and prioritize in-person hepatology care for veterans with advanced liver disease. The Veterans Affairs (VA) e-consult program aims to expand access to specialty services while reducing unnecessary in-person visits and travel for veterans. Prior literature has demonstrated that gastroenterology e-consults can address many clinical questions that can be managed by primary care providers (PCPs) without in-person specialist evaluation. However, the use of hepatology e-consults as potential decision support tools for PCPs remains understudied. This study evaluated hepatology e-consults utilization at the Iowa City VA Medical Center (IC VAMC), the proportion related to diagnosis and management of MASLD, frequency of recommended in-person evaluation, and the extent to which e-consult recommendations are implemented. **Methods:** This retrospective cohort study evaluated 786 hepatology e-consults submitted between May 2016 and May 2025 at the IC VAMC. Metabolic risk factors were identified through chart review of clinical, laboratory, and imaging data. Implementation of hepatologist recommendations was assessed through review of notes and orders within 6 months of the consultation date. **Results:** In this study, 39% of e-consults addressed MASLD, making it the most common indication for consultation, compared to other liver-related diseases, including alcohol-associated liver disease, abnormal imaging findings, and viral hepatitis. Primary care providers accounted for 91% of hepatology e-consults, including 40% from NPs, 14% from PAs, 34% from MD/DOs, and 10% from resident trainees. Of the 786 consults, only 10% resulted in a recommendation for in-person evaluation by a hepatologist. Among the MASLD-related consults, 52% of patients had documented implementation of at least one hepatologist recommendation, including management of metabolic comorbidities or referral for weight management services. **Conclusion:** MASLD is the leading reason for hepatology e-consultation in this veteran population, yet only a minority require further in-person hepatology evaluation. While e-consults provide actionable guidance, recommendations were only implemented in about half of MASLD-related e-consults. This highlights an opportunity to strengthen education on MASLD identification, risk-stratification, and management practices among primary care providers. Furthermore, this study reinforces the need to use guideline-based recommendations to improve care efficiency and clinical outcomes for veterans with metabolic liver disease. Future interventions should explore how embedding risk-stratification frameworks into e-consults could improve management of MASLD by PCPs.

2231 | IMPLEMENTATION OF A INPATIENT TELEHEPATOLOGY AND TELEPSYCHIATRY SERVICE ACROSS THE UNIVERSITY OF MICHIGAN STATE NETWORK TO IMPROVE ACCESS TO LIVER TRANSPLANT–RELATED CARE.

Alexandra Shingina[1] Seth Waits[1] Sarah Uttal[1] Michelle Muza-Moons[2] Abhishek Satishchandran[3] Ammar

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Hassan[1] Kinza Tareen[1], [1]University of Michigan, [2]University of Michigan Health-West, [3]Sparrow Hospital

Background: Telemedicine-based inpatient transplant hepatology care delivers liver-related expertise directly to patients at regional network hospitals, reducing unnecessary transfers to the main academic campus. This model improves access to transplant hepatology, accelerates multidisciplinary decision-making, and is especially valuable for patients with acute alcohol-associated hepatitis requiring timely psychosocial evaluation for sobriety protocol eligibility. **Methods:** A combined inpatient telehepatology and telepsychiatry consultation model was implemented between the University of Michigan (U-M) main campus and regional network hospitals using HIPAA-compliant telehealth equipment. Transplant hepatologist, transplant surgeon and transplant psychiatrist were telecredentialed at each site and documented consults within the network hospital's EMR. Local providers initiated consultations through M-Line, U-M's centralized consultation services line. Two sites launched: Site 1 in October 2025 and Site 2 in March 2026. **Results:** Across both sites, 21 telehepatology and 10 telepsychiatry consultations were completed, most common reason for cosnult was decompensated cirrhosis. Overall, 10 patients were transferred for transplant evaluation at the main campus, yielding 3 completed transplants and 1 active listing.At Site 1, 12 patients received telehepatology and 8 telepsichiatry consultations; 8 were transferred for transplant evaluation, resulting in 2 transplants, 3 deaths during workup, 2 closures after clinical improvement, and 1 deferral. Mean visit and documentation times were 20 and 17 minutes. At Site 2, 9 telehepatology and 2 telepsychiatry consultations were completed; 2 patients were transferred to main campus, with 1 transplanted and 1 actively listed. Mean visit and documentation times were 17 and 15 minutes. **Conclusion:** A statewide telehepatology consultation service is a feasible strategy to expand transplant hepatology access, improve transfer coordination, and preserve main-campus bed capacity. Early experience across two network hospitals demonstrates the model's ability to identify urgent transplant candidates, integrate telepsychiatry into transplant assessment, and facilitate appropriate high-priority transfers. This program has strong potential to enhance patient and provider experience, broaden access to U-M hepatology and liver transplant services, and strengthen the statewide network's capacity to deliver efficient, patient-centered care.

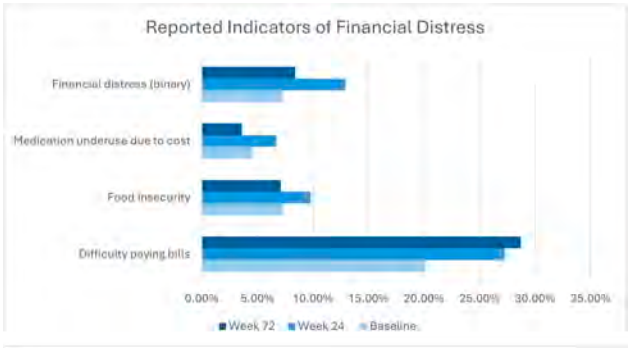
2232 | MASLD IS INDEPENDENTLY ASSOCIATED WITH HIGH FINANCIAL BURDEN AMONG PATIENTS WITH CIRRHOSIS IN A PROSPECTIVE STUDY: RESULTS FROM LIVE-SMART



Anvi Sonarikar[1] Jacqueline Theroux[1] Samantha Nikirk[2] Richard Mason[1] Sumeet Asrani[3] Donna Evon[4] Elliot Tapper[5] Marina Serper[6], [1]Division of Gastroenterology and Hepatology, University of Pennsylvania, [2]Division of Gastroenterology and Hepatology, University of Michigan, [3]Liver Consultants of Texas, [4]UNC SOM, [5]University of Michigan Medical Center, [6]University of Pennsylvania Health System

Background: Cirrhosis is associated with significant financial strain, which may negatively impact health outcomes and quality of life. However, prospective longitudinal data evaluating financial burden in cirrhosis are limited. **Methods:** We report a pre-registered ancillary study from LIVE-SMART, a prospective randomized trial designed to reduce falls in patients with cirrhosis (NCT#07140120). We aimed to quantify self-reported healthcare utilization, financial distress, financial toxicity, and work productivity, as well as identify patient factors associated with high financial burden. Financial distress was defined as the presence of two or more of the following due to cost on the Health and Retirement Survey (HRS): difficulty paying bills, food insecurity, and medication underuse. Financial toxicity was assessed using the Comprehensive Score for Financial Toxicity – Functional Assessment of Chronic Illness Therapy (COST-FACIT) survey. Work productivity was assessed using the Work Productivity and Activity Impairment (WPAI) questionnaire. The primary outcome, high financial burden, was defined as either financial distress (2 or more HRS-based financial difficulties) or financial toxicity (corrected COST-FACIT score < 26). **Results:** Among 230 participants, the mean age was 61.8; 92.6% were White; and 60% were female, 37% were college educated, and 26.3% resided in rural areas. Participants were recruited from MI, TX, and PA. Rates of financial distress fluctuated over time (Figure 1). At 72 weeks post-enrollment, financial distress was present in 28.7% of participants, most commonly reported as having difficulty paying bills, which increased over time. Healthcare utilization was high across multiple domains, particularly medication use (66.1%) and laboratory/imaging/diagnostic testing (41.7%). Nearly half of patients engaged in primary care visits (43.5%), and 35.7% reported specialty care visits within the prior 3 months. Only 34% of participants were employed; of these, 21% reported absenteeism (chronic absence from work), and 24% reported presenteeism (working at a reduced capacity while sick). In a multivariable model adjusted

for age, sex, education, liver disease severity, medications, and comorbidities, metabolic dysfunction-associated steatotic liver disease (MASLD) was the only factor independently associated with high financial burden (OR = 12.22, p = 0.01). **Conclusion:** Patients with liver cirrhosis experience substantial healthcare utilization and considerable financial burden, likely related in part to comorbid conditions. MASLD was independently associated with a higher financial burden. Interventions to reduce financial strain in this population are needed.

2233 | CHANGE IN CARE-SEEKING INTENTION AFTER TRANSIENT ELASTOGRAPHY AND COUNSELING: A COMMUNITY-BASED PRE-POST INTERVENTION STUDY

Tiange Zhang[1] Kali Zhou[1] Jennifer Dodge[1] Andrea Amaro[2] Michael Betel[3] Michael McTighe[4] Sherri Brown[3] Norah Terrault[1], [1]University of Southern California, [2]USC, [3]Fatty Liver Alliance, [4]Aegle Medical

Background: Transient elastography (TE) is increasingly used in community settings and may promote liver health. Prior studies suggest that TE may motivate lifestyle modifications; however, its influence on subsequent care-seeking remains unclear. We evaluated whether a community-based liver health intervention using TE and counseling was associated with changes in care-seeking intention. **Methods:** We conducted a pre-post intervention study among adults aged ≥21 years attending a community TE screening event. Participants completed surveys before and immediately after TE and counseling. TE measured steatosis and liver stiffness. Counseling was delivered by a trained community health worker and medical resident in the participant's preferred language and tailored to the TE result. The primary outcome was change in care-seeking intention score (range 3-12), derived from three 4-point Likert scale items assessing intention to talk to, schedule visit with, or seek help from a provider regarding liver health. Participants were classified into 3 groups: significant fibrosis (stiffness ≥7.3 kPa, equivalent to ≥F2, with or without steatosis), any steatosis (steatosis ≥238 dB/m) without significant fibrosis, no steatosis nor significant fibrosis. Within-group changes were assessed using paired t tests. **Results:** 121 of 125 participants had valid TE measurements (IQR/median ≤30%) and were included in the analysis. The median age was 53 (IQR, 26), with 74% female and 85% Hispanic. Median liver stiffness was 5.0 kPa (IQR, 2.1) and median steatosis was 284 dB/m (IQR, 54). 19 (16%) participants had significant fibrosis, 87 (72%) had steatosis without significant fibrosis, and 15 (12%) had no steatosis/significant fibrosis. Most participants had seen a primary care provider in the last year (78%). 64% had previously heard of fatty liver disease, while 18% reported a prior diagnosis. 53%, 41%, 31%, and 42% of participants self-reported overweight/obesity, prediabetes/diabetes, hypertension, and cholesterol problems, respectively. Mean care-seeking intention score before intervention was 9.37 (SD, 1.82). Mean intention score increased by 1.74 points in the significant fibrosis group (9.47 to 11.21; p < 0.001) and by 0.23 points in the steatosis without significant fibrosis group (9.34 to 9.57; p = 0.003). The no steatosis/no significant fibrosis group showed no significant change (9.40 to 9.67; mean change 0.27; p = 0.10) (**Table 1**). **Conclusion:** Community-based TE screening identified a substantial number (1 in 6) with significant liver fibrosis. Care-seeking intention significantly increased after TE with tailored counseling among participants with significant fibrosis, with no decrease in intention among those with no steatosis nor significant fibrosis, suggesting appropriate care-seeking motivation without false reassurance. Future studies should test whether TE leads to objective care-seeking.

Table 1. Change in care-seeking intention score pre- and post-intervention by TE groups

TE groups	Mean pre-test intention score (SD)	Mean post-test intention score (SD)	Change in intention score (SD)	p-value
No steatosis/no significant fibrosis (n=15)	9.40 (2.13)	9.67 (1.95)	0.27 (0.59)	0.104
Steatosis without significant fibrosis (n=87)	9.34 (1.9)	9.57 (1.71)	0.23 (0.71)	0.003
Significant fibrosis (n=19)	9.47 (1.12)	11.21 (1.23)	1.74 (1.41)	<0.001

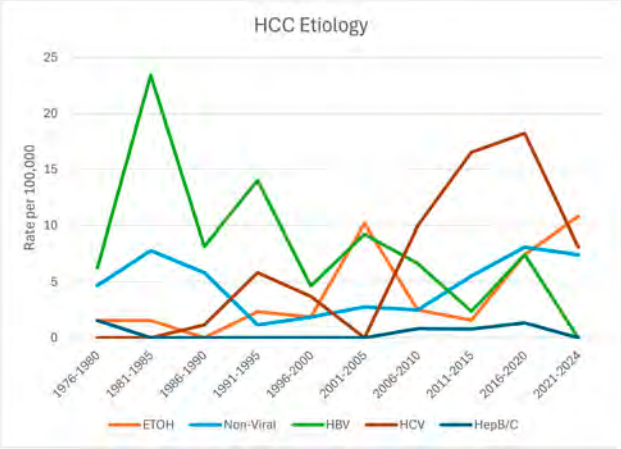
2234 | CHANGING HEPATOCELLULAR CARCINOMA ETIOLOGY IN ALASKA



Lesleigh Kowalski[1] Brian McMahon[2] Lisa Townshend-Bulson[3], [1]Alaska Native Tribal Health Consortium, [2]Alaska Native Medical Center, [3]Alaska Native Tribal Consortium

Background: Hepatocellular carcinoma (HCC) etiology varies, and rates are expected to increase worldwide. HCC rates were previously high among Alaska Native and American Indian (ANAI) peoples in Alaska yet are expected to change in parallel with changes in underlying causes of liver disease. The aim of this abstract is to describe the current etiology and survival rates of ANAI peoples with HCC living in Alaska. **Methods:** The cause of HCC was determined by the treating medical provider and maintained in a clinical registry. Incidence is reported as new HCC diagnosis within the ANAI population living in Alaska per 5-year cumulative incidence from 1970 to 2024. HCC by stage used diagnosis years 2018-2023 as the most recent six years of data. HCC observed 5-year survival among ANAI peoples diagnosed with liver cancer between 1992-2023 using an actuarial method. **Results:** HCC due to HBV decreased from its highest rate of 23.40 per 100,000 between 1981-1985 to 6.65 per 100,000 between 2016-2020 to 0 per 100,000 between 2021-2024. Incidence of HCC from HCV peaked at 18.23 per 100,000 between 2016-2020 and then declined to 8.10 per 100,000 between 2021-2024. Incidence of HCC from ALD increased between 2011-2015 from 2.50 per 100,000 and 2021-2024 to numbers 10.80 per 100,000. Incidence of HCC from non-viral causes increased from years prior to 7.80 per 100,000 between 2016-2020 and 7.43 between 2021-2024. Between 2021 and 2024 among ANAI peoples, 0% of HCC cases were attributed to HBV, 41% were attributed to ALD, 31% were attributed to HCV, and 28% were attributed to non-viral causes, including MASLD/MASH, PBC, or AIH. Specific stage at diagnosis breakdown between 2018-2023 includes stage I at 35.8%, stage II at 24.7%, stage III at 13.6%, stage IV at 17.3%, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

other at 8.6%. Among ANAI peoples in Alaska with HCC, 89.5% diagnosed with stage I or II liver cancer survived to 12 months and 47.4% of people survived to 60 months. For those diagnosed with stage III or IV liver cancer, 21.7% survived 12 months and 0% survived to 60 months. Five-year survival of liver cancer demonstrated a decreasing trend among women: between 1992-2013 the survival at 60 months post-diagnosis was nearly 38% (95% CI [20.90, 54.90]); for women diagnosed between 2014-2018 the survival at 60 months decreased to 25% (95% CI [7.80, 47.20]) while survival increased in men from 31.30% (95% CI [20.70, 42.50]) survival at 60 months between 1992-2013 to 42.90% (95% CI [21.90, 62.30]) survival at 60 months between 2014-2018. **Conclusion:** The US, and specifically Alaska, is experiencing changing trends in HCC etiology. Historically, viral hepatitis such as HBV and HCV have caused the most cases of liver cancer. However, both causes are decreasing as it relates to HCC. An increase was notable in HCC caused by MASLD and ALD, specifically among women, which highlights the need for robust preventive, interprofessional care in the treatment of early-stage MASLD and screening for ALD.

2235 | SPECIALTY CARE IN CIRRHOTIC PERITONITIS: DOES HEPATOLOGY CONSULTATION MATTER?

Kahler Doyle[1] Brayden Doyle[2] Viraj Gandhi[1] Mohammad Ashfaq[3], [1]TCU Anne Burnett School of Medicine, [2]TCU College of Science and Engineering, [3]Baylor Scott & White Liver Consultants of Texas

Background: Hepatology consultation is commonly involved in managing cirrhotic patients with peritonitis, yet its relationship to disease severity, care patterns, and outcomes is not well defined. We compared clinical characteristics, management, and longitudinal outcomes between patients who did and did not receive hepatology consultation during hospitalization. **Methods:** We performed a retrospective cohort study of cirrhotic patients admitted with peritonitis, stratified by hepatology consultation status. Demographics, laboratory data, microbiology, treatment patterns, consultations, and outcomes were compared using univariate analyses with ORs and 95% CIs. Time-to-event outcomes were assessed using Kaplan–Meier survival analysis and competing-risk regression for readmission, with log-rank and Gray's tests. AI-assisted tools improved readability and language clarity. **Results:** We included 401 patients (no hepatology consult n = 221; hepatology consult n = 180). Consulted patients had longer length of stay (7.0 [5.0–13.0] vs 10.0 [5.0–17.0], p = 0.002) and greater disease severity, including higher admission MELD 3.0 (23.0 vs 25.0, p = 0.004) and discharge MELD 3.0 (21.0 vs 24.0, p = 0.003).Hepatology consultation was associated with increased diagnostic and treatment intensity, including greater repeat paracentesis (late PFA obtained OR 3.98, 95% CI 2.62–6.04), earlier antibiotic initiation, and higher use of antifungal (OR 3.35, 1.79–6.26), broad-spectrum (OR 2.98, 1.55–5.74), and anaerobic therapy (OR 1.86, 1.03–3.36), with longer treatment durations. Prophylaxis prescribing was more common (OR 2.12, 1.38–3.27), including fluoroquinolone prophylaxis (OR 2.32, 1.44–3.74).Patients with hepatology consultation demonstrated increased healthcare utilization, including higher rates of central venous access (OR 2.01, 1.34–3.00), nephrology consultation (OR 1.75, 1.17–2.60), cardiology consultation (OR 2.03, 1.14–3.63), and imaging utilization. Microbiologic complexity was also greater, including increased multidrug-resistant organisms (OR 2.19, 1.07–4.48) and fungal peritonitis (OR 2.31, 1.02–5.22).Despite higher acuity, hepatology consultation was associated with improved long-term outcomes, including reduced 3-year (OR 0.56, 0.36–0.86), 4-year (OR 0.53, 0.34–0.82), and 5-year mortality (OR 0.58, 0.37–0.91). Survival analysis demonstrated improved overall survival in the hepatology consult group (log-rank p = 0.048), while cumulative incidence of readmission did not differ significantly (Gray's p = 0.294). **Conclusion:** Hepatology consultation in cirrhotic patients with peritonitis is associated with greater disease severity and more intensive diagnostic and therapeutic management, yet linked to improved long-term survival. These findings suggest that specialized hepatology

involvement may contribute to better longitudinal outcomes in this high-risk population.

★ 2236 | ◆ SEXUAL FUNCTION IN LIVER TRANSPLANT RECIPIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Yooyun Chung[1] Ilkay Ergenç[1] Tengfei Si[1] Alex Stagg[2] Michael Heneghan[1], [1]The Roger Williams Institute of Liver Studies, King's College London, London, SE5 9RS, UK, [2]Royal Free Hospital Medical Library, UCL Library, Culture, Collections & Open Science, Rowland Hill

Background: Sexual function (SF) is an integral part of quality of life (QOL) and is highly prevalent in patients with end-stage liver disease. Liver transplantation (LT) improves survival and QOL; however its impact on SF remains incompletely defined. This was a systematic review and meta-analysis evaluating SF outcomes following LT. **Methods:** A systematic search of MEDLINE, Embase and PsychINFO was conducted from inception to May 2026 in accordance with PRISMA 2020 guidelines. Studies evaluating SF in adult LT recipients were included. Meta-analysis was performed for studies reporting erectile function (EF) outcomes using the International Index of Erectile Function (IIEF). Standardized mean differences (SMDs) with 95% confidence intervals (CIs) were pooled using a random effects model. Narrative synthesis was performed for heterogeneous outcomes. **Results:** A total of 7289 records were identified with 48 studies included in the systematic review. Five studies involving 390 male participants (203 post-LT and 187 pre-LT) were eligible for meta-analysis (Figure 1). LT was associated with significant improvement in EF, with a pooled SMD 0.63 (95% CI 0.41-0.85, $p < 0.0001$). No significant heterogeneity was observed ($I2 = 0\%$, $p = 0.454$). Narrative synthesis indicated improvement across multiple domains including libido, sexual satisfaction and psychosocial wellbeing following LT. Restoration of endocrine function and improved overall health contributed to improved SF outcomes. However, persistent sexual dysfunction remained common and was associated with increasing age, metabolic risk factors, depression, anxiety and immunosuppression therapy. Female recipients demonstrated improvements in menstrual regularity and sexual satisfaction although data in women were limited. **Conclusion:** LT is associated with significant improvement in erectile function and broader sexual health outcomes. Despite overall improvement, persistent sexual dysfunction remains prevalent after transplantation. Routine standardised sexual health assessment should be incorporated into long-term post-transplant care pathways.

Figure 1. Forest plot of pooled effect estimate of studies assessing erectile function before (control) and after liver transplantation (experimental). Squares represent the effect estimate for each individual study, with the size of the square proportional to the weight of the study in the meta-analysis. Horizontal lines indicate the 95% confidence intervals. The diamond represents the pooled effect estimate.

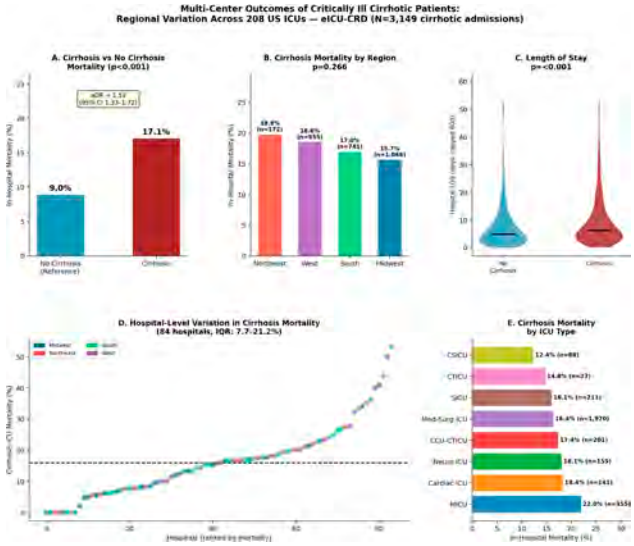
2237 | ◆ INTER-HOSPITAL VARIATION IN CIRRHOSIS ICU MORTALITY: A MULTICENTER EICU ANALYSIS OF US CRITICAL CARE



Innocent Lutaya[1] Vicki Oladoyin[1] Brian Xu[1] Shanelle Brodeur[1] Chima Amadi[1] Shaikhoon Mohammed[1] Christopher Fay[1] Henok Tafesse[1] Nicolas Bakinde[1] Emmanuel Marfo[1] Abisola Ajayi[1], [1]Morehouse School of Medicine

Background: Cirrhosis is associated with high ICU mortality, but the extent of inter-hospital variation in outcomes and the independent contribution of cirrhosis severity markers (hepatic failure co-diagnosis, APACHE IV scores) to mortality across diverse practice settings remains poorly understood uncharacterized in multi-center studies. **Methods:** We analyzed the eICU Collaborative Research Database v2.0 (eICU-CRD), comprising of 208 US hospitals and 164,573 adult ICU admissions. Cirrhosis was identified using the eICU APACHE IV admission diagnosis variable (apachePredVar.cirrhosis = 1). The primary outcome was in-hospital mortality. Multivariable logistic regression adjusted for hepatic failure co-diagnosis, APACHE IV score, age, sex, diabetes, and metastatic cancer. Inter-hospital variation in cirrhosis mortality was characterized by hospital-level mortality range, interquartile range (IQR), and Kruskal-Wallis test by region. **Results:** Cirrhosis was identified in 3,149 patients (1.91%). Cirrhosis patients had significantly higher in-hospital mortality (17.1% vs. 9.0%, $p < 0.001$; aOR

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

1.51, 95% CI 1.33-1.72; p < 0.001). Concurrent hepatic failure was present in 51.3% of cirrhosis patients and independently reduced mortality (aOR 0.80, 95% CI 0.69-0.92; p = 0.002), likely reflecting a coding artifact (hepatic failure coded with cirrhosis vs. hepatic failure alone). Hospital-level mortality in cirrhosis ranged from 0-53.3% (IQR 7.7-21.2%), representing substantial inter-hospital variation. Region was not associated with mortality (Kruskal-Wallis p = 0.27). APACHE IV score was the strongest independent predictor of mortality (aOR 1.04 per unit increase; p < 0.001). **Conclusion:** Cirrhosis independently increases ICU mortality 1.5-fold across a 208-hospital US network after adjustment for APACHE IV severity. Marked inter-hospital variation (0-53% range) not explained by regional factors suggests substantial differences in care processes, case mix, or resource availability. These data provide a multi-center benchmarking framework for quality improvement initiatives in ICU management of cirrhosis.

2238 | ◆ EARLY POST-LIVER TRANSPLANT CAREGIVER BURDEN AND PSYCHOSOCIAL OUTCOMES

Alvaro Noriega Ramirez[1] Meena Tadros[2] Dyanna Gregory[1] Arjmand Mufti[1] Madhukar Patel[1] Shannan Tujios[1] Mary Joy Tuquero[1] Samantha Kimbrough[1] Cheri Goldstein[1] Melissa Fogg[1] Brandy Brasfield[1] Derek Bartlett[1] Lisa VanWagner[1] Amit Singal[1] Sarah Lieber[1], [1]University of Texas Southwestern Medical Center, [2]University of Pennsylvania

Background: Caregivers of liver transplant recipients (LTRs) are essential to a successful patient recovery after liver transplant (LT). However, little is known about the burden of caregiver support and its impact on their quality of life. We aimed to investigate caregiver burden, psychosocial outcomes, and support pre- and post-LT. **Methods:** We conducted an interim analysis of a prospective cohort including LTRs and their caregiver at a large U.S. transplant center. LTRs and caregivers are enrolled at LT waitlist (baseline) and followed until 12 months post-LT. Sociodemographic, clinical, and caregiver reported variables were collected as well as: emotional/information support, global health, anxiety, and social isolation (PROMIS) and overall caregiver burden (Zarit Interview). We conducted multivariable linear regression to identify factors associated with higher post-LT caregiver burden and quality-of-life. **Results:** Among 83 caregivers, 75.9% were female and were the spouse/significant other (62.7%) of LTRs; 54.1 % were employed. At 6-months post-LT, 73.0% reported moderate to severe caregiver burden. Compared to pre-LT, caregivers reported decreased emotional support (p = 0.04), physical (p = < 0.0001) and mental (p = 0.005) quality-of-life, as well increased social isolation (p = 0.04) despite decreased anxiety (p = 0.0002) after LT (**Figure 1**). On multivariable modeling adjusted for covariates (caregiver age, sex, race, ethnicity, employment and LTR indication for LT, hospitalizations and inpatient LTE), caregivers of LTRs for alcohol related liver disease had lower post-LT anxiety (beta = -8.33; p = 0.001) and depression (beta = -9.09; p = < 0.0001) scores. Hispanic caregivers had higher post-LT informational (beta = 5.761; p = 0.02) and emotional support (beta = 5.76; p = 0.008), while Black caregivers reported higher emotional support post-LT (beta = 9.098; p = 0.04) compared to non-Hispanic Whites. **Conclusion:** Despite lower anxiety scores, caregivers report decreased emotional support, physical and mental quality-of-life post-LT. Increased caregiver burden and social isolation post-LT, especially among those employed. There may be more beneficial caregiver outcomes for ALD LTRs as well as differing emotional and informational support by race and ethnicity. These results highlight the crucial need to mitigate caregiver burden post-LT with interventions that promote physical and mental well-being, as well as support networks.

2239 | ◆ IMPACT OF PALLIATIVE CARE INTERVENTION ON CAREGIVERS OF PATIENTS WITH ADVANCED CHRONIC LIVER DISEASES: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Manisha Verma[1] Victor Navarro[2] Andrzej Kosinski[3] Michael Volk[4] Don Rockey[5] Gyorgy Baffy[6] Binu John[7] Richard Kalman[1] Alfred Barritt IV[8] Sofia Jakab[9] Mina Rakoski[10] Marina Serper[11] Eric Orman[12] Kristel Hunt[13] Marina Roytman[14] Nicholas Hoppmann[15] Christopher Woodrell[16] Ayse Aytaman[17] Elliot Tapper[18] Rohit Nathan[19] Maya Balakrishnan[20] Roniel Cabrera[21] Marie Bakitas[22] Tamar Taddei[23], [1]Thomas Jefferson University, [2]Jefferson Health System, [3]Duke University, [4]Baylor Scott&White Health, [5]MUSC, [6]VA Boston Healthcare System, [7]University of Miami and Miami VA, [8]UNC, [9]VA West Haven, [10]Loma Linda University, [11]University of Pennsylvania Health System, [12]Indiana University, [13]VA Bronx, [14]UCSF Fresno, [15]USC, [16]Icahn School of Medicine at Mount Sinai, [17]VA NY Harbor Healthcare System Brooklyn Campus, [18]University of Michigan Medical Center, [19]Einstein Medical Center, [20]Baylor College of Medicine, [21]University of Florida, [22]University of Alabama, Birmingham, [23]Yale University

Background: Caregivers of patients with advanced chronic liver disease (CLD) experience substantial burden and psychological distress, yet effective supportive interventions remain poorly defined. Palliative care (PC) may improve caregiver outcomes, although the comparative effectiveness of different PC delivery models is unknown. We compared the effectiveness of PC delivered by PC specialists (PC arm) versus trained hepatologists (Hep arm) on caregiver burden and related outcomes. **Methods:** This is the primary analysis of prespecified caregiver outcomes from the PAL-LIVER multicenter cluster RCT. Nineteen centers were randomized to PC delivered by 1) PC specialists (PC arm, 8 centers) or 2) trained hepatologists (Hep arm, 11 centers); conducted from 2019–2025. Hepatologists received training in PC tailored to CLD, after randomization. Caregivers were adults providing $\geq$10 hours/week of unpaid support and consistently involved in patient care and were enrolled separately from patients. Both arms followed a standardized 4-visit intervention addressing caregiver burden, disease education, and goals-of-care conversations.Caregiver outcomes were prespecified secondary outcomes in the parent trial. The primary outcome for this analysis was change in caregiver burden measured by the Zarit Burden Interview-12 (ZBI-12) at 3 months. Secondary outcomes included caregiver QoL (PROMIS-29) and caregiver-reported communication measures at 3 months. Higher score reflects higher domain assessed. Linear mixed models accounted for cluster randomization and adjusted for baseline ZBI-12 and randomization strata. **Results:** We enrolled 559 caregivers (PC arm 310, Hep arm 249). Most were female (77%), spouses (52%), college educated (68%), and employed (45%), with a mean age of 58 years (SD 14.2). Baseline caregiver burden was low [mean ZBI-12 score 9.3 (SD 8.3)].Change in ZBI-12 from baseline to 3 months did not differ between arms (Table). The PC arm had a small reduction in burden (-0.69, $P = 0.18$),

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

while the Hep arm had a small increase (0.72, $P = 0.18$). Change in PROMIS-29 physical and mental health scores were similar between arms.Communication outcomes improved significantly in both groups. Care concordant with preferences scores improved in both arms, with greater improvement in the Hep arm (0.55, $P = 0.005$). Similarly, Goals of Care (GoC) conversations scores also improved in both groups, with greater improvement in the Hep arm (0.24, $P = 0.004$). **Conclusion:** In this RCT enrolling caregivers of patients with CLD, caregiver burden remained stable over 3 months in both groups, suggesting that integration of PC principles into hepatology care may mitigate short-term worsening. Hepatologist-delivered PC was associated with greater improvement in communication outcomes, possibly reflecting advantages in liver disease-specific communication, continuity, and integration of prognostic discussions into routine hepatology care.

Table: Demographics and Outcomes in the Two Comparative Models

Demographics	**PC arm (N= 310)**	**Hep arm (N=249)**			
Mean Age (SD)	58 (14.2)	58 (14.2)			
Females	79%	75%			
High School or less education	35%	29%			
Mean Duration of caregiving (years)	5.4 (8.9) years	5.0 (7.9) years			
Mean (SD) ZBI-12	9.8 (8.4)	9.8 (8.1)			
% High Burden (ZBI-12 >=20)	12%	12%			
Primary and Secondary Caregiver Outcomes *					
Outcome (change from baseline to 3 months) * *	**PC arm (Model 1) N= 296**		**Hep arm (Model 2) N= 240**		**Adjusted mean difference [Model 2 - Model 1] (95% CI)**	**P-value**
	Adjusted mean (95% CI)	P-value	Adjusted mean (95% CI)	P-value		
ZBI-12 total score (range 0-48, MCID 2-3 points)	-0.69 (-1.72, 0.33)	0.18	0.72 (-0.34, 1.79)	0.18	1.42 (-0.09, 2.93)	0.066
PROMIS domains						
PROMIS-29 Physical Health Summary score	0.19 (-0.43, 0.82)	0.54	0.18 (-0.47, 0.84)	0.59	-0.01 (-0.94, 0.92)	0.98
PROMIS-29 Mental Health Summary score	-0.10 (-1.14, 0.94)	0.85	-0.48 (-1.58, 0.61)	0.39	-0.38 (-1.94, 1.17)	0.63
Physical Function	0.10 (-0.62, 0.82)	0.79	0.24 (-0.54, 1.03)	0.54	0.15 (-0.96, 1.26)	0.80
Anxiety	-1.31 (-2.55, -0.10)	**0.034**	0.70 (-0.62, 2.02)	0.30	2.01 (0.14, 3.87)	0.035
Depression	0.08 (-1.09, 1.25)	0.89	0.633 (-0.64, 1.91)	0.33	0.55 (-1.22, 2.33)	0.54
Fatigue	1.58 (0.28, 2.88)	0.017	0.53 (-0.88,1.94)	0.46	-1.05 (-3.04, 0.94)	0.30
Sleep disturbance	-0.01 (-1.21, 1.20)	0.99	0.40 (-0.89, 1.69)	0.55	0.40 (-1.41, 2.21)	0.66
Social roles and activities	1.46 (0.10, 2.82)	0.035	0.28 (-1.19, 1.74)	0.71	-1.18 (-3.24, 0.87)	0.26
Pain Interference	0.70 (-0.47, 1.86)	0.24	0.72 (-0.50, 1.95)	0.25	0.03 (-1.71, 1.76)	0.98
Communication Measures						
CCP scale	0.32 (0.06, 0.58)	0.016	0.87 (0.61, 1.14)	<0.001	0.55 (0.17, 0.93)	**0.005**
GoC scale	0.21 (0.09, 0.32)	<0.001	0.45 (0.33, 0.57)	<0.001	0.24 (0.08, 0.41)	**0.004**

*Higher scores reflect higher caregiver burden and better communication; and better PROMIS domain.
** Negative value indicates an improvement in caregiver burden, anxiety, depression, fatigue, sleep disturbance, and pain interference. Positive value indicates improvement in physical function, summary scores, social roles, CCP (Care Concordant with preferences) and GoC (Goals of Care) scale.

2240 | ◆ DEVELOPMENT AND VALIDATION OF A SYMPTOM-BASED PATIENT-REPORTED OUTCOME MEASURE FOR MASH: THE CLDQ-MASH SYMPTOM QUESTIONNAIRE (CLDQ-MASH-SQ)

Zobair Younossi[1] Maria Stepanova[1] Issah Younossi[1] Andrei Racila[1], [1]The Global NASH/MASH Council

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is associated with a substantial symptom burden. However, no validated symptom-focused patient-reported outcome (PRO) instrument exists for this population. We aimed to develop and validate the MASH Symptom Questionnaire. **Methods:** We analyzed MASLD subjects from the Global NASH/MASH Registry (GNR) with clinical data and completed CLDQ-MASH instruments. For the new instrument development and preliminary validation, we used CLDQ-MASH items supplemented with symptom-related items from other generic instruments (Initial Development Cohort N = 2,066) and expert input. A list of 50 symptom-related items was identified. After removal of redundancy, 36 items were retained and evaluated using exploratory factor analysis. Standard pipeline for validation of a PRO instrument was applied. The instrument was validated again using another independent validation cohort from GNR (Independent Validation Cohort N = 2541). **Results:** In the development phase, 36 items were distributed in 8 symptom

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

domains: Mental, Cognitive, Fatigue, Systemic, Abdominal, Health distress, Sleep Disturbance, and Peripheral symptoms domains. Seven of eight domains demonstrated Cronbach's alpha >0.80 (high internal consistency); the remaining Peripheral symptoms domain included diverse items. The domain scores significantly discriminated across histologic disease severity (early fibrosis vs. F2-F3 vs. cirrhosis), liver stiffness categories (<10 vs. 10-20 vs. >20 kPa) in both development and independent validation samples. The instrument discriminated well based on non-hepatic comorbidities (type 2 diabetes, hypertension, psychiatric, sleep, pruritus, clinically overt fatigue, GERD, other GI disorders). Similar strong validation properties were noted in the independent validation cohort. **Conclusion:** The 36-item, 8-domain CLDQ-MASH Symptom Questionnaire (CLDQ-MASH SQ) represents the first validated, disease-specific symptom questionnaire for patients with MASH showing good psychometric properties. With further external validation, the CLDQ-MASH-SQ has the potential to serve as a standardized tool in both clinical research and routine practice to comprehensively assess disease burden and treatment response.

2241 | ◆ PROMIS-29 DOMAINS AS PREDICTORS OF SURVIVAL AND DECOMPENSATIONS IN CIRRHOSIS

Lauren Kasmikha[1] Mounika Kanneganti[2] Sudheer Dhoop[1] Elliot Tapper[1], [1]University of Michigan Medical Center, [2]University of Michigan

Background: Patient reported outcomes (PROs) can reflect worsening in underlying disease prior to clinical progression of disease. The PROMIS-29 Profile questionnaire measures PROs and has distinct advantages in measuring health-related quality of life (HRQOL) in chronic liver disease. The prognostic value of PROMIS-29 measures in cirrhosis is unclear. **Methods:** This is a retrospective cohort study of adults with cirrhosis who completed the PROMIS-29 questionnaire between 6/1/23-6/30/25 at the University of Michigan Hospital, excluding those with prior liver transplants. PROPr summary health scores were calculated using PROMIS domain T-scores. Multivariable linear regression models were adjusted for demographics or disease burden (ascites, hepatic encephalopathy (HE), MELD score, modified Charlson Comorbidity Score (CCS)). Separate models were fit for each PROMIS-29 domain and PROPr score. Cox models assessed transplant-free survival, defined as death or transplant. Fine-Gray models assessed decompensation using subdistribution hazard ratios (sHR), and negative binomial models assessed ED visits and hospital days using incidence rate ratios (IRR). **Results:** Among 438 patients included, median follow-up time was 11 months; 37 died (8.4%) and 31 underwent transplant (7.1%). Patients were 55.3% male and 88.1% White, and alcohol accounted for 37% of cirrhosis etiology. 89.2% of patients had decompensated cirrhosis, with median MELD of 10 (IQR 8,13). After demographic adjustment, higher physical function (HR 0.92,95%CI 0.90-0.95) and social role participation (HR 0.93,95%CI 0.90-0.95) predicted better transplant-free survival, whereas fatigue predicted worse survival (HR 1.05,95%CI 1.03-1.07). After disease-burden adjustment, physical function (HR 0.97,95%CI 0.94-0.99) and social roles (HR 0.96,95%CI 0.93-0.98) remained significant. Adjusting for MELD and Charlson Comorbidity Score, physical function (sHR 0.94,95%CI 0.90-0.98), social roles (sHR 0.95,95%CI 0.92-0.98), and PROPr (sHR 0.70,95%CI 0.58-0.84) predicted lower HE risk, whereas sleep disturbance predicted higher risk (sHR 1.07,95%CI 1.02-1.11). After disease-burden adjustment, pain interference (sHR 0.94,95%CI 0.89-0.99) and cognitive function (sHR 0.94,95%CI 0.89-0.99) predicted SBP. Higher PROPr predicted fewer hospital days (IRR 0.76,95%CI 0.70-0.84) and ED visits (IRR 0.88,95%CI 0.82-0.95). **Conclusion:** PROMIS-29 domains and the summary PROPr measure are associated with transplant-free survival, decompensation, and healthcare use in cirrhosis. PROs may complement objective measures to identify high-risk patients who need additional support.

Table 1: Transplant-Free Survival Regression Analysis

	Unadjusted		Adjusted Model 1		Adjusted Model 2	
PROMIS domain T-scores for baseline questionnaire	HR (95% CI) for death/transplant	p-value	HR (95% CI) for death/transplant	p-value	HR (95% CI) for death/transplant	p-value
Physical function[2]	**0.93 (0.91-0.96)**	**<0.001**	**0.92 (0.90-0.95)**	**<0.001**	**0.97 (0.94-0.99)**	**0.016**

2242 | ◆ REALLOCATING SEDENTARY TIME TO SLEEP IS ASSOCIATED WITH IMPROVED DISEASE SEVERITY IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Lynn Gerber[1] James Paik[2] Markos Kalligeros[1] Ali Weinstein[1] Jonathen Stine[3] Shira Zelber-Sagi[4] Saleh Alqahtani[1] Kate Hallsworth[5] Elizabeth Pekas[1] Zobair Younossi[1], [1]The Global NASH/MASH Council, [2]Global NASH/MASH Council, [3]Penn State College of Medicine, Hershey, PA., USA, [4]The University of Haifa, [5]Newcastle University, UK

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is one of the leading causes of chronic liver disease worldwide. Current lifestyle recommendations address physical activity, sedentary behavior, and sleep as separate domains, even though time allocated to one behavior necessarily displaces time spent in another within the 24-hour day. Compositional data analysis (CoDA) accounts for this interdependence among movement behaviors; however, its relationship with liver stiffness measurement (LSM) (surrogate of disease severity) has not been evaluated in a nationally representative cohort of individuals with MASLD. **Methods:** Cross-sectional analysis of NHANES 2017–2018 including 889 adults with MASLD confirmed by vibration-controlled transient elastography (VCTE). Daily sleep, sedentary time, moderate-to-vigorous physical activity (MVPA), and other waking activities, summing to 1,440 minutes/day, were transformed into isometric log-ratio (ILR) coordinates and incorporated into survey-weighted regression models with log-transformed LSM, a surrogate marker of disease severity, as the outcome (Figure). Isotemporal substitution analyses estimated changes in LSM associated with reallocating 30 minutes between movement behaviors and were stratified according to alcohol use patterns. **Results:** Greater sedentary time relative to active behaviors was associated with 5.79% higher LSM (95% CI 1.14–10.66%; p = 0.027) after sociodemographic adjustment, attenuating after full cardiometabolic adjustment (3.73%; p = 0.086). Greater sleep relative to all other behaviors was independently associated with 15.55% lower LSM (95% CI −27.33% to −1.86%; p = 0.044), persisting after full adjustment (−14.38%, 95% CI −25.58% to −1.49%; p = 0.047). Reallocating 30 min/day of sedentary time to sleep yielded greater LSM reduction (−1.69%; p = 0.011) than reallocation to MVPA (−0.83%; p = 0.001), robust to obstructive sleep apnea and diet adjustment. Among former drinkers who carried the highest metabolic burden (type 2 diabetes 45%, hypertension 84%, obstructive sleep apnea 65%), sedentary-to-sleep reallocation was most beneficial (−2.24%; p = 0.005), while replacing sleep with MVPA paradoxically raised LSM (+2.57%; p = 0.021). Among low-income adults, sedentary-to-sleep yielded the largest effect (−3.09%; p < 0.001). **Conclusion:** Sleep is an independent metabolic determinant of disease severity, as assessed by LSM, in MASLD. Replacing sedentary time with sleep was associated with greater hepatic benefit than reallocating time to exercise, particularly among high-risk former drinkers and low-income adults. These findings support precision behavioral counseling in MASLD, whereby optimal daily movement and sleep targets may need to be individualized according to each patient's clinical and socioeconomic profile.

2243 | ◆ INCREASING HIGH-RISK ALCOHOL CONSUMPTION AMONG ADOLESCENTS, YOUNG ADULTS AND FEMALES OVER TIME MAY EXPLAIN INCREASING INCIDENT ALCOHOL-ASSOCIATED LIVER DISEASE

Courtney Campbell[1] Maya Djerboua[2] Kristel Leung[1] Sahar Saeed[1] Jennifer Flemming[3], [1]Queen's University, [2]ICES-Queen's, [3]Queen's University Cancer Research Institute

Background: Severe alcohol-associated liver disease (ALD) is most rapidly increasing among adolescents and young adults (AYAs) and females and typically is a consequence of high-risk alcohol consumption. Yet, data suggest that the proportion of Canadians abstaining from alcohol is increasing and per capita consumption is decreasing. However, high-risk consumption trends remain to be characterized. This study aimed to describe age- and sex-specific high-risk alcohol consumption trends in Ontario, Canada. **Methods:** A retrospective population-based cohort of Canadian Community Health Survey (CCHS) respondents from Ontario aged 15-60 years from the 2003, 2005-2018 cross-sections were included. Self-reported alcohol consumption was categorized into groups to evaluate high-risk consumption: 1) daily and weekly standard drinks [1 drink = 14g alcohol]; 2) binge drinking frequency [>5 drinks for males and >4 drinks for females on one occasion] and; 3) monthly consumption frequency. Secular proportional changes in alcohol consumption over the study period were described by proportional changes according to age group (AYAs <40 vs. adults 40+) and sex. **Results:** 153,166 CCHS respondents were included (54% female, median age 39). From 2003 to 2018 (Figure), the proportion who participated in daily alcohol consumption increased among AYAs (33%), more so among females (74%) vs. males (21%) while daily consumption decreased among female and male adults. Further, weekly binge drinking increased by 45% among female AYAs and 131% for female adults yet decreased by -12% among male AYAs and -3% among male adults. For each category of weekly total drinks, female consumption rose (peaking at 27% for 8-14 drinks among female AYAs and 75% for >15 drinks among female adults). Among males, consumption only increased for 1-2 drinks among AYAs vs. 8-14 and >15 drinks among adults. Female adults similarly increased consumption among each total daily drinks category, while female AYAs increased all but the highest category (6+ drinks). Male AYAs only increased consumption of 6+ drinks while male adults only increased consumption of 4-6+ drinks, with all other consumption categories decreasing among males. **Conclusion:** High-risk alcohol consumption is rising over time among AYAs and females in Ontario in parallel with increasing incident ALD among these groups. These results suggest that increases in high-risk alcohol consumption could be driving these trends. Public health strategies to identify and provide intervention on those with high-risk use is a modifiable risk factor that could reverse severe ALD trends for future generations.

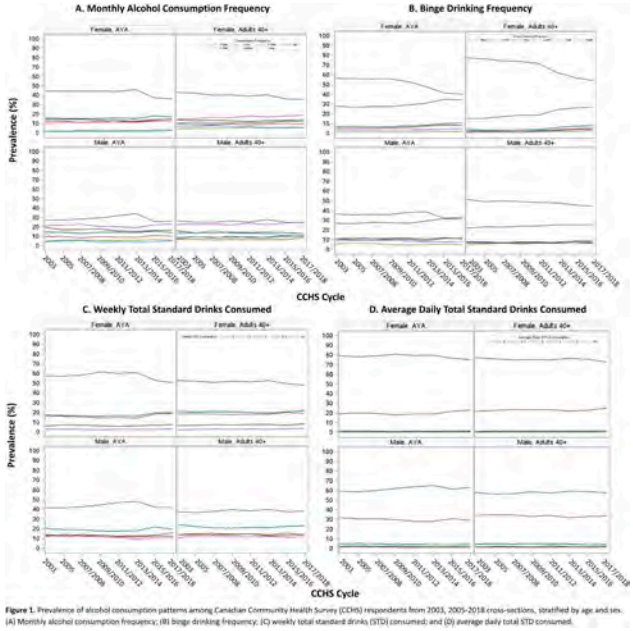

Figure 1. Prevalence of alcohol consumption patterns among Canadian Community Health Survey (CCHS) respondents from 2003, 2005-2018 cross-sections, stratified by age and sex. (A) Monthly alcohol consumption frequency; (B) binge drinking frequency; (C) weekly total standard drinks (STD) consumed; and (D) average daily total STD consumed.

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Patients with advanced liver disease (advLD) experience substantial multidimensional symptom burden associated with impaired quality of life and adverse clinical outcomes. Symptoms often occur in recognizable patterns, but whether these patterns identify patients at higher risk for near-term healthcare utilization beyond traditional clinical markers remains unclear. **Methods:** We conducted a secondary analysis of two prospective observational cohorts of patients with advLD. The first included adult outpatients with decompensated cirrhosis recruited from MGH between August 2018 and September 2022. The second included adult patients with advLD undergoing liver transplantation evaluation, recruited from 13 U.S. transplant centers between May 2023 and April 2024. Demographic and clinical characteristics were collected. Symptom burden was assessed using the revised Edmonton Symptom Assessment System (r-ESAS), a validated 10-item measure. Latent class analysis (LCA) identified empirically derived symptom clusters. Fine-Gray subdistribution hazard models, accounting for the competing risk of death, evaluated associations between symptom cluster membership and 90-day all-cause, unplanned, and liver-related hospitalization. Models were adjusted a priori for age, sex, race, ethnicity, ascites, hepatic encephalopathy, comorbidity burden, and MELD-Na score. **Results:** Among 584 patients included in the LCA, median age was 59 years, 59% were male, 52% had alcohol-related liver disease, and median MELD-Na score was 16. Four symptom clusters were identified: low burden (n = 151, 26%), tiredness/drowsiness (n = 224, 38%), SPPADE (high probability of anxiety, depression, impaired wellbeing, pain, tiredness, and drowsiness), (n = 88, 15%), and high burden (n = 121, 21%); defining symptom profiles are shown in the Table. Overall, 22% of patients were hospitalized within 90 days. Hospitalization rates were 19%, 21%, 17%, and 31% in the “low burden”, “tiredness and drowsiness”, “SPPADE”, and “high burden” clusters, respectively. Compared with the low burden cluster, the high burden cluster was associated with higher risk of all-cause hospitalization (SHR 2.09, 95% CI 1.24–3.51), unplanned hospitalization (SHR 2.47, 95% CI 1.42–4.31), and liver-related hospitalization (SHR 1.94, 95% CI 1.04–3.66). The tiredness/drowsiness and SPPADE clusters were not significantly associated with hospitalization risk. **Conclusion:** Among patients with advLD, membership in the high global symptom burden cluster was associated with increased risk of 90-day all-cause, unplanned, and liver-related hospitalization, independent of MELD-Na score and key decompensation features. These findings highlight the potential clinical value of routine multidimensional symptom screening as a complement to traditional risk assessment in hepatology practice.

Table. Symptom Clusters and 90-Day Hospitalization Risk in Advanced Liver Disease (N=584)

Symptom Cluster	Defining Symptom Profile	90-Day Hosp., % (n)	All-Cause SHR (95% CI)	Unplanned SHR (95% CI)	Liver-Related SHR (95% CI)
Low burden n=151 (26%)	Low endorsement across all 10 symptoms (all item probabilities <0.15)§	19% (28/151)	Reference	Reference	Reference
Tiredness and drowsiness n=224 (38%)	High tiredness and drowsiness; low endorsement of remaining symptoms	21% (46/224)	1.15 (0.72–1.84)	1.29 (0.78–2.13)	0.93 (0.44–1.47)
SPPADE n=88 (15%)	High probability of anxiety, depression, impaired wellbeing, tiredness, drowsiness, and pain	17% (15/88)	1.13 (0.59–2.17)	1.13 (0.55–2.33)	1.07 (0.48–2.39)
High burden n=121 (21%)	High endorsement across all 10 symptoms, including nausea, decreased appetite, and shortness of breath (most item probabilities >0.65)§	31% (38/121)	2.09 (1.24–3.51)‡	2.47 (1.42–4.31)‡	1.94 (1.04–3.66)‡

2246 | SCREENING FOR MASLD AMONG SUBJECTS WITH AND WITHOUT TYPE 2 DIABETES: IMPACT OF THE RECENT AGA PATHWAY UPDATE

Thuy-Duyen Nguyen[1] David Chascsa[2] Blanca Lizaola-Mayo[2] W. Ray Kim[2], [1]Mayo Clinic, [2]Mayo Clinic Arizona

Background: Effective screening for fibrotic MASLD remains an urgent public health priority. The 2026 updated AGA pathways suggest bypassing FIB-4 for direct elastography in high-risk (e.g. type 2 diabetes, T2DM) patients. Risk-based customization may make screening more complex and difficult to implement, whereas multivariable indices, such as the SAFE score, offer a more balanced alternative, integrating metabolic risk with laboratory parameters. **Methods:** National Health and Nutrition Examination Survey (NHANES) data from 2017-23 were used to evaluate the impact of the updated AGA pathway against (1) traditional FIB-4-first and (2) SAFE-based strategies (see Table). The updated AGA pathway was modeled using two allocation strategies: (1) allocating VCTE access proportionally between T2DM and non-T2DM patients and (2) prioritizing patients with T2DM. The high-risk screening population was identified based on updated AGA guidelines (adults with T2DM, obesity with one or more metabolic risk factors, or elevated aminotransferases). Significant liver fibrosis was defined as a median liver-stiffness measurement of $\geq$8.0 kPa. VCTE referral volume, diagnostic yield, and sensitivity were compared across the pathways. Finally, the pathways were compared with 3 scenarios with constrained VCTE capacities (top 5%, 10%, and 15% of the cohort). **Results:** The NHANES data estimated that the updated AGA screening criteria are met in 154.3 million US adults (95% CI, 143.1–165.4 million) in 2017–20 and 147.5 million (95% CI, 132.9 – 162.1 million) in 2021-23. In the Table, when elastography is available to all, the updated AGA pathways (including #1 and #2) achieved the highest sensitivity while using the most elastographies. The SAFE score approach was more efficient, with a higher positive predictive value and a lower number needed to screen than the updated pathways. In the scenarios where elastography is limited to 5%, 10%, or 15% of the eligible population, the SAFE approach maximized fibrosis detection across all utilization levels. The traditional FIB-4-first approach remained the least sensitive and efficient across all cohorts. **Conclusion:** The updated AGA pathway improves screening sensitivity by more than 50% compared to the traditional FIB-4-first method, but at the expense of a substantial increase in elastography utilization. In settings where elastography is constrained to a smaller proportion of the population, the SAFE score approach is most efficient.

2247 | HEPATITIS B PATIENT-REPORTED OUTCOMES: MULTINATIONAL INSIGHTS ON QUALITY OF LIFE AND ANTIVIRAL ADHERENCE

Yasmin Ibrahim[1] Catherine Freeland[1] Chari Cohen[1], [1]Hepatitis B Foundation

Background: Quality of life (QoL) and treatment adherence are underexplored components of care for people living with hepatitis B (PLWHB). Patient-reported outcomes (PROs) remain largely absent from routine clinical management. This study (1) longitudinally evaluates hepatitis B–related QoL; (2) assesses rates of and variables associated with antiviral adherence; and (3) compares PROs and adherence between treatment-status cohorts. **Methods:** This global, longitudinal mixed-methods study recruited adults (18+) via convenience sampling for multilingual online surveys at baseline, 3- and 6-months. Validated instruments include HBQoL, PMAI-9, and CEAT-HBV alongside supplemental questions on treatment status, patient–provider communication, and care barriers. Analyses include descriptive statistics, multivariate logistic regression, and propensity score matching. **Results:** To date, 486 PLWHB have completed the baseline survey (mean age 42.1 years, 69.6% male) from 42 countries. 50.9% reported currently taking antiviral treatment, primarily tenofovir. Among treated participants, knowledge and adherence were high: 94.5% agreed/strongly agreed they understood why they were taking medication, 93.1% understood how to take it, and 86.2% reported taking medication daily as directed.

76.1% described themselves as “quite”/“very” compliant with therapy; 84.4% expressed confidence that treatment was helping their hepatitis B. Fatigue or weakness was the most reported symptom (44.0%), and over half reported being “quite”/”extremely” concerned about liver morbidity and mortality. While most reported high medical care engagement, some (26.1%) rated the relationship with their doctor as “poor,” “somewhat poor,” or “fair”. Among participants not taking antiviral therapy, 63.7% were not engaged in any hepatitis B care. The most reported barriers were high medication/healthcare costs (37.4%), provider/medication inaccessibility (17.8% and 18.2%, respectively), and feeling healthy (17.8%). Willingness to initiate future treatment was high: 73.5% reported they would be “very willing” to start antiviral therapy if recommended and 74.4% indicated high confidence in taking a daily medication. Psychosocial burden remained substantial with concerns spanning stigma, anxiety, and long-term liver complications. **Conclusion:** This ongoing study represents one of the largest, multinational investigations of QoL and antiviral adherence among PLWHB. We elucidate QoL impact and adherence alongside systemic barriers/facilitators to adherence for future patient-centered interventions.

2248 | URINARY CANNABIS METABOLITES AND LIVER-RELATED OUTCOMES IN CIRRHOSIS: RESULTS FROM THE SOUTHERN LIVER HEALTHY STUDY (STRIVE)

Kaia Miller[1] Xintian Song[2] Eghosa Adodo[1] Marjorie Riggan[1] Alina Greene[3] Rachel Maguire[3] Lucas Li[1] Valerie Dartey-Hayford[1] Chukwuemeka Oko[4] Ashley Jowell[5] Andrew Moon[6] Joellen Schildkraut[2] Susan Murphy[1] Cathrine Hoyo[3] Cynthia Moylan[1], [1]Duke University, [2]Emory University, [3]North Carolina State University, [4]Duke University Hospital, [5]Duke University Medical Center, [6]University of North Carolina

Background: Cannabis use has become increasingly prevalent across the United States. Current studies suggest that cannabis use confers anti-inflammatory and anti-fibrotic benefits via modulation of hepatic endocannabinoid pathways, but its impact on the natural history of cirrhosis remains controversial. We aimed to determine whether cannabis use impacts disease outcomes in cirrhosis. **Methods:** We conducted a nested cross-sectional study of participants (pts) in the Southern Liver Health Study (STRIVE), a prospective multi-site study exploring environmental exposures in cirrhosis. We included pts aged 40-75 years with diagnosed cirrhosis and without hepatocellular carcinoma (HCC) at enrollment between 1/11/22 and 8/22/24 in North Carolina and Georgia. Pts were followed and medical records were abstracted for health history, including death, liver transplantation (LT), or diagnosis of HCC. The primary metabolite of cannabis (THC-COOH) was quantified from baseline urine using UPLC-MS/MS and reported as creatinine-normalized. The primary outcome was a composite of liver-related outcomes (LROs) including HCC, LT, or liver-related death. Fine-Gray subdistribution hazard models were used to estimate adjusted associations between cannabis exposure and LROs, controlling for site, age, sex, race, cigarette use, alcohol use, and diabetes. Proportional subdistribution hazard assumptions were confirmed using cumulative residual-based diagnostics and Kolmogorov–Smirnov type statistics. **Results:** 185 pts with cirrhosis and urine samples at baseline were included. 44 had detectable cannabis levels (**Table 1**). Over a median follow-up of 33 months, 58 LROs occurred, including 14 incident HCC, 15 LTs, and 29 liver-related deaths. 20 non-liver-related deaths occurred as competing events. The cumulative incidence of LROs did not differ significantly by cannabis exposure status (Gray’s test $p = 0.60$). However, cannabis-exposed pts exhibited a higher incidence of LROs within the first 1 year (23% vs. 16%), which attenuated by 2 years (25% vs. 24%) and crossed over by 3 years (27% vs. 29%). In adjusted models, cannabis exposure was not associated with LROs (sHR = 0.73, $p = 0.40$) while reported alcohol use was (sHR = 2.16, $p = 0.042$). When cannabis was modeled continuously using log-transformed THC-COOH concentration, higher concentrations showed a trend toward a protective effect (sHR per log-unit increase 0.90, $p = 0.091$). **Conclusion:** Nearly 25% of STRIVE pts with cirrhosis had detectable cannabis metabolites. Cannabis was not associated with future risk of LROs in this analysis, however findings suggest that cannabis metabolites may provide additional prognostic information in larger longitudinal cohorts. Larger future investigations in STRIVE will continue to explore this, as well as whether other environmental exposures interact

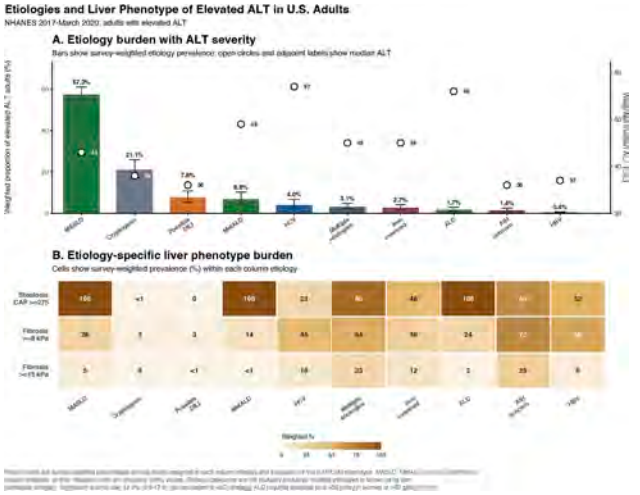
2249 | THE PREVALENCE, CAUSES, AND TEMPORAL TRENDS IN ALANINE AMINOTRANSFERASE ELEVATION AND CONCURRENT HEPATIC STEATOSIS AMONG U.S. ADULTS



Timothy Davie[1] Jesse Fletcher[1] Kartik Dapke[2] Anna Strauss[1] Serena Brosten[1] Giovanni Roldan[3] Prowpanga Udompap[4], [1]Department of Medicine, University of Minnesota, [2]Department of Medicine, Saint Vincent Hospital, Worcester, MA, [3]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, [4]Division of Gastroenterology, Minneapolis VA Medical Center

Background: Alanine aminotransferase (ALT) is the most commonly used liver enzyme for evaluating liver health. There is a lack of contemporary and historical data that estimates the prevalence of elevated ALT in the U.S population. We aim to provide a modern estimate of elevated ALT among U.S. adults, phenotype this population to identify specific underlying etiologies, and analyze national prevalence trends over a 20-year period. **Methods:** We performed a cross-sectional analysis using data from the National Health and Nutrition Examination Survey (NHANES) from 2003 to 2023 to evaluate the prevalence of U.S. adults with ALT elevation over the 20-year span. Adults aged ≥ 20 years with available ALT data were included. Elevated ALT was determined using standardized sex-specific thresholds of >33 U/L for men and >25 U/L for women. The specific etiology of ALT elevation was defined only for the participants in NHANES 2017-2020 given the availability of the data including vibration controlled transient elastography, medication, laboratory, and survey data. This allowed for classification into distinct categories: Metabolic Dysfunction Associated Steatotic Liver Disease (MASLD), MASLD with increased alcohol intake (MetALD), alcohol-associated liver disease, viral hepatitis (B or C), iron overload, suspected autoimmune hepatitis (AIH), or drug-induced liver injury (DILI). The participants without a clear etiology of ALT elevation were categorized as cryptogenic. **Results:** The proportion of participants with ALT elevation was downtrending from 24.4% in 2003-2004 to 18.4% in 2001-2023. Similar trends remained with stratification based on sex. When focusing on the most complete dataset from 2017 to 2020, 18.1% of participants, or approximately 40.8 million U.S. adults, had elevated ALT. Those with elevated ALT were more

likely to be younger (49 vs 53 years), with elevated BMI (32 vs 30 kg/m^2). MASLD was the dominant etiology of ALT elevation (57.3%), followed by cryptogenic (21.1%), possible DILI(7.6%), and the rest shown in Figure 1A. Notably, hepatic steatosis (controlled attenuation parameters $\geq$275 dB/m) was a prominent feature across the entire etiologic spectrum, extending well beyond MASLD, MetALD, and ALD to affect high proportions of patients with hepatitis B infection (52%), AIH (69%), and multi-factorial liver diseases (86%) (Figure 1B). **Conclusion:** While the prevalence of elevated ALT gradually declined from 2003 to 2023, it remains high as nearly one out of five U.S. adults had elevated ALT. While MASLD is a primary driver, concurrent hepatic steatosis frequently overlaps with non-metabolic and non-alcoholic etiologies including but not limited to hepatitis B infection, AIH. Further research is warranted to granularly phenotype these diverse cohorts and clarify the clinical intersection between steatosis and secondary liver diseases.

2250 | PSYCHOLOGICAL DISTRESS AMONG PATIENTS WITH DECOMPENSATED CIRRHOSIS AND THEIR CAREGIVERS: A LONGITUDINAL DYADIC COHORT STUDY

Brittany Bromfield[1] Grace Bizup[2] William Munroe[2] Maria Edelen[1] Chengbo Zeng[1] Nneka Ufere[3], [1]Brigham and Women's Hospital, [2]Massachusett's General Hospital, [3]Massachusetts General Hospital

Background: Patients with decompensated cirrhosis (DC) and their caregivers face high rates of psychological distress associated with poor clinical outcomes, yet are often studied in isolation rather than as an interdependent dyadic unit. Longitudinal dyadic data in hepatology remain limited. Prior cross-sectional work identified an association in which caregiver anxiety was linked to higher patient depression, but whether this association persists longitudinally remains unknown. **Methods:** We conducted a prospective cohort study of 127 patient-caregiver dyads enrolled at a single academic hepatology center from 8/2018 to 9/2022. Participants completed the validated Hospital Anxiety and Depression Scale (HADS) at baseline, 6, 12, and 24 weeks. We characterized the prevalence, co-prevalence, and longitudinal patterns of clinically significant anxiety and depression. Longitudinal associations between caregiver anxiety and patient depression were assessed using linear mixed-effects models, adjusting for age, sex, marital status, comorbidity burden, and Child-Pugh score. Sensitivity analyses used multiple imputation (MI), inverse probability weighting (IPW), and restricted follow-up windows to address approximately 50% attrition by week 24. **Results:** Among 127 dyads, patients had a median age of 60 years, 55% were male, median MELD-Na was 16, and 93% had Child-Pugh B/C cirrhosis; caregivers had a median age of 59 years, 62% were female, and 63% were spouses. Psychological distress was common and frequently co-prevalent: clinically significant anxiety was present in 48% of patients and 52% of caregivers, with both partners affected in 26% of dyads. Clinically significant depression was present in 41% of patients and 35% of caregivers, with both partners affected in 18% of dyads. Scores were stable across four timepoints; caregivers reported higher anxiety than patients through week 12, while patients reported higher depression at every timepoint. Across 24 weeks of follow-up, higher caregiver anxiety was associated with higher patient depression after adjustment (adjusted $\beta = 0.20$, 95% CI: 0.11-0.30). This association was consistent across IPW, MI, and shorter follow-up sensitivity analyses. **Conclusion:** Psychological distress was prevalent, co-prevalent, and longitudinally associated within patient-caregiver dyads affected by DC. The association between caregiver anxiety and patient depression persisted across analytic approaches despite substantial attrition, underscoring the importance of including caregivers in psychosocial assessment frameworks. These findings support consideration of dyadic screening and future trials evaluating whether caregiver-informed interventions may help improve psychological burden in advanced liver disease.

2251 | AGE-ALIGNED WHOLE-HEALTH DISEASE-TRAJECTORY MODELING IMPROVES LIVER DISEASE RISK PREDICTION

Muxue Liang[1] Ruoqian Li[2] Haibo Wang[3] You Wu[2], [1]School of Biomedical Engineering, Tsinghua Medicine, Tsinghua University, Beijing, China, [2]School of Healthcare Management, Tsinghua Medicine, Tsinghua University, Beijing, China, [3]First Affiliated Hospital of Sun Yan-Sen University, Guangzhou, China

Background: Liver disease risk reflects long-term interactions between prior diagnoses, lifestyle, clinical measurements and therapies, but these data have different temporal validity. Disease-event tokenization captures longitudinal natural-history structure, yet disease-only sequences omit important exposure and health-state information that shapes whole-health trajectories. Conversely, directly incorporating high-dimensional exposures into event sequences may overburden and dilute the disease event structure, while also introducing temporally invalid information. We therefore developed an Exposure-Period-Aware Transformer that aligns exposure information to age-indexed disease trajectories for liver risk prediction. **Methods:** Among 501,936 UK Biobank participants, we constructed a disease-event backbone sequence from longitudinal diagnostic histories and exposure-state sequences from lifestyle, clinical measurement and medication fields. The model encodes disease natural-history tokens using age embedding, while exposure branches are organized by predefined exposure validity windows so that only temporally eligible information contributes to prediction. Exposure representations are then projected into the disease-event backbone and processed by a time-masked multi-head self-attention decoder. We predicted 13 ICD-10 liver diseases across eight horizons from 1 to 120 months, compared performance with a disease-event-only baseline and evaluated healthy/unhealthy lifestyle scenarios. **Results:** Across 104 disease-horizon prediction cells, the main configuration achieved mean and median AUCs of 0.7175 and 0.7350; alcoholic liver disease was the best-performing outcome (AUC 0.9413). Relative to the disease-event-only baseline, mean AUC increased from 0.6464 to 0.7175, with improvements in 96 of 104 cells, including the 60- and 120-month horizons (+0.0772 and +0.0769). Ablation analyses supported the contribution of temporally aligned exposures: disabling exposure-branch inputs at inference reduced mean AUC by 0.0691, and training without these inputs reduced mean AUC by 0.0829. Bootstrap estimates supported robustness, with a macro-AUC 95% CI of 0.6859 to 0.7492 and both ablation contrasts excluding zero. In lifestyle scenario analyses, less healthy profiles increased disease risk by 17.0%, whereas healthier profiles reduced it by 11.8%; alcoholic liver disease showed the largest directional response (+79.2% and -34.7%). **Conclusion:** The Exposure-Period-Aware Transformer reframes liver risk prediction as age-indexed whole-health trajectory modeling. Age-aligned exposure integration improved performance over disease-event-only modeling and supported clinically plausible lifestyle responses, highlighting a promising framework for long-term liver disease risk prediction.

Center, [3]Virginia Commonwealth University Medical Center, [4]Indiana University Medical Center

Background: HSD17B13 loss-of-function variant rs72613567 is under therapeutic development for metabolic dysfunction-associated steatohepatitis (MASH) and alcohol-associated liver disease (ALD). Whether HSD17B13 effects differ across cirrhosis subtypes and ancestries has not been characterized at scale. **Methods:** Among 414,830 All of Us participants with whole-genome sequencing, we tested HSD17B13 rs72613567 per-allele effects on (1) all-cause cirrhosis (7,216 cases), (2) ALD-cirrhosis (heavy drinkers without viral hepatitis; 1,999 cases), and (3) MASH-cirrhosis (MASLD ICD + cardiometabolic criterion, no alcohol/viral hepatitis; 1,452 cases). Per-allele logistic regression adjusted for age, sex, BMI, and diabetes, stratified by genetically-determined ancestry (European [EUR], African [AFR], Admixed American [AMR; predominantly Hispanic/Latino]). Ancestry × HSD17B13 interaction was tested by likelihood ratio. **Results:** HSD17B13 effects differed significantly by ancestry (interaction $p < 0.001$ for all-cause cirrhosis), driven by larger effect in AMR vs EUR ($p < 0.001$). AMR participants showed the strongest protection: all-cause cirrhosis OR 0.70 (95% CI 0.63-0.78, $p < 0.001$) and MASH-cirrhosis OR 0.77 (0.60-0.98, $p = 0.034$), with directionally consistent ALD findings. EUR participants showed modest all-cause protection (OR 0.91, 0.86-0.96, $p < 0.001$) but no effect in MASH or ALD subsets. AFR participants showed no protection in any cohort (all-cause OR 0.97; ALD OR 1.05; MASH OR 0.94; all $p > 0.6$), despite $n = 83,064$, the largest HSD17B13 rs72613567 analysis in African-ancestry liver disease. Allele frequencies matched gnomAD (EUR 0.267; AMR 0.136; AFR 0.071), with the variant paradoxically least common in AMR, the ancestry with largest effect. In AMR, protection was observed across PNPLA3 G-carrier and non-carrier strata. ~6.8 million US Hispanic/Latino adults carry the protective allele. Findings were robust to principal component adjustment for the well-powered all-cause and MASH analyses. **Conclusion:** In the largest multi-ancestry WGS analysis of HSD17B13 in clinically-defined cirrhosis subtypes, we identify formally significant ancestry-specific effects: substantial protection in AMR, modest protection in EUR, and no detectable protection in AFR. For HSD17B13-targeted therapies in development for ALD and MASH, Hispanic/Latino patients may represent a priority population for ancestry-stratified therapeutic development.

Southwestern Medical Center, [8]King Faisal Specialist Hospital & Research Centre

Background: Statins and aspirin have been proposed as chemopreventive agents against hepatocellular carcinoma (HCC), but their independent and combined associations remain uncertain due to confounding by indication. We evaluated the association between statin and aspirin exposure and incident HCC in a large real-world cohort of patients with chronic liver disease. **Methods:** We conducted a population-based propensity-matched retrospective cohort study using the TriNetX network. Adults with chronic liver disease (MASLD, viral hepatitis, alcoholic liver disease, autoimmune/cholestatic liver disease, cryptogenic cirrhosis) with at least 12 months of prior observation between January 1, 2016, and December 31, 2025, were included. Patients with prior HCC, other primary liver malignancy, or liver transplantation were excluded. Patients were classified into four exposure groups: neither statin nor aspirin; statin only; aspirin only; statin plus aspirin. Three pairwise 1: 1 propensity-matched comparisons were constructed versus the no-therapy group, with propensity scores incorporating demographics, liver disease etiology, non-invasive markers, cirrhosis status, comorbidities, renal function, and concurrent metformin and GLP-1RA use. The primary outcome was incident HCC, analyzed by Cox proportional hazards models. **Results:** Of 428,915 eligible patients, 132,480 statin-only, 47,360 aspirin-only, and 51,220 statin+aspirin users were each matched 1: 1 to no-therapy controls (all standardized mean differences < 0.1 after matching). Over a median follow-up of 4.8 years, statin monotherapy was associated with a significant reduction in HCC hazards (HR 0.55, 95% CI 0.47–0.64). Aspirin monotherapy showed a more modest protective association (HR 0.80, 95% CI 0.66–0.97). The combination of statin plus aspirin was associated with the greatest HCC risk reduction (HR, 0.40; 95% CI, 0.33–0.49). Subgroup analyses by liver disease etiology demonstrated the most pronounced statin-associated risk reduction in MASLD and viral hepatitis; a protective effect was preserved, though attenuated, in alcoholic liver disease and cirrhosis. In exploratory models additionally adjusting for time-updated cardiovascular medications, statin HRs remained stable, whereas the aspirin-only HR moved toward the null, suggesting that the aspirin association is more susceptible to residual confounding by concomitant therapies. Results were consistent in sensitivity analyses. **Conclusion:** Statin therapy was associated with a substantial reduction in HCC risk, while statin plus aspirin conferred the greatest observed benefit. The aspirin-only association was smaller and sensitive to residual confounding, suggesting a more fragile independent effect. These findings reinforce statins as a leading chemoprevention candidate in chronic liver disease and support selective, risk-stratified evaluation of adjunctive aspirin therapy.

2254 | RELINKING PATIENTS WITH DIAGNOSED BUT UNTREATED HEPATITIS B AND C IN THE MOUNT SINAI HEALTH SYSTEM IN NYC

Tasnim Bhuiyan[1] Daemena Leocadio[1] Jihae Jeon[1] Francina Collado[1] Anna Mageras[1] Daryin Hummel[1] Lismeiry Paulino[1] Christopher Kim[1] Andrea Branch[2] Douglas Dieterich[1], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: We used digital phenotyping algorithms to find patients with chronic viral hepatitis (HBsAg+ and/or HCV RNA+) who might benefit from outreach. We aimed to provide linkage to care for patients who were not currently receiving it. **Methods:** Patient navigators (PNs) reviewed 4854 charts and excluded 2717 patients who were already in care or were otherwise ineligible (7/2024 to 4/2026). Exclusions included: a) Newly screened HBsAg+ and HCV RNA+ patients, b) Latest HCV RNA viral load negative, c) HBsAg+ but with an active prescription for HBV medication, or a visit to hepatology, gastroenterology, oncology, or infectious disease in the past 12 months, or receiving care from a PCP following AASLD guidelines for HBV management (including annual HCC surveillance), a suspected false positive test, or insurance coverage issues. At least three attempts were made to contact each of the remaining patients via multiple modalities. MyChart was used for initial outreach if available, otherwise phone and email were used. **Results:** Manual review showed that 252 HCV RNA+ patients were eligible for contact, 140 (55%) were reached; 39 (27%) expressed interest;

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

28 (11%) were linked to care; 8 (5%) were apprised of their HCV status but were later lost to follow up (LTFU); and 2 (1%) declined linkage. Among 1885 HBsAg+ patients eligible for contact, 1748 were contacted. 983 were initially messaged via MyChart, 747 by phone, and 18 by e-mail. Among them, 921 (53%) were reached; 262 (15%) expressed interest; 146 (8%) were linked to care; and 60 (5%) were apprised of their HBsAg+ status but were LTFU after repeated attempts to link them. Linkage rates were similar for MyChart messaging and other methods (p-value 0.09). Patients between 41 to 65 years of age were more likely to express interest and to be linked to care (p = 0.029). PN findings of note: 1) MyChart messaging prior to phone outreach improved communication and trust because PNs could reference the message in their introduction, 2) PCP referrals with PN outreach boosted re-linkage, 3) Patients with normal liver enzymes and low viral loads preferred monitoring with their PCP rather than a specialist. **Conclusion:** In the decades since antiviral drugs for viral hepatitis became available, many patients have been engaged in care, but concerted efforts to reach the remaining patients remains are an important public health priority. In this project, 163 patients were re-linked; many additional patients were contacted and informed of treatment options. Our results highlight both the ability of a dedicated program to overcome barriers and the need for further innovation in the delivery of care.

2255 | HEALTH-RELATED QUALITY OF LIFE IN AUTOIMMUNE HEPATITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Ilkay Ergenç[1] Jill Carlton[2] Yooyun Chung[3] Dermot Gleeson[4] Michael Heneghan[3], [1]King's College Hospital, [2]Sheffield Centre of Health and Related Research (SCHARR), University of Sheffield, Sheffield, United, [3]The Roger Williams Institute of Liver Studies, King's College Hospital, London, United Kingdom, [4]Liver Unit, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Background: Autoimmune hepatitis (AIH) is a chronic, liver condition that can impair health-related quality of life (HrQoL) through disease-related morbidity, treatment burden, and psychological impact. Biochemical remission alone may not adequately represent patient-perceived health status. This study aimed to systematically review the evidence on HrQoL in patients with AIH. **Methods:** A systematic search of MEDLINE, Embase, APA PsycInfo, and the Cochrane Library (1946–September 2025) was conducted using relevant medical subject headings (MeSH) terms. After deduplication, 1,668 records were identified. The review followed COSMIN 2.0 methodology for risk of bias assessment, evaluation of measurement properties, synthesis of results, and grading of evidence. Two reviewers independently screened records and 49 articles underwent full-text review. Twelve studies met inclusion criteria and were included in the quantitative synthesis. **Results:** Twelve studies involving 3,478 AIH patients (78.2% female) assessed PROMs including generic HRQoL (SF-12, SF-36, EQ-5D-5L), liver-specific HRQoL (CLDQ), anxiety/depression (GAD-2/7, PHQ-2/9), fatigue (FIS, CFQ), and somatic symptoms (SSS-8). Four studies included healthy controls (HC), four included disease controls, and four had no control group. The risk of bias assessment demonstrated substantial methodological limitations in structural validity, internal consistency, and measurement error. Across AIH cohorts, pooled scores were SF-12 physical component score (PCS) 46.12 (95% CI 45.44–46.80, I^2 0.0%, n = 985) and SF-12 mental component score (MCS) 47.32 (95% CI 45.46–49.18, I^2 61.6%, n = 985); SF-36 PCS 51.04 (95% CI 49.94–52.15, I^2 0.0%, n = 291) and SF-36 MCS 50.35 (95% CI 43.39–57.31, I^2 96.9%, n = 291). EQ-5D-5L (Index 0.84, 95% CI 0.77–0.92, I^2 97.7%; VAS 74.68, 95% CI 69.15–80.20, I^2 96.8%, n = 1,806), and HRQoL by CLDQ overall was 5.61 (95% CI 5.34–5.88, I^2 90.0%, n = 637). AIH was associated with lower scores than HCs: SF-12 PCS (−6.00; 95% CI: −7.77 to −4.23), SF-36 PCS (−2.50; 95% CI: −3.92 to −1.08), and SF-36 MCS (−7.73; 95% CI: −9.69 to −5.78). The CLDQ difference was −0.37 (95% CI: −1.05 to 0.32) with high

heterogeneity. **Conclusion:** Evidence regarding HRQoL in autoimmune hepatitis is constrained by methodological heterogeneity, reliance on diverse generic PROMs, lack of healthy controls, and substantial risk of bias. Although all studies reported HRQoL impairment across multiple domains, comparability and comprehensiveness remain inadequate.

2256 | DISTINCT HEALTH-RELATED QUALITY OF LIFE PROFILES ARE ASSOCIATED WITH SOCIAL VULNERABILITY, NOT LIVER DISEASE SEVERITY

Archita Desai[1] Miranda Stovall[1] Suhani Lodha[2] Lauren Boyer[1] Timothy Stump[1] Marwan Ghabril[1] Eric Orman[1] Naga Chalasani[1], [1]Indiana University, [2]Purdue University

Background: Patients with chronic liver disease (CLD) and cirrhosis experience substantial impairments in health-related quality of life (HRQOL). Whether distinct HRQOL phenotypes exist in those with liver disease remains poorly understood. We aimed to identify (1) unique HRQOL phenotypes and (2) characterize differences in demographic and clinical characteristics as well as patient reported needs. **Methods:** We performed a prospective study of adults with CLD/cirrhosis seen for routine hepatology care at an academic health center from 7/2024 to 4/2026. Participants were recruited by phone 1-2 weeks prior to their scheduled visit to complete surveys measuring HRQOL (PROMIS-29 v2.0), health related social needs (HRSN, Accountable Health Communities Screening Tool) and informational needs (Brief Health Literacy Scale, MyCirrhosisCoach, PROMIS Informational Support). Scores were interpreted using validated cutoffs. Latent class analysis was performed using categorized PROMIS-29 domain T-scores (mild-normal vs. moderate/severe symptoms) to identify distinct HRQOL phenotypes. Following class assignment, groups were compared across sociodemographic features, liver disease severity, comorbidity burden, and self-reported HRSN and informational needs. **Results:** In the study cohort of 280 individuals, 46% had cirrhosis (mean MELD 3.0: 10.1, SD 4.0), 50% had MASH, 14% had alcohol-associated liver disease (ALD) and 14% had viral hepatitis. A 4-class solution demonstrated the optimal statistical performance (model parsimony: BIC 1753, precision: entropy = 0.863, Figure) defining 4 phenotypes: (1) Poor Daily Functioning (25%), (2) High Anxiety/Depression (10%), (3) Global Poor HRQOL (8%), and (4) Preserved HRQOL (57%).Participants assigned to phenotypes without fully preserved HRQOL (classes 1-3) were younger, ($p = 0.049$), more often female ($p < 0.001$), had higher rates of high school or less education ($p = 0.040$), reported lower income ($p < 0.001$) and Medicaid insurance ($p < 0.001$, Figure). Other sociodemographic and clinical features were similar between classes including etiology of liver disease, rates of cirrhosis, MELD3.0 scores and Child-Pugh class. Classes 1-3 had poorer scores in many self-reported HRSN domains including housing ($p < 0.001$), food security ($p < 0.001$), transportation ($p = 0.017$), financial needs and utilities ($p < 0.001$). Higher informational needs were also associated with these classes including inadequate literacy ($p < 0.001$), low information support ($p < 0.001$) and medication obstacles ($p < 0.001$). **Conclusion:** Distinct HRQOL phenotypes exist among patients with CLD/cirrhosis. These phenotypes are associated with drivers of health disparity in liver disease such as health related informational and social needs but not liver disease severity. The phenotypes more directly inform how to best to bundle healthcare delivery interventions to improve patient-centered outcomes.

2257 | PALLIATIVE CARE CONSULTATION IS ASSOCIATED WITH INCREASED END-OF-LIFE CARE TRANSITIONS IN A NON-TRANSPLANT CENTER COHORT WITH END STAGE LIVER DISEASE

Keila Carrera Mejias[1] Fernando Membreno[1] Genesis Camacho[1] James Castillo[1] Fernando Pena[1] Yashita Kakarlapudi[1], [1]DHR Health

Background: End stage liver disease (ESLD) is the advance phase of most liver disease and is character and is characterized by the complications of liver disease.Palliative care (PC) can provide at any stage of serious illness including patient receiving target curative treatment including organ transplants in patient liver cirrhosis a comprehensive support including advance care planning which address code status, proxy assignation and impact on hospital length stay. PC services have shown to be underutilized for such patient. A few studies have described the role of PC at a non-transplant tertiary center may help establish a standard of care in the management of patient with ESLD regards of transplant eligibility. **Methods:** We conduct a retrospective study analysis of adult (>18 years) patient with ESLD admitted to inpatient services at non transplant center in South Texas from 2020 to 2024. Patients were divided into groups based on the presence or absent of PC involvement. The primary outcome was inpatient transition to do not resuscitated (DNR) status. Secondary outcomes included transition to hospice care, cause of liver cirrhosis, length of stay (LOS). Categorical variables were compared using chi square or fisher's exact test. Odds ratio (OR) with 95% confidence of intervals (CL) were calculated for key outcomes. **Results:** Among 915 patients with liver cirrhosis, 152 (16.6%) received inpatient palliative care consultation. Patients in the palliative care group had significantly higher rates of DNR/DNI status at discharge compared to those without palliative care involvement (46.7% vs 1.7%, $p < 0.001$), as well as increased hospice utilization (9.9% vs 0%, $p < 0.001$). Full code status at discharge remained more common in the non-palliative group (76.4% vs 59.2%, $p < 0.001$). Notably, DNR/DNI status at admission was higher among patients who received palliative care (15.8% vs 1.7%, $p < 0.001$). Sex distribution was similar between groups (male: 57.7%) in the palliative care group vs 58.7% in the non-palliative group, $p = 0.90$). Patients receiving palliative care had 50-fold higher odds of DNR/DNI at discharge compared with non-PC patients. Palliative care is associated with an extremely strong increase in hospice referral, though precision is limited due to zero events in control group. **Conclusion:** Inpatient PC consultation in liver cirrhosis is associated with significant goals of care transitions including increased DNR/DNI designation, hospice utilization, and prolonged hospitalization reflecting the complexity of cases referred for PC. Notably, PC was consulted across a range of MELD scores, suggesting a role in decisional support and symptom management beyond the terminal phase. These findings support the systematic, early integration of palliative care into cirrhosis management to align treatment with patient-centered goals and potentially optimize resource utilization.

2258 | BARRIERS AND FACILITATORS OF THE LIVE-SMART TRIAL TO REDUCE FALLS IN PATIENTS WITH CIRRHOSIS: A MIXED-METHODS STUDY

Jacqueline Theroux[1] Donna Evon[2] Lee Ang[1] Xi Chen[3] Samantha Nikirk[3] Richard Mason[1] Sumeet Asrani[4] Elliot Tapper[5] Marina Serper[6] Geraldine Hynes[7], [1]University of Pennsylvania Perelman School of Medicine, [2]UNC SOM, [3]University of Michigan, [4]Liver Consultants of Texas, [5]University of Michigan Medical Center, [6]University of Pennsylvania Health System, [7]Center for Plain Language; Sam Houston State University

Background: LIVE-SMART was a 24-week trial designed to evaluate lactulose and Tai-Chi as interventions to reduce falls in patients with cirrhosis. At the conclusion of the intervention period, a mixed-methods evaluation was conducted to assess protocol fidelity, perception of intervention characteristics, and barriers and facilitators to implementation. **Methods:** A 10-item study satisfaction survey was conducted at the conclusion of the interventions. Survey data and fidelity measures were analyzed using descriptive statistics. Factors associated with protocol fidelity were assessed via univariable logistic regression. Associations between socio-demographics, liver disease features, key comorbidities, medications, and study site were evaluated for dichotomous outcomes: 1) lactulose discontinuation, 2) unsuccessful Zoom video setup for TeleTai-Chi, and 3) low TeleTai-Chi attendance. Semi-structured interviews with patients and care partners were audio-recorded, transcribed and analyzed using NVivo 15. Two team members double-coded 20% of the transcripts (n = 7, inter-coder reliability K = 0.87) and resolved discrepancies through consensus. The remaining transcripts were independently coded (80%, n = 27). **Results:** Among 166 participants (72.1%) who completed the exit survey, overall satisfaction was high (Net Promoter Score = 51). Among TeleTai-Chi participants, 81% successfully completed Zoom setup; however, weekly attendance was low, with a median session attendance rate of 27.8% (IQR: 5.6%-72.2%). Among participants randomized to lactulose, 80% remained on therapy through study completion. Semi-structured interviews (n = 34) revealed positive experiences with participation in LIVE-SMART. Human connection with study coordinators, instructors, and fellow participants emerged as a major driver of study engagement and adherence. In contrast, logistical, physical, and technological barriers limited sustained participation in TeleTai-Chi. **Conclusion:** Mixed methods findings suggest that lactulose may be a feasible intervention for fall prevention when paired with structured dosing instructions. Remote Tai-Chi programs can be successfully implemented with adequate technological support, instructor training, and flexible participation options.

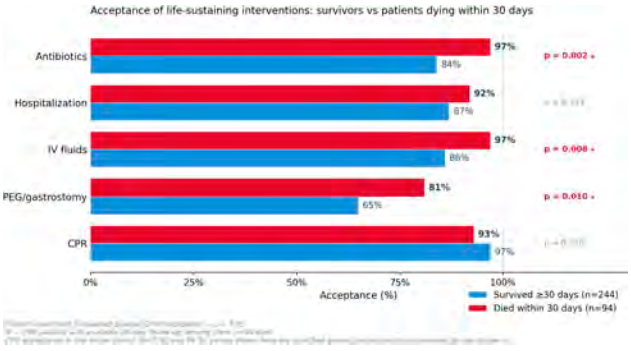
2259 | NO HOPE TOO SMALL



Daniel Jan Havaj[1] Karolina Sulejova[1] Daniela Zilincanova[2] Daniel Jan Havaj[2] Ivana Ihnatova[3] Svetlana Adamcova Selcanova[2] Lubomir Skladany[2], [1]University Hospital of F. D. Roosevelt, [2]University Hospital of F.D. Roosevelt, [3]Institute of Biology and Ecology, Faculty of Science, Pavol Jozef Safarik University in Kosice

Background: Patients with advanced chronic liver disease (ACLD) face high mortality and limited options

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

outside liver transplantation (LT). Palliative care via advanced care planning (ACP) integration is recommended, yet patient readiness and its harmonisation with objective prognostic stratification remain poorly characterized. Therefore, we evaluated ACP against disease severity in a tertiary & liver transplant unit. **Methods:** This was a cirrhosis registry study (NCT 04767945). After structured best-case/worst-case prognostic communication, consecutive patients hospitalized with dACLD completed a nurse-administered 9-item ACP questionnaire (Slovak Warren/Wilson adaptation). Responses were analyzed against demographics, etiology, MELD, Child-Turcotte-Pugh (CTP), Liver Frailty Index, refractory ascites, and 30-/90-/365-day mortality using Fisher's exact test and multivariable logistic regression. **Results:** Among 778 patients (62 % male; 60 % alcohol-associated; 36 % frail), ACP items results were as follows. Pro-CPR preference was 94 % overall and 93 % of those who died within 30 days (n = 94). Antibiotics, hospitalization, and IV fluids were expected by 80-82 %, and nasogastric tube / PEG by 55-59 %. Patients dying within 30 days displayed a higher expectation rate than survivors: antibiotics 97 % vs 84 %, p = 0.002; IV fluids 97 % vs 86 %, p = 0.008; PEG 81 % vs 65 %, p = 0.010. MELD and CTP were not associated with CPR expectancy and place-of-care preference. Only 24 % of patients had a formalized legal proxy, inversely associated with frailty (21 % vs 28 %, p = 0.042) and refractory ascites (17 % vs 28 %, p = 0.012). Of 28 patients declining CPR, 64 % were women (vs 38 % in the cohort, p = 0.005). **Conclusion:** The worse the prognosis and symptom burden, the higher the expectations for life-sustaining interventions. ACLD patients are not prepared to forgo escalation even when the prognosis is poor. ACP and palliative care discussions should begin in earlier stages of ACLD.

2260 | THE IMPACT OF PRACTICE VARIABILITY ON ENDOSCOPY TIMING FOR UPPER GI BLEEDING IN CIRRHOSIS INPATIENTS: INSIGHTS FROM A LARGE MULTI-CENTRE ONTARIO COHORT

Zuhal Mohmand[1] Surain Roberts[2] Matthew Wankiewicz[2] Sahar Saeed[1] Lauren Lapointe-Shaw[2] Siddhartha Srivastava[1] Michelle Ricci[1] Amol Verma[2] Fahad Razak[2] Florence Wong[2] Gideon Hirschfield[3] Jennifer Flemming[4] Kristel Leung[1], [1]Queen's University, [2]University of Toronto, [3]Toronto General Hospital, [4]Queen's University Cancer Research Institute

Background: Acute upper gastrointestinal bleeding (UGIB) is a life-threatening complication of decompensated cirrhosis. Guidelines recommend endoscopy within 12-24h of presentation, yet Canadian practice patterns and outcomes remain uncharacterized. **Methods:** We conducted a retrospective multicentre cohort study using administrative health data from 29 Ontario hospital medicine services (2016-2023). Adults with decompensated cirrhosis admitted from the ED with suspected UGIB who underwent inpatient upper endoscopy within 96h were included. Elective, palliative, acute care transfers, and data-incomplete admissions were excluded. Door-to-endoscopy time was divided into early (≤24h) vs. delayed (>24h). Standardized mean differences (SMD) were used for descriptives. Predictors of delay were identified using univariable and multivariable logistic regression, adjusted for patient and system factors. Outcomes were evaluated using Cox proportional hazards (in-hospital mortality), logistic regression (ICU admission, repeat endoscopy), and descriptives statistics (length of stay). **Results:** Among 3133 encounters, median age was 60 years (64.2% male). Alcohol (47.5%) and metabolic-associated liver disease (43.7%) were the most common cirrhosis etiologies. Median admission MELD-Na was 16. Median door-to-endoscopy time was 21.5h (IQR 13.4-35.0); 59.5% underwent endoscopy within 24h, while 40.5% after 24h. Early endoscopy was more common in patients transferred to ICU within 24h of admission (early: 26.8% vs. delayed: 10.3%, SMD 0.43) and those with confirmed variceal bleeds (56.9% vs. 43.4%, SMD 0.27). Repeat endoscopy was more common in the early group (14.5% vs. 10.7%, aOR 0.76, p = 0.023). Independent predictors of delay included weekend (aOR 2.13, 95% CI 1.80-2.53) and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

daytime arrival (aOR 1.89, 95%CI 1.61 – 2.17). Sex, liver disease etiology, HCC, and teaching hospital status were not independently associated with delay. Octreotide and ceftriaxone were prescribed in 69.8% and 69.2% of encounters, compared to pantoprazole at 86%. Delay was associated with longer hospital length of stay (median 5.3 vs. 4.6 days, $p < 0.001$), but not increased mortality after adjustment for patient- and system-level factors (aHR 0.87, 95% CI 0.65-1.16). **Conclusion:** In this large Canadian cohort, two-fifths of patients with decompensated cirrhosis presenting with UGIB underwent delayed endoscopy (>24h). Although higher acuity patients were more likely to undergo earlier endoscopy and were likely clinically sicker, 43.4% in the delayed endoscopy group were still confirmed to have variceal bleeds. Further investigation is warranted to better understand these observational findings and to inform hospital-level quality improvement initiatives aimed at reducing practice variability through standardized care pathways and optimized resource allocation.

2261 | HOW RECOMMENDATIONS TAKE SHAPE: CO-CONSTRUCTING EARLY LIVER TRANSPLANT SELECTION IN COMMITTEE DELIBERATIONS

Esra Alagoz[1] Megan Saucke[1] Brian Fisher[1] Sue Hyon Kim[2] John Rice[1] Marina Serper[3] Norah Terrault[4] Brian Lee[5] Michael Lucey[1], [1]University of Wisconsin, [2]University of Pennsylvania, [3]University of Pennsylvania Health System, [4]University of Southern California, [5]Keck School of Medicine

Background: Selection for early liver transplant (ELT) in patients with alcohol-associated liver disease and < 6 months sobriety involves complex, multidisciplinary deliberation. While prior work has focused on clinical and psychosocial criteria, how decisions are collaboratively produced has not been extensively analyzed. **Methods:** We analyzed transcripts of transplant selection committee meetings across three transplant centers using a modified conversation analysis approach. Focusing on the factors that influence how recommendations are collaboratively constructed, elaborated, and resolved in real time, we examined how participants built on one another's contributions through sequences of implicit, hedged (e.g. "I think"), and explicit recommendations. We also examined how opinions evolved over the course of discussion and became accepted or contested, including instances in which concerns were raised but not incorporated into subsequent discussion. **Results:** A total of 49 ELT patients were presented at 26 full length meetings. Subsequent discussions about 8 of these patients were also evaluated. Decision-making unfolded as a dynamic, interactional process rather than a series of isolated recommendations. In some cases, participants collaboratively built toward a shared position through incremental contributions, with patient factors elaborated across speakers before the group reached consensus. In others, early explicit recommendations curtailed further debate, leading to rapid alignment with limited discussion. Implicit recommendations (indirect statements signaling concern or support) frequently employed by social work, psychiatry and addiction medicine often served as building blocks for subsequent recommendations but varied in their influence depending on whether they were taken up and developed by surgeons and hepatologists. Patterns of uptake varied by speaker role and clinical involvement, with contributions from surgeons and hepatologists often shaping subsequent discussion, particularly when they had evaluated the patient in person. This suggests that the incorporation of information and preferences into decision-making is selective and interactionally mediated. **Conclusion:** Transplant committee decisions are co-constructed through interactional sequences in which participants build, modify, and ratify recommendations during deliberation. Our findings show that decision-making depends not only on the information available, but also on how that information is taken up within group discussion. As deliberations unfold, implicit biases and power dynamics may shape which contributions are amplified, minimized, or incorporated into final recommendations. Making these processes more explicit may support reflective committee practice and promote greater transparency and equity in ELT decision-making.

2262 | HIGH CO-MORBIDITY BURDEN AND RECURRENT HOSPITALIZATIONS ARE ASSOCIATED WITH ADVANCE DIRECTIVE DOCUMENTATION PRIOR TO TERMINAL HOSPITALIZATION IN PATIENTS WITH END-STAGE LIVER DISEASE

Natalie Malluru[1] Nazan Aksan[1] Paul Mueller[1] Cristal Brown[1], [1]University of Texas at Austin Dell Medical School

Background: Despite the high levels of morbidity and mortality requiring significant resource utilization, patients with end-stage liver disease (ESLD) rarely undergo timely serious illness communication with goals of care (GOC) documentation. Our prior single center retrospective study found that only 28% of hospitalized patients with ESLD had a documented advance directive (AD). There is a gap in knowledge regarding the factors that support having a documented AD and its impact on terminal hospitalizations for patients with ESLD. The objective of this study was to describe the demographic and clinical features of patients with ESLD experiencing inpatient death and identify factors associated with AD documentation prior to terminal hospitalization. **Methods:** Single center, multi-hospital retrospective study with a standardized manual chart review. Inclusion criteria are adult patients with ESLD who experienced inpatient mortality at one of 8 central Texas hospitals from 2015–2025 with a documented AD. Demographics, clinical characteristics, AD type and timing, and inpatient end-of-life care were examined. Patients were stratified by AD timing (before vs. during terminal hospitalization). Continuous outcomes were modeled with ordinary least squares regression and binary outcomes (e.g., palliative care consultation, GOC discussion) with logistic regression. **Results:** Of 91 patients meeting criteria, mean age was 58 years with 62.6% males and 53.9% being non-White race and/or Hispanic ethnicity. Most (70.3%) patients did not have a domestic partner. Based on Charlson Comorbidity Index, 93.4% of patients had 1 or 2 co-morbidities present. Mean peak MELD 3.0 score

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

was 30 and 82.4% of patients had an ICU admission during the terminal hospitalization. The mean terminal hospitalization length of stay was 11.8 days (SD 9.2) and ICU length of stay was 9.5 days (SD 9.1). 81.3% were full code at hospital admission and only 2.2% were full code at the time of death. AD documentation occurred during terminal hospitalization in 54% of patients. Only a health care power of attorney (HCPOA) was identified in 88% of patients. Pre-admission AD documentation was associated with higher comorbidity burden (OR 2.03, p = 0.057) and greater number of prior hospital admissions (5.0 vs 2.9, p < 0.001). HCPOA identification was associated with having a palliative care consultation and GOC discussion. Among 67 patients receiving both, 94% occurred on the same hospital day. **Conclusion:** Among patients with ESLD who experienced inpatient death with documented ADs, the majority were full code at admission and received aggressive care that included an average ICU admission that was 9.5 days and an average hospital stay of 12 days. AD documentation occurred most often during the terminal hospitalization and consisted primarily of HCPOA designation. Earlier AD documentation was associated with a greater number of prior hospital admissions and comorbidity burden. These findings support inpatient interventions that identify patients with ESLD earlier in the disease trajectory, even in the absence of significant co-morbidities and recurrent hospitalizations admissions, for serious illness communication and AD documentation.

Table 1: Demographic and clinical characteristics of the entire cohort

	Mean (SD)	Frequency N (%)
Demographics		
Age (years)	58.1 (12.1)	
Male		57 (62.6%)
Non-White race		15 (16.5%)
Hispanic ethnicity		34 (37.4%)
Married or domestic partner		27 (29.7%)
Clinical data		
Etiology		
Alcohol		51 (56.0%)
MASH		10 (15.4%)
Viral Hepatitis		10 (11.0%)
Other/Undocumented		27 (29.7%)
Peak MELD score	29.7 (8.8)	
Hepatic encephalopathy		42 (46.1%)
Number of co-morbidities		
1		69 (75.8%)
2		16 (17.6%)
3		5 (5.5%)
4		1 (1.1%)
AD documentation		
Power of attorney alone		78 (85.7%)
Timing		
Before hospitalization		41 (45.1%)
During hospitalization		50 (54.9%)
Hospital day of GOC conversation	6.1 (5.3)	
Hospital day of PC consult	6.3 (5.4)	
Full code at admission		74 (81.3%)
Full code at death		2 (2.2%)
Hospital utilization		
ICU admission		75 (82.4%)
Number hospitalizations during study period	3.9 (3.1)	
Terminal hospitalization LOS (days)	11.9

2263 | AWARENESS OF LIVER DISEASE AMONG AT-RISK GROUPS

Trenton White[1] Leire Agirre-Garrido[1] Lila Neal[1] Sonal Kumar[2] Melina Manolas[3] Scott Isaacs[4] Jeffrey Lazarus[5], [1]Barcelona Institute for Global Health (ISGlobal), [2]Department of Medicine, Division of Gastroenterology and Hepatology, Weill Cornell Medicine, [3]Weill Cornell, [4]Emory University School of Medicine, [5]University of Barcelona

Background: Despite low public awareness of liver disease, metabolic dysfunction-associated steatotic liver disease (MASLD) and its more progressive form, metabolic dysfunction-associated steatohepatitis (MASH), affect an estimated 30% or more of the general population. People living with MASLD-indicator conditions, e.g. obesity and type 2 diabetes (T2D), may not perceive themselves as being at risk for MASLD. Understanding these awareness gaps can generate valuable evidence to support health sector investments and help bridge critical shortfalls in public knowledge of these key public health threats. This study assesses awareness and evaluates concern regarding cardiometabolic and liver-related conditions among populations facing elevated risk. **Methods:** This cross-sectional study surveyed 3,010 adult residents of the United States via an online panel. Recruitment targeted individuals with a body mass index (BMI) greater than 30 or a self-reported diagnosis of diabetes. Respondents were matched to a sampling frame constructed from the 2023 American Community Survey (ACS) 1-year sample on the basis of gender, age, race, and education, and weighted using propensity score methods to adjust for selection bias, resulting in a final analytical sample of 1,000 adults. **Results:** Within the full sample, awareness of cirrhosis was highest (61%; n = 610), followed closely by fatty liver disease (60%). Recognition dropped markedly for more specific terminology, including NAFLD (36%), liver fibrosis (24%), MASLD (13%), and MASH (12%) (Table 1). Awareness was modestly higher across these terms among respondents with diabetes or prediabetes compared to those living with obesity alone. Individuals with indirect exposure to MASLD, such as knowing an affected parent, partner, or friend, also showed elevated awareness relative to the broader sample, though recognition of MASLD and MASH remained low across these factors. **Conclusion:** The higher awareness of fatty liver disease relative to MASLD and MASH likely reflects a lag in public and at-risk group knowledge of the names following the 2023

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

nomenclature change from NAFLD. The strong recognition of cirrhosis may stem from its longstanding public association with alcohol-related harm and advanced disease severity. Given that MASLD is reversible in early stages, these awareness gaps underscore the need for targeted interventions to promote timely detection, encourage lifestyle modifications, and prevent progression to fibrosis, cirrhosis, and other serious complications.

Table 1. Familiarity with liver disease terms by sub-groups

Terms	Full sample (n=1,000)	BMI 30+ (n=804)	Living with type 2 diabetes or prediabetes (n=441)	Reported MASLD diagnosis (n=70)	Knowing Parent with MASLD (n=18)	Knowing Partner with MASLD (n=22)	Knowing Friend with MASLD (n=62)	Knowing Colleague with MASLD (n=9)
Liver cirrhosis	61%	59%	67%	85%	79%	70%	77%	77%
Fatty liver disease	60%	59%	64%	94%	91%	80%	92%	63%
Non-alcoholic fatty liver disease (NAFLD)	36%	36%	38%	80%	63%	62%	70%	47%
Liver fibrosis	24%	23%	26%	51%	48%	25%	52%	53%
Metabolic dysfunction-associated steatotic liver disease (MASLD)	13%	13%	15%	27%	40%	14%	64%	35%

2264 | TEMPORAL TRENDS AND DISPARITIES IN CHRONIC LIVER DISEASE-RELATED MORTALITY IN THE UNITED STATES, 2010-2023

Xinrong Zhang[1] Scott Barnett[2] Ramsey Cheung[3] Fanpu Ji[4] Mindie Nguyen[3], [1]Department of Epidemiology, School of Public Health, Sun Yat-sen University, [2]Division of Gastroenterology and Hepatology, School of Medicine, Stanford University Medical Center, [3]Stanford University Medical Center, [4]Xi'an Jiaotong University

Background: Chronic liver disease (CLD) is a major cause of morbidity and mortality worldwide; however, population-based data on temporal trends in CLD-related mortality in the United States (U.S.) remain limited. We evaluated temporal changes in CLD-related mortality in the U.S. from 2010 to 2023 across subgroups stratified by age, sex, race and ethnicity, and urbanization status. **Methods:** We analyzed age-standardized mortality rates (ASMRs) for CLD-related deaths using data from the U.S. National Vital Statistics System available through the Centers for Disease Control and Prevention Wide-Ranging Online Data for Epidemiologic Research (CDC WONDER) database among adults aged $\geq$ 25 years from 2010 to 2023. Joinpoint regression analyses were performed to estimate annual percentage changes (APCs) in mortality trends overall and across subgroups stratified by age, sex, race and ethnicity, and urbanization status. **Results:** Among 204,885 CLD-related deaths between 2010 and 2023, ASMRs (per 100,000 persons) rose from 17.07 to 22.02, with APC increased from 1.55% in 2010-2018 to 7.76% in 2018-2021, but decreased at -5.82% afterwards between 2021 and 2023, resulting in an average APC (AAPC) of 1.77% ($P < 0.001$) **(Table)** . Significant age-related differences in ASMR trends were noted, with the steepest increase observed among individuals aged $\geq$ 65 years (AAPC: 5.23%, $P < 0.001$) followed by those of individuals aged 25-44 years (AAPC: 4.73%, $P < 0.001$), while trends were stable among individuals aged 45-64 years (AAPC: -0.05%, $P = 0.923$). By sex, though males had higher ASMRs than females and ASMRs increased in both groups, the AAPC was higher in females than males (3.02% vs. 1.83%). ASMRs also increased among Non-Hispanic White individuals (AAPC: 2.71%, $P < 0.001$) and Non-Hispanic American Indian and Alaska Native individuals (AAPC: 3.73%, $P < 0.001$), but decreased among Non-Hispanic Asian or Pacific Islander individuals (AAPC: -1.42%, $P = 0.002$), while remaining stable among Hispanic and Non-Hispanic Black individuals (AAPC: 0.39%, $P = 0.324$ and -0.42%, $P = 0.402$, respectively). CLD-related ASMRs also varied across metropolitan categories, with the largest increase occurring in non-metropolitan areas (AAPC: 5.21%, $P < 0.001$). **Conclusion:** CLD-related mortality increased during 2010-2023, with notable disparities among the younger (25-44 year) and older ($\geq$ 65 year) individuals, the non-Hispanic Whites and Non-Hispanic American Indian and Alaska Native groups and non-metropolitan populations.

2265 | INCREASING HIGH-RISK ALCOHOL CONSUMPTION TRANSITIONS AMONG CANADIAN YOUTH AND YOUNG ADULTS

Courtney Campbell[1] Maya Djerboua[2] Kristel Leung[1] Sahar Saeed[1] Jennifer Flemming[3], [1]Queen's University, [2]ICES-Queen's, [3]Queen's University Cancer Research Institute

Background: Severe alcohol associated liver disease (ALD) is rising among adolescents and young adults (AYAs) and is typically a consequence of high-risk alcohol consumption. Population-level self-reported alcohol use is often used to evaluate trends in consumption, yet it is unknown whether these discrete measurements are representative of an individual's consumption patterns over time. This study describes individual-level transitions in alcohol consumption by sex-specific ALD risk, stratified by age group. **Methods:** A population-level, retrospective cohort of Canadian Community Health Survey (CCHS) respondents from Ontario aged 15-60 years from the 2003, 2005-2018 cross-sections who had two survey responses were included. The transitions in alcohol consumption from no risk (0g/week alcohol), mild-moderate risk (up to 210g/week males and 140g/week females) or high-risk consumption (>210g/week males and >140g/week females) were defined. Consumption transitions between groups from the first to second survey were visualized as Sankey diagrams and stratified by age (AYAs <40 years vs. adults 40+ years). Proportional changes in each risk group between age-stratified surveys were calculated. **Results:** 1,786 individuals with two CCHS survey entries were included (41% AYAs, 56% female) with a median of 5.5 years between entries. A higher proportion of AYAs than adults transitioned between alcohol consumption categories (43.0% vs. 35.9%). Of those, 61% of AYAs *transitioned to a higher risk category* while 56% of adults *transitioned to a lower risk category*. Proportional changes in alcohol consumption between index and second survey among AYAs indicated substantial increases in the transition to mild-moderate (+24.1%) and high-risk (+6.7%) consumption, compared to a decrease in zero consumption (-17.6%). Conversely, zero alcohol consumption increased among adults (+9.1%) while mild-moderate (-9.0%) and high-risk (-1.1%) consumption decreased. **Conclusion:** After a median of 5.5 years between survey entries, nearly half of all AYA respondents transitioned to a different alcohol consumption risk category. Of those, over 60% transitioned to a higher risk category while the opposite was observed for adults. Limitations in the use of cross-sectional survey data to define alcohol exposure should be considered, and prospective documentation of alcohol consumption should be considered to explore the association between quantitative alcohol consumption and risk of ALD.

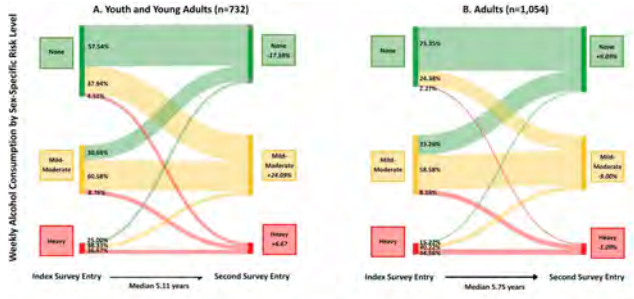

Figure. Age-Stratified Sankey Diagrams of Weekly Alcohol Consumption Transitions by Sex-Specific Liver Risk Level Among n=1,786 Individuals with Two Canadian Community Health Survey Entries Between 2003, 2005-2018.

2266 | IMPACT OF RESMETIROM ON HEALTH-RELATED QUALITY OF LIFE, WORK PRODUCTIVITY, AND DISEASE-SPECIFIC SYMPTOMS IN COMPENSATED MASH CIRRHOSIS

Zobair Younossi[1] Fatema Nader[2] Rebecca Taub[3] Andrei Racila[4] Maria Stepanova[1], [1]The Global NASH/MASH Council, [2]Center for Outcomes Research in Liver Diseases, CORLD, [3]Madrigal Pharmaceuticals, [4]The Center for Outcomes Research in Liver Disease

Background: Metabolic dysfunction-associated steatohepatitis (MASH) cirrhosis significantly impairs health-related quality of life (HRQL) with limited therapeutic options. This study evaluated the impact of resmetirom, a selective thyroid hormone receptor-β agonist, on HRQL work productivity and symptom burden in patients with compensated MASH cirrhosis. **Methods:** This post hoc analysis included 160 patients with compensated MASH cirrhosis from the MAESTRO-NAFLD-1 trial who completed HRQL assessments using the Liver Disease Quality of Life (LDQoL), Chronic Liver Disease Questionnaire-MASH (CLDQ-MASH), Chronic Liver Disease Questionnaire-MASH Symptom Questionnaire (CLDQ-MASH-SQ), and Work Productivity and Activity Impairment (WPAI) questionnaires. **Results:** At baseline, the most impaired HRQL and symptom domains were sleep- and fatigue-related. After 52 weeks of 80 mg resmetirom treatment, improvements were observed in CLDQ-MASH Worry (mean +0.30; $p = 0.001$) and LDQoL Health Distress (+3.44; $p = 0.051$) domains. Among patients with portal hypertension, improvements in both Health Distress and Worry scores were more pronounced. VCTE responders (relative decrease $\geq 25\%$) demonstrated improvement in bleeding gums and joint pain symptoms. **Conclusion:** Cirrhosis in MASH is associated with significant HRQL impairment and substantial symptom burden. Resmetirom treatment in these patients was associated with modest but significant improvements in mental health distress and worry domains, as well as specific symptom relief.

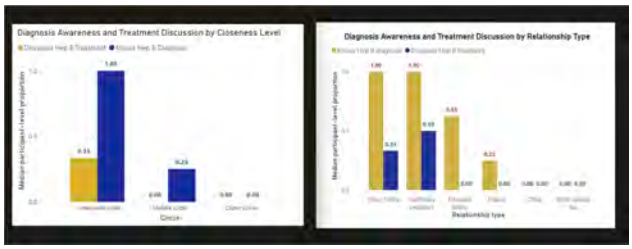
2267 | MAPPING THE SOCIAL SUPPORT NETWORKS OF ADULTS LIVING WITH CHRONIC HEPATITIS B IN CALGARY, CANADA



Md Irfan Hyder[1] Jenny Godley[2] Carla Coffin[3] Mayur Brahmania[4] Heidi Israelson[3] Danielle Tillie[3] Henry Nguyen[3] Folake Arinde[3] Pam Crotty[3] Tanvir C. Turin[5] Mark Swain[3], [1]Transdisciplinary Research Program, Faculty of Graduate studies, University of Calgary, [2]Department of Anthropology and Archaeology, Faculty of Arts, University of Calgary., [3]Department of Medicine, Cumming School of Medicine, University of Calgary., [4]Department of Medicine, Cumming School of Medicine, University of Calgary, [5]Department of Community Health Sciences, Cumming School of Medicine, University of Calgary.

Background: Chronic hepatitis B (CHB) requires long-term monitoring, treatment engagement, and support from personal networks. We report on a pilot study that gathered egocentric network data from patients receiving treatment at a CHB clinic to characterize the structure and composition of their support networks and to examine how these support networks might be activated to encourage treatment adherence. **Methods:** We conducted a descriptive egocentric social network analysis with 17 adults receiving CHB care at a Calgary liver clinic. We used Antonucci's hierarchical mapping method. Participants, treated as egos, were first asked to list "people who are important in your life right now." Each named person was treated as an alter and was placed by the participant into a hierarchical closeness map. The first level included people they felt very close to, talked to often, or relied on for support; the second level included people who were very important but not quite as close; and the third level included people who were still important but less involved in the patients' lives. Relationship types were coded as direct family, extended family, friends, work-related ties, healthcare providers, or other. For each alter, participants reported whether they discussed general health, whether the alter knew their CHB diagnosis, and whether they discussed CHB treatment/care with that alter. Counts were converted to participant-level proportions and summarized using medians and ranges. **Results:** Participants had a median age of 47 years (IQR: 41–53); 9 were female and 8 were male. They had lived in Canada for a median of 32 years (IQR: 19–44) and represented diverse ethnocultural backgrounds, commonly Chinese ($n = 8$) and Vietnamese ($n = 2$). Median network size was 11 alters per participant (IQR: 8–13; range: 4–25). The median participant placed 45.5% of their network in the innermost circle and 25.0% each in the middle and outer circles. Networks were mainly composed of direct family members and friends, representing 44.4% and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

28.6% of the median participant's network, respectively. Communication roles differed across networks. The median participant talked about general health with 33.3% of their network, while 50% knew about their CHB diagnosis and 18.2% discussed [MB3] CHB treatment/care. Diagnosis awareness was highest among innermost-circle and family ties: 100% of innermost-circle and direct-family ties knew the diagnosis, compared with 25% of middle-circle ties, 0% of outer-circle ties, 62.5% of extended-family ties, and 25% of friends. Treatment discussion was narrower, reported with 33.3% of innermost-circle ties and 33.3% of direct-family ties. **Conclusion:** CHB diagnosis awareness was broader than treatment discussion, suggesting that disclosure alone may not indicate treatment-related support. Network-informed questions may help identify trusted close or family ties who could support treatment engagement and long-term care.

2268 | NEEDLE AND SYRINGE PROGRAM WITH OUTREACH TEAM ESSENTIAL IN MANAGING OUTBREAKS OF HEPATITIS B AND GROUP A STREPTOCOCCI AMONG PEOPLE WHO INJECT DRUGS

Marianne Alanko Blomé[1] Gülsen Özkaya Sahin[2] Magnus Paulsson[2] Johan Ringlander[3] Pernilla Isendahl[4], [1]Department of Infectious Diseases, Skåne University Hospital, Malmö and Lund University, [2]Division of Medical Microbiology, Department of Laboratory Medicine, Lund University, [3]Department of Clinical Microbiology, Sahlgrenska University Hospital, Gothenburg, Sweden, [4]Department of Infectious Diseases, Skåne University Hospital, Malmö, Sweden

Background: Early evaluations (1990-93) of the Malmö needle and syringe program (NSP), run by the Infectious disease department, found hepatitis B (HBV) incidence to be 11.7 seroconversions/100 person years at risk. Vaccination against HBV was introduced to all eligible participants in 1994. Coverage and efficacy have since been sufficient to prevent outbreaks. HBV incidence declined to 3.4/100 pyr in 1997-2005. No incident cases had been observed for the past decade – until the spring of 2025 when an incident, symptomatic case presented at the NSP, followed by others. Later in the same year, several cases of invasive group A streptococci (iGAS) were detected among people who inject drugs or lack stable housing. **Methods:** A team consisting of NSP staff (nurses, assistant nurses, ID physicians and social workers) implemented an outreach routine, regularly visiting low threshold centers providing counseling, testing, vaccination and contact tracing. Information was also distributed to other health care providers and arenas. Later, visits to night shelters for wound cultures and treatment with antibiotics aimed at GAS were added on. Whole genome sequencing (WGS) was used to verify transmission patterns. **Results:** Six incident, symptomatic cases of HBV were identified between February and June 2025. Contact tracing identified three more asymptomatic cases of ongoing HBV infection. One was a person with a chronic infection acquired in childhood. This patient has been identified as the source of transmission. Whole genome sequencing revealed identical viral strains for all cases. Almost all 25 contacts were reached, and via the low threshold shelters, around 40 more persons were tested for HBV, hiv and HCV and those susceptible for HBV have been offered vaccination. No cases of hiv were detected, while 3 previously unknown HCV cases were found and treated. In the end of november 2025 a patient presented with necrotizing fasciitis, followed by another case with a fatal outcome. Both had an usual strain of GAS, emm60, ST53. From december to march 2026

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

ten more cases were detected. **Conclusion:** People who inject drugs and/or lack stable housing are under risk of viral and bacterial outbreaks. However, despite access to NSP and HBV vaccination, an outbreak of HBV may occur through introduction of a highly viremic patient with chronic HBV infection. Wound infections with GAS, predisposing for septic manifestations may also be easily transmitted. Through a warm alliance with the target population, the NSP outreach team could rapidly gain access to the persons at risk for primary and secondary prevention. Identical strains forming viral and bacterial clusters could be identified for both HBV and GAS by WGS.

2269 | ANALYSIS OF CLINICAL CHARACTERISTICS AND RELATED FACTORS OF GALLBLADDER POLYPS IN NORTHEAST CHINA

Hui Wang[1] Xiaoyu Wen[1], [1]The First Hospital of Jilin University

Background: The incidence of gallbladder polyps (GBP) is continuously increasing. This study aimed to analyze the clinical characteristics of the population with GBP in Northeast China and the factors influencing their formation and growth, to enhance public awareness of GBP, and to promote conservative management through lifestyle modifications and avoidance of relevant risk factors, thereby reducing unnecessary cholecystectomy and other surgical interventions. **Methods:** A total of 9,103 individuals with GBP who visited the Health Examination Center of the First Hospital of Jilin University from January 2022 to December 2024 were enrolled as the study group. A random sample of 15,767 individuals without GBP during the same period was selected as the control group. General data, physiological and biochemical indicators, and abdominal ultrasound reports were collected. Clinical characteristics were summarized, and factors associated with GBP formation and growth were analyzed through intergroup comparisons. **Results:** (1) The highest proportion of GBP subjects was in the 51–60 years age group (29.31%). Polyps sized 2.1–5.9 mm accounted for the majority (75.79%), and single polyps predominated (62.25%). (2) Male sex (OR = 1.338), age (OR = 1.014), elevated levels of TBiL (OR = 1.012), TBA (OR = 1.025), LDL-C (OR = 1.162), BUN (OR = 1.093), UA (OR = 1.001), HB (OR = 1.007), and PLT (OR = 1.001), as well as decreased HDL-C (OR = 0.539) and presence of fatty liver disease (OR = 1.152), were identified as independent factors associated with GBP formation. (3) Analysis across three groups stratified by GBP size ($\leq$2 mm, 2–6 mm, $\geq$6 mm) showed a progressive increase in the proportion of males, BMI, WC, ALT, GGT, TG, Cr, UA, HB, gallbladder wall roughness, fatty liver disease, overweight/obesity, central obesity, and hyperuricemia, while HDL-C levels progressively decreased. Analysis of groups based on changes in GBP size during the study period (increase >1 mm vs. no increase or increase $\leq$1 mm) revealed that AST, ALT, and GGT levels were higher in the former group. (4) Pathological results from the big data platform of the First Hospital of Jilin University for hospitalized patients with GBP who underwent cholecystectomy showed that cholesterol polyps were the dominant pathological type, while malignant or potentially malignant polyps accounted for a very low proportion. **Conclusion:** (1) The GBP population is predominantly aged 31–60 years, with polyp sizes mainly between 2.1–5.9 mm, and single polyps are the most common. (2) Sex, age, metabolic abnormalities, liver dysfunction, and inflammatory response may be factors associated with the formation and growth of GBP. (3) The majority of patients admitted with GBP and undergoing cholecystectomy are pathologically confirmed to have benign polyps without malignant potential. Rational control of surgical indications is recommended to reduce unnecessary cholecystectomies.

Figure 1. Pathological type distribution and proportional composition of surgically resected GBP-related lesions (2023 - 2025)

Pathologic type(n,%) / Year	Cholesterol polyp	Adenomyomatosis	Adenoma	ICPN	Adenocarcinoma
2025	663 (65.51)	227 (22.43)	94 (9.29)	11 (1.09)	17 (1.68)
2024	557 (70.15)	154 (19.40)	67 (8.44)	5 (0.63)	11 (1.39)
2023	432 (63.25)	156 (22.84)	61 (8.93)	19 (2.78)	15 (2.20)
Total	1652 (66.37)	537 (21.57)	222 (8.92)	35 (1.41)	43 (1.73)

Admission Diagnosis(n,%) / Pathologic type	Gallbladder malignant lesion	Gallstones	GBP	Hepatic malignant lesion
ICPN	15 (42.86)	8 (22.86)	10 (28.57)	2 (5.71)
Adenocarcinoma	17 (39.53)	20 (46.51)	5 (11.63)	1 (2.33)

2270 | EVOLVING TREATMENT REGIMENS IN FATTY LIVER DISEASE: ANALYSIS OF GLP-1 AND RESMETIROM USE

Noha Abdelgelil[1] Anna Hefner[1] Mustafa Behan[2] Jutta Kurz[2] Tresha Elaine Ramonal[2] Karen Hoyt[3] Rachma Purnama[4] Lorrinda Gray-Davis[3] Michael Tunkelrott[4] Fatma Barakat[5] Emmanuel Gorospe[6] Deanna Oliver[1] Tarek Hassanein[1], [1]Southern California Liver Centers, [2]Amsety, [3]None, [4]Amsety LLC, [5]SCTI Research Foundation, [6]Burrell College of Osteopathic Medicine

Background: Management of fatty liver disease is rapidly evolving with new treatment options. Resmetirom is approved for the treatment of liver fibrosis. However, GLP-1 receptor agonists, originally approved for diabetes and weight loss, are also used in MASLD/MASH management. **Aim:** To evaluate how pts are prescribed GLP-1 receptor agonists and resmetirom in their management of fatty liver disease and how they're integrated into clinical care and lifestyle intervention. **Methods:** The Amsety database contains close to 450,000 individuals with MASLD/MASH in the US. This is an initial analysis of 83 respondents to a survey on the use of GLP-1 and/or resmetirom. The survey addresses treatment patterns, adherence, and patient-reported outcomes, including weight change, side effects, and perceived liver health. **Results:** Average age of respondents was 41 years and a BMI of 35.8. 39% were diagnosed with MASLD in the past 12 months, 39% within the past 1-3 years, and 19% within the past 3-5 years. Comorbidities included obesity (63%), hyperlipidemia (37%), and type 2 diabetes (29%). For disease monitoring, 37% reported being on an active treatment plan (prescribed medication, scheduled imaging, and regular liver-specific follow-ups) while 33% were on periodic monitoring (scheduled tests but no medication). Resmetirom and/or GLP-1 use: 13% received resmetirom. 58% received injectable semaglutide, 11% oral semaglutide, and 20% took tirzepatide. 35% have been on GLP-1 for 6-12 months at the time of completing the survey. Side effects included nausea/vomiting (48%), fatigue/weakness (41%), and gastrointestinal issues (36%). GLP-1 prescription: was mainly by Primary Care Providers (51.8%) and Gastroenterologists/Hepatologists (43.4%). 35% were prescribed GLP-1 for weight loss and 27% for liver health. Lifestyle modifications: Almost 50% made dietary and/or physical activity changes while on GLP-1. Outcomes: 36% lost 5% of body weight, 20% lost 5-10%, and 17% reported no weight loss/gain. After stopping GLP-1 medication, 35% maintained improved eating habits and weight while 25% returned to old eating habits. 34% and 22% of pts reported improvement or stability in liver fat and/or fibrosis according to their provider, respectively. **Conclusion:** GLP-1 medications show emerging use in fatty liver disease management, primarily for weight loss and metabolic comorbidities. Patient-reported outcomes indicate improvements in weight and dietary habits. Treatment patterns vary between primary and specialist care, with specialists more often tailoring therapy to underlying metabolic or liver-related indications. These therapies are a key component of care, but long-term benefit depends on continued treatment, lifestyle adherence, and clinical follow-up. GLP-1 use in combination with resmetirom needs to be better understood with a tailored management approach applied.

Lurie Children's Hospital of Chicago, [24]UPMC Children's Hospital of Pittsburgh

Background: Activated T-cell pediatric acute liver failure (TC-PALF) is the leading cause of acute liver failure in children in North America. Prior work from the PALF Immune Response Network (PALF-IRN) identified two TC-PALF endotypes defined by CD8+ T-cell Perforin1 (Prf) expression: High Prf and Normal Prf (NL Prf). High Prf cases show an interferon-gamma (IFN-γ)–positive CD8 tissue-resident memory transcriptional signature in peripheral blood. However, tissue-level T-cell–hepatic parenchymal interactions have not been well described. We used high-resolution spatial transcriptomics to map these interactions in liver biopsies. **Methods:** Formalin-fixed paraffin-embedded liver biopsies from PALF-IRN or Children's Hospital of Philadelphia were profiled by VisiumHD, 10x. Groups: TC-PALF High Prf (n = 8), TC-PALF NL Prf (n = 6), and seropositive acute fulminant autoimmune hepatitis (AIH, n = 3) were compared. Data were binned at 8×8 µm (≍1–2 cells/bin), clustered with Seurat, and annotated using Enrichr and histologic correlation in Loupe Browser software. Pseudo-bulk comparisons across annotated clusters used R (v4.4.0). To identify shared, biologically relevant programs, we filtered for differentially expressed genes present in >50% of cell populations and significantly upregulated in >75% of annotations. Uniform Manifold Approximation and Projection (UMAP) was used to visualize the data. **Results:** Seurat clustering revealed two transcriptionally distinct T-cell populations corresponding to microanatomic locations: portal and lobular (Fig. 1A). We focused on portal T cells, where comparable bins existed across TC-PALF High Prf, NL Prf and AIH. Compared with NL Prf, TC-PALF High Prf portal T cells were enriched for effector and cytolytic-related genes (KLRG1, SH2D1A/SAP, SRGN). Compared with AIH, TC-PALF High Prf showed enrichment for pathways mediating T-cell and monocyte recruitment (chemotaxis) and integrin–collagen interactions, whereas AIH was enriched for B-cell receptor signaling (Fig. 1B). Gene programs present in >75% of cell populations in TC-PALF High Prf versus AIH or NL Prf were dominated by T-cell proliferation and IFN signaling (Fig. 1C/D), indicating that both immune cell and parenchymal compartments in TC-PALF High Prf are responsive to IFN-γ. **Conclusion:** TC-PALF High Prf liver tissue displays a unique portal microenvironment characterized by cytotoxic T-cell effector signatures, chemokines promoting T-cell/monocyte recruitment,

and enhanced integrin–extracellular matrix interactions. IFN signaling in TC-PALF High Prf is increased across immune and parenchymal cells. These spatially resolved features distinguish TC-PALF High Prf from NL Prf and AIH highlighting the importance of this cytokine in disease pathogenesis and provide key insights to disease biology.

2272 | ◆ TGR5 INHIBITION DISRUPTS BILE ACID-DRIVEN IMMUNOSUPPRESSION IN CHOLANGIOCARCINOMA

Enis Hikmet Ozmert[1] Binbin Li[1] Hannah Stumpf[1] Jingchun Yang[1] Danielle Carlson[1] Jennifer Tomlinson[1] Rory Smoot[2] Sumera Ilyas[2], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Cholangiocarcinoma (CCA) is a lethal hepatobiliary malignancy where first line therapy (durvalumab + gemcitabine/cisplatin) provides marginal survival benefit. CCA exhibits a distinct tolerogenic tumor microenvironment (TME) shaped by elevated bile acid concentrations from obstructive cholestasis. TGR5 is a key receptor in bile acid signaling. We hypothesize that bile acids promote CCA progression via TGR5 signaling on myeloid cells, targetable with SBI-364, a novel potent small molecule TGR5 inhibitor. **Methods:** We generated a comprehensive single-cell RNA sequencing (scRNA-seq) atlas of human intrahepatic (iCCA) and perihilar (pCCA) cholangiocarcinoma to map TGR5 expression across TME populations. Monocyte-derived Kupffer cells (moKCs) emerged as the major TGR5 signaling hub and we performed CellChat analysis to identify its interactors within the TME. We evaluated SBI-364 (a small molecule inhibitor of TGR5 developed through a Sanford Burnham-Mayo Clinic collaboration) efficacy in syngeneic orthotopic models of iCCA and a novel pCCA model in C57BL/6J mice, with single-cell Flex profiling of treated tumors. Two patient-derived xenografts (PDXs) with divergent tumor TGR5 (GPBAR1) expression underwent treatment studies in NOD/SCID mice. Lastly, we analyzed the Mayo Tempus CCA cohort using CIBERSORTx to correlate our murine findings with patient data. **Results:** Human scRNA-seq revealed TGR5 expression was highly enriched in myeloid cells within a “moKC” population, across iCCA and pCCA. This population was also the most immunosuppressive myeloid cell population in the TME. CellChat analysis

identified moKCs as a major outgoing signaling source to T cells across multiple tolerogenic pathways. SBI-364 significantly increased survival in orthotopic models when combined with gemcitabine/cisplatin and reduced tumor burden in murine iCCA and pCCA. In contrast, SBI-364 failed to inhibit tumor growth in both TGR5-high and TGR5-low PDXs in immunodeficient hosts, demonstrating that TGR5 blockade acts through immune-mediated mechanisms rather than tumor-intrinsic effects. Single-cell profiling of SBI-364 treated tumors demonstrated TME-wide reprogramming, including reduced moKC tolerogenic programs. In vitro, bile acids suppressed CD8+ T cell proliferation, which was abrogated by SBI-364 co-treatment. Clinically, elevated GPBAR1 expression in the Mayo Tempus cohort correlated with worse overall survival in both pCCA and iCCA, as well as with increased anti-inflammatory dendritic cell fractions. **Conclusion:** TGR5 inhibition reprograms the immunosuppressive myeloid-driven TME in CCA, reducing tumor burden by restoring effector T cell immunity. These findings establish TGR5 as a rational therapeutic target for overcoming immune evasion in cholangiocarcinoma and identify GPBAR1 expression as a candidate biomarker to guide patient selection for TGR5-directed therapy.

2273 | D-GALACTOSAMINE/LPS ACUTE LIVER FAILURE RECAPITULATES EMERGENCY GRANULOPOIESIS LIKE SIGNATURES ACROSS THE BONE MARROW–SPLEEN–LIVER AXIS

Jessica Dieudonne[1] Alexandra Caron[1] Audrey Levy[1] Maryse Malysiak[1] Valerie Daix[1] Stephanie Ferreira[1] Jean-Marie Brusq[1] Zouher Majd[1] Bart Staels[2] Sakina Sayah Jeanne[1] Alessia Galgano[1], [1]Genfit, [2]University Lille 2

Background: Emergency granulopoiesis (EG) is an inflammation-driven disturbance of neutrophil homeostasis characterized by accelerated bone-marrow neutrophil production, release of immature neutrophils, and concomitant inhibition of lymphopoiesis. Recent transcriptomic studies have suggested EG signatures in patients with acutely decompensated cirrhosis progressing to Acute-on-Chronic Liver Failure (ACLF). Whether such EG-like features can be reproduced experimentally in liver failure models remains unknown. We therefore characterized whether the D-GalN/LPS acute liver failure (ALF) model reproduces EG hallmarks. **Methods:** Mice were challenged with D-GalN/LPS and euthanized 5.5 h post-challenge. Liver, spleen and bone marrow were harvested for flow cytometry using standardized gating to quantify total neutrophils, maturation status, activation features and T-, B- and NK-cell subsets were analyzed in parallel. Circulating NET-associated biomarkers were quantified in plasma by ELISA including H3R8Cit and total extracellular histone H3.1). H3R8Cit was assessed in controls ($n = 4$) and D-GalN/LPS mice at 3h ($n = 4$) and 5.5 h ($n = 4$) while H3.1 was measured in controls ($n = 11$) and D-GalN/LPS mice at 5.5 h ($n = 9$). **Results:** D-GalN/LPS induced a marked increase of total neutrophils in liver and spleen (approximatively 2-3-fold) together with a strong decrease of bone marrow neutrophils CD11b+/Ly6g+(-40-60%), highlighting a rapid mobilization of the steady-state pool toward peripheral organs. In liver and spleen, neutrophils displayed increased activation-associated features (CD62L+/CD101+ cells) and a shift toward immaturity (CD62L+/CD101- neutrophils), suggesting an early EG-like reprogramming during acute systemic inflammatory stress. Concomitantly, NK (CD45+/NK1.1+)- and B (CD45+/B220+)-cell markedly decreased, most prominently in the liver (50-70%), while total T-cell frequencies were preserved. Circulating NET-associated biomarkers increased following D-GalN/LPS challenge, with significantly higher H3R8Cit levels (H3R8Cit, ~2-fold vs controls; $p < 0.05$) and strong increase in total extracellular H3.1.(H3.1 vs controls, $p < 0.05$). **Conclusion:** The D-GalN/LPS model recapitulates EG-like features: bone marrow neutrophil release, peripheral neutrophil expansion of immature and activated neutrophils, associated with lymphocyte subset alteration, and finally NET-associated circulating markers. This in vivo model may enable the dissection of EG-associated mechanisms and support evaluation of neutrophil-targeted therapeutic approaches in acute liver diseases such as ALF, with potential relevance to AD/ACLF.

2274 | ◆ ALCOHOL ENHANCES MYELOID-DERIVED SUPPRESSOR CELL EXPANSION THROUGH IRF3-DEPENDENT MECHANISMS AND THEREBY CONTRIBUTES TO IMMUNOSUPPRESSION

Gyongyi Szabo[1] Deepika Deepika[2] Prashanth Thevkar Nagesh[2] Stephen Samuel[2], [1]Beth Israel Deaconess Medical Center, [2]Department of Medicine, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston

Background: Alcohol-associated liver disease (ALD) is characterized by persistent inflammation and immune dysfunction. Myeloid-derived suppressor cells (MDSCs) have two types: monocytic-MDSCs (M-MDSCs) and granulocytic-MDSCs (G-MDSCs) that regulate immune responses, accumulate in the liver and may play a role in ALD. Interferon regulatory factor 3 (IRF3) is a key mediator of alcohol-induced inflammation, but its role in MDSC biology is unknown. We investigated the effects of alcohol and IRF3 signaling on MDSC differentiation and immunosuppressive function. **Methods:** Circulating blood of patients with severe alcohol-associated hepatitis (AH) and healthy controls were assessed by FACS for the frequency of G- and M-MDSCs. Mice received the NIAAA alcohol or control diet. In mice, bone marrow (BM)-derived MDSCs were generated from wild-type (WT) and IRF3 knockout (KO) mice using GM-CSF followed by LPS/IFN-γ stimulation. Cells were treated with alcohol in vitro and analyzed by flow cytometry for granulocytic (G-MDSCs; CD11b +Ly6G+) and monocytic MDSCs (M-MDSCs; CD11b +Ly6C+), IL10, Arg1, and phosphorylated IRF3 (pIRF3). Cytokine levels were measured by ELISA. T-cell suppressive function was assessed using CFSE-based proliferation assays. **Results:** We found a significant increase in the frequency of circulating G-MDSCs and M-MDSCs in AH patients compared to healthy controls (HC). A similar increase in G- and M-MDSCs was found in the livers of mice with AH compared to controls. Circulating levels of GM-CSF and IFN-gamma that are factors promoting MDSC generation were increased both in human AH subjects and AH mice compared to controls. In vitro, alcohol exposure of bone marrow progenitors significantly increased both G-MDSC and M-MDSC populations. Despite expansion of MDSCs, alcohol reduced IL10+ MDSCs and decreased IL6 and IL1β production, suggesting impaired functional activation. Alcohol-treated MDSCs demonstrated enhanced suppression of T-cell proliferation and reduced IFN-γ production compared to alcohol-naive MDSCs. Mechanistically, alcohol increased expression of phosphorylated IRF3 (pIRF3) predominantly in M-MDSCs. In IRF3 KO mice, alcohol-induced expansion of G-MDSCs was attenuated, accompanied by reduced Arg1 expression and diminished IL10+ M-MDSCs. Consistently, alcohol-treated IRF3-deficient MDSCs failed to suppress T-cell proliferation, indicating restoration of T-cell responses in the absence of IRF3 signaling. Furthermore, IRF3 deficiency significantly reduced alcohol-induced IL6 and IL1β production. These findings identify IRF3 as a critical regulator of alcohol-mediated MDSC expansion and suppressive function. **Conclusion:** Alcohol promotes MDSC expansion while impairing their inflammatory and immunoregulatory functions through IRF3-dependent mechanisms. IRF3 signaling is required for alcohol-induced MDSC-mediated suppression of T-cell proliferation and inflammatory cytokine production. These findings identify IRF3 as a key regulator of myeloid immune dysfunction in ALD and suggest that targeting IRF3-dependent pathways may restore immune function in alcohol-associated liver disease.

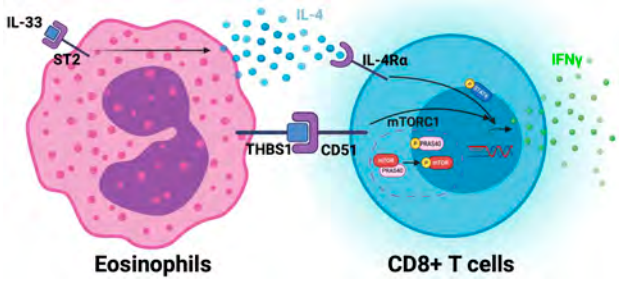
★ 2275 | EOSINOPHILS PROMOTE CYTOTOXIC CD8+ T CELL RESPONSES IN AN IL-4-DEPENDENT MANNER



Yankai Wen[1], [1]University of Texas - Houston

Background: Hepatocellular carcinoma (HCC) is an aggressive malignancy with rising global incidence and mortality. Emerging evidence supports an anti-tumorigenic role of eosinophils during HCC progression. While eosinophils have increasingly been recognized as critical modulators of anti-tumor immunity, the molecular mechanisms through which eosinophils regulate CD8+ T cell activation remain elusive. **Methods:** In this study, we adopted a coculture system of bone marrow-derived eosinophils and splenocytes or purified splenic CD8+ T cells under various stimulatory conditions. CD8+ T cell activation was determined by measuring intracellular interferon (IFN)g and tumor necrosis factor (TNF)a levels via flow cytometry.

Genetic knockout models, neutralizing antibodies, pharmacological inhibitors, trans-well assays, and reverse-phase protein assay were employed to dissect the mechanism. **Results:** We found that interleukin (IL)-33-activated eosinophils significantly enhanced CD8+ T cell activation, an effect dependent on eosinophil-derived IL-4 rather than IL-13. The data further revealed a cell-cell-contact-dependent mechanism involving the thrombospondin (THBS)1/CD51/mTORC1 signaling axis. This study demonstrates a two-pronged mechanism by which eosinophils enhance CD8+ T cell activation. On one hand, eosinophils secrete IL-4, which directly activates CD8+ T cells through STAT6 signaling. On the other hand, through cell-cell contact and engagement of the THBS1/CD51/mTORC1 signaling axis, eosinophils further amplify IL-4-induced CD8+ T cell activation. **Conclusion:** Collectively, these findings provide novel mechanistic insights into eosinophil-based therapeutic strategies for augmenting anti-tumor CD8+ T cell responses in HCC.

2277 | DIET-INDUCED ALTERNATIVE MRNA SPLICING AS A KEY INITIATOR OF LIVER INFLAMMATION

Aizhan Surumbayeva[1] Sajjan Rajpoot[2] Michael Levin[3] Riley Williams[2] Yunyun Zhou[2] Siddharth Balachandran[2] Igor Astsaturov[2], [1]Fox Chase Cancer Center; Lewis Katz School of Medicine, Temple University, [2]Fox Chase Cancer Center, [3]College of Engineering, Temple University; Fox Chase Cancer Center

Background: The modern hypercaloric diet, rich in refined carbohydrates, is a major contributor to metabolic dysfunction-associated steatotic liver disease (MASLD). While it is well-known that a hypercaloric diet causes obesity and MASLD, about 30% of patients with MASLD develop metabolic syndrome-associated steatohepatitis (MASH) over time, which features advanced inflammation, steatosis, and hepatocyte damage. However, it remains unclear *what initially triggers this inflammation* and whether insulin could play a role in provoking an inflammatory response in the liver. **Methods:** Mice were fed a high-carbohydrate diet (HCD) or western diet (WD) and compared to fasted animals or mice on regular chow diet. Bulk RNA sequencing and alternative splicing analysis were performed on isolated hepatocytes. Immunofluorescence staining with antibodies against double-stranded RNA (dsRNA) was used to detect endogenous retroviral element (ERE)-derived dsRNA species in liver sections. Genetic knockouts (*Mavs*$^{-/-}$, *Ifnar1*$^{-/-}$) and pharmacological inhibitors of AKT and serine-arginine rich protein kinase 1 (SRPK1) were employed to interrogate pathway dependencies. Findings were validated in transcriptomic datasets from MASLD patients. **Results:** Feeding mice a HCD induces a type I interferon (IFN-I) response in hepatocytes and activates inflammatory signaling pathways in the liver. This IFN-I response is linked to infiltration of the liver with activated T cells and is absent in *Mavs* or *Ifnar1* knockout mice. Surprisingly, we discovered significantly increased alternative splicing events in the total transcriptomes of hepatocytes from mice on HCD. Notably, retained introns were most enriched in transcripts from HCD-fed hepatocytes and were predominantly found in genes regulated by insulin. Since retained introns contain EREs that tend to form double-stranded RNA (dsRNA), we demonstrated the presence of dsRNA through immunofluorescent staining of HCD-conditioned liver sections. Notably, mice fed a WD similarly exhibited aberrant splicing perturbations and dsRNA accumulation in hepatocytes, corroborating that these effects are a shared feature of obesogenic, hyperinsulinemic dietary conditions. Insulin may regulate alternative splicing in hepatocytes by inducing excessive phosphorylation of SR-family splicing factors. Blocking AKT or SRPK1 with selective inhibitors *in vivo* completely reversed the effects of HCD. Importantly, transcriptome analysis of patients with MASLD, compared to normal livers showed similarly increased alternative splicing and a dramatic rise in human ERE expression. We ***hypothesize*** that dsRNAs produced by chronic and excessive insulin signaling in hepatocytes are a key early trigger of liver inflammation. **Conclusion:** Our findings reveal a previously unrecognized mechanism and new therapeutic opportunities for preventing or treating MASLD and other inflammatory conditions related to obesity.

2278 | CONTRIBUTION OF CYTOTOXIC NATURAL KILLER CELLS INFLAMMATION AND LIVER INJURY IN ALD

Shelene Mitchell[1] Emmanuel Boafo[1] Colin Varnet[1] Adam Kim[1], [1]UConn Health

Background: Alcohol-associated Hepatitis (AH) is a severe inflammatory disease with high short-term mortality. In AH, dysfunctional immune cells lead to uncontrolled inflammation and exacerbate hepatocellular damage. In the liver, cytotoxic lymphocytes like NK cells and CD8 T-cells detect and kill damaged cells, which should be protective, but they also produce a pro-inflammatory cytokines like interferon gamma (IFNG) that can contribute to liver inflammation. Previous work from our lab found that circulating NK-cells in AH are dysfunctional and lack Perforin (Prf1), a key factor in NK cell cytotoxic function. Less is known about the contribution of liver resident NK cells in alcohol-associated liver disease (ALD) and AH. **Methods:** Perforin knockout (Prf1-KO) mice were used to assess loss of cytotoxic function in NK cells in multiple chronic alcohol feeding models of ALD. Livers were collected for histology and multi-panel flow cytometry for detection of diverse immune populations. Additionally, we used a combination of publicly available single-cell RNA-seq and spatial RNA-seq datasets to assess the gene expression changes and tissue distribution of NK cells and CD8 T-cells in human ALD. **Results:** Prf1-KO mice have NK cells and CD8 T-cells with no ability to kill targeted cells, making these mice very sensitive to viral infections. Prf1-KO mice had similar levels of liver damage due to alcohol, as measured by ALT and AST, to wildtype controls in chronic 6% diet models and the NIAAA-model. qPCR and flow cytometry did not reveal increased inflammation in Prf1-KO mice. Except, in the NIAAA-model, Prf1-KO mice had significantly higher monocyte infiltration. Human RNA-seq studies reveal that liver resident NK cells are not reduced in ALD, but gene expression suggests decreased NK cell maturity. **Conclusion:** In recent years, NK cells have become a neglected cell type of study in the liver, despite being the second most common immune cell. Our studies reveal that NK-cell cytotoxic function does not contribute to or protect from alcohol in mouse models of ALD. These data suggest that NK cells can contribute to ALD by worsening inflammation, and cytotoxic functions. Future studies will focus on how NK-cells communicate to other important cells in ALD and AH, like monocytes, hepatocytes, and stellate cells.

2279 | CELL INTRINSIC PROGRAMMED DEATH-LIGAND 1 (PD-L1) SIGNALING LIMITS LOW AFFINITY T CELL RESPONSES AND LIVER PATHOLOGY DURING ACUTE INFECTION WITH *LISTERIA MONOCYTOGENES*

Lucy Fry[1] Jessica Olivas-Corral[1] Jaime Shirley[1] David Orlicky[1] Beth Tamburini[1], [1]University of Colorado Anschutz medical campus

Background: Programmed Cell Death Protein-1 (PD-1)/Programmed Death-Ligand 1 (PD-L1) interactions act as an immune checkpoint. Upon PD-1 ligation, T cells undergo downregulation to prevent excessive tissue damage. During chronic infections such as hepatitis B or C, aberrant PD-1/PD-L1 signaling leads to T cell exhaustion. Interestingly, the intracellular PD-L1 domain has also been demonstrated to have immune regulatory functions, particularly in myeloid cells. *Listeria monocytogenes* (*Lm*) is a food-borne bacterial pathogen that rapidly localizes to the liver upon entry into the blood. Systemic administration of *Lm* elicits a well-characterized immune response that largely depends on myeloid cells for clearance, making this an ideal model to study tissue-specific responses that may be regulated by the PD-L1 intracellular domain. **Methods:** To determine how the PD-L1 intracellular domain regulates liver specific immune responses during infection, we utilized a novel mouse model containing mutations in the cytoplasmic tail of PD-L1 (*Pdl1*^{CyMt}), where signaling via the extracellular domain of PD-L1 remains intact. WT and *Pdl1*^{CyMt} mice were infected with *Lm, Lm* expressing Ovalbumin *(Lm-Ova),* or *Lm* expressing H2-Kb peptides of ovalbumin with altered amino acids (altered peptide ligands-*Lm-APL*) that bind MHC I equally but vary in their ability to stimulate ovalbumin specific TCR transgenic, OT-I, cells. We euthanized mice at numerous time-points following *Lm* infection and evaluated bacterial counts, serum cytokine levels, histologic analysis, tissue staining, and flow cytometry on liver tissue. **Results:** *Pdl1*^{CyMt} mice exhibit decreased inflammatory foci at day 7 post infection (p.i.) compared to control mice and increased endogenous CD8^{+} T cell cytokine production. Following OT-I CD8^{+} cell transfer and *Lm-APL* infection, we found that in *Pdl1*^{CyMt} mice, OT-I CD8^{+} T cells expanded more independent of the alterations in the peptide affinity for the T cell receptor, suggesting non-specific T cell activation, while also displaying a reduction in the inflammatory foci observed within the liver. These findings could be a result of increased myeloid cell populations in the *Pdl1*^{CyMt} mice at both early and late timepoints after infection. Intriguingly, *Pdl1*^{CyMt} mice exhibit enhanced bacteremia at day 7 when control mice have cleared the infection.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Conclusion: These data suggest that the PD-L1 intracellular domain decreases the threshold of activation for lower affinity T cell responses and limits inflammatory foci associated with *Lm* infection and clearance. Additionally, these data suggest the intracellular domain of PD-L1 modulates myeloid cell dynamics in the liver, which may limit non-specific bystander T cell activation. Thus, in the *Pdl1*^{CyMt} mice aberrant myeloid cell activity could result in non-specific T cell responses that delay *Lm* clearance from the liver, defining a role for the intracellular domain of PD-L1 during infection.

2280 | ROLE OF PERMISSIVE CHROMATIN MODIFICATION IN THE DEVELOPMENTAL REGULATION OF THE HEPATOCYTE-SPECIFIC INNATE IMMUNE RESPONSE

Natarajan Balasubramaniyan[1] Nazanin Kazemi-Buterffield[2] Ken Jones[3] Lijun Zheng[2] Mack Solar[2] Megan Fisher[4] Sarah Taylor[5] Clyde Wright[6],
[1]University of Colorado Denver Anschutz Medical Campus, [2]Section of Neonatology, Department of Pediatrics ,University of Colorado School of Medicine, Aurora, [3]Bioinformatic Solutions LLC, Sheridan, WY, [4]Section of Neonatology, Department of Pediatrics, University of Colorado School of Medicine, Aurora,, [5]Section of Gastroenterology, Hepatology,Pediatrics, University of Colorado school of Medicine,Aurora, [6]Section of Neonatology, Department of Pediatrics, University of Colorado School of Medicine, Aurora

Background: Gene expression in mouse liver tissue undergoes a significant transition between postnatal day 3 (P3) and adulthood, shifting from a proliferative, neonatal state to a mature, metabolic, and detoxifying state. While P3 livers are characterized by high rates of cell expansion and metabolic adaptation, adult livers are defined by established hepatocyte zonation and mature drug metabolism. Hepatocytes, the major parenchymal cells in the liver, are responsible for a variety of cellular functions including carbohydrate, lipid and protein metabolism, detoxification and immune cell activation to maintain liver homeostasis. Recent studies show hepatocytes play a pivotal role in liver inflammation, however, the age-specific epigenetic modifications that orchestrate the interplay between the chromatin state and inflammatory gene expression are not well known. The objective of this study is to determine the nuclear association between H3k27ac, CBP/p300, and NFκB-p65 and acetylation changes of p65 binding site in the promoters of specific genes in p3 and adult hepatocytes. Further we assessed ATAC seq and bulk RNA seq in p3 and adult isolated hepatocytes to find out chromatin accessibility and gene expression. **Methods:** We isolated p3 and adult mice hepatocytes and used an assay for transposase-accessible chromatin using sequencing (ATAC-seq) combined with whole liver quantitative chromatin immunoprecipitation (ChIP) and bulk ribonucleic acid sequencing (RNA-seq) to provide a detailed description of gene expression. Promoter-associated histone modifications were investigated via ChIP qPCR at three transcriptionally relevant sites known for NFκB occupancy on the Tnf, cxcl2, ccl3, cxcl10, Il1rn, Icam1 and A20 promoters. Purified murine hepatocytes were treated with JQ1 (2.5μM x24h) and exposed to IL1b+IL6 (20 ng/mL each X 1h). mRNA was isolated followed by RT-qPCR for NFkB primary response genes (Cxcl2, Cxcl10, and Tnf) and several other genes were assessed. Each experiment was performed in triplicate. Results were statistically analyzed using t-test and significance defined as $p < 0.05$. **Results:** Quantitative ChIP using p65, CBP/p300 and h3k27ac antibodies give significantly more binding of NFkBp65 binding site on Tnf, cxcl2, ccl3, cxcl10, Il1rn, Icam1 and A20 promoters in adult liver when compared to p3. IgG was used as isotypic antibody control; normalized with 5% input (data represented as mean ± SEM,for three replicates). Chromatin accessibility was strongly linked to gene expression. To further understand the relations among variations in gene expression and chromatin accessibility, we performed integrated analysis of the ATAC-seq and RNA-seq from the isolated hepatocytes. Several genes transcriptional alterations linked to differentially accessible chromatin regions. Differentially expressed genes were related to immune responses to determine the relationship between chromatin accessibility and gene expression levels, we conducted RNA-seq using the p3 and adult hepatocytes samples. **Conclusion:** A growing amount of evidence has demonstrated stressed hepatocytes exert a pivotal role in the development of inflammation and fibrosis via cell-cell interactions during liver injury. In this study, we summarize the role of hepatocytes during development of their links to liver inflammation. Furthermore, we introduce a wide variety of proinflammatory signals carried by hepatocyte that can deliver the message to neighbor target cells and in the circulation to modulate immune response. Understanding of the molecular mechanisms involved in the regulation of hepatocytes damage, as well as role of hepatocyte in immune regulation may provide novel insights of dysregulated

2281 | P2Y2 PURINERGIC SIGNALING IS ESSENTIAL FOR THE EFFICIENT INDUCTION OF TLR4-MEDIATED MACROPHAGE ACTIVATION

Eric Dybbro[1] Aalekhya Biswas[2] Subapradha Narayanan[2] Moreshwar Desai[2] Sundararajah Thevananther[2], [1]Phoenix Children's Hospital, [2]Baylor College of Medicine

Background: P2Y2 purinergic receptor gene deletion protects mice from bacterial endotoxin and sepsis-associated liver injury and mortality. TLR4 activation of macrophages leads to nucleotide release, contributing to elevated nucleotide levels in the extracellular milieu. Extracelluar nucleotide-mediated activation of P2Y2 purinergic receptor signaling, via the activation of ERK-MAPK and NF-kB signaling and the induction of endoplasmic (ER) stress, has the potential to influence macrophage function. However, the functional significance of TLR4-mediated activation of P2Y2 signaling and its contribution to macrophage activation is currently unknown. Experiments were designed to test the **hypothesis** that extracellular nucleotide-mediated activation of P2Y2 purinergic signaling is necessary for the efficient induction of TLR4-mediated macrophage activation. **Methods:** BMDM (WT vs P2Y2-/- mice) were treated with LPS (100 ng/ml or 1.0 µg/ml, TLR4 agonist) for 0.5, 8, and 24 hr. BMDM (WT) were treated with AR-C118925 (100 µM, P2Y2 antagonist, 30 min) prior to LPS treatment. Total protein extracts were analyzed by Western blotting for the induction of phosphorylated and total p42/44-ERK (MAPK signaling), p65-NF-kB (NF-kB signaling), IRE1alpha, eIF2alpha, and GRP78 (ER Stress), and iNOS (pro-inflammatory polarization). The rank order of nucleotide agonist preference for the activation of ERK (5 min) and ER stress (24 hr) in BMDM (WT) was evaluated. Fold change was calculated based on the densitometric analysis of band intensity, and statistical significance was determined by unpaired Student's t-test ($p < 0.05$). **Results:** TLR4-mediated induction of p42/44-ERK and NF-kB signaling, ER stress, and pro-inflammatory iNOS protein expression were significantly attenuated in KO BMDM, as compared to WT controls [Fold change, FC: WT v P2Y2-/-; phos-ERK, 14.1 v 6.0; phos-NF-kB, 45.8 v 17.3; phos-IRE-1alpha, 19.9 v 8.9; phos-eIF2alpha, 12.6 v 1.3; Grp78, 4.9 v 0.7; iNOS: 11.2 v 4.4. $p < 0.05$]. P2Y2 antagonist treatment attenuated LPS-induced activation of ERK and NF-kB signaling [LPS v ARC118925+LPS, phos-ERK: 34.8 v 9.7; phos-NF-kB, 50.0 v 2.4] in the WT-BMDM. UTP (P2Y2 agonist) treatment showed the higher rank order potency for ERK activation in the WT BMDM [Veh v UTP, UDP, ATP, ATPgS, ADP: 3.3, 2.0, 1.4, 1.4, 1.1]. UTP-mediated induction of ERK (FC: phos-ERK: 2.8 v 1.6) and ER stress (phospho-IRE1alpha: 8.0 v 1.4; Grp78, 15.5 v 1.5) was attenuated in P2Y2-/- BMDM. **Conclusion:** Our findings, based on a combination of genetic and pharmacologic approaches, suggest that P2Y2 purinergic signaling is an essential co-determinant of TLR4-mediated macrophage activation. Considering the pathophysiologic role of macrophage-mediated hyperinflammation in the induction of liver injury in patients and animal models of sepsis, our findings highlight the potential for the development of novel therapeutics targeting P2Y2 purinergic receptors.

2282 | RSPO2 DRIVES LIVER REGENERATION BUT FUELS FIBROTIC REMODELING

Bhupesh Singla[1] Ravi Varma Aithabathula[1] Frank Park[1] Srija Rairao[1] Bal Krishan Sharma[2], [1]The University of Tennessee Health Science Center, Memphis, TN, USA, [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA

Background: The liver plays a central role in macronutrient metabolism and detoxification, and undergoes regeneration. Its regenerative ability is essential for functional recovery following liver resection and injury. However, the mechanisms regulating hepatic regeneration, injury, and fibrosis remain incompletely understood. Previously, we identified R-spondin 2 (RSPO2), a matricellular protein, as a key suppressor of diet-induced hepatic steatosis. The present study was designed to investigate the role of RSPO2 in hepatic regeneration, injury, and fibrosis. **Methods:** Multiple complementary mouse models, including 2/3 partial hepatectomy (PHx), acetaminophen (APAP)-induced liver injury, and carbon tetrachloride (CCl_4)-induced hepatic fibrosis, were utilized following AAV-mediated *Rspo2* overexpression in wild-type mice. Histochemical

and molecular analyses were performed to determine metabolic zonation, injury, regeneration, and fibrosis in liver tissues. **Results:** *Rspo2*-AAV-injected mice exhibited a higher liver weight/body weight ratio at 3 and 6 days post-PHx compared with control AAV-administered mice, suggesting accelerated recovery of liver mass with *Rspo2* overexpression. Western blotting data demonstrated increased expression of proliferation markers, including PCNA and cyclin D1, at both time points in *Rspo2*-overexpressing mice. These changes were accompanied by reduced mRNA levels of pro-inflammatory molecules *Il1b*, *Il6*, and *Tnfa*. Additional immunostaining analyses revealed significantly elevated cyclin D1 and Ki67 expression in the periportal and mid zones, along with increased glutamine synthase staining in the pericentral zone, and a uniform distribution of Cyp1a2 throughout the liver lobule in *Rspo2*-AAV-injected mice. *Rspo2* overexpression also reduced APAP-induced pericentral hepatocyte apoptosis, as shown by decreased cleaved caspase-3 staining. Consistently, Western blotting experiments showed decreased expression of apoptosis signature proteins PARP and caspase 9 in *Rspo2*-overexpressing livers. Interestingly, *Rspo2* overexpression exacerbated CCl_4-induced hepatic fibrosis, as indicated by increased Sirius red- and Col1a1-positive areas. These results were further supported by elevated protein expression of Col1a1, TGFβ, vimentin, and αSMA in immunoblotting. Furthermore, *Rspo2*-AAV-injected mice treated with CCl_4 had augmented hepatic accumulation of F4/80-positive macrophages. **Conclusion:** These results reveal that RSPO2 exerts a dual role in liver pathophysiology by promoting hepatic regeneration and hepatoprotection while enhancing fibrotic remodeling. These findings identify RSPO2 as a potential therapeutic target for regulating liver regeneration, repair, and fibrosis.

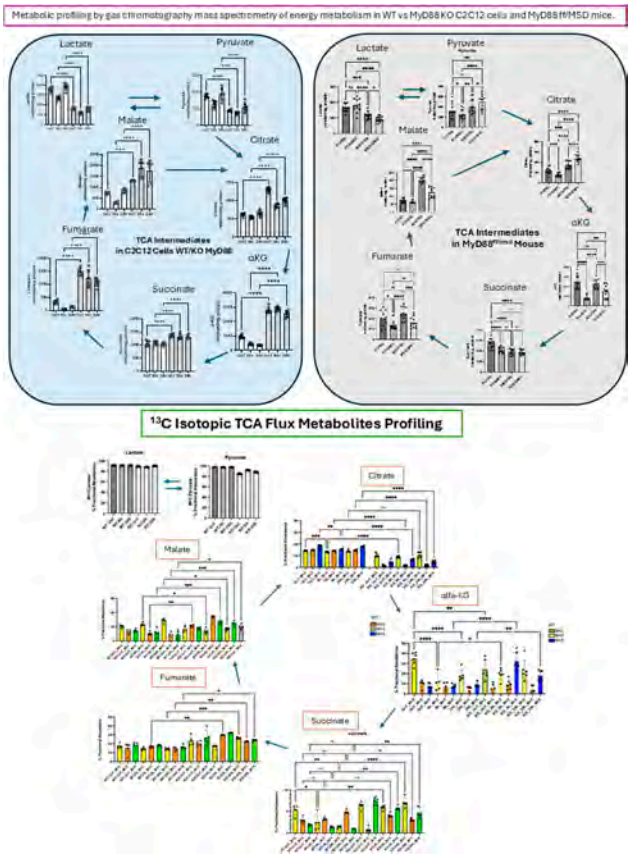
2283 | MYD88-DEPENDENT MITOCHONDRIAL OXIDATIVE DYSFUNCTION AND MALADAPTIVE METABOLIC RESPONSES DURING HYPERAMMONEMIA



Seshu Vardhan Pothabathula[1] Saurabh Mishra[1] Annette Bellar[1] Pugazhendhi Kannan[1] Yana Sandlers[2] Takhar Kusumov[3] Nicole Welch[4] Srinivasan Dasarathy[4], [1]Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [2]Department of Chemistry, Cleveland State University, OH., [3]Pharmaceutical Sciences, Northeast Ohio Medical University, OH, [4]Cleveland Clinic

Background: Myeloid differentiation primary response 88 (MyD88) is a canonical adaptor protein that mediates Toll-like receptor and interleukin-1 receptor signaling through NF-κB activation. During hyperammonemic stress response (HASR), MyD88 interacts with the ammonia transceptor RhBG with TLR-independent inflammatory signaling in skeletal muscle with consequent sarcopenia. We have identified decreased cellular ATP content due to mitochondrial oxidative dysfunction by metabolic perturbations, including cataplerosis of aKG during HASR. We hypothesized reversal of mitochondrial oxidative dysfunction, dysregulated protein homeostasis, and sarcopenia via non-canonical activation of MyD88. **Methods:** Studies were performed in differentiated murine C2C12 myotubes with wild-type or MyD88-knockout backgrounds and in C57BL/6 mice with muscle-specific MyD88 deletion ($MyD88^{msd}$) or floxed controls ($MyD88^{fl/fl}$) exposed to HAS. MyD88-interacting proteins were identified by LC/MS untargeted proteomics. Tricarboxylic acid (TCA) cycle metabolic perturbations were assessed using targeted GC-MS profiling and ^{13} C-isotope tracing to quantify isotopomer enrichment pool sizes of TCA-cycle intermediates over 6- and 24-hour intervals in $13C_6$ glucose enrichment for differentiated C2C12 cells. **Results:** MYD88-dependent mitochondrial oxidative dysfunction and adaptive metabolic responses were observed by proteomics and metabolomics profiling. LC/MS data showed MyD88 interacting with mitochondrial import proteins (TOM/SAM) and matrix-associated ATP synthase subunit ATP5PD. Total concentrations of TCA cycle intermediates in HAS-exposed mice (N = 12) revealed a highly significant increase in pyruvate, citrate, and α-ketoglutarate, within the $MyD88^{msd}$ group compared to $MyD88^{fl/fl}$ controls ($p < 0.0001$). In vitro differentiated C2C12 MyD88 KO showed there is a decrease in lactate and pyruvate concentrations in both untreated and AmAc-treated wild-type cells, whereas citrate and α-ketoglutarate showed a significant increase, recapitulating in vivo data. In vitro 13C6 glucose enrichment in WT/MyD88 KO groups showed equal fractional abundance of M+3 lactate and pyruvate in AmAc-treated cells. In MyD88 KO, the isotopologue distribution of α-ketoglutarate (M +2 and M+5) flux increased compared to WT untreated and AmAc treated cells ($p < 0.0001$). **Conclusion:** MyD88 functions as a non-canonical regulator of mitochondrial bioenergetics during hyperammonemic stress. Beyond its inflammatory adaptor role, MyD88 associates with mitochondrial protein-import machinery and contributes to impaired oxidative metabolism, disrupted TCA-cycle flux, and depletion of intermediary metabolites linked to sarcopenia. Targeting the MyD88-TOM complex interaction axis may represent a novel

2284 | RIPK1 INHIBITION ATTENUATES NET RELEASE AND HAEMORRHAGIC LIVER INJURY IN D-GALACTOSAMINE/LPS MICE

Jessica Dieudonne[1] Alexandra Caron[1] Audrey Levy[1] Maryse Malysiak[1] Stephanie Ferreira[1] Jean-Marie Brusq[1] Zouher Majd[1] Bart Staels[2] Sakina Sayah Jeanne[1] Valerie Daix[1] Alessia Galgano[1], [1]Genfit, [2]University Lille 2

Background: Acute liver failure (ALF) is exhibiting severe immune dysregulation, and growing evidence implicating neutrophils and neutrophil extracellular traps (NETs) in liver injury. However, the upstream regulated cell-death pathways contributing to NET formation in liver failure remain incompletely defined. Because RIPK1 is a key regulator of immunogenic cell death in LPS-driven liver injury, making it a plausible candidate for linking inflammatory stress to NETosis. We investigated whether RIPK1 activity functionally contributes to NET release and liver pathology in the D-galactosamine/lipopolysaccharide (D-GalN/LPS) mouse model. **Methods:** ALF was induced in mice by D-GalN/LPS administration. RIPK1 was inhibited using Necrostatin-1S (Nec1S; 1-20 mg/kg). Neutrophil subsets distribution was analyzed by flow cytometry in liver, bone marrow, and spleen. Circulating markers of NET were assessed using immunoassays for extracellular histone H3.1 and citrullinated histone H3 (H3R8cit) (control n = 3; D-GalN/LPS n = 6). Liver injury biomarkers, histopathological features, systemic cytokines, and survival were evaluated. **Results:** D-GalN/LPS challenge induced marked neutrophil dysregulation and a robust (~5–10-fold) increase in circulating NET markers compared to controls. Nec1S administration did not significantly alter neutrophil subset distribution across examined tissues. In contrast, Nec1S treatment at 10 and 20 mg/kg led to an almost complete (>90%) suppression of circulating extracellular histone H3.1 and citrullinated histone H3 (H3R8cit). These findings support a functional link between RIPK1 activity and NET release in this model. NET marker suppression was associated with a dose-dependent reduction in liver injury biomarkers (ASAT, ALAT, TBA, TBIL) and marked attenuation of intrahepatic bleeding. Nec1S treatment was associated with a partial (~50%) survival benefit, with low effects on systemic cytokine release (IL-6, IL-1β, MCP-1). Despite effective NET release inhibition, liver injury and mortality were not fully prevented. **Conclusion:** RIPK1 inhibition with Nec-1S abrogates circulating NET-associated markers and attenuates haemorrhagic liver injury in the D-GalN/LPS model of ALF, resulting in improved liver function parameters and partial survival benefit. The incomplete survival rescue despite efficient suppression of NET-associated markers indicates the contribution of additional NET-independent pathogenic mechanisms. These results identify necroptosis and NETosis as a functionally relevant component of liver injury in acute liver Failure conditions settings and support further investigation of complementary injury pathways.

2285 | HYPERAMMONEMIA IMPAIRS MITOCHONDRIAL QUALITY CONTROL THROUGH MYD88-DEPENDENT MECHANISMS IN SKELETAL MUSCLE

Saurabh Mishra[1] Seshu Pothabathula[1] Pugazhendhi Kannan[1] Vandana Agrawal[1] jamsine Cunnighan[1] Annette Bellar[1] Nicole Welch[1] Srinivasan Dasarathy[1], [1]Cleveland Clinic

Background: Hyperammonemia is a consistent abnormality in cirrhosis and contributes to sarcopenia and contractile dysfunction in chronic liver disease. Skeletal muscle mitochondrial oxidative dysfunction with cataplerosis of tricarboxylic acid cycle intermediates are recognized consequences of hyperammonemia and contribute to fatigue, decreased aerobic fitness, and dysregulated protein homeostasis. Whether impaired mitochondrial quality control (mitochondrial dynamics, biogenesis, and mitophagy) contributes to oxidative dysfunction during hyperammonemia is not known. We recently identified that myeloid differentiation primary response protein 88 (MyD88), a key adaptor of innate immune signaling, inhibits mitochondrial oxidative function in skeletal muscle. **Methods:** Studies were done in differentiated murine C2C12 wild type and CRISPR/Cas9-mediated knockout (KO) of MYD88 myotubes either untreated (unt) or treated with 10 mM ammonium acetate (AmAc) for 24h . Male and female C57/Bl6J hyperammonemic and control mice without/with muscle-specific deletion of MyD88 (MYD88msd) were infused with 2.5 mmol/kg/d of AmAc or vehicle (phosphate buffered saline-PBS) for 4 weeks . Mitochondrial quality control measures included biogenesis, dynamics, and mitophagy were studied by expression of proteins associated with mitochondrial biogenesis and dynamics, and mitophagy analyzed by immunoblotting of PINK1 with proteinase K protection assay. **Results:** Hyperammonemia significantly impaired mitochondrial biogenesis, as reduced expression of nuclear respiratory factor-1 (NRF-1), NRF-2, and mitochondrial transcription factor A (TFAM) in skeletal muscle and differentiated myotubes. These effects were reversed with MyD88 deletion in myotubes and skeletal muscle from Myd88msd mice during HAS, indicating a critical role for MyD88 in altering mitochondrial homeostasis. HAS affects the mitochondrial dynamics as mitochondrial fusion markers mitofusin1,2, OPA-1 were inhibited during HAS, while mitochondrial fission proteins Fis1, Mitochondrial fission factor (MFF) were increased in skeletal muscle tissue and myotubes, supporting alteration of mitochondrial dynamics during hyperammonemia while MyD88 deletion reversed the effect of HAS in in vitro with $Myd88^{KO}$ in $Myd88^{msd}$ mice against HAS. Proteinase K protection assay confirmed the accumulation of PINK-1 on the outer membrane as the PINK-1 was digested in the mitochondrial fraction with ammonia. compared to untreated mitochondria where PINK1 internalizes to inner membrane. **Conclusion:** Defects in mitochondrial quality control mechanisms during hyperammonemia are mediated via activation of Myd88. Use of muscle targeted MYD88 is a novel therapeutic approach to sarcopenia of cirrhosis.

2286 | COVID-19 AS A NATURAL EXPERIMENT: IMMUNOSUPPRESSION PRESERVES LIVER FUNCTION WITHOUT INCREASING SYSTEMIC RISK IN AUTOIMMUNE HEPATITIS

Clarimar Diaz Lopez[1] Rami Basmaci[2] Henry Colorado[3], [1]ECU Health Medical Center/Brody School of Medicine, [2]ECU Health Medical Center, [3]East Carolina University

Background: The emergence of novel viruses, such as SARS-CoV-2, poses a challenge for patients with chronic autoimmune diseases who depend on lifelong immunosuppression (IS). For people with autoimmune hepatitis (AIH), the dilemma was whether to discontinue IS to reduce the risk of severe infection or continue it to avoid a potentially life-threatening flare or liver decompensation. To clarify this issue, we analyzed the largest population-based AIH cohort to understand how COVID-19 affected this immunosuppressed population and to guide the management of similar situations during future viral outbreaks. **Methods:** We analyzed 63,644 hospitalizations of patients with AIH, including 3,685 with COVID-19. Outcomes of interest included mortality, organ failure, respiratory compromise, thrombotic events, and liver-related

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

complications. Although individuals with immunosuppressive medications were not captured, AIH patients are typically maintained on chronic steroid or antimetabolite therapy. As a result, this cohort provides a practical way to examine COVID-19 outcomes in a population that is characteristically immunosuppressed at baseline. **Results:** COVID-19 caused substantial systemic injury in patients with AIH, but it did not worsen liver-related complications. COVID-positive AIH patients had much higher mortality (12.7% vs. 4.2%; aOR 3.84, $p < 0.001$) and were far more likely to develop serious systemic problems, including shock (aOR 1.65), sepsis (aOR 1.73), mechanical ventilation (aOR 3.30), noninvasive ventilation (aOR 3.46), pulmonary embolism (aOR 2.28), and acute kidney injury (aOR 1.20). In contrast, liver-specific complications such as acute liver failure (aOR 0.76, $p = 0.003$) and ascites (aOR 0.63, $p = 0.001$) were actually less common in COVID-positive patients. These findings suggest that ongoing IS did not trigger hepatic deterioration during infection, and that the severe outcomes seen in this group were more likely driven by the systemic effects of COVID-19 rather than by their immunosuppressive therapy. **Conclusion:** The AIH–COVID-19 experience offers important lessons for managing chronic autoimmune diseases during future viral outbreaks. In our cohort, patients with AIH did not experience higher rates of liver-specific complications during infection, suggesting that maintaining IS may help protect against organ-specific failure, such as AIH flare or acute liver injury. These findings support a practical approach in which clinicians continue baseline IS to preserve autoimmune organ function while focusing preventive and therapeutic efforts on managing the systemic effects of viral illness. This perspective may help guide future care strategies for immunosuppressed autoimmune populations during emerging viral threats.

2287 | BILIRUBIN TARGETS KEAP1 CYS513 TO DISSOCIATE KEAP1-IKKβ COMPLEX AND DRIVE HEPATIC INFLAMMATION VIA THE NF-κB PATHWAY

Yuping Yang[1] Caiyan Wang[1], [1]Guangzhou University of Chinese Medicine

Background: Aberrant accumulation of bilirubin is a critical pathological feature in liver diseases and is closely associated with hepatic inflammation and apoptosis. However, the molecular mechanisms by which bilirubin initiates inflammatory signaling remain poorly defined. This study aimed to elucidate the molecular mechanism linking bilirubin to inflammatory signaling. **Methods:** Mouse liver ductal organoids were used as the primary model to recapitulate hyperbilirubinemia-induced liver injury, complemented *in vivo* and *in vitro* systems (hyperbilirubinemia mouse models, primary hepatocytes, and human normal liver cells). Proximity labeling, NanoBiT, and Surface Plasmon Resonance analyses were performed to characterize the Keap1-IKKβ interaction. Structural biology, molecular dynamics simulations, and site-directed mutagenesis were applied to elucidate the underlying mechanism, followed by structure-based virtual screening targeting Keap1 Cys513 to identify potential modulators. **Results:** We demonstrate that bilirubin covalently modifies Kelch-like ECH-associated protein 1 (Keap1) at cysteine 513 (Cys513), disrupting the Keap1-IKKβ complex. This dissociation promotes IKKβ phosphorylation, induces nuclear translocation of p50/p65, and activates NF-κB-dependent inflammatory gene expression. Mechanistically, Cys513 modification induces conformational changes in Keap1, expands its binding pocket, and facilitates IKKβ release. Mutagenesis and structural analyses further confirm that Cys513 is a key regulatory node governing IKKβ activation and NF-κB signaling. Importantly, virtual screening identifies curcumin as a potent Cys513-targeting small molecule that restores the Keap1-IKKβ interaction, reverses bilirubin-induced conformational disruption, and significantly attenuates hyperbilirubinemia-induced liver injury. **Conclusion:** We identify a previously unrecognized bilirubin-Keap1 Cys513 axis that links hyperbilirubinemia to NF-κB-driven inflammation. Targeting Keap1 Cys513 represents a promising therapeutic strategy, and curcumin emerges as a potential lead compound. These findings establish Keap1 Cys513 as a druggable molecular switch with both mechanistic and translational significance in hyperbilirubinemia-associated liver diseases.

2288 | HISTOLOGIC PATTERNS AND OUTCOMES IN HEPATIC LARGE GRANULAR LYMPHOCYTE LEUKEMIA

Rachel Cruz Nieves[1] Madison Turner[1] Felicia Allard[1] Thomas Loughran[1] David Feith[1] Nicolas Intagliata[1] Jeffery Craig[1], [1]University of Virginia

Background: Large granular lymphocyte leukemia (LGLL) is a rare lymphoproliferative disorder of cytotoxic T cells or NK cells. Hepatic involvement is poorly characterized and may present as unexplained liver enzyme abnormalities in medically

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

complex patients, posing a challenge for hepatologists. Potential associations between the extent and patterns of hepatic LGLL infiltration with liver function and clinical outcomes remain unknown. We aimed to characterize the clinicopathologic features and histologic patterns of hepatic LGLL infiltration. **Methods:** Retrospective cohort study of patients in the LGL Leukemia Registry at the University of Virginia. A total of 16 patients with biopsy-proven hepatic LGLL infiltration were included. Clinical, laboratory, imaging, histologic features, treatments, and outcomes were collected and analyzed. **Results:** The degree of LGLL infiltration in each liver biopsy (total n = 25) from 11 T-LGLL and 5 NK-LGLL patients was quantified as the average number of LGLL cells across three high-power fields and designated as either minimal (< 50/HPF, n = 6), moderate (50-100/HPF, n = 6) or extensive (> 100/HPF, n = 13). For each biopsy, the pattern(s) of inflammation (lobular, n = 23; portal, n = 17; both, n = 16) and other pathological changes (e.g., fibrosis, necrosis, etc.) were documented (Figure 1). Clinically, the most common indication for liver biopsy was elevated liver enzymes (LFTs) (13/16). Hepatology was involved in the care of 11/16 total patients. Median age at first biopsy was 54 years. Associated underlying diagnoses commonly associated with LGLL included immunodeficiency (25%), autoimmune diseases (56%), solid organ transplants (18%), and malignancy (3%). Laboratory evaluation demonstrated a predominantly mild mixed hepatocellular–cholestatic pattern, with median AST 65.6 U/L, ALT 58.5 U/L, total bilirubin 0.8 mg/dL and alkaline phosphatase 209 U/L. Treatment strategies varied and included methotrexate (7/16), prednisone (6/16), cyclophosphamide (4/16), and rituximab (1/16). Overall, 7 deaths occurred out of the total 16 patients. **Conclusion:** This study represents the first and largest description of liver pathology in patients with LGLL. In our cohort, patients frequently had coexisting autoimmune disease and immunodeficiency and commonly presented with elevated liver enzymes prompting hepatology evaluation and liver biopsy. Histopathology most often demonstrated lobular intrasinusoidal infiltration regardless of biologic subtype, although portal-based inflammation was observed in a subset of cases. Despite LGLL generally being considered an indolent disorder, mortality in this cohort was unexpectedly high, suggesting that hepatic involvement may identify a higher-risk population. Recognition of characteristic histologic patterns may improve the diagnostic evaluation and multidisciplinary management of patients with suspected hepatic LGLL.

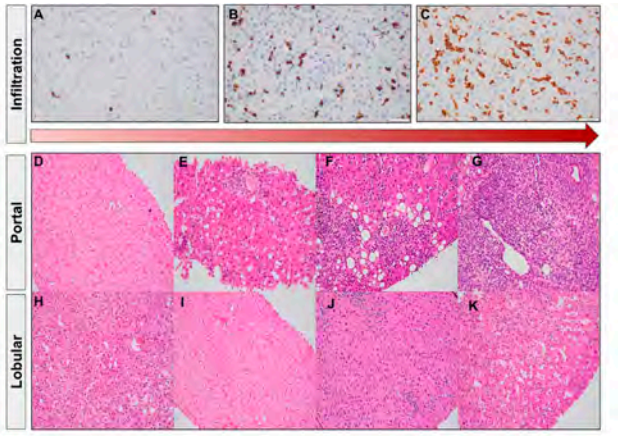

Figure 1: The degree of LGLL infiltration in each liver biopsy categorized as either minimal (A), moderate (B) or extensive (C) with the use of CD8 stains at 400X total magnification. Histologic sections of liver biopsies, assessed for both portal and lobular inflammation on a semiquantitative scale and categorized as no significant portal inflammation (D), mild portal inflammation (E), moderate portal inflammation (F) or severe portal inflammation (G). Similarly, lobular inflammation was categorized as no significant lobular inflammation (H), mild lobular inflammation (I), moderate lobular inflammation (J) or severe lobular inflammation (K). Photomicrographs D-K were taken of H&E slides at 200X.

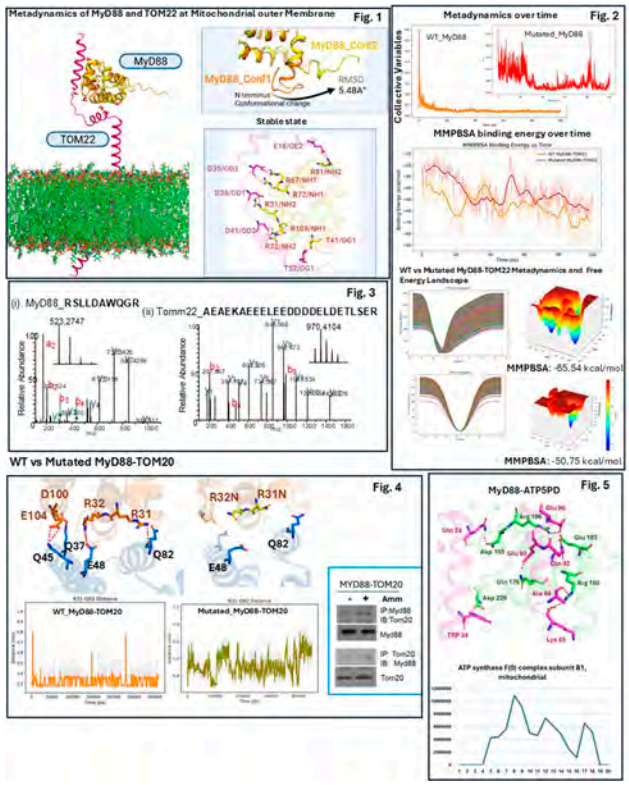
2289 | MYD88 IMPAIRS MITOCHONDRIAL TRANSLOCASE PROTEINS IN SKELETAL MUSCLE DURING HYPERAMMONEMIA



Srinivasan Dasarathy[1] Seshu Vardhan Pothabathula[2] Saurabh Mishra[2] Dhanachandra Khuraijam[3] Pugazhendhi Kannan[3] Annette Bellar[2] Nicole Welch[1] Jason A Mears[4] Sadashiva Karnik[2], [1]Cleveland Clinic, [2]Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [3], Lerner Research Institute, Cleveland Clinic, Cleveland, OH, [4]School of Medicine, Case Western Reserve University, OH

Background: Myeloid differentiation primary response 88 (MyD88) is a canonical adaptor protein that mediates Toll-like receptor and interleukin-1 receptor signaling through NF-κB activation. During hyperammonemic stress (HAS), MyD88 interacts with the ammonia transceptor RhBG with TLR-independent

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

inflammatory signaling in skeletal muscle with consequent sarcopenia (loss of muscle mass). We identified an unexpected role for MyD88 in mitochondrial oxidative dysfunction during HAS and sought to define the structural and metabolic basis of this effect. We hypothesized that hyperammonemia promotes MyD88 association with mitochondrial protein import and bioenergetic machinery, including TOM20, TOM22, and ATP5PD, thereby disrupting mitochondrial protein import functions. **Methods:** MyD88 interactions with mitochondrial membrane proteins were evaluated using AlphaFold3 modeling, HADDOCK molecular docking, Gromacs molecular dynamics, Molecular Mechanics Poisson-Boltzmann Surface Area (MMPBSA), and Free energy landscape. OpenMM-PLUMED meta-dynamics simulations were used for the MyD88 complex with TOM20, TOM22, and ATP5PD. During hyperammonemia, physical binding partners were evaluated by LC/MS proteomics and immunoprecipitation (IP) analysis. **Results:** Proteomics and targeted co-immunoprecipitation identified stress-induced MyD88 association with mitochondrial import proteins, including TOM20, TOM22, SAM50, TIM50, and the matrix-associated ATP synthase subunit ATP5PD. Metadynamics simulations reveal a significant conformational rearrangement of the MyD88 N-terminus when interacting with TOM22 by root mean square deviations (RMSD) of 5.48 Å for 200 ns. The interaction sites were TOM22 (D35, D38, D41, E18, T41, T52) and MyD88 (R31, R32, R67, R72, R81, R108). The Collective Variables (CV) were plotted for a 100 ns trajectory, which showed rapid initial convergence within the first 10–20 ns in WT/mutated proteins. The MMPBSA binding energy for WT is -65.54 kcal/mol, and for the mutated (-50.75 kcal/mol) complexes. MyD88 Fragment (RSLLDAWQGR) exhibited prominent sequence ions with a precursor mass-to-charge ratio m/z peak highlighted at 523.27. MyD88 R31 and R32 interact with D100, E104, Q37, E48, and Q82 on TOM20. IP anti-MyD88 reveals a significant increase in co-precipitated Tom20, ATP5PD, and proposed physical interaction with MyD88. MyD88-ATP5PD, followed by K85-R180, Q92-E183, E96-R196, Q24-D195, and A88-Q176 residues, were observed by molecular modelling and LC/MS. **Conclusion:** These findings identify MyD88 as a potential non-canonical regulator of mitochondrial function during (HASR). MyD88 interaction with TOM20, TOM22, and ATP5PD may cause mitochondrial oxidative stress and impair bioenergetics. Targeting this mitochondrial MyD88 interaction network may represent a novel strategy to preserve mitochondrial integrity under hyperammonemia conditions.

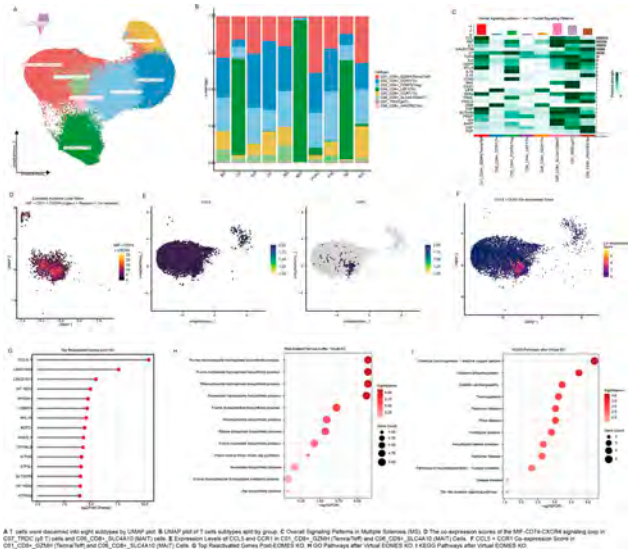
2290 | PAN-AUTOIMMUNE DISEASE SINGLE-CELL ANALYSIS IDENTIFIES MAIT CELLS MIGHT PLAY A ROLE IN INFLAMMATION-RELATED METABOLIC REGULATION



Jia-Wen Chen[1] Chao Cai[2] Mingqin Lu[2], [1]he First Affiliated Hospital of Wenzhou Medical University, [2]The First Affiliated Hospital of Wenzhou Medical University

Background: Autoimmune diseases (AID) exhibit diverse clinical phenotypes, yet the cellular communication logic and disease-specific regulatory mechanisms within their peripheral immune

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

microenvironments lack systematic cross-disease understanding. By integrating large-scale, pan-immunity single-cell data (>600,000 cells), we systematically characterize disease-specific cell subpopulations and intercellular interactions to elucidate the key immune drivers of pathological inflammation. **Methods:** This study integrated single-cell transcriptome (scRNA-seq) data from 67 peripheral blood mononuclear cell (PBMC) samples across nine autoimmune diseases obtained from the GEO database, encompassing over 600,000 cells. Through systematic comparative analysis of transcriptomic features across diseases, we observed a unique expansion of MAIT cells within the immune microenvironment of multiple sclerosis (MS). Consequently, this study focused on MAIT cells within the MS cohort, employing CellChat for cellular communication analysis, SCENIC for the construction of regulatory networks to identify key transcription factors, and scTenifoldKnk for virtual knockout experiments to deeply investigate their pathological regulatory mechanisms. **Results:** CellChat analysis revealed that MAIT cells exhibit the most pronounced signaling intensity within the MS immune microenvironment, particularly involving the MIF and CCL pathways. Co-expression patterns suggest these cells form an autocrine MIF-CD74/CXCR4 loop, which may support their survival and sustained activation. Furthermore, high CCL5 and low CCR1 expression in MAIT cells points toward a paracrine function. Supported by pathway enrichment, we hypothesize that MAIT cells likely utilize CCL5 to recruit CCR1+ peripheral myeloid cells, potentially initiating T cell-myeloid crosstalk via downstream TNF signaling and driving inflammatory cascade amplification. Additionally, pySCENIC identified EOMES as a core transcription factor. scTenifoldKnk virtual knockout simulations indicate that EOMES ablation may induce metabolic reprogramming—shifting toward active purine synthesis and oxidative phosphorylation (OXPHOS)—alongside reactive oxygen species (ROS) accumulation. Consequently, EOMES appears critical for maintaining MAIT cell homeostasis, potentially limiting their neurotoxic pathogenic risk in MS. **Conclusion:** This study elucidates a dual pathogenic network orchestrated by MAIT cells in autoimmune disease, exemplified in multiple sclerosis, characterized by a MIF-mediated autocrine survival loop and a CCL5-mediated paracrine myeloid recruitment axis. Furthermore, we identified EOMES as a crucial "metabolic and inflammatory brake" that prevents MAIT cells from acquiring a pathogenic effector phenotype. Targeting the EOMES regulatory axis represents a promising novel therapeutic strategy for autoimmune diseases.

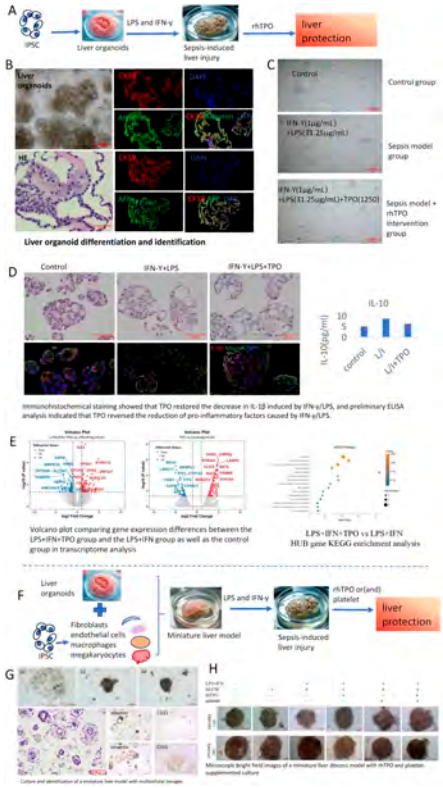
2291 | RHTPO PROTECTS LIVER CELL FUNCTION IN SEPSIS-INDUCED LIVER ORGANOIDS THROUGH BOTH DIRECT AND INDIRECT MECHANISMS



Lihua Shao[1] Minghao Fang[2], [1]HUST (Huazhong University of Science and Technology), [2]Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology

Background: Sepsis frequently induces acute liver dysfunction, exacerbating systemic inflammation and mortality. Existing models often fail to recapitulate sepsis pathology within the human liver microenvironment. Hepatic organoids reconstitute native hepatic composition, offering a humanized platform to study septic injury. Recombinant human thrombopoietin (rhTPO) exhibits tissue-protective properties, yet its role in septic liver injury remains undefined. We utilized induced pluripotent stem cell(iPSC)-derived hepatocyte-only and multicellular micro-hepatic organoids to investigate the hepatoprotective mechanisms of rhTPO. **Methods:** iPSCs were differentiated into hepatocyte-only organoids (Figure A) and validated via hematoxylin and eosin staining(HE staining)and immunohistochemistry (Figure B). A sepsis model was induced using LPS/IFN-γ, followed by rhTPO treatment and subsequent viability/liver function assays. Molecular mechanisms were identified through transcriptome sequencing, KEGG enrichment, and PPI analyses. Furthermore, a multicellular micro-liver model, co-cultured with fibroblasts, endothelial cells, macrophages, and megakaryocytes (Figure F), was validated using flow cytometry

and functional assays (Figure G). In this model, the therapeutic effects of rhTPO and platelets were evaluated via TEM, cytokine profiling, single-cell sequencing, and viability assays . **Results:** rhTPO did not affect normal hepatocyte viability but significantly reversed LPS/IFN-γ-induced viability loss in organoids (Figures C and D). Transcriptomic analysis revealed that rhTPO significantly upregulated *IGF2*, with hub genes enriched in the p53 signaling pathway (Figure E). In the multicellular micro-liver model (Figure F), both rhTPO and platelet monotherapies mitigated septic injury (Figure H). Notably, combined treatment with rhTPO and platelets synergistically enhanced cell viability compared to either agent alone. Cell Counting Kit-8(CCK-8)assays confirmed this synergistic rescue, suggesting that rhTPO indirectly exerts hepatoprotection via platelet-mediated mechanisms. **Conclusion:** This study successfully established a humanized liver organoid and a multicellular micro-liver model to simulate sepsis-induced liver injury. We demonstrated that rhTPO effectively reverses LPS/IFN-γ-induced liver injury. Transcriptomic analysis indicates that this protective effect is associated with the upregulation of IGF2 and the p53 signaling pathway. Furthermore, the combination of rhTPO and platelets synergistically improves hepatocyte viability in the micro-liver model. These findings provide novel in vitro experimental evidence for the mechanistic investigation of sepsis-induced liver injury, suggesting that targeting the IGF2/p53 axis or leveraging platelet-based therapeutic strategies may represent promising interventions for clinical management.

2292 | HEPATOBILIARY SAFETY OF TNF-ALPHA INHIBITOR THERAPY IN PRIMARY SCLEROSING CHOLANGITIS WITH INFLAMMATORY BOWEL DISEASE: A PROPENSITY-MATCHED COHORT STUDY USING THE TRINETX RESEARCH NETWORK

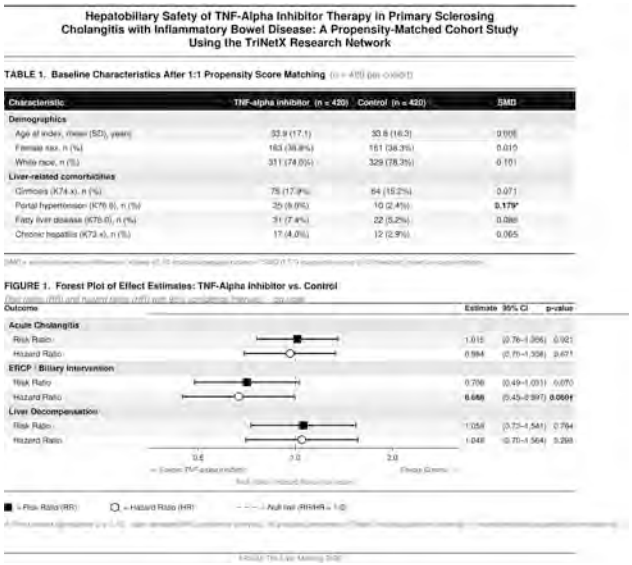
Osamah Salim[1] Mazen Elsheikh[2] Karim Adhem[2] Hamza Salim[3] Mohammad Mahdi[1] Sherry Fares[2] Youseph Karouni[2] Prasun Jalal[2], [1]Sam Houston State University College of Osteopathic Medicine, [2]Baylor College of Medicine, [3]University of Texas Medical Branch

Background: Primary sclerosing cholangitis (PSC) co-occurs with inflammatory bowel disease (IBD) in most western patients and carries substantial risk of biliary complications, liver failure, and cholangiocarcinoma. Tumor Necrosis Factor (TNF)-alpha inhibitors are widely used for IBD control in this population. A prior single-center study that explored the risks of TNF-alpha inhibitor therapy in patients with PSC (Kulkarni et al., 2021; n = 148) reported a 7-fold increase in acute cholangitis odds with TNF-alpha inhibitor therapy. To address this potential safety concern, we aimed to rigorously evaluate whether TNF-alpha inhibitor therapy is independently associated with acute cholangitis, ERCP utilization, or liver decompensation in a large, propensity-matched real-world cohort. **Methods:** We performed a retrospective propensity-matched cohort study using the TriNetX Research Network (112 U.S. healthcare organizations, data accessed April 27, 2026). Adults with PSC (ICD-10: K83.01) and IBD (K50/K51) were stratified into a TNF-alpha inhibitor cohort (infliximab, adalimumab, certolizumab pegol, or golimumab; n = 423 pre-match) and a control cohort (no TNF-alpha inhibitor exposure; n = 7,308 pre-match). After 1: 1 nearest-neighbor propensity score matching on age, sex, race, cirrhosis, portal hypertension, fatty liver disease, and chronic hepatitis, 420 matched pairs were retained (n = 840). Propensity score matching yielded robust baseline balance across the cohort covariates, with standardized mean differences tightly controlled post-match. **Results:** Rates of acute cholangitis were comparable with or without biologic exposure (20.8% vs. 20.5%; RR 1.02, 95% CI: 0.76–1.36; p = 0.921), and risk profiles remained similarly comparable regarding liver decompensation (HR 1.048, 95% CI: 0.702–1.564; p = 0.298). Notably, TNF-alpha

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

inhibitor patients had a significantly lower mean number of ERCP instances (0.19 vs. 0.45; p = 0.006), with a trend toward reduced ERCP hazard (HR 0.668, 95% CI: 0.447–0.997; p = 0.060). **Conclusion:** In this propensity-matched real-world cohort of 840 PSC-IBD patients, TNF-alpha inhibitor therapy was not associated with increased hepatobiliary risk. A significant reduction in ERCP burden among TNF-alpha inhibitor-treated patients was observed, suggesting that effective IBD mucosal control may confer a protective effect by attenuating biliary bacterial seeding and reducing subsequent biliary interventions. These data do not support routine avoidance of TNF-alpha inhibitor agents on hepatobiliary safety grounds in PSC-IBD.



Hepatobiliary Safety of TNF-Alpha Inhibitor Therapy in Primary Sclerosing Cholangitis with Inflammatory Bowel Disease: A Propensity-Matched Cohort Study Using the TriNetX Research Network

TABLE 1. Baseline Characteristics After 1:1 Propensity Score Matching

Characteristic	TNF-alpha inhibitor (n = 420)	Control (n = 420)	SMD
Demographics			
Age at index, mean (SD), years	33.9 (17.1)	33.8 (16.3)	0.006
Female sex, n (%)	163 (38.8%)	161 (38.3%)	0.010
White race, n (%)	311 (74.0%)	329 (78.3%)	0.101
Liver-related comorbidities			
Cirrhosis (K74.x), n (%)	75 (17.9%)	64 (15.2%)	0.071
Portal hypertension (K76.6), n (%)	35 (8.0%)	10 (2.4%)	0.179*
Fatty liver disease (K76.0), n (%)	31 (7.4%)	22 (5.2%)	0.086
Chronic hepatitis (K73.x), n (%)	17 (4.0%)	12 (2.9%)	0.055

FIGURE 1. Forest Plot of Effect Estimates: TNF-Alpha Inhibitor vs. Control

Outcome	Estimate	95% CI	p-value
Acute Cholangitis			
Risk Ratio	1.015	(0.78–1.306)	0.921
Hazard Ratio	0.984	(0.70–1.358)	0.671
ERCP / Biliary Intervention			
Risk Ratio	0.706	(0.49–1.031)	0.070
Hazard Ratio	0.668	(0.45–0.997)	0.060†
Liver Decompensation			
Risk Ratio	1.054	(0.73–1.541)	0.784

2293 | WHEN AIH DOESN'T RESPOND AS EXPECTED: A CASE SERIES OF AIH–PBC AND AIH–PSC OVERLAP SYNDROMES

Clarimar Diaz Lopez[1] Rami Basmaci[2], [1]ECU Health Medical Center/Brody School of Medicine, [2]ECU Health Medical Center

Background: Autoimmune hepatitis (AIH) overlap syndromes with primary biliary cholangitis (PBC) or primary sclerosing cholangitis (PSC) are difficult to recognize early and often behave more aggressively than classic AIH. They may begin with routine elevations in liver enzymes but gradually evolve into cholestasis, bile duct injury, portal hypertension, or recurrent flares. Early identification is essential, as timely recognition can meaningfully change management and help prevent progression. **Methods:** Retrospective review of four patients (ages 21–57) evaluated at a tertiary academic center between 2023 and 2025 with serologic, radiologic, and histologic evidence of AIH–PBC or AIH–PSC overlap. Clinical presentation, autoimmune markers, MRCP findings, biopsy features, treatment course, and biochemical outcomes were analyzed. **Results:** Two female patients (57 and 41) demonstrated AIH–PBC overlap with AMA positivity, cholestatic enzyme elevation, and biopsies showing interface hepatitis with bile duct injury or duct loss. Both had persistent cholestasis despite prednisone and azathioprine; one improved partially with ursodiol, while the other developed refractory disease with azathioprine failure, 6-MP intolerance, and worsening cholestasis (ALP up to 900 U/L), requiring escalation to mycophenolate, seladelpar, and budesonide, with tacrolimus under consideration. Two male patients (21 and 23) demonstrated AIH–PSC overlap, each with recurrent hepatocellular flares and failure to achieve biochemical remission on corticosteroids and azathioprine. One developed intrahepatic ductal beading on MRCP, confirming PSC, and his biopsy (similar to the others) showed interface hepatitis with bile duct–centered injury, ductular reaction, and peri-ductal fibrosis; his course was complicated by thiopurine-induced pancreatitis. The other had biopsy-proven PSC overlap despite a normal MRCP, and cytopenias related to advanced liver disease prevented thiopurine use. Across all four cases, overlap syndromes showed aggressive behavior, often presenting with cirrhosis complications, esophageal varices, and steroid dependence. Delayed diagnosis was common due to early nonspecific or evolving biochemical features. **Conclusion:** Overlap syndromes can exhibit unpredictable and aggressive behavior. Autoimmune liver diseases are often nonspecific and easy to miss, mainly when abnormal liver enzymes are not thoroughly investigated. As a result, many patients are diagnosed only after features of end-stage liver disease are already present. Recognizing evolving cholestasis or a treatment response that does not follow the expected course should prompt earlier biopsy or MRCP to detect overlap disease. Achieving biochemical remission early is essential, as delayed remission has been clearly associated with increased mortality in AIH.

2294 | ◆ BILE ACID UPTAKE ACTIVATES STAT SIGNALING AND IMPAIRS NATURAL KILLER CELLS IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOHEPATITIS

Johnny Amer[1] Ahmad Salhab[2] Rifaat Safadi[1], [1]Hadassah Hebrew University Hospital, [2]Hadassah University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) encompasses a spectrum of fatty liver diseases ranging from steatotic liver disease to metabolic dysfunction-associated steatohepatitis (MASH), and its prevalence is increasing worldwide due to the pandemic of obesity. Liver damage, such as cholestatic conditions in which bile secretion and flow are disturbed, is associated with impaired innate and adaptive immunity. NK cells play a crucial role in inhibiting liver fibrosis. However, how bile acids affect natural killer (NK) cells remains unknown. We aimed to assess the impact of bile acid concentration on NK cell functionality and identify the molecular and metabolic NK cell signaling pathways that influence liver fibrosis pathogenesis. To this end, we studied peripheral NK cells from patients with MASH, healthy donors, and a mouse model of MASH. **Methods: Results:** Sodium +/taurocholate cotransporting polypeptide (NTCP) expression was 2.5-fold higher in peripheral blood NK cells from MASH patients with advanced liver fibrosis than in those from early liver fibrosis patients and healthy donors. Greater taurocholic acid (TCA) uptake was observed in peripheral NK^{NTCP+} cells from the early and advanced liver fibrosis MASH patient groups than in NK^{NTCP-} cells from the same patients. It was associated with increased levels of exhaustion markers and decreased activity. Moreover, single-cell RNA sequencing and functional analyses demonstrated that $NTCP^{+}$ NK cells in advanced MASH adopt stress- and exhaustion-associated transcriptional programs with reduced translational activity, accompanied by increased STAT3 activation and diminished STAT1 signaling, highlighting their impaired cytotoxic function. Following STAT3 inhibition, $trNK^{NTCP+}$ cells presented significantly reduced NTCP expression, reduced NK cell exhaustion, and restored NK cell activity. In MASH mice, epigallocatechin gallate-mediated inhibition of NTCP expression reduced TCA uptake and attenuated liver fibrosis. Additionally, in immunodeficient liver fibrosis model mice, reconstitution with $trNK^{NTCP-}$ cells alleviated liver fibrosis, decreased proinflammatory and profibrotic cytokine levels, and ameliorated lipid homeostasis. **Conclusion:** Our findings suggest that enhancing immune responses by restoring NK cell activity through NTCP antagonism may offer a clinically beneficial strategy to prevent liver fibrosis in patients with metabolic disorders, autoimmune diseases, and chronic viral hepatitis.

Background: Genetic and environmental factors influence MASLD severity and progression. We evaluated associations between single nucleotide polymorphisms (SNPs) and advanced fibrosis and clinical outcomes in a multinational MASLD cohort. **Methods:** Adults with MASLD from 13 countries in the G-MASLD SNP subproject with genotyping data for four SNPs (rs738409 [*PNPLA3*], rs58542926 [*TM6SF2*], rs641738 [*MBOAT7*], rs62305723 [*HSD17B13*]) were included. Outcomes included presence of advanced fibrosis (F3–F4 or LSM $\geq$ 10 kPa) and time to clinical event (hepatic decompensation, HCC, transplantation, or death). **Results:** A total of 5,970 patients with MASLD were analyzed [mean ages 54 ± 13 years; 53% male; 67% obesity; 41% T2D; 63% hypertension; regions of enrollment - North America (30%), Europe (28%), Asia (26%), Latin America (11%), Middle East and North Africa (5%). The highest frequency of the minor allele (G) in rs738409 (*PNPLA3*) was observed in Latin America (72%), the lowest in North America (51%), while *MBOAT7* CC genotype predominated in Asia (49% vs. 30% in Europe and North America; pooled 35%). The *PNPLA3* C > G was independently associated with both histologic and LSM-defined advanced fibrosis. Advanced fibrosis prevalence increased with G allele dosage: histologic fibrosis 16% (CC), 24% (CG), 29% (GG); LSM-defined fibrosis 14%, 21%, 30%; respectively (all $p < 0.0001$). The *MBOAT7* C > T was associated with LSM-defined advanced fibrosis, with higher rates in TT versus CC/CT carriers (13% vs. 9%; $p = 0.0226$). TM6SF2 and HSD17B13 SNPs were not significantly associated with the outcomes ($p > 0.05$). In multivariate analysis adjusted for enrollment site, age, sex, obesity, and T2D status, *PNPLA3* variant independently predicted advanced histologic fibrosis (CG vs. CC: OR = 1.71, 95% CI: 1.35–2.18; GG vs. CC: OR = 2.61, 95% CI: 1.98–3.44; $p < 0.0001$). For LSM-defined advanced fibrosis, both *PNPLA3* GG (OR = 2.39, 95% CI: 1.58–3.62) and *MBOAT7* TT (OR = 1.91, 95% CI: 1.23–2.95) showed independent associations ($p < 0.01$). Regional subgroup analyses revealed that *PNPLA3* effects were consistent across regions. In contrast, the *MBOAT7* TT genotype association was present only in European patients (OR = 2.83; 95% CI: 1.41–5.70). In time-to-event analysis adjusted for region, age, sex, obesity, T2D, and hypertension, the *PNPLA3* GG genotype (vs. CC) was the only genetic modifier independently associated with increased risk of clinical event risk (adjusted HR = 2.46; 95% CI: 1.44–4.20, $p < 0.0001$). **Conclusion:** In this large, globally diverse MASLD cohort, *PNPLA3* rs738409 was consistently associated with advanced fibrosis and clinical events across regions, whereas the effect of *MBOAT7* rs641738 variant varied by geographic region.

★ 2296 | ◆ ALDH2 DEFICIENCY BLUNTS SERUM ALT ELEVATION DESPITE ONGOING HEPATOCELLULAR INJURY BY ALCOHOL CONSUMPTION

Takuya Seike[1] Yi-Hsun Chen[2] I-Chen Wu[2] Taro Yamashita[1] Daria Mochly-Rosen[3], [1]Kanazawa University, [2]Kaohsiung Medical University Hospital, [3]Stanford University

Background: Serum alanine aminotransferase (ALT) is the most widely used biomarker of hepatocellular injury. However, whether genetic or metabolic factors alter the reliability of serum ALT as an indicator of liver injury remains unclear. Aldehyde dehydrogenase 2 (ALDH2) detoxifies acetaldehyde generated during ethanol metabolism, and the inactive ALDH2*2 variant (rs671), carried by approximately 560 million individuals worldwide, results in increased aldehyde stress after alcohol exposure. We investigated whether ALDH2 deficiency and alcohol consumption

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

uncouple serum ALT levels from the hepatocellular injury. **Methods:** We analyzed biobank data from 91,743 participants to evaluate the interaction among ALDH2 genotype, alcohol consumption, and serum liver enzyme levels. Mechanistic studies were performed using ALDH2*2 knock-in mice acutely exposed to ethanol (1 g/kg) to determine whether ALDH2 deficiency alters hepatic injury responses and serum ALT dynamics. **Results:** After multivariable adjustment for age, body mass index (BMI), and γ-glutamyl transferase (GGT), alcohol consumption was associated with significantly lower serum ALT levels in both ALDH2*1/*1 carriers (normal enzymatic activity) and ALDH2*1/*2 carriers (reduced enzymatic activity), with decreases of 4.97 U/L and 7.56 U/L, respectively ($P < 0.001$). Stratified analyses according to BMI and GGT demonstrated that the reduction in ALT levels was most pronounced in individuals with BMI > 25 kg/m² and GGT > 50 U/L. Specifically, among non-drinkers, serum ALT levels were comparable regardless of ALDH2 genotype (48 U/L). In contrast, among drinkers, ALT levels were significantly lower in ALDH2*1/*1 carriers (37 U/L) and were further reduced in ALDH2*1/*2 carriers (29 U/L), whereas AST levels did not differ between groups.In ALDH2*1/*2 mice exposed to ethanol, accumulation of the lipid peroxidation product 4-hydroxynonenal was comparable to or greater than that observed in ethanol-treated wild-type mice. This was accompanied by enhanced MAPK activation, increased chemokine expression, and markedly aggravated histological necrosis. Despite evidence of liver injury, the elevation in serum ALT levels remained minimal in ALDH2*1/*2 mice. Furthermore, hepatic ALT mRNA and protein expression were both reduced in ethanol-treated ALDH2*1/*2 mice. **Conclusion:** ALDH2 deficiency suppresses hepatic ALT expression and blunts serum ALT elevation despite ongoing hepatocellular injury by alcohol consumption, thereby uncoupling serum ALT levels from the severity of alcohol-associated liver damage. These findings identify a genetically determined mechanism of biomarker underestimation and suggest that serum ALT levels may substantially underestimate liver injury in individuals carrying the ALDH2*2 variant.

2297 | ◆ A MULTI-MODAL SINGLE-CELL AND SPATIAL ATLAS REVEALS PATHOLOGY-SPECIFIC IMMUNE DIVERGENCE IN HUMAN LIVER CIRRHOSIS

Diana Vucevic[1] Sumana Srinivasan[1] Shankar Subramaniam[1], [1]University of California San Diego

Background: Chronic liver disease progresses through steatosis, fibrosis, and cirrhosis, yet a comprehensive map of how this progression remodels cell types, cell states, zonation, and intercellular communication at single-cell and spatial resolution is lacking. Whether alcoholic, metabolic, and autoimmune cirrhosis follow divergent cellular trajectories has not been systematically compared. We built a multi-modal atlas integrating scRNA-seq (~150,000 cells), MERFISH (~310,000 cells), and Visium (17,573 spots) across healthy, NAFLD, MAFLD, and three cirrhosis etiologies (alcohol, NAFLD, PBC). **Methods:** scRNA-seq data (27 cell types) from four published cohorts were harmonized via Harmony, with all cirrhosis etiologies from a single dataset to eliminate batch confounding. Functional cell states were scored using literature-derived gene sets. Cell2location deconvolution mapped cell types onto Visium spots. Cell-cell communication (CCC) was analyzed via LIANA (five-method consensus). MERFISH provided independent spatial validation of cell state and compositional changes. **Results:** The disease cascade followed an ordered sequence. First, hepatocytes underwent lineage loss: lipid-laden states dominated in early disease (NAFLD/MAFLD), then gave way to senescent and ER-stress programs in cirrhosis. MERFISH mapping confirmed this transition spatially (Lipid_Laden 0.73x, Senescent 2.8x, ER_Stress 3.6x in fibrotic tissue). Hepatocyte zonation universally collapsed to midzone-only identity, with MERFISH mapping revealing loss of pericentral-periportal spatial complementarity. Second, the sinusoidal niche remodeled. LSEC capillarization was near-complete in cirrhosis (normal LSECs 48% to < 2%), and Visium deconvolution resolved Stellate_Activated and Signature_Fibrosis enrichment in fibrotic septa with Hepatocyte_Lipid_Laden in pericentral regions. Stellate activation was pathology-dependent (40% myofibroblast in alcoholic vs 18% in NAFLD cirrhosis). Third, the immune landscape diverged by pathology. Alcoholic cirrhosis preserved Kupffer cells (1.89x metabolic ratio) with compensatory SLC40A1 upregulation maintaining HAMP iron homeostasis, while metabolic cirrhosis showed Kupffer-to-SAM replacement and HAMP collapse. MERFISH mapping confirmed this shift in situ (Kupffer 0.31x, Monocyte 3.2x). CCC revealed that this divergence extended to signaling: SPP1-integrin remodeling and ZG16B-TLR2 gut-liver axis in alcoholic, collagen-DDR1 fibrogenesis in NAFLD, and HLA-G immune evasion with checkpoint activation (LAG3, BTLA) in PBC. **Conclusion:** Liver disease progression follows a conserved structural cascade, hepatocyte dedifferentiation, zonation collapse, sinusoidal remodeling, but branches into pathology-specific immune and communication programs at cirrhosis. These divergent architectures suggest antifibrotic strategies may need to be pathology tailored.

2298 | ◆ ELEVATED LIVER ENZYMES UNDER CONTEMPORARY THRESHOLDS HIGHLIGHT A MISSING HEPATIC DIMENSION IN METABOLIC RISK ASSESSMENT

Chaojian He[1] Qingqiang Yi[2] Lei Zhao[3], [1]Rocky Vista University, [2]Tai'an Eighty-Eight Hospital, [3]Tai'an City Central Hospital

Background: The liver is the central orchestrator of systemic metabolism, yet no metabolic syndrome (MetS) criteria include liver enzymes. Notably, these stricter criteria, lower ALT thresholds (men >35, women >25 U/L) and age-/sex-specific GGT thresholds (men and women ≥45y: >38 U/L; women <45y: >27 U/L), have rarely been adopted in studies examining the association between liver enzymes and cumulative metabolic burden. Using a large Chinese cohort, we tested whether these contemporary thresholds associate with metabolic dysfunction, highlighting an overlooked hepatic dimension of metabolic risk assessment. **Methods:** We conducted a cross-sectional study of 13,335 consecutive participants from a health check-up center in Northern China. Metabolic burden score (MBS) (0-3) was defined as the number of metabolic abnormalities, including glucose, triglycerides, and HDL-C (ADA/IDF criteria). The primary outcome was elevated ALT/GGT (as defined in Background). Multivariable logistic regression assessed the independent association between MBS (continuous) and the outcome, adjusting for age, sex, BMI, and systolic blood pressure (SBP). Linear trend across increasing MBS categories was assessed. Age was modeled categorically (18-29, 30-39, 40-49, 50-59, ≥60 years). AUC was compared between a base model (age, sex, BMI, SBP) and a full model (base + MBS), using DeLong's test for paired ROC curves. An interaction term (MBS × sex) was tested. **Results:** Among 13,335 participants (mean age 44.5±12.9 years; 55.2% male), 29.7% met the composite outcome for ALT/GGT elevation. In the fully adjusted model, each 1-point increase in MBS was associated with higher odds of ALT/GGT elevation (adjusted OR = 1.63; 95% CI: 1.55-1.72; P < 0.001). A strong linear trend was observed across MBS categories (P for trend < 0.001). Age exhibited a non-linear association with the outcome, with the highest risk observed among individuals aged 40-49 years (OR = 2.96; 95% CI: 2.54-3.44) compared to those 18-29 years. A significant interaction was observed between MBS and sex (P for interaction = 0.032), indicating a stronger effect in men (sex-stratified ORs: men 1.71, women 1.49). Adding MBS significantly improved the AUC from 0.746 to 0.764 (P < 0.0001). **Conclusion:** Even using contemporary lower ALT/GGT thresholds that have rarely been applied in metabolic research, liver enzyme elevation was strongly, independently, and dose-dependently associated with cumulative metabolic burden. These findings suggest that the exclusion of liver biomarkers from current MetS frameworks may overlook an important hepatic manifestation of metabolic dysfunction. Incorporating contemporary ALT/GGT thresholds into metabolic risk stratification may facilitate earlier identification of individuals at increased metabolic risk.

Background: Efimosfermin alfa, a once-monthly (Q4W) FGF21 analog, led to improvements in fibrosis versus placebo at 24 weeks in participants (pts) with metabolic dysfunction-associated steatohepatitis (MASH) with stage 2/3 fibrosis (F2/3) in a Phase 2 study (NCT04880031). This analysis of a separate cohort of the Phase 2 study assessed changes in non-invasive tests (NITs) for fibrosis and safety of efimosfermin 225 mg and 300 mg in pts with F2–4 MASH. **Methods:** Pts willing/able to undergo liver biopsy with body mass index ≥ 25 kg/m^2, magnetic resonance imaging-proton density fat fraction (MRI-PDFF) $\geq 8\%$, vibration-controlled transient elastography liver stiffness measurement (LSM) ≥ 12.0–25.0 kPa, and enhanced liver fibrosis (ELF) ≥ 9.8 were included in this analysis. Pts with F1 at baseline were excluded from this analysis. In total, 24 pts had F2/3 (efimosfermin 225 mg: n = 13; 300 mg: n = 11) and 15 had F4 (efimosfermin 225 mg: n = 7; 300 mg: n = 8) at baseline. Changes in steatosis (MRI-PDFF) from baseline were assessed. Safety and changes in NITs for fibrosis improvement (LSM, ELF, and type III collagen pro-peptide [PRO-C3]) from baseline were assessed through 52 weeks. **Results:** Among all analyzed pts, mean (standard deviation [SD]) age was 60.6 years and 51.3% were female. For pts with F2/3 and F4, greater reductions in MRI-PDFF from baseline were observed with efimosfermin 300 mg (mean [SD] reductions of −58.5% [43.3; n = 7] and −71.1% [13.4; n = 6], respectively), versus 225 mg. Changes in LSM score from baseline were similar between pts with F2/3 and F4 and between doses (mean [SD] changes: F2/3 225 mg, −33.6% [13.6; n = 11]; F2/3 300 mg, −42.6% [11.6; n = 7]; F4 225 mg, −48.5% [11.7; n = 2]; F4 300 mg, −20.7% [10.4; n = 7]; **Figure**). Similar changes in ELF score from baseline were also observed across fibrosis stages (F2/3 versus F4) and dose groups (mean [SD] changes: F2/3 225 mg, −0.5 [0.665; n = 11]; F2/3 300 mg, −0.843 [0.789; n = 7]; F4 225 mg, −0.533 [0.603; n = 3]; F4 300 mg, −0.729 [0.81; n = 7]; **Figure**). For pts with F2/3 receiving efimosfermin 225 mg and 300 mg, mean (SD) changes in PRO-C3 from baseline were −19.5% (25.6; n = 11) and −24.8% (27.3; n = 7), respectively. For pts with F4 receiving efimosfermin 225 mg and 300 mg, mean (SD) changes in PRO-C3 from baseline were −21.8% (32.3; n = 3) and −23.5% (14.1; n = 7), respectively. Pharmacokinetics were similar between F2/3 and F4 pts at the same dose, with higher efimosfermin exposure observed with 300 mg versus 225 mg. No pts with F2/3 and 20% (n = 3) of pts with F4 had a serious adverse event; none were related to study treatment. **Conclusion:** Efimosfermin 225 mg and 300 mg demonstrated similar improvements in non-invasive markers of fibrosis and an acceptable, well-tolerated safety profile with comparable pharmacokinetics through 52 weeks in pts with F2–4 MASH. These results support continued evaluation of pts with advanced fibrosis and compensated cirrhosis in Phase 3 trials.

Figure. Distributions of change from baseline in (A) LSM score and (B) ELF score after 52 weeks of treatment

ELF, enhanced liver fibrosis; F, fibrosis stage; LSM, liver stiffness measurement.

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is highly prevalent among individuals with type 2 diabetes (T2D) and significantly increases the risk of liver-related events. Individuals with at-risk MASH [MASH +NAS $\geq$ 4+F $\geq$ 2] are the main target population for emerging therapies. We aimed to develop and validate a non-invasive model to identify at-risk MASH and predicting long-term outcomes in adults with T2D. **Methods:** A multicenter biopsy-based derivation cohort from China (n = 525) was used for model development. External validation was conducted in an independent multicenter China DLIM-biopsy cohort (n = 423); three vibration-controlled transient elastography (VCTE)-based cohorts, including the China DLIM-VCTE cohort (n = 3,711), the Singapore cohort (n = 422), and the US NHANES cohort (n = 1,674); and the UK Biobank MRI cohort (n = 1,146). At-risk MASH was defined histologically in the derivation and biopsy-based validation cohorts, by the FibroScan-AST (FAST) score in the VCTE-based cohorts, and by proton density fat fraction and corrected T1 in the UK Biobank MRI cohort. Model performance was compared with the Fibrosis-4 index (FIB-4), non-alcoholic fatty liver disease fibrosis score (NFS), LiverRisk score, and AST-to-ALT ratio (AAR). In addition, the prognostic utility of the model for predicting liver-related events was evaluated in the UK Biobank cohort (n = 31,066). **Results:** The DiabetesMASH Index (DMI), incorporating age, AST, triglycerides, and high-density lipoprotein cholesterol, demonstrated robust discriminatory performance in the derivation and validation cohorts. The AUCs were 0.79 (95% CI 0.75-0.83), 0.75 (0.71-0.80), 0.91 (0.89-0.94), 0.88 (0.80-0.96), 0.90 (0.86-0.94), and 0.80 (0.73-0.86), respectively, outperforming the FIB-4, NFS, LiverRisk score, and AAR. Calibration analyses demonstrated good agreement between predicted and observed risks. The indeterminate zone comprised 35.8% of participants in the derivation cohort and 48.2%, 19.9%, 24.8%, 19.1%, and 74.3% across the validation cohorts. Furthermore, compared with the low-risk group, the intermediate- and high-risk groups had significantly increased risks of 10-year liver-related events, with multivariable-adjusted hazard ratios of 1.41 (95% CI 0.90-2.22) and 3.27 (95% CI 2.84-3.78), respectively. **Conclusion:** DMI is a validated, affordable, and accessible non-invasive tool for identifying at-risk MASH and stratifying the risk of liver-related events in individuals with T2D.

2301 | ◆ GENETIC EVIDENCE LINKS OPA1-RELATED MITOCHONDRIAL QUALITY-CONTROL NETWORKS TO LIVER FIBROSIS IN MASLD

Xinting Yu[1] Shisong Rong[2] Pinzhu Huang[3] Yoshiko Nanki[4] Edward O'Neill[1] Enzo Cabrera[1] Jerry Cruz Rodriguez[1] Marla Sagatelian[1] Zaur Abilov[4] Chandra Shankar[4] Rene Gomez-Esquivel[1] Yuting Huang[5] Kawtar Al Khalloufi[6] Yury Popov[7], [1]University of South Florida, [2]Harvard Medical School, [3]Harvard University Medical School, [4]BIDMC, Harvard Medical School, [5]Mayo Clinic Florida, [6]Tampa General Hospital, [7]BIDMC Harvard Medical School

Background: Liver fibrosis is a major determinant of morbidity and mortality in metabolic dysfunction-associated steatotic liver disease (MASLD). Mitochondrial dysfunction is a hallmark of MASLD, and our prior work showed that damage-associated molecular pattern mitochondrial DNA (mtDNA), released from hepatocytes s activates hepatic stellate cells and promotes MASH fibrosis. In our prior large-scale Multi-trait GWAS - Multi-marker Analysis of GenoMic Annotation (MTAG-MAGMA) gene-based analyses of mitophagy, mitochondrial fusion, and mitochondrial fission pathways across datasets encompassing approximately 7 million individuals, *OPA1* emerged as a leading candidate linked to liver fibrosis. **Methods:** We performed gene-based association analyses of common and rare variants in genes encoding known OPA1 direct interactors (n = 27) and genes directly involved in OPA1-related pathways (n = 29). Common variants were evaluated using our MTAG-MAGMA pipeline applied to fibrosis-related GWAS summary statistics. Rare variants were assessed by in silico gene-based burden analyses using Genebass v0.13.0-43c83cc-202402232123 from UK Biobank data. Loss-of-function and missense variants were evaluated using SKAT-O, burden, and SKAT models for liver fibrosis and cirrhosis. To interrogate biological significance in vivo, we measured a circulating mtDNA using novel duplex ddPCR assay and assessed liver histology in mice with selective hepatocyte-specific OPA1 deletion and fibrotic MASH induced induced by 8 weeks of HF-CDAA diet. **Results:** In common-variant analyses, MIEF1, a mitochondrial fission-related gene, showed nominal association with liver fibrosis ($P <= 0.015$), as did CHCHD3, an OPA1 direct interactor ($P = 0.013$). Rare-variant burden analyses identified 16 OPA1-related genes with nominal associations with liver fibrosis or cirrhosis ($P <= 0.05$), including OPA1 ($P = 0.049$), MTCH2 ($P <= 0.004$), and 14 additional genes. In mice with MASH, hepatocyte-specific loss of OPA1 gene markedly increased circulating mtDNA after HF-CDAA diet feeding. OPA1 loss reduced overall liver steatosis and fibrosis. Intriguingly, OPA1 knockdown led to remarkable shift in scarring pattern from pericellular “chicken-wire” fibrosis to moderate interstitial fibrosis. **Conclusion:** OPA1 is a genetic and biological anchor linking mitochondrial quality-control pathways to MASLD fibrosis. These findings support OPA1-related mitochondrial dynamics and damage signaling as direct contributors to fibrotic liver disease, and provide a framework for functional studies and innovative therapies in MASLD.

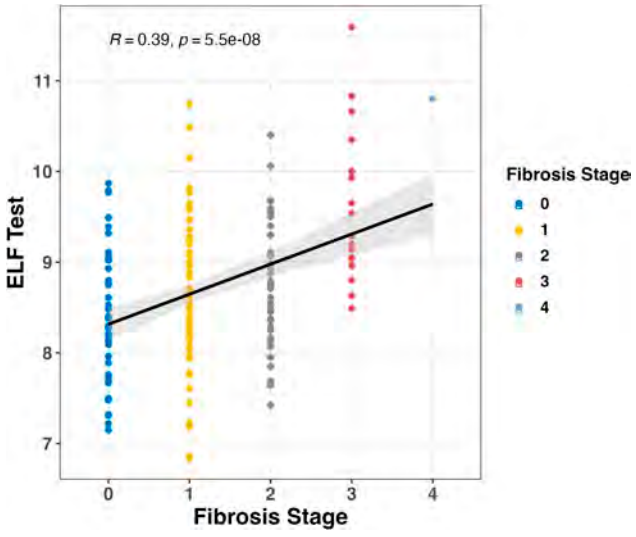
2302 | ◆ ELF TEST PREDICTS ADVANCED FIBROSIS AND FIBROSIS CHANGE IN CHILDREN WITH MASLD



Adam Telega[1] Xinlian Zhang[1] Andrea Schreck[1] Raphael Yoo[1] Rush Chewning[1] Denise Malicki[1] Phillipp Hartmann[1], [1]University of California San Diego

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects 5-10% of children globally, and it is associated with severe comorbidities and long-term mortality. However, there is a paucity of reliable biomarkers that predict the degree of fibrosis in children with MASLD. Prior studies provided mixed results for the performance of the Enhanced liver fibrosis (ELF) test in pediatric nonalcoholic fatty liver disease (NAFLD) and lacked strict temporal association with biopsy. We aimed to validate the ELF test in pediatric MASLD after the recent change in terminology while anchoring it more closely in proximity to the biopsy. **Methods:** We prospectively enrolled 182 children with biopsy-confirmed MASLD and an ELF test within 30 days of biopsy as well as 20 healthy controls at an academic Children’s Hospital between 2023 and 2026. Analyses included t-tests, areas under the curve (AUCs), and Pearson correlations. **Results:**

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Children with MASLD had mean age 12.9 years, 79.1% were boys, mean body mass index was 33.5, mean NAFLD activity score (NAS) was 4.00, and fibrosis stages were F0 n = 45, F1 n = 73, F2 n = 45, F3 n = 18, and F4 n = 1. Mean ELF scores were significantly higher in patients with MASLD compared with controls (8.72 vs 8.32, p = 0.014). Amongst children with MASLD, the mean ELF scores of F1-F4 vs F0 were 8.82 vs 8.40 (p = 0.001), 9.03 for F2-F4 vs 8.55 for F0-F1 (p < 0.001), and 9.64 for F3-F4 vs 8.61 for F0-F2 (p < 0.001).The ELF scores correlated with fibrosis stage (R = 0.39, p < 0.001) (Figure). The ELF test had a higher AUC for detection of F1-F4, F2-F4, and F3-F4 than the basic biochemical markers ALT, AST, and GGT. It performed particularly well for detection of advanced fibrosis and outperformed ALT, AST, and GGT (AUC 0.82 with a threshold of 8.8; 0.74, 0.81, 0.73, respectively). Of note, an ELF score > 9.87 ruled in fibrosis (100% specificity/PPV), whereas an ELF score < 8.49 ruled out advanced fibrosis (100% sensitivity/NPV).Among 33 patients, repeat liver biopsy was performed a mean of 1 year and 5 months after the initial biopsy, with corresponding ELF scores obtained within 30 days of the second biopsy. Relative ELF change correlated with fibrosis stage change (R = 0.37, p = 0.036). ELF change predicted no fibrosis worsening (AUC 0.94, sensitivity 1.00, specificity 0.76), and improving ELF scores ruled out worsening of fibrosis. **Conclusion:** The ELF test correlates with fibrosis stage at baseline and its change predicts fibrosis response on repeat biopsy in children with MASLD. It may hence serve as a valuable noninvasive tool in clinical practice and clinical trials for pediatric MASLD.

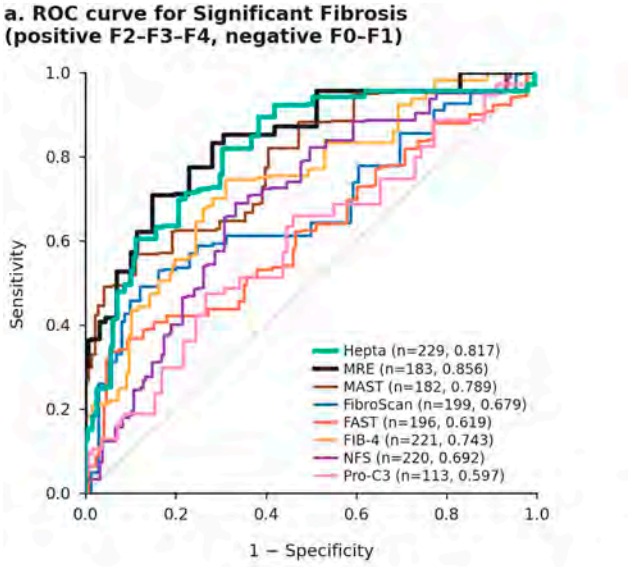
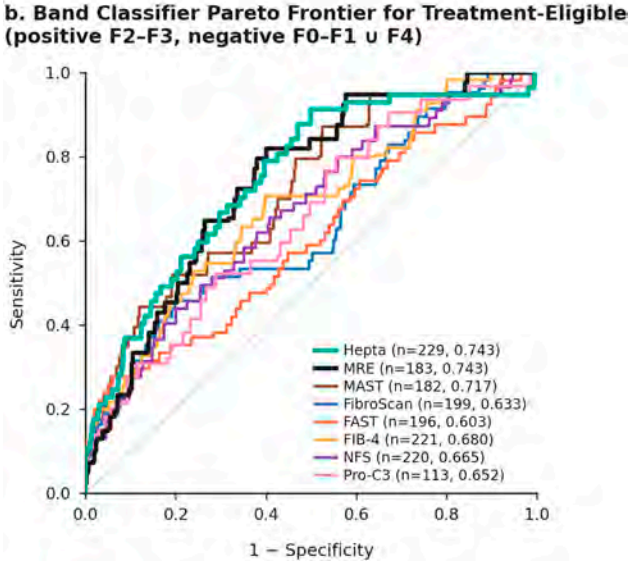
2303 | ◆ EXTERNAL VALIDATION OF LIQUIDTRANSFORMER IN MADRIGAL MASH PROGRAM: HEPTA'S AI-POWERED CELL-FREE DNA METHYLATION BIOMARKER OUTPERFORMS ALL EVALUATED BLOOD-BASED AND ELASTOGRAPHY MARKERS FOR DETECTING TREATMENT-ELIGIBLE MASH



Rohit Loomba[1] Soheil Damangir[2] James Hennan[3] Manal Abdelmalek[4] Jörn Schattenberg[5] Chong Lu[2] Leila Bazargan[2] Suneil Hosmane[3] Hamed Amini[2] Rebecca Taub[3] Anna Mae Diehl[6], [1]University of California, San Diego, [2]Hepta Bio, Inc., [3]Madrigal Pharmaceuticals, [4]Mayo Clinic Rochester, [5]Saarland University Medical Center, [6]Duke University



Background: The approval of resmetirom and semaglutide for MASH with moderate-to-advanced fibrosis (F2-F3) has made accurate, scalable identification of treatment-eligible patients a clinical priority. Existing NITs were largely developed to detect advanced fibrosis (F3-F4) and underperform at the F0/1-vs-F2 boundary that defines treatment eligibility. We previously developed LiquidTransformer, an AI-powered cell-free DNA (cfDNA) methylation technology, for non-invasive measurement of fibrosis and MASH. Here we report an independent validation of the test in the Madrigal MASH program and a head-to-head comparison against established NITs. **Methods:** LiquidTransformer was trained on a large biopsy-confirmed MASLD cohort, with no samples from the Madrigal MASH program used during training. Independent validation was performed on 229 biopsy-confirmed participants from the Madrigal MASH program. The primary endpoint was detection of significant fibrosis (F2+) and the secondary endpoint was detection of treatment eligible (F2-F3). Hepta was compared head-to-head against FAST, MAST, MRE, FibroScan/TE, Pro-C3 and FIB-4. Performance was measured using AUC for F2+ and Pareto frontier for F2-F3 classification. To make comparisons clinically interpretable, we reported case-mix-adjusted performance under two reference fibrosis-stage distributions: a general MASLD-population (Younossi 2016) and the LITMUS biomarker-validation cohort (Hardy 2023), alongside unweighted values. **Results:** Hepta's LiquidTransformer achieved an F2+ AUC of 0.85 (unweighted), 0.81 (MASLD-weighted), and 0.82 (LITMUS-weighted) on the Madrigal validation set. In all three weighting conditions, Hepta outperformed every blood- and TE-based NITs. Using LITMUS weighting Hepta outperformed FAST (AUC 0.62, Δ +0.20), MAST (0.79, Δ +0.04), FibroScan/TE (0.68, Δ +0.14), Pro-C3 (0.60, Δ +0.17) and FIB-4 (0.74, Δ +0.08). The only NIT with higher AUC was MRE (0.86, Δ −0.02), a specialized imaging modality available in a subset of Radiology centers. For treatment-eligible classification, Hepta's Pareto frontier equaled that of MRE and exceeded all other tests. Hepta's advantage over aforementioned NITs

widened under realistic case-mix reweighting, reflecting robust discrimination at the clinically critical F1-vs-F2 boundary where conventional NITs lose performance. **Conclusion:** In an independent validation in the Madrigal MASH program, Hepta's LiquidTransformer accurately identified treatment-eligible patients and those with significant fibrosis and outperformed all evaluated blood-based and FibroScan (a type of TE system), including the composite scores FAST and MAST. Performance approached that of MRE for F2+ and matched MRE for treatment-eligible classification. These results support Hepta as a promising scalable blood-based approach for identifying treatment-eligible MASH patients.

2304 | MASH PRECIS FIBROSIS SCORE: DEVELOPMENT, VALIDATION, AND HEAD-TO-HEAD COMPARISON WITH ELF FOR F2-F3 TREATMENT ELIGIBLE PATIENT SELECTION IN BIOPSY-PROVEN MASH

Rohit Loomba[1] Paul Pockros[2] Jessica Ho[3] John Whitaker[4] Manal Abdelmalek[5], [1]MASLD Research Center, University of California San Diego, [2]Scripps Clinic; Scripps Research Institute, [3]Prometheus Laboratories, [4]SoCal CompBio, [5]Mayo Clinic Rochester

Background: Approved therapies for metabolic dysfunction-associated steatohepatitis (MASH) currently target non-cirrhotic F2–F3 fibrosis, creating an urgent need for noninvasive tests (NITs) that reliably identify this population. The Enhanced Liver Fibrosis (ELF) score, an FDA-cleared serum-based NIT used to identify patients at risk for advanced fibrosis, has been incorporated into treatment algorithms; however, it was not designed for fibrosis staging and it generates indeterminate results in many patients at precisely the boundary where treatment eligibility is determined. We report the development, blinded multi-cohort validation, and head-to-head comparison of the MASH Precis fibrosis score, designed to improve classification accuracy and diagnostic yield, with ELF to support treatment eligibility decisions. **Methods:** The MASH Precis fibrosis score uses a five-biomarker panel [hyaluronic acid (HA), tissue inhibitor of metalloproteinases-1 (TIMP1), alpha-2-macroglobulin (A2MG), thrombospondin-2 (THBS2), vascular cell adhesion molecule-1 (VCAM1)] with ordinal logistic regression to estimate stage-specific probabilities across F0–F1, F2–F3, and F4, reported as a 0–100 fibrosis staging score. Thresholds were locked prior to validation. Training used 10,000-resamples and 10-fold cross-validation (n = 456). Validation used an independent blinded set (n = 450). ELF combines TIMP1, HA, and procollagen III N-terminal peptide (PIIINP) via linear regression, including a gray zone (7.7–9.8) where no classification is assigned per guidelines. **Results:** The MASH Precis fibrosis score demonstrated robust discrimination across fibrosis classes: training and validation AUCs were 0.905 and 0.871 (F0–F1 vs. rest), 0.818 and 0.782 (F2–F3 vs. rest), and 0.862 and 0.922 (F4 vs. rest) (Figure 1A-B). In head-to-head comparison, MASH Precis fibrosis score outperformed or trended higher than ELF on boundaries relevant to treatment selection: ruling out low-risk patients (AUC 0.871 vs. 0.802; $p < 0.001$) and detecting cirrhosis (AUC 0.922 vs. 0.888; $p = 0.131$). MASH Precis fibrosis score correctly classified 70.1% (164/234) of F0–F1, 56.7% (102/180) of F2–F3, and 77.8% (28/36) of F4 patients with 100% diagnostic yield (Figure 1C). ELF correctly classified 16.2%, 36.1%, and 41.7% across the same groups; gray zone results rendered 59.8% of patients unclassifiable, including 50.0% of F2–F3 cases, yielding an overall diagnostic yield of 40.2% (Figure 1D). **Conclusion:** The MASH Precis fibrosis score demonstrated robust multi-cohort validation and superior classification performance versus ELF across all fibrosis stages with 100% diagnostic yield. The high rate of indeterminate ELF results, particularly among F2–F3 patients, has direct implications for treatment eligibility. These findings support prospective evaluation of MASH Precis fibrosis score to guide treatment decision-making in MASH.

★ 2305 | ETHNIC DIFFERENCES IN NON-INVASIVE TESTS, DISEASE SEVERITY, AND CLINICAL OUTCOMES IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A LONGITUDINAL RETROSPECTIVE COHORT STUDY

Andre Jeyarajan[1] Chinmay Bera[2] Ravi Kiran[3] Maxwell Tong[4] Natalie Simonian[3] Leila Amiri[4] Nashla Hamdan[1] Keyur Patel[1], [1]University of Toronto, [2]University of Arkansas for Medical Sciences, [3]Toronto General Hospital, [4]University Health Network

Background: Non-invasive tests (NITs) are recommended to identify metabolic dysfunction-associated steatotic liver disease (MASLD) persons with advanced fibrosis (F3-4) at increased risk of liver-related outcomes. Although there are ethnic disparities in disease severity and outcomes, NITs were developed in predominantly White populations. Therefore, our aims were to characterize the performance of NITs in predicting advanced fibrosis and describe risk for MASLD severity and outcomes based on ethnicity. **Methods:** Retrospective study of a diverse ethnic cohort of 817 persons with biopsy-proven MASLD at a single Canadian tertiary-care centre. Ethnicity was self-reported and verified using machine learning models. NITs evaluated were FIB-4, NAFLD Fibrosis Score (NFS), liver stiffness measurement (LSM), Agile 3+, and MAFLD Fibrosis Score (MFS). **Results:** Race/ethnicity breakdown in the cohort was as follows: 434 (53.1%) White, 90 (11%) South Asian, 88 (10.8%) East Asian, 94 (11.5%) Southeast (SE) Asian, 61 (7.5%) Latin American, and 50 (6.1%) Other (27 Black, 22 Middle Eastern, and one Indigenous). Advanced fibrosis (F3-4) range was 31.8% (East Asians) to 56% (Whites). FIB-4 significantly outperformed for F3-4 in SE Asians compared to Whites and negative predictive value for FIB-4 was highest in East and SE Asians (Table 1). NFS, LSM, and Agile 3 + had poor sensitivity at validated thresholds for F3-4 in SE Asians (26-50%). Agile 3+ also had low sensitivity in Latin Americans (44%). LSM, Agile 3+, and MFS classified fewer indeterminates in Whites (Table 1). In prevalence modelling for F3-4, FIB-4 and MFS appeared to have stronger positive predictive value (PPV) at low (5%) prevalence in SE Asians compared to Whites (56% vs 25% and 47% vs 16%, respectively). LSM also had higher PPV at low prevalence in East Asians (48%) relative to Whites (24%). The recommended two-tier sequential approach using FIB-4 and LSM did not improve F3-4 classification rates in SE Asians (76% vs 83%), perhaps due to lower sensitivity of LSM at validated thresholds in this cohort. East Asian ethnicity was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

negatively associated with F3-4 at baseline compared to Whites (OR 0.52, p = 0.021). During mean follow-up up 5.0 +/- 5.1 years, both East (aHR 0.32, p = 0.05) and SE Asians (aHR 0.37, p = 0.006) had lower risks for hepatic decompensation compared to Whites. East Asians also had significantly lower all-cause mortality relative to Whites (aHR 0.24, p = 0.048). The rate of HCC and transplant were highest for South Asians (1.30 and 2.08 events per 100 person-years) while East Asians had the lowest rates of HCC and transplant (0.56 and 0.37 events per 100 person-years). **Conclusion:** There are ethnic differences in NIT sensitivity for F3-4 association with advanced MASLD fibrosis on biopsy and clinical outcomes. Further evaluation of NIT thresholds and liver-related events in low prevalence and underepresented ethnicities is warranted.

Table 1. Diagnostic performance of NITs in predicting advanced fibrosis using validated dual cut-offs.

2306 | HEPATIC EXTRACELLULAR VESICLES FROM MASLD REPROGRAM HUMAN CARDIOMYOCYTE METABOLISM

Emeli Chatterjee[1], [1]Massachusetts General Hospital, Harvard Medical School.

Background: Metabolic dysfunction-associated steatic liver disease (MASLD) is a prevalent chronic liver condition epidemiologically linked to increased cardiovascular events and adverse cardiac remodeling. Extracellular vesicles (EVs) are candidate mediators of this inter-organ communication, transporting RNA species that reprogram distant cells. **Methods:** MASLD-relevant EVs were generated from a perfused multicellular human liver-on-chip model and characterized by size-exclusion chromatography, NTA, TEM, and immunoblotting. Small RNA sequencing prioritized RNAs by fold change, abundance, and predicted cardiac targets. Functional assays applied MASLD or control EVs to human induced pluripotent stem cell-derived cardiomyocytes, assessing uptake, lipid accumulation, mitochondrial morphology, transcriptomics, and metabolomics. **Results:** MASLD EVs selectively enriched microRNAs are predicted to target regulators of mitochondrial β-oxidation, glucose metabolism, and stress responses. MASLD EVs induced transcriptional repression of fatty acid transport/β-oxidation genes, lipid accumulation, and mitochondrial dysfunction in cardiomyocytes, accompanied by contractile disorganization. Metabolomics revealed elevated acylcarnitines and incomplete β-oxidation intermediates in treated cardiomyocytes, indicating impaired mitochondrial energetics. In MASLD ExoMap1 mice, hepatocyte EVs carried the prioritized RNA signature, and cardiac tissue exhibited concordant transcriptional remodeling, lipid deposition, and mild diastolic dysfunction. Inhibiting hepatic EV release attenuated cardiac abnormalities; enriching circulating EVs with these RNAs recapitulated the phenotype. **Conclusion:** MASLD-derived hepatic EVs convey a distinct RNA signature that reprograms cardiomyocyte metabolic and transcriptional networks, promoting lipid accumulation and mitochondrial dysfunction. This inter-organ communication axis identifies candidate biomarkers (e.g., EV-RNAs) and therapeutic targets for MASLD-related cardiac complications, highlighting the potential for EV-based diagnostics and RNA-targeted therapies to mitigate cardiovascular risk in MASLD patients

2307 | SHEAR WAVE ELASTOGRAPHY PERFORMS COMPARABLY TO VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY IN A FIB-4–BASED TWO-STEP RISK STRATIFICATION STRATEGY FOR MASLD

Soon Kyu Lee[1] Jaejun Lee[1] Soon Woo Nam[1] Jung Hyun Kwon[2], [1]College of Medicine, The Catholic University of Korea, [2]The Catholic University of Korea

Background: We compared the risk stratification performance of shear wave elastography (SWE) and vibration-controlled transient elastography (VCTE) using two-step algorithms proposed by the American Gastroenterological Association (AGA) and the European Association for the Study of the Liver (EASL). **Methods:** Patients with MASLD who underwent both VCTE and SWE during the same session between 2019 and 2025 were included. Risk stratification was performed using AGA- and EASL-based two-step approaches. The primary endpoint was liver-related events (LRE), defined as hepatocellular carcinoma (HCC), liver transplantation, liver-related death, and hepatic decompensation events. **Results:** Among 2,817 patients, 2,196, 140, and 481 were classified as low-, intermediate-, and high-risk, respectively, using the AGA algorithm with SWE, whereas 1,475, 721, 188, and 433 were classified as low-, intermediate-low, intermediate-high, and high-risk, respectively, using the EASL algorithm with SWE (Fig. A). Using the AGA-SWE algorithm, both intermediate- and high-risk groups showed increased risks of LREs compared with the low-risk group (hazard ratio [HR] 7.58 and 11.49, respectively) (Fig. B). The EASL-SWE algorithm also stratified LRE risk relative to the low-risk group, with higher HRs observed for the intermediate-low, intermediate-high, and high-risk groups (HR 2.98, 10.80, and 22.05, respectively) (Fig. C). The mean time-dependent area under the curve at 60 months was 0.764 and 0.766 for AGA-SWE and AGA-VCTE, respectively (Fig. D), and 0.785 for both EASL-SWE and EASL-VCTE, with no significant differences between SWE and VCTE in either algorithm. Moreover, SWE and VCTE demonstrated good concordance (Spearman's ρ = 0.713, p < 0.001). **Conclusion:** SWE-based two-step risk stratification showed predictive performance comparable to VCTE-based models in MASLD. These findings support SWE as a viable alternative for LSM within guideline-recommended two-step algorithms.

2308 | FIB-4 AND APRI LINKED TO CARDIOMETABOLIC RISK AND MACE IN A REAL-WORLD TYPE 2 DIABETES COHORT

Melina Manolas[1] Sarah Barenbaum[1] Michele Yeung[1] Xiaoyue Ma[1] Sanaa Tejani[1] Sangeeta Kashyap[1], [1]Weill Cornell Medicine

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is strongly linked with cardiovascular disease, the leading cause of mortality in affected individuals. Noninvasive fibrosis markers are increasingly used for risk stratification in type 2 diabetes mellitus (T2DM), but their prognostic significance for cardiovascular outcomes remains incompletely defined. We evaluated associations between fibrosis indices, cardiometabolic risk profiles, and major adverse cardiovascular events (MACE) in a large real-world T2DM cohort. **Methods:** We conducted a retrospective cohort study of 6,379 adults with T2DM at Weill Cornell Medicine. Fibrosis-4 (FIB-4) and AST-to-platelet ratio index (APRI) scores were calculated using temporally aligned AST, ALT, and platelet values. Age-adjusted FIB-4 categories (low, indeterminate, high) and APRI categories (<0.5, $0.5–<1.0$, ≥ 1.0) were applied. Because age is incorporated into FIB-4 and independently correlates with cardiovascular risk, APRI, which does not include age, was evaluated as an age-independent comparator. Outcomes included 4-component MACE (myocardial infarction, stroke, heart failure, or death). Multivariable logistic regression models adjusted for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

demographic and clinical covariates were used to assess associations with cardiovascular outcomes. **Results:** Higher FIB-4 identified a distinct high-risk phenotype. Patients with high FIB-4 were older (75.0 vs 65.7 years, $p < 0.001$), more frequently male, and had lower BMI despite greater multimorbidity, including higher rates of heart failure, atrial fibrillation, chronic kidney disease, and Charlson Comorbidity Index ≥ 4 (all $p < 0.001$, see Table 1). They also demonstrated lower use of SGLT2 inhibitors and GLP-1 receptor agonists (both $p < 0.001$).High FIB-4 was independently associated with increased odds of MACE (adjusted odds ratio [aOR] 1.53, 95% CI 1.25–1.86; $p < 0.001$), heart failure (aOR 1.56, 95% CI 1.28–1.89; $p < 0.001$), and mortality (aOR 1.45, 95% CI 1.09–1.92; $p = 0.011$). Indeterminate FIB-4 was also associated with heart failure (aOR 1.16, 95% CI 1.01–1.33; $p = 0.034$).To address potential age confounding within FIB-4, APRI was evaluated as an age-independent comparator. APRI ≥ 1.0 was associated with higher odds of MACE (aOR 1.56, 95% CI 1.01–2.41; $p = 0.048$), while APRI 0.5–<1.0 was associated with MACE, heart failure, and coronary artery disease. **Conclusion:** In patients with T2DM, elevated FIB-4 identifies a high-risk cardiometabolic phenotype with substantially increased cardiovascular risk. Similar findings observed with APRI suggest these associations are not solely driven by the age component embedded within FIB-4. Noninvasive fibrosis indices may serve as integrated prognostic tools for cardiovascular risk stratification in MASLD and T2DM.

Table 1: Baseline Characteristics by FIB-4 Category

Characteristic	Low FIB-4 (N=4057)	Indeterminate FIB-4 (N=1652)	High FIB-4 (N=670)	P value
Age, years	65.7 (11.3)	67.3 (10.8)	75.0 (9.7)	<0.001
Male sex	2141 (52.8)	1040 (63.0)	441 (65.8)	<0.001
BMI, kg/m²	31.2 (6.9)	30.3 (6.3)	28.3 (5.8)	<0.001
HbA1c ≤7.0%	1457 (48.3)	694 (57.5)	279 (56.7)	<0.001

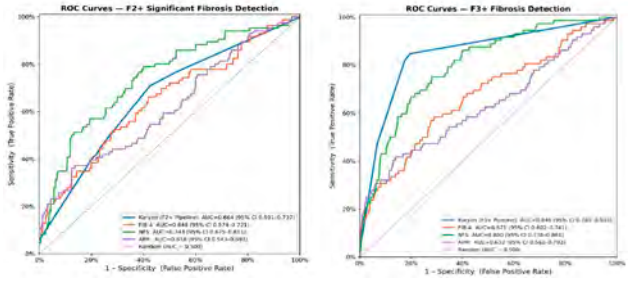
2309 | A NOVEL LARGE LANGUAGE MODEL TRAINED USING AASLD GUIDELINES CAN ACCURATELY DISTINGUISH SIGNIFICANT OR ADVANCED FIBROSIS AMONG ADULTS WITH MASLD/MASH USING ROUTINE CLINICAL DATA

Robert Wong[1] Anand Badarkhe[2] Parneet Kaur[2] Maytha Alshammari[3] Lakshmi Balasubramanian[2] Srinivas Thirunagari[2], [1]Stanford/VA Palo Alto Healthcare System, [2]Karyon Bio, [3]Kayon Bio



Background: Accessible non-invasive tools that accurately risk-stratify patients with significant fibrosis (F2+) or advanced fibrosis (F3+) in primary care settings is critical for streamlining metabolic dysfunction-associated steatotic liver disease/steatohepatitis (MASLD/MASH) clinical care pathways to GI/Liver specialty clinics, imaging-based fibrosis assessment (e.g. transient elastography), and linkage to approved therapies for MASH F2+. **Methods:** Using the 2017-2020 pre-pandemic National Health and Nutrition Examination Survey dataset, adults (age $\geq$ 20y) with MASLD/MASH who had available transient elastography data were categorized into significant fibrosis (liver stiffness measurement [LSM] $\geq$ 8.0kPa) or advanced fibrosis (LSM $\geq$ 9.5kPa). A large language model (Karyon) was trained using AASLD guidelines on MASLD/MASH and Noninvasive Liver Disease Assessment, and incorporated demographics (age, sex, ethnicity), anthropometric measurements, standard laboratory test results (e.g. complete blood count, comprehensive metabolic panel, lipid panel, hemoglobin A1c), and relevant risk factors (tobacco and alcohol use), to predict F2+ or F3+. Sensitivity, specificity, and area under the receiver operating curve (AUROC) of Karyon was compared against fibrosis-4 (FIB-4), AST to platelet ratio index (APRI), and NAFLD fibrosis score (NFS). **Results:** Among 2,585 adults with MASLD/MASH (48.7% men, mean age 50.0y, 34.0% non-Hispanic white, 24.4% African American, 23.4% Hispanic, 39.4% BMI $\geq$ 30kg/m^2, 12.7% diabetes, 43.9% hypertension), median LSM was 4.9 kPA, 5.3% with F2+, 2.9% with F3+. The sensitivity of Karyon for F2+ was 84.9% (95%CI 75.8-90.9), higher than FIB-4 (10.8%, 95%CI 5.6-10.0), APRI (17.4%, 95%CI 10.9-20.0), or NFS (20.9%, 95% CI 13.7-30.0), all $p < 0.01$. The sensitivity of Karyon for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

F2+ was higher in women vs. men (87.8% vs. 82.2%) and higher in older patients (age ≥ 60: 90.2% vs. 50.0% in age 18-39). The AUROC of Karyon for F2+ was 0.664 (95%CI 0.591-0.737), similar to NFS and FIB-4 (Figure). The sensitivity of Karyon for F3+ was 88.9% (95%CI 79.6-94.3), higher than FIB-4 (15.3%, 95%CI 8.8-20.0), APRI (5.6%, 95%CI 2.2-10.0), or NFS (26.4%, 95%CI 17.6-30.0), all $p < 0.01$. The sensitivity of Karyon for F3+ was similar in men vs. women (89.2% vs. 88.6%) and higher in older patients (age ≥ 60: 91.9% vs. 85.7% in age 18-39). The AUROC of Karyon for F3+ was 0.846 (95%CI 0.789-0.903), significantly higher than FIB-4 (AUROC 0.671, 95% CI0.602-0.741, $p < 0.01$). **Conclusion:** A novel large language model trained using AASLD guidelines shows promise in accurately risk-stratifying MASLD/MASH patients with significant or advanced fibrosis, which can be integrated into existing care pathways to improve the efficiency of the MASLD/MASH cascade of care. Refining the Karyon model with longitudinal data and liver biopsy confirmation of liver fibrosis stage will further enhance its performance and real-world utilization.

Figure. Performance characteristics of Karyon Model compared to FIB-4, APRI, and NFS in Accurately Risk Stratifying MASH with F2+ or MASH with F3+.

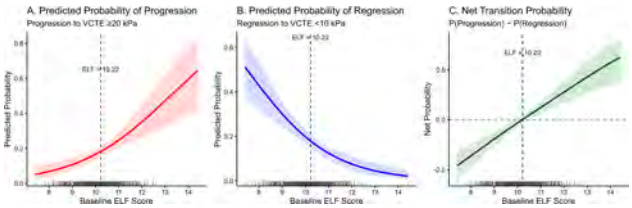
2310 | ELF PREDICTS VCTE PROGRESSION AND REGRESSION AT 1 YEAR IN PATIENTS WITH ADVANCED FIBROSIS DUE TO MASH



Matthew Gee[1] Jordan Feld[2] Keyur Patel[1], [1]University of Toronto, [2]Toronto General Hospital

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a leading cause of cirrhosis and liver-related mortality. Current clinical practice guidance from the AASLD and other societies recommends the use of non-invasive tests (NITs), including Enhanced Liver Fibrosis (ELF) and vibration-controlled transient elastography (VCTE), to identify patients at greatest risk of progression to cirrhosis and liver-related events, with widely used thresholds frequently implying clinical interchangeability between the two modalities. We previously demonstrated that baseline ELF predicts histologic fibrosis progression and regression at 1 year. In the current study, we evaluated whether baseline ELF similarly predicts VCTE-defined fibrosis progression and regression over 1 year. **Methods:** Data were pooled from 5 large placebo-controlled trials in patients with MASH and advanced fibrosis (NCT01672866, NCT01672879, NCT02462967, NCT03053050, NCT03053063). Patients with baseline VCTE ≥ 10 to < 20 kPa and available baseline ELF and 1-year VCTE were analyzed. Logistic regression estimated probabilities of progression at 1-year (VCTE ≥ 20 kPa) and regression (VCTE < 10 kPa) as a function of baseline ELF. Predicted and net transition probabilities were calculated across the ELF spectrum at the cohort mean baseline VCTE, with 95% CIs from 1000 bootstrap resamples. Odds ratios were used to assess associations between baseline ELF and VCTE progression/regression at 1 year. Rates of progression, regression, and mean ΔVCTE were calculated across ELF strata using established cutoffs: low (< 9.80), mid (≥ 9.80 to < 11.30), and high (≥ 11.30). Continuous ΔVCTE was modeled using least squares regression with baseline ELF, baseline VCTE, and their interaction. **Results:** 722 patients with F3&F4 MASH met inclusion criteria. 307 patients (43%) with VCTE ≥ 10 to < 20 kPa had discordant ELF scores (< 9.80 or ≥ 11.30). In logistic regression models, higher baseline ELF score was associated with increased odds of 1-year VCTE progression (OR 1.65, CI 1.32, 2.06), decreased regression odds (OR 0.57, CI: 0.46, 0.71), and a positive net transition toward progression, with progression and regression probabilities converging at ELF = 10.22 (see Figure). Across increasing ELF strata, progression rates increased (13.6% to 35.1%), regression rates decreased (30.4% to 8.8%), and mean ΔVCTE increased (−0.1 to +4.0 kPa). In a least squares linear regression model with an interaction term,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

baseline ELF was the strongest predictor of the direction of 1-year VCTE change. **Conclusion:** Baseline ELF identifies fibrotic activity associated with short-term VCTE change. These findings suggest that baseline discordance between ELF and VCTE may reflect active fibrotic remodeling rather than measurement disagreement, with VCTE primarily reflecting structural fibrosis burden and ELF capturing dynamic processes associated with future fibrosis transition.

2311 | SERIAL LIVER STIFFNESS MEASUREMENT TRAJECTORIES AND INCIDENCE OF MAJOR ADVERSE LIVER OUTCOMES (MALO) IN

Binu John[1] Dustin Bastaich[2] Bassam Dahman[2], [1]University of Miami and Miami VA, [2]Virginia Commonwealth University

Background: Vibration-controlled transient elastography (VCTE) derived liver stiffness measurements (LSMs) are validated non-invasive tools for fibrosis assessment and risk stratification in metabolic dysfunction-associated steatotic liver disease (MASLD). While baseline LSM predicts major adverse liver outcomes (MALO), the independent prognostic significance of longitudinal LSM change, beyond baseline values alone, remains less well characterized. We examined MALO incidence rates stratified by the magnitude of change in LSM between serial VCTE assessments in a large in a North American cohort of patients with MASLD **Methods:** This retrospective cohort study utilized data from the VHA from January 2011 to November 2025. Adults with MASLD who underwent VCTE >10 valid measurements were eligible. Exclusion criteria included alternative liver disease etiologies, < 6 months of follow-up, or MALO within 6 months of VCTE. Serial LSM analysis required a follow-up VCTE between 6 months and 5 years with no intervening MALO. LSM trajectory was categorized as a ≥20% increase, <20% change (stable), or ≥20% decrease relative to baseline. MALO was defined as the composite of decompensation, HCC, liver transplantation, or liver-related death. Poisson regression estimated MALO incidence rates (IR) per 1,000 person-years (PY) with 95% confidence intervals, stratified by LSM category. **Results:** Of 29,823 patients with MASLD who underwent VCTE and met study criteria (median age 63 years (IQR = 18), 90.9% male), 7,241 were included in the analytic sample with a follow-up LSM between 6 months and 5 years with 18,196 person-years of follow-up from the second LSM. In the reference group of patients with stable LSM (<20% change), the MALO incidence increased progressively from LSM <10 kPa (IR 8.38, 95% CI 6.32-11.12), to 10-14.9 (12.16, 7.06-20.95), 15-19.9 (IR 21.54, 10.27-45.18), 20-24.9 (IR 30.80, 12.82-73.99), and ≥25 kPa (IR 64.80, 39.07-107.49). In comparison, MALO rates were lower across all categories in patients with a >20% decrease in LSM: from <10 kPa (IR 5.61, 3.49-9.02), 10-14.9 (IR 11.13, 7.01-17.66), 15-19.9 (IR 9.53, 4.28-21.20), 20-24.9 (IR 11.94, 4.48-31.82), and ≥25 kPa (IR 35.88, 23.15-55.61). MALO rates were highest in patients with a 20% increase in LSM, across all categories, increasing from LSM <10 kPa (IR 9.25, 6.61-12.95), to 10-14.9 (IR 29.17, 18.13-46.92), 15-19.9 (IR 53.11, 25.32-111.41), 20-24.9 (IR 51.36, 19.27-136.83), and ≥25 kPa (IR 231.36, 124.49-430.00). **Conclusion:** In this large national cohort, longitudinal LSM trajectory significantly modified MALO risk with a ≥20% LSM increase markedly increasing MALO incidence, particularly in patients with advanced fibrosis, while LSM improvement was associated with substantial risk reduction. These findings support serial VCTE monitoring as a dynamic, clinically actionable tool for risk stratification in MASLD.

2312 | LIVERPRO SCORES CAPTURE SUBTLE BIOLOGICAL DETERIORATION ACROSS INCREASING LIVER STIFFNESS IN STEATOTIC LIVER DISEASE

Maja Thiele[1] Julie Astono[1] Katrine Bech[2] Helle Schnefeld[2] Peter Andersen[2] Katrine Thorhauge[2] Stine Johansen[2] Ida Villesen[2] Sönke Detlefsen[3] Johanne Hansen[4] Camilla Hansen[2] Katrine Lindvig[1] Mads Israelsen[2] Aleksander Krag[2], [1]Evido Health, Copenhagen, Denmark, [2]Center for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospital, [3]Department of Clinical Research, University of Southern Denmark, Odense, Denmark, [4]Center for Liver Research, Department of Gastroenterology and Hepatology, Odense University Hospit

Background: Patients with steatotic liver disease (SLD) often have normal routine liver blood tests until decompensated cirrhosis. It remains unclear whether fibrosis progression causes incremental biochemical changes. We examined the association between increasing liver stiffness and biochemical biomarkers in asymptomatic individuals with SLD and assessed whether multivariable blood-based scores capture gradients across liver stiffness strata. **Methods:** We combined data from two single-centre cohorts of individuals at risk of SLD. All individuals underwent vibration-controlled transient elastography (VCTE), with liver biopsy offered in those with elevated VCTE. Participants were grouped into five VCTE strata based on proposed MASH therapy thresholds: low (<8 kPa), mildly elevated (8–9.9 kPa), moderate (10–14.9 kPa), high (15–19.9 kPa), and very high (≥ 20 kPa). Within strata, normalised median differences were calculated for age, 10 routine blood biomarkers, FIB-4, and LiverPRO relative to the low-VCTE group. LiverPRO is a medical device software estimating the risk of $\geq$F2, $\geq$F3 and F4 fibrosis. We visualised differences as heatmaps and validated findings in the NHANES cohort and in the biopsy-confirmed fibrosis subgroup. **Results:** We included 7,110 participants, 51% females, mean age 57 ± 8 years, BMI 29 ± 6 kg/m^2, 9% type 2 diabetes. 92% belonged to the low-VCTE group, while 3.0%, 2.6%, 0.6% and 1.7% had mildly elevated, moderate, high, or very high liver stiffness. Among 572 participants with liver biopsy, median VCTE was 9.6 kPa (IQR 6.7-16.4) and 29% had $\geq$ F3.All 10 biomarkers showed gradients across increasing VCTE. ALP, ALT, AST, and GGT changed in mildly elevated VCTE, whereas albumin, bilirubin, INR, platelets, and sodium changed at VCTE ≥ 15 kPa. Total cholesterol was inversely associated with VCTE from early strata onward, independent of lipid-lowering therapy. Despite these patterns, median biomarker values remained within conventional reference ranges across nearly all strata.Multivariable scores tracked VCTE significantly better than individual biomarkers. LiverPRO-F2 increased across all strata, while LiverPRO-F3 and LiverPRO-F4 showed greater separation in high and very high VCTE groups, consistent with model tuning. FIB-4 changed mainly at very high VCTE, and only 53-57% of participants had FIB-4 ≥ 1.30 in the moderate and high VCTE strata. We confirmed findings in the biopsy subgroup and NHANES cohort. **Conclusion:** Reference ranges and single routine blood tests are poorly suited to detect subtle fibrosis-associated biochemical changes. LiverPRO integrated biochemical deviations into a signal reflecting increasing liver stiffness and fibrosis stage more precisely than FIB-4. These findings support algorithmic interpretation of routine blood tests for earlier identification of patients with SLD eligible for therapy.

2313 | MASH RESOLUTION INDEX 2.0 PREDICTS FIBROSIS IMPROVEMENT IN PATIENTS TREATED WITH THE DGAT2 ANTISENSE OLIGONUCLEOTIDE ION224: POST HOC ANALYSIS OF THE RANDOMIZED PLACEBO-CONTROLLED ION224-CS2 PHASE 2B TRIAL

Rohit Loomba[1] Erin Morgan[2] Keyvan Yousefi[2] Dan Li[2] Sanjay Bhanot[2], [1]University of California, San Diego, [2]Ionis Pharmaceuticals, Inc

Background: Liver biopsy remains the gold standard for assessing treatment response in metabolic dysfunction–associated steatohepatitis (MASH). The challenges of an invasive and costly biopsy limit clinical development efficiency; thus, validating non-invasive predictive biomarkers of histologic response represents a major unmet need. The MASH Resolution Index (MASHResInd) is a validated biomarker composite of MRI-PDFF, ALT, and AST that detects histologic MASH resolution. ION224, a liver-targeted antisense inhibitor of DGAT2, previously showed meaningful histologic benefit in patients with MASH and fibrosis (ION224-CS2). We used this trial to evaluate MASHResInd as a predictor of treatment response. **Methods:** ION224-CS2 (NCT04932512) was a phase 2b, randomized, double-blind, placebo-controlled trial in adults with biopsy-confirmed MASH and fibrosis (F1–F3) treated with ION224 or placebo every 4 weeks for 49 weeks. MASHResInd was calculated using the published equation in participants with paired baseline and end-of-treatment (EOT) MRI-PDFF, ALT, AST, and liver biopsy (post hoc analysis set). Endpoints were MASH resolution without worsening of fibrosis and $\geq$1-stage fibrosis improvement without worsening of steatohepatitis. Univariable and **multivariable logistic regression** (adjusted for baseline MRI-PDFF, ALT, AST, BMI, age, and type 2 diabetes: MASHResInd 2.0) were used to estimate discrimination (area under the ROC curve [AUC]) and to define "rule-out" (~90% sensitivity) and "rule-in" (~90% specificity) cutpoints. **Results:** The post hoc analysis set (n = 111) had mean age 53 yr, BMI 37.7 kg/m², and 49.5% had type 2 diabetes. Baseline mean MRI-PDFF, ALT, and AST were 22.6%, 58.6 U/L, and 39.6 U/L, respectively; all improved by EOT as previously reported. For MASH resolution without worsening of fibrosis, MASHResInd showed excellent discrimination (multivariable AUC 0.81; 95% CI 0.72–0.90). A high-sensitivity "rule-out" threshold identified a large subgroup with negative predictive value (NPV) 93%, while a high-specificity "rule-in" threshold enriched for responders with positive predictive value (PPV) 67% and specificity 90%. For fibrosis improvement without worsening steatohepatitis, MASHResInd alone had AUC 0.64 (0.53–0.76), and after multivariable adjustment (MASHResInd 2.0) significantly improved to 0.71 (0.59–0.82) which is among the highest discriminative biomarkers for predicting fibrosis improvement. **Conclusion:** In ION224-CS2, MASHResInd 2.0 meaningfully improved discrimination for fibrosis improvement compared with the original index, while preserving excellent performance for MASH resolution. This is a major advancement in predicting fibrosis improvement in early MASH trials. Simple rule-out and rule-in cutpoints yielded high NPV and useful enrichment for responders, supporting MASHResInd as a valuable tool for patient selection and monitoring in future trials.

2314 | THE MASH RESOLUTION INDEX FOR NON-INVASIVE DETECTION AND MONITORING OF MASH RESOLUTION: A SYSTEMATIC REVIEW AND POOLED ANALYSIS

Rahul Falodia[1] Ehsanullah Alokozay[2] Muhammad Junaid Azhar[3] Farhan Murtaza[4] Abdullah Imtiaz[5] Hamza Farooq Khan[6] Muhammad Ahmad Imran[3] Miriam Michael[3] Bacel Nseir[7] Wehbi Hanayni[6] Anand Deonarine[3], [1]All India Institute of Medical Sciences, Jodhpur, [2]Faculty of Medicine, Kandahar University, Kandahar, Afghanistan, [3]Howard University Hospital, [4]HCA Houston Healthcare/University of Houston Program, [5]Vassar Brothers Medical Center, [6]Corewell Health Dearborn, [7]HCA Houston healthcare/ University of Houston Program

Background: The MASH Resolution Index (MASHResInd) is a novel non-invasive score comprising baseline MRI-proton density fat fraction (MRI-PDFF), percentage change in MRI-PDFF, baseline alanine aminotransferase (ALT), change in ALT, and baseline aspartate aminotransferase (AST), developed to detect histological resolution of metabolic dysfunction-associated steatohepatitis (MASH) without worsening fibrosis. Despite its development in 2024, no synthesis of its diagnostic performance, comparative accuracy, and responsiveness to intervention exists. This systematic review and pooled analysis aimed to comprehensively evaluate the evidence for MASHResInd across pharmacological and non-pharmacological intervention settings. **Methods:** A systematic search of PubMed, Embase, and Cochrane databases was conducted through May 2026 using the terms "MASH Resolution Index," "MASHResInd," and related terms. Studies reporting diagnostic accuracy metrics or intervention-related changes in MASHResInd were included. Pooled sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated using a bivariate random-effects model. Comparative performance against the FibroScan-AST (FAST) score and individual non-invasive markers was assessed narratively. **Results:** Four studies comprising five independent cohorts (total n = 583 patients with biopsy-confirmed MASH) were included. Across two diagnostic cohorts (derivation n = 95; validation n = 163), MASHResInd achieved pooled AUCs of 0.81–0.83. At the rule-out cut-point (≤ -2.67), pooled NPV was 100% in the validation cohort, indicating high accuracy for excluding MASH resolution. At the rule-in cut-point (≥ -0.67), pooled PPV was 29%, reflecting the low prevalence of MASH resolution across cohorts (18–22%). In a head-to-head comparison (n = 160), MASHResInd significantly outperformed the FAST score (AUC 0.83 vs. 0.65; p = 0.001), with superior sensitivity, NPV, and positive likelihood ratio. In a pooled analysis of three aerobic exercise RCTs (n = 83), exercise training produced a significantly greater MASHResInd versus control (mean difference −0.66 units; p = 0.046), with 36% of exercising participants meeting the MASH resolution threshold versus 19% of controls (OR 2.2), representing the first evidence of MASHResInd responsiveness to a non-pharmacological intervention. **Conclusion:** MASHResInd demonstrates consistent and superior diagnostic accuracy for MASH resolution compared to existing non-invasive tests across independent pharmacological and exercise intervention cohorts. Its high NPV at the rule-out threshold supports its utility in sparing patients from unnecessary liver biopsies. Further validation in ethnically diverse cohorts, recently approved therapies, and long-term outcomes studies is warranted.

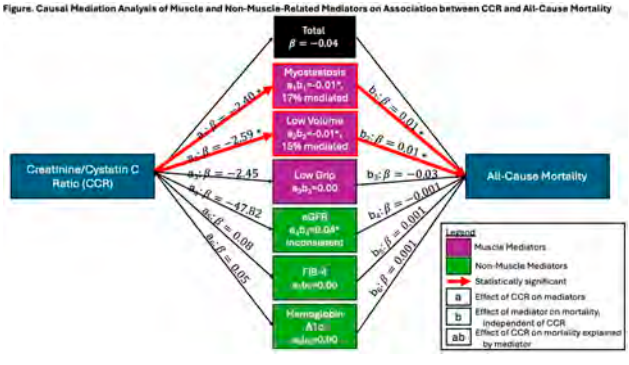
2315 | CREATININE-TO CYSTATIN-C RATIO (CCR) IS ASSOCIATED WITH ALL-CAUSE MORTALITY THROUGH MUSCLE PHENOTYPES AMONG ADULTS WITH SUSPECTED MASLD: A UK BIOBANK STUD

Melinda Wang[1] Dorothea Kent[1] Lisa Catalli[2] Giuseppe Cullaro[3] Mazen Nourredin[4] Naga Chalasani[5] Jennifer Lai[1], [1]UCSF, [2]University of California, San Francisco, [3]Columbia University, [4]Houston Methodist Hospital, [5]Indiana University Medical Center



Background: Metabolic syndrome myopathy, defined as dysfunction in mass, quality, and function, is common among MASLD patients and associated with poor outcomes. CCR is a readily available laboratory index for muscle-related measures in the general population. We

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

sought to evaluate the prognostic significance of CCR among MASLD patients and explore its relationship with muscle-related measures. **Methods:** Adults with suspected MASLD defined as Fatty Liver Index ≥ 60 with ≥ 1 cardiometabolic risk factor (CMRF) in UK Biobank. Baseline CCR was categorized into quartiles. A sub-cohort of patients who subsequently completed MRI was also identified. Logistic regression estimated adjusted prevalences of muscle-related measures: myosteatosis, low muscle volume, and low grip strength. Cox proportional hazards models examined CCR associations with all-cause mortality, adjusting for age, sex, BMI, diabetes, and FIB-4. Causal mediation analysis evaluated the relationship between muscle- and non-muscle-related measures (eGFR, FIB4, HbA1c) as mediators of the CCR-mortality relationship. **Results:** Of 134,321 MASLD participants, mean age was 57 (SD 8), 36% were women, and mean number of CMRFs was 4 (SD 1); 8,111 underwent subsequent abdominal MRI a median of 8 years (IQR 7–9) after baseline assessment. Patients with lower CCR were older (Q1: 59, Q2: 58, Q3: 57, Q4: 56 years), more likely women (Q1: 79%, Q2: 41%, Q3: 17%, Q4: 7%), and have greater CMRFs (Q1: 4.5, Q2: 4.3, Q3: 4.2, Q4: 4.0) ($p < 0.001$). Lower CCR was associated with higher adjusted prevalence of all muscle-related measures ($p < 0.001$). Higher CCR was also associated with decreased risk of all-cause mortality (aHR 0.87, 95%CI 0.85-0.88, p-value < 0.001). In causal mediation analyses, myosteatosis and low muscle volume each significantly mediated the CCR-mortality association, accounting for 17% (95%CI 4–55%, $p = 0.02$) and 15% (95%CI 1–58%, $p = 0.04$) of the total effect, respectively; low grip strength, and non-muscle-related measures were non-significant (Figure). **Conclusion:** Lower CCR is associated with worse metrics across all measures of metabolic syndrome myopathy and independently predicts all-cause mortality. This relationship appears to be, partially mediated through myosteatosis and low muscle volume. Future studies should assess the use of CCR as a laboratory-based tool to identify adults most vulnerable to metabolic syndrome myopathy who may benefit from targeted muscle-related therapy.

Figure. Causal Mediation Analysis of Muscle and Non-Muscle-Related Mediators on Association between CCR and All-Cause Mortality

2316 | ADAPT AND VCTE SHOW COMPARABLE PERFORMANCE FOR IDENTIFYING PATIENTS ELIGIBLE FOR THERAPY (F2-F3), ADVANCED FIBROSIS (F3-F4), AND CIRRHOSIS (F4) IN PATIENTS LIVING WITH MASH

Ida Lønsmann Sorribes[1] Peder Frederiksen[1] Cecilie Bager[1] Mikkel Werge[2] Liv Hetland[2] Nina Kimer[2] Marie Louise Nautrup Therkelsen[3] Morten Karsdal[1] Diana Leeming[1] Lise Lotte Gluud[4], [1]Nordic Bioscience, [2]Gastro Unit, Copenhagen University Hospital, Amager and Hvidovre Hospital, Hvidovre, Denmark, [3]Novo Nordisk Foundation Center for Protein Research & Gastro Unit, Copenhagen University Hospital, [4]Department of Clinical Medicine, Copenhagen University & Gastro Unit, Copenhagen University Hospital

Background: Following the recent approval of pharmacological therapies for metabolic dysfunction–associated steatohepatitis (MASH), there is a need for reliable non-invasive tests (NITs) to accurately identify distinct liver fibrosis subgroups to optimize patient stratification and treatment decisions. In particular, therapy-eligible fibrosis (F2-F3), advanced fibrosis (F3-F4), and cirrhosis (F4) represent clinically important subgroups. We evaluated the diagnostic performance of two well-established NITs for fibrosis assessment—the PRO-C3–based ADAPT algorithm and vibration-controlled transient elastography (VCTE)—in a Danish prospective outpatient cohort. **Methods:** This specialized single-centre, high-risk cohort included 259 patients with histologically confirmed F0–F4 MASLD from the Copenhagen Cohort of MASLD (CoCoMASLD; > 1,000 participants), recruited at Hvidovre Hospital between 2017 and 2022. Among participants, 51 (19.7%) had F2 fibrosis, 40 had F3 (15.4%), and 48 (18.5%) had cirrhosis (F4). ADAPT® was calculated using Elecsys® (Roche) PRO-C3, platelet count, age, and diabetes status, and VCTE by FibroScan® (Echosens). FIB-4 and standard biochemical parameters were collected. Predefined cut-offs for F3-F4 were ≥ 11 for ADAPT and ≥ 12 kPa for VCTE; for F4 ≥ 11 for ADAPT and ≥ 15 kPa for VCTE; for F2–F3 it was9–11

for ADAPT and 8–15 kPa for VCTE. Diagnostic performance was assessed by calculating AUROC, sensitivity, specificity, PPV, and NPV. **Results:** The cohort had a median age of 56 years (Q1–Q3: 43–64), 56.4% male, BMI 33.2 (29.4–38.1), and 41.3% had diabetes. Median AST was 48 U/L (34–63.2), ALT 69 U/L (40–98), PRO-C3 39.4 ng/mL (33–51), ADAPT 9 (7.8–10.9), and VCTE 10.3 kPa (7–15.4). For both fibrosis subgroups F3-F4/F4 alone, ADAPT and VCTE demonstrated strong diagnostic accuracy: AUROC 83/84% for ADAPT (sens 0.68/0.65, spec 0.85/0.86, PPV 70/51%, NPV 0.84/91%) and 88/88% for VCTE (sens 0.76/0.77, spec 0.83/0.84, PPV 70/52%, NPV 87/94%), with no statistically significant differences between tests (AUROC $p = 0.10/0.25$; sens $p = 0.23/0.18$, spec 0.75/0.64). While PPV was modest, limiting the ability to rule in cirrhosis (~50%), NPV was high (~91%) for ruling out. For F2–F3 fibrosis, diagnostic performance was lower: ADAPT sensitivity/spec 0.31/0.78, PPV 43%, NPV 68%; VCTE 0.61/0.67, PPV 50%, NPV 75%. Sensitivity was higher for VCTE ($p < 0.001$), whereas specificity was higher for ADAPT ($p = 0.017$). Both tests demonstrated modest rule-in capability, but some capability of ruling out F2–F3 patients (NPV 68-77%). **Conclusion:** ADAPT and VCTE performed similarly in detecting F2-F3, F3-F4, or F4 fibrosis, one being blood-based and the other imaging-based. These findings support the use of NITs for non-invasive fibrosis assessment independently of liver fibrosis subgroup.

2317 | 40% OF FIBROTIC MASLD MISSED BY GUIDELINE-BASED SCREENING: COMPOSITE METABOLIC CRITERIA OPTIMIZE THE SENSITIVITY-EFFICIENCY TRADEOFF IN A PROSPECTIVE COMMUNITY COHORT

Alina Allen[1] Rachel Canning[2] Olivia Bobek[2] Maysa Eslami[2] Sudhakar Venkatesh[1] Joanne Benson[2] Meng Yin[2] Richard Ehman[1] Graham Rondell[2] Fang-Shu Ou[2], [1]Mayo Clinic Rochester, [2]Mayo Clinic

Background: Current guidelines recommend screening for fibrotic MASLD by identifying high-risk metabolic risk factors followed by FIB-4 scoring. Community-level performance of this strategy and evidence-based alternatives are poorly characterized. Prior comparisons focus on sensitivity alone, neglecting referral burden. We evaluated 12 screening strategies using a dual sensitivity-efficiency framework. **Methods:** This is a cross-sectional analysis of the TONES prospective community screening cohort (Olmsted County, MN). Between 2018-2026, all underwent MRI-PDFF and MRE for MASLD screening, irrespective of metabolic burden or age; liver biopsy was performed in participants with abnormal MRE and interpreted by one study pathologist blinded to imaging results. Fibrotic MASLD was defined by histologic fibrosis stage ≥ 2 or MRE LSM ≥ 3.1 kPa. MetSyn2 was defined as ≥ 2 metabolic syndrome components. Twelve strategies were evaluated for sensitivity, specificity, percent referred, and number-needed-to-screen (NNS). Strategies achieving $\geq 75\%$ sensitivity were ranked by NNS to identify optimal efficiency. **Results:** Among 621 adults (mean age 53 years; 56% women; 90% White; mean BMI 29.2 kg/m²; 10% diabetes), MASLD and fibrotic MASLD were present in 254/621 (41%) and 25/621 (4%) of the cohort, respectively; 13/25 (52%) of fibrotic MASLD had diabetes. The guideline-based strategy (metabolic risk factor identification followed by FIB-4 ≥ 1.3) achieved only 60% sensitivity, referred 8% of the population (NNS 3.3, Figure), and missed all 6 fibrotic MASLD cases under age 50. Among those with diabetes and fibrotic MASLD, 8/13 (62%) had normal AST and ALT, representing patients who would not undergo further evaluation in routine clinical practice. Strategies achieving $\geq 75\%$ sensitivity included MetSyn ≥ 2 (sensitivity 96%, NNS 8.8, 34% referred) and Age ≥ 50 AND MetSyn ≥ 2 (sensitivity 76%, NNS 7.3, 22% referred), both substantially outperforming current guidelines. **Conclusion:** Guideline-based FIB-4 screening misses 40% of community fibrotic MASLD, including all cases in adults under 50, and 62% of diabetic individuals with fibrotic MASLD. Composite metabolic criteria (MetSyn ≥ 2 alone or combined with age ≥ 50) represent the leading alternatives, offering superior sensitivity with acceptable referral burden; the optimal choice will depend on local referral capacity and acceptable sensitivity threshold. These data provide a framework for evidence-based guideline revision in community-level fibrotic MASLD screening.

Background: Some patients diagnosed with MASLD by imaging show steatosis grade S0 on liver biopsy, creating a diagnostic gray zone. We investigated the frequency, causes, and clinical implications of this imaging-biopsy discordance. **Methods:** Steatosis 0 was defined as imaging-detected MASLD with biopsy-defined steatosis grade S0. We analyzed a global follow-up cohort of 3,273 biopsy-confirmed individuals

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

from 16 centers to assess long-term outcomes and a paired-biopsy cohort of 1,865 patients from 40 centers to evaluate histologic evolution. Possible mechanisms were explored using MRI-PDFF assessment of segmental liver fat distribution, blinded re-reading of biopsy slides by multiple pathologists, and comparison of serial sections from the same tissue sample. **Results:** Among 3,273 individuals, 123 (3.8%) had steatosis 0. Of these, 36 (29.3%) had advanced fibrosis, consistent with burnt-out MASLD, and this subgroup accounted for all observed liver-related events; no liver-related events occurred in patients without advanced fibrosis during a median follow-up of 54 months. In the paired-biopsy cohort, 74 of 1,865 patients (4.0%) had steatosis 0 at baseline, and 69 of 74 (93.2%) remained within the S0-S1 range on follow-up biopsy. Among 516 patients assessed by MRI-PDFF, 42 showed at least one liver segment with PDFF-defined S0 despite overall MASLD, supporting heterogeneous fat distribution as a source of biopsy underestimation. Re-reading of 25 biopsy sections showed that 3-6 cases were reclassified from S0 to S1, and serial section analysis from 10 liver samples further demonstrated intra-sample variability. **Conclusion:** Imaging-defined MASLD with histological S0 is uncommon but clinically important. This phenotype reflects multiple mechanisms, including burnt-out MASLD, heterogeneous hepatic fat distribution, and pathologic sampling or reader variability. Fibrosis stage is critical for risk stratification: patients without advanced fibrosis appear low risk, whereas those with advanced fibrosis require closer attention.

2319 | SPONTANEOUS NON-INVASIVE TEST RESPONSE IN UNTREATED T2DM-MASLD: REAL-WORLD BENCHMARKS FOR MASH TRIAL INTERPRETATION

Mona Ismail[1], [1]Imam Abdulrahman Bin Faisal University

Background: AASLD-endorsed NIT response thresholds, ≥30% relative reductions in liver stiffness measurement (LSM) and controlled attenuation parameter (CAP), and ≥20% ALT reduction are used for MASH pharmacotherapy monitoring. Spontaneous (placebo-equivalent) achievement of these thresholds in untreated type 2 diabetes (T2DM)–MASLD is poorly quantified. We measured one-year spontaneous response rates and their predictors to provide real-world benchmarks for trial interpretation. **Methods:** This was a retrospective analysis of 142 adults with T2DM-MASLD who had paired FibroScan-derived LSM and CAP, weight, and laboratory data at baseline and 1-year follow-up ±2 months. Patients on GLP-1 receptor agonists, SGLT2 inhibitors, and thiazolidinediones were excluded. Primary endpoints were spontaneous LSM ≥30% and CAP ≥30% relative reduction. Secondary endpoints included ALT ≥20% reduction, dual LSM+CAP response, triple LSM+CAP +ALT response, weight-stratified response, and predictors of LSM response using multivariable logistic regression. **Results:** The mean age was 54.7 ± 11.3 years, with 58.5% female; BMI was 33.1 ± 5.8 kg/m²; median baseline LSM was 5.9 kPa (IQR 4.2–9.4), and CAP was 306 dB/m (IQR 265–337). Spontaneous thresholds achievement were LSM ≥30% in 28/142 patients (19.7%; 95% CI, 13.4–26.8), and CAP ≥30% in 11/142 (7.7%; 95% CI, 3.5–12.7). Dual LSM+CAP response was uncommon (4/142; 2.8%; 95% CI, 0.7–5.6), and triple response occurred in 2/142 (1.4%). While, ALT r ≥20% response occurred in 64/142 patients (45.1%; 95% CI, 36.6–53.5) (Figure 1). LSM response was independently predicted by higher baseline LSM (advanced fibrosis ≥9.7 kPa: OR 6.92, 95% CI 2.56–18.74, $p < 0.001$) and inversely by hypertension (OR 0.30), but not by weight loss ($p = 0.203$). CAP response was weight-dependent (22.0% with ≥5% loss vs 0% if weight-stable, $p < 0.001$) and was predicted only by baseline BMI (OR 1.11, $p = 0.033$). In contrast, LSM response occurred in 15.6% of weight-stable patients and 29.3% of those losing ≥5% body weight. **Conclusion:** In T2DM-MASLD patients receiving no approved MASH-directed pharmacotherapy, spontaneous achievement of NIT response thresholds occurs at clinically meaningful rates, particularly for ALT and LSM. ALT responses largely reflect within-normal-range biochemical fluctuations rather than a true inflammatory signal. LSM improvement was strongly associated with baseline fibrosis severity rather than weight change, the CAP response, by contrast, required weight loss. These real-world background rates provide a benchmark for interpreting NIT-based endpoints in MASH trials and clinical practice, particularly in populations enriched for advanced fibrosis.

Figure 1. Prevalence of Spontaneous Achievement of AASLD-Endorsed NIT Response Thresholds in Untreated T2DM-MASLD (N=142)

2320 | CLINICAL SUBTYPES OF COMPENSATED CIRRHOSIS IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOHEPATITIS (MASH) IDENTIFIED BY UNSUPERVISED MACHINE LEARNING

Peiyun Ni[1] Olga Demler[2], [1]Massachusetts General Hospital, [2]Brigham and Women's Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a heterogeneous condition driven by genetic, environmental, and metabolic factors. Although distinct phenotypes, such as insulin resistance–associated and lean MASLD, were described previously, differential risks of decompensation of the subgroups remain unclear. This study applies unsupervised machine learning to classify patients with compensated cirrhosis in metabolic dysfunction-associated steatohepatitis (MASH) and evaluate subgroup-specific risks of decompensation and hepatocellular carcinoma (HCC). **Methods:** We conducted a retrospective cohort study of adults with compensated MASH cirrhosis in the Mass General Brigham system (2005–2024). K-means clustering was performed to identify clinical phenotypes based on normalized clinical and laboratory variables within 3 months of cirrhosis diagnosis. The optimal cluster number was determined by the elbow method and Silhouette scores. Cox regression models were used to compare risks of decompensation and HCC across clusters. **Results:** Two clinically distinct clusters were identified among 636 MASH patients with compensated cirrhosis, with a median follow-up of 4.2 years. Cluster 1 (N = 547) was characterized by older age (mean age 60.8 vs. 53.5) and higher body mass index (BMI) (32.1 vs. 28.1 kg/m^2), whereas cluster 2 (N = 89) had higher liver enzymes (mean ALT 115.9 vs. 43.4 U/L), lower albumin level (3.5 vs. 4.1 g/dL), higher low-density lipoprotein (LDL) (91.8 vs. 87.8 mg/dL), and lower platelet count (154,400 vs. 176,700/μL) (Table 1). When compared to cluster 1, cluster 2 showed an increased risk of decompensation (HR 1.21, 95% CI 1.07–1.37), but a similar risk of HCC (HR 1.10, 95% CI 0.63-1.58). **Conclusion:** We identified two distinct clinical phenotypes of MASH patients with compensated cirrhosis: one characterized by older age and higher BMI, and the other by higher liver enzymes, lower albumin, higher LDL, and lower platelet. The second group had an increased risk of decompensation but a similar risk of HCC. These findings reveal distinct risk profiles within MASH, underscoring the need for tailored management strategies, and warrant validation in larger cohorts.

Table 1: Phenotype characteristics of two clusters of patients with compensated cirrhosis from metabolic dysfunction-associated steatotic liver disease (MASLD)

Cluster	1	2
N	547	89
Female, N (%)	253 (46.3%)	33 (37.1%)
Age, mean (SD), years	60.8 (10.7)	53.5 (11.9)
BMI, mean (SD), kg/m^2	32.1 (6.6)	28.1 (6.8)
AST, mean (SD), U/L	47.4 (23.1)	138.7 (82.6)
ALT, mean (SD), U/L	43.4 (26.2)	115.9 (101.4)
ALP, mean (SD), U/L	104.5 (43.2)	220.1 (136.1)
Total bilirubin, mean (SD), mg/dL	0.8 (0.5)	2.9 (4.3)
Albumin, mean (SD), g/dL	4.1 (0.4)	3.5 (0.7)
Creatine, mean (SD), mg/dL	0.9 (0.3)	0.8 (0.3)
Sodium, mean (SD), mEq/L	139.2 (2.5)	137.3 (2.8)
Hemoglobin A1c, mean (SD), %	6.5 (1.2)	6.2 (1.2)
HDL, mean (SD), mg/dL	50.2 (15.8)	49.7 (20.5)
LDL, mean (SD), mg/dL	87.8 (23.4)	91.8 (25.1)
Platelet, mean (SD), x10^3/μL	176.7 (72.7)	154.4 (88.9)
INR, mean (SD)	1.2 (0.2)	1.3 (0.3)

SD: standard deviation; BMI: body mass index; AST: aspartate transaminase; ALT: alanine transaminase; ALP: alkaline phosphatase; HDL: high-density lipoprotein; LDL: low-density lipoprotein; INR: international normalized ratio.

2321 | PFHXS IS INVERSELY ASSOCIATED WITH HEPATIC FIBROSIS IN STEATOTIC LIVER DISEASE: A CROSS-SECTIONAL ANALYSIS OF NHANES 2017–2020

Jonathan Hong[1] Eduardo Reyes[1], [1]Mountain Area Health Education Center

Background: Per- and polyfluoroalkyl substances (PFAS) have consistently been associated wtih hepatotoxicity, with emerging evidence of sex-dependent effects on liver disease. However, the association between PFAS exposure and hepatic fibrosis across steatotic liver disease (SLD) subtypes defined by the 2023 multisociety nomenclature has not been examined. We evaluated the association between National Academies of Sciences, Engineering, and Medicine (NASEM) defined PFAS exposure and Vibration-Controlled Transient Elastography (VCTE) assessed fibrosis in Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) and Metabolic Dysfunction and Alcohol-Associated Liver Disease (MetALD). **Methods:** We analyzed NHANES 2017–March 2020 adults with VCTE-defined steatosis (CAP $\geq$275 dB/m), excluding viral hepatitis, pregnancy, and alcoholic liver disease (ALD) range alcohol use. MASLD and MetALD were classified per the 2023 Delphi consensus criteria. NASEM PFAS sum was calculated from seven serum analytes (PFOS, PFOA, PFHxS, PFNA, PFDA, PFUnDA, MeFOSAA). The primary outcome was liver stiffness measurement (LSM) $\geq$8 kPa. Survey-weighted logistic and linear regression assessed log-transformed NASEM sum with fibrosis outcomes, adjusting for age, sex, race/ethnicity, BMI, diabetes, and poverty-

income ratio. Sex-stratified and individual PFAS component analyses were performed. **Results:** Among 3,444 adults with steatosis, 3,059 met MASLD and 151 met MetALD criteria. Complete PFAS data were available for 906 MASLD and 48 MetALD participants. Median NASEM sum was similar across subtypes (MASLD 8.5, MetALD 8.6 ng/mL). Overall, log-transformed NASEM sum was not associated with LSM $\geq$8 kPa (aOR 0.71, 95% CI 0.39–1.30; p = 0.245) or continuous LSM in MASLD (β −1.36 kPa, 95% CI −3.51 to 0.79; p = 0.193) or MetALD (β 0.08 kPa, 95% CI −0.72 to 0.88; p = 0.811). In sex-stratified analysis, the PFAS–fibrosis association was directionally stronger in males (aOR 0.59, 95% CI 0.26–1.35; p = 0.192) compared to females (aOR 0.90, 95% CI 0.21–3.98; p = 0.868), though neither reached significance. Among individual PFAS components, PFHxS was inversely associated with significant fibrosis (aOR 0.60, 95% CI 0.39–0.94; p = 0.029). No significant PFAS-by-SLD subtype interaction was observed (p = 0.483). **Conclusion:** In this early application of the NASEM PFAS framework to the 2023 SLD nomenclature, total PFAS exposure was not associated with VCTE-defined hepatic fibrosis in MASLD or MetALD. However, PFHxS was significantly and inversely associated with fibrosis, suggesting compound-specific effects that may be obscured by mixture-level analyses. PFHxS signal and sex-stratified trends warrant confirmation in larger, longitudinal cohorts with direct fibrosis assessment.

2322 | ENRICHMENT PANEL DESIGNED FOR THE STUDY OF CHRONIC LIVER DISEASE: TARGETED METHYLATION CFDNA ASSAY ENABLES COST-EFFECTIVE ULTRA-DEEP SEQUENCING FOR IDENTIFICATION OF TREATMENT-ELIGIBLE MASH PATIENTS

Jörn Schattenberg[1] Hamed Amini[2] Pourya Naderi Yeganeh[3] Amin Naghdloo[2] Leila Bazargan[2] Fereshteh Abedini[2] Chong Lu[2] Reshma Shringarpure[4] Lynn Lipps[4] Brent Neuschwander-Tetri[5] Rohit Loomba[6] Manal Abdelmalek[7] Anna Mae Diehl[8] Soheil Damangir[2], [1]Saarland University Medical Center, [2]Hepta Bio, Inc., [3]Harvard Medical School, [4]Akero Therapeutics, Inc, [5]Saint Louis University, [6]University of California, San Diego, [7]Mayo Clinic Rochester, [8]Duke University

Background: We previously reported LiquidTransformer (LT), an AI model on whole-methylome cell-free DNA (cfDNA) sequencing that outperforms guideline non-invasive tests (NITs) for detecting significant fibrosis (F2+), treatment-eligible fibrosis (F2-F3), and at-risk MASH. We designed a cfDNA methylation enrichment panel derived from LT for the study of metabolic diseases and chronic liver disease, with MASH diagnosis as the initial application. The compact footprint enables cost-effective ultra-deep sequencing. Here we test whether diagnostic performance is retained when the genome-wide footprint is reduced by more than two orders of magnitude. **Methods:** Panel regions were selected to capture disease related methylation signal, by integrating LT feature attributions with plasma and liver tissue methylation from training samples. The panel covers less than 1% of the genome. Panel content was compared at CpG and base-pair level to all major commercial methylation panels combined, including large methylome-wide research assays. Performance of three detections were assessed: significant fibrosis, treatment-eligible fibrosis, and at-risk MASH. For each task we cross-validated three variants across three independent cohorts (Duke MASLD Biobank, UMC Mainz, Akero SYNCHRONY), on samples held out from panel design: whole-methylome LT, the panel, and the panel subset overlapping commercial content. **Results:** Across all three tasks, the panel matched whole-methylome LT (AUC panel vs whole-methylome: F2+ 0.90 vs 0.90; F2–F3 0.77 vs 0.76; at-risk MASH 0.79 vs 0.78), with point estimates equivalent. The commercial-overlap subset showed substantially lower AUC across all tasks (F2+ 0.81, F2–F3 0.69, at-risk MASH 0.72), indicating that regions outside existing commercial panels carry substantial diagnostic signal. The majority of panel content, by CpG and base-pair, lay outside the combined coverage of all commercial methylation panels surveyed. **Conclusion:** A compact cfDNA methylation panel designed for chronic liver disease accurately diagnoses MASH and fibrosis across three cohorts. The performance depends on regions selected by LT that are absent from existing commercial methylation panels. Whole-methylome sequencing remains the discovery substrate; the targeted panel supports cost-effective ultra-deep cfDNA methylation profiling, translating validated diagnostic signals into a deployable assay and a scalable tool for broader chronic liver disease investigation.

2323 | AI-ASSISTED ULTRASOUND FAT FRACTION OUTPERFORMS CONVENTIONAL ULTRASOUND MODELS FOR LIVER FAT QUANTIFICATION: A PROSPECTIVE STUDY USING MRI-PDFF AS THE REFERENCE STANDARD

Negaur Iranpour[1] Amir Hossein Gougol[1] Gary Ng[2] Ronald Hidalgo[3] Manish Dhyani[4] Madhvi Yadav[4] Rotonya Carr[4], [1]Stanford University, [2]Samsung HME, [3]Springfield Clinic, [4]University of Washington

Background: Noninvasive quantification of hepatic steatosis is essential for diagnosing and monitoring MASLD. Although MR-PDFF is the most accurate noninvasive method, its use is limited by cost and availability. Ultrasound fat fraction Noninvasive quantification of hepatic steatosis is essential for diagnosing and monitoring MASLD. Although MR-PDFF is the most accurate noninvasive method, its use is limited by cost and availability. Ultrasound fat fraction (USFF) offers a low-cost, real-time point-of-care alternative, but has limited accuracy. In this study, we aim to assess the agreement of different models of USFF (DeepUSFF and conventional USFF) with MR-PDFF. **Methods:** This multicenter prospective study included patients from Stanford University, Springfield Clinic, and the University of Washington. Adults aged 18–75 years with MASLD confirmed by MR-PDFF were included. Patients with alternative causes of chronic liver disease were excluded. Ultrasound examinations were performed within 4 weeks of MR-PDFF.USFF was assessed using three models: (1) tissue attenuation imaging (TAI) alone, which measures ultrasound signal attenuation through liver tissue; (2) a multiparametric USFF (mUSFF) model combining TAI and tissue scatterer density; and (3) Deep-USFF, a deep learning–based AI model that analyzes raw radiofrequency ultrasound data to extract liver features and generate fat fraction estimates trained against MR-PDFF. Correlations with MR-PDFF were assessed using Pearson correlation coefficients, and agreement analyses were performed using Bland-Altman methods. **Results:** A total of 47 patients from three institutions were enrolled. The mean age was 58.7 years,

the mean BMI was 33.8 kg/m², 65% were female, and 34% had diabetes.In pooled analysis, TAI-only and mUSFF demonstrated moderate correlation with MR-PDFF (TAI-R = 0.67; mUSFF R = 0.63). After applying DeepUSFF model, agreement has significantly improved (DeepUSFF R = 0.90). Site-specific analyses demonstrated similar findings. Bland-Altman analysis further confirmed the superiority of DeepUSFF compared with multiparametric [GN1] USFF. Deep-USFF demonstrated minimal bias relative to MR-PDFF (mean bias 0.11%) with narrower limits of agreement (−6.73% to 6.96%). In comparison, multiparametric USFF demonstrated greater variability and wider limits of agreement (mean bias −0.88%; −11.91% to 10.14%). **Conclusion:** Deep learning–assisted USFF estimation substantially improves agreement with MR-PDFF compared with conventional multiparametric USFF. DeepUSFF may represent a promising point-of-care noninvasive tool for steatosis assessment and longitudinal monitoring in MASLD.

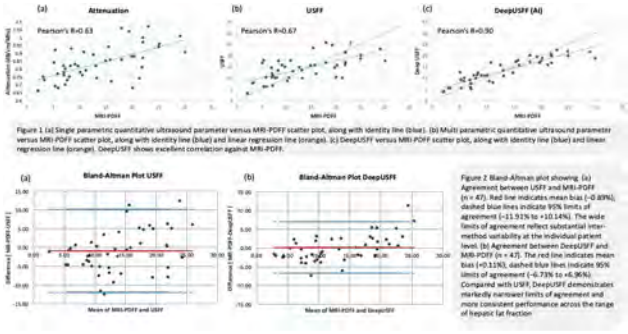

Figure 1. (a) Single parametric quantitative ultrasound parameter versus MRI-PDFF scatter plot, along with identity line (blue). (b) Multi parametric quantitative ultrasound parameter versus MRI-PDFF scatter plot, along with identity line (blue) and linear regression line (orange). (c) DeepUSFF versus MRI-PDFF scatter plot, along with identity line (blue) and linear regression line (orange). DeepUSFF shows excellent correlation against MRI-PDFF.

Figure 2 Bland-Altman plot showing. (a) Agreement between USFF and MRI-PDFF (n = 47). Red line indicates mean bias (−0.89%), dashed blue lines indicate 95% limits of agreement (−11.91% to +10.14%). The wide limits of agreement reflect substantial inter-method variability at the individual patient level. (b) Agreement between DeepUSFF and MRI-PDFF (n = 47). The red line indicates mean bias (+0.11%), dashed blue lines indicate 95% limits of agreement (−6.73% to +6.96%). Compared with USFF, DeepUSFF demonstrates markedly narrower limits of agreement and more consistent performance across the range of hepatic fat fraction

2324 | INTEGRATED CODING AND NON-CODING TRANSCRIPTOMICS IDENTIFY A TGFB1–E2F FIBROGENIC REGULATORY AXIS IN AFRICAN AMERICANS WITH MASLD

Tanmoy Mondal[1] Coleman Smith[2] Christopher Loffredo[3] Ruth Quartey[1] Charles Howell[4] Brent Korba[3] Zaki Sherif[1] Gail Nunlee-Bland[1] Leanna Rucker[3] Gemeyel Moses[1] Ghosh Ghosh[1], [1]Howard University, [2]Georgetown University Hospital, [3]Georgetown University, [4]Howard University College of Medicine

Background: The prevalence of MASLD in the US has risen to 30%. African Americans (AAs) demonstrate paradoxically lower MASLD prevalence despite higher metabolic risk burdens, suggesting the presence of distinct molecular regulatory mechanisms. Our previous transcriptomic studies identified dysregulation of T*GFB1* and *E2F*-associated signaling in AA MASLD patients. However, the contribution of non-coding RNA (ncRNA) networks regulating these pathways remains poorly characterized. This study integrated coding and non-coding whole-blood transcriptomic datasets to identify coordinated fibrogenic regulatory mechanisms in AA MASLD. **Methods:** Whole-blood transcriptomic datasets from AA MASLD participants and matched controls were integrated from two independent studies. The coding transcriptomic cohort included 23 MASLD and 24 controls, while the ncRNA cohort included 18 MASLD and 20 controls. MASLD was confirmed by imaging and/or liver biopsy, demonstrating hepatic steatosis with metabolic dysfunction. Global transcriptomics was performed using Affymetrix arrays, whereas miRNA/lncRNA profiling was performed using small RNA sequencing. Differential expressions, Ingenuity Pathway Analysis (IPA), canonical pathway (CP), upstream regulator, and network analyses were performed. Selected miRNAs were validated using qRT-PCR. **Results:** We identified hepatic fibrosis signaling as the top overlapping CP across both coding and ncRNA datasets. Coding transcriptomics demonstrated activation of TGFB1-centered fibrogenic networks associated with *hepatic stellate cell activation*, *IL-6 signaling*, and *hepatocellular carcinoma pathways*, while E2F-associated transcriptional programs were concurrently dysregulated within fibrosis- and cell cycle-related pathways. ncRNA transcriptomics identified 35 significantly dysregulated miRNAs and 28 ncRNAs in MASLD subjects. Among the most significant fibrosis-associated miRNAs, miR-218-5p, miR-370-3p, miR-1343-5p, miR-224-5p, and miR-193a-5p were consistently downregulated, whereas miR-206 was significantly upregulated. IPA integration demonstrated overlap between dysregulated miRNAs and pathways involving AMPK/TGFB signaling, epithelial–mesenchymal transition, and hepatic fibrosis/hepatic stellate cell activation. Additionally, dysregulated lncRNAs, including LINC01138, LINC00461, and SNHG29, were associated with proliferative signaling hubs involving *AKT*, *YAP1*, and *EZH2*. **Conclusion:** Integrated coding and ncRNA transcriptomics identified a coordinated TGFB1–E2F regulatory axis associated with hepatic fibrosis signaling in AA MASLD patients. Dysregulated miRNA and lncRNA networks appear to modulate key fibrogenic and proliferative pathways, supporting whole-blood transcriptomics as a minimally invasive platform for ancestry-informed biomarker discovery and mechanistic stratification in MASLD.

2325 | A PRIVACY-PRESERVING SYNTHETIC KOREAN MASLD COHORT PRESERVES FIBROSIS RISK STRATIFICATION AND NONINVASIVE TEST PERFORMANCE

Soon Kyu Lee[1] Jaejun Lee[2] Soon Woo Nam[2] Jung Hyun Kwon[2] W. Ray Kim[3] Joseph Ahn[4], [1]College of Medicine, The Catholic University of Korea, [2]The Catholic University of Korea, [3]Mayo Clinic Arizona, [4]Mayo Clinic

Background: SAFE has been proposed as an alternative to FIB-4 for MASLD risk stratification, but Asian validation is limited. Privacy-preserving synthetic data could enable international collaboration with patient-level data, but its ability to preserve clinical findings is uncertain. We evaluated whether TabDDPM-generated synthetic data could reproduce fibrosis risk stratification and comparative SAFE vs FIB-4 performance in a Korean MASLD FibroScan cohort. **Methods:** We applied MASLD criteria to a single-center Korean FibroScan cohort (n = 2,655; 23 continuous and 12 categorical baseline variables) and trained a TabDDPM model to generate 10,000 synthetic patients. Fidelity was assessed by standardized mean differences (SMD), Wasserstein distance, correlation preservation, and PCA/t-SNE/UMAP. Privacy was evaluated by exact-copy detection, distance-to-closest-record, k-anonymity, and re-identification risk. Clinical validity was tested by comparing FIB-4 and SAFE—neither used as model input—for advanced fibrosis (LSM ≥ 8 kPa) and cirrhosis (LSM ≥ 15 kPa), two-step screening pathways, and LSM-stratified Kaplan–Meier curves for decompensation, HCC, and death. **Results:** The synthetic cohort closely reproduced real-data distributions (mean |SMD| = 0.050, correlation preservation r = 0.974) (Figure A). Privacy was favorable: 0 exact copies, median k-anonymity = 31, re-identification risk 0.56%. Notably, downstream-derived variables not seen by the model (FIB-4, SAFE, LDL, globulin) matched real distributions (Figure B). LSM-stratified KM curves preserved dose-response gradients for decompensation, HCC, and death (log-rank $p < 0.001$), though absolute event rates were attenuated given low source event counts (Figure C). SAFE outperformed FIB-4 for significant fibrosis in both real (AUROC 0.804 vs 0.747) and synthetic data (0.844 vs 0.781), with similar superiority for advanced fibrosis (0.890 vs 0.857 real; 0.919 vs 0.892 synthetic) (Figure D). In two-step screening, SAFE ruled out more patients (65.6% real, 69.7% synthetic) than FIB-4 (51.3%, 50.4%) with higher diagnostic yield and specificity but lower sensitivity. **Conclusion:** In a Korean MASLD FibroScan cohort, TabDDPM-generated synthetic data preserved baseline distributions, multivariable correlation structure, privacy, and clinically meaningful fibrosis risk stratification, while reproducing SAFE's superior discrimination over FIB-4. These findings support synthetic Korean MASLD cohorts as privacy-preserving tools for international validation of noninvasive fibrosis algorithms; larger datasets are needed for rare-event outcome modeling.

2326 | MULTI-OMICS DEFINE DISTINCT FIBROGENIC REMODELING ENDOTYPES IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS

Zoltan Derdak[1] Ying-Wooi Wan[1] Mingshi Gao[1] Stephen Hoang[2] Banishree Saha[3] Cristina Alonso[4] Alejandro Montilla[4] Maria Martinez-Vives[4] Vandana Gupta[1] Lara Murray[5] Shima Nofallah[5] Guillaume Chhor[5] Dean Tai[6] Kutbuddin Akbary[6] Regina Lemus[1] Andressa de Zawadzki[7] Diana Leeming[7] Morten Karsdal[8] Jennifer Sayne[2] Amon Asgharpour[2] Juan Pablo Arab[2] Vinayagam Arunachalam[1] Haakan Wennbo[1] Paresh Thakker[1] Arun Sanyal[2], [1]Takeda Development Center Americas, Inc., [2]Virginia Commonwealth University, [3]Takeda Pharmaceuticals, [4]Rubio Metabolomics, S.L.U., [5]PathAI, [6]HistoIndex Pte Ltd, [7]Nordic Bioscience A/S, [8]Nordic Bioscience

Background: In Metabolic Dysfunction-Associated Steatohepatitis (MASH), progression to advanced fibrosis and cirrhosis occurs in some but not everyone, and fibrosis stage may not fully reflect fibrogenic activity. We identified inflammatory-enriched ("hot") and lower-inflammatory ("cold") fibrosis endotypes using AI-derived macrophage density. However, biologic profiles of these endotypes across fibrosis stages remain incompletely characterized.Aims: (1) To define subpopulations across fibrosis stages of MASH with distinct inflammatory-fibrogenic profiles using digital pathology, and (2) to identify the biological basis of these fibrosis-related endotypes. **Methods:** Quantitative digital pathology using LiverExplore (For Research Use Only. Not for use in diagnostic procedures; PathAI) was performed in 150 biopsy-confirmed MASH patients. Unsupervised clustering of LiverExplore features identified consensus inflammatory-fibrogenic subgroups. Conventional biomarkers, plasma proteomics (Olink), and metabolomics (Rubio) were analyzed using univariate, multivariable, and elastic net regression models adjusted for age, BMI, and sex. Top markers were prioritized by combined ranking and validated in an independent Virginia Commonwealth University transcriptomic cohort. **Results:** A total of 150 individuals with MASH spanning fibrosis stages F0–F4 (F0 = 14, F1 = 18, F2 = 56, F3 = 53, F4 = 7) underwent deep phenotyping; Masson's Trichrome staining was unevaluable in 2 cases. Consensus clustering identified active inflammatory ("hot", n = 32), intermediate mixed ("other", n = 60), and low inflammatory/metabolic ("cold", n = 58) fibrogenic endotypes (Fig. 1A). Hot fibrosis demonstrated higher PRO-C3, TSP2, ELF, fibrosis stage, liver stiffness, portal inflammation, and macrophage/neutrophil density. Cold fibrosis showed lower fibrosis stage, PRO-C3, and macrophage density, with enrichment for F0–F1 disease. Proteomics identified 155 proteins associated with hot fibrosis, enriched for immune activation, ECM remodeling, and inflammatory signaling. LY96 (TLR4 signaling) and MZB1 (plasma cell-associated ER chaperone) correlated with fibrosis and inflammatory features; LY96 was independently validated in the VCU cohort. Metabolomics demonstrated enrichment of taurine-conjugated bile acids in hot fibrosis, whereas cold fibrosis was enriched for ceramides and triglycerides, supporting a lower-inflammatory metabolic phenotype (Fig. 1B). **Conclusion:** Hot and cold fibrosis represent distinct fibrogenic rather than fixed histologic stages. Hot fibrosis reflects an inflammatory, injury-driven state, while cold fibrosis represents a metabolically driven, lower-inflammatory state. Multi-omics validation supports endotype-based patient selection beyond fibrosis stage alone to improve alignment between mechanism of action and therapeutic response in anti-fibrotic clinical development.

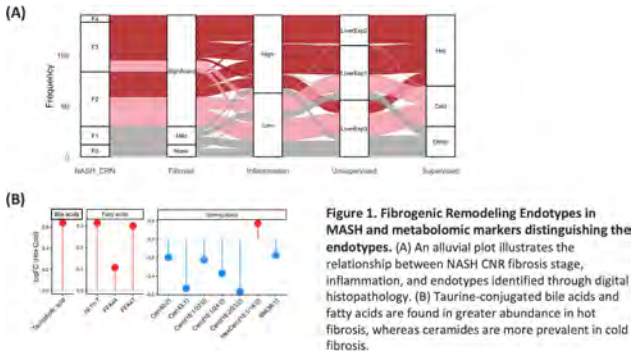

Figure 1. Fibrogenic Remodeling Endotypes in MASH and metabolomic markers distinguishing the endotypes. (A) An alluvial plot illustrates the relationship between NASH CNR fibrosis stage, inflammation, and endotypes identified through digital histopathology. (B) Taurine-conjugated bile acids and fatty acids are found in greater abundance in hot fibrosis, whereas ceramides are more prevalent in cold fibrosis.

2327 | HEPATOCYTE-SPECIFIC AND GLOBAL CIRCULATING EXTRACELLULAR VESICLE PROTEOMICS IDENTIFIES FIBROSIS-ASSOCIATED BIOMARKERS AND HEPATOCYTE-SPECIFIC METABOLIC SIGNATURES IN MASH

Saman Farahmand[1] Banishree Saha[2] Maria Paraskevopoulou[1] Sachin Kumar[1] Zoltan Derdak[1] Lauren Newman[3] Andrew Rowland[3] Paresh Thakker[1] hakaan wennbo[1] Alin Rai[4] David Greening[5], [1]Takeda Pharmaceutical, [2]Takeda Pharmaceuticals, [3]College of Medicine and Public Health, Flinders University, Australia, [4]Baker Department of Cardiovascular Research, La Trobe University, Melbourne, Victoria, Australia, [5]Baker Heart and Diabetes Institute, Melbourne, Victoria, Australia

Background: Metabolic dysfunction–associated steatohepatitis (MASH) poses a global health burden with few approved therapies. Liver biopsy remains the reference standard for fibrosis staging and treatment-response assessment, yet its invasiveness underscores the need for noninvasive biomarkers that track disease activity. Circulating extracellular vesicles (EVs) are candidates, as they are quantifiable in biofluids and carry cargo reflective of their cell of origin. Plasma EV proteomes respond to regulated metabolic processes in MASLD (DiStefano et al., 2024). Here, we extend this paradigm to a chronic fibrosis cohort by profiling paired global and hepatocyte-specific circulating EV proteomes across MASH fibrosis stages. **Methods:** Plasma was collected from healthy controls and clinically confirmed MASH patients (F2–F4) via academic/commercial biorepositories. Global EVs were isolated by density-based ultracentrifugation, and matched aliquots underwent ASGR1 immunoprecipitation for hepatocyte-derived EV enrichment (Newman et al., 2022). Particle concentration/size were measured by NTA, and proteomic profiling used SP3 with label-free DIA-MS. Proteins were mapped to a human liver snRNA-seq atlas for cell-of-origin assignment, followed by differential abundance and pathway enrichment analyses. **Results:** Across both workflows, we validated a conserved set of 182 hallmark circulating EV proteins—including ADAM10, STEAP3, and STX7—previously reported in plasma small EVs, supporting robust EV enrichment and proteome capture (Rai et al., Nature Cell Biology, 2025). In global EVs from MASH subjects versus controls, pathway analysis revealed dysregulated fibroinflammatory and metabolic pathways, including TGFβ signaling, complement signaling, bile acid metabolism, and coagulation. Global EVs from MASH patients were further enriched for disease-related proteins (e.g., BSG, ITGB1, LTBP1, P4HB, HSPD1) reflecting a dynamic crosstalk between hepatocytes, immune, and stromal compartments. ASGR1$^+$ EV particle concentration was positively associated with fibrosis stage and revealed distinct hepatocyte-derived signatures encompassing oxidative phosphorylation, fatty acid β-oxidation, cholesterol homeostasis and mTORC1 signaling. Top hepatocyte-specific biomarkers included PCSK9, LAMA2, LUM, CFB, and the hepatocyte-exclusive bile salt exporter ABCB11. **Conclusion:** Paired global and hepatocyte-specific EV proteomics support a noninvasive strategy to monitor metabolic, immune, and fibrotic processes driving MASH fibrosis progression. Global EVs captured broad inflammatory and profibrotic signaling, while ASGR1$^+$ hepatocyte derived EVs increased with fibrosis stage and revealed distinct hepatocellular dysfunction. Together, these findings highlight the added value of ASGR1$^+$ EVs in resolving hepatocyte-specific disease biology beyond bulk circulating EV analyses.

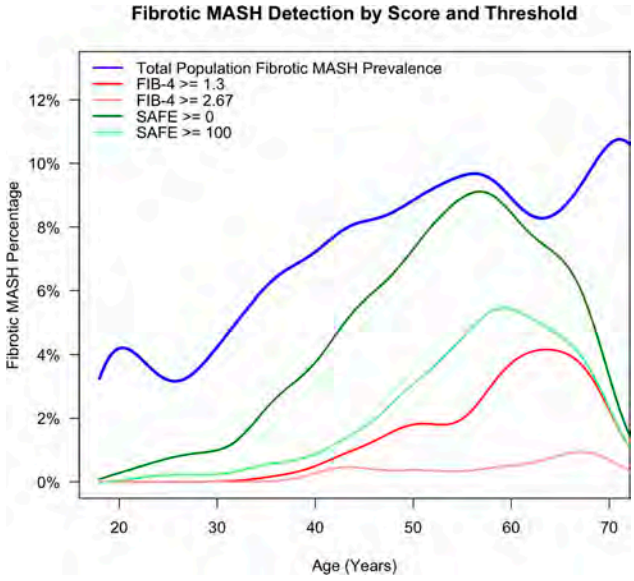
2328 | MISSING THE MARK: CHALLENGES IN SCREENING FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS IN PEOPLE UNDER 40



Thuy-Duyen Nguyen[1] W. Ray Kim[2], [1]Mayo Clinic, [2]Mayo Clinic Arizona

Background: Young adults with metabolic dysfunction-associated steatohepatitis (MASH) represent the highest lifetime-risk group for liver-related complications, standing to benefit most from currently available interventions. Screening for early MASH in this group is challenging because the prevalence of fibrosis is low and the performance of non-invasive markers remains poorly characterized. We evaluated age-stratified performance of the FIB-4 index in a U.S. population sample, in comparison to the SAFE score, a multivariable score that includes metabolic parameters, including diabetes and body mass index. **Methods:** Using National Health and Nutrition Examination Survey (NHANES) 2017–2023 data, we measured the prevalence of fibrotic MASH, defined as a liver stiffness measurement (LSM) $\geq$ 8.0 kPa with a controlled attenuation parameter (CAP) $\geq$ 275 dB/m or LSM $\geq$ 15.0 kPa regardless of CAP by vibration-controlled transient elastography (VCTE). Among the survey

respondents, at-risk individuals were identified by the presence of obesity/overweight, prediabetes/Type 2 diabetes, or ≥ 2 cardiometabolic risk factors. We evaluated the diagnostic performance of FIB-4 with thresholds of 1.3 and 2.67, and SAFE with thresholds of 0 and 100, for identifying fibrotic MASH across age strata from 20 to 70. **Results:** Among the at-risk subjects in NHANES 2017–2023, projecting to 84 million US civilian adults, the prevalence of fibrotic MASH was 8.2%. The prevalence was lower in the 20–29 and 30–39-year-old strata with fibrotic MASH found in 5.1% and 7.5%, respectively. In Figure 1, FIB-4 ≥1.3 identified 0% of cases in the 20–29-year-old group and 1.7% in the 30–39-year-old group. The traditional 'rule-in' threshold of SAFE, namely >100, demonstrated better sensitivity at 5.4% in the 20–29 year-old group and 7.3% in the 30–39 year-old group. The SAFE score ≥0 threshold further increased the sensitivity to 22.0% and 31.6% in the corresponding age groups. For the AUROC analysis, SAFE consistently outperformed FIB-4 across all age strata (0.725–0.768 vs 0.503–0.573), with the largest performance gap in individuals <40 years. Specifically, in the 20–29 age group, the SAFE AUROC was 0.738 [95% CI: 0.620–0.856] compared to a FIB-4 AUROC of 0.556 [95% CI: 0.424–0.688], while in the 30–39 age group, the SAFE AUROC was 0.725 [95% CI: 0.654–0.796] compared to 0.528 [95% CI: 0.435–0.620] for FIB-4. Sensitivity analysis using LSM > 10 yielded similar results. **Conclusion:** In this important age group under 40 years, a group with high lifetime risk, the current FIB-4–based screening strategies are ineffective for identifying fibrotic MASH. Alternative approaches incorporating metabolic parameters, such as the SAFE score, demonstrate improved performance but may require age-specific optimization. These findings highlight a critical gap in early detection and the need for tailored screening strategies in younger populations.

2329 | CT1 IS A VIABLE, SCALABLE NIT IN THE SECOND STEP OF THE MASLD SCREENING CARE PATHWAY

Niharika Samala[1] Kento Imajo[2] Atsushi Nakajima[3] Masato Yoneda[4] Adriaan Holleboom[5] Stephen Harrison[6] Winston Dunn[7] Dan Yock Young[8] Mark Mutiah[8] Mazen Noureddin[9], [1]Indiana University School of Medicine, Indianapolis, Indiana, USA, [2]Shin-yurigaoka General Hospital, Kawasaki, Japan, [3]National Hospital Organization Yokohama Medical Center, Japan, [4]Yokohama City University Graduate School of Medicine, Yokohama, Japan, [5]Amsterdam UMC, Amsterdam, The Netherlands., [6]Summit Clinical Research, San Antonio, Texas, USA, [7]University of Kansas Medical Center, Kansas, USA, [8]National University of Singapore, Singapore, [9]Houston Methodist Hospital, Houston, Texas, USA

Background: Current practice guidance suggest screening individuals at risk of metabolic dysfunction-associated steatohepatitis (MASH) using two-step sequential noninvasive tests (NIT) to identify MASH patients with significant disease for referral to specialist care. However, compliance to the MASH screening pathway is sub-optimal, partly due to limited access to NITs. We evaluated sequential screening strategies starting with FIB-4, followed by either vibration controlled transient elastography (VCTE) or corrected T1 (cT1), for the identification of at-risk MASH (treatment eligible MASH). **Methods:** We conducted a pooled analysis using data from individuals with biopsy-proven MASLD enrolled in four observational studies (conducted in United States, The Netherlands, Japan, and Singapore) alongside standard clinical assessment. Accurate risk stratification for those with biopsy confirmed at-risk MASH was assessed for FIB-4 <1.3 (or < 2 for ≥65 years) and 1.3-2.67 (or 2.0-2.67 for ≥65 years), VCTE ≥8kPa and cT1 ≥800ms, individually and applied sequentially. Diagnostic accuracy statistics were reported to allow different pathways to be compared. **Results:** Among 578 individuals included in the analysis (41% female; median age: 56 [50, 63] years; median BMI: 31 [28, 34] kg/m^2 ; 46% type 2 diabetes), 57% had MASH, 34% at-risk MASH and 31% had advanced fibrosis on biopsy. In those with intermediate FIB-4 (n = 155), 68% had MASH, 48% had at-risk MASH on biopsy. The two-step stratification with either VCTE (sensitivity: 55% ; specificity: 82%) or cT1 (sensitivity: 58%; specificity: 83%) in intermediate FIB-4 performed comparably in identifying at-risk MASH. In the intermediate-risk FIB-4 group, adding cT1 ≥800ms

as third step after VCTE (8-12kPa), only marginally increased specificity (86%), while lowering sensitivity (53%) compared to using cT1 ≥ 800ms alone as the second step. Notably, in those with low FIB-4 (< 1.3, or < 2; n = 346), 48% had MASH and 22% had at-risk MASH on biopsy. Even in this low-risk group cT1 ≥ 800 ms identified 83% of those with at-risk MASH. **Conclusion:** In the MASH screening pathway, cT1 is a viable and scalable alternative to VCTE as the second step NIT. Our study results suggest that cT1, an MRI adaptable technology, could potentially increase patient access to MASH screening in non-urban settings without access to VCTE.

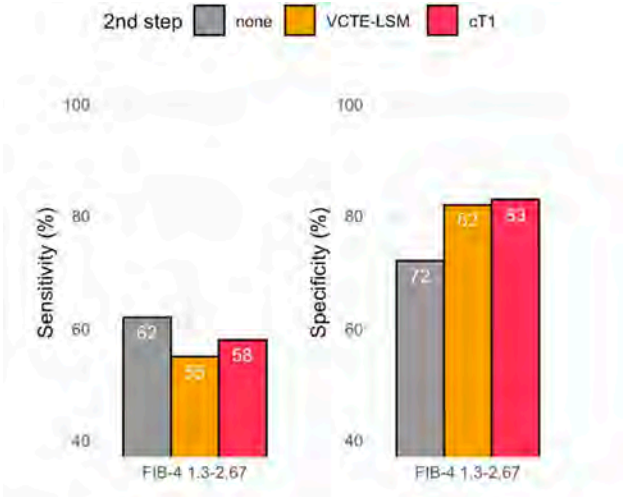

Figure. The sensitivity (left) and specificity (right) of the two-step risk stratification strategies, starting with FIB-4, followed by either VCTE-LSM (≥8kPa) or cT1 (≥800ms) as the second tests.

2330 | REDUCING CV RISK IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS INDEPENDENT OF BASELINE BASED ON LP(A) AND LDL LOWERING BY RESMETIROM

Meena Bansal[1] Rebecca Taub[2] Dominic Labriola[2] David Soergel[2] Yestle Kim[2] Naim Alkhouri[3] Mazen Noureddin[4] Seth Baum[5] Rohit Loomba[6], [1]Icahn School of Medicine at Mount Sinai (ISMMS), [2]Madrigal Pharmaceuticals, [3]Summit Clinical Research, [4]Houston Methodist Hospital, [5]Florida Atlantic University, [6]University of California, San Diego

Background: Patients with metabolic dysfunction-associated steatohepatitis (MASH) have high cardiovascular morbidity and mortality. Resmetirom, a selective thyroid hormone receptor-beta agonist, is approved for treatment of patients with noncirrhotic MASH with moderate to advanced liver fibrosis. Resmetirom reduces atherogenic lipids and lipoproteins. In a secondary analysis of the Phase 3 MAESTRO-NASH clinical trial, the effects of resmetirom over 52 weeks on MASH efficacy parameters, atherogenic lipids, lipoproteins, and safety were evaluated according to baseline statin use. **Methods:** Data from the MAESTRO-NASH and MAESTRO-NAFLD-1 trials were analyzed. Analyses assessed MASH and lipid responses, shift in LDL and lipoprotein(a) [Lp(a)] risk profiles, and standard safety assessments including serial liver enzymes and adverse events according to baseline statin use. **Results:** Approximately half (n = 473; 49%) of MAESTRO-NASH participants were on statins at baseline. Atorvastatin was the most commonly used statin (47.1%), and 26.9% of statin-treated patients were receiving high-intensity statin therapy. Baseline characteristics were generally similar across statin subgroups; however, a greater proportion of patients receiving statins, compared with those not receiving statins, had diabetes (79.5% vs 55.0%), dyslipidaemia (100% vs 43.8%), and advanced fibrosis (F3: 64.3% vs 56.6%) at baseline. The dual primary endpoints remained directionally consistent with the overall MAESTRO-NASH results and were nominally statistically significant for both resmetirom 80 mg and 100 mg versus placebo, regardless of baseline statin use.A numerically greater reduction in liver fat as measured by MRI-PDFF at Week 52 was also observed with resmetirom compared with placebo irrespective of baseline statin use. At Week 24, placebo-corrected reductions were observed for LDL-C, ApoB, TGs, and Lp(a) across statin and non-statin subgroups. In patients on statins 44.4% with LDL-C $\geq$ 70 mg/dL at baseline shifted to LDL-C < 70 mg/dl with 100 mg resmetirom; 36.3% and 37.5% with Lp(a) $\geq$ 30 or $\geq$ 50 mg/dL at baseline shifted to < 30 or < 50 mg/dL with 100 mg resmetirom. Patients in the highest CV risk quartile of baseline Lp(a) showed significant reductions in Lp(a) with resmetirom independent of statin use (Figure). **Conclusion:** Independent of statin use, treatment with resmetirom was efficacious at multiple MASH endpoints and improved lipid profiles for LDL-C, ApoB and Lp(a).

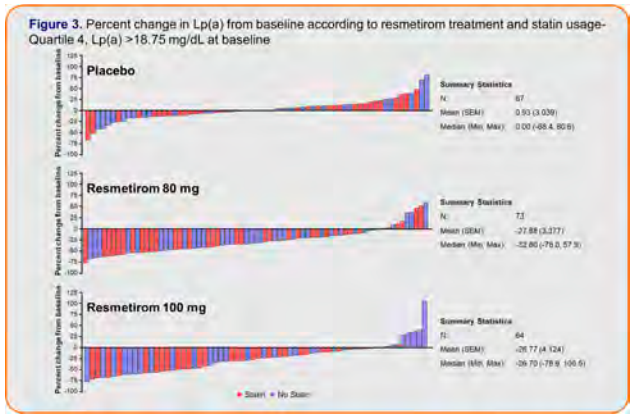

Figure 3. Percent change in Lp(a) from baseline according to resmetirom treatment and statin usage-Quartile 4, Lp(a) >18.75 mg/dL at baseline

2331 | SCALE-MASLD: SCALING CARE PATHWAYS FOR ADVANCED LIVER ENGAGEMENT IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Rena Fox[1] Kenneth Cusi[2] Sun Kim[1] Diana Barb[2] Anu Sharma[2] Gopanandan Parthasarathy[1] Varalakshmi Niranjan[1] Bilal Hameed[3] Radha Pachpor[4] Kristi Cohn[4] Paul Kwo[5], [1]Stanford University School of Medicine, Stanford, CA, [2]University of Florida, [3]University of California San Francisco, San Francisco, CA, [4]Petauri Kinect, [5]Stanford University Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) affects approximately 38% of the global adult population, including 60-70% of individuals with type 2 diabetes and 70-80% with obesity, yet it remains underdiagnosed. While guidelines recommend screening for MASLD related fibrosis in high-risk populations, implementation in routine clinical practice remains limited. Electronic health record (EHR) enabled MASLD pathways are needed to streamline screening, risk stratification, and diagnosis, particularly in primary care where clinical demands compete for early identification and management. **Methods:** Building upon the framework established in a previous study involving four health systems, this pilot project scales EHR-enabled MASLD care pathway interventions to an additional six institutions: University of Florida, Stanford University, University of California, San Francisco, Duke Health, Methodist, and Northwestern University. Table 1 depicts interventions deployed. Targeted education was delivered to participating clinicians. Performance was evaluated using a common data framework measuring baseline (2-6 months) and intervention (6-12 months) time frames. **Results:** Preliminary data from three of the six health systems identified 6,283 patients seen in participating primary care and endocrinology clinics. Among the 6,283 patients seen at baseline, 63.3% (3,976) had labs available for FIB-4 calculation and were eligible for fibrosis screening. Of the 3,976 patients with available labs, 18% (723) met criteria for secondary assessment (i.e., FIB-4 $\geq$1.3). Of the 723 patients, 28.2% (204) were referred for secondary assessment (VCTE and/or hepatology referral), and 13.6% (99) completed VCTE and/or hepatology referral.Preliminary follow-up data from two of the six health systems identified 11,159 patients seen in participating clinics. Of the 11,159 patients seen over the follow-up period (ranging from 4-12 months), 46% (5,145) had labs available for FIB-4 calculation and were eligible for fibrosis screening. Of the 5,145 patients with available labs, 14.8% (763) met criteria for secondary assessment (i.e., FIB-4 $\geq$1.3). Of the 763 patients, 20.4% (156) were referred for secondary assessment (VCTE and/or hepatology referral), and 21.2% (162) completed VCTE and/or hepatology referral.Data collection underway at 5 of 6 systems. **Conclusion:** Baseline data highlights major gaps in MASLD fibrosis assessment in high-risk patients. Further data collection is needed to evaluate the impact of the EHR-enabled interventions on MASLD fibrosis assessment. However, early data suggest modest improvements in follow-up rate of referral to secondary diagnostics.

Table 1:

Institution	University of Florida	UCSF	Stanford University
Target population	DM only	DM and/or Obesity	DM only
Care setting	Internal Medicine and Endocrinology	Internal Medicine	Primary care
Intervention	System-initiated Care Path[1]	Back-end FIB-4 Calculation[2]	Clinician-activated Age Adjusted FIB-4 SmartPhrase[3]
Total, no. of clinicians	57	115	30

Intervention definitions:

1. System-initiated: EPIC clinical care path infrastructure using silent Our Practice Advisories (OPAs) and reminders to prompt FIB-4 screening at the point of care.

2. Back-end: Retrospective FIB-4 calculation across patient panels with outreach for high and intermediate risk patients.

3. Clinician-activated: An age-adjusted FIB-4 SmartPhrase that facilitates real-time calculation of the FIB-4 score, alongside interpretation and recommendations for subsequent actions.

2332 | NON-INVASIVE TWO-STEP TRIAGE IMPROVES ACCESS TO HEPATOLOGY CARE AND ACCELERATES DETECTION OF ADVANCED LIVER FIBROSIS IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE: A TERTIARY CARE PROGRAM EVALUATION

Yasamin Farbod[1] Neha Sharma[1] France Martineau[1] Dana Kablawi[2] Philip Wong[1] Xun Zhao[1] Marc Deschenes[1] Tianyan Chen[1] Sahar Saeed[3] Amine Benmassaoud[1] Giada Sebastiani[2], [1]McGill University Health Centre, [2]McGill University, [3]Queen's University

Background: The growing burden of metabolic dysfunction-associated steatotic liver disease (MASLD) is placing increasing pressure on hepatology services. Although transient elastography (TE; FibroScan®) is recommended as a first-line non-invasive fibrosis assessment tool, limited access to TE and specialist consultation remains a major barrier to timely care. In 2021, our tertiary hepatology program implemented a biomarker-guided, TE-confirmed two-step triage pathway to optimize resource allocation by prioritizing high-risk patients while safely retaining low-risk patients in primary care. We evaluated the impact of this model on access to TE and hepatology services, referral efficiency, referral efficiency, and early detection of advanced fibrosis. **Methods:** We conducted a quasi-experimental study including all consecutive referrals for liver assessment between 2013-2020 (pre-implementation) and 2021-2025 (post-implementation). The triage algorithm used age-adjusted FIB-4 cut-offs as the first tier (low risk: <1.3 if <65 years or <2.0 if ≥ 65 years), with non-low-risk patients proceeding to TE for fibrosis confirmation. Primary outcomes were time from referral to TE and time from referral to hepatology consultation. Secondary outcomes included the proportion of patients managed without in-person hepatology consultation, hepatology no-show rate, and detection of advanced fibrosis ($\geq$ F3) within 12 months of referral as a safety indicator. **Results:** Among 3,953 patients with MASLD who underwent TE (mean age 62; 73% male), 1,750 (44.3%) were pre- and 2,203 (55.7%) post-implementation. Following implementation of the two-step triage pathway, mean time from referral to TE decreased from 13.2 to 5.5 months (absolute reduction −7.7 months; 95% CI -8.9, -6.5). Mean time from referral to hepatology consultation decreased from 30 to 13.2 months (absolute reduction −16.8 months; 95% CI -18.5, -15). The proportion of referrals managed without hepatology consultation increased from 45% to 80%, while hepatology no-show rates declined from 23% to 15%. As a safety signal, the proportion of patients diagnosed with advanced fibrosis within 12 months of referral doubled from 10% to 20%, consistent with improved prioritization and earlier identification of higher-risk patients. Relative changes for all outcomes are reported in the Figure. **Conclusion:** Implementation of a biomarker-guided, TE-confirmed two-step triage pathway substantially reduced delays in access to liver care, improved referral efficiency, and accelerated detection of advanced fibrosis in patients with MASLD. These real-world findings support scalable, cost-neutral strategies to decongest hepatology services and improve equitable access to specialized liver care in the context of population-level management of the growing MASLD epidemic.

Haakan Wennbo[1] Paresh Thakker[1] Bernard Allan[1] Hirokazu Takahashi[8] Atsushi Nakajima[9] Maria Paraskevopoulou[1] Banishree Saha[1], [1]Takeda Pharmaceuticals, [2]Takeda Development Center Americas, Inc., [3]Kyushu University, [4]Saga University, Hyogo Life Care Clinic Hiroshima, [5]Saga University, Loco Medical General Institute, [6]Hiroshima University, [7]Yokohama City University, [8]Saga University, [9]National Hospital Organization Yokohama Medical Center

Background: Background & Aims: Non-invasive biomarkers that accurately stage hepatic fibrosis and quantify disease activity remain an unmet need in MASH. Serum ECM biomarkers reflecting collagen synthesis and degradation are mechanistically plausible candidates, but integration with multi-modal molecular and tissue-level data from the same cohort remains limited. We evaluated the discriminative performance of serum ECM biomarkers and characterized their proteomic correlates in a Japanese MASH cohort with multi-omics data. **Methods:** Serum ECM biomarkers were profiled in a Japanese biopsy-confirmed MASH cohort (F0–F4; n = 242). The panel included markers of fibrolysis (C4M, CTX-III), fibrogenesis/matrix turnover (PRO-C3, PRO-C4, PRO-C5, PRO-C6), perisinusoidal fibrosis (PRO-C8, PRO-C18L), and fibrosis-associated markers including TSP-2, C6Mα3, ELF, HA, PIIINP, and TIMP-1. Fibrosis- and NAS-based endpoints (significant fibrosis ($F \geq 2$), advanced fibrosis ($F \geq 3$), NAS group (NAS < 4, NAS > = 4), Active MASH with Significant Fibrosis (FibStage > = 2 & NAS > = 4), Active MASH with Advanced Fibrosis (FibStage > = 3 & NAS > = 4)) were assessed by ROC-based univariate analysis. Multivariate elastic net models were generated using the ECM panel alone or combined with FIB-4, AST, and ALT. Serum ECM biomarkers were correlated with SomaScan serum proteomics (11K proteins) by Spearman correlation, followed by Reactome over-representation analysis. Correlated proteins were integrated with single nucleus RNA-sequencing (sNuc-seq) data from patients with MASH to map potential liver source cells. **Results:** TSP-2 and PRO-C3 were the top-performing biomarkers, positively associated with all five disease-state variables, with AUCs ranging from 0.73–0.88 and 0.68–0.73, respectively. C4M and C6Mα3 were inversely associated with fibrosis and active MASH, whereas PRO-C6 and CTX-III showed no significant associations. TSP-2 was retained across all multivariate models, but no model outperformed univariate TSP-2. TSP-2 and PRO-C3 correlated with 255 and 1348 SomaScan serum proteins enriched for ECM remodeling, collagen formation/degradation, and fibrogenesis pathways, with THBS2, ADAMTSL2, C7, and COL5A1 among the strongest correlates. These proteins were enriched in the liver mesenchyme and validated in independent multi-omics MASH datasets, anchoring the serum ECM signal in fibrogenic biology. Inversely associated markers were linked to inflammatory and immune pathways. **Conclusion:** In a Japanese MASH cohort, TSP-2 and PRO-C3 were the most informative serum ECM biomarkers for fibrosis staging and disease activity and were strongly anchored to molecular and cellular signatures, supporting their prioritization for prospective validation.

2334 | REAL-WORLD PERFORMANCE OF ULTRASOUND FOR CIRRHOSIS DETECTION: SIGNIFICANT OVERDIAGNOSIS COMPARED TO MAGNETIC RESONANCE ELASTOGRAPHY

Morgan Ford[1] Garrett Coleman[1] William Southall[1] Jad Allam Saab[1] Elizabeth Statham[1] Fernando Bril[1] Meagan Gray[1], [1]University of Alabama at Birmingham

Background: Ultrasound (US) is commonly ordered as an initial evaluation in patients with liver disease because it is inexpensive and easily accessible in clinical practice. Prior studies assessing the diagnostic accuracy of US for cirrhosis were largely performed in higher prevalence populations. We evaluated the accuracy of US compared with magnetic resonance imaging (MRE) for detection of cirrhosis in a low prevalence population. **Methods:** This was a retrospective analysis of real-world patients who underwent both liver US and MRE within one year of each other. Cirrhosis on US was defined by radiology reports describing the liver as “nodular” or “cirrhotic.” MRE-defined cirrhosis was defined as liver stiffness ≥ 5 kPa. **Results:** A total of 521 patients were included (54 ± 13 years; 55.3% female; 75.0%

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

White, 16.4% African American, and 8.6% other). The predominant liver disease etiologies were metabolic dysfunction-associated steatotic liver disease (MASLD, 69.7%) and metabolic and alcohol-related liver disease (Met-ALD, 9.4%). Mean BMI was 33.5 ± 6.9 kg/m2. Diabetes was present in 23.6% of patients, with mean hemoglobin A1C of 6.1 ± 1.2%. Cirrhosis prevalence by MRE was 6.3% (n = 33). US identified cirrhosis in 120 patients, of whom 25 had confirmed cirrhosis on MRE and 95 did not. Among 401 patients without cirrhosis on US, 8 had cirrhosis on MRE and 393 did not. Compared with MRE, US demonstrated a sensitivity of 75.8%, specificity of 80.5%, positive predictive value of 20.8%, and negative predictive value of 98.0%. **Conclusion:** Ultrasound demonstrated moderate sensitivity and specificity but poor positive predictive value for detection of cirrhosis compared with MRE in this MASLD-predominant cohort. Nearly 4 out of 5 patients identified as cirrhotic on ultrasound did not meet MRE criteria for cirrhosis. Because ultrasound findings frequently influence cirrhosis labeling, surveillance strategies, and clinical management in real-world practice, these findings have important implications for patient care. Consistent with prior reports, our findings suggest US may function better as a rule-out rather than rule-in test for cirrhosis in MASLD populations. The markedly low PPV observed in this low-prevalence cohort highlights the influence of disease prevalence on diagnostic utility. Confirmatory fibrosis assessment with elastography-based modalities may be warranted in patients with ultrasound findings suggestive of cirrhosis.

2335 | INTENTIONAL CALCULATION OF FIB-4 BY PRIMARY CARE PROVIDERS PREDICTS HEPATOLOGY SPECIALTY CARE REFERRAL

Alejandra Meza[1] Jonathan Dranoff[2], [1]Yale School of Medicine, [2]Yale University

Background: Chronic liver disease affects over 1.5 billion people worldwide, with Metabolic dysfunction-Associated Steatotic Liver Disease (MASLD) as the leading cause. The Fibrosis-4 (FIB-4) Index is a low-cost, validated tool for risk stratification of patients with MASLD and other chronic liver diseases. FIB-4 ≥ 1.3 should prompt elastography or hepatology referral. However, this score remains underutilized, and appropriate follow-up is suboptimal. This project aimed to evaluate both the rates of appropriate follow-up after identification of an elevated FIB-4 score and the extent of provider utilization of the FIB-4 score in clinical practice. **Methods:** We conducted a retrospective cross-sectional study of adult patients (≥ 18 years) seen at Fair Haven Community Health Care (New Haven, CT) over the past two years. Patients with available AST, ALT, and platelet counts were included to calculate FIB-4 scores; those with FIB-4 ≥ 1.3 formed the study cohort. Data were extracted from the electronic medical record. Descriptive statistics were used to characterize the cohort. Group comparisons were performed using Chi-square or Fisher's exact test for categorical variables and t-test or Mann–Whitney U for continuous variables. Predictors of failure to receive elastography or hepatology referral were assessed using multivariable logistic regression. Statistical significance was defined as $p < 0.05$. **Results:** Among 781 patients with FIB-4 ≥ 1.3, only 11.8% underwent elastography or hepatology referral. While most patients had FIB-4 scores between 1.3-2.67, referral rates were substantially higher in those with FIB-4 ≥ 2.67 (37.6% vs 8.3%). Provider calculation of FIB-4 occurred in only 9% of cases but was strongly associated with referral in both univariable (OR = 9.1, 95% CI 5.1-16.1; $p < 0.0001$) and multivariable analysis (OR = 13.3, 95% CI 6.83-26.2; $p < 0.001$). Cirrhosis was the strongest predictor of referral (multivariable OR = 54.4, 95% CI 22.2-146; $p < 0.001$). Elevated LDL cholesterol was associated with lower odds of evaluation (OR = 0.29, 95% CI 0.09-0.81; p = 0.03). Other studied factors were not independently associated with referral. **Conclusion:** Despite elevated FIB-4 scores, the vast majority of high-risk patients did not receive elastography or hepatology referral, highlighting a major care gap. Provider calculation of FIB-4 emerged as a strong predictor of referral, suggesting that improving provider recognition and integration of noninvasive fibrosis assessment may represent an important target for quality improvement interventions.

Table 1. Univariable and Multivariable analysis

	Univariable			Multivariable		
Variable	OR	95% CI	p-value	OR	95% CI	p-value
Age*	0.97	0.95-0.99	0.0002	0.98	0.95-1.01	0.11
FIB-4 ≥2.67	6.68	4.04-11	<0.0001	1.42	0.44-4.05	0.5
FIB-4*	1.82	1.55-2.18	<0.0001	1.19	0.9-1.67	0.3
Diagnosis of cirrhosis	52.2	25.6-116	<0.0001	54.4	22.2-146	<0.001
High LDL-C	0.34	0.13-0.73	0.004	0.29	0.09-0.81	0.03
Calculated score	9.1	5.1-16.1	<0.0001	13.3	6.83-26.2	<0.001

Hospital General Universitario Gregorio Marañón., [31]Virgen del Rocio University Hospital, [32]Virgen del rocío University Hospital, Seville, Spain

Background: Treatment for MASLD is currently indicated for non-cirrhotic patients with histologically confirmed significant fibrosis. This study aimed to identify factors able to discriminate which of these patients are more likely to progress to cirrhosis or decompensation during follow-up. **Methods:** 752 histologically confirmed F2-F3 MASLD patients from the HEPAMET registry were included. Anthropometric, biochemical, and metabolic parameters were analyzed to identify predictors in uni- and multivariate analyses including or not histological readouts. Patients were classified as progressors when cirrhosis or liver decompensation were reported during follow-up. Biopsy, ultrasound, or transient elastography were used to defined cirrhosis. Liver decompensation with the occurrence of one or more major complications of liver disease (ascites, hepatic encephalopathy, gastrointestinal bleeding, or bacterial infection) during follow-up. **Results:** Mean age was 55.5 ± 11.4 years and mean BMI 34.8 ± 7.9 kg/cm^2 (69.2% obese); 51.7% were men. Type-2 Diabetes Mellitus (T2DM) was present in 57.2% of patients. MASH in 56.2% and fibrosis stages were F2 46.5% and F3 53.5%. Mean follow-up was 6.28 ± 4.4 years. Progression to cirrhosis or decompensation occurred in 17.7%. Cox regressions indicated positive associations between progression and advanced fibrosis, T2DM, AST, GGT, glucose and bilirubin, while inverse associations to MASH, ballooning, inflammation cholesterol, albumin and platelets. T2DM, age, GGT and platelets together with the prevalence of advanced fibrosis remained significant after multivariate correction and were integrated in a histology (right model) and histology-free scores (left model). Both of them showed a good prognostic ability to identify patients more likely to progress to cirrhosis or develop liver related complications (Figure 1). **Conclusion:** Age, GGT, platelets and T2DM can be useful and combined or not to liver fibrosis stage to estimate the risk of progression and prioritize which patients should first receive treatment for MASLD.

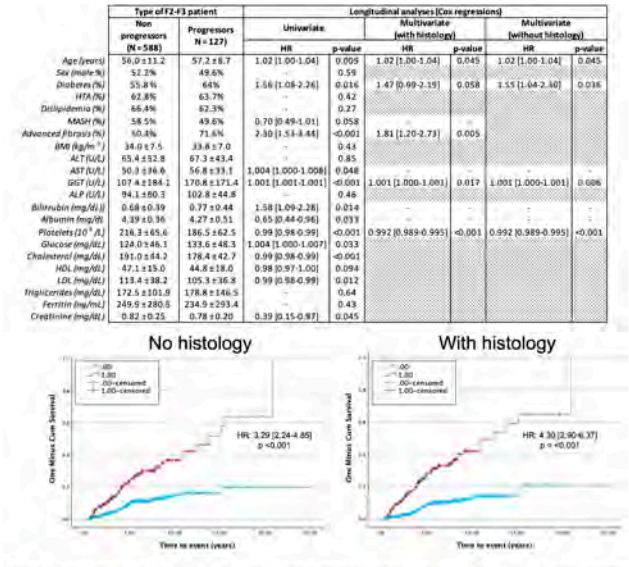

Figure 1: upper panel: Summary results of descriptive statistics and Cox regression analyses. Lower graphs. Kaplan Meyer results obtained for predictor models integrating or not histological features.

2337 | AGREEMENT BETWEEN VCTE AND 2D-SWE FOR LIVER FIBROSIS ASSESSMENT IN MASLD: EVIDENCE AGAINST INTERCHANGEABILITY

Vasily Isakov[1] Alexei Goncharov[1] Murad Israpilov[2], [1]Federal Research Center of Nutrition, Biotechnology & Food Safety, [2]Federal Research Ceter of Nutrition, Biotechnology & Food Safety

Background: Liver stiffness measurement (LSM) is widely used for non-invasive fibrosis assessment in metabolic dysfunction-associated steatotic liver disease (MASLD), but values obtained using different elastography technologies may not be interchangeable. We evaluated agreement between vibration-controlled transient elastography (VCTE; FibroScan 530) and two-dimensional shear wave elastography (2D-SWE; LOGIQ E9) in patients with MASLD and explored factors associated with inter-method discrepancy. **Methods:** We analyzed 228 adults with MASLD examined from 2024 to 2026. All participants underwent fasting VCTE and 2D-SWE performed by different blinded operators. Agreement was assessed using Bland–Altman analysis, intraclass correlation coefficient (ICC), F0–F4 reclassification tables, and weighted Cohen's kappa. Restricted cubic spline models were used to examine whether absolute inter-method differences were associated with waist circumference and VCTE measurement variability. **Results:** Agreement between VCTE and 2D-SWE was only moderate. The ICC was 0.436 (95% CI, 0.383–0.582). Bland–Altman analysis demonstrated systematic positive bias for VCTE versus 2D-SWE, with a mean difference of 2.60 kPa and wide limits of agreement from −7.82 to 13.03 kPa (Figure). The discrepancy increased as mean LSM increased, indicating proportional bias ($\beta = 1.037$; $p < 0.001$). Complete F0–F4 stage agreement was observed in 107/228 patients (46.9%). Agreement was highest at the extremes, F0 (72.3%) and F4 (64.7%), but substantially lower in intermediate stages F1–F3 (20.0%–35.7%). Weighted Cohen's kappa was 0.645 (95% CI, 0.554–0.723). Reclassification was asymmetric: 2D-SWE more frequently assigned patients to a lower fibrosis category than VCTE. Larger waist circumference and higher VCTE variability were associated with greater absolute inter-method discrepancy; the waist-circumference association was significant ($p = 0.002$), with marked divergence beyond approximately 110 cm. **Conclusion:** In patients with MASLD, VCTE and 2D-SWE showed moderate categorical agreement but poor individual-level interchangeability, particularly across intermediate fibrosis stages where clinical decisions are most uncertain. Severe abdominal adiposity and VCTE variability appear to amplify method-dependent differences. These findings support using the same elastography modality and device for longitudinal monitoring and caution against direct substitution of 2D-SWE for VCTE-derived fibrosis thresholds without device-specific validation.

2338 | TRANSITIONING MASH DRUG DEVELOPMENT FROM PHASE 1 TO PHASE 2: THE EVOLVING ROLE OF NON-INVASIVE ENDPOINTS

Judith Hey-Hadavi[1] Sigrunn Blacoe[1] Casey Ustick[1] Frederic Flandrin[1] Andrew Kuhlman[1], [1]Worldwide Clinical Trials

Background: Noninvasive tests (NITs) are increasingly integrated for metabolic dysfunction-associated steatohepatitis (MASH) drug development to inform proof-of-mechanism (PoM), dose selection, and early efficacy assessment. This is driven by the limitations of liver biopsy. However, comparative performance of imaging, serum, and composite biomarkers across therapeutic classes remains incompletely characterized. This review evaluated the utility of NITs in early interventional studies of MASLD/MASH therapies. **Methods:** Peer-reviewed publications, abstracts, ClinicalTrials.gov postings, and publicly available company reports through May, 2026 were screened. Interventional clinical studies in MASLD/MASH with a defined mechanism of action and quantifiable NIT endpoints were included. Observational studies, lifestyle interventions, and studies without measurable biomarker or imaging outcomes were excluded. 14 representative studies in multiple therapeutic classes were analyzed, including THR-β agonists, FGF analogs, GLP-1–based therapies, FXR agonists, ACC inhibitors, and other metabolic or fibrosis-directed agents. **Results:** MRI-proton density fat fraction (MRI-PDFF) consistently demonstrated the strongest evidence for detecting early clinical activity, distinguishing dose-response relationships, and supporting early efficacy assessment across therapeutic classes. Relative MRI-PDFF reductions ≥30% were repeatedly associated with later histologic response. Imaging-based endpoints generally surpassed serum biomarkers for short-term dose and exposure-response characterization. Across programs, steatosis-oriented endpoints changed earlier and more consistently than fibrosis-oriented NITs, while stiffness measures such as MRE and VCTE demonstrated slower and/or weaker short-term responsiveness. Fibrogenesis markers incl. ELF and PRO-C3 showed encouraging supportive utility, particularly when interpreted alongside imaging biomarkers. Several studies suggested that combining imaging, serum biomarkers, and composite measures may provide more clinically informative assessment than reliance on single endpoint modality. FAST score showed emerging value for corroborating histologic improvement in post hoc analyses. (See table 1) **Conclusion:** Among currently studied NITs, MRI-PDFF is the most robust in early phase MASH drug development, particularly for PoM evaluation, dose selection, and early efficacy detection. Fibrosis-oriented biomarkers may provide complementary information but are less sensitive in short trial durations. The findings support a multimodal NIT strategy of imaging, serum biomarkers, and composite indices to improve interpretation of pharmacodynamic and early efficacy signals in MASH studies. Continued NIT standardization, validation and innovation are essential to accelerate early development decisions and ultimately patient's care.

Category	NIT / Biomarker	Pathology	Proof-of-Mechanism (PoM) use	Dose / Exposure–Response	Early Efficacy Signal	Temporal Response	Key Strengths	Limitations
Serum Biomarkers	ALT, AST	Hepatocellular injury	Moderate – reflects liver injury and activity	Moderate (broke dose-dependent changes)	Supportive, indirect	Rapid (weeks)	Widely available, dynamic, low cost	Limited specificity for MASH inflammation
	CK-18	Apoptosis	Variable – inconsistent signal	Limited	Weak/inconsistent	Variable	Mechanistic relevance to cell death	Poor standardization, high variability
	PRO-C3	Fibrogenesis	Moderate – early signal anti-fibrotic activity	Limited–moderate	Emerging predictive value	Slow	Specific to collagen formation	Small early changes, less sensitive short-term
Composite Scores	Fibrosis-4 (FIB-4)	Fibrosis risk	Low for PoM	Limited	Low (short-term)	Slow	Simple, widely used, cost effective	Insensitive to short-term change
	Enhanced Liver Fibrosis (ELF) score	Fibrogenesis	Moderate	Limited	Moderate (longer-term)	Slow	Reflects ECM remodeling	Modest early changes
	Fibroscan-AST (FAST) score	Steatosis + inflammation + fibrosis	Limited as PD marker	Limited	Moderate (not synchronous)	Moderate	Identifies "at-risk MASH" (F2–F3)	Limited validation for dynamic response
Imaging Biomarkers	MRI-PDFF	Hepatic steatosis	High – robust PoM marker	High – detects dose response	Strong predictor (≥30% reduction linked to histologic response)	Rapid (4-12 weeks)	Highly sensitive, reproducible	Focuses on fat, not fibrosis directly
	Magnetic Resonance Elastography (MRE)	Fibrosis (& fibrosis)	Moderate	Limited (short-term)	Moderate (long-term)	Slow	High sensitivity for fibrosis	Cost, accessibility constraints
	VCTE (FibroScan)	Fibrosis (& fibrosis)	Low–moderate	Limited	Limited	Slow	Widely available non-invasive, FDA accepted letter intent	Less sensitive than MRE, variability
	Iron-corrected T1 (cT1)	Inflammation + Fibrosis	Moderate	Moderate	Emerging predictive value	Moderate	Monitoring and risk stratification	Less standardized, fewer datasets than MRI-PDFF

2339 | UTILITY OF VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY IN PATIENTS WITH ELEVATED BMI: BIOPSY-VALIDATED ASSESSMENT OF BMI-DEPENDENT DISCORDANCE WITH FIB-4

Neharika Bandaru[1] Allen Luo[1] Chester Hui[1] Kali Zhou[1] Emilie Mitten[2] Marvin Ryou[3] Thomas Wang[1], [1]Keck School of Medicine of USC, [2]Brigham and Women's Hospital, Massachusetts General Hospital, [3]Brigham and Women's Hospital

Background: Vibration-controlled transient elastography (VCTE) and Fibrosis-4 index (FIB-4) are commonly used noninvasive tools for fibrosis risk stratification in metabolic dysfunction-associated steatotic liver disease (MASLD). Although FIB-4 has shown stable performance across body mass index (BMI) classes, obesity may reduce the diagnostic accuracy of VCTE. We aimed to (1) evaluate the relationship between BMI and discordance between FIB-4 and VCTE results and (2) determine which modality more accurately predicts advanced fibrosis when discordance is present. **Methods:** We performed a retrospective multicenter study across three healthcare systems from 2016 to 2025, including

adults aged ≥18 years old. Adults with biopsy-proven MASLD, VCTE, laboratory testing within 1 year were included. Patients with alternative liver disease etiologies or ≥10% total body weight loss between testing and biopsy were excluded. Patients were stratified by BMI (<30, 30–34.9, 35–39.9, and ≥40 kg/m²). FIB-4 and VCTE thresholds for advanced fibrosis were defined according to AASLD guidance (<1.3 low risk and >2.67 high risk for FIB-4; <8 kPa low risk and >12 kPa high risk for VCTE). Diagnostic performance for advanced fibrosis was assessed using AUROC analysis across BMI categories. Discordance was defined as low-risk FIB-4 with high-risk VCTE or high-risk FIB-4 with low-risk VCTE. **Results:** A total of 597 patients were included, of whom 188 (31.5%) had biopsy-confirmed advanced fibrosis (F3+). Overall, VCTE and FIB-4 showed similar diagnostic accuracy for advanced fibrosis (AUROC 0.774 vs 0.734, p = 0.17). There was a trend towards lower diagnostic accuracy with FIB-4 across all BMI categories, reaching statistical significance only in patients with BMI <30 kg/m² (0.826 vs 0.713, p = 0.0069). Rates of discordance between FIB-4 and VCTE increased with BMI and were driven predominantly by low FIB-4/high VCTE discordance. Specifically, low FIB-4/high VCTE discordance increased from 4.2% in patients with BMI <30 kg/m² to 30.5% in patients with BMI ≥40 kg/m² (p < 0.0001). In these discordant cases, FIB-4 correctly predicted fibrosis stage in 81.3% of patients with BMI ≥40 kg/m². The reverse discordance pattern (high FIB-4/low VCTE) was uncommon, with no cases among those with BMI ≥40 kg/m². For patients with BMI <30 kg/m², VCTE was more accurate for the reverse discordance pattern (83.3%, p = 0.02). **Conclusion:** Increasing BMI was associated with greater discordance between FIB-4 and VCTE assessment of advanced fibrosis risk in MASLD. In patients with BMI ≥40 kg/m², discordance most often occurred with high-risk VCTE but low-risk FIB-4 results, with biopsy more frequently supporting FIB-4 classification. These findings suggest standard VCTE thresholds may overestimate advanced fibrosis in severe obesity and that BMI-adjusted interpretation may improve risk stratification.

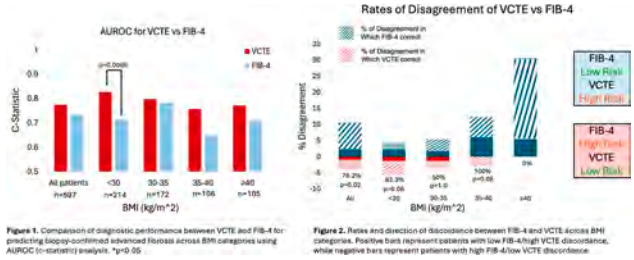

Figure 1. Comparison of diagnostic performance between VCTE and FIB-4 for predicting biopsy-confirmed advanced fibrosis across BMI categories using AUROC (c-statistic) analysis. *p<0.05

Figure 2. Rates and direction of discordance between FIB-4 and VCTE across BMI categories. Positive bars represent patients with low FIB-4/high VCTE discordance, while negative bars represent patients with high FIB-4/low VCTE discordance.

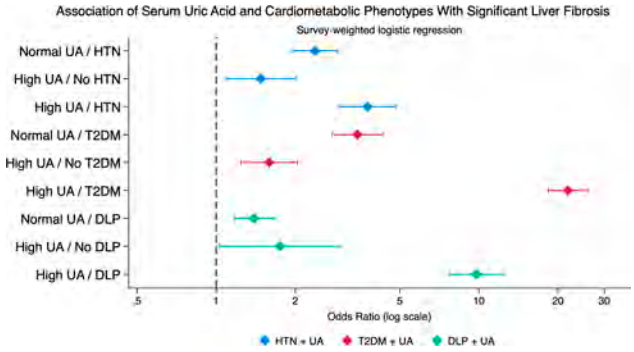
2340 | ELEVATED SERUM URIC ACID ENHANCES THE ASSOCIATION BETWEEN CARDIOMETABOLIC RISK FACTORS AND SIGNIFICANT LIVER FIBROSIS: A NHANES ANALYSIS 2021-2023



Angela Sato Espinoza[1] Ruchita Jadhav[1] Manaal Babar[1] Javier Diaz Ferrer[2], [1]Sinai Hospital of Baltimore, [2]Hospital Rebagliati Martins

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide. Cardiometabolic risk factors are well-established as independent drivers of MASLD and progression to liver fibrosis. In addition to these metabolic risk factors, elevated serum uric acid has also emerged as a potential independent contributor to MASLD. However, limited studies have evaluated the combined impact of elevated serum uric acid and cardiometabolic risk factors. We aimed to evaluate the association between elevated serum uric acid, cardiometabolic risk factors, and significant liver fibrosis among U.S. adults. **Methods:** We used NHANES 2021-2023 data to identify individuals aged 18 years and older. Type 2 Diabetes (T2DM) was defined with HbA1C ≥6.5%, while no diabetes as HbA1C <6.5%. Hypertension (HTN) status was determined from survey questionnaire responses. Dyslipidemia (DLP) was defined as HDL <50mg/dL for females, <40 mg/dL for males, and/or triglycerides >150 mg/dL for both sexes. Significant fibrosis was defined as a liver stiffness measurement (LSM) > 8kPa, and no significant fibrosis as LSM ≤8 kPa. High uric acid was defined as >6 mg/dL for females and >7 mg/dL for males. We classified cardiometabolic phenotypes based on serum uric acid (UA) level and the presence or absence of metabolic comorbidities. **Results:** We included 11,933 individuals in our analysis. The combination of elevated serum uric acid and cardiometabolic risk factors was associated with higher odds of significant liver fibrosis. The T2DM phenotype with elevated UA had the strongest association with significant fibrosis, with nearly 22-fold higher odds of significant fibrosis (OR 21.80, 95% CI 18.35–25.89, p < 0.001). T2DM with normal UA was significantly associated with fibrosis (OR 3.44, 95% CI 2.76–4.29, p < 0.001), while elevated UA without T2DM showed a modest association (OR 1.59, 95% CI 1.24–2.04, p = 0.001). In the HTN phenotype, the highest risk for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

significant fibrosis was observed with both elevated UA and HTN (OR 3.76, 95% CI 2.94-4.82, p < 0.001), compared with HTN and normal UA (OR 2.38, 95% CI 1.95–2.90, p < 0.001) and elevated UA without HTN (OR 1.48, 95% CI 1.09–2.00, p = 0.015). In the DLP phenotype, the highest risk for significant fibrosis was in elevated UA and dyslipidemia (OR 9.78, 95% CI 7.70–12.42, p < 0.001), compared with DLP and normal UA (OR 1.40, 95% CI 1.17–1.66, p = 0.001), and elevated UA without DLP (OR 1.75, 95% CI 1.03–2.97, p = 0.040) (Figure 1). **Conclusion:** Elevated uric acid appeared to amplify the risk of significant fibrosis in the presence of cardiometabolic risk factors, particularly among individuals with diabetes. These findings suggest that serum uric acid could serve as an additional marker to improve risk stratification for significant liver fibrosis in individuals with cardiometabolic diseases.

2341 | MULTIMODAL DISCOVERY AND CLINICAL VALIDATION OF CIRCULATING FIBROSIS BIOMARKERS IN MASH

Elisabeth Galsgaard[1] Gianluca Mazzoni[1] Lea Harder[1] Marie Louise Therkelsen[1] Annabelle Hoegl[1] Mads Grønborg[1] April Hartley[1] Steen Ladelund[1] Anouk Oldenburger[1] Diana Samodova-Sommer[1] Christian Madsen[1] Dres Damgaard[1] Naba Al-Sari[1] Morten Fog-Tonnesen[1] Lise Lotte Gluud[2] Michelle Long[1] Trine Pagh Ludvigsen[1], [1]Novo Nordisk, [2]Copenhagen University Hospital Copenhagen Hvidovre

Background: Omics platforms offer a new frontier for characterising the molecular heterogeneity of hepatic fibrosis in metabolic dysfunction-associated steatohepatitis (MASH), yet the field has not delivered clinically actionable tools. Most omics-based fibrosis studies rely on single-platform approaches, small sample sizes, and lack independent external validation. **Methods:** We conducted a cross-validated biomarker study anchored in a *discovery cohort* Copenhagen Cohort of MASLD (CoCoM) with paired liver and plasma multi-omics and systematically evaluated candidate fibrosis BMs across complementary independent resources. *Genetic support*: Summary-level Mendelian randomization using published genome-wide association studies (GWAS) for metabolic dysfunction-associated steatotic liver disease (MASLD), MASH, and cirrhosis as exposures and proteomics from UK Biobank (UKB, Olink) and DECODE (SomaScan, SomaLogic) for outcomes. *Preclinical study*: Disease progression and antifibrotic treatment effect in rat choline-deficient high-fat diet (CDHFD) study with hepatic liquid chromatography-mass spectrometry (LC-MS) proteomics and transcriptomics. *Validation cohorts*: Semaglutide MASH phase 2 randomized controlled trials (RCTs) with serum SomaScan proteomics at baseline or pre-screening visits. *Clinical feasibility*: Evaluation of immuneassays and recombinant proteins from commercial suppliers. *Statistical analysis*: see table. **Results:** Plasma SomaScan and LC-MS proteomics analyses in the *discovery* cohort identified 43 circulating biomarkers linked to MASH fibrosis stage, strongly correlated with their encoding transcript expression levels in liver biopsy samples. Genetic analysis provided support for 21 of the 43 candidate BMs showing that MASH was driving the observed change in circulating levels. BM candidates were evaluated in i) longitudinal analysis of CDHFD data correlating BM changes in hepatic protein and gene expression levels with disease progression, ii) BM modulation by pharmacological intervention with ALK5 inhibitor in the pre-clinical study, iii) RCTs for validation of association of circulating BM levels with fibrosis stages, and iv) availability of BM immunoassay from trusted vendors. We ranked the identified proteins and present the top 4 candidate BMs: C7 Complement Factor, IGF-1 Binding Protein 7 (IGFBP7), Tissue Inhibitor of Metalloproteinases 1 (TIMP1), and ADAMTS-like 2 (ADAMTSL2). **Conclusion:** This study identified biologically anchored, clinically feasible candidate fibrosis BMs ready for prospective analytical validation and qualification. Several candidate BMs have been previously identified, further validating this approach. If confirmed in larger independent cohorts, these proteins, individually or as a composite panel, have the potential to

2342 | PORTAL HYPERTENSIVE COMPLICATIONS IN PATIENTS WITH MASLD AND ALPHA-1 ANTITRYPSIN DEFICIENCY

Madeha Irfan[1] Talal Bhatti[1] Sajid Jalil[2] Ashwani Singal[3] Ahmed Ibrahim[4] Shahzad Ashraf[5] Sanjaya Satapathy[1], [1]Northwell Health, [2]Stanford University, [3]University of Louisville, [4]San Joaquin General hospital, [5]Prime Medical and Dental college

Background and Aims: Portal hypertension represents a major driver of morbidity and transition to decompensated liver disease in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). Alpha-1 Antitrypsin Deficiency (A1ATD) is associated with progressive hepatic fibrosis and cirrhosis; however, its impact on portal hypertension-related complications in MASLD remains poorly characterized. This study evaluated the association between concomitant A1ATD and clinically significant portal hypertensive outcomes in patients with MASLD. **Methods:** A retrospective cohort study was conducted using the TriNetX US Collaborative Network comprising 66 healthcare organizations. Adult patients with MASLD diagnosed between January 1, 2005, and May 21, 2021, were identified and stratified according to the presence (A1+) or absence (A1−) of A1ATD. Patients with competing chronic liver diseases were excluded. Following 1: 1 propensity score matching, 2,122 patients were included in each cohort. Primary outcomes included variceal hemorrhage, ascites, and hepatic encephalopathy (HE). Secondary outcomes included spontaneous bacterial peritonitis (SBP) and hepatorenal syndrome (HRS). Relative risks (RRs), Kaplan–Meier analyses, and hazard ratios (HRs) were evaluated. **Results:** Among 4,244 propensity score-matched patients, A1ATD was associated with significantly increased portal hypertension-related morbidity. Patients with A1ATD demonstrated higher risks of variceal hemorrhage (2.3% vs. 1.1%; RR 1.97, 95% CI 1.21–3.20; $p = 0.006$), ascites (8.2% vs. 4.9%; RR 1.68, 95% CI 1.31–2.16; $p < 0.001$), and HE (10.7% vs. 7.0%; RR 1.53, 95% CI 1.24–1.88; $p < 0.001$). A1ATD was additionally associated with increased risks of SBP (2.0% vs. 0.7%; RR 3.04, 95% CI 1.67–5.56; $p < 0.001$) and HRS (2.6% vs. 1.2%; RR 2.22, 95% CI 1.39–3.55; $p = 0.001$). Detailed outcomes are summarized in Table 1. **Conclusion:** In this large propensity score-matched cohort, concomitant A1ATD was associated with significantly increased risks of portal hypertensive complications and downstream systemic sequelae in patients with MASLD. These findings identify A1ATD as an important risk modifier requiring earlier recognition and closer clinical surveillance.

Table 1. Portal Hypertensive Outcomes in Propensity Score-Matched Cohorts

Outcome	MASLD + A1ATD	MASLD Alone	RR (95% CI)	P value
Variceal hemorrhage	2.3%	1.1%	1.97 (1.21–3.20)	0.006
Ascites	8.2%	4.9%	1.68 (1.31–2.16)	<0.001
Hepatic encephalopathy	10.7%	7.0%	1.53 (1.24–1.88)	<0.001
Spontaneous bacterial peritonitis	2.0%	0.7%	3.04 (1.67–5.56)	<0.001
Hepatorenal syndrome	2.6%	1.2%	2.22 (1.39–3.55)	0.001

2343 | THE FIB-4 BLIND SPOT: ELEVATED GGT IDENTIFIES VCTE-DEFINED ADVANCED FIBROSIS MISSED BY CONVENTIONAL FIB-4 RISK STRATIFICATION IN T2DM-ASSOCIATED MASLD

Mona Ismail[1], [1]Imam Abdulrahman Bin Faisal University

Background: The Fibrosis-4 index (FIB-4) is a first-line non-invasive test for fibrosis risk stratification in MASLD. Patients classified as low risk may not undergo further assessment. We evaluated whether elevated gamma-glutamyl transferase (GGT) identifies VCTE-defined advanced fibrosis among patients classified as low-risk FIB-4. **Methods:** We retrospectively studied 209 adults with T2DM-associated MASLD who underwent reliable VCTE at a tertiary university hospital. MASLD was defined by controlled attenuation parameter ≥247 dB/m with sonographic steatosis. Elevated GGT was defined a priori as >38 U/L. Guideline-recommended age-adjusted FIB-4 thresholds were applied. The primary outcome was VCTE-defined advanced fibrosis (liver stiffness measurement [LSM] ≥8.0 kPa); cirrhosis (LSM ≥13.0 kPa) was secondary. Patients were categorized by FIB-4 risk status and GGT level. A modified FIB-4–GGT pathway flagged patients with indeterminate/high-risk FIB-4 or elevated GGT despite low-risk FIB-4. **Results:** Overall, 43/209 (20.6%) had advanced fibrosis and 25/209 (12.0%) had cirrhosis. FIB-4 classified 173/209 patients (82.8%) as low risk, including 27/43 with advanced fibrosis (62.8%) and 16/25 with cirrhosis (64.0%). Within the low-risk FIB-4 group, advanced fibrosis was more prevalent with elevated versus normal GGT (21/70 [30.0%] vs 6/103 [5.8%]), as was cirrhosis (13/70 [18.6%] vs 3/103 [2.9%]). This pattern persisted among patients with normal aminotransferases (advanced fibrosis: 9/29 [31.0%] vs 4/79 [5.1%]). Among low-risk FIB-4 patients, elevated GGT was present in 21/27 (77.8%) advanced fibrosis cases and 13/16 (81.3%) cirrhosis cases. Adding GGT to FIB-4 captured 37/43 (86.0%) advanced fibrosis and 22/25 (88.0%) cirrhosis cases, versus 16/43 (37.2%) and 9/25 (36.0%) with FIB-4 alone **(Figure 1). Conclusion:** In T2DM-associated MASLD, most patients with VCTE-defined advanced fibrosis or cirrhosis were classified as low risk by FIB-4. Elevated GGT identified a higher-risk subgroup within the low-risk FIB-4 group, including patients with normal aminotransferases, and captured most cases missed by FIB-4 alone. GGT may complement FIB-4 in fibrosis risk stratification, warranting prospective validation within risk-stratification pathways.

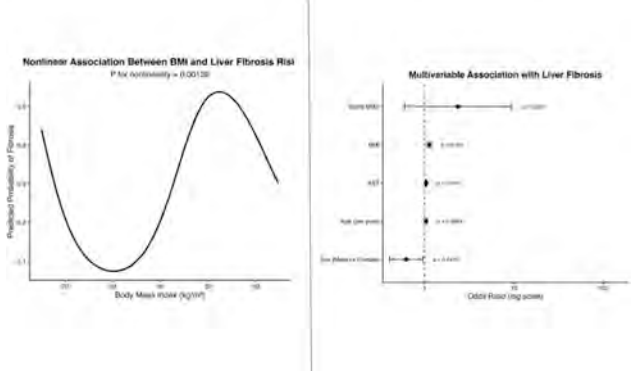
2344 | METABOLIC THRESHOLD PATTERN OF OBESITY AND LIVER FIBROSIS SEVERITY IN A NATIONALLY REPRESENTATIVE U.S. COHORT



Narissa Nursjamsi[1] Prateeka Kodali[2] Elsa Sasongko[3] Kesava Achuta[4] Pranay Gupta[1] Sujata Kambhatla[1], [1]garden city hospital/msucom, [2]Sichuan University, Chengdu, China, [3]Faculty of Medicine, Universitas Padjadjaran, [4]garden city hospital/ msucom

Background: BMI has been linked to hepatic fibrosis, although the relationship may not be strictly linear, particularly in severe obesity. In addition, shared metabolic and inflammatory pathways have raised interest in the potential association between bone mineral density (BMD) and liver fibrosis, though existing evidence remains inconsistent. Using the NHANES cohort, we

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

evaluated the association between BMI and liver fibrosis severity and explored nonlinear BMI effects and potential interaction with BMD. **Methods:** This cross-sectional analysis was conducted using the NHANES 2017-2020 cycles. Data collected included participant demographics, CBC, HbA1c, hepatic function panel, lumbar spine DXA, controlled attenuation parameter (CAP), and vibration-controlled transient elastography. The dataset was merged using participant unique identifier SEQN. Prticipants with missing DXA, BMI, or other survey design variables were excluded. All analyses incorporated NHANES complex survey design variables (sampling weights, strata, and clusters). Multivariable logistic regression was used to evaluate independent variables associated with liver fibrosis. Restricted cubic spline modeling was used to assess associations between BMI and fibrosis. **Results:** The final analytic cohort included 1918 participants, predominantly older adults due to lumbar spine DXA availability. BMI was broadly distributed falling within 20-40 with highest fibrosis prevalence observed among participants with BMI $\geq$35. Restricted cubic spline analysis showed a significant nonlinear association between BMI and liver fibrosis (P for nonlinearity = 0.00139) with disproportionate increase in fibrosis risk beginning in the obese range, suggesting a threshold-dependent metabolic relationship rather than a linear dose-response relationship. In multivariable survey-weighted analysis, BMI and AST were independently associated with increased odds of liver fibrosis. BMI (OR 1.14 and 1.07 respectively with both p < 0.001), followed by age (OR 1.03; p = 0.0354). Sex independently associated with liver fibrosis (OR 0.60, p = 0.0416) . Spine BMD did not show association with odds of liver fibrosis (OR 2.04; p = 0.235). **Conclusion:** BMI was non linearly associated with liver fibrosis, with disproportionately higher risk in severe obesity. AST remained the strongest predictor, while BMD was not associated. These findings support earlier fibrosis surveillance and risk stratification in patients with high BMI.

Santiago, Chile, [23]Escuela de Medicina, Universidad de los Andes, Santiago, Chile, [24]Escuela de Medicina, Universidad del Alba, Santiago, Chile, [25]Hospital Nacional Edgardo Rebagliati Martins, Jesús María, Lima, Perú, [26]Liver Unit, Hospital Central de Mendoza, Mendoza, Argentina, [27]National Institute of Diabetes, Nutrition, and Endocrinology, Santo Domingo, Dominican Republic, [28]Departamento de Medicina Interna, Hospital Clínico Universidad de Chile, Santiago, Chile, [29]University of Chile, [30]Virginia Commonwealth University, [31]MASLD Research Center, University of California, San Diego School of Medicine, [32]Facultad de Medicina Pontificia Universidad Católica de Chile

Background: Latin America faces a growing burden of steatotic liver disease (SLD), yet previous assessments of most non-invasive tests (NITs) for fibrosis risk stratification have demonstrated poor performance in this population, particularly in retrospective cohorts. We aimed to compare the performance of commonly used serum-based and laboratory-derived NITs for predicting fibrosis in a well-characterized multinational Latin American SLD cohort. **Methods:** Cross-sectional analysis of prospectively enrolled adults with steatotic liver disease (SLD) at 16 tertiary centers across seven countries (Argentina, Brazil, Chile, Colombia, Dominican Republic, Mexico, and Peru). Fibrosis severity was assessed using liver biopsy, vibration-controlled transient elastography (VCTE), or clinical diagnosis of cirrhosis. Evaluated NITs included composite fibrosis indices, such as FIB-4, MAF-5, APRI, GGT-to-platelet ratio (GPR), and AST/ALT ratio, as well as individual laboratory markers such as AST, ALT, GGT, and platelet count. Diagnostic performance was assessed using AUROC, sensitivity, and specificity analyses, as well as logistic regression models. **Results:** The cohort included 923 participants (85.1% MASLD, 6.0% MetALD, and 8.9% ALD). The median age was 62 [52–69] years, and 56.6% were women. Significant and advanced fibrosis were present in 45.9% and 35.5% of participants, respectively. Among composite fibrosis index NITs, FIB-4 demonstrated the strongest discriminatory performance for significant fibrosis (AUROC: 0.723, 95% CI: 0.685–0.761) and advanced fibrosis (AUROC: 0.707, 95% CI: 0.669–0.745), followed closely by APRI (AUROC: 0.719, 95% CI: 0.679–0.758; and 0.704, 95% CI: 0.666–0.742, respectively). Platelet count also demonstrated strong discrimination across fibrosis stages (AUROC: 0.720, 95% CI: 0.683–0.757 and 0.726, 95% CI: 0.680–0.762, respectively). Compared with the lowest-risk category, FIB-4 >2.67 was associated with markedly increased odds of significant fibrosis (OR: 13.05, 95% CI: 7.03–24.23) and advanced fibrosis (OR: 13.45, 95% CI: 8.03–22.52). Platelet count $<150\times10^9$ /L was similarly associated with substantially increased odds of significant fibrosis (OR: 23.05, 95% CI: 10.56–50.33) and advanced fibrosis (OR: 15.89, 95% CI: 9.04–27.95). **Conclusion:** In this multinational Latin American SLD cohort, FIB-4 and APRI demonstrated the strongest performance among serum-based NITs for predicting fibrosis severity. Platelet count alone also showed strong discriminatory ability and robust associations with fibrosis progression. These findings support the utility of inexpensive and widely accessible NITs for fibrosis risk stratification in Latin American populations with SLD (Fondecyt #1241450).

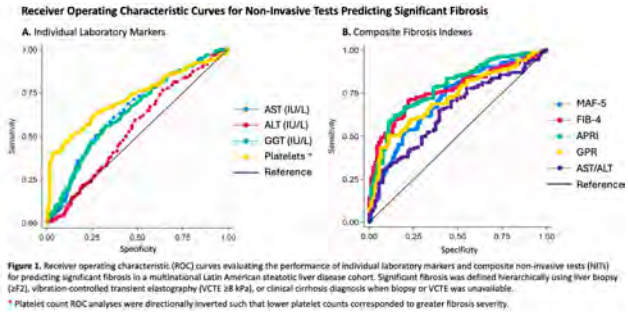

Figure 1. Receiver operating characteristic (ROC) curves evaluating the performance of individual laboratory markers and composite non-invasive tests (NITs) for predicting significant fibrosis in a multinational Latin American steatotic liver disease cohort. Significant fibrosis was defined hierarchically using liver biopsy (≥F2), vibration-controlled transient elastography (VCTE ≥8 kPa), or clinical cirrhosis diagnosis when biopsy or VCTE was unavailable.
* Platelet count ROC analyses were directionally inverted such that lower platelet counts corresponded to greater fibrosis severity.

2346 | OPTIMIZING MASH CLINICAL TRIAL SCREENING USING LIVERPRO: ANALYSIS OF THE PHASE 2B EMMINENCE TRIAL

Julie Astono[1] Katrine Lindvig[1] Jerry Colca[2] Maja Thiele[1], [1]Evido Health, [2]Western Michigan University

Background: Efficient identification of patients eligible for clinical trials in metabolic dysfunction-associated steatohepatitis (MASH) is difficult with screen failure rates (SFR) often exceeding 80%. Non-invasive tests like FIB-4 can reduce biopsies but may miss eligible patients due to low sensitivity. We evaluated the potential of LiverPRO, a novel flexible blood-based medical device software for detecting liver fibrosis, to optimize screening compared with FIB-4. We conducted a retrospective analysis of the phase 2b EMMINENCE trial of the insulin sensitizer MSDC-0602K, which was handicaped by recruitment strategy and showed statistical histological benefit only on post-hoc analysis. **Methods:** We modeled four screening pathways using data from the EMMINENCE trial: (a-b) LiverPRO at cut-offs 0.25 and 0.65, (c-d) FIB-4 at cut-offs 1.3 and 2.67. Our primary outcome was SFR, secondary outcomes were proportion of unnecessary biopsies and missed eligible cases. The target of this analysis was enrollment with eligibility criteria commonly used in recent MASH trials: fibrosis stage $\geq$ F2 + non-alcoholic fatty liver disease activity score $\geq$ 4 with at least one in each component; steatosis, ballooning and inflammation, reflecting recruitment to both pre-cirrhosis and cirrhosis trials. **Results:** The EMMINENCE trial screened 1,090 individuals and performed liver biopsy in the 725 with aspartate aminotransferase $\geq$ 20 U/L, controlled attenuation parameter $\geq$ 270 dB/m and liver stiffness measurement $\geq$ 8.5 kPa. Of those, 222 (31%) met the target. The LiverPRO $\geq$ 0.25 pathway identified 628/1,090 individuals, of whom 460 had a biopsy, and 184 met target yielding a SFR of 71%. FIB-4 $\geq$ 1.3 yielded a slightly lower SFR of 67%. However, FIB-4 missed 35% of cases compared with 17% for LiverPRO, a relative reduction of 51%. The rate of unnecessary biopsies remained comparable: LiverPRO 60% and FIB-4 57%. At higher thresholds, LiverPRO $\geq$ 0.65 achieved the lowest SFR of 55%, while FIB-4 $\geq$ 2.67 had a slightly higher SFR of 63%, although at the expense of missed cases. LiverPRO missed 77%, while FIB-4 missed 89%. Unnecessary biopsy rates were 46% for LiverPRO and 51% for FIB-4. The AUROCs were 0.702 (95% CI: 0.661–0.742) for LiverPRO and 0.689 (95% CI: 0.648–0.730) for FIB-4. **Conclusion:** LiverPRO captures a greater proportion of eligible patients than FIB-4 without markedly increasing the unnecessary liver biopsies, suggesting that LiverPRO can enhance recruitment efficiency. Stricter screening thresholds reduce screen failures at the expense of more missed cases. The high screening thresholds can be used if sites are able to widen the screening funnel to achieve the required enrollment. LiverPRO's flexible design supports large-scale screening. This screening strategy will facilitate the recruitment and conduct of Phase 3 registration studies.

2347 | REPRODUCIBILITY BETWEEN AND REPEATABILITY OF FREE-BREATHING AND BREATH-HOLD 2D SE-EPI MRE FOR QUANTIFYING LIVER STIFFNESS

Gage Tanzman[1] Lael Ceriani[1] Nicholas Tripathi[1] Tanya Wolfson[1] Gavin Hamilton[1] Mary Dalupang[1] Egbert Madamba[1] Michael Middleton[1] Richard Ehman[2] Kevin Glaser[2] Yuan Le[2] Jiahui Li[2] Meng Yin[3] Yesenia Covarrubias[1] Mustafa Bashir[4] Scott Reeder[5] Bachir Taouli[6] Rohit Loomba[1] Claude Sirlin[1], [1]University of California, San Diego, [2]Mayo Clinic Rochester, [3]Mayo Clinic, [4]Duke University, [5]University of Wisconsin, Madison, [6]Icahn School of Medicine at Mount Sinai (ISMMS)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Free-breathing (FB) 2D spin-echo EPI (SE-EPI) magnetic resonance elastography (MRE) is an ~40-s investigational alternative to conventional ~16-s breath-hold (BH) 2D SE-EPI MRE. It uses the same 4-slice pulse sequence design but reduces the TR from ~1600ms to ~450ms, increases the number of phase offsets from 4 to 40, and uses temporal averaging. This increases the sampling efficiency, maintains the signal-to-noise ratio (SNR), reduces motion artifacts, and can be used when patients have difficulty suspending respiration. We sought to assess reproducibility between and repeatability of FB and BH 2D MRE for quantifying liver stiffness (LS) in adults with chronic liver disease (CLD). **Methods:** This prospective, single-center study enrolled adults with known or suspected CLD who received same-day FB and BH 2D SE-EPI MRE exams, a subset of whom had repeat exams after repositioning. Images were acquired at 60Hz on a GE 3T system with a 420-mm field-of-view reconstructed to a 256x256 final matrix. Expert analysts placed regions of interest (ROIs) in areas of planar wave propagation and recorded LS and cumulative ROI size (cROI). Exams were scored successful if cROI $\geq$ 700 pixels (Px). Success rate (SR) of each method was calculated. cROI (paired t-test) and SR (McNemar's test) were compared between methods. Inter-method reproducibility (all participants) and intra-method repeatability (of repeated exams) for quantifying LS were assessed by Bland-Altman analysis, yielding bias and its p-value, limits of agreement (LoA), proportional reproducibility (RDC %) or repeatability (RC%) coefficient, and intraclass correlation coefficient (ICC) with 95% confidence intervals (CIs). RC% were compared between methods using nonparametric bootstrap. **Results:** This study included 256 participants (136 female; mean age 56 ± 13 yrs; mean body mass index 31 ± 6 kg/m^2), 15 of whom had repeated exams. Median (range) cROIs were 4,349 (863-11,644) Px for FB and 4,398 (781-11,038) Px for BH 2D MRE (p = 0.366). The SR of FB (94%) and BH (95%) 2D MRE were also similar (p = 0.387). In 236 participants, both methods were successful. In these, mean LS (range) was 3.1 (1.0-12.2) kPa for FB and 3.0 (1.5-12.2) kPa for BH 2D MRE. Bias (p-value), LoA, RDC%, and ICC (95% CI) were 0.06 kPa (p = 0.002), (-0.5 kPa, 0.6 kPa), 19.4%, and 0.985 (0.980, 0.989), respectively. The difference in RC% for FB (8.3%) and BH (14.6%) 2D MRE was -6.3% (p = 0.013). **Conclusion:** In adults with CLD imaged at 3T, FB 2D MRE agreed with and had better repeatability than BH 2D MRE, with precision metrics akin to test-retest repeatability of BH 2D MRE in prior studies and negligible bias. FB 2D MRE is feasible as a repeatable alternative to BH 2D MRE.

2348 | ASSOCIATION OF PROGNOSTIC NUTRITIONAL INDEX WITH HISTOLOGICAL STAGE AND MORTALITY IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Yixuan Zhu[1] Jie Li[2], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University, [2]Nanjing Drum Tower Hospital

Background: Nutritional–metabolic dysregulation is a central driver of metabolic dysfunction–associated steatotic liver disease (MASLD), yet quantitative assessment of nutritional status remains limited.This study aimed to investigate the associations between the prognostic nutritional index (PNI), an indicator of nutritional reserve, immune competence, and systemic inflammation, with histological severity and mortality in MASLD. **Methods:** This study included four population-based cohorts: two cross-sectional cohorts, the liver biopsy cohort and the vibration-controlled transient elastography (VCTE; FibroScan) cohort from 7 medical centers across China from 2004 to 2024, and two longitudinal cohorts, the National Health and Nutrition Examination Survey (NHANES) III cohort from the United States and the UK Biobank cohort from the United Kingdom. Logistic regression and restricted cubic splines were used to investigate the association between PNI levels and significant steatosis, moderate-to-severe inflammation and advanced fibrosis.The relationship between PNI and all-cause and cardiovascular-related mortality were subsequently assessed by cox and competing risk models in two follow-up cohorts. **Results:** We included 969 biopsy-proven and 1,967 VCTE-based Chinese MASLD patients. In the biopsy cohort, PNI showed a biphasic pattern across disease stages, initially rising and subsequently declining, with the inflection point corresponding to the onset of moderate-to-severe inflammation or advanced fibrosis. Higher PNI was independently and linearly associated with significant steatosis (P for nonlinear = 0.209), whereas lower PNI was linearly associated with moderate-to-severe inflammation, advanced fibrosis, and "burnt-out" MASLD (all P for nonlinear > 0.05), with these associations particularly evident in individuals aged ≥ 45 years.Findings were replicated in the VCTE cohort. In two longitudinal cohorts, lower PNI was associated with higher risks of all-cause, cardiovascular, and liver-related mortality, with a pronounced increase in risk observed in the lowest PNI category. **Conclusion:** PNI reflects histological disease phenotype and may serve as an independent prognostic marker. PNI may be a helpful tool to monitoring nutritional status and improve risk stratification in individuals with MASLD.

2349 | DIFFERENTIAL CANCER RISKS AND NONINVASIVE PREDICTORS IN MASLD, METALD, AND ALD: A LONGITUDINAL ANALYSIS

Hana Park[1] Ji Young Lee[2] Ja Eun Koo[2] Jong Soo Lee[2] Sungwon Park[2] Hye Won Park[2] Hye-Sook Chang[2] Hong-Kyu Kim[2] Jaewon Choe[2] Ju Hyun Shim[2], [1]Konkuk University School of Medicine, [2]Asan Medical Center

Background: The recently proposed classification of steatotic liver disease (SLD) includes metabolic dysfunction–associated steatotic liver disease (MASLD), MASLD with increased alcohol intake (MetALD), and alcohol-related liver disease (ALD). However, differences in long-term cancer risk across these phenotypes remain incompletely characterized. This study investigated cancer incidence across SLD subgroups. **Methods:** This longitudinal cohort study included 43,994 adults who underwent health check-ups between 2010 and 2011. Liver steatosis was diagnosed by ultrasonography. The predictive potential of the Fibrosis-4 Index (FIB-4) and the Steatosis-Associated Fibrosis Estimator (SAFE) score for cancer incidence was evaluated. **Results:** During a median follow-up period of 10.5 years (398,202 person-years), 3,169 cancers were documented (7.2%; 796.4 per 100,000 person-years). Compared with individuals without SLD, overall cancer risk was elevated in ALD (IRR 1.38, 95% CI 1.08–1.79) but not in MASLD or MetALD. Hepatocellular carcinoma risk was increased across all SLD groups. ALD was associated with an elevated risk of esophageal cancer (IRR 3.69) and stomach cancer (IRR 1.81), while MetALD was associated with an increased risk of stomach cancer (IRR 1.61). MASLD in women showed elevated risks of overall (IRR 1.19) and gynecological cancers (IRR 1.49). FIB-4 and SAFE scores demonstrated dose-response associations with cancer risk in all SLD subgroups. **Conclusion:** Cancer risk profiles differ across MASLD, MetALD, and ALD, with alcohol-related phenotypes showing the highest cancer burden. Noninvasive fibrosis indices such as FIB-4 and SAFE can stratify cancer risk and inform tailored surveillance strategies in patients with SLD.

2350 | A PROGNOSTIC COMPARISON OF SIMPLE BLOOD TESTS FOR THE FIRST-LINE STRATIFICATION OF THE SEVERITY OF STEATOTIC LIVER DISEASE

Jerome Boursier[1] Adrien Lannes[2] Isabelle Fouchard[2] Frederic Oberti[2] Marine Roux[1], [1]Angers University, [2]Angers University Hospital

Background: The new blood tests Liver Risk Score (LRS), SAFE, MAF-5 and eLIFT are potential alternatives to the recommended FIB-4 for identifying at-risk patients in steatotic liver disease (SLD). Diagnostic studies that compared these simple non-invasive tests (NITs) used liver stiffness as the reference, which is only a surrogate of SLD severity. Here, we aimed: i) to determine which simple NITs best rule out patients at low liver risk in a longitudinal study with hard outcomes as the endpoint; and ii) to evaluate whether accuracy in diagnosing liver stiffness translates into prognostic accuracy. **Methods:** The ARPPEGE Registry aggregates data from all patients who have been managed at our Hepatology Department since 2004. From the Registry, we selected patients with SLD (MASLD or excessive alcohol consumption) who had data for NITs calculation, and who had no history of liver-related events (LRE) before or within 3 months after baseline. Eight simple NITs were evaluated (rule-out threshold): FIB-4 (< 1.30), APRI (≤ 0.5), NAFLD Fibrosis Score (NFS; < -1.455), Forns Index (FI; < 4.2), LRS (< 6), MAF-5 (< 0), SAFE (< 0), eLIFT (< 8). The study endpoint was LRE defined as cirrhosis complication or hepatocellular carcinoma. Discrimination for LRE was evaluated using integrated area under the receiver-operating characteristics (iAUC). **Results:** 2,682 patients were included (MASLD: n = 1,557; alcohol: n = 1,125). 350 LRE occurred during the median 5.9 years follow-up [IQR: 3.4-10.3], including 259 cirrhosis decompensations and 91 HCC. iAUC for LRE prediction was 81.8 [95%CI: 81.1-82.5] for eLIFT, FIB-4: 81.0 [80.2-81.8], SAFE: 80.7 [79.9-81.4], FI: 80.2 [79.4-81.0], LRS: 76.6 [75.8-77.4], APRI: 75.4 [74.6-76.3], NFS: 75.0 [74.2-75.9], MAF-5: 68.3 [67.4-69.2]. Using rule out threshold, the best balance between rate of patients in the low-risk group and sensitivity for LRE was achieved with eLIFT (low risk: 42%/sensitivity: 89%), FIB-4 (41%/89%), and LRS (30%/93%). SAFE, MAF-5 and FI provided better sensitivity (94-97%), but lower rate of low-risk patients (17-22%). Sensitivity for LRE was the lowest with NFS (81%) and APRI (66%). The iAUCs in the alcohol group (MAF-5: 67.8 to eLIFT:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

76.1) were lower than those in the MASLD group (APRI: 74.9 to SAFE: 86.4), but the NITs ranking remained similar between the two aetiologies. Finally, higher accuracy in diagnosing elevated liver stiffness (≥ 8, ≥ 10, ≥ 12 kPa) did not translate into better prognostic accuracy in the MASLD group. Especially, MAF-5 ranked among the top two tests for diagnostic accuracy, even though it has the lowest iAUC (prognosis) along with APRI. Conversely, FIB-4 provided one of the lowest diagnostic accuracies, yet it had the second highest iAUC. **Conclusion:** New simple blood tests do not provide better prognostic accuracy than FIB-4 in SLD. Diagnostic studies should be completed by prognostic evaluation to definitively determine which NITs are the most appropriate for clinical practice.

2351 | α-HYDROXYBUTYRATE, A CIRCULATING MARKER OF HEPATIC REDUCTIVE STRESS, PREDICTS HEPATIC STEATOSIS, VISCERAL FAT AND ATHEROGENIC RISK IN A LARGE, MULTICENTER COHORT

Wesley Dixon[1] Joseph Bonventre[1] Ayumi Takakura[1] Esperance Schaefer[1] Russell Goodman[1], [1]Mass General Brigham

Background: Hepatic reductive stress, defined by increased hepatic NADH/NAD$^+$, is mechanistically implicated in steatotic liver disease pathogenesis, insulin resistance, and dyslipidemia, and is reflected by the circulating biomarker α-hydroxybutyrate (α-HB). Biobank-based phenotyping enables integrated analysis of hepatic steatosis, body composition, and metabolomics to characterize reductive stress-associated disease in humans at scale. **Methods:** We identified adults in the Mass General Brigham Biobank with an abdominal CT scan within one year of biospecimen collection. Demographic and clinical data were from the time of imaging. Body composition features, including visceral fat, subcutaneous fat, and skeletal muscle area, were extracted using automated machine-learning algorithms and reported using z-scores relative to the corresponding demographics ("high" is $z > 0$, "low" is $z < 0$). Hepatic steatosis was quantified using the liver-to-spleen attenuation (L/S) ratio. Metabolomic profiling was performed using Nightingale Health nuclear magnetic resonance spectroscopy. α-HB was measured using the XpressGT kit. **Results:** Among 499 patients, median age was 62.1 (interquartile range 51.7-70.4) years and 45% were female. α-HB did not differ between body mass index (BMI) >30 vs. <25 kg/m^2 (60.3 vs. 56.2 mM; $p = 0.14$) or high vs. low skeletal muscle (56.4 vs. 58.4 mM; $p = 0.82$), but was increased in severe vs. mild-to-no steatosis (63.1 vs. 56.1 mM; $p = 0.026$), high vs. low subcutaneous fat (61.1 vs. 55.4 mM; $p = 0.019$), and high vs. low visceral fat (62.3 vs. 54.3 mM; $p = 2.6e\text{-}4$). Visceral and subcutaneous fat were correlated ($R^2 = 0.47$), with visceral fat primarily driving the increases in α-HB (**Figure 1A**). α-HB correlated with A1c, transaminases, visceral fat, and degree of hepatic steatosis in univariable regression (**Figure 1B**). In multivariable regression of body composition metrics, increased α-HB was independently associated with higher visceral fat ($\beta = 11.50$, $p = 8.7e\text{-}6$), but not subcutaneous fat ($\beta = -6.28$, $p = 0.065$), skeletal muscle ($\beta = 0.63$, $p = 0.78$), or BMI ($\beta = -0.09$, $p = 0.88$). Examining broad metabolomic profiling, α-HB was associated with the metabolically unfavorable saturated/total fatty acid ratio (**Figure 1C**). α-HB was inversely associated with the polyunsaturated/total fatty acid ratio and the omega-6/total fatty acid ratio, metabolic biomarkers associated with cardiovascular health. **Conclusion:** Consistent with mechanistic insights from preclinical studies, circulating α-HB reflects metabolically deleterious fat distribution—particularly visceral adiposity—rather than overall adiposity, as well as hepatic steatosis and atherogenic metabolic profiles. These data support the role of α-HB as a biomarker of steatotic liver disease and metabolic dysfunction.

Figure 1. (A) α-HB compared by visceral and subcutaneous fat ("high" is z-score >0, "low" is z-score <0). (B) Univariable regression between α-HB and select clinical variables and (C) metabolites (predictors are per 1 standard deviation; FA, fatty acids).

2352 | DEVELOPMENT AND VALIDATION OF M-SLD, A BIOPSY-ANCHORED NO-WAIST NONINVASIVE MODEL FOR STEATOTIC LIVER DISEASE

Hyo Jin Nam[1] Hae Young Kim[1] Sung Won Chung[1] Byungchul Cho[1] Won-Mook Choi[1] Jonggi Choi[2] Danbi Lee[1] Ju Hyun Shim[1] Seung Soo Lee[1] Kang Mo Kim[1] Young Suk Lim[1] Han Chu Lee[1], [1]Asan Medical Center, [2]University of Ulsan, Asan Medical Center

Background: FLI is widely used to estimate hepatic steatosis, but most validation studies have relied on ultrasonography rather than histology. We aimed to develop and validate M-SLD, a biopsy-anchored no-waist noninvasive model for steatotic liver disease, compare it with FLI, and externally validate the model in a large ultrasound screening cohort. **Methods:** We conducted a retrospective cross-sectional diagnostic accuracy study. The pathology source cohort included 3,062 patients with biopsy-based steatosis assessment; 363 without alcohol intake data were excluded from the main analysis, leaving 2,699 patients for temporal derivation (n = 1,787) and validation (n = 912). The primary endpoint was biopsy-defined steatosis ≥ S1. M-SLD was developed using ordinary multivariable logistic regression with age, sex, BMI, ln(TG), ln(GGT), ln(ALT), HDL, and diabetes. External validation used an ultrasound-defined health-screening cohort. **Results:** M-SLD outperformed FLI in both derivation (AUROC 0.772 vs 0.710; $p < 0.001$) and validation (0.760 vs 0.683; $p < 0.001$) cohorts. A rule-out threshold of 0.235 yielded validation sensitivity 89.7% and NPV 84.9%, whereas a rule-in threshold of 0.585 yielded validation specificity 88.3%. In the external ultrasound cohort (n = 120,785), M-SLD modestly but significantly outperformed FLI (AUROC 0.873 vs 0.865; $p < 0.001$). Retaining anti-HBc IgG-positive individuals in a sensitivity cohort yielded similar results (0.855 vs 0.849; $p < 0.001$). **Conclusion:** M-SLD is a biopsy-anchored, no-waist noninvasive model that improves upon FLI and provides clinically interpretable rule-out and rule-in thresholds for screening-oriented use.

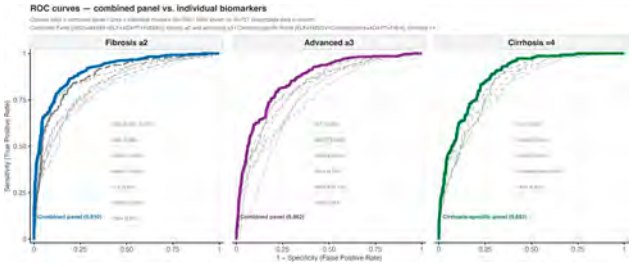
2353 | COMBINATORIAL MODELS OF BIOMARKER PANELS REFLECTING ACTIVITY VERSUS FIBROSIS ALLOW IDENTIFICATION OF MASLD SUB-PHENOTYPES WITH HIGH PRECISION



Gamze Bulut[1] Rohit Loomba[2] Ekaterina Smirnova[1] Katherine Yates[3] Anthony Samir[4] Claude Sirlin[5] Sarah Sherlock[6] Patricia Grebenstein[7] Tania Kamphaus[8] Anna Mae Diehl[9] Kris Kowdley[10] Brent Neuschwander-Tetri[11] David Kleiner[12] Bryce Hatfield[1] Roberto Calle[13] Arun Sanyal[1], [1]Virginia Commonwealth University, [2]University of California, San Diego, [3]Johns Hopkins University, [4]Harvard University Medical School, [5]University of California San Diego, [6]Pfizer, [7]FNIH, [8]NIH, [9]Duke University, [10]Liver Institute Northwest, [11]San Louis University, [12]National Cancer Institute, Bethesda, [13]GSK

Background: None of the currently available circulating biomarker panels identify all key specific phenotypes with high precision. Further, even for specific phenotypes, there is a steep decline in specificity at high sensitivity and vice versa reducing precision. **Aims:** To develop and validate a combinatorial approach leveraging biomarkers reflecting different aspects of disease biology and histology to identify MASH with clinically significant (≥ stage 2), advanced (≥ stage 3) fibrosis or cirrhosis (stage 4). **Methods:** A prespecified analysis of the NIMBLE cohort, a subset of the NIDDK NASH CRN study population, with complete cases of data (n = 764) including NIS2+™, MASEF, ADAPT, ELF, Fibrometer-V 3rd Gen (FM3GV), PROC3-6 and FIB-4 was performed. Non-negative matrix factorization identified biomarkers along 3-factors reflecting disease activity, fibrosis stage and demographic/clinical parameters. Biomarkers were included in the model based on natural elbow in Pearson |r| ranking and individual AUROC ≥ 0.80. Ridge-regression was trained using threshold-specific panels 10x5 repeated stratified cross-validation with stacked out of fold predictions providing stable AUROC estimates. **Results:** For at risk MASH (MASH + NAS ≥ 4 + fibrosis stage ≥ 2), the 5-biomarker model (NIS2+™ + MASEF + ELF + ADAPT + FM3GV), referred to as "combined

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

panel", outperformed (AUROC 0.91, Sens = 86.4%, Spec = 80.9%, PPV = 91.0%, NPV = 72.6%) all of the individual panels including NIS2^{+TM} which had the best AUROC 0.86 for this context of use. Combined panel also performed well for MASH with ≥ stage 3 fibrosis (AUROC = 0.863; Sens = 80.8%, Spec = 77.2%, PPV = 73.4%, NPV = 83.8%) with threshold-specific selection (ELF+ADAPT+FM3GV) offering no meaningful gain (AUROC = 0.859; SD = 0.030). For stage 4 (prevalence = 18.8%), a cirrhosis-specific panel [ELF+FM3GV+CirrhosisScore+ ADAPT+FIB-4] outperformed the combined panel (AUROC = 0.883 vs 0.879), yielding NPV = 96.2% — correctly ruling out cirrhosis in 96% of predicted-negative cases (FN = 18/144). Ridge coefficient analysis revealed divergent biomarker weights across phenotypes: NIS2+^{TM} dominated ≥ stage 2 prediction but not for cirrhosis, while ELF strengthened monotonically from stage 2, to 3 to 4, confirming that a single model does not optimally serve all clinical purposes. **Conclusion:** Optimization of a combinatorial biomarker panel leveraging the ability of different biomarkers to reflect different aspects of MASLD allows identification of its key phenotypes for each stage with higher precision.

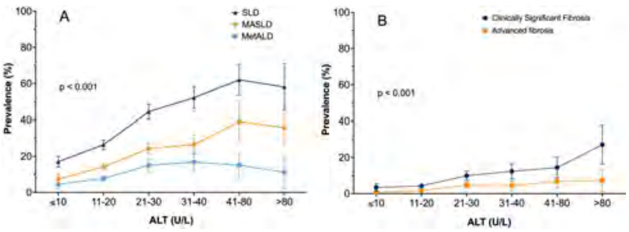
2354 | NORMAL ALANINE AMINOTRANSFERASE LEVELS UNDERESTIMATE THE BURDEN OF STEATOTIC LIVER DISEASE AND FIBROSIS IN US ADULTS: A CROSS-SECTIONAL ANALYSIS



Jad Allam Saab[1] Paul Nietert[2] Don Rockey[2], [1]The University of Alabama at Birmingham, [2]Medical University of South Carolina

Background: Despite the wide use of serum alanine aminotransferase (ALT) in screening and evaluating

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

liver disease, the definition of a normal ALT has long been debated. **Methods:** A cross-sectional analysis of the National Health and Nutrition Examination Survey (NHANES) from 2021-2023 was performed. A total of 5,245 US adults ≥18 years with available liver elastography, ALT, and BMI data were included. Steatotic liver disease (SLD) was defined by a controlled attenuation parameter of ≥285 dB/m. Metabolic dysfunction-associated steatotic liver disease (MASLD) was defined as SLD with ≥1 cardiometabolic risk factor and no or light alcohol use, whereas metabolic dysfunction and alcohol-associated liver disease (MetALD) was defined as SLD with ≥1 cardiometabolic risk factor and moderate alcohol use. Serum ALT levels were stratified into the following categories: ≤10, 11-20, 21-30, 31-40, 41-80, and >80 U/L. Our outcomes included the prevalence of SLD, MASLD, MetALD, clinically significant and advanced fibrosis across these distinct ALT strata, as well as the association between every 10 U/L increment in ALT and each outcome in multivariable logistic regression. **Results:** Of 5,245 adults, SLD prevalence increased stepwise from 17% at ALT ≤10 U/L to 26% at ALT 11-20 U/L, 44% at 21-30 U/L, and 52% at 31-40 U/L ($p < 0.001$) (**Figure A**). MASLD and MetALD followed similar graded patterns (both $p < 0.001$). Clinically significant fibrosis increased from 3% at ALT ≤10 U/L to 10% at ALT 21-30 U/L, and 12% at ALT 31-40 U/L, with similar increases in advanced fibrosis (both $p < 0.001$) (**Figure B**). After multivariable adjustments for age, sex, race/ethnicity, and BMI, each 10 U/L increase in ALT was associated with 24% greater odds of SLD (aOR, 1.24 [CI, 1.17 to 1.32]), 18% greater odds of MASLD (aOR, 1.18 [CI, 1.13 to 1.26]), 18% greater odds of clinically significant fibrosis (aOR, 1.18 [CI, 1.08 to 1.29]), and 13% greater odds of advanced fibrosis (aOR, 1.13 [CI, 1.00 to 1.24]). **Conclusion:** A significant burden of SLD, MASLD, MetALD, and hepatic fibrosis exists at ALT values commonly considered normal, including at levels 11-30 IU/L, suggesting current reference ranges may be too high to reliably exclude liver disease. We suggest that ALT should be interpreted alongside metabolic risk factors rather than as a standalone threshold.

2355 | METABOLOME ANALYSIS REVEALED RED FLAG SIGNATURES FOR THE IDENTIFICATION OF MASLD RISK ACROSS PATIENTS WITH DYSMETABOLIC TRAITS

Miriam Longo[1], [1]Fondazione IRCCS Cà Granda OMP Milano

Background: Adolescents and adults with dysmetabolic traits can either develop MASLD or show no evidence of fatty liver despite comparable cardiometabolic burden. However, it is still unclear whether patients with MASLD exhibit a specific circulating metabolic fingerprint compared to non-MASLD dysmetabolic subjects. Therefore, we aimed to analyze the serum metabolomic profile in a dysmetabolic cohort (n = 383), including adolescents with MASLD (n = 100, A-MASLD), adults with biopsy-proven (n = 95, B-MASLD) or non-invasive MASLD (n = 88, NI-MASLD) diagnosis, and a control group of dyslipidemic patients (n = 100, Dys) without MASLD. **Methods:** Targeted metabolomics (TM) was performed by UHPLC and analyzed through MetaboAnalyst 6.0. **Results:** Serum TM analysis revealed two main hierarchical clusters across dysmetabolic patients, highlighting that A/B-MASLD and NI-MASLD/Dys showed a similar metabolic pattern, respectively. In particular, ∼100 species were dysregulated (adjusted $p < 0.05$ FDR) in A/B-MASLD *vs* NI-MASLD/Dys patients. Among them, 64 metabolites were shared between the A/B-MASLD groups, suggestive of a conserved signature across pediatric and adult biopsied cases potentially due to a comparable rate of severe disease. To discover candidate MASLD-specific biomarkers, we performed the intersection analysis of differentially abundant species across the 4 groups. Sixteen metabolites were consistently altered in all MASLD patients (A-, B-, NI-MASLD) vs Dys. Two of them, glutamic acid and phosphatidylcholine (PC) O-40: 6, accurately discriminated MASLD from non-MASLD with 94% AUC (sens: 95%, spec: 88%), remaining stable after 10-fold cross-validation. Next, in the attempt to identify compounds with potential prognostic value, we stratified the dysmetabolic cohort according to MASLD severity. Nine metabolites were mainly dysregulated in severe disease vs controls (Dys). At multivariate and cross-validation analyses, a 5-metabolite model (Decanoylcarnitine, Ocatnoylcarnitine, Leucine, LysoPC 18: 2,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

SM 41: 2) achieved the best performance in distinguishing between severe MASLD vs controls (AUC 93%; sens: 87%; spec: 88%). **Conclusion:** Serum TM analysis captured a specific circulating profile shared across young and adult MASLD patients, possibly linked to an advanced clinical phenotype, which may be a red flag for cardiometabolic complications in pediatric cases. Furthermore, we disclosed 2 compounds specific for MASLD and 5-metabolites highly predictive of severe MASLD.

2356 | CLINICAL UTILITY OF AN AI-BASED MODEL INCLUDING ULTRASOUND DERIVED FAT FRACTION FOR RISK STRATIFICATION OF ADVANCED FIBROSIS IN MASLD ACROSS METABOLIC PHENOTYPES

Ipshita Gupta[1] Sujoy Kar[2] Yassin Labyed[1] Akash Roy[2] Sudhakar Kattoju[2] Arati Gurung[1] Dhivya Josphin[2], [1]Siemens Healthineers, [2]Apollo Hospitals

Background: Non-invasive detection of advanced fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD) remains suboptimal, particularly in metabolically heterogeneous populations. We evaluated the clinical utility of an artificial intelligence-based liver fibrosis (AILF) model and its performance across diabetic and non-diabetic subgroups. **Methods:** A total of 822 patients with suspected MASLD were included, comprising 454 diabetics and 368 non-diabetics. The AILF model integrated clinical variables, laboratory markers, medication history, and quantitative ultrasound parameters including ultrasound-derived fat fraction (UDFF) and used automated point shear-wave elastography (Auto pSWE) as the reference. **Results:** In diabetic subjects (n = 454), baseline AILF achieved an AUROC of 0.92, accuracy of 83%, sensitivity of 76%, specificity of 89%, and MCC of 0.66. Addition of continuous UDFF percentage improved AUROC to 0.93, while categorical UDFF integration also achieved an AUROC of 0.93 with sensitivity improving from 76% to 78% and specificity maintained at 87%.In non-diabetic subjects (n = 368), baseline AILF achieved an AUROC of 0.88, accuracy of 86%, specificity of 91%, and MCC of 0.69. Integration of continuous UDFF percentage maintained AUROC at 0.88 while improving specificity to 93% and precision to 85%. Addition of categorical UDFF achieved accuracy of 86%, specificity of 92%, F1 score of 0.81, and improved MCC to 0.71, representing the strongest overall balanced performance within the non-diabetic cohort. Across the overall cohort, AILF and AILF+UDFF class showed AUROCs of 0.92, while AILF+UDFF percentage showed an AUROC of 0.91. DeLong analysis demonstrated significant superiority of all AILF configurations over FIB-4 (all $p < 0.0001$), with no significant difference between AILF variants ($p > 0.35$). In diabetics, both AILF+UDFF percentage and AILF+UDFF class achieved AUROCs of 0.93 compared with 0.92 for baseline AILF, while in non-diabetics AILF and AILF +UDFF percentage showed AUROCs of 0.88 and AILF +UDFF class achieved 0.87. No significant within-model DeLong differences were observed in diabetic or non-diabetic subgroups. **Conclusion:** Integration of multiparametric ultrasound biomarkers may enable scalable, non-invasive risk stratification and support improved clinical decision-making for liver fibrosis assessment. The observed improvement in diabetic cohorts suggests that incorporation of quantitative liver fat biomarkers may be particularly valuable in metabolically high-risk populations where fibrosis progression risk is elevated and early detection is clinically important. In non-diabetic patients, UDFF integration improved specificity and overall classification balance, supporting its role in reducing false-positive fibrosis classification while maintaining diagnostic robustness.

Background: Changes in liver stiffness (VCTE) and ELF are proposed as surrogate endpoints for fibrosis response in MASH. Weight loss (WL) reduces liver stiffness and collagen markers in F0-F1 pts who have obesity/metabolic risk in whom serum markers of fibrosis may be elevated. In Res and Pbo pts, the impact of ≥5% WL on VCTE and ELF and association with biopsy fibrosis improvement (FI) was examined in F0-F1+F2-F3 MASH from MAESTRO program. **Methods:** Baseline (BL) and Week 52 (W52) VCTE+ELF components were determined in MAESTRO-NASH (NCT03900429) and MAESTRO-NAFLD-1 (NCT04197479). Logistic regression models explored associations between Res or Pbo changes (absolute difference for ELF, difference of log transformed for VCTE), weight change (≥5% vs < 5% WL) and biopsy FI. **Results:** In F0-F1, Res did not significantly reduce ELF v. Pbo. Approximately 14% pts w/F0-F1 had ≥ 5% WL at W52; ELF showed greater reduction in those with ≥5 % WL, with the P3NP component showing the greatest reduction in pts with WL, independent of treatment. P3NP is the major fibrogenesis biomarker in ELF. Baseline F0-F1 VCTE was mean 7.4 kPa, median 6.5 kPa. Res did not significantly reduce VCTE compared with Pbo in F0-F1 pts. VCTE was significantly reduced in ≥5 % WL vs. < 5% WL independent of treatment. In F2-F3, mean baseline ELF score was 9.8. At W52, 17% and 22% (80 and 100 mg Res) v. 12% (Pbo) had ≥ 5% WL. Absolute changes in ELF were evaluated using observed and modeled data from 758 F2-F3 pts (MAESTRO-NASH) with paired fibrosis, weight, and ELF data. There were independent associations of WL and FI with changes in ELF, and associations of change in ELF with WL were more pronounced than associations of change in ELF with FI; most noticeable effects were observed in the F3 pts. ≥5% WL on ELF attenuated a relationship between ELF and FI in Res and Pbo patients with <5% WL. Change in ELF with FI was more pronounced in <5% WL vs. ≥5% WL. Changes in ELF were strongly associated with FI only in F3 pts with < 5% WL. In F2-F3 baseline VCTE was 13.3 kPa. Relative changes in VCTE were evaluated using observed and modeled data from a cohort of 724 F2-F3 pts (MAESTRO-NASH) with paired fibrosis, weight, and VCTE data. There were independent associations of WL and FI with changes in VCTE, and associations of change in VCTE with WL were more pronounced than associations of change in VCTE with FI. The association of VCTE with FI was pronounced in < 5% WL vs. ≥ 5% WL in both res and pbo pts. Change in liver stiffness by VCTE predicted FI on biopsy in F2-F3 without WL. **Conclusion:** In patients with F2-F3 MASH, weight loss ≥5% and fibrosis improvement independently associated with reductions in VCTE and ELF. Fibrosis improvement was clearly associated with VCTE and ELF reduction in patients without weight loss treated with resmetirom or placebo. Confounding effects of weight loss on ELF and VCTE, independent of histologic fibrosis improvement, should be considered when evaluating MASH treatments.

2358 | DIAGNOSTIC ACCURACY OF THE METABOLOMICS-ADVANCED STEATOHEPATITIS FIBROSIS (MASEF) SCORE FOR THE IDENTIFICATION OF AT-RISK MASH: A BIVARIATE RANDOM-EFFECTS META-ANALYSIS

Rahul Falodia[1] Ehsanullah Alokozay[2] Farhan Murtaza[3] Muhammad Junaid Azhar[4] Rameen Khalid[5] Abdul Wahab Ali[5] Muhammad Ikram[6] Waqas Anwar[7] Muhammad Hammad ul Hassan[8] Ahmed Ibrahim[9] Anand Deonarine[4] Miriam Michael[4] Bacel Nseir[3], [1]All India Institute of Medical Sciences, Jodhpur, [2]Faculty of Medicine, Kandahar University, Kandahar, Afghanistan, [3]HCA Houston Healthcare/ University of Houston Program, [4]Howard University Hospital, [5]Rawalpindi Medical University, [6]Allama Iqbal Memorial Teaching Hospital, Sialkot, [7]Wyckoff Heights Medical Center, [8]South Brooklyn Health NY, [9]University of Buffalo, Catholic Health System

Background: Non-invasive identification of "at-risk" metabolic dysfunction-associated steatohepatitis (MASH) defined histologically as MASH with a NAFLD Activity Score (NAS) >4 and significant fibrosis (> F2) is critical for clinical trial enrichment and targeted therapeutic strategies. The Metabolomics-Advanced Steatohepatitis Fibrosis (MASEF) score is a novel serum panel combining 12 lipid species with clinical parameters (BMI, AST, ALT). We performed a systematic review and diagnostic test accuracy (DTA) meta-analysis to determine the pooled global efficacy of the MASEF score at its standard clinical threshold of 0.33. **Methods:** Public databases were systematically screened to identify clinical verification datasets reporting diagnostic boundaries for the MASEF score. Raw 2x2 diagnostic frequencies (true positives, false positives, false negatives, true negatives) were extracted or mathematically reconstructed. To account for the inherent correlation between diagnostic parameters, a rigorous bivariate random-effects meta-analysis (Reitsma linear mixed-effects model) was executed using the mada engine in R. The primary model (Model A) strictly included cohorts utilizing histological liver biopsy as the reference standard. An exploratory sensitivity model (Model B) integrated additional cohorts using non-invasive clinical routing frameworks. **Results:** Four unique validation cohorts across three independent data publications encompassing 1,584 total subjects were modeled. In the primary biopsy-confirmed framework (Model A; 3 cohorts, n = 1,479), the bivariate model demonstrated a pooled sensitivity of 75.4% (95% CI: 67.8%–81.7%) and a pooled specificity of 68.3% (95% CI: 60.4%–75.2%), with a summary Area Under the Curve (AUC) of 0.779. Between-study heterogeneity for both sensitivity and false positive rates was exceptionally low (I^2 = 0%). In the all-inclusive sensitivity analysis (Model B; 4 cohorts, n = 1,584), diagnostic robustness remained stable, yielding a pooled sensitivity of 73.1% (95% CI: 64.6%–80.2%), a pooled specificity of 70.7% (95% CI: 62.9%–77.5%), and an overall AUC of 0.778 (I^2 = 0%). **Conclusion:** The MASEF score demonstrates high diagnostic reproducibility and zero statistical heterogeneity across international cohorts. Operating with a stable summary AUC of ~0.78, this blood-based metabolomic profile provides a highly reliable, reproducible non-invasive pathway to rule out or triage at-risk MASH, successfully minimizing reliance on secondary tissue histology or expensive specialized elastography inside clinical trial validation screens and frontline specialty clinics.

2359 | MACHINE LEARNING ENABLED RISK STRATIFICATION IN MASLD: A NON-INVASIVE DECISION SUPPORT TOOL FOR EARLIER IDENTIFICATION AND REFERRAL FOR INTERVENTION

James Rickard[1] Jorg Taubel[2] Edward Jackson[2] Ulrike Lorch[2] Charlene Cheong[3], [1]Richmond Research Institute, [2]Richmond Pharmacology, [3]Richmond Research Institute

Background: Metabolic associated steatotic liver disease (MASLD) affects approximately one in three of the global adult population, and ranges in severity from benign fatty liver infiltration to hepatitis and cirrhosis. With growing rates of MASLD there is a need to identify patients earlier in the clinical pathway for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

appropriate referral and intervention. This will require additional tools to complement existing early assessment points in the clinical pathway, utilising routinely available clinical assessments only. Earlier identification and triaging of patients between low, medium and higher clinical risk will aid those in greater need earlier. We set out to develop a tool using Machine Learning approaches to support this opportunity of earlier identification. **Methods:** An observational cross-sectional study of 2081 volunteers aged 18-90 years was conducted (NCT04873258). The dataset was split into training, validation and test (60/20/20%). Two Random Forest (RF) binary classifiers were independently trained using two separate MASLD case definitions as defined by Fibroscan measurements (RF1: CAP $\geq$ 248 dB/m; RF2: CAP > 290 dB/m. RF1 was optimised as a high-sensitivity rule-out model to identify individuals unlikely to have MASLD, while RF2 was optimised as a high-specificity rule-in model to identify highly likely MASLD cases. Predicted probabilities from both models were subsequently combined into a threshold-based triage model to classify participants into low CAP < 248, medium > 248 & < 290 and high > 290dB/m groups. Thresholds were optimised on the validation dataset (negative predictive value (NPV) $\geq$ 95% and sensitivity $\geq$ 95% for the rule-out classification; positive predictive value (PPV) $\geq$ 90% and specificity $\geq$ 90% for the rule-in classification). Final triage model performance was evaluated on the independent test dataset. **Results:** The final RF models utilised age, weight, waist-to-height ratio, BMI, waist circumference, ALT, GGT and HbA1c for MASLD prediction. RF1 achieved sensitivity (0.890) and AUROC (0.887), while RF2 achieved specificity (0.788) and AUROC (0.879). The combined threshold-based triage model classified participants into low, medium and high-risk MASLD categories. The low-risk group achieved high NPV (0.940 [95% CI 0.903-0.975]) and sensitivity (0.951 [95% CI 0.919-0.978]), while the high-risk group achieved high PPV (0.900 [95% CI 0.750-1.00]) and specificity (0.993 [95% CI 0.982-1.00]). **Conclusion:** The proposed dual RF triage model demonstrated promising performance for non-invasive MASLD identification and triage, utilising simple test parameters. This three-classification framework minimises misclassifications by allocating uncertain cases into the medium category while achieving high NPV for < 248dB/m and high PPV in > 290dB/m classifications. We now plan to pilot this tool in primary care settings in the UK.

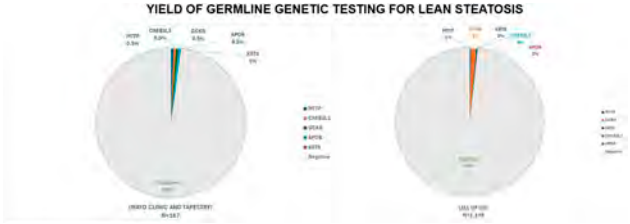
2360 | GENETIC VARIANT BURDEN IN LEAN MASLD: A LARGE MULTI-COHORT EXOME SEQUENCING STUDY



Jee Won Shin[1] Kirk Wangensteen[2] Samuel Antwi[2] Hunter Miller[2] Karina Sato-Espinoza[2] Filippo Pinto e Vairo[2] Jun Ma[2], [1]Mayo Clniic, [2]Mayo Clinic

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) affects ~25–30% of adults worldwide. Lean steatosis is a distinct subgroup associated with increased fibrosis and mortality, yet its biological drivers remain unclear. We previously showed enrichment of common *PNPLA3* risk alleles in lean individuals with steatosis. Small studies also suggest rare loss-of-function (LoF) variants in other genes may contribute to lean steatosis risk. To better define its genetic architecture, we analyzed clinical and exome sequencing data from > 100,000 Mayo Clinic biobank participants and > 400,000 All of Us Research Program participants. **Methods:** We analyzed whole-exome sequencing and clinical data from the Mayo Clinic Biobank, Tapestry Study, and the All of Us Research Program. Lean steatosis cases were defined by diagnosis codes in individuals with BMI $\leq$ 25 kg/m². Mayo Clinic participants underwent detailed chart review. Joint variant calling was performed for 458 liver disease-associated genes. Rare variants were defined as minor allele frequency $\leq$ 1%. Gene-based LoF burden testing used REGENIE adjusted for age, sex, and ancestry principal components; significance was assessed by nominal p values and false discovery rate (FDR). **Results:** The Mayo Clinic cohort included 188 lean cases with steatosis and 694 lean controls. No gene reached FDR significance. Nominal LoF enrichment was observed for *AGL* (OR 12.4 [2.65,58.3]; p < 0.01]), *PEX11B* (OR 29.8 [1.52,585], p < 0.05), *ABCG8* (OR 17.0 [1.30, 222], p < 0.05), *TSFM* (OR 14.7 [1.02, 211], p < 0.05), and *SKIC3* (OR 25.7 [1.31, 502]; p < 0.05). Replication in All of Us (1,178 cases and 15,095 controls) identified only *PEX11B* (OR 8.0 [1.34, 47.6]; p < 0.05) as associated with steatosis. Among 34 genes reported to be associated with steatotic liver disease in OMIM or Pubmed 29 were autosomal recessive, and no patients had biallelic variants. Among the 5 autosomal dominant genes, there was one carrier for *CREB3L3*, *GCKR*, *APOB*, and *MTTP* among cases, and none for *KRT8*. Overall, 4/187 (2.1%) Mayo cases had a potential monogenic explanation. In All of Us, 21/1,178 (1.78%) lean steatosis cases carried LoF variants in autosomal dominant steatosis genes, with enrichment for *MTTP* (OR 6.13 [1.66,22.6]; p < 0.05) and *KRT8* (OR 7.98 [1.50,42.5]; p < 0.05). **Conclusion:** Rare LoF variants showed nominal associations with lean steatosis, with replication only for *PEX11B* across two large biobanks. The predominance of single

variants in recessive genes and absence of biallelic variants argue against haploinsufficiency as a disease mechanism. These findings suggest lean steatosis is more likely driven by complex/polygenic architecture or other host/environmental factors than by monogenic disorders. Genetic testing in lean patients with steatosis will likely have low yield without additional distinguishing clinical, host, or environmental features.

2361 | REFINING VCTE CUTOFFS IN PATIENTS WITH HIGH BMI: A SIMPLE ADJUSTMENT REDUCES FALSE POSITIVES FOR IDENTIFYING F3–F4 FIBROSIS FOR CLINICAL TRIALS

Mazen Noureddin[1] Winston Dunn[2] Gražina Binkauskiene[3] Elizabeth Brombosz[3] Rashmee Patil[2] Rohit Puskoor[4] David Huang[5] Nirupama Esther Jerome[4] John Poulos[6] Alaa Abousaif[7] Aasim Sheikh[8] Alma Laura Ladrón de Guevara[9] Marcelo Kugelmas[10] Mousab Tabbaa[11] Sam Moussa[12] Sudha Kodali[13] Vlad Ratziu[14] Meena Bansal[15] Jörn Schattenberg[16] Naim Alkhouri[17], [1]Houston Methodist Hospital, Houston Research Institute, Summit Clinical Research Solutions, [2]Pinnacle at San Antonio, Summit Clinical Research Solutions, [3]Summit Clinical Research Solutions, [4]Pinnacle at Austin, Summit Clinical Research Solutions, [5]Houston Research Institute – Main, [6]Coastal Research Institute, [7]Providence St. Joseph Hospital-Orange, [8]GI Specialists of Georgia, [9]CENTRO DE INVESTIGACION Y GASTROENTEROLOGIA, [10]South Denver Gastroenterology, [11]Clinical Research Institute of Ohio, [12]Adobe Clinical Research, [13]JC Walter Jr Transplant Center, Houston Methodist Hospital, [14]Service D' Hepatogastroenterologie (FR), [15]Icahn School of Medicine at Mount Sinai (ISMMS), [16]Saarland University Medical Center, [17]Summit Clinical Research

Background: VCTE is increasingly utilized to identify patients with advanced fibrosis in both trial and clinical settings. However, high BMI alters the relationship between LSM and fibrosis risk. As a result, reliance on these measures alone may overstage fibrosis compared with biopsy, with important implications for patients selection and trial enrichment. The purpose of this study is to identify whether a correction algorithm can improve the performance of LSM in identifying patients with F2+, F3+, and F4 among patients with high BMI. **Methods:** Patients with available biopsy, VCTE, and BMI data were identified from a multicenter database of patients (n = 24491) screened for inclusion in MASH clinical trials, split into development (internal network centers) and external validation (external network centers) cohorts. Separate analyses were performed for F2+, F3+, and F4. Logistic regression was used to model fibrosis stage with LSM, BMI, and an LSM x BMI interaction term were used to assess BMI effects on fibrosis prediction. Multiple BMI-adjusted LSM thresholds were evaluated across BMI categories using standard highly specific cut offs commonly used in clinical trials of 8 kPa (F2+), 15 kPa (F3+), and 20 kPa (F4). Performance was assessed using sensitivity, specificity, and Youden index. **Results:** Of the 4549 patients with biopsy, BMI, and VCTE data, 2165 were included in the development cohort and 2,384 were included in the validation cohort. The LSM x BMI interaction term was statistically significant for F2+, F3+, and F4 in both cohorts (all $p < 0.05$). A BMI-adjusted strategy improved specificity and reduced false positives across fibrosis stages. For F2+, specificity increased from 18.9% to 45.4%, with corresponding reductions in false positives, although sensitivity declined from 92.0% to 79.0%. For F3+, specificity increased from 83.3% to 88.6%, with a 32% reduction in false positives, while sensitivity decreased from 46.5% to 40.1%. For F4, while sensitivity decreased from 45.0% to 39.7% specificity increased from 89.8% to 93.4%, with a 35% reduction in false positives. Adding 2 kPa in patients with BMI 35- < 40 and 4 kPa in patients with BMI ≥ 40 yielded the highest Youden index in both F3/F4 and F4 patients. **Conclusion:** Adjusting LSM by +2 kPa in patients with BMI 35- < 40 and +4 kPa in patients with BMI ≥ 40 kg/m2 increases the performance of VCTE in identifying patients with F2, F3 and F4 fibrosis.

2362 | AST AND ALT FLARES AS A RISK FACTOR FOR PROGRESSION TO MAJOR ADVERSE LIVER OUTCOMES IN CLINICALLY COMPENSATED INDIVIDUALS WITH MASLD AT INTERMEDIATE RISK OF MORTALITY

Vinay Jahagirdar[1] Breda Munoz-Hernandez[2] Julie Crawford[3] Philip Newsome[4] Brent Neuschwander-Tetri[5] A. Sidney Barritt[6] Michael Fried[3] Arun Sanyal[1], [1]Virginia Commonwealth University, Richmond, VA, [2]Headwater Science, Durham, NC, [3]Pedestal Health, Durham, NC, [4]Foundation for Liver Research and King's College Hospital; University of Birmingham, [5]Saint Louis University, St. Louis, MO, [6]University of North Carolina, Chapel Hill, NC

Background: Liver enzymes fluctuate over time in MASLD, but whether these fluctuations drive disease progression and predict major adverse liver outcomes (MALO) is unclear. We assessed the association between AST and ALT fluctuations and subsequent MALO risk in a predominantly non-cirrhotic population with clinically compensated MASLD. **Methods:** We performed a retrospective analysis of adults enrolled in the prospective, multicenter TARGET-NASH registry. Patients with FIB-4 1.3-2.6 were selected to enrich for outcome risk while minimizing confounding by advanced cirrhosis. Individuals with baseline AST or ALT >60 U/L were excluded. Liver enzymes obtained through routine care from enrolment through year 3 were analyzed as predictors of MALO between years 3 and 5. Fine-Gray competing risk and Kaplan-Meier analyses compared outcome risk between patients in the lowest versus highest quartile of relative AST or ALT change from baseline. **Results:** A total of 687 individuals were evaluated. Mean baseline FIB-4 was 1.8 (SD 0.35); 41% had type 2 diabetes and 79% had hypertension. Liver stiffness was available in 111 patients, with mean 10.9 kPa (SD 8.5). From enrollment to year 3, AST and ALT fluctuated widely, with median relative changes of 26% and 20%, respectively. These fluctuations were not explained by documented acute events, medication changes, or reported alcohol use, and returned to baseline without intervention. From years 3 to 5, 56 individuals developed MALO and 4 died. Baseline parameters did not predict outcomes. Patients who developed MALO demonstrated greater enzyme excursions from baseline than those without MALO, with mean AST rising 36% versus 30% ($p = 0.02$) and mean ALT rising 42% versus 36% ($p = 0.055$) from baseline. Compared with the lowest quartile, the highest quartile of AST relative change was associated with higher MALO risk, with 5-year MALO-free survival of 85% vs 94% and HR 2.66 (95% CI 1.11–6.37). The highest quartile of ALT relative change showed a nonsignificant trend toward lower 5-year MALO-free survival, 88% vs 94%, HR 2.03 (0.82–5.02). **Conclusion:** AST and ALT fluctuate widely over time in clinically compensated MASLD. A relative AST or ALT increase of approximately 50% from baseline identified patients with higher subsequent MALO risk, with the strongest association for AST. Aminotransferase flares may represent a clinically relevant risk marker for progression, although under-reported alcohol use requires further study.

Outcomes	N Obs	Variable	N	Change with respect to Baseline: Lower Quartile	Upper Quartile	Median
censored	420	max relative change AST	420	0.04	0.36	0.20
		max relative change ALT	420	0.08	0.42	0.25
MALO outcome	56	max relative change AST	56	0.07	0.45	0.26
		max relative change ALT	56	0.10	0.50	0.32
death (competing risk)	4	max relative change AST	4	0.25	0.49	0.41
		max relative change ALT	4	0.23	0.43	0.37

2363 | SEQUENTIAL NON-INVASIVE FIBROSIS PATHWAYS FOR ADVANCED FIBROSIS IN MASLD: A SYSTEMATIC REVIEW AND META-ANALYSIS USING AN INTENTION-TO-DIAGNOSE FRAMEWORK

Abidemi Akinrinmade[1] Bright Nwatamole[2] Olanrewaju Adeniran[3] Olutomiwa Omokore[4] Savio John[1], [1]SUNY Upstate Medical University, [2]Zucker School of Medicine at Hofstra/Northwell at Vassar Brothers Medical Center, [3]West Virginia University, [4]Benjamin S. Carson College of Health and Sciences, Babcock University

Background: Accurate identification of advanced fibrosis in metabolic dysfunction-associated steatotic liver disease (MASLD) remains essential for risk stratification and clinical management. Sequential non-invasive fibrosis pathways incorporating serum biomarkers and elastography have emerged as alternatives to liver biopsy. However, real-world diagnostic performance remains incompletely characterized due to exclusion of indeterminate and failed tests in many studies. This study aims to evaluate the diagnostic accuracy and clinical performance of sequential non-invasive fibrosis pathways for detecting advanced fibrosis in MASLD using an intention-to-diagnose (ITD) framework. **Methods:** A systematic review was conducted according to PRISMA 2020 guidelines. PubMed, Embase, Scopus, Web of Science, and Cochrane Library databases were searched for U.S.-based studies published between 2010 and 2025 evaluating sequential non-invasive fibrosis testing pathways in adults with MASLD. Studies assessing serum-based indices, vibration-controlled transient elastography (VCTE), enhanced liver fibrosis (ELF), and related sequential approaches were included. For quantitative synthesis, studies were required to provide biopsy-confirmed advanced fibrosis (F3-F4) and reconstructable diagnostic contingency data. Diagnostic contigency data were reconstructed into 2×2 tables and analyzed using a bivariate random-effects model with restricted maximum likelihood estimation. **Results:** Twenty-five studies met criteria for qualitative synthesis, and four biopsy-based cohort studies comprising 619 patients were included in quantitative meta-analysis. Pooled sensitivity and specificity of VCTE for detecting advanced fibrosis were 0.80 (95% CI, 0.48-0.94) and 0.79 (95% CI, 0.68-0.87), respectively. The false-positive rate was 0.21 (95% CI, 0.13-0.32), and the area under the receiver operating characteristic curve was 0.84, supporting good discriminatory performance. Moderate heterogeneity was observed (I^2 = 65.4%). Sequential strategies combining Fibrosis-4 Index (FIB-4), NAFLD Fibrosis Score (NFS), ELF, and VCTE improved risk stratification while reducing unnecessary biopsy and specialty referral across included studies. **Conclusion:** Sequential non-invasive fibrosis pathways demonstrate clinically meaningful utility for identifying advanced fibrosis in MASLD. Application of an ITD framework provides more clinically relevant estimates of diagnostic performance by incorporating indeterminate and failed tests into analysis. Integration of serum biomarkers with elastography-based approaches may support structured, clinically applicable fibrosis risk stratification and reduce reliance on liver biopsy in routine clinical practice.

2364 | AUTOMATED FIB-4 INTEGRATION INTO THE ELECTRONIC HEALTH RECORD ENHANCES MASLD RISK ASSESSMENT

Theodore Feldman[1] Brittany Bromfield[2] Jeremy Chimene-Weiss[3] Gregory Gheewalla[4] Emilie Mitten[2] Nathanael Fillmore[1] Nhan Do[1] Gyorgy Baffy[1], [1]VA Boston Healthcare System, [2]Brigham and Women's Hospital, [3]Boston University Medical Center, [4]Boston Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is underrecognized in patients with diabetes despite increased risk for advanced liver disease. In 2020, our VA medical center implemented automated reporting of the fibrosis-4 (FIB-4) index within the electronic health record (EHR), integrating this noninvasive fibrosis assessment tool into the comprehensive metabolic panel. We evaluated the impact of this intervention on referral practices.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Preliminary findings were presented previously. **Methods:** Patients with diabetes (HbA1c >6.5% on ≥1 occasion) seen in primary care clinics between 2010-2025 were identified. Patients were categorized into low (<1.3), intermediate (1.3-2.67), and high (>2.67) FIB-4 groups. Annual GI consults were reviewed to compare referral patterns in 2010-2019 and 2020-2025. Temporal trends were analyzed using interrupted time series and piecewise linear regression. **Results:** A total of 21,274 unique patients with diabetes were identified, with an average annual cohort size of 10,730. The median annual proportion with sufficient laboratory data for FIB-4 calculation was 45.0% (range, 37.0%-53.3%). Among these, 36.2% (26.8%-39.8%), 51% (48.9%-55.9%), and 12.7% (11.2%-17.3%) were categorized as low-, intermediate-, and high-risk, respectively, without significant annual variation. Annual outpatient GI consult volumes ranged from 614-1,090 (6.8%-9.5% of patients, NS), with annual liver-related referrals accounting for a median of 10.3% (8.5%-15.4%, NS). Referral patterns changed substantially during the study period. Hepatitis C-related referrals declined markedly (50.8%-2.2%, $p<0.001$), consistent with widespread antiviral treatment before 2020. Referrals prompted by abnormal liver tests showed no significant temporal change (range, 18.3%-38.5% of liver-related consults, NS), whereas MASLD/NAFLD-related ICD-9/10 codes emerged as a major referral indication (0.0%-42.0%, $p<0.001$). Annual rates of referrals among patients with elevated FIB-4 values that could already be calculated prior to liver-related referral did not change significantly (median, 54.8%; range, 44.8%-64.7%; NS), suggesting that lower MASLD-related referral rates before automated reporting were not primarily due to unavailable laboratory data. **Conclusion:** Automated inclusion of FIB-4 in the EHR may influence referral behavior and facilitate recognition of patients with diabetes at risk for advanced liver disease. However, peak annual referral rates represented only 5.1% and 22.3% of patients with intermediate and high FIB-4 scores, respectively, without significant positive trends over time. These findings highlight persistent gaps in MASLD risk assessment and the need for additional strategies to improve screening, clinician awareness, and risk stratification.

2365 | RECALIBRATING ELF AGAINST MRE IN MASH: TOWARD A DATA-DERIVED THRESHOLD FOR TREATMENT-ELIGIBLE FIBROSIS

Cecilia Katzenstein[1] Anna Mageras[2] Mark Miller[2] Victor Llanes[2] Xiaotao Zhang[1] Meena Bansal[3], [1]Icahn School of Medicine at Mount Sinai, [2]Icahn School of Medicine at Mount Sinai, New York, United States, [3]Icahn School of Medicine at Mount Sinai (ISMMS)

Background: The Enhanced Liver Fibrosis (ELF) test is FDA-approved for prognostication but is increasingly proposed for fibrosis risk stratification in MASH, where identifying treatment-eligible patients is now a clinical priority given approved MASH therapies. As an operator-independent, blood-based test, ELF shows promise as second-line testing in FIB-4 pathways where elastography is unavailable or unreliable. Recent guidance has incorporated lower ELF values than the standard 9.8 (AGA ≥9.2 for significant fibrosis; AASLD 9.2–10.5 for treatment-eligible F2–F3 disease), though cutoffs have historically been derived from biopsy-anchored prognostic cohorts. ELF has not been benchmarked against magnetic resonance elastography (MRE), the reference standard used in many academic medical centers. **Methods:** We conducted a prospective study of 200 consecutive patients evaluated for MASH at a tertiary center, all with ELF, vibration-controlled transient elastography (VCTE), and MRE. Significant fibrosis was defined as MRE ≥3.1 kPa and cirrhosis as ≥5.0 kPa. Discrimination was assessed by AUC (DeLong). Optimal thresholds were derived by the Youden index with 1,000-replication bootstrap validation. Predictive values were extrapolated across significant-fibrosis prevalence scenarios (5–49%) within the FIB-4 >1.3 pathway using Bayes theorem. **Results:** ELF and VCTE showed comparable discrimination for significant fibrosis (AUC 0.75 vs 0.78, $p=0.51$). The Youden-optimal ELF threshold was 9.42 in the full cohort, 9.58 in the FIB-4 >1.3 subgroup, and 9.60 in the indeterminate FIB-4 subgroup, consistently below the standard 9.8. Bootstrap validation confirmed negligible optimism (full-cohort bias-corrected 95% CI 0.68–0.82). Within the FIB-4 >1.3 pathway, ELF ≥9.5 and VCTE ≥8.0 kPa had identical sensitivity (79.4%) and referred a near-identical number of patients (71 vs 68). Across prevalence scenarios representative of non-hepatology settings (10–20%), ELF ≥9.5 and VCTE ≥8.0 kPa yielded closely matched negative predictive value (92–97%). **Conclusion:** This prospective MRE-anchored derivation places the optimal ELF threshold for significant fibrosis near 9.5. The value sits below the manufacturer cutoff, lies within the AASLD treatment-eligibility

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

range, and falls within the narrow 9.37–9.6 range of data-derived thresholds from biopsy- and composite-reference cohorts. At this threshold ELF performs comparably to VCTE within FIB-4 pathways, and a negative result appears to reliably exclude significant fibrosis at non-hepatology prevalence, allowing patients to be managed without referral or elastography where access is limited.

Recalibrating the ELF threshold against MRE in MASH (n=200)

A MRE-anchored optimal ELF thresholds vs the standard cutoff

Population (n)	Reference standard	Optimal ELF threshold
Full cohort (200)	MRE	9.42
FIB-4 >1.3 (109)	MRE	9.58
Indeterminate FIB-4, 1.3–2.67 (78)	MRE	9.60
Manufacturer / standard cutoff	Biopsy-anchored prognostic	9.8

Youden-optimal thresholds (1,000-replication bootstrap-validated; full-cohort bias-corrected 95% CI 0.68–0.82). All three MRE-anchored optima fall below the manufacturer cutoff of 9.8 and cluster with data-derived optima reported from independent biopsy and composite-reference cohorts (range 9.37–9.6), suggesting a reproducible optimal ELF range near 9.5 across differing reference standards.

B Predictive values across modeled prevalence, FIB-4 >1.3 pathway

Significant fibrosis prevalence	ELF ≥9.5 PPV / NPV (%)	VCTE ≥8.0 kPa PPV / NPV (%)
5%	9.1 / 98.2	10.9 / 98.4
10%	17.5 / 96.2	20.6 / 96.6
15%	25.2 / 94.1	29.1 / 94.8
20%	32.4 / 91.9	36.8 / 92.8
30%	45.1 / 86.9	49.9 / 88.2
49% (observed cohort)	64.8 / 74.7	69.1 / 76.9

Bayes extrapolation applying observed FIB-4 >1.3 pathway operating characteristics (ELF ≥9.5: sensitivity 79.4%, specificity 58.5%; VCTE ≥8.0 kPa: sensitivity 79.4%, specificity 65.3%). Across non-hepatology prevalence (10–20%), ELF and VCTE yield closely matched negative predictive value; the highlighted 15% row is representative of endocrinology and diabetology populations.

2366 | IMPACT OF OBESITY ON CONTROLLED ATTENUATION PARAMETER PERFORMANCE IN PATIENTS EVALUATED FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Chester Hui[1] Allen Luo[1] Neharika Bandaru[1] Kali Zhou[1] Emilie Mitten[2] Marvin Ryou[2] Thomas Wang[1], [1]Keck School of Medicine of USC, [2]Brigham and Women's Hospital, Massachusetts General Hospital

Background: Controlled attenuation parameter (CAP) obtained during vibration-controlled transient elastography (VCTE) is a widely used noninvasive measure of hepatic steatosis in metabolic dysfunction-associated steatotic liver disease (MASLD). Recent studies suggest these thresholds may overestimate steatosis severity in patients with obesity and propose substantially higher CAP cutoffs in patients with body mass index (BMI) > 30 kg/m². We aimed to further evaluate the impact of elevated BMI on CAP performance and propose BMI-stratified CAP thresholds. **Methods:** We performed a retrospective multi-center cohort study of adults with biopsy-proven MASLD who underwent VCTE with CAP assessment within 12 months of the liver biopsy between 2016 and 2025. Three academic centers were included. CAP measurements, liver stiffness measurement, probe type, fibrosis stage, diabetes status, and BMI were obtained. Histologic steatosis was graded as S0 (< 5%), S1 (5–33%), S2 (34–66%), and S3 (> 66%). Patients were stratified by BMI category: < 30, 30 to < 40, and ≥ 40 kg/m². Diagnostic performance of CAP for predicting S1, S2, and S3 steatosis was assessed using area under the receiver operating characteristic (AUROC) analysis. Optimal CAP thresholds for BMI subgroups were derived using the Youden Index, with calculation of AUROC, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). **Results:** Out of 597 patients who underwent VCTE, 557 had a CAP score available. 94 patients had no steatosis (S0), 202 had S1 grade, 169 had S2 grade, and 92 had S3 grade on biopsy. CAP diagnostic performance for S1 steatosis on biopsy was preserved as BMI increased (AUROC 0.749 and 0.749 for BMI < 30 and ≥ 40, respectively) (Figure 1). However, performance declined for S2 (AUROC 0.811 to 0.710) and S3 (AUROC 0.740 to 0.597) as BMI increased. CAP performance for S3 for BMI ≥ 40 did not significantly perform better than reference (p = 0.28), thus, Youden index was not measured for S3. Patients with BMI 30 to < 40 demonstrated significantly reduced discrimination for S2 and S3 steatosis compared with BMI < 30 (p = 0.03 for both). Optimal CAP thresholds increased with BMI across all steatosis grades, from 283 to 324 dB/m for S1 and from 302 to 330 dB/m for S2 (Figure 2). PPV declined as steatosis grading increased and was significantly lower for S3 steatosis across all BMI strata, ranging from 22-30%. **Conclusion:** Our study suggests that BMI impacts CAP performance and optimal thresholds for hepatic steatosis grading in MASLD. While performance for S1 steatosis is relatively preserved regardless of BMI,

discrimination for more severe steatosis declines with increasing BMI. These findings may support the use of BMI-stratified CAP thresholds or alternative testing in patients with obesity if grading of hepatic steatosis is desired.

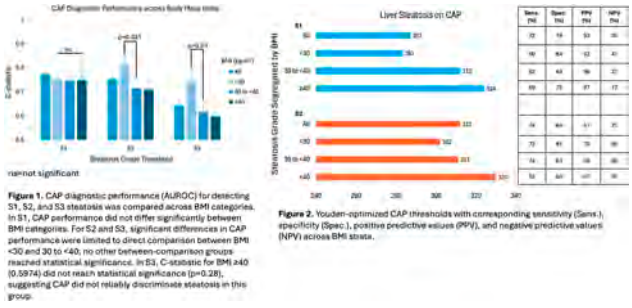

Figure 1. CAP diagnostic performance (AUROC) for detecting S1, S2, and S3 steatosis was compared across BMI categories. In S1, CAP performance did not differ significantly between BMI categories. For S2 and S3, significant differences in CAP performance were limited to direct comparison between BMI <30 and 30 to <40; no other between-comparison groups reached statistical significance. In S3, C-statistic for BMI ≥40 (0.5974) did not reach statistical significance (p=0.28), suggesting CAP did not reliably discriminate steatosis in this group.

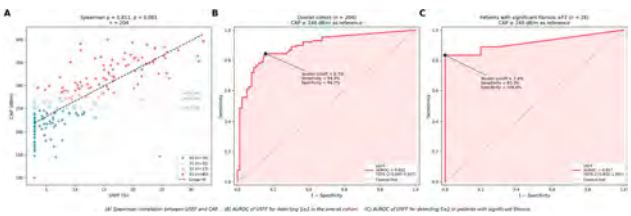

Figure 2. Youden-optimized CAP thresholds with corresponding sensitivity (Sens.), specificity (Spec.), positive predictive values (PPV), and negative predictive values (NPV) across BMI strata.

2367 | COMPARATIVE PERFORMANCE OF ULTRASOUND-DERIVED FAT FRACTION (USFF - COMBINING TISSUE ATTENUATION AND TISSUE SCATTER DISTRIBUTION IMAGING) VERSUS CONTROLLED ATTENUATION PARAMETER (CAP) FOR HEPATIC STEATOSIS ASSESSMENT IN A REAL-WORLD COHORT

Joao Marcello de Araujo-Neto[1] Flavia Fernandes[2] Priscila Flores[3] Juliana Baptista Piedade-Barrocas[2] Vania Cristina de Sant`Anna R. Nunnes[1] Larissa Miranda[1] Melina Torres[1] Mauren Machado[4] Claudia Oliveira[5], [1]Federal University of Rio de Janeiro, [2]Hospital Federal de Bonsucesso, [3]UNIVERSIDADE FEDERAL FLUMINENSE, [4]Federal Universisty of Rio de Janeiro, [5]University of Sao Paulo School of Medicine

Background: Ultrasound-derived Fat Fraction (USFF) is a novel quantitative ultrasound technique that combines attenuation and backscatter coefficient measurements to estimate hepatic fat content, with the integration of both parameters potentially improving diagnostic accuracy. Data on its performance remain scarce. This study aims to compare USFF with the Controlled Attenuation Parameter (CAP), the most widely used point-of-care tool for hepatic steatosis quantification in clinical practice, in a real-life cohort. **Methods:** In this single-centre cross-sectional study, 442 consecutive adults were prospectively assessed with same-day transient elastography stiffness (Fibroscan), CAP and Ultrasound-derived Fat Fraction (Samsung RS85). USFF and CAP were measured in 204 patients. CAP-based steatosis grades followed the Karlas thresholds (S0 <248, S1 $248–<268$, S2 $268–<280$, S3 ≥ 280 dB/m). Significative fibrosis (F2) was considered $\geq$ 7kPa on trnasient elastography. Statistical tests were non-parametric throughout. **Results:** In the paired USFF and CAP cohort (n = 204), median age was 56 years (45–65), 51% were male, and CAP-defined steatosis grades were S0: 37.3%, S1: 17.2%, S2: 6.4%, and S3: 39.2%. USFF correlated strongly with CAP (Spearman ρ = 0.811, p < 0.001). USFF yielded AUROCs of **0.892 (95% CI 0.843–0.933)** for detecting any steatosis ($\geq$S1), **0.927 (0.888–0.958)** for $\geq$S2, and **0.919 (0.878–0.954)** for $\geq$S3, with Youden-optimal cutoffs of **6.7%, 8.1%, and 10.0%**, respectively. Sensitivity was **84.4%, 90.3%, and 86.3%**, and specificity was **84.2%, 81.1%, and 83.9%** for $\geq$S1, $\geq$S2, and $\geq$S3, respectively. The prevalence of significant fibrosis ($\geq$F2) by vibration-controlled transient elastography was 13.7%. Subgroup analysis by fibrosis stage (F0/F1 vs $\geq$F2) showed preserved USFF performance: AUROCs in F0/F1 (n = 176) were **0.89, 0.92, and 0.91**, versus **0.92, 0.97, and 0.97** in $\geq$F2 (n = 28), suggesting that hepatic fibrosis did not impair USFF accuracy. USFF was also compared with tradicional B-mode visual grading of steatosis. USFF correlated strongly with B-mode grading (Spearman ρ = 0.837, p < 0.001) and showed a clear dose-response: median USFF values were **3.0%, 7.7%, 13.0%, and 20.9%** for absent, mild, moderate, and severe steatosis, respectively (p < 0.001). AUROCs for detecting $\geq$S1, $\geq$S2, and $\geq$S3 were **0.92 (95% CI 0.88–0.96)**, **0.94 (0.90–0.97)**, and **0.94 (0.90–0.97)**, with Youden-optimal cutoffs of **7.3%, 9.0%, and 15.6%**, respectively. **Conclusion:** USFF demonstrated strong correlation with CAP and excellent agreement with visual B-mode steatosis grading, achieving high diagnostic accuracy for the detection and grading of hepatic steatosis in a real-life cohort, with consistent performance across fibrosis stage, sex, and age subgroups. These findings support USFF as a reliable, B-mode integrated alternative for non-invasive quantification of liver fat in routine clinical practice.

2368 | ROBUST REPRODUCIBILITY OF LOCAL VERSUS CENTRAL MAGNETIC RESONANCE ELASTOGRAPHY READS ACROSS FIBROSIS STAGES AND BMI IN MASLD: AN INTERNATIONAL, PROSPECTIVE GOLDMINE STUDY

Monica Tincopa[1] Suzanne Sharpton[2] Meng Yin[3] Kay Pepin[3] Hao Wu[3] Valentina Medici[4] Arpan Mohanty[5] Claude Sirlin[6] Cynthia Behling[7] Ricki Bettencourt[6] Kaleb Tesfai[6] Jiahui Li[3] Egbert Madamba[6] Seema Singh[6] Richard Ehman[8] Rohit Loomba[1], [1]University of California, San Diego, [2]Vanderbilt University Medical Center, [3]Mayo Clinic, [4]University of California Davis Medical Center, [5]Boston University, [6]UCSD, [7]Pacific Rim Pathology, [8]Mayo Clinic Rochester

Background: Magnetic resonance elastography (MRE) is the most accurate non-invasive imaging biomarker for hepatic fibrosis assessment in metabolic dysfunction-associated steatotic liver disease (MASLD). However, variability between local and centralized expert reads remains a critical knowledge gap for deployment in multicenter clinical trials and real-world practice. The aim of this study was to assess the reproducibility of local versus centralized MRE liver stiffness measurements (LSM) in a prospective multicenter cohort of adults with biopsy-confirmed MASLD. **Methods:** GOLDMINE is a prospective, multicenter, international, operator-blinded cohort study of adults with MASLD undergoing contemporaneous liver biopsy and MRE. Liver biopsies were scored by one expert liver pathologist blinded to clinical data using the NASH CRN histologic scoring system. LSM by MRE was analyzed 1) manually by an expert analyst locally and 2) centrally using an automated method (Hepatogram plus+, Resoundant, Inc) with expert analyst review. Reproducibility was assessed using intraclass correlation coefficient (ICC), within-subject coefficient of variation (wCV), repeatability coefficient (RDC%), Bland-Altman analysis, and Spearman correlation. Diagnostic accuracy for advanced fibrosis on central biopsy read (stage $\geq$3) was assessed by receiver operating characteristic (ROC) analyses. **Results:** A total of 293 adults with biopsy-proven MASLD were included; 59% were female, with a mean age 53.9 ($\pm$ 12.8 years) and BMI 31.7 ($\pm$ 4.9 kg/m^2). The distribution of fibrosis stage on central liver biopsy read was: stage 0 = 33% (N 89), 1 = 23% (N 63), 2 = 17% (N 45), 3 = 16% (N 43), 4 = 11% (N 29). Local and central MRE LSM demonstrated excellent reproducibility: ICC 0.97 (95% CI: 0.96-0.98), wCV 6.45%, RDC 17.89%, Bland-Altman bias 0.10 kPa with limits of agreement (-0.45; 0.67) kPa and Spearman correlation coefficient 0.97 (95% CI: 0.96-0.98) (**Table, Figure 1a**). Reproducibility was consistent across fibrosis stages and BMI subgroups. The AUROC to diagnose advanced fibrosis was 0.90 (95% CI 0.86–0.94) for the local MRE read versus 0.89 (95% CI 0.85–0.94) for the central read (Delong p = 0.27 indicating no significant difference between AUROCs) **(Figure 1b). Conclusion:** In this prospective, international multicenter cohort of adults with biopsy-confirmed MASLD, local and centralized MRE LSM demonstrated excellent reproducibility with minimal systematic bias across the full spectrum of fibrosis stages and BMI. These findings support the interchangeability of local and centralized MRE reads in multicenter MASLD trials and clinical practice, strengthening the utility of MRE as a scalable imaging biomarker across diverse international settings.

Table. Reproducibility Assessments for Local Versus Central MRE Reads

Subgroup	N	wCV (%)	RDC% (95% CI)	ICC (95% CI)	Bias (kPa)	Abs. Rel. Bias (%)	Rho (95% CI)
Overall cohort	293	6.45	17.89 (15.19, 20.89)	0.97 (0.96, 0.98)	0.10	6.47	0.97 (0.96, 0.98)
MRE LSM — by central liver biopsy fibrosis stage							
F0–F1	152	6.10	16.91 (13.91, 20.11)	0.91 (0.87, 0.94)	0.07	6.19	0.92 (0.89, 0.94)
F2	45	6.40	17.73 (12.23, 23.58)	0.97 (0.94, 0.99)	0.12	6.80	0.94 (0.89, 0.97)
F3–F4	72	7.12	19.74 (12.80, 29.02)	0.96 (0.91, 0.98)	0.18	6.74	0.95 (0.92, 0.97)
MRE LSM — by BMI							
BMI < 30 kg/m²	106	5.32	14.75 (12.72, 16.96)	0.99 (0.98, 0.99)	0.09	5.92	0.97 (0.96, 0.98)
BMI ≥ 30 kg/m²	187	7.02	19.44 (15.64, 23.66)	0.96 (0.94, 0.97)	0.12	6.79	0.96 (0.95, 0.97)

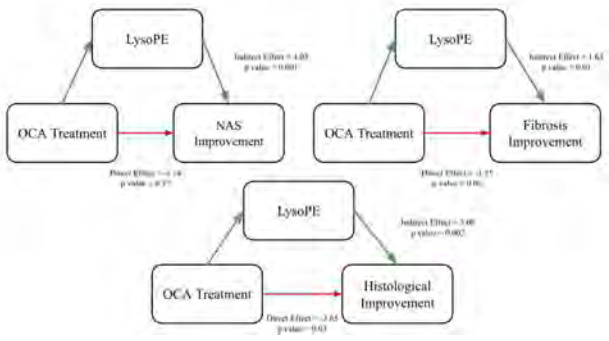
2369 | LYSO- PHOSPHATIDYL ETHANOLAMINE (LYSOPE) MEDIATES THE EFFECT OF OBETICHOLIC ACID (OCA) IN INDIVIDUALS WITH NON-CIRRHOTIC METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH) WITH FIBROSIS: RESULTS OF METABOLOMICS IN THE FLINT STUDY

Niharika Samala[1] Xincheng Li[2] Matthew Smith[3] Wanyu Zhang[4] Maiying Kong[5] David Hein[5] Dean Jones[6] Jianzhu Luo[5] Hongmei Zhang[2] Naga Chalasani[7] Matthew Cave[5], [1]Indiana University, [2]Northwestern University, [3]Atlanta VA Medical Center; Emory University, [4]Brown Cancer Center, University of Louisville, [5]University of Louisville, [6]Emory University, Children's Healthcare of Atlanta, [7]Indiana University Medical Center



Background: Metabolic dysfunction-associated steatohepatitis (MASH) has limited treatment options, and the molecular mechanisms underlying therapeutic response remain insufficiently understood. Using data from the Farnesoid X Receptor (FXR) Ligand, obeticholic acid (OCA) in MASH Treatment (FLINT) trial, we wanted to understand metabolic underpinnings of response to FXR-agonists. **Methods:** Serum samples from 192 participants from FLINT-trial, including 99 in OCA and 93 in placebo arms were analyzed. Samples from weeks 0, 36, and 72 were analyzed to investigate the dynamic metabolomic pathways mediating the impact of FXR-agonism on histologic outcomes. Outcomes evaluated included MASH histologic improvement by FLINT-trial (reduction in MASLD activity Score (MAS) by ≥ 2 points without worsening fibrosis), any improvement in -MAS and, -fibrosis. A trajectory-based longitudinal causal mediation framework analysis was performed to summarize complex temporal mediator profiles using subject specific slopes. FDR < 0.05 was deemed significant. **Results:** The mean age of the cohort was 51.5 years, 67% were females, and 76% had obesity. A total of 13,893 metabolites across 566 samples were identified, of which slope of change in concentrations of 169 metabolites were significantly associated with the OCA treatment over duration of the study. Of the 169 metabolites, lyso-phosphatidyl ethanolamine (lysoPE), an important metabolite of glycerophospholipid metabolism, was identified as a key mediator of response to OCA, with significant indirect effects on all three histologic outcomes. The effect of OCA on MASH histologic improvement was primarily mediated through lysoPE (indirect effect: 5.08, $p = 0.002$), despite a negative direct (non-metabolomic) effect of OCA (-3.65, $p = 0.03$). LysoPE also mediated the effect of OCA on both MAS improvement (indirect

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

effect: 4.03, p = 0.001) and fibrosis improvement (indirect effect: 1.63, p = 0.01), with no direct (non-metabolomic) effect. (Figure 1) LysoPE enriched glutathione, amino-acid and carnitine metabolism pathways. **Conclusion:** Longitudinal causal mediation analysis of metabolomics in the FLINT trial identified lysoPE as a key mediator of response to FXR-agonism. Our results show that early metabolomic changes during treatment with FXR-agonists class of medications, and possibly other classes of medications as well, in clinical trials could help identify patients who might be most likely to benefit from continuing therapy.

2370 | PERFORMANCE OF THE FATTY LIVER INDEX AND HEPATIC STEATOSIS INDEX FOR IDENTIFYING METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE IN A SAUDI COHORT: THE GENESIS STUDY

Saleh Alqahtani[1] Shadan AlMuhaidib[2] Faisal Sanai[3] Bandar Al-Judaibi[4] Feras Altunusi[2] Basmah Khoja[1] Sahar Alnasrallah[2] Abdulraheem Bayameen[5] Abdullah Alharthi[6] Mona Ismail[7] Mohammed Alghamdi[8] Khalid Alswat[9] Waleed Alhazzani[2], [1]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [2]Ministry of Defense Health Services, Riyadh, Saudi Arabia, [3]King Abdulaziz Medical City,King Abdullah International Medical Research Center Jeddah, Saudi Arabia, [4]King Faisal Specialist Hospital and Research Center, Riyadh, Saudi Arabia, [5]King Fahad Armed Forces Hospital, Jeddah, Saudi Arabia, [6]Prince Sultan Military Medical City, Riyadh, Saudi Arabia, [7]College of Medicine at Imam Abdulrahman bin Faisal University, Dammam, Saudi Arabia, [8]King Fahad Military Medical Complex, Dhahran, Saudi Arabia, [9]King Saud University/KKUH

Background: Non-invasive scores are widely used to case-find metabolic dysfunction-associated steatotic liver disease (MASLD) in primary care and endocrinology settings, but data from Middle Eastern populations remain limited. We evaluated the Fatty Liver Index (FLI) and Hepatic Steatosis Index (HSI) against vibration-controlled transient elastography (VCTE)-defined MASLD in the Saudi GENESIS cohort. **Methods:** We analyzed baseline data from GENESIS, a prospective, population-based study conducted across seven primary care centers in Saudi Arabia between March 2024 and June 2025. MASLD was defined as hepatic steatosis on VCTE (controlled attenuation parameter ≥ 268 decibels per metre) plus at least one of the five cardiometabolic risk factors per the 2023 multisociety Delphi consensus. We calculated FLI and HSI using published formulas. We assessed discrimination using the area under the receiver operating characteristic curve (AUC). We reported sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy at the lower cutoff threshold (< 30 for both scores) and the rule-in cutoffs (FLI ≥ 60; HSI ≥ 36) with Wilson 95% confidence intervals (CIs). **Results:** MASLD was present in 1,111 of 2,979 participants (37.3%) based on VCTE. FLI showed numerically higher discrimination than HSI (AUC, 0.806 [95% CI 0.791–0.822] vs. 0.788 [95% CI 0.771–0.805]. At the rule-out cutoff, HSI had higher sensitivity and NPV than FLI (99.5% and 98.1% vs. 92.4% and 91.5%) but lower specificity (15.6% vs. 49.2%). At the rule-in cutoff, FLI had higher specificity, PPV, and accuracy than HSI (76.5%, 64.1%, and 73.9% vs. 49.7%, 51.4%, and 64.5%). **Conclusion:** FLI demonstrated numerically higher overall discrimination and better rule-in performance than HSI for identifying MASLD in this Saudi population-based cohort. HSI provided near-complete rule-out sensitivity but had limited rule-in utility at published cutoffs, supporting population-specific recalibration before clinical implementation in Saudi primary care.

2371 | IMPACT OF OBESITY ON VIBRATION-CONTROLLED TRANSIENT ELASTOGRAPHY PERFORMANCE IN PATIENTS WITH METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Allen Luo[1] Chester Hui[1] Neharika Bandaru[1] Kali Zhou[1] Emilie Mitten[2] Marvin Ryou[2] Thomas Wang[1], [1]Keck School of Medicine of USC, [2]Brigham and Women's Hospital, Massachusetts General Hospital

Background: Vibration-controlled transient elastography (VCTE) is a validated noninvasive tool for liver fibrosis assessment in MASLD, with AASLD guidance endorsing liver stiffness measurement (LSM) thresholds of < 8 kPa and > 12 kPa to rule in and rule out advanced fibrosis in MASLD, respectively, and < 10 kPa and ≥ 15 kPa for advanced chronic liver disease (ACLD). Whether these thresholds perform equally across BMI categories remains uncertain, as increasing abdominal adiposity may attenuate probe signal transmission. We aimed to evaluate BMI-stratified VCTE performance in predicting liver fibrosis stages. **Methods:** We performed a retrospective cohort study of adults with biopsy-proven MASLD who underwent VCTE within 12 months of liver biopsy from 2016-2025 at three academic centers. LSM (kPa) and fibrosis stage (NASH CRN) on biopsy were obtained. Patients were stratified by BMI at time of biopsy: < 30, 30-40, and ≥ 40 kg/m². LSM performance for various fibrosis stages (F2-F4) was assessed by area under the receiver operating characteristic (AUROC) analysis. Optimal thresholds were derived using the Youden Index. Evaluation of existing AASLD thresholds for advanced fibrosis and ACLD were performed with BMI stratification. **Results:** 597 patients were included, including 188 (31.5%) with advanced fibrosis (F3) and 76 (12.7%) with ACLD (F4) on liver biopsy. VCTE overall performance for predicting liver fibrosis stages (F2-F4) was moderate (AUROC 0.75-0.77), with decreasing accuracy as BMI increased (not statistically significant) [Figure 1]. Youden-derived optimal thresholds were highest for patients with BMI ≥ 40 [Figure 2]. Rule-out performance of VCTE remained robust. Across all BMI categories, LSM of < 8 kPa demonstrated a negative predictive value (NPV) of 86-91% for advanced fibrosis and LSM of < 10 kPa had NPV 93-100% for ACLD. In contrast, rule-in performance of VCTE deteriorated with increasing BMI. Positive predictive value (PPV) for LSM > 12 kPa in predicting advanced fibrosis decreased from 73.3% in patients with BMI < 30 to 38.5% for BMI ≥ 40 (p = 0.0003) [Figure 3]. PPV for LSM ≥ 15 kPa in predicting ACLD declined similarly from 38.3% in BMI < 30 to 17.5% in BMI ≥ 40 (p = 0.0362). PPV in predicting ACLD at higher CSPH thresholds (LSM ≥ 20 kPa with PLT < 150K and LSM ≥ 25 kPa) also remained poor despite higher cutoff values. **Conclusion:** Higher BMI substantially impacts VCTE diagnostic performance in patients with MASLD. While rule-out thresholds for cirrhosis and CSPH retain excellent NPV across all BMI categories, rule-in performance declined as BMI increases, suggesting obesity-associated inflation of LSM and increased risk of false positives. BMI-stratified VCTE thresholds or alternative testing may improve fibrosis risk stratification in patients with obesity.

2372 | PROSPECTIVE REAL-WORLD MASH SCREENING IN PRIMARY CARE YIELDS HIGH PREVALENCE OF SIGNIFICANT FIBROSIS AND IDENTIFIES HIGH-RISK METABOLIC PHENOTYPES

Janet Chu[1] Nghiem Ha[1] Max Goldman[2] Bilal Hameed[1] Maria Tolentino[1] Mohsen Merati[1] Mandana Khalili[1] Rena Fox[1], [1]University of California, San Francisco, [2]Kaiser Permanente

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a leading cause of advanced chronic liver disease, yet fibrosis screening remains underutilized in primary care, resulting in underdiagnosis of significant fibrosis. We evaluated the prevalence and predictors of significant fibrosis among primary care patients with metabolic dysfunction-associated steatotic liver disease (MASLD) risk factors undergoing prospective FIB-4–based screening. **Methods:** We conducted a prospective pragmatic implementation trial in a large primary care network with ~60,000 annual visits. Adults with type 2 diabetes mellitus (DM), obesity, or both were identified through the electronic medical record (EMR); patients with viral hepatitis or alcohol use disorder were excluded. Annual FIB-4 score from 2019-2023 were calculated and age-adjusted for fibrosis assessment. Primary care providers (PCPs) received standardized EMR recommendations for vibration-controlled transient elastography (VCTE). Significant fibrosis was defined as F2–4 on VCTE. Multivariable logistic regression identified factors associated with significant fibrosis. **Results:** Among 7,014 patients with DM and/or obesity, 3,835 patients aged 30-75 had at least one calculable FIB-4. Of these, 3,232 (84%) were low-risk and 603 (16%) had indeterminate- or high-risk FIB-4. PCPs were contacted for 453 patients; 32 had prior VCTE through a pilot study and 55 through usual care. Overall, 211 patients completed fibrosis assessment and 208 had available VCTE results. The majority were male (61%) with mean age of 62 years, and race/ethnicity included 36% white, 29% Asians, 16% Latinx and 12% Black patients. Metabolic phenotypes included obesity alone (41%), DM alone (30%) and both obesity/DM (29%). Most patients had indeterminate-risk (81%) while 19% had high-risk FIB-4. Overall, 65 of 208 (31%) patients had significant fibrosis with F2-4 fibrosis. On multivariable analysis, high-risk FIB-4 (aOR 2.52, 95%CI 1.04-6.08), DM (aOR 2.71, 95%CI 1.23-5.98), and higher BMI (aOR 1.17, 95%CI 1.09-1.27) were independently associated with significant fibrosis after adjusting for age, sex, race/ethnicity, metabolic factors including hypertension and hyperlipidemia. Combined obesity and DM was also independently associated with significant fibrosis (aOR 2.99, 95% CI 1.30-6.86) when adjusting for similar factors as above. **Conclusion:** In this prospective real-world primary care MASH screening trial, nearly one-third of patients with elevated FIB-4 had significant fibrosis on secondary assessment. Furthermore, combined DM and obesity conferred approximately three-fold higher odds of significant fibrosis compared with either condition alone, highlighting a particularly high-risk metabolic phenotype. These findings support the call for FIB-4-based screening in primary care to improve identification of patients with MASH and progressive liver disease.

2373 | IMPACT OF CONCOMITANT ALPHA-1 ANTITRYPSIN DEFICIENCY ON CLINICAL OUTCOMES IN PATIENTS WITH MASLD: A PROPENSITY SCORE-MATCHED COHORT STUDY

Madeha Irfan[1] Talal Bhatti[1] Sajid Jalil[2] Ahmed Ibrahim[3] Ashwani Singal[4] Sanjaya Satapathy[5] Shahzad Ashraf[6], [1]Northwell Health, [2]Stanford University, [3]San Joaquin General Hospital, [4]University of Louisville, [5]Northshore University Hospital/Northwell Health, [6]Prime medical and Dental health

Background: Background and Aims: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a leading cause of chronic liver disease worldwide. Alpha-1 Antitrypsin Deficiency (A1ATD) is associated with progressive hepatic fibrosis and cirrhosis; however, its impact in MASLD remains incompletely characterized. This study evaluated hepatic decompensation, liver transplantation (LT), and mortality outcomes associated with concomitant A1ATD in patients with MASLD. **Methods:** A retrospective cohort study was performed using the TriNetX US Collaborative Network comprising 66 healthcare organizations. Adult patients with MASLD diagnosed between January 1, 2005, and May 21, 2021, were identified using ICD codes and stratified according to the presence or absence of concomitant A1ATD. Patients with competing chronic liver diseases were excluded. Following 1: 1 propensity score matching, 2,122 patients were included in each cohort (Table 1). Outcomes assessed included hepatic decompensation, hepatocellular carcinoma (HCC), LT, and all-cause mortality. **Results:** MASLD patients with concomitant A1ATD demonstrated higher cumulative risk of hepatic decompensation compared with MASLD alone (11.7% vs. 7.6%; RR 1.54, 95% CI 1.25–1.89; $p < 0.001$). Portal hypertensive complications were more frequent among patients with concomitant A1ATD, including ascites (8.2% vs. 4.9%; RR 1.68, 95% CI 1.31–2.16; $p < 0.001$), variceal hemorrhage (2.3% vs. 1.1%; RR 1.97, 95% CI 1.21–3.20; $p = 0.006$), and hepatic encephalopathy (10.7% vs. 7.0%; RR 1.53, 95% CI 1.24–1.88; $p < 0.001$). Concomitant A1ATD was additionally associated with increased risks of hepatorenal syndrome (2.6% vs. 1.2%; RR 2.22, 95% CI 1.39–3.55; $p = 0.001$) and spontaneous bacterial peritonitis (2.0% vs. 0.7%; RR 3.04, 95% CI 1.67–5.56; $p < 0.001$). LT rates were markedly higher among patients with concomitant A1ATD (5.0% vs. 1.6%; RR 3.12, 95% CI 2.13–4.58; $p < 0.001$). Mortality was significantly higher among patients with concomitant A1ATD (14.4% vs. 11.5%; RR 1.25, 95% CI 1.07–1.46; $p = 0.006$), whereas HCC incidence did not significantly differ between groups (2.2% vs. 1.5%; RR 1.48, 95% CI 0.94–2.33; $p = 0.085$). **Conclusion:** Concomitant A1ATD was associated with increased risks of hepatic decompensation, portal hypertensive complications, and LT in patients with MASLD.

Table 1. Baseline Characteristics of Propensity Score-Matched Cohorts

Characteristic	MASLD + A1ATD (n=2,122)	MASLD Alone (n=2,122)	SMD
Age, mean ± SD (years)	51.5 ± 17.6	52.5 ± 17.2	0.056

2374 | A SIMPLE MODEL TO PREDICT ADVANCED FIBROSIS IN MASLD PATIENTS WITH INDETERMINATE FIB-4

Laith Alomari[1] Zaid Al-Fakhouri[2] Ahmad Al-Riyalat[1] Daniel Simadibrata[2] Ghideon Ezaz[1], [1]Jefferson Einstein Philadelphia Hospital, Thomas Jefferson University, Philadelphia, PA, [2]The MetroHealth System, Case Western Reserve University, Cleveland, OH

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: The Fibrosis-4 (FIB-4) index is recommended as a first-line screening tool for advanced fibrosis in patients with metabolic dysfunction-associated steatotic liver disease (MASLD). However, 25–35% of patients fall in the indeterminate range (1.3–2.67), where FIB-4 provides limited guidance. We developed and validated a simple, laboratory-based model to further stratify fibrosis risk in this population. **Methods:** Using a biopsy-proven MASLD cohort (n = 1,810; 608 indeterminate), we developed an L2-regularized logistic regression model using recursive feature elimination. Eight clinical and laboratory variables were selected from 24 candidates. The model was internally validated in a held-out subset (n = 213) and externally validated in a multi-center Asian cohort from China and Malaysia (n = 203 indeterminate). Generalizability was assessed in the National Health and Nutrition Examination Survey (NHANES) 2017–2020 (n = 1,503 indeterminate). **Results:** In internal validation, the model achieved an area under the receiver operating characteristic curve (AUROC) of 0.826 (95% CI, 0.762–0.880). External validation in the Asian cohort demonstrated preserved discrimination (AUROC 0.737, 95% CI 0.668–0.801). In NHANES, the model maintained good discrimination (AUROC 0.743, 95% CI 0.698–0.788). At a rule-out threshold of 0.256, sensitivity was 94.4% with negative predictive value of 88.1% in internal validation. Subgroup analyses demonstrated consistent performance across age groups, BMI categories, and diabetes status. **Conclusion:** A simple, interpretable model using routine laboratory values can provide additional risk stratification for patients with indeterminate FIB-4 scores. Prospective validation in primary care settings is warranted.

2375 | CLIPS (CROHN'S LIVER FIBROSIS PREDICTION SCORE): A NON-INVASIVE RISK SCORE FOR SIGNIFICANT LIVER FIBROSIS IN CROHN'S DISEASE. DEVELOPMENT AND EXTERNAL VALIDATION

Maria Teresa Arias-Loste[1] Coral Rivas-Rivas[1] Sandra García-Mateo[2] Samuel Martinez-Dominguez[2] Maria del Henar Ruiz Saez[1] Inmaculada Sánchez-Ojeda[1] sergio García-Mateo[2] Monserrat Rivero[1] Maria Escuin[2] Maria Jose Garcia[1] Beatriz Gallego[2] Angela Puente[1] Jose Ignacio Fortea[1] Juan Carlos Rodriguez-Duque[3] Carla Gargallo[2] Antonio Cuadrado[1] Fernando Gomollon[2], [1]Clinical and Translational Research Group in Digestive Diseases, IDIVAL. Santander. Spain, [2]Hospital Clínico Universitario Lozano Blesa. Instituto Investigación Sanitaria de Aragon. CIBERehd, [3]Clinical and Translational Research Group in Digestive Diseases, IDIVAL

Background: Crohn's disease (CD) confers an independent fibrogenic risk beyond classic metabolic factors, yet available non-invasive fibrosis scores (FIB-4, NAFLD Fibrosis Score) were developed in metabolic populations and show suboptimal performance in CD. We developed and externally validated CLIPS, a novel non-invasive risk score for significant liver fibrosis in CD, applicable regardless of concomitant steatotic liver disease (SLD). **Methods:** CLIPS was developed in 390 consecutive CD patients undergoing vibration-controlled transient elastography (VCTE) at Hospital Universitario Marqués de Valdecilla (Santander, Spain). Patients with chronic liver disease outside the SLD spectrum were excluded. Significant fibrosis was defined as liver stiffness $\geq$8 kPa. Penalised Firth logistic regression with FDR-corrected variable selection was used; internal validation employed 200-iteration bootstrap resampling. External validation was performed in 347 independent CD patients from Hospital Clínico Universitario Lozano Blesa (Zaragoza, Spain), applying identical exclusion criteria. **Results:** Significant fibrosis prevalence was 13.1% in the development cohort and 9.5% in the validation cohort; one-third of fibrosis cases in each cohort occurred without concomitant SLD, highlighting a non-metabolic fibrogenic pathway in CD. CLIPS incorporates nine routinely available variables, with leucocyte count (OR 0.678; p < 0.001) and GGT (OR 1.017; p = 0.003) as primary independent predictors. Bootstrap-validated AUROC was 0.798 (95% CI 0.741–0.862), with good calibration (Hosmer-Lemeshow p = 0.272; Brier score 0.094), significantly outperforming

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

FIB-4 (AUROC 0.652) and NFS (AUROC 0.660) (DeLong $p < 0.05$ for both). External validation AUROC was 0.729 (95% CI 0.616–0.843), with a Youden-optimal threshold virtually identical to development ($p \geq 0.163$ vs. $p \geq 0.162$). A dual-threshold approach yielded a low-risk zone (NPV 96.0%/95.4% in development/validation cohorts) and a high-risk zone with equivalent sensitivity (64.6% vs. 67.7%), with statistically comparable risk stratum distribution across cohorts. **Conclusion:** CLIPS is a well-calibrated, externally validated non-invasive tool for significant liver fibrosis risk stratification in CD, outperforming metabolic-population scores. Its dual-threshold design enables clinical rule-out of fibrosis with high NPV and identification of patients warranting elastography referral, regardless of SLD status, addressing a critical gap in the hepatological follow-up of CD patients.

2376 | REAL-WORLD PERFORMANCE OF FIB-4 USING MRE AS REFERENCE STANDARD IS NOT AFFECTED BY BMI OR HEMOGLOBIN A1C

Garrett Coleman[1] Morgan Ford[1] William Southall[1] Elizabeth Statham[1] Jad Allam Saab[1] Meagan Gray[1] Fernando Bril[1], [1]The University of Alabama at Birmingham

Background: The fibrosis-4-score (FIB-4) is a widely used non-invasive test to screen for patients at risk of clinically significant fibrosis. Recent data suggests that FIB-4 may underestimate clinically significant fibrosis in patients with diabetes and/or obesity. The implications of these findings are concerning as metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common cause of newly diagnosed cirrhosis in the United States. Using magnetic resonance elastography (MRE) as the gold standard, we compared real-world performance of FIB-4 across various BMI and A1c ranges at our tertiary center. **Methods:** Patients seen between April 2018 and September 2025 at the University of Alabama at Birmingham with MRE and FIB-4 data available were included in this study ($n = 521$). Laboratory values within 6 months of MRE were used to calculate FIB-4. Standard areas under receiver operator curve (AUROC) were calculated for BMI groups ($< 30 kg/m^2$, 30-40kg/m^2, and $> 40 kg/m^2$) and A1c categories ($< 6\%$, 6-8%, and $> 8\%$) to assess FIB-4 performance in detecting clinically significant fibrosis, defined as ≥ 3.14 kilopascals (kPa) on MRE. **Results:** A total of 521 patients were included (54 ± 13 years; 55.3% female; 75.0% White, 16.4% African American, and 8.6% other; BMI: 33.5 ± 6.9 kg/m^2; 23.6% with diabetes, and hemoglobin A1C $6.1 \pm 1.2\%$). The predominant liver disease etiologies were MASLD (69.7%) and metabolic and alcohol-related liver disease (Met-ALD, 9.4%), and 120 (23.0%) had clinically significant fibrosis. The performance of FIB-4 to detect clinically significant fibrosis in patients with diabetes was 0.71 (0.61-0.82) vs. 0.76 (0.70-0.81) in individuals without diabetes, $p = 0.48$. FIB-4 performance was also similar in all A1c subgroups ($< 6.0\%$: 0.77 [0.70-0.84], 6-8%: 0.71 [0.61-0.81], and $> 8\%$: 0.84 [0.67-1.00], $p = 0.41$). This was also true when limiting the analysis to only patients with diabetes ($p = 0.47$). FIB-4 also performed similarly across BMI groups (< 30: 0.78 [0.70-0.86], 30-40: 0.70 [0.62-0.78], and > 40: 0.81 [0.70-0.93], $p = 0.21$). Performance of FIB-4 across groups remained similar when limiting the analysis to patients with MASLD. **Conclusion:** Overall, FIB-4 performed similarly across A1c and BMI groups to detect clinically significant fibrosis using MRE as a reference standard. Despite reports that FIB-4 may underperform in individuals with diabetes, this does not seem to be driven by hyperglycemia or increased adiposity. FIB-4 remains a useful non-invasive diagnostic tool to assess for clinically significant fibrosis.

2377 | RELIANCE ON THE FIB-4 INDEX DEPRIVES PATIENTS WITH F2 FIBROSIS FROM PHARMACOTHERAPEUTIC OPPORTUNITIES: EVIDENCE FROM A 5,000 SUBJECT COHORT STUDY

Natalie Vellutini[1] Dameia Brewster[1] Qingxia Chen[1] Jackson Resser[1] Ashley Spann[1] Manhal Izzy[1], [1]Vanderbilt University Medical Center

Background: The FIB-4 index is a noninvasive liver disease assessment that was initially developed to predict advanced hepatic fibrosis and cirrhosis (i.e., stage F3-4). Multiple society guidelines continue to recommend the FIB-4 index as the first line screening test. However, now that recently approved pharmacotherapies for metabolic-associated liver disease (MASLD) are initiated at the F2 stage, it is critical to investigate if continued reliance on FIB-4 may inappropriately exclude F2 patients from opportunities for treatment. Our aim is to assess the prevalence and predictors of FIB-4 misclassification rates in patients with elastography-proven F2 in real-world clinical settings. **Methods:** We conducted a single center retrospective analysis of patients undergoing transient elastography (TE) and/or MRI elastography (MRE) with concurrently available FIB-4 data between 01/01/2018 – 12/31/2025. Liver transplant recipients and those with poor quality elastography studies were excluded. The normalcy cutoff for FIB-4 index was 1.3 for patients age < 65 and 2.0 for patients age ≥ 65. Transient elastography and MRI elastography cutoffs for F0 - F4 were based on current society guidelines. We evaluated the misclassification rate of the FIB-4 index compared to the respective elastography assessment and applied generalized linear regression modeling to compare likelihood of misclassification, adjusted for relevant clinical characteristics. **Results:** The study included 5045 patients with 5292 elastography studies ([TE] = 3997 and [MRE] = 1295). Of those classified as F2 by elastography study, 312/747 (41.8%) in the TE group and 37/110 (33.6%) in the MRE group were misclassified as having a normal FIB-4. Patients without a diagnosis of diabetes (OR: 1.39 [1.01, 1.92]), patients of a race other than non-Hispanic white (OR: 1.73 [1.10, 2.77]), and patients having BMI above 25.3 (OR: 1.06 [1.03, 1.09]) were associated with higher odds of this misclassification event (F2 patient/normal FIB-4) relative to patients with diabetes, non-Hispanic whites, and having one unit lesser BMI, respectively. **Conclusion:** In this large study cohort, patients with clinically significant fibrosis were frequently misclassified with a normal FIB-4 score. In practice, this inappropriately normal FIB-4 score could lead to missed opportunities for advanced care such as initiation of pharmacotherapy in eligible patients with MASLD. Further refinement of this model with improved sub-group (DM, BMI, race/ethnicity) predictive accuracy is critically needed.

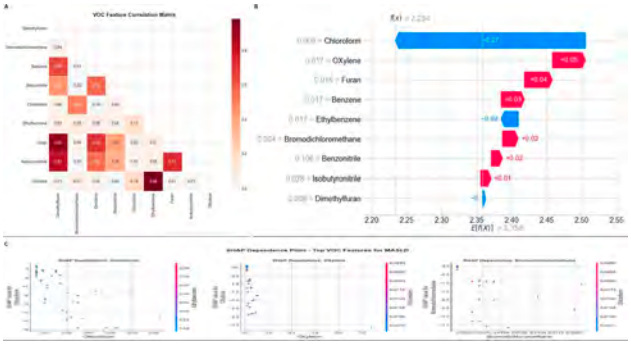
2378 | ENVIRONMENTAL VOLATOMIC SIGNATURES ASSOCIATED WITH LEAN MASLD IDENTIFIED THROUGH EXPLAINABLE AI



Sarpong Boateng[1] Guy loic Nguefang Tchoukeu[2] Khaled Halwani[3] Chimezirim Ezeano[4] Yazan Al-ajlouni[5] Eunice Omeludike[6] Ihunanya Kanu[7] Basile Njei[8], [1]Yale New Haven Health, [2]Texas Tech University Health Science Center, Permian Basin, [3]Yale University School of Medicine, [4]Advocate Aurora Healthcare, [5]Montefiore Medical Center, [6]Piedmont Athens Regional Medical Center, [7]Baptist Memorial Hospital- Golden Triangle, [8]Yale University

Background: Lean metabolic dysfunction-associated steatotic liver disease (MASLD) affects up to 20% of individuals with normal body mass index, yet its environmental determinants remain poorly characterized. Volatile organic compounds (VOCs), including disinfection byproducts and petroleum-derived toxicants, possess hepatotoxic properties and may contribute to liver injury through mechanisms independent of adiposity, representing a potentially underrecognized etiologic pathway in lean MASLD. **Methods:** We performed a cross-sectional analysis of lean adults (BMI < 25 kg/m²) in the NHANES 2017–March 2020 dataset with whole-blood measurements of nine VOCs and transient elastography data. MASLD was defined using steatosis and consensus metabolic criteria, while advanced fibrosis was defined as liver stiffness ≥ 8.6 kPa. Explainable machine learning with SHapley Additive exPlanations (SHAP) was applied to identify VOCs associated with MASLD and characterize exposure-response patterns across the volatomic profile. **Results:** Among 860 lean adults, 77 (9.0%) had MASLD and 14 (1.6%) had advanced fibrosis. Participants with MASLD were older (median 62 vs. 52 years) and had

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

higher prevalences of metabolic syndrome, diabetes, and hypertension (all $p < 0.001$). Chloroform emerged as the dominant VOC associated with MASLD (mean absolute SHAP 0.82), followed by o-xylene (0.29), bromodichloromethane (0.23), benzene (0.20), and furan (0.17). Notably, chloroform demonstrated weak intercorrelation with other VOCs, supporting an independent environmental exposure signal rather than shared-source clustering. SHAP analyses revealed complex nonlinear exposure-response relationships at low VOC concentrations. Advanced fibrosis analyses were substantially underpowered and should be considered hypothesis-generating. **Conclusion:** In a nationally representative cohort of lean adults, blood volatomic profiling identified distinct systemic VOC signatures associated with MASLD, dominated by chloroform, a water disinfection byproduct whose CYP2E1-mediated bioactivation generates phosgene and depletes hepatic glutathione. These findings support environmental toxicant exposure as a plausible mechanistic contributor to lean MASLD independent of classical adiposity-driven metabolic pathways. Explainable AI enabled transparent characterization of complex environmental exposure patterns and highlights the emerging potential of volatomics for environmental biomarker discovery in hepatology.

2379 | FIB-4 DISCORDANCE WITH VCTE-DEFINED FIBROSIS RISK AMONG NON-HISPANIC ASIAN ADULTS

Jonathan Hong[1] Adrian Singson[1], [1]Mountain Area Health Education Center

Background: Non-Hispanic Asian(NHA) adults may develop MASLD and fibrosis risk at lower BMI levels than non-Hispanic White(NHW) adults, suggesting that conventional fibrosis screening may miss liver disease. FIB-4 is widely used for fibrosis risk stratification, but its performance across NHA ethnicity-specific BMI categories is not well studied. **Methods:** We analyzed adults ≥ 18 years in NHANES 2017–March 2020 with valid FibroScan liver stiffness measurement (LSM), AST, ALT, and platelet counts. Participants with significant alcohol use, hepatitis B/C, or pregnancy were excluded. Elevated liver stiffness was defined as LSM ≥ 8 kPa and low risk FIB-4 as < 1.3. Asian specific BMI categories were applied to NHA adults (lean < 23, overweight 23–27.5, and obese ≥ 27.5). Standard BMI categories were applied to NHW adults. The primary outcome was low risk FIB-4 despite LSM ≥ 8 kPa. Descriptive analyses focused on NHA adults, with comparison between NHA ethnicity specific overweight and NHW standard overweight. Regression models evaluated FIB-4/LSM discordance by ethnicity-specific BMI category, adjusting for age and sex. **Results:** Among 875 NHA adults of 7,006 adults, mean age was 45.4 years, 46.6% were male, and mean BMI was 25.9 kg/m². 6.5% of NHA adults had LSM ≥ 8 kPa, of whom nearly two-thirds had low-risk FIB-4, corresponding to an overall FIB-4/LSM discordance prevalence of 4.4%. Discordance increased across Asian-specific BMI categories (lean 0.7%; overweight: 3.3%; obese: 9.2%). Among ethnicity-specific overweight adults, NHA had lower mean BMI than NHW adults but higher prevalence of LSM ≥ 8 kPa (6.1% vs. 3.4%). Among those with LSM ≥ 8 kPa, low risk FIB-4 was present in 54.9% of NHA adults with BMI 23–27.5, 50.7% of NHA adults with BMI 25–29.9, and 28.6% of NHW adults with BMI 25–29.9. In age/sex adjusted models, ethnicity-specific overweight NHA adults had higher odds of discordance than standard overweight NHW (OR 3.31, 95% CI 1.00–10.94, $p = 0.049$). In a separate interaction model, a significant NHA × overweight interaction (OR 9.84, 95% CI 1.11–87.51, $p = 0.041$) indicated that the lean-to-overweight transition was associated with a disproportionately larger increase in discordance for NHA than NHW adults. **Conclusion:** NHA adults with Asian-specific overweight BMI thresholds had higher FIB-4/LSM discordance than NHW adults, with more than half of overweight NHA adults with elevated liver stiffness classified as low risk by FIB-4. FIB-4 was originally derived in HCV/HIV-coinfected cohorts with limited racial and ethnic diversity and subsequently validated predominantly in Western populations. These findings highlight how fibrosis screening tools derived predominantly from non-Asian populations may systematically under-detect disease in NHA adults. Earlier VCTE referral for overweight NHA adults should be considered in MASLD screening pathways.

2380 | PREDICTING 7-YEAR OUTCOMES IN CHRONIC LIVER DISEASE: A COMPARISON OF L1-DERIVED AND WHOLE-BODY MRI MUSCLE METRICS

Wile Balkhed[1] Mattias Ekstedt[1] Olof Dahlqvist Leinhard[2] Shan Cai[1] Simone Ignatova[3] Peter Lundberg[1] Nils Dahlström[1] Stergios Kechagias[1] Mikael Forsgren[2] Patrik Nasr[1], [1]Linkoping University, [2]AMRA Medical AB, [3]Region Östergötland

Background: While patients with advanced liver disease are at risk of sarcopenia, no practical established imaging-based screening method exists. In this study we validated liver MRI-derived L1-level body composition assessment against whole-body MRI body composition assessment and investigated the prognostic value of these measurements for adverse clinical outcomes. **Methods:** Patients with suspected chronic liver disease with clinical indication for liver biopsy underwent a same-day liver MRI. In half of the cohort whole-body MRI was also performed. MRI measurements used AMRA® Researcher. Liver MRI body composition was assessed from the craniocaudal extent of the L1 vertebral level, including fat-free erector spinae muscle volume indexed to height (L1-ESMI), muscle fat infiltration (L1-MFI) and visceral adipose tissue indexed to height (L1-VATI). Whole-body MRI assessed the thighs for total fat-free muscle volume (FFMV), mean MFI, and total abdominal VAT volume. Z-FFMV and Z-VAT were sex- and BMI standardized Z-scores; sex-adjusted MFI was reported in percentage points (pp). Low FFMV was defined as Z-FFMV $<25^{th}$ percentile, and high MFI as $>75^{th}$ sex-specific percentile from a UK Biobank reference population. A retrospective follow-up review of patient records was performed $\geq$1 year after baseline visit to screen for adverse outcomes, including all-cause mortality, major adverse cardiovascular events (MACE) and major adverse liver-related outcomes (MALO). **Results:** 161 participants were included (whole-body MRI n = 80) with mean age of 55 ± 14 years and BMI 28.5 ± 5.2 kg/m^2 . The most common etiology was MASLD (47%), and 29% had advanced fibrosis. L1 muscle volume, L1-MFI and L1-VAT had strong correlation with thigh FFMV (R^2 = 0.75), MFI (R^2 = 0.54) and total VAT (R^2 = 0.89), all P < 0.001. During a mean follow-up time of 7.0 yrs 35 adverse events were captured (MALO n = 18; MACE n = 13, deaths n = 4). Mean follow-up time in whole-body MRI subgroup was 4.7 years and 15 events were recorded. Cox proportional hazards regression analysis found no correlation between L1-level body composition variables and risk of adverse event in follow-up. Meanwhile lower Z-FFMV (per SD increase; cHR 0.53, 95% CI 0.34–0.84, P < 0.01) and higher sex-adjusted MFI (pp) (cHR 1.20 95% CI 1.04–1.38, P < 0.05) and Z-VAT (SD) (cHR 1.55, 95% CI 1.05–2.29, P < 0.05) increased risk. Presence of high MFI also increased risk (cHR 3.52, 95% CI 1.27–9.77, P < 0.05) while no associations were shown for low Z-FFMV. Adjusting for age and baseline fibrosis stage, only lower Z-FFMV (SD) (aHR 0.58, 95% CI 0.36–0.97, P < 0.05) and presence of high MFI (aHR 3.33, 95% CI 1.07–10.34, P < 0.05) remained significant. **Conclusion:** L1-derived body composition from liver MRI has strong anatomic correlation to whole body MRI body composition, but lacks in prognostic accuracy, whereas lower thigh Z-FFMV and presence of high thigh MFI were independent predictors of adverse events in longitudinal follow-up.

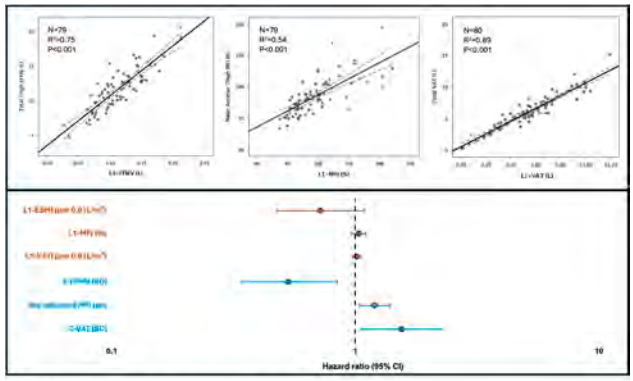

Figure 1. Validation and prognostic performance of L1-derived body composition markers

Panel A: Associations between L1-derived and whole-body MRI measures with fitted linear regression and 95% CI.
Panel B: Crude hazard ratios (95% CI) from Cox regression for MACE, MALO, or death. L1-derived measures were analyzed in 161 participants (35 events; mean follow-up 7.0 years) and whole-body MRI measures in 80 participants (15 events; mean follow-up 4.7 years).

2381 | DIAGNOSTIC UTILITY OF AN AUTOMATED PLASMA CARBOXYLESTERASE 1 ASSAY FOR HEPATIC STEATOSIS: A COMPARATIVE STUDY BETWEEN SCREENING AND CHRONIC HEPATITIS B COHORTS

Shingo Tanaka[1] Makito Tanaka[1] Kayoko Ochi[2] Ryo Kobayashi[2] Ryosei Murai[2] Satoshi Takahashi[1], [1]Sapporo Medical University, [2]Sapporo Medical University Hospital

Background: Steatotic liver disease (SLD) is a global health priority, increasing the demand for non-invasive biomarkers. Carboxylesterase 1 (CES1) is a key hepatic enzyme in lipid metabolism. We previously established a high-throughput automated ELISA platform for plasma CES1 and validated its excellent analytical stability, confirming its readiness for clinical research. However, its diagnostic performance across different clinical backgrounds remains to be fully elucidated. This study compared the diagnostic utility of plasma CES1 for hepatic steatosis between a screening outpatient cohort and a chronic hepatitis B (CHB) cohort. **Methods:** We analyzed two distinct cohorts who underwent same-day blood sampling and abdominal ultrasonography: (1) a screening cohort of 212 outpatients (excluding advanced fibrosis and significant alcohol consumption) and (2) a CHB cohort of 108 patients. Plasma CES1 levels were measured using our automated ELISA platform. Hepatic steatosis was quantified using ultrasound-derived attenuation imaging (Aplio i700, Canon Medical Systems) to determine the attenuation coefficient (AC; cutoff $\geq$ 0.66 dB/cm/MHz). Clinical profiles associated with diagnostic discordance (false-negative and false-positive) between AC and CES1 were also evaluated. **Results:** In both cohorts, plasma CES1 levels consistently demonstrated significant positive correlations (all $r \geq 0.3$, $P < 0.001$) with metabolic markers, liver injury indicators, and ultrasound parameters: BMI ($r = 0.469$ in screening, 0.409 in CHB), ALT ($r = 0.578$, 0.341), GGT ($r = 0.442$, 0.337), hepatorenal index ($r = 0.607$, 0.390), and AC ($r = 0.692$, 0.483). ROC analysis for diagnosing steatosis yielded an AUC of 0.87 in the screening cohort and 0.80 in the CHB cohort, indicating slightly higher diagnostic performance in the screening population. Although clinical characteristics of false-negative and false-positive cases were thoroughly analyzed in each cohort, no common contributing factors for diagnostic discordance were identified between the two groups. **Conclusion:** Plasma CES1 holds promise as a reliable, non-invasive biomarker for hepatic steatosis across distinct clinical settings. Despite minor variations in diagnostic performance between the cohorts, plasma CES1 consistently reflected hepatic fat accumulation. These findings highlight its clinical utility and warrant further large-scale, multi-etiology studies to confirm its generalizability.

2382 | RANKING FIBROSIS BIOMARKERS IN STEATOTIC LIVER DISEASE: A MACHINE LEARNING APPROACH

Cristiane Tovo[1] Juliana Czermainski[1] Maria Goyer[2] Luis Ferreira[1] Randhall Carteri[3], [1]Federal University of Health Sciences of Porto Alegre (UFCSPA), Porto Alegre, Brazil, [2]Federal University of Health Sciences of Porto Alegre (UFCSPA), Porto Alegre, Brazil., [3]CESUCA University Center, Cachoeirinha, Brazil

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the major leading causes of chronic liver disease worldwide, and noninvasive fibrosis detection remains a challenge. Machine learning (ML), emerge as an alternative to improve well-established scores and features. This study aimed to evaluate ML algorithms for fibrosis prediction and rank the most relevant biomarkers associated with fibrosis in MASLD patients using routine clinical and laboratory data. **Methods:** Transversal study, with data were obtained from the National Health and Nutrition Examination Survey (NHANES) 2017–2020 cycle. All adults with hepatic steatosis (controlled attenuation parameter- CAP >275) were included. Fibrosis was defined by transient elastography (TE) $\geq$ 8 kPa. Machine learning models were developed using demographic, anthropometric, and blood biomarker data. Data preprocessing included normalization, 70: 30 train-test split, and SMOTE balancing. The evaluated classifiers included Logistic Regression, Random Forest, XGBoost, LightGBM, Extra Trees, AdaBoost, Gaussian Naive Bayes, Decision Tree, and Support Vector Classifier with K-Fold cross-validation. Performance was assessed using F1-score, accuracy, AUC-ROC, and AUC-PR. **Results:** 2,474 participants were included , being 1,970 without fibrosis (79.6%) and 504 with fibrosis (20.4%). The group with fibrosis showed

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

significantly increased body mass index (BMI) (38.6kg/m² vs 32.6kg/m²; p < 0.001), and higher rates of severe obesity (37.1% vs 12.5%; p = 0.001), type 2 diabetes mellitus (29.2% vs 14.4%; p = 0.001), low HDL cholesterol (47.8% vs 39.9%; p = 0.001), and higher waist circumference - WC (121cm vs 108cm; p < 0.001). Several biomarkers also differed significantly between groups, all with higher levels in fibrosis group. Logistic Regression analyzing the whole blood panel demonstrated the best overall performance, achieving F1-score = 0.50 ± 0.03, AUC-PR = 0.52 ± 0.04, and AUC-ROC = 0.78 ± 0.02. . WC and BMI were identified as the strongest overall predictors of fibrosis, followed by AST, GGT, total bilirubin and age. Using only the five highest-ranked biomarkers, has been noted an improved predictive performance (F1-score = 0.51 ± 0.03; AUC-ROC = 0.79 ± 0.02). A predictive equation was developed incorporating hemoglobin, BMI, age, AST, and GGT. The new equation is as follows: (0.098 × Haemoglobin) + (0.899 × BMI) + (0.452 × AGE) + (0.398 × AST + (0.238 × GGT) + (-1.641). **Conclusion:** ML models using routine blood biomarkers and anthropometric measurements can effectively identify fibrosis in MASLD patients, using less biomarkers than a complete blood work. This approach may contribute to scalable, low-cost, and noninvasive fibrosis screening strategies in clinical practice.

2383 | OPPORTUNISTIC CT IDENTIFIES A SIGNIFICANT POPULATION OF CLINICALLY UNRECOGNIZED STEATOTIC LIVER DISEASE IN CARDIOMETABOLIC AT-RISK PATIENTS

Vignesh Rajasekaran[1] Asad Aali[2] Alexandria Jensen[3] Allison Kwong[4] Andrew Johnston[5] Ates Fettahoglu[2] Hye Na[5] Luyao Shen[5] Taiyo Shimizu[5] Luke Yoon[5] David Svec[6] Robert Boutin[5] Jason Hom[6] Akshay Chaudhari[2] Laura Derry[6], [1]Stanford University Department of Internal Medicine, [2]Stanford University, Department of Biophysics, [3]Stanford University, Quantitative Sciences Unit, [4]Stanford University, Department of Gastroenterology and Hepatology, [5]Stanford University, Department of Radiology, [6]Stanford University, Department of Hospital Medicine

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) - hepatic steatosis with at least one cardiometabolic risk factor - is the most common form of steatotic liver disease (SLD) and is a leading cause of chronic liver disease globally, yet it remains substantially underdiagnosed. We previously showed that Comp2Comp, a validated deep-learning algorithm, identifies hepatic steatosis on contrast-enhanced CT more often than radiology reports or ICD-coding. We aimed to determine how often patients with ≥1 cardiometabolic risk factor for MASLD lack formal clinical recognition and to characterize their demographic, metabolic, and fibrosis risk profile. **Methods:** We conducted a retrospective cohort study of adults ≥18 years old who had ≥ 1 cardiometabolic risk factor for MASLD (2023 multisociety consensus) in the three years preceding the qualifying CT and underwent contrast-enhanced or non-contrast abdominal CT at a multisite academic health system (2013–2018, 2021–2024). Patients were classified into one of two groups: (1) ICD-coded SLD prior to or within 30 days of the qualifying CT scan (clinically recognized [CR]) or (2) incidentally detected SLD by radiology report or Comp2Comp deep-learning algorithm without ICD-coding (clinically unrecognized [CU]). Patients with ICD-9 or ICD-10 diagnosis codes for other chronic liver disease (including cirrhosis), alcohol use disorder, prior hepatic decompensation (ascites, hepatic encephalopathy, variceal bleed), prior hepatocellular carcinoma, liver transplant, or a cardiovascular event within 30 days of the qualifying CT were excluded. **Results:** Of 13,506 patients with a qualifying abdominal CT, 9,395 had ≥1 cardiometabolic risk factor. Among these, 2,361 had identified SLD by ICD-coding, radiology report, or Comp2Comp. Of those, 553 (23.4%) were clinically recognized (CR) and 1,808 (76.6%) were clinically unrecognized (CU). Compared with CR patients, CU patients were older (mean 64.5 vs 59.6 yr) and had a lower burden of metabolic comorbidities (type 2 diabetes 22.3% vs 32.7%; obesity 22.1% vs 41.8%; OSA 16.2% vs 26.4%; all p < 0.001). Among CU patients with available FIB-4, 36.9% had indeterminate-or-higher fibrosis risk (≥1.3) and 2.9% met the high-risk threshold (>3.25). FIB-4 was unable to be calculated in 23.7% of CU vs 12.8% of CR patients. **Conclusion:** Even among patients who unambiguously met MASLD criteria, approximately three of four were clinically unrecognized, including many with existing fibrosis risk. The high rate of unavailable FIB-4 assessment in the unrecognized cohort exposes a potential gap in liver risk stratification. Integrating opportunistic CT with a deep-learning algorithm into clinical pathways may identify a large, at-risk population not captured by conventional screening and detection pathways.

2384 | AI-ASSISTED OCULAR PHENOTYPING FOR LIVER–METABOLIC RISK STRATIFICATION: A REAL-WORLD EXPLAINABLE FRAMEWORK FOR PRECISION HEPATOLOGY

Fangpin Huang[1] Yichen Peng[1], [1]Chengdu University of TCM, China

Background: Metabolically-dysfunction-associated steatotic liver disease (MASLD) is closely linked to systemic cardiometabolic dysfunction, yet scalable non-invasive screening strategies remain limited. Ocular phenotyping enables direct assessment of microvascular and tissue-level alterations and may reflect broader metabolic abnormalities. Although artificial intelligence (AI)-assisted ocular analysis has shown diagnostic potential, its application in hepatology remains limited by concerns regarding confounding and interpretability. This study evaluated whether real-world ocular diagnostic patterns could support liver-metabolic risk stratification. **Methods:** A structured clinical dataset comprising 350 patients, 512 visits, and 2,054 diagnostic observations across 52 disease categories was analyzed. Diagnoses were grouped into liver/hepatobiliary, metabolic/endocrine, cardiovascular, renal, and neurologic domains. Co-occurrence mapping was used to assess systemic clustering. In parallel, a conceptual explainable artificial intelligence (XAI) framework integrating saliency mapping, counterfactual auditing, and confounder isolation was developed to outline interpretable ocular AI pipelines. **Results:** Among 350 patients, 21.7% had liver/hepatobiliary findings, 58.3% had metabolic/endocrine diagnoses, and 74.9% had cardiovascular conditions. Marked overlap was observed among hepatic, metabolic, and cardiometabolic disease domains. Repeated visit-level observations revealed persistent disease co-expression rather than isolated organ-specific manifestations. The convergence of metabolic, cardiovascular, and hepatic categories suggests that ocular biomarkers may capture systemic signatures relevant to MASLD risk. Variability in disease burden across visits also highlighted potential confounding effects, supporting the need for explainable and fairness-aware AI models. **Conclusion:** This real-world ocular phenotyping study identified substantial co-occurrence among liver/hepatobiliary, metabolic/endocrine, and cardiovascular diseases, suggesting that ocular phenotypes may reflect cardiometabolic burden associated with MASLD. Clinical co-occurrence analysis was integrated into a conceptual XAI framework, providing an interpretable approach for AI-assisted ocular risk stratification in hepatology. These findings support the eye as a scalable, non-invasive biomarker platform for precision liver-metabolic medicine. Prospective multicenter validation and standardized ocular imaging workflows are needed to further evaluate the clinical applicability of AI-assisted ocular biomarkers for MASLD screening and risk stratification.

2385 | ENHANCED LIVER FIBROSIS (ELF) TEST FOR ADVANCED FIBROSIS IN MASLD: A BIOPSY-REFERENCED DIAGNOSTIC TEST-ACCURACY META-ANALYSIS

Gabriel Prusch Fernandes[1] Hamza Sadhra[1] Advait Suvarnakar[1] Eliabe Abreu[2] Diego Drumond Westgeest e Sousa[2] Kamalpreet Hara[2] Douglas Simonetto[2], [1]Montefiore Einstein, [2]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) has become the leading chronic liver disease, and advanced fibrosis (≥F3) drives liver-related outcomes and pharmacologic treatment eligibility. Guidelines recommend a two-step case-finding pathway: FIB-4 first, then a second test such as the Enhanced Liver Fibrosis (ELF) test, to reduce unnecessary referral. How accurately ELF detects ≥F3 across contemporary biopsy-referenced MASLD cohorts remains uncertain, and no prior systematic review has synthesized the biopsy-referenced sequential FIB-4-then-ELF pathway. **Methods:** We conducted a PRISMA-DTA systematic review of studies evaluating ELF against liver biopsy for advanced fibrosis (≥F3) in MASLD/NAFLD across PubMed, Embase, Cochrane Library, and Web of Science databases. From 868 records, 31 studies were eligible for review; 9 distinct studies reported extractable biopsy-referenced 2x2 data at ≥F3 and entered the meta-analysis, contributing 8 standalone-ELF cohorts and 6 sequential FIB-4-then-ELF cohorts (5 studies contributed to both pools). We pooled standalone ELF accuracy with a bivariate (Reitsma) model and prespecified sensitivity analyses; the sequential FIB-4-then-ELF pathway was summarized as a forest plot. Analyses used R (mada). **Results:** The 8 standalone-pool cohorts included 6,019 biopsied participants (≥F3 prevalence 18–71%; cross-sectional diagnostic cohorts and one trial-screening cohort). Pooled standalone ELF for ≥F3 had sensitivity 0.73 (95% CI, 0.63–0.81) and specificity 0.80 (95% CI, 0.70–0.86), with summary ROC AUC 0.825; the estimate stayed stable on leave-one-out analysis, in the ELF≥9.8 subset (5 cohorts: sensitivity 0.74, specificity 0.81, AUC 0.844), and after excluding a trial-enriched cohort (AUC 0.833). Across the 6 sequential FIB-4-then-ELF cohorts, sensitivity ranged 0.57–0.86 and specificity 0.61–0.94, with the second ELF step tending to favor specificity. We did not pool these because thresholds, denominators, and derivations differed and the bivariate fit was unstable. Most other included studies reported ELF only as an AUROC or at stages other than ≥F3, leaving too few data to pool the pathway. **Conclusion:** ELF accurately identifies advanced fibrosis in MASLD and, applied as a confirmatory second step, raises specificity to reduce unnecessary referral. Evidence on the sequential pathway remains heterogeneous and sparsely reported. Standardized reporting and prospective validation are needed before the two-step pathway can be pooled or recommended.

2386 | OBESITY-ASSOCIATED ATTENUATION OF THE BAVENO VII LSM RULE-IN THRESHOLD FOR CLINICALLY SIGNIFICANT PORTAL HYPERTENSION IN MASLD: A SYSTEMATIC REVIEW AND META-ANALYSIS

Rubab Fatimaa[1] Rida Fatima[2], [1]Fatima Jinnah Medical University, [2]Shaukat Khanum Memorial Hospital

Background: Clinically significant portal hypertension (CSPH; HVPG ≥10 mmHg) identifies patients with compensated advanced chronic liver disease (cACLD) at high risk for decompensation. Baveno VII liver stiffness measurement (LSM) thresholds and ANTICIPATE-NASH are increasingly used as HVPG surrogates; however, most fixed CSPH thresholds were derived largely from viral hepatitis and alcohol-related cACLD cohorts. In MASLD, obesity may independently elevate LSM and reduce the reliability of fixed thresholds. We evaluated the accuracy of non-invasive tests (NITs) for CSPH in MASLD-cACLD, stratified by obesity, and compared fixed Baveno VII thresholds with BMI-integrated ANTICIPATE-NASH. **Methods:** PubMed, Embase, and Cochrane were searched from inception through April 2026 per PRISMA. Eligible studies included adults with MASLD/NAFLD/NASH-related cACLD and HVPG as the reference standard. Extractable NIT metrics included sensitivity, specificity, AUC, PPV, or NPV. Two reviewers independently screened studies, extracted data, and assessed bias using QUADAS-2. When available, 2×2 tables were

extracted or reconstructed. Prespecified Baveno VII thresholds were prioritized. Bivariate random-effects models pooled sensitivity, specificity, and diagnostic odds ratios. Obesity (BMI ≥30 vs <30 kg/m²) was the primary subgroup. Sensitivity analyses evaluated threshold effects, cohort overlap, and heterogeneity. Duplicate populations were excluded where applicable. **Results:** Six studies contributed data from seven independent cohorts (N = 1,284); CSPH prevalence ranged from 39% to 74%. For Baveno VII rule-in (LSM ≥25 kPa), PPV was ~91% in non-obese MASLD but ~63–67% in obese MASLD, an estimated 24–29 percentage-point reduction. Baveno VII rule-out (LSM ≤15 kPa plus platelets ≥150×10⁹/L) maintained high NPV among patients meeting rule-out criteria across BMI strata: 99% (95% CI 97–100%). In obese MASLD, ANTICIPATE-NASH showed higher discrimination than LSM alone: AUC 0.83 (95% CI 0.80–0.85) vs 0.69 (95% CI 0.62–0.76). An ANTICIPATE-NASH probability threshold ≥75% yielded PPV 83%, compared with ~63–67% for fixed LSM rule-in. LSM-alone estimates showed substantial heterogeneity (I^2 > 55%; up to 82% for specificity), whereas ANTICIPATE-NASH showed low heterogeneity (I^2 < 10%). Available 100-Hz spleen stiffness measurement data suggested high accuracy (AUC 0.95) and grey-zone reduction from 60% to 15–20%, but were limited to one MAFLD cohort. **Conclusion:** In MASLD-cACLD, obesity attenuates Baveno VII LSM rule-in performance while preserving rule-out reliability among patients meeting rule-out criteria. BMI-integrated models such as ANTICIPATE-NASH may improve CSPH probability estimation in obese MASLD. Spleen stiffness is promising but needs external validation. These findings support BMI-calibrated, phenotype-specific interpretation of NITs rather than reliance on fixed LSM thresholds alone.

Test / Threshold	Key Result	Context
Baveno VII Rule-In (LSM ≥25 kPa)	PPV ~91% → ~63–67%	~24–29 pp reduction; non-obese vs obese MASLD
Baveno VII Rule-Out (LSM ≤15 + PLT ≥150)	NPV 99% (95% CI 97–100%)	Among patients meeting rule-out criteria; preserved across BMI strata
ANTICIPATE-NASH Pooled AUC	0.83 (95% CI 0.80–0.85)	vs LSM alone in obese: 0.69 (95% CI 0.62–0.76)
ANTICIPATE-NASH ≥75% threshold	PPV 83% in obese MASLD	Supported by prior IPD analysis; vs ~63–67% fixed LSM
SSM 100-Hz VCTE (AUC 0.95)	Grey zone: 60% → 15–20%	Single MAFLD cohort (N=60); external validation needed

2387 | DIAGNOSTIC ACCURACY OF ARTIFICIAL INTELLIGENCE-BASED MODELS FOR LIVER FIBROSIS ASSESSMENT IN MASLD: A SYSTEMATIC REVIEW AND META-ANALYSIS

Raja Chandra Chakinala[1] Era Gupta[1] Aryan Gupta[2] Omar Oudit[3] Harmanjeet Singh[4] Gautam Maddineni[5] Aakash Desai[6] Chaitanya Chandrala[7], [1]Guthrie/Robert Packer Hospital, PA, USA, [2]Bangalore Medical College and Research Institute, India, [3]Brookdale University Hospital Medical Center, NY, USA, [4]Mahatma Gandhi Memorial Medical College, India, [5]Creighton University, NE, USA, [6]Allegheny Health Network, PA, USA, [7]Guthrie/Robert Packer Hospital,PA,USA

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is a major cause of chronic liver disease and can progress to advanced fibrosis, cirrhosis, and liver-related complications. Accurate fibrosis assessment is important for prognostication and disease monitoring; however, liver biopsy is invasive and unsuitable for large-scale screening. Artificial intelligence (AI)-based models have emerged as promising noninvasive tools for fibrosis detection in MASLD. We performed a systematic review and meta-analysis evaluating the diagnostic accuracy of AI-based approaches for liver fibrosis assessment in MASLD. **Methods:** This review was conducted in accordance with PRISMA guidelines. PubMed, Google Scholar, and ScienceDirect were systematically searched using a comprehensive search strategy. Studies evaluating AI-based models for fibrosis detection in MASLD and reporting area under the receiver operating characteristic curve (AUC) values were included. Pooled AUC values were calculated using inverse-variance random-effects models. Subgroup analyses comparing deep learning (DL) approaches and traditional machine learning methods, including random forest (RF), support vector machine (SVM), and logistic regression (LR), were performed. Statistical heterogeneity was assessed using the I^2 statistic. Data were analyzed in RStudio using the meta, metadata, and metafor packages. **Results:** Eleven studies were included in the final analysis. The pooled AUC for AI-based fibrosis detection models was 0.91 (95% CI 0.86–0.97), demonstrating high overall diagnostic accuracy. DL models demonstrated the highest pooled AUC (0.93), followed by ML models (0.90). RF, SVM, and LR approaches demonstrated pooled AUCs of 0.84, 0.81, and 0.81, respectively. Okanoue et al. reported the highest-performing DL algorithm among included studies. No significant interstudy heterogeneity was observed (I^2 = 0%), and subgroup analyses demonstrated comparable diagnostic performance across AI model categories. **Conclusion:** AI-based models demonstrate high diagnostic accuracy for liver fibrosis assessment in MASLD and may serve as promising noninvasive tools for fibrosis risk stratification. Further large-scale prospective studies with standardized external validation frameworks are needed to support routine clinical implementation.
