Background: Intrahepatic cholestasis of pregnancy (ICP) is a liver disease unique to pregnancy associated with significant maternal and fetal morbidity. The long-term implications of ICP on future liver disease remain unclear; however, emerging evidence suggests that gene variants associated with ICP may be associated with future hepatobiliary disease and cholangiocarcinoma. Prior estimates suggest ~20% of patients with severe ICP have pathogenic variants in hepatobiliary transporter genes but were limited by small sample sizes and predominantly European cohorts. We aimed to identify the prevalence of cholestatic gene variants among ICP patients in a diverse US cohort. **Methods:** We performed a retrospective review of exome sequence data from a previously established cohort of patients with ICP identified between 2009-2024 within the Mount Sinai BioMe Biobank, an EHR-linked biobank of 50,000+ consented participants in the New York City metropolitan area. Confirmed ICP was defined as total serum bile acids (TSBA) $\geq$ 10 µmol/L. We evaluated five genes previously implicated in ICP: *ABCB4, ABCB11, ATP8B1, ABCC2* and *TJP2.* Variants were annotated with variant effect predictors (VEP) and evaluated using ClinVar, CADD, REVEL, Polyphen2 and SIFT. Cumulative pathogenicity scores reflected the number of tools whose scores exceeded predefined pathogenic thresholds. **Results:** Of 888 patients with confirmed ICP, 111 had genetic data available in BioMe: 80 (72%) with TSBA 10-39, 17 (15%) with TSBA 40-99, and 14 (13%) with TSBA $\geq$ 100 µmol/L. Mean age was 32.3 years (SD 6.2); the cohort was 37% Hispanic, 34% White, 10% Asian, and 9% Black. Elevated liver enzymes were present in 77 (69%) individuals, and 23 (21%) had preexisting liver disease, led by viral (n = 6) and autoimmune hepatitis (n = 6). Ten individuals (9%) carried 15 variants: TJP2 (n = 5), ABCB11 (n = 3), ABCC2 (n = 3), ABCB4 (n = 2), and ATP8B1 (n = 2). Variants were identified in 6/42 Hispanic patients (14%) and 2/31 patients with TSBA $\geq$ 40 (7%). Seven variants (47%) had a pathogenicity score of 2 and 8 variants (53%) had a score of 1. ClinVar identified one pathogenic stop-gained variant in ATP8B1. **Conclusion:** In this diverse US cohort, 9% of patients with ICP carried potentially pathogenic variants in hepatobiliary transporter genes. TJP2 was the most implicated gene in our cohort – unlike prior studies in which ABCB4 was most common – and four patients carried multiple variants. The prevalence of genetic variants is lower than reported in European studies, which may reflect our inclusion of milder disease and greater ancestral diversity. These candidate variants should be further explored to inform risk stratification for ICP and future hepatobiliary disease.

Demographics, peak bile acids, and peak liver enzymes in patients with cholestatic gene variants

1156 | SAFETY, PHARMACOKINETICS AND TARGET ENGAGEMENT OF AX-0810 A FIRST-IN-CLASS RNA EDITING THERAPY DESIGNED TO MODULATE BILE ACID TRANSPORT FOR CHOLESTATIC DISEASE

Robert Bart Takkenberg[1] Gideon Hirschfield[2] Henkjan Verkade[3] Golnar Karimian[4] Nicole Cnubben[4] Galja Pletikapic[4] Sjef de Kimpe[4] Lianne Stevens[4] Walter Boiten[4] Eva Coll de la Rubia[4] Francesco De Chiara[5] Agathe Plichta[4] Robin Besuyen[4] Cristina Lopez Lopez[4], [1]Amsterdam University Medical Centers, [2]Toronto General Hospital, [3]University Medical Center Groningen, [4]ProQR Therapeutics, [5]Almirall

Background: Cholestatic liver disease, such as primary sclerosing cholangitis (PSC) and biliary atresia, involve toxic intrahepatic bile acid (BA) accumulation leading to

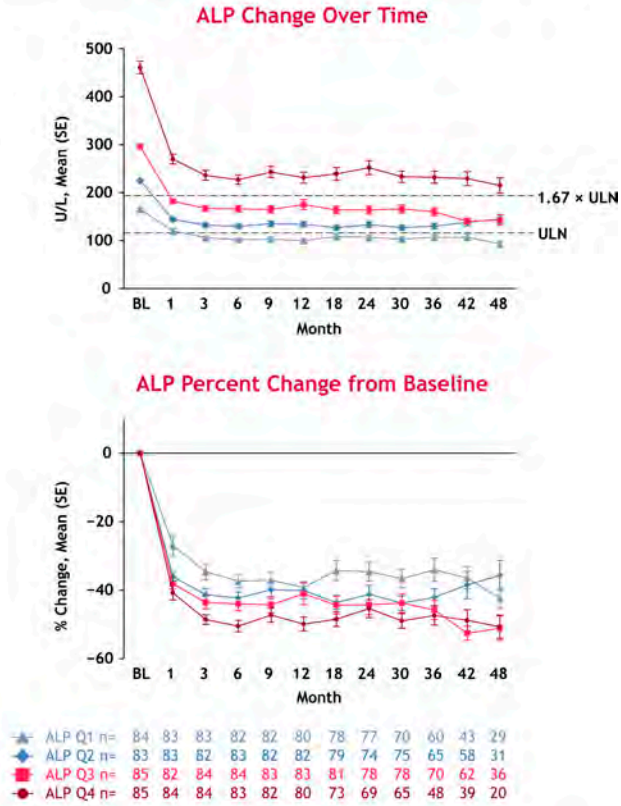
hepatocellular injury, inflammation, and fibrosis. There are no approved disease-modifying therapies for PSC and biliary atresia, and many patients require liver transplantation. Sodium taurocholate co-transporting polypeptide (NTCP; SLC10A1) is the dominant basolateral conjugated BAs transporter and a therapeutic target to reduce hepatocellular BA uptake. AX-0810 is a novel modality and first-in-class GalNAc-conjugated RNA editing oligonucleotide designed to induce a site-specific adenosine-to-inosine edit in NTCP mRNA, leading to reduced NTCP-mediated hepatocellular BA uptake. This first-in-human study evaluates the safety, tolerability, pharmacokinetics (PK), and target engagement of AX-0810 in healthy participants [EU CT number: 2025-521876-77-00]. **Methods:** This ongoing randomized, double-blinded, placebo-controlled, multiple-ascending-dose study evaluates subcutaneous AX-0810 in healthy adults (18–55 years) in 3 sequential dose cohorts (3, 6, and 9 mg/kg; total N = 33), with safety and PK review before dose escalation. Participants received an initial dose followed by a 2-week observation period, then 3 weekly doses with 12-week follow-up. Primary endpoints are safety and tolerability; the secondary endpoint is PK of AX-0810. Exploratory objectives evaluate pharmacodynamics with NTCP biomarker-based target engagement, including total serum BAs, serum BA composition, and the clearance of orally administered tauro-ursodeoxycholic acid (TUDCA) as a functional NTCP biomarker. BAs are measured after a standardized diet with calculated caloric and fat content at baseline and at multiple timepoints during dosing and follow-up. **Results:** Based on interim blinded data from the 3 mg/kg and 6 mg/kg cohorts (22 participants), AX-0810 was well tolerated with no serious adverse events (AEs), or AEs leading to discontinuation of the study treatment. All reported AEs were of mild or moderate severity. No clinically meaningful trends were observed in safety laboratory parameters, vital signs, or other safety assessments. PK parameters were consistent with preclinical predictions and supported the translational assumptions used for dose selection. Target engagement was evaluated through changes in total serum BAs, serum BA composition (conjugated vs unconjugated), and TUDCA clearance. **Conclusion:** AX-0810 is a potential novel hepatoprotective RNA-editing therapy to induce NTCP loss of function in cholestatic liver disease. This first-in-human study combines single and multiple ascending dose features to evaluate safety, PK, and NTCP target engagement using linked biomarkers of NTCP activity. The overall safety, tolerability, and PK profile observed support future studies in patients with cholestatic disease. **Disclosures:** Robert Bart Takkenberg:Nothing to Disclose, Gideon Hirschfield:Intercept: Consultant, GSK: Consultant, CymaBay: Consultant, Ipsen: Consultant, Falk: Consultant, Pliant: Consultant, Mirum: Consultant, Advanz: Consultant, Chemomab: Consultant, Gilead: Consultant, Kowa: Consultant, Henkjan Verkade:Nothing to Disclose, Golnar Karimian:proqr: Employee, Galapagos: Employee, Nicole Cnubben:Nothing to Disclose, Galja Pletikapic: Nothing to Disclose, Sjef de Kimpe:Nothing to Disclose, Lianne Stevens:Nothing to Disclose, Walter Boiten:Nothing to Disclose, Eva Coll de la Rubia:Nothing to Disclose, Francesco De Chiara:Nothing to Disclose, Agathe Plichta: Nothing to Disclose, Robin Besuyen:Nothing to Disclose, Cristina Lopez Lopez:Nothing to Disclose.

1157 | SELADELPAR LEADS TO RAPID AND SUSTAINED ALKALINE PHOSPHATASE REDUCTION, REGARDLESS OF BASELINE LEVELS, OVER 5 YEARS OF TREATMENT IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Christopher Bowlus[1] Cynthia Levy[2] Christophe Corpechot[3] Aparna Goel[4] Kyung min Kwon[5] Johnny Chew[5] Valentina Shakhnovich[5] Xin Qi[5] Alejandra Villamil[6], [1]University of California, Davis, [2]University of Miami, [3]Assistance Publique-Hôpitaux de Paris, Sorbonne University, [4]Stanford University Medical Center, [5]Gilead Sciences, Inc., Foster City, CA, United States, [6]The Liver Autoimmunity Unit, Hospital Italiano de Buenos Aires, Buenos Aires, Argentina



Background: Alkaline phosphatase (ALP) is a key marker of disease activity in primary biliary cholangitis (PBC), with higher ALP levels associated with negative long-term outcomes. In the pivotal placebo-controlled, Phase 3 RESPONSE trial (NCT04620733), seladelpar, a first-in-class delpar indicated for the second-line treatment of PBC, significantly reduced ALP levels compared with placebo. Here, we report changes in ALP across baseline (BL) ALP quartiles, as well as consistency and depth of ALP response, in patients with PBC receiving seladelpar for up to 4 years in the ongoing, open-label, Phase 3 ASSURE study (NCT03301506). **Methods:** Patients from RESPONSE and legacy seladelpar trials enrolled in ASSURE and received seladelpar 10 mg daily. BL was defined as seladelpar initiation either in RESPONSE or ASSURE. Patients were pooled and categorized by BL ALP quartile (data cutoff: Jan 2026). ALP changes from BL, along with depth of response (ALP reductions of $\geq$ 20%, 30%, or 40%), were assessed up to Month (M) 48. ALP changes from BL up to M48 were also assessed in patients who did not achieve ALP normalization and/or composite biochemical response (CBR; defined as ALP $<$ 1.67 × upper limit of normal [ULN], $\geq$ 15% reduction in ALP, and total bilirubin $\leq$ ULN) at M12. Safety was evaluated up to M60. **Results:** Overall, 337 patients were included in the analysis; 94.4% were female and 15.4% had cirrhosis at BL. BL demographics were similar across BL ALP quartiles, defined as: ALP (U/L) $<$ 198.5, Q1; $\geq$ 198.5 to $<$ 259, Q2; $\geq$ 259 to $<$ 352, Q3; and $\geq$ 352, Q4. ALP was reduced at M1 in all quartiles, with reductions

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

sustained through M48 (mean change from BL [standard error; SE]: −42.4% [2.98], Q1; −35.7% [4.33], Q2; −51.1% [3.56], Q3; −50.7% [3.42], Q4; **Figure**). In the overall population, 88.8%, 82.8%, and 63.8% of patients achieved ALP reductions of ≥ 20%, 30%, and 40%, respectively, at M48. Of 330 patients evaluable at M12, 228 (69.1%) achieved CBR and 115 (34.8%) achieved ALP normalization. For the 102 (30.9%) who did not achieve CBR, mean (SE) ALP change from BL at M48 was −34.7% (6.18). For the 215 (65.2%) who did not achieve ALP normalization, mean (SE) ALP change from BL at M48 was −43.5% (2.72). Adverse event incidence was similar across quartiles. **Conclusion:** Seladelpar treatment led to rapid reductions in ALP, sustained up to 4 years, across ALP quartiles. Treatment with seladelpar was associated with significant and sustained ALP reductions, including in patients who did not achieve biochemical response at M12. Seladelpar appeared well tolerated regardless of BL ALP.

Figure. ALP Changes in Patients Treated with Seladelpar by Baseline ALP Quartile in ASSURE

ALP Q1: < 198.5 U/L; ALP Q2: ≥ 198.5 to < 259 U/L; ALP Q3: ≥ 259 to < 352 U/L; ALP Q4: ≥ 352 U/L.
The ULN for ALP is 116 U/L for male and female patients.

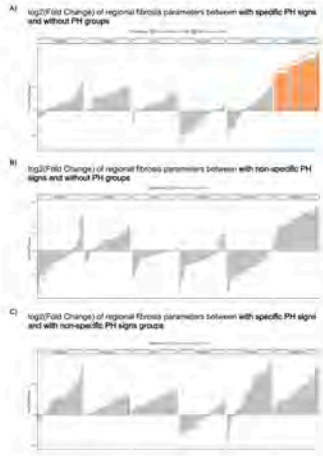
1158 | AI-BASED DIGITAL PATHOLOGY IDENTIFIES CHICKEN-WIRE FIBROSIS ASSOCIATED WITH THE DEVELOPMENT OF PORTAL HYPERTENSION AND PREDICTS CLINICAL OUTCOMES IN EARLY-STAGE PRIMARY BILIARY CHOLANGITIS

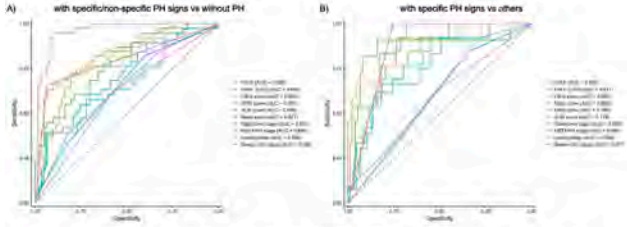
Lin Ma[1] Shuxiang Lee[1] Tingting Lv[1] Weijia Duan[1] Sha Chen[1] Hong You[1] Jidong Jia[1] Xinyan Zhao[1], [1]Liver Research Center, Beijing Friendship Hospital, Capital Medical University, Beijing, China



Background: The pathogenesis of portal hypertension (PH) in early-stage primary biliary cholangitis (PBC) remains unclear. This study aimed to explore

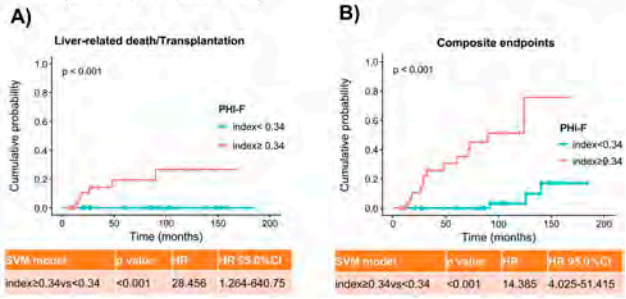
Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



the pathological mechanisms underlying PH in early-stage PBC using an artificial intelligence (AI)-based digital pathology platform. **Methods:** This retrospective study included patients with early-stage PBC (Ludwig stage 0–2) at our institute between June 2008 and September 2025. According to the current diagnostic criteria for porto-sinusoidal vascular disorder, patients were categorized into three groups based on PH manifestations: specific PH signs, non-specific PH signs, and no PH. Second harmonic generation/two-photon excitation fluorescence (SHG/TPEF) microscopy was used to quantify collagen features. Collagen parameters were compared among groups using one-way ANOVA or the Kruskal–Wallis test, as appropriate. A Fibrosis-based Portal Hypertension Index (PHI-F) was developed using a support vector machine (SVM) algorithm with leave-one-out cross-validation based on collagen parameters. Model performance was compared with conventional serological models and histological staging systems using the area under the receiver operating characteristic curve (AUC). Prognostic implications were assessed using Kaplan–Meier analysis and Cox regression with Firth's penalized likelihood. **Results:** A total of 101 patients were enrolled, including 62 without PH, 26 with non-specific PH signs, and 13 with specific PH signs. Among 184 collagen features quantified by SHG/TPEF imaging, 20 showed significant differences among the three groups ($P < 0.05$). Post-hoc analysis revealed that chicken-wire fibrosis parameters were selectively elevated in patients with specific PH signs compared with those without PH. PHI-F accurately discriminated PH status. For distinguishing patients with PH signs from those without PH, the AUC was 0.959 (95% CI, 0.922–0.995) in the full cohort and 0.802 (95% CI, 0.715–0.890) in cross-validation. For distinguishing patients with specific PH signs from the other two groups, the AUC was 0.890 (95% CI, 0.811–0.969) in the full cohort and 0.811 (95% CI, 0.692–0.930) in cross-validation. PHI-F outperformed conventional models, including four scoring systems (FIB-4, ALBI, APRI, and Mayo), three histological staging systems (Ludwig, METAVIR, and Nakanuma), and the Baveno VII criteria. Based on PHI-F predictions, patients were stratified into two prognostic groups with significantly different risks of liver-related death/transplantation and composite endpoints (hepatic decompensation, liver transplantation, or all-cause death) (both log-rank $P < 0.001$). **Conclusion:** AI-based SHG/TPEF quantitative fibrosis analysis identifies chicken-wire fibrosis as a key collagen feature associated with specific PH signs in early-stage PBC. PHI-F accurately identifies PH signs and helps stratify patients at high risk of adverse clinical outcomes.

Figure 1.Quantified fibrosis parameters in different liver regions demonstrated changes in fibrosis among with specific PH signs, with non-specfic PH signs and without PH groups.



Histogram showing the log2(Fold Change) of liver fibrosis characteristics assessed by regional fibrosis parameters between (A) with specific PH signs and without PH groups, (B) with non-specific PH signs and without PH groups, (C) with specific PH signs and with non-specific PH signs groups (one way-ANOVA or Kruskal-Wallis test). The variables that had been found significant by post hoc testing were colored (Tukey's HSD or Dunn's test).

Figure 2. ROC plots of PHI-F compared with ALBI score, APRI score, Baveno VII criteria, FIB-4 score, Mayo score, Ludwig stage, METAVIR stage and Nakanuma stage for the discrimination between A) with specific/non-specific PH signs vs without PH; B) with specific PH signs vs others. Abbreviation: LOO, leave-one-out

1159 | FRACTURE EPIDEMIOLOGY FOR ADULTS WITH PRIMARY SCLEROSING CHOLANGITIS, PRIMARY BILIARY CHOLANGITIS, AND CIRRHOSIS: A NATIONWIDE UNITED STATES CLAIMS-BASED COHORT STUDY

Nataliya Razumilava[1] Kurt Hankenson[1] Daniel Whitney[1], [1]University of Michigan

Background: Primary sclerosing cholangitis (PSC), primary biliary cholangitis (PBC), and cirrhosis are chronic liver diseases with extrahepatic consequences in which fractures are increasingly recognized as major contributors to morbidity, mortality, and socioeconomic burden. Non-U.S. population-based data demonstrate increased fracture risk and excess post fracture mortality in cirrhosis and PBC. In contrast, evidence in PSC has largely emphasized low bone mineral density and osteoporosis rather than incident fractures, and contemporary population level estimates of fracture risk remain limited. Aim of this study was to compare data across PSC, PBC, and cirrhosis to quantify fracture risk and to inform targeted surveillance and prevention strategies in different chronic liver disorders and their stages. **Methods:** This retrospective cohort study used private and public nationwide U.S. claims data from calendar years 2017–2023. Adults $\geq$ 18 years of age with PSC, PBC, cirrhosis, or without these conditions (comparator cohort) were included if they had at least 1 year of continuous health plan enrollment. We estimated sex-stratified 1-year period prevalence of fracture at any site (primary outcome), by skeletal region (secondary outcome), and by specific site (tertiary outcome), and compared PSC, PBC, and cirrhosis cohorts with the comparator cohort. Sex-stratified logistic regression estimated odds ratios (ORs) for fracture outcomes using the comparator cohort as the reference and adjusting for age, insurance type, and study entry year. **Results:** There were 3,328 adults with PSC (mean age, 51.4 years; 52.8% women), 10,519 adults with PBC (62.6 years; 89.5% women), 232,452 adults with cirrhosis (62.3 years; 44.8% women), and 10,000,000 adults in the comparator cohort. The 1-year period prevalence of fracture at any site was highest for cirrhosis (men, 16.8%; women, 23.7%), followed by PBC (men, 14.2%; women, 19.4%), PSC (men, 8.4%; women, 12.2%), and the comparator cohort (men, 4.2%; women, 6.1%). The adjusted OR for any fracture increased stepwise from PSC to PBC to cirrhosis, and there was strong evidence of effect modification by age, with PSC and PBC demonstrating a growing fracture risk disparity with aging and cirrhosis showing the greatest relative excess risk in younger adults. **Conclusion:** Adults with PSC, PBC, and cirrhosis have substantially elevated fracture risk compared with the general insured population, with distinct age- and site-specific patterns across liver disease types. These findings position hepatic osteodystrophy as a clinically relevant complication across the spectrum of cholestatic liver disease and cirrhosis and support earlier, liver disease–, site-, and age-specific strategies for fracture risk assessment, bone health surveillance, and fall prevention in clinical practice.

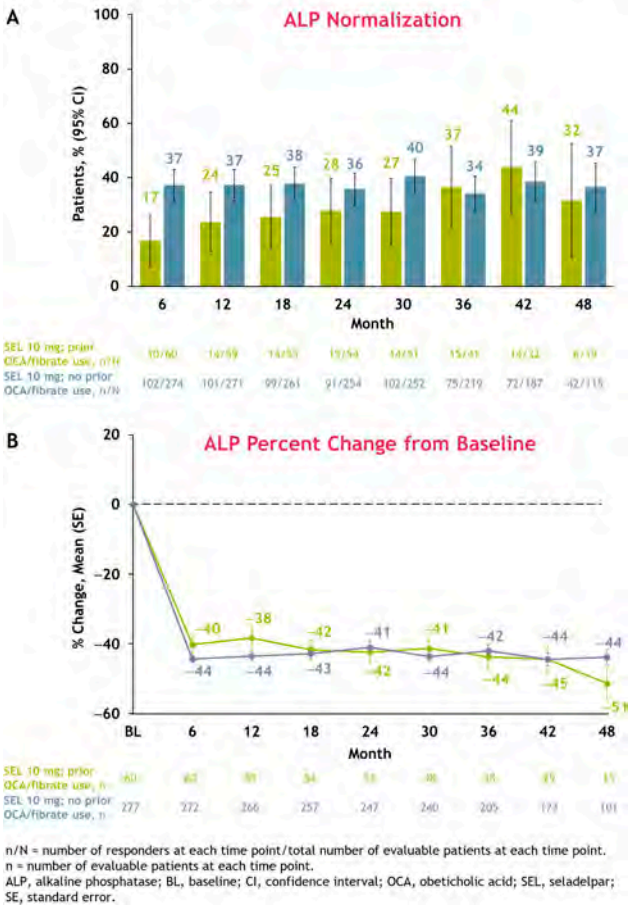
1160 | SELADELPAR LEADS TO LONG-TERM EFFICACY AND SAFETY IN PATIENTS WITH PRIOR OCA AND/OR FIBRATE EXPOSURE

Andreas Kremer[1] Palak Trivedi[2] Alejandra Villamil[3] Sonal Kumar[4] Kyung min Kwon[5] Xin Qi[5] Daria Crittenden[5] Justin Smith[5] Stuart Gordon[6], [1]University Hospital Zürich, University of Zürich, Zürich, Switzerland, [2]National Institute for Health and Care Research Birmingham Biomedical Research Centre, United Kingdo, [3]Hospital Italiano de Buenos Aires, Buenos Aires, Argentina, [4]Weill Cornell Medical College, New York, NY, United States, [5]Gilead Sciences, Inc., Foster City, CA, United States, [6]Henry Ford Health System



Background: Seladelpar, a first-in-class delpar (selective peroxisome proliferator-activator receptor delta [PPARδ] agonist), is an approved second-line treatment for primary biliary cholangitis (PBC). Second-line obeticholic acid (OCA) was withdrawn from markets due to safety concerns, while off-label fibrates have variable efficacy and safety data. In the pivotal Phase 3 RESPONSE trial (NCT04620733), seladelpar improved alkaline phosphatase (ALP) and pruritus in patients with and without prior OCA/fibrate use, with a similar safety profile to placebo, up to 1 year. Here, we report updated long-term efficacy and safety up to 5 years in patients with or without prior OCA/fibrate use in ASSURE (NCT03301506). **Methods:** ASSURE is an ongoing, open-label study of patients receiving once-daily oral seladelpar 10 mg, who enrolled from RESPONSE or earlier legacy seladelpar studies. OCA and fibrates were prohibited, and a 6-week washout was required prior to study entry. Patients were pooled, with baseline (BL) defined as seladelpar initiation in RESPONSE or ASSURE. Analyses were conducted in patients with prior OCA and/or fibrate vs no prior use. Biochemical efficacy endpoints include ALP normalization and ALP percent change from BL to Month (M) 48. In patients with BL moderate to severe pruritus (numerical rating scale [NRS] $\geq$ 4), clinically meaningful improvement ($\geq$ 3-point reduction) is reported to M36. A subset analysis evaluated biochemical endpoints through

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

M36 in patients with prior fibrate-only use. Safety was assessed using all available data through M60 in this interim analysis (data cutoff: Jan 2026). **Results:** Among 337 seladelpar-treated patients, 60 had prior OCA/fibrate use and 277 had no prior use. BL mean ALP was numerically higher in patients with prior vs no prior use (331 U/L and 278 U/L, respectively). At M48, both groups achieved similar ALP normalization rates (32% and 37%) and showed rapid and sustained reductions in ALP from BL (51% and 44%; **Figure 1**). In patients with BL moderate to severe pruritus (prior use: n = 20; no prior use: n = 88), similarly high rates of clinically meaningful improvement were observed at M36 (58% and 65%). In patients with prior fibrate-only use (n = 19), 44% (4/9) of patients achieved ALP normalization at M36, with ALP reductions of 45% from BL. No treatment-related serious adverse events were reported, and no new safety signals were observed in patients with prior OCA/fibrate use. **Conclusion:** Seladelpar led to marked and sustained biochemical response, with pruritus improvement, through up to 4 years in ASSURE, regardless of prior OCA and/or fibrate exposure. Seladelpar was well tolerated in both groups through up to 5 years of treatment.

1161 | IMPACT OF BASELINE ALKALINE PHOSPHATASE LEVELS ON ELAFIBRANOR TREATMENT OUTCOMES IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS IN REAL-WORLD SETTINGS

Cynthia Levy[1] Channa Jayasekera[2] Seema Meloni[3] Deborah Nikolla[3] Matthew Sobiesk[3] Christelle Pommie[4] Hugo Gomes Da Silva[4] Christopher Bowlus[5], [1]Schiff Center for Liver Diseases, University of Miami, Miami, FL, USA, [2]Liver Transplant Program, Mayo Clinic Arizona, Pheonix, AZ, USA, [3]Ipsen, Cambridge, MA, USA, [4]Ipsen, Paris, France, [5]Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, CA, USA

Background: Reductions in alkaline phosphatase (ALP) and bilirubin are surrogate markers of disease activity and predictors of long-term clinical outcomes in primary biliary cholangitis (PBC). In the phase III ELATIVE® trial, elafibranor demonstrated rapid and sustained improvements in multiple biochemical markers; in a post hoc analysis, baseline (BL) ALP values were demonstrated to impact biochemical response and ALP normalization rates. Here, we evaluated real-world data to determine if similar patterns with elafibranor are seen in routine clinical practice. **Methods:** This non-interventional, retrospective observational study used medical, pharmacy, and laboratory data from the HealthVerity network. Adult patients with PBC who initiated elafibranor and had BL ALP above the upper limit of normal (ULN) and ≥1 pre-index and ≥1 post-index ALP measurement were included. The date of first observed elafibranor exposure was defined as the index date (BL). Biochemical responses (including change from baseline [CfB]) were assessed using laboratory data through Month (M)6 post-index. Patients were stratified by BL ALP relative to the ULN: >1 to <1.67×, ≥1.67 to <3×, and ≥3×. Outcomes were analyzed using the Wilcoxon test. **Results:** Among 91 patients with PBC who initiated elafibranor with BL ALP >ULN and available pre-and post-index measurements, proportions by BL ALP were: >1–<1.67× ULN (58.2%), ≥1.67–<3× ULN (33.0%), and ≥3× ULN (8.8%). Most patients (93.4%) were female and mean age was 58.9 (SD: 11.4) years at BL. Substantial reductions were observed in mean ALP levels from BL to M6, including in those with mildly elevated BL ALP (>1–<1.67× ULN: −22.1%) and highly elevated BL ALP (≥3x ULN: −29.9%; **Figure A**). At M6, 48.4% of patients achieved normal ALP. ALP normalization was achieved in greater proportions of patients with BL ALP >1–<1.67× ULN (60.4%) and ≥1.67–<3× ULN (36.7%) than those with BL ALP ≥3× ULN (12.5%; **Figure B**); however, overall improvements from BL were observed across all subgroups after up to 6 months of elafibranor treatment. **Conclusion:** This analysis corroborated findings from the ELATIVE® trial, where patients who initiated elafibranor treatment with lower BL ALP values had higher ALP normalization rates compared to those with higher BL ALP. Importantly, reductions in ALP were consistent across all BL ALP subgroups, supporting the effectiveness of elafibranor across BL ALP strata.

Figure. Mean CfB in ALP (A) and proportions of patients with ALP normalization (B) at M6, stratified by ALP level at BL

ALP: alkaline phosphatase; BL: baseline; CfB: change from baseline; M: Month; ULN: upper limit of normal.

1162 | STATIN INITIATION AND LOWER HEPATIC DECOMPENSATION RISK IN PRIMARY BILIARY CHOLANGITIS: A POPULATION-BASED TARGET TRIAL EMULATION

Bryce Tkachuk[1] Aldo Montano-Loza[2] Juan Abraldes[2] Abdel-Aziz Shaheen[1], [1]University of Calgary, [2]University of Alberta

Background: A recent target trial emulation (TTE) reported lower hepatic decompensation risk with statin use in primary biliary cholangitis (PBC). Whether this association persists in a universal health system and among patients with PBC and dyslipidemia is unknown. We emulated a sequential target trial of statin initiation and liver outcomes in incident PBC. **Methods:** EMR-validated incident PBC patients in Alberta, Canada (2005–2024) were identified using linked health data. After excluding prior decompensation, early death, and prevalent statin use, monthly eligibility windows were used in a single-entry target trial emulation. New statin initiators entered at first dispensation and compared with statin-naive non-users assigned one randomly sampled eligible month to preserve temporal alignment. A 30-day pre-induction exclusion was applied before propensity-score weighting. Stabilized inverse probability weights were estimated from demographics, comorbidity, time since PBC diagnosis, ursodeoxycholic acid and cardiovascular medication use, LDL cholesterol, and calendar time. Weighted Cox models with robust standard errors (SEs) estimated hazard ratios (HRs) for hepatic decompensation (ascites, variceal bleeding, encephalopathy/failure, hepatorenal syndrome, or spontaneous bacterial peritonitis). Secondary analyses evaluated major adverse liver outcome (MALO; decompensation, HCC or liver transplantation), a dyslipidemia-restricted active-indication cohort, induction windows, and cumulative statin duration. **Results:** The primary cohort included 1,347 patients (286 statin initiators, 1,061 non-users). After weighting, all standardized mean differences (SMDs) were <0.08. Median follow-up was 5.3 and 4.8 years. During 7,747 person-years, 176 decompensation events occurred: 27 among statin initiators (15.5/1,000 PY) and 149 among non-users (24.8/1,000 PY). Statin initiation was associated with lower decompensation risk (HR 0.63, 95% CI 0.41–0.96; $P=.031$). MALO showed a concordant trend (190 events; HR 0.69, 95% CI 0.47–1.01; $P=.058$). Estimates were stable across 0-, 30-, 60-, and 90-day induction windows (HR range, 0.59–0.63). In the dyslipidemia-restricted cohort ($n=942$), the effect estimate remained similar but not statistically significant (HR 0.66, 95% CI 0.43–1.03; $P=.067$). Brief exposure (<90 days) was not associated with decompensation (HR 0.94; $P=.89$), whereas sustained exposure (≥ 90 days) was associated with lower decompensation risk (HR 0.59, 95% CI 0.37–0.94; $P=.025$), and with lower risk per additional year of use (HR 0.89, 95% CI 0.85–0.93; $P<.001$). **Conclusion:** In this Canadian sequential target trial emulation of incident PBC, statin initiation was associated with lower hepatic decompensation risk in all patients with a similar but not statistically significant estimate in the dyslipidemia-restricted cohort.

1163 | CLINICAL MEANINGFULNESS OF LINERIXIBAT EFFICACY IN PRURITUS IN PRIMARY BILIARY CHOLANGITIS (PBC): POST HOC ANALYSES FROM THE PHASE 3 GLISTEN STUDY

Brooke Currie[1] Cynthia Levy[2] David Jones[3] Gideon Hirschfield[4] Ivana Lazic[5] Alexander Cobitz[1] Danielle Podmore[5] Jennifer Shannon[6] Megan McLaughlin[7] Marlyn Mayo[8], [1]GSK, Collegeville, USA, [2]University of Miami, [3]Newcastle University, UK, [4]Toronto General Hospital, [5]GSK, London, UK, [6]GSK, Durham, NC, USA, [7]GSK, Collegeville, USA (at time of study conduct), [8]University of Texas Southwestern Medical Center

Background: Cholestatic pruritus affects up to 89% of patients (pts) with PBC, negatively impacting sleep and quality of life (QoL). Linerixibat, an ileal bile acid transporter inhibitor, is the first medicine approved in the US for the treatment of cholestatic pruritus in pts with PBC, based on the Phase 3 GLISTEN study (NCT04950127), which demonstrated a rapid, significant, and sustained improvement in pruritus and itch-related sleep interference vs placebo. This post hoc analysis further assessed the clinical meaningfulness of GLISTEN efficacy results, including the proportion of pts who achieved a rapid (Week 2) and clinically meaningful (3-point) reduction in Worst Itch Numerical Rating Scale (WI-NRS), the proportion who decreased from moderate–severe itch to mild/no itch, those who reported perceived improvements in itch, and those who experienced improvements in itch-related QoL and sleep interference. **Methods:** Post hoc analyses were performed on patient-reported outcome (PRO) data collected at Week 2 and up to Week 24 of GLISTEN in pts with PBC and moderate-to-severe pruritus (WI-NRS ≥ 4). PROs included: WI-NRS; Sleep Interference NRS (SI-NRS); Patient Global Impression of Severity (PGI-S) and Change (PGI-C); PBC-40. Sleep responders were pts with a ≥ 2.5-point improvement in SI-NRS. **Results:** Cochran-Mantel-Haenszel (CMH) analysis confirmed a significantly higher proportion of itch responders with linerixibat vs placebo for the 3-point reduction in WI-NRS ($p = 0.035$) at Week 2. A higher proportion of pts on linerixibat vs placebo achieved mild/no itch (WI-NRS < 4) across all 24 weeks (Figure A). A higher proportion of pts reported their itch as "very much improved" (PGI-C) with linerixibat vs placebo (Figure B). CMH analysis confirmed a greater proportion of pts on linerixibat had change in itch that was meaningful (PGI-C item 2) compared with placebo across all visits (all $p < 0.02$). Despite not reaching a significant difference at Week 24 as a single timepoint, when itch-related QoL (PBC-40 Itch domain) was evaluated over the whole 24-week period using a mixed-effect model for repeated measures, linerixibat resulted in greater QoL improvement than placebo (least square mean difference [LSMD] −0.88, $p = 0.005$). Pts with moderate–severe sleep impairment (SI-NRS ≥ 4) at baseline experienced a significant improvement in SI-NRS and PBC-40 Sleep item score over 24 weeks with linerixibat vs placebo (SI-NRS: LSMD −0.76, $p = 0.006$; PBC-40 Sleep: LSMD −0.41, $p = 0.003$); there were consistently more sleep responders on linerixibat vs placebo across all weeks, including at Week 24 (72% [58/81] vs 57% [51/90]). **Conclusion:** Linerixibat treatment in pts with PBC and moderate–severe pruritus resulted in clinically meaningful reductions in itch severity, often to mild/no itch, as well as subjective global improvements in itch, improvements in itch-related QoL, and reduced itch-related sleep impairment.

Figure: Proportion of patients (A) achieving mild/no itch (WI-NRS weekly score <4) by week* and (B) reporting itch as "very much improved" based on PGI-C (PGI-C score=1)† by visit in GLISTEN

*The number of patients at Week 24 is lower than the other timepoints because of visit scheduling. WI-NRS measures worst itch on a 0–10 NRS: 0 to <4 = absent to mild; ≥4 to <7 = moderate; ≥7 = severe. The WI-NRS weekly itch score is the average of worst daily itch scores recorded over a 7-day period; †PGI-C response scale ranged from 1-very much improved to 7-very much worse.

BL, baseline; NRS, numerical rating scale; PGI-C, Patient Global Impression of Change; WI-NRS, Worst Itch Numerical Rating Scale.

1164 | SELADELPAR DOWNREGULATES INFLAMMATORY AND FIBROTIC PATHWAYS: INSIGHTS FROM SERUM PROTEOMIC ANALYSIS

Michael Trauner[1] Yan Liang[2] Peyvand Amini[2] Grant Budas[3] Valentina Shakhnovich[2] Kyung min Kwon[2] Daria Crittenden[3] Anna Zagorska[2], [1]Medical University of Vienna, Vienna, Austria, [2]Gilead Sciences, Inc., Foster City, CA, USA, [3]Gilead Sciences, Inc. Foster City, CA, USA

Background: Seladelpar, a first-in-class selective PPAR-δ agonist (delpar), is approved for second-line treatment of primary biliary cholangitis (PBC) and significantly improved cholestasis and pruritus in the pivotal Phase 3, placebo-controlled RESPONSE study (NCT04620733). In a recent serum proteomic analysis of RESPONSE samples, seladelpar led to reductions in known markers of cholestasis, inflammation, fibrosis, and pruritus, along with increases in serum levels of PPAR-δ targets involved in improving lipid metabolism. The aim of this analysis was to further characterize the top biological processes and pathways affected by seladelpar using an unbiased pathway analysis approach. **Methods:** In the RESPONSE study, 193 patients with PBC were randomized 2:1 to receive seladelpar 10 mg or placebo daily for 12 months. Serum proteomic profiles from 180 patients (862 samples) were measured using the SomaScan 11k Assay version 5.0, which quantifies 9,852 human proteins. Data normalization, calibration, and quality control processes were performed according to the manufacturer's instructions. Longitudinal changes in protein levels at Months 1, 3, 6, and 12 were analyzed using mixed-effects models that estimated placebo-adjusted changes from baseline at each post-baseline time point. Pathway analyses were then conducted for all seladelpar-treated patients and for seladelpar responders based on the magnitude of alkaline phosphatase (ALP) decline, using QIAGEN® Ingenuity Pathway Analysis (IPA®). Adjusted P-values and z-scores were used to infer pathway significance and directionality, respectively. **Results:** Pathway analysis of seladelpar-induced changes in serum proteomic profiles at Month 12 showed significant downregulation of pathways associated with fibrosis and inflammation (adjusted $P < .05$) and upregulation of pathways associated with PPAR agonism (adjusted $P < .05$). Seladelpar treatment downregulated >15 fibrosis-related proteins ($P < .05$) including ACVR1, ITGB1, ACTA2, WNT5A, WNT10A, and LTBP1. Seladelpar treatment also downregulated >20 inflammation-related proteins ($P < .05$) including CHIT1, LGALS3, MIF, HSPA5, RALB, BIRC2, and TRADD. The magnitude of observed reductions in inflammatory and pro-fibrotic pathways increased over time and were stronger in patients with greater ALP reduction. **Conclusion:** Unbiased serum proteomic analysis of 180 patient samples reflects the antifibrotic and anti-inflammatory actions of seladelpar in PBC. In addition to the well-established anticholestatic effects of seladelpar in RESPONSE, these data provide insights into the mechanistic underpinnings for the reduction in liver injury markers, and stabilization or improvement in liver stiffness, with seladelpar treatment.

1165 | THE UTILITY OF LIVER BIOPSY IN DIAGNOSING AUTOIMMUNE HEPATITIS

Previn Ganesan[1] Karimar Amador-Martinez[2] Kelly Hu[2] Aparna Goel[3], [1]Stanford University, [2]Stanford University School of Medicine, [3]Stanford University Medical Center

Background: Liver biopsy is recommended to establish the diagnosis of autoimmune hepatitis (AIH). Prior studies have questioned the necessity of histology in diagnosing AIH, especially when typical serologic biomarkers are present. We aimed to evaluate how frequently liver histology altered the probability of an AIH diagnosis as assessed by the simplified AIH (sAIH) score. **Methods:** We identified patients with autoimmune hepatitis (AIH) established with our hepatology group since 2020 using a research repository (STARR, Stanford University). Diagnosis date was defined by earliest use of AIH ICD-9/10 codes or mention of AIH in clinical notes. Serologies and pathology closest to diagnosis date were used. Histology descriptions were analyzed to identify AIH features (interface hepatitis, lymphoplasmacytic inflammation, and hepatic rosettes). A compatible histologic diagnosis of AIH was defined as presence of ≥ 1 and < 3 of these features or inclusion of AIH in the differential diagnosis. A typical histologic diagnosis required presence of 3 of these features. The sAIH score was calculated in two stages: first excluding histology, where a maximum score of 6 denoted probable AIH, and then including histology, where scores of ≥ 7, ≥ 6, and < 6 indicated definite, probable, and possible AIH, respectively. We compared patients whose diagnostic category changed with histology and those whose category remained unchanged. Patients without histology available within 90 days of diagnosis were excluded. Data extraction was done using R (*v.4.5.1, RStudio*) with AI-assisted coding tools (*Claude, Anthropic*) **Results:** There were 130 eligible patients included in the cohort (*Table 1*). Median age at AIH diagnosis was 56 (IQR 39-67) and 107 (82.3%) patients were female. Histology was typical of AIH in 4 (3.1%) patients and otherwise compatible. Excluding histology from the sAIH score, the diagnosis of AIH was probable for 1 patient and possible for 129 patients. Including histology, the diagnosis of AIH was probable or definite for 19 (14.6%) and possible for 111 (85.4%) patients. Of the patients whose probability of AIH increased with histology, 18 (100%) demonstrated ANA and/or ASMA positivity and IgG levels ≥ 1.1 times the upper limit of normal (ULN). In these 18 patients, IgG/ULN ratio was 1.59 (IQR 1.36-2.17) compared to 0.82 (IQR 0.21-1.23,) for those whose diagnostic category of AIH remained unchanged despite histology ($p < 0.001$, Mann-Whitney U). **Conclusion:** In this cohort of AIH patients, histology altered the diagnostic category of AIH in a minority of patients (14.6%), highlighting the limited additional value of liver biopsy in this setting. In certain clinical contexts, serologic parameters - specifically IgG/ULN > 1.1 with concurrent ANA/ASMA positivity - may be sufficient to diagnose AIH without histology. Biopsy may be best reserved for cases where diagnostic uncertainty remains after serologic evaluation.

Table 1. Clinical characteristics of AIH Patients (N = 130)

Characteristic	n (%) or Median [IQR]
Age, years	56 [38.5–66.5]
BMI	26.6 [23.1–30.1]

1166 | TRUE SERONEGATIVE AUTOIMMUNE HEPATITIS IS RARE: A SYSTEMATIC REVIEW AND META-ANALYSIS REVEALS A DIAGNOSTIC GAP DRIVEN BY INCOMPLETE AUTOANTIBODY TESTING

Keeranmayee Mishra[1] Chedis Joseph[2] Bireera Muzaffar[3] Mrudulla Alla[1] Apurba Mishra[4] Rakshana Ravichandran[1] Aditya Kohli[1] Ravi Patel[1] Ramy Mansour[1], [1]Trinity Health Oakland/Wayne State University, [2]Ross University, [3]University of Oklahoma, [4]Nootan Medical College,Gujarat,India

Background: Seronegative autoimmune hepatitis (snAIH) is reported in 7-35% of clinical cohorts, but prevalence estimates vary widely depending on the autoantibody panel used. No prior meta-analysis has, to our knowledge, quantified the pooled prevalence of apparent snAIH or examined how standardized second-line testing affects classification. We aimed to pool the prevalence of apparent snAIH across published cohorts and to assess the impact of comprehensive autoantibody re-evaluation on seronegative classification. **Methods:** A systematic review of PubMed (2000-2026) identified 22 studies on snAIH. Six cohorts (1,123 patients, 119 seronegative) provided verified raw data for quantitative synthesis. Proportions were pooled using a random intercept logistic regression model with maximum-likelihood estimation and logit transformation. Apparent snAIH was defined as negativity for standard autoantibodies (ANA and/or SMA, with or without LKM1). Statistical analyses were performed in R (meta package). An AI-based tool was used for literature screening assistance and manuscript drafting; all outputs were validated by the authors. **Results:** Apparent snAIH prevalence was 17% (95% CI: 10-28%), but confirmed snAIH after adequate testing was approximately 1%, suggesting that roughly 1 in 6 AIH patients may carry an incorrect seronegative label. Heterogeneity was substantial (I-squared = 91.3%). Pediatric cohorts showed higher apparent prevalence (28%, 95% CI: 20-37%) compared to adult cohorts (10%, 95% CI: 6-16%; p = 0.0003), though limited by small study numbers (k = 3 per group). Among the six pooled cohorts, anti-SLA/LP testing was documented in only 2 (33%). Across all 16 original cohort studies, anti-SLA/LP was documented in 25%, atypical pANCA in 13%, and anti-LC1 in none. In the largest multicenter study (Colapietro et al., 2026; 760 patients), 52 initially seronegative patients (6.8%) were re-evaluated; only 9 (1.18%) remained seronegative after accounting for incomplete serological workup. Given that delayed immunosuppression in AIH is associated with progression to cirrhosis and reduced survival, this diagnostic gap has direct clinical implications. **Conclusion:** Apparent seronegativity is common (approximately 17%), but confirmed seronegativity after comprehensive testing is rare (approximately 1%). The diagnostic gap is primarily driven by omission of anti-SLA/LP testing. Misclassification as seronegative may delay initiation of immunosuppression, risking progression to fibrosis and cirrhosis in patients with otherwise treatable disease. Untreated AIH carries 10-year survival as low as 27%, compared to over 90% with timely immunosuppression. These findings support the implementation of standardized reflexive second-line autoantibody panels before assigning a seronegative diagnosis, to avoid diagnostic delay and preventable disease progression.

1167 | ORAL VANCOMYCIN IS NOT ASSOCIATED WITH MEANINGFUL CHANGES IN LIVER-RELATED ENDPOINTS AMONG ADULTS WITH PRIMARY SCLEROSING CHOLANGITIS: A RANDOMIZED, PLACEBO-CONTROLLED TRIAL

Mitchell Clayton[1] John Eaton[1] Denise Harnois[2] Duke Butterfield[3] Nan Zhang[3] Sudhakar Venkatesh[1] Nicholas Nguyen[1] Andrea Gossard[1] Keith Lindor[4] Nicholas LaRusso[1] Elizabeth Carey[3], [1]Mayo Clinic Rochester, [2]Mayo Clinic Florida, [3]Mayo Clinic Arizona, [4]Arizona State University

Background: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease without approved medical therapies. We examined the efficacy and safety of oral vancomycin (OV) in those with PSC. **Methods:** In this multicenter, phase 3, 18-month,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

double-blind, placebo-controlled trial, we randomly assigned adults with large duct PSC and a serum alkaline phosphatase (SAP) greater than 1.5 times the upper limit of normal to placebo or oral vancomycin (OV) with dosages ranging from 125-375 mg four times daily pending biochemical response. The primary endpoint was normalization of SAP. **Results:** Of the 82 patients who underwent randomization, 73 individuals had at least one outcome assessment. Individuals who withdrew early were less likely to rate their baseline health as excellent or very good (23.4% vs 54.5%, $p < 0.01$) despite having similar PSC prognostic features to those who completed the study. Except for one subject, all participants receiving OV had their dosages increased at the month 6 and 12 time points. Increasing the OV dose did not impact SAP levels. SAP normalization rates were similar (5% placebo, 6.7% OV, $p = 1.00$) after 18 months. Rates of lowering SAP less than 1.5 times the ULN were identical in both groups by month 18 (20.0% placebo, 20.0% OV, $p = 1.00$). Those who received OV had greater reduction in SAP (+1.2% placebo, -21.9% OV, $p = 0.03$). Six months after stopping OV, there was not a significant change in SAP: 11.2% (95% confidence interval: -1.0% -34.3%). There were no differences in the changes in either the Mayo PSC risk score (-0.1 placebo, -0.1 OV, $p = 0.88$), liver stiffness values (+0.1 kPa placebo, -4.0 kPa OV, $p = 0.15$), and 5-D itch scale (-1.2 placebo, -2.0 OV, $p = 0.46$). Four participants developed at least one episode of ascending cholangitis (4.8% placebo, 5.0% OV, $p = 0.96$) and 2 subjects developed hepatic decompensation (ascites $n = 1$, variceal hemorrhage $n = 1$) (0% placebo, 5.0% OV, $p = 0.14$). One patient who received OV developed cholangiocarcinoma. The proportion of individuals with serious adverse events was similar between groups (placebo 16.7%, OV 12.5%, $p = 0.59$). Discoloration of the teeth and tongue was the most common side effect of OV (17.5%). **Conclusion:** OV was not associated with clinically significant reductions in markers of PSC disease severity. Impairments in quality of life that are independent of liver disease severity may influence patient retention in clinical trials.

1168 | INVOLVEMENT OF DECREASED PERIBILIARY PLEXUS AND PRIMARY CILIA OF BILIARY EPITHELIAL CELLS ASSOCIATED WITH CELLULAR SENESCENCE IN THE PATHOGENESIS OF PRIMARY BILIARY CHOLANGITIS

Motoko Sasaki[1] Yasunori Sato[2] Yasuni Nakanuma[3], [1]Kanazawa University, [2]Kanazawa University Graduate School of Medical Sciences, [3]Fukui Saiseikai Hospital

Background: We previously demonstrated that cellular senescence in bile duct lesions—namely chronic non-suppurative destructive cholangitis (CNSDC) and ductular reaction (DR)—may be involved in disease progression in primary biliary cholangitis (PBC). Damages of primary cilia of biliary epithelial cells (BECs) due to ischemia and DNA damage responses (DDR) are reportedly related to biliary epithelial senescence in transplantation-related cholangiopathy. We investigated an association of cellular senescence with the status of primary cilia and peribiliary vascular plexus (PBP) feeding bile ducts, and their clinicopathological significance in PBC. **Methods:** Subjects included liver biopsy and resected liver specimens from 125 patients with PBC (90 and 35 cases with early and advanced stages, respectively) and 115 control liver diseases, including primary sclerosing cholangitis (PSC). Immunohistochemical analyses were performed to evaluate the expression of senescence markers ($p16^{INK4a}$ and $p21^{WAF1/Cip1}$), senescence-associated secretory phenotypes (SASPs; CCL2 and Ifit3), a primary cilia marker alpha-tubulin, a DDR marker gamma-H2AX, PD-L1, and stimulator of interferon genes (STING) in BECs and CD34-positive PBP. An association of senescent BECs with the status of cilia, number of PBP and clinicopathological parameters were analyzed. **Results:** Expression levels of $p16^{INK4a}$ and $p21^{WAF1/Cip1}$, SASPs, gamma-H2AX, PD-L1, and STING were significantly increased in small bile ducts in PBC compared with control livers ($p < 0.01$). In ductular cells, expression of $p16^{INK4a}$ and $p21^{WAF1/Cip1}$ was significantly elevated in advanced-stage PBC, and increased $p16^{INK4a}$ expression correlated with inadequate response for UDCA ($p < 0.01$). PD-L1 expression was localized specifically to bile ducts involved in CNSDC lesions, suggesting heterogeneity among senescent BECs. Primary cilia were decreased in senescent BECs in small bile ducts involved in CNSDC in 75% of PBC and were significantly decreased in bile ductules in advanced stage of PBC, compared with normal liver ($p < 0.05$). Number of PBP was significantly decreased in small bile ducts in PBC, and the decrease was correlated with cholangitis activity and cellular senescence

($p < 0.01$). **Conclusion:** Decreased primary cilia and PBP in association with biliary epithelial senescence may play roles in the pathogenesis of PBC.

1169 | RENALASE IS A NOVEL CANDIDATE BIOMARKER OF HEPATIC INFLAMMATION AND DISEASE ACTIVITY IN AUTOIMMUNE HEPATITIS

Kanika Malani[1] Bonnie Chen[2] Scott Roberts[2] Swathi Krishnan[2] Marina Silveira[2] James Boyer[3] Xiaojia (Sasha) Guo[4] Gary Desir[4] David Assis[3], [1]Department of Medicine; Yale School of Medicine New Haven, CT, [2]Section of Digestive Diseases; Yale School of Medicine New Haven, CT, [3]Yale University, [4]Section of Nephrology; Yale School of Medicine New Haven, CT

Background: Autoimmune hepatitis (AIH) is a chronic immune-mediated liver disease, yet reliable immune-based biomarkers to guide treatment and prognosis are lacking. Renalase (RNLS), a kidney-secreted flavoprotein with immunomodulatory properties, has been implicated in autoimmune disease but has not been evaluated in AIH. We aimed to determine whether peripheral RNLS levels serve as a biomarker of hepatic inflammation and disease activity in AIH. **Methods:** Stored AIH samples were obtained from the Yale Liver Center Patient Biorepository. Free RNLS (F-RNLS) and acid-release RNLS (AR-RNLS) were measured using a validated ELISA. Clinical data (Table 1) were obtained through chart review. Spearman correlations and Mann-Whitney U tests, with Benjamini-Hochberg false discovery rate correction, assessed associations between each RNLS fraction and clinical variables. Among patients with serial RNLS measurements, within-person stability was assessed using Intraclass Correlation Coefficient (ICC). **Results:** The cohort comprised 40 unique patients with AIH (83 RNLS samples; 1–4 samples/patient). Mean age was 57 ± 16 years. 88% were women, 18% Hispanic/Latino, and 32% had cirrhosis (mean fibrosis stage 1.9 ± 1.4). At the time of RNLS collection, 64% were in biochemical remission. F-RNLS and AR-RNLS demonstrated distinct correlation profiles. F-RNLS was higher in biochemical remission than active disease ($r = -0.37$, FDR $p = 0.018$) and correlated positively with histologic grade of inflammation on biopsy ($\rho = +0.28$, FDR $p = 0.041$). AR-RNLS, which can bind to circulating IgG, correlated strongly with IgG ($\rho = +0.49$, FDR $p < 0.001$). Relapses within 6-12 months of RNLS collection were infrequent with no correlation between RNLS levels and AST, ALT, or IgG trends over this period. Among patients with serial RNLS measurements ($n = 24$, 67 samples), F-RNLS was temporally stable (ICC = 0.70) while AR-RNLS varied more (ICC = 0.19); within-patient changes in AR-RNLS over time correlated with changes in IgG ($\rho = +0.36$, $p = 0.023$, $n = 40$ pairs), while changes in F-RNLS did not correlate with any inflammatory marker. **Conclusion:** This is the first study to examine RNLS in AIH. F-RNLS and AR-RNLS reflect distinct biological processes. F-RNLS varies between patients according to degree of hepatic inflammation and disease control. However, within the same patient over time it remains stable and uncorrelated with inflammatory marker changes, consistent with a fixed patient-level process. AR-RNLS correlates with IgG-driven humoral immune activation, a relationship that holds dynamically within the same patients over time. Higher F-RNLS in biochemical remission despite tissue-level inflammation may suggest RNLS is sensitive to subclinical disease activity not reflected by standard labs. Immunohistochemical studies of RNLS in liver tissue are ongoing to address this question. Our findings support RNLS as a promising immune-based candidate biomarker in AIH.

Table 1. Associations Between Circulating Renalase Fractions and Clinical Variables in Autoimmune Hepatitis

Clinical Variable	Free RNLS FDR-adjusted p	Acid-Release RNLS FDR-adjusted p	Median (IQR) or n (%)
Labs (n=83 samples)			
Sodium	0.479	0.039*	139.0 (137.5–140.5)
Blood urea nitrogen	0.042*	0.494	14.0 (12.0–18.0)
Aspartate aminotransferase	0.041*	0.936	23.0 (19.5–41.0)
Hemoglobin	0.010*	0.161	13.5 (12.5–14.7)
Hematocrit	0.041*	0.175	40.4 (37.3–44.1)
Immunoglobulin G (IgG)	0.631	<0.001*	1247.0 (1119.5–1594.5)
Disease Activity & Severity (n=83 samples)			
Biochemical remission	0.018*	0.665	In remission: 53 (64%) Not in remission: 30 (36%)
Grade of inflammation on biopsy (n=70)	0.041*	0.270	2.5 (2.0–3.0)
Elastography CAP (n=18)	0.004*	0.980	242.0 (230.0–279.8)
Demographics (n=83 samples)			
Sex	0.005*	0.821	Women: 35 (88%) Men: 5 (12%)
Hispanic/Latino ethnicity	0.001*	0.667	Hispanic/Latino: 7 (18%)
Serial RNLS Measurements (n=24 patients, 67 samples)			
Intraclass correlation coefficient	0.70	0.19	—
Within-Patient Changes (n=40 consecutive sample pairs)			
Δ Acid-Release RNLS *vs* Δ IgG/ULN	—	0.023* (ρ=+0.36)	—

RNLS: Renalase. FDR: False Discovery Rate. IQR: Interquartile Range. CAP: Controlled Attenuation Parameter. Δ: Change in. ULN: Upper limit of normal.

1170 | SUSTAINED BIOCHEMICAL EFFICACY AND SAFETY OF SELADELPAR IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS, INCLUDING THOSE AT HIGH RISK FOR PROGRESSION, UP TO 5 YEARS OF TREATMENT FROM ASSURE

Kris Kowdley[1] Javier Ampuero Herrojo[2] Cynthia Levy[3] David Jones[4] Pietro Invernizzi[5] Xin Qi[6] Justin Smith[6] Kyung min Kwon[6] Alan Bonder[7], [1]Liver Institute Northwest, [2]Hospital Universitario Virgen del Rocío, Sevilla, Spain, [3]University of Miami, [4]Newcastle University, Newcastle, United Kingdom, [5]European Reference Network on Hepatological Diseases (ERN RARE-LIVER), Hamburg, Germany, [6]Gilead Sciences, Inc., Foster City, CA, United States, [7]Beth Israel Deaconess Medical Center, Boston, MA, United States

Background: Seladelpar (SEL), a first-in-class delpar (selective peroxisome proliferator-activator receptor delta [PPARδ] agonist), is approved as second-line treatment for primary biliary cholangitis (PBC) based on 1-year data in the pivotal RESPONSE study (NCT04620733). PBC is a chronic, slowly progressive disease requiring long-term therapy, making sustained efficacy and safety critical. Here, we report updated long-term efficacy and safety from the ASSURE (NCT03301506) study, including high-risk subgroups. **Methods:** ASSURE is an ongoing, open-label study of SEL 10 mg. Patients enrolled after the placebo-controlled RESPONSE trial or participation in prior SEL legacy trials. Data were pooled from SEL initiation (baseline [BL] defined as RESPONSE entry for patients randomized to SEL, and ASSURE entry for all others). Efficacy endpoints included alkaline phosphatase (ALP) percent change in ALP from BL through Month (M) 48, the latest timepoint with N > 100 patients. Clinically meaningful improvement (≥ 3-point reduction) in pruritus by numerical rating scale (NRS) was assessed in patients with moderate to severe pruritus (BL NRS ≥ 4). ALP percent change was also explored in subgroups considered to be at higher risk of progression, including those age ≤ 62 years and those with liver stiffness measurement (LSM) ≥ 10 kPa at BL. Patients with PBC clinical outcomes or who met liver safety criteria leading to SEL discontinuation were considered non-responders for all subsequent timepoints. Safety was assessed using all available data through M60 in this interim analysis (data cutoff: Jan 2026). **Results:** Among 337 patients, 242 received SEL for ≥ 3 years and 109 for ≥ 4 years, as of the data cutoff. SEL led to sustained ALP reductions, with > 30% achieving ALP NL across annual timepoints. At M48, mean ALP decreased by 45% (**Figure**). In patients with moderate to severe pruritus (N = 108), a sustained proportion achieved NRS change of −3.0 through M48 (55% [18/33]). Patients with age ≤ 62 years (N = 218) and LSM ≥ 10 kPa (N = 104) had higher ALP at baseline (298–308 vs 287 U/L overall) with higher rates of cirrhosis in the LSM ≥ 10 kPa subgroup (42%). SEL led to sustained ALP reductions at M48 (−46% in age ≤ 62; −32% in LSM ≥ 10 kPa). Safety analysis showed no treatment-related serious AEs reported through M60 of SEL exposure. **Conclusion:** Seladelpar led to sustained improvements in biochemical markers of cholestasis, including in high-risk patients, and pruritus reductions observed with long-term treatment. Seladelpar was well tolerated with a consistent safety profile and no new safety signals identified up to 5 years.

Figure. ALP Percent Change from Baseline in the Pooled Population Through 48 Months of Seladelpar Treatment

1171 | HEALTH-RELATED QUALITY OF LIFE AMONG PATIENTS WITH PBC BY RESPONSE STATUS: ANALYSIS OF A REAL-WORLD DATASET

Ira Jacobson[1] Robert Gish[2] Gideon Hirschfield[3] Marvin Rock[4] Chong Hoon Kim[5] Caroline Burk[5] Hayley Wallinger[6] William Johnson[6] Lena Amari[6] David Jones[7] Robert Wong[8], [1]NYU Langone Health, New York, NY, USA, [2]Hepatitis B Foundation, Doylestown, PA, USA, [3]UHN's Francis Family Liver Clinic and Toronto Centre for Liver Disease, Toronto, ON, Canada, [4]Gilead Sciences Inc., Foster City, CA, USA, [5]Gilead Sciences, Inc., Foster City, CA, USA, [6]Adelphi Real World, Bollington, United Kingdom, [7]Newcastle University, Newcastle Upon Tyne, United Kingdom, [8]Stanford University School of Medicine, Palo Alto, CA, USA

Background: Primary biliary cholangitis (PBC) is a chronic, progressive autoimmune disease that damages the liver and can negatively impact quality of life. A key marker of disease activity in PBC is elevated levels of alkaline phosphatase (ALP) which is associated with negative long-term outcomes. Second line (2L) therapies such as seladelpar and elafibranor work by reducing cholestasis measured by ALP and other markers. This abstract aims to compare health-related quality of life (HRQoL) outcomes between patients that have exhibited normalized ALP levels between diagnosis and most recent lab results compared with those that have not. **Methods:** Data were drawn from the Adelphi Real World PBC Disease Specific Programme, a cross-sectional survey, with retrospective data collection in France, Germany, Italy, Spain, United Kingdom and the United States between November 2024 and May 2026. Patients with PBC were invited to complete a questionnaire including the Work Productivity and Activity Index (WPAI), PBC-40, Itch-Numerical Rating Scale (NRS), 5D-Itch, and EuroQol Visual Analogue Scale (EQ-VAS). Patients were grouped into 'abnormal ALP' (ALP >1 × upper limit of normal (ULN = 116 U/L) at diagnosis and most recent) and 'normalized ALP' (ALP >1 × ULN at diagnosis and ≤1 × ULN most recently). Cohorts were compared using bivariate analyses. **Results:** Analysis included 268 patients; 195 with abnormal ALP and 73 with normalized ALP. Those with abnormal ALP reported higher scores across all WPAI domains including impairment while working (33% vs 15%; $P < .0001$) and activity impairment (40% vs 21%; $P < .0001$). Those with abnormal ALP reported lower EQ-VAS scores (64.4 vs 78.1; $P < .0001$). Those with abnormal ALP reported more severe itch via the itch NRS (3.5 vs 2.1; $P = .0003$) and worse HRQoL at PBC-40 itch (6.7 vs 4.3; $P < .0001$) and fatigue (28.2 vs 21.5; $P < .0001$). 5D-Itch indicated that those with abnormal ALP were impacted by itch more than normalized ALP patients; a higher proportion reported experiencing itch 6+ hours a day (44% vs 17%; $P = .0001$), affecting 6+ body parts (33% vs 21%; $P = .0277$). **Conclusion:** Patients with PBC who achieved ALP normalization reported significantly better HRQoL outcomes compared with those who didn't. These findings highlight the clinical importance of achieving ALP normalization and support the need to offer alternative or 2L therapies to those with elevated levels of ALP to improve disease control and reduce the overall burden of PBC.

Table. Patient-reported Outcomes Measures

1172 | PRIMARY BILIARY CHOLANGITIS AND PREGNANCY IN ONTARIO: A POPULATION-BASED EVALUATION OF MATERNAL, FETAL, AND LIVER-RELATED OUTCOMES

Kristel Leung[1] Manisha Jogendran[1] Wenbin Li[2] Maria Velez[3] Gail Wright[4] Jennifer Flemming[5] Gideon Hirschfield[6], [1]Queen's University, [2]ICES Queen's, [3]McGill University, [4]PBC Society, [5]Queen's University Cancer Research Institute, [6]Toronto General Hospital

Background: Primary biliary cholangitis (PBC) is a rare autoimmune liver disease predominantly affecting women, with most diagnosed after childbearing years. Despite being the most common autoimmune liver disease, no comparative population-level studies have evaluated how PBC relates to preceding (if age >50 at diagnosis) or subsequent (if age <50 at diagnosis) pregnancy, infertility, or obstetrical complications. **Methods:** Using population-level health administrative databases in Ontario, Canada with linked mother-baby data for deliveries >20 weeks' gestation, we characterized reproductive health patterns and complications in a validated incident cohort of PBC women. For obstetrical complications, comparisons were made to inverse probability weighted general population controls, including composites of severe maternal morbidity (SMM), severe neonatal morbidity (SNM), and multiple secondary outcomes. Liver-related outcomes (liver decompensation, transplant, death) within 1y were assessed if PBC was diagnosed before childbirth. **Results:** Amongst 3,264 women with PBC incident diagnosis from 2002 to 2021, 1,013 (31%) were diagnosed before age 50 (median 44y), while 2,251 (69%) were diagnosed after age 50 (median 61y). Overall, 1,090 women (33%) had at least one pregnancy recorded during the same timeframe, with overall pregnancy incidence of 45.7 per 1000 person-years (95%CI 43.7-47.7). There were 1,069 pregnancies that occurred before PBC diagnosis, with a median time of 17y postpartum to diagnosis (IQR 11-23); 45 pregnancies occurred amongst women already diagnosed with PBC before conception (median time 1y, IQR 1-2). Only 35 women had an estimated conception date within 9 months of PBC diagnosis (21 before, 14 after). Out of all women with a PBC diagnosis, 13% had 1+ infertility healthcare encounter.Women with PBC who had a pregnancy before age 50 (n = 638) experienced more than double the risk of SMM compared to general population controls (adjusted incidence rate ratio [IRR] 2.18, 95%CI 1.32-3.60; p = 0.002). Puerperal sepsis and maternal ICU admission were the most common SMM events among PBC women. There were no significant differences in SNM (IRR 0.86, 95%CI 0.55-1.35; p = 0.51). There were higher proportions of cholestasis of pregnancy, antepartum hemorrhage, hypertensive disorders of pregnancy, neonatal jaundice, and preterm birth compared to the general population (all p < 0.05, Table 1). There were no differences in labour induction, C-section, or forceps-/vacuum-assisted delivery. None of the patients with PBC diagnosed before pregnancy experienced postpartum liver-related complications within 1y of delivery. **Conclusion:** In this epidemiological study, adverse obstetrical outcomes were linked to PBC diagnosis, despite most pregnancies pre-dating PBC diagnosis by several years. These findings suggest that women suspected of having PBC should be evaluated for prior adverse obstetrical history.

Table 1. Population-Level Outcomes for Pregnancies Among Women Who Develop PBC in Their Lifetime, Compared to Inverse Probability Weighted General Population Controls in Ontario, Canada

Variable	PBC Childbirths	Control Childbirths	p-value
C section	216 (34%)	799 (31%)	0.12
Forceps-/vacuum-assisted birth	56 (8.6%)	240 (9.2%)	0.73
Induction of labour	150 (23.5%)	654 (25.1%)	0.40
Postpartum hemorrhage	39 (6.1%)	176 (6.8%)	0.56
Antepartum hemorrhage	66 (10.3%)	199 (7.6%)	0.026*

1173 | PATIENT REPORTED PRURITUS WITH HORMONAL CONTRACEPTION USE IN PATIENTS WITH A HISTORY OF INTRAHEPATIC CHOLESTASIS OF PREGNANCY

Laura Bonebrake[1] Cecilia Duenas[2] Gerry Nesbitt[3], [1]SSM Health/St. Louis University, [2]PBC Research Foundation, [3]PBC Ireland

Background: Intrahepatic Cholestasis of Pregnancy (ICP) is a rare, pregnancy liver disorder where bile acid transport is disrupted. The cause is thought to be multifactoral with both hormones and a genetic predisposition contributing. Some ICP patients report continued pruritus postpartum, including with the use of hormonal birth control but incidence has not been published. We aim to assess the incidence of patient-reported pruritus with the use of hormonal contraception after a pregnancy with ICP. **Methods:** Data was obtained from an IRB approved, ICP Patient Registry, in collaboration with a patient advocacy group, ICP Care.Participants with a history of ICP self-reported pregnancy and postpartum data. The key outcome measure was recurrence of pruritus with use of a variety of hormonal contraception types.Patients were also stratified by timing of their ICP diagnosis, including early-onset ICP (less than 28 weeks gestation) and late-onset ICP ($\geq$28 weeks).Due to ICP being a rare disorder in only 0.2-0.5% of pregnancies, we are aware that statistical significance may not be met. **Results:** A total of 102 patients had taken a combination oral contraceptive pill (OCP) containing both estrogen and progesterone. Of these, 23.5% of these patients had pruritus.Further analysis showed that if a patient had intolerance to a combination OCP, they had a 45-53% chance of also reacting to use of a progesterone only birth control method.Pruritus with progesterone only contraceptive methods was then reported. Patients had recurrent pruritus in 18.6% of cases with the progesterone pill and 22.2% of cases with a progestin IUD.In looking at diagnosis timing of ICP, patients with early-onset ICP had recurrent pruritus in 38.2% of patients using combination OCPs while late-onset ICP patients only had a 17% chance of pruritus. Odds Ratio was noted to be 1.34 but not significant (p = 0.37) most likely due to small sample size. **Conclusion:** This data is the first to show the proportion of patients with a history of ICP who experience recurrent pruritus with hormonal contraception. One in four ICP patients exhibit pruritus with an oral contraceptive with both estrogen and progesterone. Fewer patients had pruritus with progesterone only methods, but 1 in 5 patients still had a reaction.Patients with early onset ICP appeared more sensitive to hormone use and more likely to report recurrent pruritus, suggesting a genetic predisposition and possible sub-groups.Further studies are needed to determine predictors of pruritus with hormonal contraception, risks of long-term use of hormones in ICP patients and liver surveillance plans after pregnancy, especially with hormonal use.

Birth Control Method	Pruritus	No Pruritus
Combination Estrogen/Progesterone pill (N=102)	24 (23.5%)	78
Progesterone only pill (N=43)	8 (18.6%)	35
"Mirena" IUD (N=36)	8 (22.2%)	28

1174 | CYP2E1 DEFICIENCY DRIVES SPONTANEOUS FEMALE-BIASED CHOLANGIOPATHY WITH FEATURES OF PRIMARY BILIARY CHOLANGITIS

Kristina Stayer[1] Zaria KIllingsworth[1] Kylie Driggers[1] Hyland Gonzalez[1] Alexandra Tomasevich[1] Melinda Engevik[1] Jessica Hartman[1], [1]Medical University of SC

Background: Cytochrome P450 2E1, or CYP2E1, is a mammalian monooxygenase that is expressed at high levels in the liver. While CYP2E1 is well-studied for its role in toxicity of xenobiotic compounds such as benzene or acetaminophen, its role in endogenous metabolism remains incompletely understood. Notably, genetic variation in CYP2E1 regulatory regions has been associated with disease severity in patients with Primary Biliary Cholangitis (PBC), and hepatic CYP2E1 expression is reduced in PBC compared to healthy controls. PBC is a chronic cholestatic autoimmune liver disease that predominantly affects middle-aged women, with female-to-male ratios approaching 9:1. Consistent with these clinical observations, we previously identified spontaneous biliary abnormalities in female Cyp2e1 knockout (KO) mice that resemble features of PBC and are detectable as early as 14 weeks of age. In this study, we evaluated liver pathology in 6-month-old female KO mice using established histopathologic criteria modeled after the Paris classification system used for human PBC.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Methods: Female WT and Cyp2e1 KO (KO) mice aged 6-7 months were evaluated. Consistent with our previous observations in young mice, approximately 50% of KO females exhibited hepatic pathology in hematoxylin and eosin stained liver slides. Therefore, mice were stratified post-hoc into pathology-positive and pathology-negative groups based on histology. Serum biochemistry was assessed, serum autoreactivity against isolated mitochondrial and nuclear protein fractions was evaluated by Simple Western analysis. Liver pathology was scored by an expert veterinary pathologist using criteria adapted from the Paris classification system for PBC. **Results:** Despite severe liver pathology present in 50% of KO animals, serum biochemistry parameters were not significantly different between WT and KO mice regardless of pathology. In contrast, pathology-positive KO mice exhibited significantly increased serum immunoreactivity toward both mitochondrial and nuclear protein fractions compared with WT and pathology-negative KO animals, consistent with increased autoreactive antibody responses. **Conclusion:** Female Cyp2e1 KO mice develop spontaneous and age-associated liver pathology that is more severe than that observed in male KO animals and is associated with increased serum autoreactivity toward mitochondrial and nuclear antigens. These findings support a previously unrecognized role for CYP2E1 in maintaining liver homeostasis and suggest that loss of CYP2E1 may promote sex-dependent autoimmune or cholangiopathic liver injury. Given the large number of dietary constituents and pharmaceuticals reported to inhibit CYP2E1 activity, reduced CYP2E1 function may represent a previously unappreciated susceptibility factor in females. Ongoing studies are investigating the underlying mechanisms and the translational relevance of this phenotype across species.

1175 | A 90-DAY POSTPARTUM ALP CUTOFF IDENTIFIES WOMEN WITH PSC AT RISK FOR DISEASE PROGRESSION AFTER PREGNANCY

Katherine Cooper[1] Daniel Pratt[1], [1]Massachusetts General Hospital, Harvard Medical School

Background: Immune-mediated diseases may flare after pregnancy, though data in primary sclerosing cholangitis (PSC) are limited. We previously reported that increased alkaline phosphatase (ALP) following pregnancy may predict changes in magnetic resonance cholangiopancreatography (MRCP). We now aimed to identify clinically meaningful postpartum ALP thresholds associated with MRCP progression after pregnancy. **Methods:** Women with pregnancy after PSC diagnosis were identified from a longitudinal registry at Massachusetts General Hospital. The primary outcome was progression, defined as interval change on MRCP after delivery compared with pre-pregnancy. Pre-pregnancy ALP (Pre-ALP) and post-pregnancy ALP (post-ALP) were defined for each patient using the mean ALP level during the 12 months before conception and 12 months after delivery, respectively. Overall ΔALP was calculated as the relative change between pre- and post-pregnancy ALP. Additional ΔALP measures were calculated using the closest ALP level at 90 and 180 days postpartum. Group differences were compared using Wilcoxon rank-sum tests. Firth logistic regression was used to evaluate the association between ΔALP and progression. Receiver operating characteristic (ROC) curves were used to evaluate discrimination of ALP markers and identify optimal ΔALP thresholds at 90 and 180 days. Longitudinal ALP burden over the first 6 months postpartum was calculated using trapezoidal area-under-the-curve methods based on baseline-normalized ALP. **Results:** Among 28 pregnancies, 28.7% (n = 8) experienced MRCP progression. Pre- ALP was similar between groups (143 vs 125 U/L, p = 0.647), whereas post-ALP (339 vs 136 U/L, p = 0.022) and Overall ΔALP were higher among progressors (118.8% vs 39.5%, p = 0.0015). Each 10% increase in ΔALP was associated with 1.22-fold higher odds of progression (95% CI 1.04–1.52; p = 0.006), persisting after adjustment for pre-ALP and age at delivery (aOR 1.20, 95% CI 1.03–1.54; p = 0.009). Discrimination was strong for 90-day ΔALP and 180-day ΔALP, with AUCs of 0.88 and 0.77, respectively. The optimal 90-day ΔALP threshold was 83.8% (100% sensitivity, 80% specificity) and the optimal 180-day threshold was 58.1%. (87.5% sensitivity, 75% specificity). During the first 6 months postpartum, mean relative ALP burden was higher among progressors, corresponding to 2.4-fold versus 1.4-fold elevation above pre-pregnancy baseline (p = 0.006, Figure 1b). **Conclusion:** Women with PSC who experience MRCP progression after pregnancy demonstrate greater and more persistent postpartum ALP elevation. Incomplete biochemical recovery after delivery may serve as an early marker of postpartum PSC activity, with 90- and 180-day ΔALP thresholds demonstrating strong discrimination for imaging progression, though larger studies are needed to validate these findings.

1176 | SUBSEQUENT PPAR AGONIST THERAPY AFTER FENOFIBRATE FAILURE OR INTOLERANCE IN PRIMARY BILIARY CHOLANGITIS (PBC): A REAL-WORLD CASE SERIES

Vivian Rotman[1] Mariko Maxwell[2] Yanhong Deng[2] Bonnie Chen[2] Marina Silveira[2] James Boyer[2] David Assis[2], [1]1.Yale University and 2. Federal University of Rio de Janeiro, [2]Yale University

Background: Approximately 40% of patients with PBC treated with ursodeoxycholic acid (UDCA) require add-on therapy to achieve adequate biochemical response. Peroxisome proliferator-activated receptor (PPAR) agonists have become a central therapeutic option in this setting. While seladelpar and elafibranor demonstrated efficacy in phase III trials, fibrates, including fenofibrate and bezafibrate, remain a widely used off-label alternative. However, data regarding subsequent PPAR agonist use, after fibrate failure or intolerance, are scarce. We describe a real-world experience with second-line PPAR agonists in PBC patients with inadequate response or intolerance to UDCA plus fenofibrate. **Methods:** Retrospective case series of PBC patients, at a tertiary referral center, who discontinued second-line fenofibrate due to intolerance or inadequate biochemical response, followed by elafibranor or seladelpar treatment. PBC diagnosis was established according to AASLD criteria. **Results:** A total of 59 PBC patients were treated with fenofibrate associated with UDCA (40 non-responders based on Paris II criteria; 33 based on POISE criteria). The cohort was predominantly female (86.4%) and white, with median age below 50 years at both diagnosis and fenofibrate initiation. Mean liver stiffness (LS) before fenofibrate initiation was 9.2 ± 3.5 kPa.Fenofibrate was discontinued in 6 patients (10% of the cohort) after a median of 3 months (M), due to intolerance (n = 5) or inadequate response (n = 1). Median age at the time of receiving a second PPAR agonist was 65.5 y. Two patients had compensated cirrhosis. Median LS in non-cirrhotics was 7.15 kPa. Obeticholic acid was previously used in 3 and discontinued due to inadequate response or severe pruritus.Seladelpar was initiated in 5 patients and elafibranor in 1, with a median treatment duration of 5.5 M. Baseline median ALP was1.8 x ULN. Five of the 6 achieved normalization of ALP at a median of 6 M. One developed nephrotoxicity during seladelpar therapy. Three reported stable pruritus and fatigue, two experienced symptomatic improvement (one in pruritus and one in fatigue) and one reported worsening of fatigue. **Conclusion:** Sequential second-line PPAR agonist therapy is a feasible and successful therapeutic strategy for select PBC patients with intolerance or inadequate biochemical response to fenofibrate. Further prospective studies to determine optimal sequential treatment strategies with PPAR agonists in PBC are indicated.

1177 | ASPIRIN USE DURING PREGNANCY IS ASSOCIATED WITH FEWER LIVER-RELATED COMPLICATIONS IN PREGNANT WOMEN WITH PRIMARY SCLEROSING CHOLANGITIS

Katherine Cooper[1] Victoria Abadi-Ron[2] Natalia Rojas Amaris[2] Libby Bell[3] Fernando Munguia[2] Ana Marenco-Flores[2] Vilas Patwardhan[2] Alan Bonder[2] Daniel Pratt[1], [1]Massachusetts General Hospital, Harvard Medical School, [2]Beth Israel Deaconess Medical Center, [3]Indiana University

Background: Aspirin use is indicated for obstetric risk reduction in high risk patients, including those with liver disease and inflammatory bowel disease (IBD). Whether aspirin use influences pregnancy outcomes and postpartum liver-related outcomes in women with primary sclerosing cholangitis (PSC) is not known. **Methods:** We performed a multicentral cohort analysis of pregnancies following PSC diagnosis from two longitudinal PSC registries at Massachusetts General Hospital and Beth Israel Deaconess Medical Center. Patients were categorized by aspirin exposure during pregnancy. Primary liver outcomes included liver complication after delivery (e.g., jaundice, obstruction,

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

need for a procedure) and intrahepatic cholestasis of pregnancy (ICP), peak bile acid level, change in alkaline phosphatase (ALP) at six months postpartum relative to pre-pregnancy. Among those with longitudinal imaging data, change in magnetic resonance cholangiopancreatography (MRCP) from pre to post pregnancy also assessed. Pregnancy outcomes included pre-eclampsia, fetal distress, postpartum hemorrhage (PPH), emergent cesarean section, and preterm birth. Unadjusted rates were compared using Fisher's exact test and continuous variables using Wilcoxon rank-sum test. To account for confounding, stabilized inverse probability of treatment weighting (IPTW) was performed using age at PSC diagnosis, IBD status, pre-pregnancy ALP, and ursodiol use. Firth's penalized logistic regression with stabilized weights was applied to all adjusted outcome models and reported as adjusted odds ratios (aOR). **Results:** Among 31 pregnancies, 10 were aspirin-exposed. There were no statistically significant differences in preterm birth (20% vs. 29%), pre-eclampsia (0% vs. 10%), PPH (10% vs. 5%), or emergent cesarean section (20% vs. 0%) in aspirin-exposed compared to unexposed, though birth weight was higher in aspirin-exposed (median 3.4 kg vs. 2.8 kg, p = 0.02). Peak bile acid levels during pregnancy (median 4.5 vs. 21.6 µmol/L, p = 0.04) and relative rise in ALP levels (median 20% vs. 56%, p = 0.040) were significantly lower in aspirin-exposed. There were also fewer cases of postpartum liver complications (0% vs. 23%) and MRCP progression (10% vs. 33%) in the aspirin group as well. In IPTW models, there were trends toward decreased liver complications (aOR 0.16, 95% CI 0.00-1.68, p = 0.14) and MRCP progression (aOR 0.22, 95% CI 0.01-1.50, p = 0.13) while the relative change in ALP at 6 months remained significant lower in the aspirin-exposed group (21% vs. 55%, p = 0.049). **Conclusion:** In this exploratory mutlicenter cohort, aspirin use during pregnancy was associated with more favorable liver outcomes but did not significantly impact pregnancy related outcomes. With small sample size, these may be considered as hypothesis-generating findings to support prospective evaluation of aspirin in pregnant women with PSC.

Outcome	Unadjusted Comparisons			IPTW Comparisons

1178 | GLP-1 RECEPTOR AGONISTS ARE ASSOCIATED WITH REDUCED POST-ERCP SEPSIS COMPARED WITH SGLT-2 INHIBITORS: A PROPENSITY-MATCHED RETROSPECTIVE REAL-WORLD ANALYSIS

Emeka Stanley Obi[1] Danielle Luskind[1] Adedeji Adenusi[2] Chimezirim Ezeano[3] Gedion Amdetsion[4] Abdulrahman Atasi[1] Javed Jagroo[1] Olachi Egbo[5] Joshua Kalu[6] Chidiebele Omaliko[1] Olanrewaju Adeniran[7], [1]Brookdale University Hospital and Medical Center, [2]Interfaith Medical Center, [3]Advocate Aurora Healthcare, [4]John H Stroger Hospital of Cook County, [5]NYCHHC/Harlem Hospital, NY, [6]Suny Downstate Medical Center, [7]West Virginia University, Morgantown

Background: Sepsis is among the most feared complications of endoscopic retrograde cholangiopancreatography (ERCP), mostly indicated for malignant biliary strictures and choledocholithiasis. Sepsis arises from instrumentation of an often obstructed, infected biliary tree. GLP-1 receptor agonists (GLP-1RA) and SGLT-2 inhibitors (SGLT-2i) are groundbreaking glucose-lowering agents with benefits beyond glycemic control, and both carry anti-inflammatory properties—GLP-1RA attenuate pro-inflammatory cytokines, while SGLT-2i suppress the NLRP3 inflammasome and lower IL-6 and CRP. Despite this shared mechanistic plausibility, no study to date has compared their independent post-ERCP safety profiles. **Methods:** Using the TriNetX US Collaborative Network, we identified adults (≥ 18 years) undergoing ERCP with antecedent exposure to either a GLP-1RA (n = 3,293) or an SGLT-2i (n = 4,056), with mutually exclusive drug classes. The index event was the patient's first ERCP procedure; outcomes were assessed over the window beginning 1 to 365 days after the index event. Cohorts underwent 1:1 propensity-score matching on 18 covariates spanning demographics (age at index, sex, race, ethnicity) and cardiometabolic comorbidities. Matching yielded 2,195 well-balanced pairs (all standardized differences < 0.1). The primary outcome was incident sepsis, with 9 secondary outcomes, evaluated by risk ratios (RR) and Kaplan–Meier survival **Results:** GLP-1RA exposure was associated with a **significantly lower risk of post-ERCP sepsis**, occurring in **11.4% versus 14.1% of SGLT-2i patients** (absolute risk reduction 2.8%; SGLT-2i RR 1.24, 95% CI 1.04–1.49; p = 0.016). Survival analysis reinforced this protective

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

signal: **365-day sepsis-free survival was higher with GLP-1RA (86.5% vs 83.4%; log-rank p = 0.013; HR 1.27, 95% CI 1.05–1.53)**, with an approximate number-needed-to-treat of 37. Among secondary outcomes, SGLT-2i was also associated with significantly higher euglycemic diabetic ketoacidosis (RR 2.59, 95% CI 1.33–5.03; p = 0.003). No significant differences emerged for GI bleeding (RR 1.31; p = 0.075), acute pancreatitis, cholangitis, all-cause mortality, hospital readmission, aspiration pneumonia, or choledocholithiasis. **Conclusion:** Among diabetic patients undergoing ERCP, antecedent GLP-1RA therapy was associated with a **clinically meaningful reduction in post-procedural sepsis** relative to SGLT-2i, despite both classes' recognized anti-inflammatory effects. GLP-1RA suppress sepsis-driven TNF-α via central neuronal GLP-1R signaling, expand regulatory T cells, and fortify the gut barrier through microbiome-mediated butyrate production—while avoiding the glycosuria-related infection risk and osmotic volume depletion seen with SGLT-2i. GLP-1RA may represent a preferable glucose-lowering strategy in patients anticipating biliary intervention. Further prospective studies needed to validate these findings.

1179 | FIBRATE THERAPY FOR PRIMARY SCLEROSING CHOLANGITIS: SYSTEMATIC REVIEW AND META-ANALYSIS

Gabriel Silva[1] Priscille Jones[2] Bhavya Yarlagadda[3] Carlos Marin[4] Omar Kasimieh[5] Valentina Saracino[6] Glaucia De Souza[7] Ana-Alicia Velarde-Pineda[8] Suellen Da Silva[9] Gabriele De Geroni[10], [1]University of Pernambuco, [2]Universidade de Pernambuco, [3]MUSC Kershaw Medical Center, [4]University of Kansas Medical Center (KUMC), [5]University of the East Ramon Magsaysay Memorial Medical Cent, [6]Cape Fear Valley Medical Center/UNC Health Southeastern, [7]Escola Superior de Ciências da Saúde do Distrito Federal, [8]University Center for Health Sciences (CUCS), [9]National University of Ecology, Santa Cruz de La Sierra, [10]Federal University of Rio Grande do Sul

Background: Primary sclerosing cholangitis (PSC) is a progressive hepatobiliary disease whose pathophysiology relies on fibrotic damage to the bile ducts, leading to cholestasis, which subsequently perpetuates and potentiates sclerosis. Fibrates can alter bile composition, decreasing bile toxicity and potentially reducing cholestasis-driven injury. As they do not act on the core fibrosing process of the disease, it remains uncertain whether they can function as disease-modifying drugs. This study aims to assess the safety and efficacy of fibrates for PSC. **Methods:** A systematic review was conducted to identify randomized controlled trials (RCTs) and observational studies assessing fibrate therapy in patients with PSC. PubMed, Embase, and Cochrane were used as databases. We performed a meta-analysis evaluating changes in laboratory parameters from baseline to the last available follow-up assessment. The primary outcome was the reduction in alkaline phosphatase (ALP) levels. Secondary outcomes included changes in aspartate aminotransferase (AST), alanine aminotransferase (ALT), gamma-glutamyl transferase (GGT), and total bilirubin (TB) levels. All statistical analyses were conducted using R software (version 4.6.0). **Results:** A total of five studies met the inclusion criteria, comprising 85 patients included in the meta-analysis. ALP, GGT, and ALT levels demonstrated statistically significant reductions (ALP: −177.91 [95% confidence interval (CI) −237.69 to −118.12]; GGT: −127.04 [95% CI −163.35 to −90.72]; ALT: −29.82 [95% CI −41.42 to −18.21]). In contrast, reductions in AST and TB did not demonstrate statistically significant improvement (AST: −8.95 [95% CI −19.46 to 1.55]; TB: −0.09 [95% CI −0.27 to 0.09]). **Conclusion:** This is the first meta-analysis to date evaluating the impact of fibrates on liver and cholestatic enzymes in patients with PSC. Reductions in ALP, GGT, and ALT reinforce the potential benefit of fibrates in attenuating cholestatic injury. In contrast, the lack of statistically significant improvement in AST and TB limits conclusions regarding the ability of these agents to mitigate disease progression or substantially improve liver function. Larger RCTs are warranted to determine whether these biochemical improvements translate into clinically meaningful outcomes, including transplant-free survival and quality of life.

1180 | SELADELPAR EFFECTIVENESS A SECOND-LINE THERAPY ACROSS PRIOR TREATMENT COHORTS IN PRIMARY BILIARY CHOLANGITIS: A REAL-WORLD STUDY

Adrielly Martins[1] Cynthia Levy[2], [1]Schiff Center for Liver Diseases, University of Miami Miller School of Medicine, [2]Division of Digestive and Liver Diseases, University of Miami Miller School of Medicine

Background: Seladelpar, a PPAR-δ agonist, was recently approved as second-line therapy for primary biliary cholangitis (PBC) in patients with inadequate response or intolerance to ursodeoxycholic acid. Many patients reaching seladelpar have prior exposure to obeticholic acid (OCA), the earlier second-line agent, yet real-world effectiveness of seladelpar in OCA-experienced patients is not well characterized. We evaluated the real-world effectiveness of seladelpar across OCA-experienced and OCA-naïve patients in Epic Cosmos. **Methods:** In this retrospective cohort study using Epic Cosmos, we identified adults with PBC who initiated seladelpar following its August 2024 approval, with the index date defined as the first seladelpar dispense. Patients were classified by prior therapy as OCA-experience, OCA-naïve or triple therapy. The primary outcome was POISE biochemical response (alkaline phosphatase [ALP] $<1.67\times$ULN, total bilirubin [TB] $\leq 1.0\times$ULN, and $\geq 15\%$ reduction in ALP from baseline) at 3, 6, and 12 months, assessed among patients with baseline ALP $\geq 1.67\times$ULN; secondary endpoints included ALP normalization and bilirubin response. Response proportions were estimated with Wilson 95% confidence intervals, and OCA-experienced and OCA-naïve cohorts were compared using Fisher's exact test in exploratory analyses. **Results:** Among 851 seladelpar-treated patients (432 OCA-naïve, 374 OCA-experienced, 45 triple therapy), median age was 64 years, 90% were female, and approximately 40% had cirrhosis. Baseline median ALP was 193-199 U/L (1.6-1.7xULN) and TB 0.5-0.6 md/dL (0.5xULN) across cohorts. POISE response in OCA-experienced patients rose from 44.2% at 3 months to 54.5% (95% CI 40.1–68.3) at 6 months and 60.9% (40.8–77.8) at 12 months (Figure). OCA-experienced response exceeded OCA-naïve at 6 and 12 months (+13.0 and +14.2 percentage points), a directionally consistent but non-significant difference (Fisher's $p=0.24$ and 0.41). Approximately 70% of patients across cohorts achieved $\geq 15\%$ ALP reduction at all timepoints. Among cirrhotic patients, POISE response was numerically higher in OCA-experienced patients (45.8% vs 37.1%), and biochemical responses remained stable ($\geq 15\%$ ALP reduction 73.5% vs 63.9%; bilirubin $\leq 0.6\times$ULN 70.2% vs 61.1%). **Conclusion:** In this real-world cohort, seladelpar produced clinically meaningful biochemical responses in OCA-experienced patients with PBC, with POISE response rates comparable to OCA-naïve patients and durable through 12 months. Biochemical activity was preserved across cohorts and in patients with cirrhosis. These findings support seladelpar as an effective second-line option in patients previously treated with OCA, including populations underrepresented in clinical trials.

1181 | VEDOLIZUMAB OR USTEKINUMAB AND BILIARY DISEASE OUTCOMES IN PSC-IBD OVERLAP: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Mahmoud Al-Bataineh[1] Jashnaveer Singh Johal[1] Om Patel[1] Abdallah Hussein[1] Yecheskel Schneider[1] Jason Hyman[2], [1]Virtua Health, [2]Virtua

Background: Primary sclerosing cholangitis has no proven pharmacotherapy, yet vedolizumab and ustekinumab are increasingly prescribed off-label in patients with PSC-IBD overlap, vedolizumab via gut-selective α4β7 integrin blockade disrupting hepatic homing of gut-activated lymphocytes, and ustekinumab via IL-12/23 inhibition reducing Th1/Th17-mediated biliary inflammation. Real-world data on biliary disease progression, cholangitis episodes,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and transplant outcomes with these agents are essentially absent. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised adults with both PSC (K83.01) and IBD (K50 or K51) who received vedolizumab or ustekinumab within one year of diagnosis. Cohort 2 comprised PSC-IBD patients receiving conventional IBD therapy (infliximab, mesalamine, or azathioprine) without vedolizumab or ustekinumab. Both cohorts excluded prior HCC, liver transplant, and other cholangitis. Cohorts were balanced via 1:1 PSM yielding 494 patients per arm over a 6–120 month follow-up window. Pre-specified outcomes included ALP normalization as a biochemical biliary response surrogate, acute cholangitis episodes, incident cirrhosis, cholangiocarcinoma, need for ERCP, liver transplant listing, and all-cause mortality. **Results:** Post-PSM cohorts were balanced across matched covariates. ALP normalization rates were equivalent between arms (24.3% vs. 23.3%; HR 0.99, 95% CI 0.70–1.40; p = 0.97). Acute cholangitis episodes did not differ significantly on time-to-event analysis (HR 1.18, 95% CI 0.80–1.75; p = 0.40). Incident cirrhosis was numerically lower in the vedolizumab/ustekinumab arm but did not reach significance (6.0% vs. 7.2%; HR 0.85, 95% CI 0.50–1.44; p = 0.55). Cholangiocarcinoma rates were equivalent (2.4% vs. 2.7%; HR 0.90, 95% CI 0.41–1.98; p = 0.80). Need for ERCP was significantly lower in the vedolizumab/ustekinumab arm on both MOA (6.5% vs. 10.3%; RR 0.63; p = 0.029) and KM analysis (HR 0.60, 95% CI 0.39–0.93; p = 0.022). All-cause mortality was significantly lower in the vedolizumab/ustekinumab arm on both analyses (3.6% vs. 7.9%; RR 0.46; HR 0.45, 95% CI 0.25–0.78; p = 0.004), with proportionality holding (p = 0.33). **Conclusion:** In this propensity-matched real-world cohort of PSC-IBD patients, vedolizumab/ustekinumab were associated with significantly lower need for ERCP and markedly lower all-cause mortality compared to conventional IBD therapy, without significant differences in ALP normalization, cholangitis, cirrhosis, or cholangiocarcinoma rates. Findings suggested that gut-selective immunomodulation may reduce biliary interventions and improve survival in PSC-IBD, though the small cohort size limits causal interpretation. Prospective studies with dedicated biliary endpoints and ALP trajectory monitoring are urgently needed in this population.

1182 | HEALTHCARE RESOURCE UTILIZATION AND COSTS IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS IN THE UNITED STATES

Robert Wong[1] Robert Gish[2] Ira Jacobson[3] Marvin Rock[4] Garrett Gremel[4] Samina Dhuliawala[4] Gary Leung[4] Maria Agapova[4] Chong Kim[4], [1]Division of Gastroenterology and Hepatology, Stanford University, Stanford, CA, USA, [2]Hepatitis B Foundation, Doylestown, PA, USA, [3]New York University Grossman School of Medicine, New York, NY, USA, [4]Gilead Sciences, Inc., Foster City, CA, USA

Background: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease associated with significant clinical and healthcare economic burden. Ursodeoxycholic acid (UDCA) is the first-line treatment for PBC; however, up to 40% of patients with PBC have an inadequate response (defined as persistently elevated alkaline phosphatase levels >1.67 times the normal upper limit or abnormal bilirubin levels after 1 year of therapy) and require second-line treatment. We evaluated healthcare resource utilization (HCRU) and costs in untreated and newly treated patients with PBC in the US. **Methods:** In this retrospective observational study, adults ≥18 years of age with a diagnosis of PBC (based on *ICD-10-CM*) and ≥12 months of continuous insurance enrollment pre- and post-index were identified within the study period using the IQVIA US Pharmetrics Plus database from January 1, 2016, to June 30, 2024. The index date was defined as the earliest PBC diagnosis (among untreated) or earliest UDCA or obeticholic acid (OCA) prescription claim (among treated). HCRU and costs were evaluated for untreated, UDCA, and OCA (with or without UDCA) were adjusted and reported in 2025 US dollars (maximum amount payable to provider or sum of paid, copay, coinsurance, and deductible costs). Follow-up ended at treatment discontinuation (treated population), death, end of enrollment, or study end date. All-cause HCRU and costs per patient per month were compared across groups; adjusted analyses used a generalized linear model (GLM) of cost ratios adjusting for baseline demographics and clinical characteristics. **Results:** Among 6,968 adults with PBC, 2,416 (35%) were untreated, and 4,552 (65%) were treated (UDCA, n = 3,893 [86%]; OCA, n = 659 [14%]). Untreated patients had significantly more inpatient and emergency room visits vs UDCA and OCA patients; OCA patients also had significantly lower inpatient ($757) and outpatient ($433) costs vs untreated ($2,719 and $574) and UDCA ($1,596 and $597) patients (**Table**). However, prescription costs were generally lower for untreated and UDCA patients vs OCA patients. Based on the adjusted GLM, costs were lower (cost ratio, 0.81; 95% CI, 0.77–0.86) for UDCA vs untreated patients, but higher (2.26; 95% CI, 2.04–2.50) for OCA vs untreated patients (P < .001 each).

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Conclusion: Patients treated with UDCA and OCA had significantly fewer inpatient and emergency room visits than untreated patients, suggesting reduced HCRU. Further, patients receiving OCA had significantly lower inpatient and outpatient costs vs both untreated and UDCA, indicating reduced healthcare-related costs. Overall, these data suggest that the appropriate implementation of OCA may reduce HCRU and costs for patients with PBC; further data are needed to understand how recent approvals of seladelpar and elafibranor as second-line PBC treatments may impact overall HCRU and costs.

1183 | HORMONE THERAPY USE ACROSS THE REPRODUCTIVE AGE IN WOMEN WITH PRIMARY BILIARY CHOLANGITIS: AN OPPORTUNITY FOR INTEGRATED CARE

Julia Foote[1] Cynthia Fenton[1] Marcelle Cedars[1] Monika Sarkar[1], [1]University of California, San Francisco

Background: Primary biliary cholangitis (PBC) disproportionately affects women, although the patterns of exogenous hormone use in this population have not been characterized. In the absence of decompensated cirrhosis, hormonal agents are safe for contraception and treatment of menopausal symptoms. Use of exogenous hormone therapy is also relevant regarding second-line PBC treatment, given the potential for drug-drug interactions with elafibrinor. **Methods:** We performed a retrospective cohort study of women with PBC at a tertiary care center between January 1, 2013 and December 31, 2025. Index date was defined as 6 months prior to first hepatology clinic visit. Patients were censored at liver transplantation, death, or loss to follow-up. Systemic hormone exposures, including formulations, dosing, and duration, were captured. Menopausal status was defined first by age (<51 for pre-menopausal women vs $\geq$ 51 years for post-menopausal women) and refined by diagnosis code for menopausal status, documented surgical menopause, and use of menopausal hormone therapy (MHT). Hormone formulations and dosing were reviewed to adjudicate hormonal contraceptive versus MHT exposures. Data were collected on PBC-related comorbidities, MASLD, and PBC-directed treatments. Rates of hormone use were characterized over time with test of trend p-values. **Results:** Among 593 women with PBC, 157 (26.5%) were pre-menopausal and 436 (73.5%) were post-menopausal at index date. Among pre-menopausal women, the median age was 42 years (IQR 35-46 years), 19.1% had concurrent MASLD, and 92.4% had received ursodiol, 10.8% seladelpar, and 3.2% elafibranor. Among post-menopausal women, the median age was 64 years (IQR 57-70 years), 19.7% had concurrent MASLD, and 87.4% had received ursodiol, 5.5% seladelpar, and 1.1% elafibranor. Across the study period, prevalence of hormonal contraceptive and MHT

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

use was 17.2% and 3.7%, respectively. Prevalence remained stable over time but lower than contemporary national estimates (Figure 1). Prevalence of MASLD and use of second-line PBC therapies were similar by hormone exposure. **Conclusion:** Compared to national estimates, the use of hormone therapy was lower in both pre- and post-menopausal patients with PBC, suggesting potential underutilization of these therapies. As access to hormone therapies expand, these findings highlight an opportunity to integrate women's health and PBC care.

1184 | PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS: FROM DIAGNOSIS TO THE MOST RECENTLY APPROVED TREATMENTS - A SYSTEMATIC REVIEW WITH DESCRIPTIVE ANALYSIS

Parsia Vazirnia[1] Kirellos Mikhail[2] Marie Balfour[3] Kerollos Roufael[4] Yuri Kwon[1] Moura Girgis[2] Matthew Ghebrial[1] Beshoy Yanny[1], [1]University of California, Irvine., [2]University of California, Los Angeles., [3]Univeristy of California, Irvine., [4]California State University, Long Beach.

Background: Progressive Familiar Intrahepatic Cholestasis (PFIC) is a rare group of inherited liver disorders affecting hepatocyte bile secretion occurring in infants, young children, and adults. 13 types of PFIC have been identified based on their specific gene mutations. The most common types include PFIC 1-3. Key lab findings often overlap with other common liver diseases, making diagnosis challenging. Definitive diagnosis requires specialized genetic testing which can occur years after initial presentation typically manifesting as jaundice and severe pruritus. Historically, treatment options were limited to ursodeoxycholic acid (UDCA) or surgical options such as bile diversion or liver transplantation. However, newer therapies such as Ileal Bile Acid Transporter (IBAT) inhibitors are now more commonly used. This study aimed to investigate the efficacy of different PFIC treatment options. **Methods:** A literature review was conducted across PubMed through April 2026. Studies included case reports, case series, and clinical trials. Primary outcomes investigated were improvement in pruritus intensity and labs including serum bile acids, transaminases, GGT, total bilirubin, and alkaline phosphatase. Treatment success was defined as resolution of symptoms and improvement in labs. Secondary outcomes included age of diagnosis, length of time until diagnosis was made, and gender. An illustration of treatment options was created with BioRender.com. **Results:** Twenty-six studies were included, all consisting of case reports and case series; no clinical trials were identified. PFIC 3 was the most common subtype (n = 11), followed by PFIC 2 (n = 4) and PFIC 1 (n = 3). Treatment success was highest with odevixibat (100%) and biliary diversion (87.5%), followed by liver transplant (75%), and lowest with UDCA (37.5%). Liver transplant was associated with the greatest improvement across nearly all laboratory parameters (Table 1). Patient ages ranged from 1 month to 35 years (mean 8 years), with a male predominance (18 male, 12 female). The average time from symptom onset to diagnosis was 5 years. **Conclusion:** The high treatment success rate of odevixibat (100%) is promising, as it offers a nonsurgical alternative with outcomes comparable to biliary diversion (87.5%) and liver transplant (75%). PFIC remains a challenging diagnosis, presenting in early childhood and persisting into adulthood, with an average of 5 years from symptom onset to confirmatory genetic testing. Keeping PFIC on the radar of hepatologists for patients with unexplained cholestasis is important to reduce diagnostic delay and facilitate initiation of effective therapy.

1185 | A CHOLANGIOCYTE-MAIT CELL-HEPATIC STELLATE CELL AXIS IN PRIMARY SCLEROSING CHOLANGITIS

Adiba Azad[1] Florencia Guttierez[1] Gregory Gores[1] Alexander Wixom[1] Konstantinos Lazaridis[1], [1]Mayo Clinic

Background: PSC is an immune-mediated cholangiopathy in which periductal fibrosis drives strictures, parenchymal injury, and liver failure. MAIT cells are unconventional T cells enriched at barrier surfaces and implicated in tissue repair and mucosal inflammation, but their role within the human bile duct niche in PSC and the cholangiocyte-derived cues that shape them remain unclear. **Methods:** Bile and bile duct brushings/bile obtained at endoscopic retrograde cholangioscopy (ERC) were examined by flow cytometry, ELISA and used to derive cholangiocyte organoids. **Results:** MAIT cells were enriched in PSC bile duct compared to non-PSC controls (40% vs 20% of T cells). PSC cholangiocyte organoid secretome profiling identified IL-17C, and ELISA confirmed 10X enrichment of IL-17C in PSC bile. In situ hybridization localized IL-17C transcripts to PSC cholangiocytes. Secondary analysis of published intrahepatic T cell single cell RNA-seq datasets showed that IL17RE, the cognate receptor for IL-17C, was preferentially enriched on MAIT cells in PSC, but this MAIT cell preference was not observed in primary biliary cholangitis, a disease comparator.IL-17C-treated primary MAIT cells showed activation of hepatic fibrogenesis and T cell activation pathways by RNA-seq. Conditioned media from IL-17C-treated MAIT cells activated hepatic stellate cells (2X), supporting a MAIT cell derived soluble mediator. Targeted profiling of MAIT cell secretome identified secreted protein acidic and rich in cysteine (SPARC), whose release was significantly enhanced by IL-17C (2X). Recombinant SPARC augmented hepatic stellate cell activation, and SPARC was increased in PSC bile and periductal PSC liver tissue.10X Xenium single cell spatial transcriptomics confirm that MAIT cells comprise a substantial fraction of spatially resolved T cells in PSC tissue. In situ annotation using profibrogenic, pro-inflammatory, and regulatory signatures showed that profibrogenic MAIT cells preferentially associated with stellate cell neighborhoods, and stellate cell activation scores were highest in regions containing both MAIT cells and cholangiocytes. **Conclusion:** We identify a cooperative cholangiocyte-MAIT cell-stellate cell niche that promotes periductal fibrogenesis in PSC. We show that PSC cholangiocytes upregulate IL-17C and that its receptor, IL17RE, is preferentially enriched on MAIT cells. IL-17C instructs MAIT cells to express the matricellular protein SPARC, which directly activates hepatic stellate cells and increases collagen production. By integrating bile duct immune profiling, patient-derived cholangiocyte organoids, RNA sequencing, functional assays, and 10X Xenium spatial transcriptomics, this work provides mechanistic evidence that MAIT cells are actively shaped by cholangiocyte-derived cues to drive fibrosis. Thus, the IL-17C-MAIT-SPARC axis, represents a therapeutically actionable driver of fibrosis in PSC.

1186 | IMPACT OF LINERIXIBAT ON METABOLIC PROFILES IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS (PBC) IN THE PHASE 3 GLISTEN STUDY

Christopher Bowlus[1] Cynthia Levy[2] Linda Casillas[3] Alexander Cobitz[3] Jennifer Shannon[4] Megan McLaughlin[5] Gideon Hirschfield[6], [1]University of California, Davis, [2]University of Miami, [3]GSK, Collegeville, PA, USA, [4]GSK, Durham, NC, USA, [5]GSK, Collegeville, PA, USA (at time of study conduct), [6]Toronto General Hospital

Background: PBC is a rare, chronic, autoimmune-mediated liver disease commonly associated with metabolic comorbidities such as dyslipidemia.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Linerixibat is a minimally absorbed ileal bile acid transporter (IBAT) inhibitor recently approved for treatment of cholestatic pruritus in patients (pts) with PBC. Inhibition of IBAT blocks intestinal bile acid reabsorption, forcing greater liver conversion of cholesterol to bile acids (similar to cholestyramine) and modulates farnesoid X receptor, improving lipid and glucose metabolism. This analysis evaluated linerixibat's effect on these metabolic profiles in the Phase 3 GLISTEN study (NCT04950127). **Methods:** GLISTEN was a randomized, multicenter, double-blind, placebo-controlled trial of adults with PBC and moderate-to-severe pruritus.In the primary intervention period, pts received oral linerixibat 40 mg or placebo (pbo) twice daily for 24 weeks. This post hoc analysis of the safety population analyzed change from baseline at Week 24 in lipids (total cholesterol [TC], low-density lipoprotein cholesterol [LDL-c], high-density lipoprotein cholesterol [HDL-c], and triglycerides [TG]) in all pts, pts receiving statins (baseline), pts with high baseline LDL-c ($\geq$160 mg/dL), and IFG (impaired fasting glucose; $\geq$100 mg/dL). **Results:** Of 237 pts included, mean (SD) baseline lipids (mg/dL) in pts receiving linerixibat vs pbo were: TC: 224.8 (61.9) vs 229.4 (65.9); HDL-c: 70.0 (23.9) vs 70.3 (27.1); LDL-c: 127.6 (47.0) vs 130.2 (44.5); TG: 116.9 (50.1) vs 115.9 (56.1). Mean (SD) baseline fasting glucose was: linerixibat, 98.8 (40.7) vs pbo, 95.9 (25.8) mg/dL. Greater improvements from baseline to Week 24 were observed with linerixibat vs pbo in TC (least squares mean difference [LSMD] −11.65 [95% confidence interval, CI: −19.73, −3.57] mg/dL), LDL-c (−14.48 [−21.02, −7.95] mg/dL) and HDL-c (2.77 [−0.99, 6.53] mg/dL); for TG, LSMD was 2.47 (−6.69, 11.63) mg/dL. Of 36 (15%) pts receiving statins, greater improvements in cholesterol from baseline to Week 24 were observed with linerixibat vs pbo (**Table**). Forty-nine (21%) pts had baseline LDL-c $\geq$160 mg/dL (linerixibat n = 20; pbo n = 29); of these, greater improvements in lipids from baseline to Week 24 were observed with linerixibat vs pbo (**Table**). Overall change from baseline in fasting glucose at Week 24 in pts receiving linerixibat vs pbo (LSMD) was −4.51 (95% CI: −8.16, −0.86) mg/dL. Sixty (25%) pts had IFG (linerixibat n = 28; pbo n = 32); in these pts, greater improvements from baseline to Week 24 were also observed with linerixibat vs pbo (**Table**). **Conclusion:** Linerixibat was associated with an improvement in lipid and glucose profiles compared with pbo in pts with PBC, even among those receiving statins, with higher LDL, or IFG at baseline. Aside from effectively treating pruritus, linerixibat may also have metabolic benefits by influencing pathways involved in lipid and glucose metabolism in pts with PBC. Funding: GSK (212620)

Table: Analysis of covariance of change from baseline in lipid and glucose profile at Week 24 in GLISTEN Part A (post hoc analyses)

Treatment group	N (Baseline)	n (Week 24)	Baseline measurements (mean [SD])	Change from baseline at Week 24 (LS mean [95% CI])	Difference vs placebo at Week 24* (LS mean difference [95% CI])
Patients receiving statins at baseline					
Total cholesterol (mg/dL)					
Placebo	21	19	203.5 (83.9)	−1.25 (−17.65, 15.14)	−9.69 (−36.78, 17.39)
Linerixibat	15	11	211.2 (89.6)	−10.95 (−32.50, 10.61)	
LDL-c (mg/dL)					
Placebo	21	19	100.0 (43.5)	−1.08 (−11.75, 9.58)	**−20.31 (−38.08, −2.55)**
Linerixibat	15	11	116.4 (78.2)	**−21.40 (−35.47, −7.33)**	
HDL-c (mg/dL)					
Placebo	21	19	73.8 (46.5)	−1.86 (−7.11, 3.40)	5.91 (−2.84, 14.66)
Linerixibat	15	11	69.6 (19.0)	4.05 (−2.88, 10.98)	
Triglycerides (mg/dL)					
Placebo	21	19	107.2 (34.9)	3.14 (−14.17, 20.45)	10.04 (−18.86, 38.94)
Linerixibat	15	11	109.2 (39.6)	13.18 (−9.67, 36.03)	
Patients with high LDL-c (≥160 mg/dL) at baseline					
Total cholesterol (mg/dL)					
Placebo	29	26	300.5 (46.8)	**−26.47 (−39.97, −12.97)**	**−27.77 (−49.43, −6.10)**
Linerixibat	20	17	317.2 (76.5)	**−54.24 (−70.98, −37.49)**	
LDL-c (mg/dL)					
Placebo	29	26	187.9 (31.9)	**−21.69 (−32.76, −10.61)**	**−30.08 (−47.89, −12.27)**
Linerixibat	20	17	203.0 (53.8)	**−51.77 (−65.52, −38.02)**	
HDL-c (mg/dL)					
Placebo	29	26	81.7 (37.4)	**−7.31 (−12.49, −2.13)**	**10.98 (2.72, 19.25)**
Linerixibat	20	17	74.1 (33.0)	3.67 (−2.74, 10.09)	
Triglycerides (mg/dL)					
Placebo	29	26	122.9 (57.5)	6.36 (−5.41, 18.13)	**−23.17 (−42.24, −4.11)**
Linerixibat	20	17	146.4 (60.8)	**−16.81 (−31.46, −2.16)**	
Patients with impaired fasting glucose (≥100 mg/dL) at baseline					
Fasting glucose (serum) (mg/dL)					
Placebo	32	29	120.6 (39.1)	**−11.20 (−18.18, −4.22)**	**−11.78 (−21.97, −1.59)**
Linerixibat	28	26	128.7 (76.8)	**−22.98 (−30.36, −15.61)**	

*Mean difference >0 favors active treatment, mean difference <0 favors placebo, bold indicates statistical significance (95% CI excludes 0).

CI, confidence interval; HDL-c, high-density lipoprotein cholesterol; LDL-c, low-density lipoprotein cholesterol; LS, least squares; SD, standard deviation.

1187 | REAL-WORLD USE OF PPAR AGONISTS IN PBC: INDICATIONS, BIOCHEMICAL RESPONSE, AND TOLERABILITY

Victoria Abadi-Ron[1] Natalia Rojas Amaris[1] Ana Marenco-Flores[1] Fernando Munguia[1] Giuliana Arevalo[2] Romelia Barba[3] Daniela Goyes[4] Esli Medina Morales[5] Leandro Sierra[6] Behnam Saberi[7] Vilas Patwardhan[1] Alan Bonder[1], [1]Beth Israel Deaconess Medical Center, [2]Department of Internal Medicine, University of Miami / Jackson Memorial Hospital, [3]Texas Tech University, [4]Yale School of Medicine, New Haven, [5]Washington University in St Louis, [6]Cleveland Clinic Foundation, [7]BIDMC Harvard Medical School

Background: Peroxisome Proliferator-Activated Receptors (PPAR) agonists are emerging therapies for primary biliary cholangitis (PBC) with inadequate response to ursodeoxycholic acid (UDCA), but real-world data remain limited. We aimed to describe indications, biochemical response, and tolerability of Elafibranor and Seladelpar in patients with PBC and overlap syndromes. **Methods:** We conducted a descriptive real-world analysis of a prospective cohort of patients with PBC as the primary diagnosis, with or without overlap autoimmune liver disease, initiated on PPAR agonists at Beth Israel Deaconess Medical Center from 2024 to present. Data were manually extracted from electronic medical records, including physician notes and routine clinical labs. Inadequate UDCA response was based on treating physician assessment. POISE-like response was defined as ALP $\leq$1.65×ULN, normal total bilirubin, and $\geq$15% ALP reduction; deep biochemical response was defined as ALP normalization with normal total bilirubin. Continuous variables are reported as median (IQR), categorical variables as n (%). Mann–Whitney U and Fisher's exact tests were used. **Results:** Seventy-eight patients were included; 46 (59.0%) initiated elafibranor and 32 (41.0%) seladelpar. Median age was 61.5 vs 67.5 years, and most were female. AIH-PBC overlap was present in 7 (15.2%) vs 4 (12.5%) patients; PBC-PSC overlap was present in 1 (2.2%) elafibranor-treated patient. The main indication was inadequate UDCA response, occurring in 40 (87.0%) vs 26 (81.3%); UDCA intolerance occurred in 3 (6.5%) vs 1 (3.1%). Baseline symptoms were documented in 19 (41.3%) vs 15 (46.9%), most commonly pruritus. Baseline ALP was similar: 218 vs 200.5 U/L; baseline total bilirubin was 0.5 mg/dL in both groups. Baseline FibroScan was 6.9 kPa (5.4–11.0; n = 39) vs 6.8 kPa (6.0–8.8; n = 25). At 6 months, median ALP reduction was greater with elafibranor than seladelpar: 44.0% vs 30.0% (p = 0.020). Total bilirubin remained stable, with median 6-month reduction of 15.5% vs 0.0% (p = 0.164).Six-month treatment completion occurred in 34 (73.9%) vs 27 (84.4%), where POISE-like response was achieved by 21 (65.6%) vs 14 (53.9%) patients (p = 0.425), and deep biochemical response by 11 (34.4%) vs 12 (46.2%) (p = 0.425). Side effects occurred in 8 (17.4%) vs 5 (15.6%), including gastrointestinal symptoms, myalgia, fatigue, pruritus, and headache. Discontinuation occurred in 2 (4.3%) vs 4 (12.5%). **Conclusion:** In this real-world PBC cohort, PPAR agonists were primarily initiated for physician-assessed inadequate UDCA response and were associated with meaningful 6-month ALP improvement. Elafibranor showed greater median ALP reduction, while bilirubin remained stable in both groups. Both agents showed favorable tolerability, with low discontinuation rates often related to insurance/access barriers rather than intolerance.

Figure 1. Six- and Twelve-Month Biochemical Reduction by PPAR Agent

Boxplots show percent reduction from baseline in alkaline phosphatase (ALP) and total bilirubin at 6 and 12 months after PPAR agonist initiation, stratified by treatment group. Percent reduction was calculated as [(baseline value − follow-up value) / baseline value] × 100; positive values indicate biochemical reduction from baseline. Six-month ALP reduction was greater with elafibranor than seladelpar (median 44.0% vs. 30.0%; p=0.020), while total bilirubin reduction did not differ significantly between groups (p=0.164). At 12 months, ALP and total bilirubin reductions did not differ significantly between elafibranor and seladelpar groups (p=0.553 and p=0.383, respectively). P-values were calculated using the Mann–Whitney U test. One total bilirubin outlier below −100% was excluded from the 6-month bilirubin panel for visualization. ALP, alkaline phosphatase; PPAR, peroxisome proliferator-activated receptor.

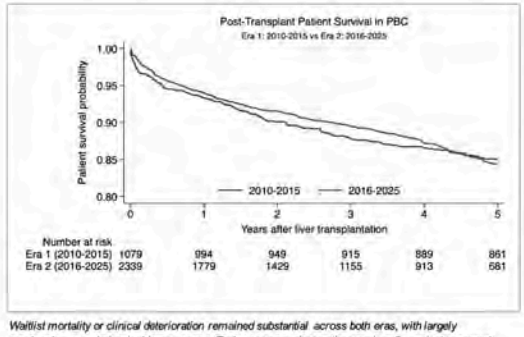
1188 | TEMPORAL TRENDS IN WAITLIST OUTCOMES AND POST-TRANSPLANT SURVIVAL IN PRIMARY BILIARY CHOLANGITIS FOLLOWING INTRODUCTION OF SECOND-LINE THERAPIES: A UNOS ANALYSIS



Romelia Barba[1] Ana Marenco-Flores[2] Giuliana Arevalo[3] Victoria Abadi-Ron[2] Natalia Rojas Amaris[2] Fernando Munguia[2] Khawaja Hassam[4] Miriam Paz Sierra[5] Daniela Goyes[6] Behnam Saberi[2] Vilas Patwardhan[2] Alan Bonder[2], [1]Texas Tech University, [2]Beth Israel Deaconess Medical Center, [3]University Of Miami Miller School of Medicine, [4]Lahey Hospital and Medical Center, [5]Texas Tech Medical Center, [6]Yale Medical School

Background: Primary biliary cholangitis (PBC) remains a major indication for liver transplantation despite advances in medical therapy. Prior studies demonstrated disproportionately high waitlist mortality among patients with PBC under the MELD-Na allocation system, suggesting that disease severity may be underestimated in this population. In 2016, obeticholic acid became the first FDA-approved second-line therapy for PBC.We evaluated temporal trends in waitlist mortality or clinical deterioration and post-transplant outcomes among patients with PBC before and after the introduction of second-line therapy in 2016. **Methods:** We performed a retrospective cohort study using the United Network for Organ Sharing (UNOS) database including adult patients with PBC listed for liver transplantation between 2010 and 2025. Patients were stratified into two eras: Era 1 (2010–2015) and Era 2 (2016–2025). The primary waitlist outcome was a composite of death or removal for clinical deterioration. Kaplan–Meier analyses evaluated waitlist outcomes, post-transplant patient survival, and graft survival. Baseline demographic and clinical characteristics were compared using chi-square and Kruskal–Wallis tests. **Results:** A total of 5,076 patients with PBC were identified, including 1,721 in Era 1 and 3,355 in Era 2. Compared with Era 1, patients in Era 2 had higher MELD scores at listing (mean MELD 19.7 vs 17.8, $p < 0.001$). Hispanic recipients represented a larger proportion of the contemporary cohort (23.8% vs 18.4%, $p < 0.001$), while other baseline characteristics were similar between eras. Waitlist mortality or clinical deterioration remained substantial after 2016, with largely overlapping cumulative incidence curves over 5 years of follow-up (Figure1). In the isolated 2016–2025 cohort, estimated freedom from waitlist death or clinical deterioration declined to 74.7% at 1 year, 57.9% at 2 years, 48.8% at 3 years, and 30.1% at 5 years after listing. Post-transplant outcomes showed modest early improvement during Era 2. Patient survival remained approximately 92% at 2 years, 88% at 4 years, and 74% at 9 years in the contemporary cohort. Similarly, graft survival remained approximately 90% at 2 years, 85% at 4 years, and 70% at 9 years after transplantation, although long-term survival curves converged over time. **Conclusion:** Despite the introduction of second-line therapy for PBC after 2016, waitlist mortality and clinical deterioration remain high among patients with advanced disease. Although modest improvements in early post-transplant patient and graft survival were observed in the contemporary era, long-term outcomes remained similar between eras. These findings suggest that advances in pharmacologic therapy have not yet translated into substantial reductions in transplant-related disease burden in PBC and support continued reassessment of transplant allocation strategies for this population.

Figure 1. Waitlist Outcomes and Post-Transplant Survival in Patients with Primary Biliary Cholangitis Before and After Introduction of Second-Line Therapy

Waitlist mortality or clinical deterioration remained substantial across both eras, with largely overlapping cumulative incidence curves. Early post-transplant patient and graft survival appeared modestly improved in the contemporary era, although long-term outcomes converged over extended follow-up.

1189 | REAL-WORLD BIOCHEMICAL RESPONSE TO ELAFIBRANOR AND SELADELPAR IN PRIMARY BILIARY CHOLANGITIS CONTRASTING ALKALINE PHOSPHATASE RESPONSE, DEEP RESPOSE AND NORMALIZATION.

Hussein Harb[1] Fabian Rodas[2], [1]Texas Institute of Graduate Medical Education (TIGMER), [2]University of Texas San Antonio

Background: Persistent elevation of alkaline phosphatase (ALP) and bilirubin in primary biliary cholangitis (PBC) predicts disease progression, liver transplantation, and death. Despite trial efficacy of elafibranor and seladelpar, real-world response across clinically relevant ALP thresholds remains limited. **Methods:** We performed a retrospective real-world cohort study of adults with PBC treated with elafibranor or seladelpar with baseline ALP/bilirubin and follow-up labs. Follow-up windows were 3-6 and 8-12 months post-initiation. ALP response thresholds used ULN = 104 U/L: ALP < 1.67×ULN (< 174 U/L; POISE-like threshold), ALP < 1.5×ULN (< 156 U/L; Paris II ALP threshold), and ALP normalization (< 104 U/L). Paired ALP/bilirubin changes were assessed using Wilcoxon signed-rank testing. Therapies were compared using Fisher exact and Wilcoxon rank-sum tests **Results:** 71 patients were included: 39 received elafibranor and 32 seladelpar. Paired ALP/bilirubin data were available for 61 patients at 3-6 months and 13 at 8-12 months. Median ALP decreased from 218 U/L [IQR, 172-314] to 118 [100-201] at 3-6 months, with median change -79 U/L [-151 to -22] and percent change -41.8% [-56.2 to -11.2] ($p < 0.0001$). At 8-12 months, ALP decreased from 357 [191-400] to 137 [120-162], with median change -196 U/L [-239 to -59] and percent change -55.7% [-59.8 to -37.3] ($p = 0.0017$). At 3-6 months, 43/61 (70.5%) achieved ALP < 1.67×ULN, 42/61 (68.9%) achieved ALP < 1.5×ULN, and 17/61 (27.9%) achieved ALP normalization. At 8-12 months, corresponding rates were 11/13 (84.6%), 8/13 (61.5%), and 2/13 (15.4%). Median bilirubin changed from 0.6 [0.4-0.8] to 0.5 [0.4-0.7] at 3-6 months ($p = 0.0577$) and from 0.5 [0.5-0.7] to 0.5 [0.3-0.7] at 8-12 months ($p = 0.2316$). At 3-6 months, ALP < 1.67×ULN was achieved in 23/34 elafibranor-treated patients (67.6%) and 20/27 seladelpar-treated patients (74.1%; $p = 0.7782$). ALP < 1.5×ULN and normalization rates were also similar between therapies. **Conclusion:** In this real-world PBC cohort, elafibranor and seladelpar were associated with substantial ALP reduction and frequent achievement of trial-informed ALP thresholds by 3-6 months, while bilirubin remained low and stable. Response rates were similar between therapies in exploratory comparisons. Longer-term findings suggest continued ALP response but are limited by small 8-12-month denominators.

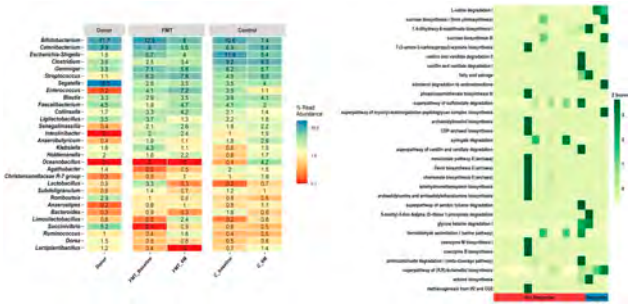
1190 | FAECAL MICROBIOTA TRANSPLANTATION FOR REFRACTORY AUTOIMMUNE LIVER DISEASE: GUT MICROBIOME RESTORATION AND METABOLIC REMODELLING IN A PILOT RANDOMISED CONTROLLED TRIAL



Shalimar[1] Arnav Aggarwal[1] Manjeet Kaur[2] Bharti Kandiyal[2] Samagra Agarwal[1] Sagnik Biswas[1] Bhabatosh Das[2], [1]All India Institute of Medical Sciences, [2]Translational Health Science and Technology Institute

Background: Patients with autoimmune liver disease (AILD) who have an inadequate response to standard immunosuppression remain at risk of progressive liver injury and fibrosis. We evaluated the efficacy, microbiome dynamics, and functional remodelling associated with faecal microbiota transplantation (FMT) in refractory AILD. **Methods:** In this pilot open-label randomized controlled trial, patients with insufficient or non-response to first- or second-line immunosuppression

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

were randomized to receive either FMT plus standard immunosuppressive therapy (FMT arm) or standard immunosuppressive therapy (control arm). Clinical outcomes, liver stiffness measurement (LSM), gut microbiome composition, predicted microbial metabolic pathways, donor microbiome engraftment, and presence of antimicrobial resistance (AMR) gene prevalence were assessed at baseline and 6 months. A total of 68 faecal samples from FMT recipients (n = 15), controls (n = 17), and donors (n = 4) underwent microbiome analysis by targeted metagenomics. **Results:** FMT recipients demonstrated significant restoration of gut microbial diversity at 6 months, with post-FMT microbial profiles becoming comparable to donor profiles based on Observed and Shannon diversity indices. Principal coordinate analysis revealed distinct compositional shifts in the FMT group; controls exhibited only modest temporal variation. FMT was associated with trends toward reduced abundance of potentially pathogenic genera, including Klebsiella, Enterobacter, and Escherichia/Shigella, and enrichment of beneficial taxa such as Lachnospira, Agathobacter, and Intestinimonas (Figure). Donor engraftment > 50% occurred in 60% of FMT recipients. Functional profiling identified 61 significantly enriched microbial pathways following FMT, predominantly involving amino acid metabolism, aromatic compound degradation, cofactor biosynthesis, and anti-inflammatory polyphenol metabolism. Responders demonstrated enrichment of pathways linked to metabolic versatility and reduced methanogenesis-associated functions. In contrast, controls exhibited limited functional remodelling. Non-responders in both arms retained higher AMR gene prevalence, whereas FMT responders showed lower detection of several resistance determinants, including CTX-M, TEM, ermB, and qnrS. No major safety concerns were identified. **Conclusion:** FMT induces donor-like microbiome restoration and substantial functional metabolic remodelling in refractory AILD, with distinct microbial and AMR signatures associated with clinical response. These findings support the therapeutic potential of microbiome-directed interventions in difficult-to-treat AILD, warranting evaluation in larger trials (CTRI/2022/10/046773).

1191 | THE PBC IRELAND PATIENT REGISTRY: REAL-WORLD INSIGHTS INTO THE MEDICAL HISTORY OF PEOPLE LIVING WITH PBC IN IRELAND

Gerry Nesbitt[1] Alexandra Curley[1], [1]PBC Ireland

Background: Primary biliary cholangitis (PBC) is a rare, chronic autoimmune liver disease with significant symptom burden and variable treatment response. In Ireland, there is a lack of national real-world data describing patient medical history, limiting understanding of disease characteristics, care gaps and outcomes. The PBC Ireland Patient Registry was established as a patient-led initiative to generate real-world evidence and ensure the patient voice is represented in research and policy. **Methods:** This is an observational, web-based registry of adults (≥ 18 years) with a self-reported diagnosis of PBC. Participants are recruited through patient communities and complete electronic informed consent. Data are collected via a secure, GDPR-compliant platform called CLIRINX and include demographics, detailed medical history, treatment exposure, and clinical investigations. Medical history captures diagnostic timelines, comorbidities, FibroScan and bone density results, and treatment response. **Results:** A total of 65 participants contributed medical history data. Family history of autoimmune or liver disease was reported by 46.2%. Most participants (84.6%) had undergone FibroScan, with 21.6% reporting moderate-to-advanced fibrosis (F2–F4), while 23.1% reported that results were not shared with them. Bone density abnormalities were common, with 29.3% reporting osteopenia or osteoporosis. UDCA use was reported by 95.4%, with 23.1% an inadequate response. Symptom burden remained high, particularly fatigue (87.7%) and pruritus (55.4%), alongside cognitive and musculoskeletal symptoms. Over half of participants reported comorbid autoimmune conditions. **Conclusion:** These findings demonstrate the feasibility of a patient-led registry to capture detailed real-world data in PBC. The data highlight ongoing symptom burden, variable treatment response, and potential gaps in communication and care. This registry provides a foundation for future research, supports patient-centred advocacy, and can inform clinical practice and policy decisions in Ireland.

1192 | BIOCHEMICAL NON-INVASIVE TESTS FOR FIBROSIS AND LIVER STIFFNESS MEASUREMENTS CAN BE USED TO EVALUATE PROGNOSIS IN THE POPULATION WITH PRIMARY BILIARY CHOLANGITIS

Ellen Werner[1] Tiki Blom[1] Gemma Weijsters[1] Merle M.F. Vos[1] Maria van Hooff[1] Rozanne de Veer[1] Ulrich Beuers[2] Joost Drenth[2] Frans J.C. Cuperus[1] Remco van Dijk[3] Bart J. Veldt[4] Michael Klemt-Kropp[5] Suzanne van Meer[6] Robert Verdonk[7] Hajo J. Flink[8] Jan Maarten Vrolijk[9] Cyriel Ponsioen[2] Matthijs Kramer[10] J. Kemenade[11] Edith M.M. Kuiper[12] Menno Beukema[13] Kirsten Boonstra[14] Femke Boersma[15] Elsemieke de Vries[16] Hendrik J.M. de Jonge[17] Franciscus Wolfhagen[18] L.C. Baak[19] Susanne L. Onderwater[20] Harry Janssen[1] Bettina Hansen[1] Adriaan J. van der Meer[1], [1]Erasmus University Medical Center, [2]Amsterdam University Medical Center, [3]Leiden University Medical Center, [4]Reinier de Graaf Gasthuis, [5]Noordwest Ziekenhuisgroep, [6]University Medical Center Utrecht, [7]St. Antonius Hospital, [8]Catharina Hospital, [9]Rijnstate, [10]Maastricht University Medical Center, [11]Van Weel-Bethesda Hospital, [12]Spijkenisse Medical Center, [13]Streekziekenhuis Koningin Beatrix, [14]Radboud University Medical Center, [15]Gelre Hospitals, [16]Isala Hospital, [17]Jeroen Bosch Hospital, [18]Albert Schweitzer Hospital, [19]Onze Lieve Vrouwe Gasthuis, [20]Diakonessenhuis

Background: Biochemistry is used to evaluate therapeutic management in people with primary biliary cholangitis (PBC). Liver stiffness measurement (LSM) is considered a non-invasive staging parameter with added prognostic value, but its availability varies. We aimed to assess biochemical non-invasive tests (NITs) for fibrosis as compared to LSM, including their association with clinical outcomes. **Methods:** The Dutch PBC Cohort Study includes every identifiable individual with PBC in the Netherlands from 1990 up to last data collection (2019-2023) across all 71 Dutch hospitals. These analyses included UDCA-treated individuals with ≥1 LSM during follow-up (FU) and available FIB-4 (based on age, AST, ALT and platelets) and APRI (based on AST and platelets) obtained within three months of LSM. In survival analyses of liver transplantation (LT)-free survival and liver disease progression (LDP) (decompensated cirrhosis, LT or liver-related death) first LSM was defined as index date. LSM, FIB4 and APRI were log transformed. A LSM ≥10kPa was considered to indicate advanced disease. **Results:** In total, 728 people were included; 648 (89.0%) were female and median age was 59y (IQR 51–67). First LSM was available after a median FU of 5.2 years (IQR 1.1-10.5). Median LSM was 6.9 kPa (IQR 5.3–10.0), with 184 (25.3%) having a LSM ≥ 10 kPa. Median FIB-4 was 1.3 (IQR 0.97–1.8) and median APRI 0.4 (IQR 0.3–0.7). The LSM correlated weakly with both APRI ($r = 0.4$, $p < 0.01$) and FIB-4 ($r = 0.4$, $p < 0.01$). Using a FIB-4 cutoff of 3.25, specificity for LSM ≥ 10 kPa was 97.9% and sensitivity 23.4%. With an APRI cutoff of 0.54, specificity was 77.8% with a sensitivity of 38.6%. Table 1 shows the decrease in specificity and increase in sensitivity with lower cut-offs of the biochemical NITs, as well as positive and negative predictive values. Median FU after index LSM was 2.7 years (IQR 1.1–4.5), during which 44 patients died, 11 were transplanted and 36 developed decompensated cirrhosis. Univariately, LSM (HR 3.0, 95%CI 2.1–4.3), FIB-4(HR 3.7, 95%CI 2.6–5.2) and APRI (HR 2.2, 95%CI 1.6-2.9) were all associated with LT/death (all $p < 0.01$). The corresponding C-stats were 0.72 for LSM vs 0.77 for FIB-4 ($p = 0.352$), and 0.69 for APRI ($p = 0.474$). Both FIB-4 (aHR 2.9, 95%CI 1.9–4.3) and LSM (aHR 1.9, 95%CI 1.2–2.9) remained associated with LT/death when combined in a model, as was the case for APRI (aHR 1.6, 95%CI 1.2–2.3) combined with LSM (aHR 2.5, 95%CI 1.7–3.7), all $p < 0.01$. Addition of LSM to each NIT improved the C-stat (0.78 for LSM and FIB-4 and 0.73 for LSM and APRI, $p < 0.01$ as compared to the NITs alone. Results were consistent in people 35-65y and when looking to LDP, although effect sizes were more pronounced (all C-stat > 0.80). **Conclusion:** Both FIB4 and APRI showed good prognostic discrimination in patients with PBC and may be considered as a readily available alternative for LSM. However, combining LSM with the biochemical staging parameters improved their prognostic performance.

FIB-4	LSM <10	LSM≥10		APRI	LSM <10	LSM≥10	
FIB-4 > 3.25	12	43	PPV 78.2%	APRI >0.66	90	87	PPV 49.2%
FIB-4 ≤ 3.25	532	141	NPV 79.0%	APRI ≤0.66	454	97	NPV 82.4%
	Specificity 97.8%	Sensitivity 23.4%			Specificity 83.5%	Sensitivity 47.3%

1193 | WHAT IS IT LIKE TO TREAT PRIMARY BILIARY CHOLANGITIS IN A LOW-RESOURCE SETTING? REAL-WORLD EXPERIENCE FROM A MEXICAN REFERRAL CENTER

Ricardo Gutierrez Monterrubio[1] Nayelli Flores-García[2] Astrid Ruiz-Margain[2] Jose Gonzalez Regueiro[2], [1]Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubirán, [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran

Background: Primary Biliary Cholangitis (PBC) is a relevant cause of cirrhosis worldwide although in Latin America epidemiologic data remain scarce; delayed diagnosis is still a concern. We aimed to describe the clinical characteristics of patients with PBC at a referral center in Mexico City. **Methods:** This retrospective single-center cohort included adults with PBC between May 2012 and May 2026. Data were obtained from medical records. Diagnosis required two of the following: cholestatic biochemical abnormalities, positive antimitochondrial antibodies (AMA), or compatible liver histology. Descriptive statistics summarized demographic, clinical, and treatment variables. Continuous variables were reported as mean ± SD or median (IQR). Categorical comparisons were performed using Cochran's Q and McNemar tests, while agreement between diagnostic approaches was assessed using Cohen's κ coefficient. Analyses were performed using IBM SPSS Statistics version 27.0; $p < 0.05$ considered statistically significant. **Results:** 500 patients were included; 467 (93.4%) were women. Median age at diagnosis was 49 years (IQR 41–58). UDCA and bezafibrate were used in 94.4% and 52.2%, respectively. Pruritus-directed therapy was required in 41.8% of patients; antihistamines were the most common (34%). During the first year after diagnosis, 91.8% reported symptoms; fatigue (77%), pruritus (70.8%), and weight loss (43.6%). Autoimmune disease was present in 69.8%, with 22 disorders identified. Hypothyroidism (28%), systemic sclerosis (21.6%), and Sjogren syndrome (20.6%) were most common. Low bone density was present in 88.6% of patients. AMA were positive in 84%. Cirrhosis at diagnosis was present in 50.8%. Median MELD score was 12 (IQR 8–17); median liver stiffness was 11.1 kPa (IQR 6.8–17.0). Esophageal varices were present in 24% of non-cirrhotic patients undergoing upper endoscopy. After a median follow-up of 4.1 years (IQR 2.0–8.2), 20% of patients had died; pneumonia (26.2%) and acute upper gastrointestinal bleeding (14.6%) were the main causes. Overlap syndrome decreased from 32.4% in medical records to 13.2% after applying Paris criteria ($p < 0.001$; $\kappa = 0.439$). Paris II response rates increased from 7.8% at baseline to 16.3 and 24.2% at 6 and 12 months respectively (all $p < 0.001$). A total of 75 (15%) patients underwent liver transplantation; recurrence and graft rejection were both 24%. **Conclusion:** In this real-world cohort, patients with PBC showed a substantial burden of symptoms, autoimmune comorbidities, advanced liver disease, and low bone mineral density, suggesting delayed diagnosis. Overdiagnosis of overlap syndrome was identified, potentially leading to overtreatment. Biochemical response at 12 months was low, while differences between 6 and 12-month response suggest delayed biochemical improvement in this setting. These findings may also apply to vulnerable subpopulations within high-income countries.

1194 | NONINVASIVE PREDICTORS OF HISTOLOGICALLY DEFINED PRECLINICAL PRIMARY BILIARY CHOLANGITIS IN AMA-POSITIVE PATIENTS WITH NORMAL ALKALINE PHOSPHATASE

Emily Larrea[1] Maria Gema Crespo Sanchez[1] Maria del Carmen Mendez Diaz[1] Blanca Eimil[1] Leire Sancho[1] Sofía Criado[1] Marta Molero Luis[1] Pablo Puente[1] Verónica Ucle[1] Miriam Romero[1] Pilar Castillo[1] Javier Garcia-Samaniego[1] Sonia Álvarez[1] Marta Abadia[1] Araceli Garcia[1] María Patricia Sanz de Pedro[1] Gemma Serrano[1] Pilar Nozal[1] María Dolores Martín-Arranz[1] Antonio Buño[1] Antonio Olveira[1], [1]La Paz University Hospital, Madrid, Spain

Background: Currently, PBC can be diagnosed in most patients without liver biopsy, based on AMA positivity and elevated ALP. This noninvasive criterion overlooks the subgroup of patients with AMA positivity and normal ALP (N-ALP) but with typical PBC lesions on liver biopsy. ALP and baseline histologic stage are two of the main prognostic factors. Therefore, early identification and treatment of these AMA+/N-ALP patients could lead to better outcomes. To date, reliable noninvasive predictors of preclinical PBC have not been established. **Methods:** Prospective study (Sep/25-Apr/26). Liver biopsy (LB) was offered to consecutive patients followed in the Hepatology clinic at our center for AMA >1:40 and persistently N-ALP. Patients with other liver diseases or who declined LB were excluded. LB was evaluated by two expert hepatopathologists. The results were classified as: 1) typical PBC (chronic nonsuppurative destructive cholangitis ± granulomatous inflammation); they were graded and staged according to Nakanuma; 2) possible PBC (foci of bile duct injury, cholangitis, bile duct loss, and/or portal inflammation); and 3) no PBC (other nonimmune diseases or nonspecific changes). Before LB, blood count, biochemistries, bile acids, autoantibodies, immunoglobulins, CRP, Pro-C3 (Roche Diagnostics), and FGF-19, TNFα, IL-6, IL-12, IL-23 and TGFβ (all by Merck) were assessed. Patients with typical PBC were treated with ursodeoxycholic acid. The study was approved by the center's Research Ethics Committee. All patients provided written informed consent. **Results:** We included 76 patients: 55.9 years, female 65 (85.5%), ALP 78.3 U/L ± 30.8 (ULN 116 U/L). Seven patients (9.2%) were receiving steroids, 9 (11.8) immunosuppressants, 3 (3.9%) anti-TNF therapy, 1 (1.3%) IL-6 inhibitors, and 7 (9.2%) hydroxychloroquine for other conditions. The median LB length was 25 ± 3 mm. Typical PBC was identified in 25/76 patients (32.9%; 95%CI 23.4–44.1; Nakanuma stage I 19 [76%], stage II 6 [24%]), possible PBC in 14 (18.4%), and no PBC in 37 (48.7%). Univariate comparisons of clinically relevant variables between no PBC and possible/typical PBC are shown in Table 1. After adjusting for anti-TNF therapy, AMA ≥1:1280 (OR 22.72 [95%CI 4.49–115.1]; p<0.001), ALP (OR 1.06 [95%CI 1.02–1.1]; p=0.002), and TNFα, (OR 1.36 [95%CI 1.1–1.7]; p=0.010) were independently associated with an AUROC of 0.89 (95%CI 0.81–0.96; Se 85.3%, Sp 78.1%, PPV 80.6%, NPV 83.3%). A simplified model using AMA ≥1:1280 and ALP >75 U/L (≍0.6xULN) retained good discrimination (AUROC 0.81, 95%CI 0.7–0.91), identifying patients with both markers as having an 87% probability of possible/typical histological PBC versus 15% in those with neither marker. **Conclusion:** More than half of patients with AMA positivity and normal ALP have definite or possible PBC on liver biopsy. AMA titer, ALP and TNFα levels may help refine the need for liver biopsy in order to start earlier therapeutic intervention.

Table 1. Univariate comparisons between no PBC and possible/typical PBC

Variable	No PBC (n = 37)	Possible/typical PBC (n = 39)	p value
Age, years (mean ± SD)	53.0 ± 10.5	58.7 ± 11.2	**0.025**

1195 | HEIGHTENED KRÜPPEL-LIKE-FACTOR-6 ALTERS TREG LIPID METABOLISM IN AUTOIMMUNE HEPATITIS

William Li[1] Cortney Cagle[1] Lina Zhang[1] Barbora Gromova[1] Silvia Nastasio[2] Alan Bonder[1] Vilas Patwardhan[1] Simon Robson[1] Maria Serena Longhi[1], [1]Beth Israel Deaconess Medical Center, [2]Boston Childrens Hospital

Background: Autoimmune hepatitis (AIH) is a severe liver disease of unknown etiology that typically follows a relapsing/remitting course and often becomes refractory to immunosuppression. In AIH, regulatory T cell (Treg) impairment contributes to T effector-mediated liver damage. We have previously linked the dysfunction of AIH Tregs to altered response to aryl hydrocarbon receptor (AhR) activation. AhR is a transcription factor that modulates Treg immune responses upon binding its canonical partner, aryl hydrocarbon receptor nuclear translocator (ARNT). AhR also binds to Krüppel-like-factor-6 (KLF6), which modulates the expression of genes involved in lipid metabolism, on which Tregs rely for survival and function. We investigated if KLF6 alterations could contribute to Treg dysfunction in AIH. **Methods:** Tregs were isolated from the peripheral blood of AIH patients and age and sex-matched healthy subjects (HS). Treg KLF6 levels were measured by qPCR, flow cytometry, and western blot. KLF6 and AhR interaction in Tregs was verified by co-immunoprecipitation. Intrahepatic $KLF6^+$ Tregs were identified by immunofluorescence. Treg lipid peroxidation was measured by flow cytometry using BODIPY 581/591 C11 undecanoid acid, in the absence or presence of KLF6 silencing via Silencer Select siRNAs. Treg suppressive function was tested in co-culture experiments and measured as inhibition of $CD4^+$ $CD25^-$ responder cell proliferation. **Results:** KLF6 is upregulated in peripheral Tregs of AIH patients at both mRNA and protein levels. Greater levels of KLF6 are bound to AhR in AIH Tregs compared to HS. Higher frequencies of $KLF6^+$ Tregs are noted in liver biopsies of AIH patients compared to HS. It is known that low peroxidation is usually associated with cell survival, and medium/high peroxidation levels result in increased oxidative damage and cell apoptosis. We therefore tested Treg peroxidation levels and found that compared with HS, AIH Tregs display heightened intracellular lipid peroxidation and higher oxidized-to-nonoxidized lipid ratio. Intracellular lipid peroxidation in AIH Tregs is directly correlated with ALT levels. Silencing of KLF6 using specific siRNAs effectively downregulates lipid peroxidation and ameliorates suppressive function in AIH but not HS Tregs. Analysis of publicly available datasets derived from RNAseq studies conducted on Tregs from healthy subjects showed that high KLF6 levels are associated with gene sets linked to T cell activation and inflammation, including PI3K, ERK and Notch signaling pathways. **Conclusion:** KLF6 is aberrantly upregulated in AIH Tregs that also display heightened lipid peroxidation levels. Blockade of KLF6 limits lipid peroxidation and enhances Treg suppression in AIH Tregs. These data suggest that increased KLF6 expression impacts Treg function by altering lipid peroxidation. Blockade of KLF6 may have therapeutic potential by rebalancing Treg lipid metabolism in AIH.

1196 | POST-LIVER TRANSPLANT OUTCOMES IN PSC-AIH OVERLAP SYNDROME COMPARED WITH ISOLATED PSC: A SYSTEMATIC REVIEW

Haniya Waseem[1] Ramish Rafay[1] Michael Harris[1], [1]Advent Health Tampa

Background: Primary sclerosing cholangitis–autoimmune hepatitis (PSC-AIH) overlap syndrome is a rare autoimmune condition that may progress to end-stage liver disease requiring liver transplantation (LT). Post-transplant outcomes in PSC-AIH remain

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

poorly characterized. We performed a systematic review evaluating post-LT outcomes in PSC-AIH compared with isolated PSC. **Methods:** A PRISMA-guided systematic review protocol was registered on PROSPERO. PubMed, Embase, and Web of Science were searched through January 2026. Of 974 identified records, 32 duplicates were removed. After screening 942 records, 6 full-text studies underwent eligibility assessment and 3 comparative studies were included in the qualitative synthesis. Adult studies reporting LT outcomes in PSC-AIH with a direct PSC comparator group were included. Outcomes extracted included recurrent PSC (rPSC), graft rejection, patient survival, graft survival, and mortality. **Results:** Three retrospective comparative studies comprising over 390 total patients, including approximately 58 PSC-AIH patients, were included. PSC-AIH patients appeared younger at diagnosis and more frequently female compared with isolated PSC cohorts. Across included studies, reported post-LT rPSC rates ranged from 16.6–50.0% in PSC-AIH compared with 19.2–41.3% in isolated PSC cohorts. Rejection rates were also broadly comparable between groups, including chronic rejection rates of 8.0% versus 26.0% and 26.0% versus 17.0% in two cohorts . Mortality outcomes remained similar across studies, with no significant differences in post-transplant patient or graft survival between PSC-AIH and isolated PSC cohorts. (See Table).Disease recurrence remained an important post-transplant complication across studies. **Conclusion:** PSC-AIH overlap syndrome is a progressive autoimmune cholangiopathy that may require LT despite immunosuppressive therapy. Available comparative evidence suggests broadly comparable post-transplant outcomes between PSC-AIH overlap syndrome and isolated PSC, supporting similar therapeutic and surveillance strategy in this population including LT. Larger multicenter prospective studies are needed to better define recurrence risk and long-term outcomes.

Table 2. Summary of Post-Transplant Outcomes Across Included Studies

Study	PSC-AIH (n)	PSC Comparator (n)	rPSC (PSC-AIH vs PSC)	Rejection (PSC-AIH vs PSC)	Mortality (PSC-AIH vs PSC)
Dhanji et al. (2013)	5	84	50.0% vs 29.0%	Chronic rejection: 8.0% vs 26.0%	0.0% vs 19.0%
Péverelle et al. (2025)	47	216	41.8% vs 41.3% p: 0.46	Chronic rejection: 26.0% vs 17.0% p: 0.15	10.6% vs 26.2% p: 0.023
Choudhary et al. (2020)	6	26	16.6% vs 19.2% p: 1.0	Acute rejection: 33.3% vs 12.5% p: 0.245 Chronic rejection: 0.0%	16.6% vs 15.3% p: 1.0

PSC = recurrent primary sclerosing cholangitis

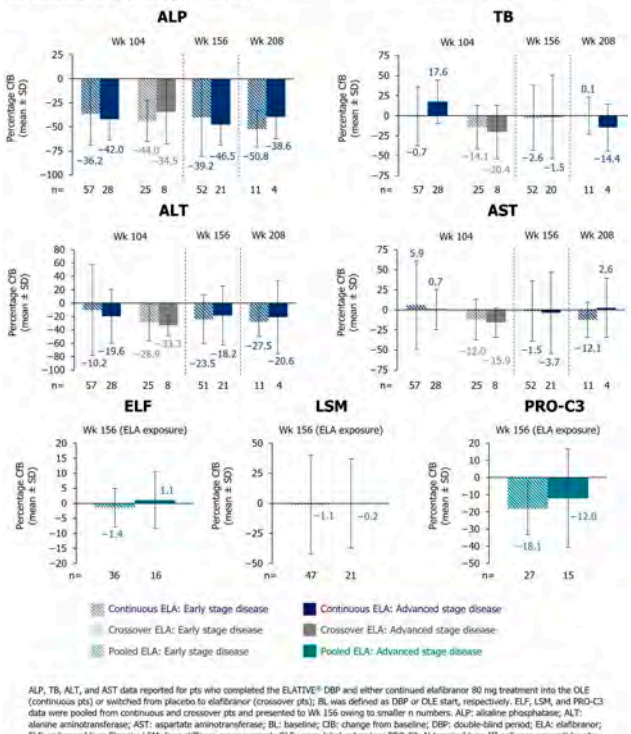
1197 | ELAFIBRANOR IMPROVES MARKERS OF DISEASE ACTIVITY IN PRIMARY BILIARY CHOLANGITIS ACROSS DISEASE STAGES IN PATIENTS WITH UP TO 4 YEARS OF TREATMENT

Marlyn Mayo[1] Kris Kowdley[2] Christopher Bowlus[3] John Vierling[4] Ira Jacobson[5] Nuno Antunes[6] Darren Asquith[7] Seema Jaitly[7] Nathan Touati[8] Cynthia Levy[9], [1]University of Texas Southwestern Medical Center, Dallas, TX, USA, [2]Liver Institute Northwest, Seattle, WA, USA, [3]Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, CA, USA, [4]Departments of Medicine and Surgery, Baylor College of Medicine, Houston, TX, USA, [5]Division of Gastroenterology and Hepatology, NYU Langone Health, New York, NY, USA, [6]Ipsen, Cambridge, MA, USA, [7]Ipsen, London, UK, [8]Ipsen, Paris, France, [9]Schiff Center for Liver Diseases, University of Miami, Miami, FL, USA



Background: Elafibranor is a second-line treatment for primary biliary cholangitis (PBC). In the phase III ELATIVE® trial (NCT04526665), elafibranor improved markers of disease activity through 52 weeks (wks) in patients (pts) with early or advanced stage PBC at baseline (BL). We evaluated the efficacy and safety of elafibranor, stratified by disease stage at BL, up to Wk 208 (Year 4) of the ELATIVE® open-label extension (OLE). **Methods:** Pts who completed the ELATIVE® double-blind period (DBP) and continued elafibranor 80 mg treatment into the OLE (continuous pts) or switched from placebo to elafibranor (crossover pts) were included; BL was defined as DBP or OLE start, respectively. PBC disease stage was categorized as early or advanced based on liver stiffness measurement (LSM; $\leq$10 or >10 kPa) or histology (Nakanuma fibrosis score <2 [absent/mild fibrosis] or $\geq$2 [bridging fibrosis/cirrhosis]) among pts with a liver biopsy. Mean (standard deviation [SD]) percentage change from BL (CfB) in biochemical markers were reported up to Wk 208. Due to low pt numbers at Wk 208, achievement of biochemical response (alkaline phosphatase [ALP] <1.67× upper limit of normal [ULN] with $\geq$15% reduction from BL, and total bilirubin [TB] $\leq$ULN) and ALP normalization were reported to Wk 156. Data for continuous and crossover pts were pooled for percentage CfB in non-invasive tests (NITs) of fibrosis, also reported to Wk 156. Safety findings were reported to Wk 208. **Results:** For continuous and crossover elafibranor pts, 73 and 31 had early stage and 35 and 14 had advanced stage disease at BL. Pts with advanced vs early stage disease had higher mean (SD) ALP levels at BL (continuous pts: 351.9 [109.1] U/L vs 306.6 [125.7] U/L; crossover pts: 345.9 [162.8] U/L vs 331.3 [200.6] U/L). For continuous pts with early vs

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

advanced stage disease, 73.1% vs 52.4% had biochemical response and 28.9% vs 23.8% had ALP normalization at Wk 156. Through Wk 208, continuous pts across disease stages had reductions in ALP and alanine aminotransferase, while TB and aspartate aminotransferase remained stable. In crossover pts with early vs advanced stage, 60.0% vs 37.5% had biochemical response at Wk 104; 24.0% vs 25.0% had ALP normalization. Reductions in biochemical markers were seen in the OLE across disease stages in crossover pts (**Figure**); trends in ALP reductions to Wk 52 were similar to those who received elafibranor in the DBP. In pooled analysis of continuous and crossover pts, mean enhanced liver fibrosis scores, LSM, and PRO-C3 values were stable in both the early and advanced stage disease groups during 156 wks of elafibranor exposure (**Figure**). Elafibranor was well tolerated across early and advanced disease stages. **Conclusion:** Elafibranor was well tolerated and provided a consistent treatment effect regardless of disease stage for up to 4 years, with stabilization or improvements in markers of disease activity and NITs of fibrosis.

Figure. Percentage change from baseline in biochemical markers of disease activity up to Week 208 and non-invasive tests of fibrosis up to Week 156

ALP, TB, ALT, and AST data reported for pts who completed the ELATIVE® DBP and either continued elafibranor 80 mg treatment into the OLE (continuous pts) or switched from placebo to elafibranor (crossover pts); BL was defined as DBP or OLE start, respectively. ELF, LSM, and PRO-C3 data were pooled from continuous and crossover pts and presented to Wk 156 owing to smaller n numbers. ALP: alkaline phosphatase; ALT: alanine aminotransferase; AST: aspartate aminotransferase; BL: baseline; CfB: change from baseline; DBP: double-blind period; ELA: elafibranor; ELF: enhanced liver fibrosis; LSM: liver stiffness measurement; OLE: open-label extension; PRO-C3: N-terminal type III collagen propeptide; pts: patients; SD: standard deviation; TB: total bilirubin; Wk: Week.

1198 | INTERFERON-DRIVEN EXPANSION OF CD169⁺ MONOCYTES AND HEPATIC MACROPHAGES IS ASSOCIATED WITH DISEASE ACTIVITY IN AUTOIMMUNE HEPATITIS

Gil Won Lee[1] Pil Soo Sung[2] Jeong Won Jang[3] Ji Won Han[3] Kwon Yong Tak[3] Mi Hyun Kwon[1] Gawon Han[1] Hee Sun Cho[3], [1]The Catholic University Liver Research Center, [2]Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic Korea, [3]Seoul St. Mary's Hospital, The Catholic University of Korea

Background: Autoimmune hepatitis (AIH) is driven by intrahepatic interferon signaling, antigen presentation, and T cell–mediated hepatocellular injury, yet the

inflammatory macrophage phenotypes shaped within this milieu remain undefined. CD169 (Siglec-1), a type I interferon-inducible sialic acid–binding lectin, marks an inflammatory antigen-presenting monocyte/macrophage phenotype linked to disease activity in other autoimmune disorders but is uncharacterized in AIH. This study aimed to investigate the functional characteristics, and clinical relevance of CD169$^+$ monocytes in patients with AIH. **Methods:** PBMCs and liver biopsy samples were obtained from AIH patients and healthy controls. CD169$^+$ total monocyte frequency was quantified by flow cytometry (Normal; $n = 5$, AIH; $n = 29$) and correlated with clinical parameters; paired PBMC–liver tissue analyses were performed in matched cases. Liver tissue mRNA of CD169, IFN-γ, CD14, and lymphocyte/NK markers (CD3/CD4/CD8/CD56) was assessed by qRT-PCR. CD169 was evaluated by immunohistochemistry (IHC) in 25 AIH biopsies stratified by portal–periportal activity (Low; $n = 10$, High; $n = 15$), with CD68 co-staining for macrophage localization. Sorted CD14$^+$ monocytes from healthy donors were stimulated with recombinant IFN-α, IFN-β, or IFN-γ (10–30 ng/mL, 24–72 h) to assess CD169 induction in vitro. **Results:** The frequency of CD169$^+$ total monocytes was significantly higher in AIH PBMCs than in healthy controls ($p < 0.05$). CD169$^+$ total monocyte frequency correlated positively with serum AST ($R = 0.43$, $p = 0.024$), ALT ($R = 0.45$, $p = 0.020$), and total bilirubin ($R = 0.47$, $p = 0.013$). In paired samples, the CD169$^+$ proportion of monocytes was significantly higher in liver tissue than in matched PBMCs ($p < 0.05$). qRT-PCR of AIH livers showed elevated CD169, IFN-γ, CD14, and lymphocyte/NK marker mRNA compared with normal livers. IHC demonstrated that the CD169$^+$ area was significantly greater in livers with high portal–periportal inflammatory activity than in those with low activity ($p = 0.0219$) and co-localized with CD68$^+$ macrophage-rich regions. In vitro, IFN-γ induced CD169 on sorted CD14$^+$ monocytes time- and dose-dependently; type I interferons (IFN-α, IFN-β) elicited even more potent induction ($> 85\%$ CD169$^+$ at 48–72 h), consistent with Siglec-1 as a canonical type I IFN response gene, while IFN-γ also produced robust induction. **Conclusion:** CD169$^+$ inflammatory monocytes/macrophages are expanded in the circulation of AIH patients, further enriched within the inflamed liver, and tightly linked to biochemical and histological measures of hepatic injury. Both type I and type II interferons drive their induction, defining CD169$^+$ cells as an IFN-driven inflammatory macrophage phenotype that integrates the interferon, antigen-presenting, and T cell–dominated immunopathology of AIH. This phenotype may therefore serve as a clinically relevant biomarker and a therapeutic target in AIH.

1199 | MODERATE TO SEVERE FATIGUE IS COMMON AND IMPACTFUL, BUT UNDER-RECORDED IN MEDICAL RECORDS OF PATIENTS WITH PRIMARY BILIARY CHOLANGITIS (PBC)

Channa Jayasekera[1] Cynthia Levy[2] Seema Meloni[3] Deborah Nikolla[3] Christelle Pommie[4] Sophia Abner[5] Joy Chen[5] Philip Troke[6] Christopher Bowlus[7], [1]Division of Gastroenterology and Hepatology, Mayo Clinic Arizona, Phoenix, Arizona, USA, [2]Schiff Center for Liver Diseases, University of Miami, Miami, Florida, USA, [3]Ipsen, Cambridge, Massachusetts, USA, [4]Ipsen, Paris, France, [5]PicnicHealth, San Francisco, California, USA, [6]Ipsen, London, UK, [7]Division of Gastroenterology & Hepatology, UC Davis School of Medicine, Sacramento, California, USA

Background: Fatigue affects up to 80% of patients with primary biliary cholangitis (PBC), with 20% experiencing severe fatigue unrelieved by rest. It substantially impacts daily functioning, work productivity, and emotional well-being. Fatigue correlates poorly with biochemical and histologic markers of PBC, may occur early, and is historically under-recorded in medical records due to a lack of systematic assessment and few effective targeted therapies. We quantify the gap between patient-reported and physician-documented fatigue utilizing data from the PicnicHealth PBC Registry. **Methods:** Cross-sectional, non-interventional analysis of secondary data from the PicnicHealth PBC Registry. Adult US participants with confirmed PBC enrolled January 2021-May 2022 who completed the PBC-40 Fatigue Domain were included, with longitudinal medical record data through August 2025. Index date was date of the first completed PBC-40 Fatigue Domain. PBC-40 fatigue severity was categorized as none (0–11), mild (12–28), moderate (29–39), or severe (≥ 40); moderate-to-severe was ≥ 29. Medical record–documentation (MRD) of fatigue refers to fatigue captured in the medical record on or before index. Clinico-demographic characteristics, fatigue-related treatment use (antidepressants, stimulants, sleep aids), and other PBC-40 domains were summarized descriptively. **Results:** 210 participants were included (at index, mean age was 57 [SD 11] years; 98% female; 93% White; 44% with cirrhosis; mean ALP 157 [SD 131] IU/L; 99% prior UDCA). Mild to severe fatigue was reported in the PBC-40 in 204

(97%); of these, 166 (81%) reported moderate-to-severe fatigue (**Table**). None of the 6 patients reporting no PBC-40 fatigue had MRD fatigue. Of participants with any PBC-40 reported fatigue, only 93 (46%) had MRD fatigue: 14/38 (37%) with mild fatigue and 79/166 (48%) with moderate-to-severe fatigue, leaving 111 (54%) overall under-recorded. Greater fatigue severity was associated with broader moderate-to-severe impairment across other PBC-40 domains in patients with severe vs mild fatigue: cognitive (89% vs 37%), emotional (93% vs 37%), social (86% vs 11%), itch (70% vs 21%), general symptoms (44% vs 11%). Fatigue-related treatments were more frequently utilized in participants with MRD vs those without: antidepressants 70% vs 44%, sleep aids 48% vs 18%, stimulants 11% vs 5%. **Conclusion:** Almost all patients in the included study cohort reported fatigue. Despite 81% reporting moderate-to-severe fatigue, over half had no medical record documentation, indicating substantial under-recording. Greater fatigue severity was associated with broader health-related quality of life impairment across cognitive, emotional, social, and itch domains. These findings highlight an unmet need for improved fatigue assessment, documentation, and intervention as part of PBC care.

Table. Demographics and Clinical Characteristics by Overlap in Fatigue Documentation Source

Background: Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease featuring bile duct strictures that lead to hepatic injury, cirrhosis, and liver failure. Cholestatic pruritus is a common and burdensome symptom in PSC that negatively impacts patients' quality of life (QoL), work productivity, activities of daily living, and interpersonal relationships. Volixibat (VLX), a minimally absorbed ileal bile acid transporter inhibitor, interrupts enterohepatic bile acid recirculation. Initial results from the VISTAS study showed statistically significant and clinically relevant improvements in pruritus after treatment with VLX using the Adult Itch Reported Outcome (Adult ItchRO) assessment in participants with moderate-to-severe pruritus. Here, we report pruritus results across multiple patient-reported outcome measures in both the primary and secondary cohorts. **Methods:** VISTAS is a 28-week randomized, multicenter, double-blind, placebo (PBO)-controlled Phase 2b study in participants with PSC and cholestatic pruritus. Following dose selection period and blinded interim analysis, the confirmatory portion evaluated oral VLX 20 mg BID versus PBO. Participants were enrolled into primary (moderate-to-severe pruritus) and secondary (mild pruritus) cohorts based on baseline symptom severity. This analysis evaluated pruritus outcomes across the Adult ItchRO, 5 Dimension-Itch (5D-Itch), and Patient Impression of Severity-Itch (PIS-Itch) measures in both cohorts using mixed models repeated measures and descriptive statistics. **Results:** 111 participants with moderate-to-severe pruritus and 47 with mild pruritus were randomized into the primary (VLX = 54; PBO = 57) and secondary (VLX = 23; PBO = 24) cohorts, respectively. In the primary cohort, significant improvements in pruritus (LS mean [SE]) were observed across all three assessment tools (Adult ItchRO: VLX: -2.72 [0.240], PBO: -1.08 [0.241], $P < 0.0001$; 5D-Itch: VLX: -4.47 [0.755], PBO: -0.83 [0.717], $P = 0.0005$; PIS-Itch: VLX:-0.70 [0.138], PBO: -0.24 [0.131], $P = 0.0142$). Similar improvements were observed in the secondary cohort (Adult ItchRO: VLX:-1.38 [0.1803], PBO:-0.75 [0.1686], $P = 0.0138$; 5D-Itch: VLX:-2.853[0.7351], PBO:-0.2600[0.6432], $P = 0.0108$; PIS-Itch: VLX:-0.3423[0.1661], PBO:-0.02821[0.1384] , $P = 0.1648$). **Conclusion:** These results demonstrate improvements in pruritus with VLX in patients with PSC across all severities of pruritus using multiple assessment tools.

1201 | REAL-WORLD SURVEY IN PATIENTS WITH PSC ASSESSING THE IMPACT OF PRURITUS ON WORK PRODUCTIVITY IN FRANCE, GERMANY, ITALY AND THE UNITED STATES

Marlyn Mayo[1] Marco Carbone[2] Will Johnson[3] Lena Amari[3] Guy Lacey[4] Jolan Terner-Rosenthal[4] Jonathan Ieyoub[4] Lucia Quadrado[4] Robin Howard[4] Verena Keitel[5], [1]University of Texas Southwestern Medical Center, [2]University of Milano-Bicocca, ASST GOM Niguarda, [3]Adelphi Real World, [4]Mirum Pharmaceuticals, Inc., [5]University Hospital Magdeburg

Background: Primary sclerosing cholangitis (PSC) is a chronic, progressive liver disease characterized by damage to intra- and extrahepatic bile ducts. One of the most burdensome PSC symptoms is pruritus, with studies indicating almost 90% of patients with PSC have experienced pruritus at some point in their lives. A recent physicians survey reported that 42% of their patients with PSC had pruritus and almost all physicians (90%) believe that pruritus has a profound impact on a patient's quality of life (QoL). However, there are limited specific data on the impact of pruritus on work productivity. The purpose of the current study is to describe the burden of pruritus on the ability to work and impairment of daily activities among patients with PSC. **Methods:** Data were extracted from the Adelphi Real World PSC Disease Specific Programme™, a cross-sectional survey with retrospective data collection of adult patients ($\geq$18 years old) with PSC in France, Germany, Italy, and the United States from November 2024 to April 2025. The current presentation is focused on patients' perceptions around the impact pruritus had on their ability to work and impairment of activities utilizing the standardized Work Productivity and Activity Impairment (WPAI) assessment tool. Analyses used bivariate and descriptive statistics. **Results:** Results from 187 patients with PSC (Germany: n = 87; France: n = 40; US: n = 36; Italy: n = 24) who had the opportunity to complete the WPAI were included in this analysis. 74% of patients reported pruritus in the last 24 hours (via a numeric rating scale) prior to the survey. Almost 30% (mean: 29.8 [SD: 24.63]) of patients with PSC reported impairment while working, with the highest levels observed in Germany (32.0 [20.12]) and the US (35.8 [30.78]). Similar results were reported in overall work impairment (Global: 30.4 [28.11]; Germany: 34.5 [26.80]; US: 37.8 [33.14]) and activity impairment (Global: 28.7 [23.31]; Germany: 30.8 [20.82]; US: 31.7 [26.67]). Globally, an average of 7.5% (SD: 18.17) of patients with PSC missed work time with the highest impact observed in Germany (mean [SD]; 9.0 [21.53] and the US (8.2 [18.88]). When looking specifically at the impact of pruritus on WPAI,

there was a significantly greater burden in those currently experiencing pruritus in percent missed work time (pruritus: 10.3 [21.21]; no pruritus: 1.4 [4.37]; P = 0.033), impairment while working (pruritus: 34.3 [24.91]; no pruritus: 16.7 [18.63]; P = 0.0005), overall work impairment (pruritus: 36.5 [29.69]; no pruritus: 17.7 [19.36]; P = 0.0035), and activity impairment (pruritus: 35.0 [22.48]; no pruritus: 13.4 [17.45]; P < 0.0001). **Conclusion:** These initial data highlight the considerable impact that PSC symptoms, and more specifically pruritus, have on patients' ability to work and their daily activities.

1202 | THE TL1A-DR3 AXIS IS ENGAGED IN PRIMARY SCLEROSING CHOLANGITIS, PROVIDING A RATIONALE FOR ANTI-TL1A THERAPY

Michail Kokkorakis[1] Suyavaran Arumugam[1] Wajahat Mehal[1] Bubu Banini[1] Saumya Srivastava[1] Aida Rodriguez Murillo[1], [1]Yale University

Background: Primary sclerosing cholangitis (PSC) has no approved targeted therapy and frequently progresses to liver disease requiring transplant. Anti-TL1A monoclonal antibodies, including tulisokibart (MK-7240), have shown phase 2 efficacy in IBD, with phase 3 programs underway. 60–80% of patients with PSC have concurrent IBD, which has risk alleles for the TL1A gene (TNFSF15). PSC and IBD share Th1/Th17 epithelial inflammation and fibrogenesis at gut and biliary surfaces. We tested whether there is evidence for engagement of the TL1A-DR3 axis in PSC by examining plasma from patients with PSC, other autoimmune diseases, and healthy controls. **Methods:** Plasma from 110 subjects (43 PSC, 24 PBC, 23 AIH, 20 healthy; 199 samples across two timepoints) was analyzed: TL1A ELISA, a 21-analyte Luminex panel including soluble DR3 (TNFRSF25). In plasma from subjects with 30 PSC (at two time points), and 20 controls, further analysis was performed by Olink Explore HT (5,416 proteins). Within-PSC activity was classified by alkaline phosphatase (ALP) $\geq$ 1.5× ULN. Group comparisons used Kruskal-Wallis / Mann-Whitney; differential protein abundance and ALP correlations applied Benjamini-Hochberg correction across 5,416 proteins. **Results:** Plasma TL1A was detectable above LOD in 33% of PSC samples, 25% of PBC, 13% of AIH, and 0% of controls (PSC vs control q = 0.008; PBC vs control q = 0.037; Fig. A). Soluble DR3 was reduced in PSC vs controls (median 129 vs 326 pg/mL, q = 0.014). Across 132 matched same-patient samples, plasma TL1A and soluble DR3 were inversely correlated (Spearman ρ = −0.18, p = 0.035). On a curated TL1A-DR3 pathway protein set (Olink Explore HT; Fig. B), PSC plasma showed BH q < 0.05 elevation of the decoy receptor DcR3 (TNFRSF6B), Th1 effectors CXCL9, CXCL10 and granzyme B, Th17 cytokine IL-17A, TNF-superfamily co-stimulators OX40 (TNFRSF4) and 4-1BB (TNFRSF9), innate cytokines IL-12p40 (IL12B) and IL-18, and fibrosis marker TIMP-1, with TNFSF15 itself directionally elevated. Within PSC, 82 of 5,416 proteins distinguished ALP-Active from Quiescent samples (q < 0.05), led by biliary epithelial markers (GGT1, ANPEP, CXADR, CEACAM1, and KRT18); 418 proteins correlated with continuous ALP (q < 0.05). Plasma TL1A separated PSC from controls at the cohort level but did not track within-PSC biochemical activity (ρ with ALP $\asymp$ 0). **Conclusion:** Across three orthogonal platforms (ELISA, Luminex, Olink), PSC plasma shows concordant evidence of TL1A-DR3 axis engagement: ligand elevation, decoy-receptor (DcR3) elevation, soluble DR3 depletion, and a coherent downstream Th1/Th17/TNF-superfamily/fibrosis pathway signature. Together with TNFSF15 genetic risk in IBD and overlapping cholangiocyte–intestinal epithelial biology, these data support repurposing anti-TL1A therapy for PSC, with plasma TL1A as a candidate enrollment biomarker and the pathway-protein signature as a pharmacodynamic readout for clinical trials.

Figure. Plasma evidence of TL1A-DR3 axis engagement in PSC. (A) Plasma TL1A detection rate (≥ LOD 18.75 pg/mL) by group; Fisher's exact vs control, BH-adjusted. (B) Curated TL1A-DR3 pathway proteins (Olink Explore HT) grouped by functional class. NPX (Normalized Protein eXpression) is Olink's arbitrary log2-scale unit of relative protein abundance. Bars = median NPX (log2) difference for PSC vs Control (first TP, n = 30 vs 20; left) and ALP-Active vs Quiescent PSC (n = 24 vs 36; right). Bars extending right indicate higher protein abundance in PSC (left panel) or Active PSC (right panel). Asterisks = BH q < 0.05 within the pathway panel.

1203 | PREVALENCE OF INDEPENDENTLY ASSESSED PATIENT-REPORTED OUTCOMES IN SUBJECTS WITH CHOLESTATIC LIVER DISEASE AND THEIR IMPACT ON HEALTH-RELATED QUALITY OF LIFE

Paulo Bittencourt[1] Debora Terrabuio[2] Claudia Couto[3] Vivian Rotman[4] Liana Codes[1] Eduardo Cancado[2] Guilherme Cancado[3] Michele Braga[2] Luciana Faria[3] Andreia Evangelista[4] Maria Lucia Ferraz[5], [1]Escola Bahiana de Medicina e Saúde Pública, Bahia, Brazil; Hospital Português, Bahia, Brazil, [2]Faculdade de Medicina da Universidade de São Paulo, São Paulo, Brazil, [3]Hospital das Clínicas, Universidade Federal de Minas Gerais, Brazil, [4]Faculdade de Medicina, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [5]Universidade Federal de São Paulo, São Paulo, Brazil

Background: Patient-reported outcomes (PROs), such as pruritus, fatigue, and sleep disturbances, are often underreported and overlooked in clinical practice despite their detrimental impact on health-related quality of life (HRQoL). **Aims**: To investigate the prevalence of these PROs in patients with primary biliary cholangitis (PBC) and primary sclerosing cholangitis (PSC), independently assessed by healthcare personnel not involved in patient care, and to evaluate their impact on HRQoL. **Methods:** Clinical, demographic, and laboratory data were obtained from medical records of patients with PBC and PSC from five referral centers in Brazil. All participants underwent structured interviews conducted by independently trained healthcare personnel using the 5-D Itch Scale, ItchRO, PROMIS Fatigue Short Form (7a), PROMIS Sleep Disturbance Short Form (7b), and the Chronic Liver Disease Questionnaire–Brazilian version (CLDQ-BR). **Results:** A total of 325 patients (265 females; mean age 57 ± 15 years) were included, of whom 238 had PBC (214 females; mean age 61 ± 14 years) and 79 had PSC (55 females; mean age 47 ± 16 years). Lifetime self-reported itching and fatigue were observed in 78% and 71% of patients with PBC and in 75% and 72% of patients with PSC, respectively. Overall, itching in the last month was reported by 106 (33%) patients, with mean ItchRO and 5-D Itch scores of 3 [0–7] and 13 ± 5, respectively. Mean T-scores for PROMIS Fatigue (7a), Sleep Disturbance (7b), and mean CLDQ-BR scores were 44 ± 8, 52 ± 12, and 147 ± 39, respectively. Patients reporting itching in the last month had higher PROMIS Fatigue T-scores (46.5 ± 8.3 vs. 42.6 ± 8.3; $p < 0.001$) and higher PROMIS Sleep Disturbance T-scores (54.2 ± 12.7 vs. 51.0 ± 12.3; $p = 0.035$) compared to those without pruritus. Additionally, CLDQ-BR scores were significantly lower among patients with pruritus (131.2 ± 39.2 vs. 154.3 ± 36.1; $p < 0.001$), indicating worse HRQoL. Moreover, patients with pruritus had significantly higher levels of AST, ALT, ALP and total bilirubin. **Conclusion:** Pruritus is a common and clinically significant symptom in patients with PBC and PSC, strongly associated with impaired HRQoL, fatigue, and sleep disturbance. Routine and independent assessment of PROs should be incorporated into clinical care to better identify and manage this burden.

1204 | PSC SYMPTOM BURDEN AND SEVERITY ARE PREDICTORS OF ACUTE CHOLANGITIS POST-TREATMENT OUTCOMES INDEPENDENT OF ANTIBIOTIC USE AND HOSPITALIZATION

Brian Thorsen[1] Martine Walmsley[2] David Assis[3] Nora Cazzagon[4] Veronica Miller[5] Michael Trauner[6] Stephen Rossi[1], [1]PSC Partners Seeking a Cure, [2]PSC Support UK, [3]Yale University, [4]University Hospital Policlinico

Consorziale, [5]Forum for Collaborative HIV Research, [6]Medical University of Vienna

Background: Acute cholangitis (AC) is a significant but poorly understood complication of PSC, partly due to the lack of standardized diagnostic and treatment criteria. Proposed diagnostic criteria include worsening liver pain, fever/chills, and other abdominal pain along with LFTs, WBC, and antibiotic use. Despite its frequency, little is known about the patient symptom experience of AC or its relationship to post-treatment outcomes. In prior survey analyses, we found a broader range of symptoms occurring during AC. Here, we further analyze how symptoms during AC relate to post-treatment outcomes, as an initial step toward a simplified risk score. **Methods:** A survey of adults with PSC and ≥ 1 AC episode, distributed by PSC Partners Seeking a Cure and PSC Support UK, captured patient characteristics, AC symptom frequency/severity, antibiotic use, medical interventions, hospitalization, and return to baseline health. A simple screening tool captured the incidence and severity of key symptoms at their worst during the most recent AC episode. Patient-reported outcomes were a return to baseline health, assessed by a binary Patient Global Impression of Change (PGIC) in patients with ≥ 30 days of follow-up. Antibiotic use included oral and/or IV treatment received in a medical facility or self-administered at home. Logistic regression models were used to predict PGIC using the presence and severity of Core Symptoms (CSx: fever/chills, RUQ pain, other abdominal pain) and the aggregate of 6 Expanded Symptoms (ESx: fatigue, other pain/aches, nausea, pruritus, brain fog, jaundice). Model performance was evaluated by area under the ROC curve (AUC), with symptom-based models adjusted for antibiotic use and hospitalization. **Results:** Among 366 respondents, baseline characteristics were consistent with an adult PSC population by sex, age, race/ethnicity, PSC duration, and IBD status. Worsened post-AC health status by PGIC was reported by 28%. Only 45% had all three CSx; 31% had two, 20% had one, and 3% had none. The most frequent CSx was RUQ pain (65%), followed by fever/chills (60%) and other abdominal pain (48%). Antibiotics were used in 63% of patients (oral 37%, IV 5%, IV+oral 53%) and 20% were hospitalized (inpatient or ICU). ESx predicted worsening PGIC better than CSx, even adjusting for antibiotic use or hospitalization (Table 1). Combining CSx and ESx further improved predictive power. Individual ESx showed similar predictive value, but their aggregate performed best. Antibiotic use or hospitalization alone was less predictive than any symptom-based model. **Conclusion:** Patient-reported symptoms predict post-AC health status even without clinical or laboratory data and provide a foundation for a practical risk model. The proposed model uses a simple symptom screening tool that could be readily incorporated into practice. Next steps include model refinement and prospective collection of clinical, laboratory, and additional outcome data.

Table 1: Symptom Burden Logistic Regression Model Performance

Variables in LR Model	Area Under Curve (AUC)	AUC Adjusted for Antibiotics	AUC Adjusted for Hospitalization
Core Symptoms	0.63	0.67	0.68
Expanded Symptoms	0.71	0.72	0.73
Core + Expanded Symptoms	**0.72**	**0.73**	**0.74**

1205 | FEMALE SEX AND HISPANIC ETHNICITY INDEPENDENTLY PREDICT ADVERSE WAITLIST OUTCOMES DESPITE INCREASED TRANSPLANT ACCESS IN PRIMARY BILIARY CHOLANGITIS: A UNOS COMPETING-RISK ANALYSIS

Christopher Dorizas[1] Jade Pace[2] Michael Attanasi[1] Sanjaya Satapathy[3], [1]Zucker School of Medicine at Hofstra/Northwell, [2]Northwell North Shore University Hospital/Long Island Jewish Medical Center, [3]Northshore University Hospital/Northwell Health

Background: Primary biliary cholangitis (PBC) is a female-predominant cholestatic liver disease in which MELD-based allocation may incompletely capture physiologic vulnerability. We evaluated waitlist and post-transplant outcomes among PBC versus non-PBC candidates using competing-risk methods in a national transplant cohort. **Methods:** Adult liver transplant candidates listed in the MELD-era UNOS/OPTN STAR database were identified. Candidates with prior liver transplantation, multiorgan listing, malignancy-related etiologies, or graft failure were excluded. Primary analyses excluded hepatocellular carcinoma. Fine-Gray models evaluated waitlist death/dropout and transplant access while accounting for transplantation as a competing event. Interaction analyses assessed whether sex or MELD strata modified associations between PBC and waitlist outcomes. Cause-specific Cox models served as sensitivity analyses. Kaplan-Meier analyses evaluated post-transplant patient and graft survival. **Results:** A total of 33,588 waitlist candidates without hepatocellular carcinoma were included, including 1,045 with PBC. Compared with non-PBC candidates, PBC patients were older, predominantly female, and had lower MELD scores, creatinine levels, and portal hypertensive burden at listing. Although PBC candidates had worse unadjusted waitlist outcomes despite lower MELD severity, PBC was not independently associated with cumulative waitlist death/dropout after multivariable competing-risk adjustment (SHR 0.96, 95% CI 0.79–1.16, p = 0.66). In contrast, PBC independently predicted greater transplant access (SHR 1.27, 95% CI 1.17–1.37, p < 0.0001). Female sex independently predicted higher waitlist mortality (SHR 1.16, 95% CI 1.08–1.25, p < 0.0001) and lower transplant access (SHR 0.91, 95% CI 0.88–0.94, p < 0.0001). Hispanic ethnicity similarly predicted higher waitlist mortality (SHR 1.31, 95% CI 1.20–1.43, p < 0.0001) and lower transplant probability (SHR 0.84, 95% CI 0.80–0.87, p < 0.0001). No significant interactions were observed between PBC and sex or MELD category. Cause-specific Cox models showed modestly increased mortality hazard among PBC candidates, suggesting that greater transplant access may mitigate cumulative mortality risk. Post-transplant analyses showed superior patient and graft survival among PBC recipients (both log-rank p < 0.0001). **Conclusion:** PBC was not independently associated with cumulative waitlist mortality after competing-risk adjustment, but was associated with greater transplant access and excellent post-transplant outcomes. Female sex and Hispanic ethnicity independently predicted adverse waitlist outcomes and reduced transplant access across models, suggesting that demographic and physiologic vulnerability may drive persistent MELD-era disparities more than liver disease etiology itself.

Table 1. Multivariable Fine-Gray Competing-Risk Model for Waitlist Death or Dropout Among Adult Liver Transplant Candidates

Variable	Subdistribution Hazard Ratio (sHR)	95% Confidence Interval	P value
Primary biliary cholangitis (PBC)	0.96	0.79–1.16	0.66
Age at listing (per year)	1.04	1.04–1.05	<0.001
Female sex	1.16	1.08–1.25	<0.001
Race/Ethnicity			
— Hispanic vs White	1.31	1.20–1.43	<0.001
— Black vs White	1.02	0.86–1.20	0.85
— Asian vs White	1.03	0.82–1.29	0.80
— Other/Unknown vs White	0.96	0.77–1.20	0.71
MELD score at listing (per point)	1.03	1.02–1.03	<0.001
Serum sodium (per mmol/L)	1.02	1.01–1.03	<0.001
Serum albumin (per g/dL)	0.82	0.76–0.87	<0.001
Body mass index (per kg/m²)	1.01	1.00–1.01	0.08

Statistical analysis:

Fine-Gray competing-risk regression analysis evaluating factors associated with waitlist death or dropout. Liver transplantation was treated as a competing event.

Interpretation:

Primary biliary cholangitis was not independently associated with increased waitlist mortality after multivariable adjustment. Female sex and Hispanic ethnicity were independently associated with increased risk of waitlist death or dropout.

1206 | LIVER ATROPHY PROVIDES INCREMENTAL PROGNOSTIC VALUE BEYOND MELD IN SEVERE ACUTE AUTOIMMUNE HEPATITIS AND AIH-RELATED ACUTE LIVER FAILURE

Keisuke Ojiro[1] Ko Goto[1] Rei Shimizu[1] Makoto Ueno[1] Yukie Nakadai[1] Takaya Tabuchi[1] Ryosuke Kasuga[1] Nobuhito Taniki[1] Shingo Usui[1] Nobuhiro Nakamoto[1] Takanori Kanai[1], [1]Keio University

Background: Liver atrophy is frequently observed in patients with severe acute autoimmune hepatitis (SA-AIH) and AIH-related acute liver failure (AIH-ALF). However, its clinical significance and prognostic impact remain poorly characterized. We aimed to evaluate the prognostic significance of liver atrophy and its incremental value beyond MELD score in patients with SA-AIH/AIH-ALF. **Methods:** We retrospectively analyzed data from a nationwide survey of acute liver failure in Japan. Acute liver failure was defined as PT-INR ≥ 1.5 regardless of the presence of hepatic encephalopathy. Among 2,070 patients, 298 patients with SA-AIH/AIH-ALF were included. Liver atrophy was diagnosed based on CT findings at each participating institution, generally corresponding to a liver volume $\leq 80\%$ of the standard liver volume. The primary endpoint was death or liver transplantation. Logistic regression, Cox proportional hazards, ROC, and Kaplan–Meier analyses were performed using MELD score and liver atrophy. **Results:** Liver atrophy was more frequently observed in AIH patients than in non-AIH patients (44.6% vs. 25.1%, $p < 0.001$). In univariable logistic regression analysis, both MELD score (OR 1.19, 95%CI 1.11–1.28) and liver atrophy (OR 18.70, 95%CI 9.44–40.19) were significantly associated with death or liver transplantation (both $p < 0.001$). Similar findings were observed in Cox proportional hazards analysis, in which MELD score (HR 1.13, 95%CI 1.09–1.17) and liver atrophy (HR 10.56, 95%CI 5.79–19.26) were independently associated with poor outcomes (both $p < 0.001$). The AUC of MELD alone for predicting poor outcomes was 0.673, whereas the addition of liver atrophy significantly improved the AUC to 0.860 (DeLong test $p < 0.001$). Kaplan–Meier analysis demonstrated significant prognostic stratification among four groups classified according to MELD score (cutoff 25.9) and liver atrophy status (log-rank $p < 0.001$). Notably, the MELD value corresponding to a predicted 50% probability of death/transplantation was substantially lower in patients with liver atrophy than in those without atrophy (20.9 vs. 37.9). No significant interaction was observed between MELD score and liver atrophy. **Conclusion:** Liver atrophy is a strong prognostic factor in SA-AIH/AIH-ALF and provides incremental prognostic information beyond MELD score. These findings suggest that liver atrophy may represent an imaging marker associated with severe structural liver injury and impaired hepatic regenerative potential that may not be fully captured by conventional physiological severity scores. Integrating structural imaging findings with physiological severity assessment may improve risk stratification in patients with SA-AIH/AIH-ALF.

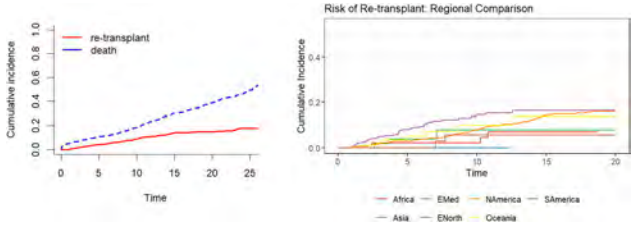
1207 | BURDEN OF RE-TRANSPLANTATION ACROSS TIME AND REGION IN A GLOBALLY REPRESENTATIVE COHORT OF PATIENTS OF >1500 PSC PATIENTS UNDERGOING LIVER TRANSPLANT



Aisha Alawi[1], [1]Toronto Centre for Liver Disease, University Health Network

Background: Primary sclerosing cholangitis (PSC) is an enigmatic chronic cholestatic disease that results in a disproportionate burden of transplant activity across the globe. Herein, we characterize a globally representative cohort of patients (pts) with PSC who underwent liver transplantation (LT) and report burden of re-transplantation across time and region. **Methods:** Descriptive statistics were used to describe baseline characteristics. Summary statistics were reported as proportions and medians with interquartile ranges. Kaplan-Meier analyses were used to evaluate time dependent differences in re-transplantation risk over time and across regions, after excluding early re-transplant within the first year post initial LT. Death was considered as a competing risk in evaluation of survival free of re-LT. **Results:** In total, 1546 pts were included in the analysis from Africa (n = 114), Northern Europe (NE) (n = 405), Mediterranean Europe (n = 61), Oceania (n = 117), North America (NA) (n = 791) and South America (SA) (n = 58). The mean age of PSC diagnosis was 36 (25-48) years

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(yrs), 65% were male, 55% Caucasian, 76% had IBD, and 10% labelled with an autoimmune hepatitis variant. Mean age at LT was 44 yrs (32-57) and median MELD 14 (8-21). Surgically, 61% had a donation after brain death graft, 9% had a donation after cardiac death graft, 16% had a living donor graft, and 55% had a Roux-en-Y anastomosis. UDCA was used in 39% of pts pre-LT and 22% in the first year post LT. Tacrolimus (83%) and mycophenolate mofetil (52%) were the most common immunosuppressive agents used post LT. Re-LT occurred in 14.1% (n = 219). Seventy-nine patients were re-transplanted within the first year post initial transplant and were excluded from the analysis. Survival free of re-LT was 90%, 84%, 77%, and 75% at 5-, 10-, 15-, and 20-years post initial LT. When considering death as competing risk, the cumulative incidence of re-LT was 4% at 5 years, 9% at 10 years, 14% at 15 years and 15% at 20 years post initial LT. There was no significant difference in risk of re-LT across decades of time from 1980-89, 1990-99, 2000-2009, 2010-2019, 2020-present. Furthermore, no significant differences were demonstrated in re-LT across regions, over time ($p = 0.12$, Figure 1) **Conclusion:** PSC pts undergoing LT are at high risk of re-transplantation and this risk has remained consistent over time and is similar across regions. Understanding predictors of such impactful outcomes remains an important priority.

Disclosures: Aisha Alawi:Nothing to Disclose.

1208 | FENOFIBRATE AND LONG-TERM OUTCOMES IN UDCA-TREATED PRIMARY BILIARY CHOLANGITIS WITH COMPENSATED CIRRHOSIS: A PROPENSITY-MATCHED ANALYSIS

Mohammad Alabbas[1] Akram Alnounou[2] Mohammad Alali[3] Omar Sims[1] Dian Chiang[4], [1]Cleveland Clinic Foundation, [2]Department of Internal Medicine, Western Michigan University Homer Stryker M.D. School of Medicine, [3]Henry Ford Macomb Hospital, [4]Cleveland Clinic

Background: Fenofibrate is used as adjunctive therapy in primary biliary cholangitis (PBC) with incomplete response to ursodeoxycholic acid (UDCA), but outcomes in patients with compensated cirrhosis are uncertain. We evaluated long-term hepatic, cardiovascular, hospitalization, mortality, biochemical, and synthetic-function outcomes associated with fenofibrate exposure versus UDCA alone in PBC with compensated cirrhosis. **Methods:** Using the TriNetX Research Network of 111 healthcare organizations, we identified adults with PBC and compensated cirrhosis receiving UDCA. Compensated cirrhosis was defined by cirrhosis codes without prior hepatic decompensation, including ascites, variceal bleeding, hepatic encephalopathy, portal hypertension, or hepatorenal syndrome. Fenofibrate users were compared with UDCA-treated nonusers after 1:1 propensity-score matching on demographics, comorbidities, medications, and laboratory values. Patients with major competing liver diseases were excluded. Outcomes were assessed from day 1 after index through 3 and 5 years. The primary outcome was major adverse liver outcomes (MALO), a composite of decompensation-related events, hepatocellular carcinoma, and death. Secondary outcomes included hospitalization, MACE, mortality, ALP, albumin ≤ 3.5 g/dL, and incident hepatic decompensation. **Results:** The matched cohort included 194 fenofibrate users and 194 nonusers at both timepoints. At 3 years, fenofibrate was associated with lower MALO (21.6% vs 31.4%; RR 0.69, 95% CI 0.49–0.97), hospitalization (17.5% vs 31.4%; RR 0.56, 95% CI 0.39–0.81), and albumin ≤ 3.5 g/dL (8.9% vs 21.9%; RR 0.41, 95% CI 0.22–0.76). Mortality, MACE, ALP, and incident hepatic decompensation did not significantly differ. At 5 years, fenofibrate remained associated with lower MALO (25.3% vs 42.3%; RR 0.60, 95% CI 0.45–0.80), hospitalization (22.7% vs 37.6%; RR 0.60, 95% CI 0.44–0.83), mortality (7.7% vs 14.9%; RR 0.52, 95% CI 0.29–0.93), albumin ≤ 3.5 g/dL (11.1% vs 28.1%; RR 0.40, 95% CI 0.23–0.69), and incident hepatic decompensation (21.6% vs 32.0%; RR 0.68, 95% CI 0.48–0.95). MACE and ALP did not differ. **Conclusion:** In this propensity-matched cohort of UDCA-treated PBC with compensated cirrhosis, fenofibrate exposure was associated with lower 3- and 5-year MALO, hospitalization, and hypoalbuminemia, with additional reductions in mortality and incident hepatic decompensation at 5 years. These observational findings support prospective evaluation of fenofibrate in carefully selected patients with PBC and compensated cirrhosis.

1209 | UNMET NEEDS IN PRIMARY BILIARY CHOLANGITIS (PBC): A REAL-WORLD, CROSS-SECTIONAL SURVEY OF THE BURDEN OF PRURITUS AND TREATMENT GAPS FROM THE MULTINATIONAL PBC DISEASE SPECIFIC PROGRAMME™

Zsofia Kiss[1] Hayley Wallinger[2] Will Johnson[2] Nathalie Heirman[3] Ashley Core[4] Megumi Koyano[5] Megan McLaughlin[6] Atsushi Tanaka[7] Mark Swain[8] Sonal Kumar[9] Stephen Ryder[10] Jörn Schattenberg[11] Maria Carlota Londono[12] Afisi Ismaila[13], [1]GSK, Munich, Germany, [2]Adelphi Real World, Bollington, UK, [3]GSK, Wavre, Belgium, [4]GSK, Collegeville, USA, [5]GSK, Tokyo, Japan, [6]GSK, Collegeville, USA (at time of study conduct), [7]Teikyo University School of Medicine, [8]University of Calgary, [9]Weill Cornell Medical College, New York, USA, [10]NIHR Biomedical Research Centre at Nottingham University Hospitals NHS Trust, [11]Saarland University Medical Center, [12]University of Barcelona, [13]GSK, London, UK

Background: PBC is a rare, chronic autoimmune liver disease characterized by progressive destruction of intrahepatic bile ducts. Cholestatic pruritus in PBC is common (25–53% of patients report clinically significant or moderate/severe itch); it impairs daily functioning, contributing to sleep disturbance, fatigue, and depression. Guideline-recommended pruritus therapies have limited efficacy, and safety and/or tolerability concerns. This study describes physician attitudes and behaviors toward PBC management and itch, and patient treatment patterns/satisfaction. **Methods:** Data were taken from the Adelphi PBC Disease Specific Programme™, a real-world, cross-sectional survey of physicians and their patients with PBC in Canada, Europe (France, Italy, Germany, Spain, UK), Japan, and the US (October 2024–June 2025). Physicians completed a survey on their characteristics and attitudes/perceptions regarding itch management and completed patient record forms (PRFs) for their next four consecutive patients (demographics, clinical characteristics, and treatment history). Voluntary patient self-completed forms (SCFs) collected demographics, health-related quality of life (HRQoL), itch severity, and work productivity and impairment (WPAI) data. Pruritus severity was physician-rated (0–10 numerical rating scale [no/mild: 0–3; moderate/severe: ≥4]). All analyses were descriptive. **Results:** Results from 274 physician surveys, 1322 physician-completed PRFs and 420 SCFs were included. Patients (mean 53.8 years) were mostly female (82% [1081/1321]) and White (89% [892/997]). Most physicians agreed that itch has a profound impact on patient QoL, sleep, physical well-being, and emotional state (91%) and that current treatments for PBC do not adequately address itch, so new targeted itch therapies are needed (86%). The most commonly reported current symptoms (n = 1311 PRFs) were pruritus (62%), fatigue (50%), and sleep disturbance due to itch (17%). Cholestyramine was the most common itch therapy for patients with moderate/severe (47%, 191/410) and no/mild (38% [71/188]) itch (between groups p = 0.0507). Physicians reported satisfaction with current pruritus treatment for a lower proportion of patients with moderate/severe itch than no/mild itch (53% [219/410] vs 87% [163/188]; p < 0.0001). A higher proportion of patients with moderate/severe itch reported sleep disturbance as a most bothersome symptom compared to patients with no/mild itch (35% [51/144] vs 4% [9/242]; p < 0.0001). Patients with moderate/severe itch also reported poorer HRQoL outcomes such as work impairment (WPAI) compared to patients with no/mild itch (**Table;** all dimensions/questionnaires p < 0.0001). **Conclusion:** These real-world findings highlight the impact of pruritus on HRQoL (particularly as itch severity increases) and the need for pruritus therapies and improved symptom management for patients with PBC. **Funding:** GSK (223363/223653)

Table: Patient-reported health-related quality of life (PBC-40 and EQ-5D) and work productivity and impairment (WPAI), stratified by physician-reported itch severity*

	No/mild itch (NRS 0–3)	Moderate/severe itch (NRS ≥4)	p-value
PBC-40 questionnaire†			
Symptoms domain (range: 6–35)			
n	248	143	<0.0001
Score, mean (SD)	12.8 (5.1)	16.7 (5.5)	
Itch domain (range: 0–15)			
n	259	147	<0.0001‡
Score, mean (SD)	4.2 (2.6)	8.6 (2.7)	
Fatigue domain (range: 11–55)			
n	261	146	<0.0001
Score, mean (SD)	22.4 (8.5)	30.4 (9.5)	
Cognitive domain (range: 6–30)			
n	259	146	<0.0001
Score, mean (SD)	9.7 (4.7)	13.1 (5.2)	
Emotional domain (range: 3–15)			
n	260	146	<0.0001
Score, mean (SD)	6.6 (2.6)	9.1 (2.7)	
Social domain (range: 8–45)			
n	258	146	<0.0001
Score, mean (SD)	22.5 (7.3)	30.6 (6.2)	
EQ-5D-5L questionnaire†§			
EQ-5D VAS			
n	264	149	<0.0001
Score, mean (SD)	73.6 (15.8)	62.0 (18.3)	
WPAI questionnaire¶			
Percent overall work impairment due to PBC			
n	104	57	<0.0001
Percent, mean (SD)	20.8 (25.5)	45.3 (27.4)	

n represents the number of respondents who completed the question on the form (patient self-completed forms, overall N=420)

*5-D itch questionnaire also collected: patients with physician-reported moderate/severe itch reported significantly higher mean scores (indicating QoL more severely impacted by itch) across all measures (all p<0.0001; data not shown); †higher PBC-40 scores, and lower EQ-5D-5L scores, indicate a larger impact/worse QoL; ‡statistical comparison warrants careful consideration as itch intensity (symptom severity) was used for group stratification; §VAS data shown only; scores were significantly lower (indicating worse QoL) in patients with physician-reported moderate/severe itch versus no/mild across all EQ-5D-5L tariffs measured (Germany, US, Japan, Canada; all p<0.0001); ¶overall work impairment shown only; percent work time missed, percent impairment while working and percent activity impairment due to PBC were also all significantly (all p<0.0001) higher in patients with physician-reported moderate/severe itch versus no/mild itch

EQ-5D-5L, EuroQol 5-Dimension 5-level; NRS, numerical rating scale; PBC, primary biliary cholangitis; QoL, quality of life; SD, standard deviation; WPAI, work productivity and impairment; VAS, visual analog scale.

1210 | PROGNOSTIC RISK SCORES AND QUALITY OF LIFE IN PBC-AIH OVERLAP SYNDROME: A SINGLE-CENTER PROSPECTIVE COHORT ANALYSIS

Ana Marenco-Flores[1] Victoria Abadi-Ron[2] Natalia Rojas-Amaris[3] Fernando Munguia[2] Romelia Barba Bernal[4] Daniela Goyes[5] Esli Medina-Morales[2] Leandro Sierra[6] Behnam Saberi[2] Vilas Patwardhan[2] Alan Bonder[2], [1]Harvard Medical School, [2]Beth Israel Deaconess Medical Center, [3]Beth Israel Deaconess Center, [4]Texas Tech University Health Sciences, [5]Yale Medical School, [6]Cleveland Clinic Foundation

Background: In autoimmune liver disease (AILD), overlap syndrome (OS) refers to conditions with features of more than one disease, including autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC). Reported prevalence ranges from 2-20%, and these conditions remain challenging due to variable disease courses and limited prognostic data. Validated prognostic tools (Mayo, UK-PBC, and GLOBE) predict transplant-free survival in PBC but have not been systematically evaluated in OS, and their relationship with patient-reported outcomes (PROs) is unclear. This study aims to characterize the clinical and quality of life (QoL) profile of PBC-AIH overlap patients using the PBC-40 questionnaire and assess the ability of the Mayo, UK-PBC, and GLOBE risk scores to predict QoL burden. **Methods:** We analyzed 550 prospectively enrolled patients at a U.S. tertiary care center (2018-2025). After excluding AIH-PSC overlap, incomplete PRO data, and non-overlap diagnoses, patients with PBC-AIH overlap meeting Paris II criteria were included. Baseline demographics, liver biochemistry, treatment data, and PBC-40 scores were collected. Mayo Risk, UK-PBC 5-year risk, and GLOBE scores were calculated from baseline laboratory values. Associations between prognostic scores and PBC-40 burden were assessed using Spearman correlation and AUROC analysis for high QoL burden (PBC-40 $\geq$ cohort median). Longitudinal changes in risk scores from baseline to 1-year and $\geq$5-year follow-up were evaluated using Wilcoxon signed-rank tests. **Results:** Sixty-five patients (13%) met inclusion criteria (95.4% female; median age 55.0 years). Median baseline PBC-40 score was 89.5. Baseline prognostic scores included Mayo 1.28 [IQR 1.06-1.50], UK-PBC 5-year risk 0.22% [IQR 0.20-0.22], and GLOBE 1.34 [IQR 0.64-2.37]. UK-PBC and GLOBE scores strongly correlated with ALP (Spearman $\rho = 0.78$ and 0.66, both $p < 0.001$), while Mayo did not ($\rho = 0.22$, $p = 0.18$). None of the prognostic models correlated with PBC-40 burden (all $p > 0.70$), and all showed poor discrimination for high QoL burden (AUROCs: Mayo 0.57, UK-PBC 0.53, GLOBE 0.51). Longitudinally, only UK-PBC improved over time, with lower 5-year risk at 1-year (mean difference -0.36 ± 0.52, $p < 0.0001$) and near 5 years (-0.28 ± 0.57, $p = 0.024$), while Mayo and GLOBE remained stable. **Conclusion:** In this study, prognostic risk scores showed strong biochemical performance but limited ability to capture QoL burden in PBC-AIH OS. These findings highlight a disconnect between traditional measures of disease severity and patients' lived symptom experience. Incorporating PROs into routine assessment may provide a more complete measure of disease impact. Overall, these results support further evaluation of integrated clinical and QoL-based approaches to better characterize disease burden and improve risk stratification in this population.

1211 | INSIGHTS FROM A NOVEL CASE-FINDING AND OUTREACH INITIATIVE FOR LOST TO FOLLOW UP PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Christopher Kim[1] Francina Collado[2] Lital Aliasi-Sinai[1] Liliana Vittini Hernandez[1] Xiaotao Zhang[1] Andrea Branch[1] Anna Mageras[1] Frances Lee[1], [1]Icahn School of Medicine at Mount Sinai, [2]Ichan School of Medicine at Mount Sinai

Background: The availability of effective treatments for primary biliary cholangitis (PBC) heightens the need to identify patients who may benefit, especially those who are lost to follow up (LTFU) with elevated alkaline phosphatase (ALP). Outreach methods used for other therapies (e.g., HCV DAA) have not been evaluated for PBC. We conducted an outreach effort between January and April 2026 at a large urban health center in New York City to re-engage LTFU PBC patients. **Methods:** Adult patients (18+) with a PBC ICD-10 code, ALP > 170 U/L, and ≥ 1 encounter with a provider between January 2000 and November 2025 were identified by EHR review. Records were reviewed in REDCap to confirm diagnosis, demographics, PBC medications, and LTFU status. LTFU patients were contacted using a standardized escalation protocol in this order: calls to patients, MyChart messages, calls to emergency contacts (EC), and mailed letters. Descriptive analyses, including Fisher's exact test and Mann-Whitney test, were completed using R v.4.5.3. **Results:** Of 2,524 patients with PBC dx code, 193 (8%) were eligible for outreach. Patients were deemed ineligible for the following reasons: ALP < 170 (83%), already in care (15%), no PBC via review (1%), deceased (< 1%), medically too ill (< 1%), relocated (< 0.1%), and self-scheduled appointment (< 0.1%) (Figure 1). Those eligible for outreach were predominantly female (90%), had a mean age of 66.4 years (SD = 11.57), and most (78%) had an active ursodiol prescription. Of those eligible, 93 (48%) patients did not respond to contact attempts. Patients were more likely to respond if they had an active ursodiol prescription (P = .015). Thirteen (7%) patients were successfully re-engaged in care. Re-engaged patients had a significantly shorter time since their last liver clinic visit (P < 0.001), with the median being 2 years versus 6 years for non-re-engaged. None of the following demographic or clinical characteristics distinguished re-engaged from non-re-engaged patients: sex, race, ethnicity, age, preferred language, interpreter need, marital status, insurance, previous visits, distance from clinic, training of last seen provider, provider affiliation with clinic, MyChart status, or PBC prescriptions. Escalated outreach did not increase the likelihood of re-engagement. There was no significant difference in total outreach attempts, calls made, or MyChart messages sent between the groups. However, non-re-engaged patients received significantly more EC calls (P = .007) and more letters (P = .003), while re-engaged patients had a mean of zero for both, indicating that re-engaged patients did not require EC calls or letters to re-engage with their care. **Conclusion:** Re-engagement of LTFU PBC patients is most successful for those who have been previously seen within the last two years. Patients who re-engaged in care responded earlier in the outreach process. More effective strategies are needed to improve engagement in PBC care.

Figure 1. *Patient outcomes from outreach efforts*

*Patients were deemed ineligible for outreach for the following reasons: deceased (16, 76.2%), medically too ill (2, 9.5%), relocated (2, 9.5%), and self-scheduled appointment (1, 4.8%).

Medicine, The University of Osaka, [2]Osaka University Graduate School of Medicine, [3]The University of Osaka

Background: Autoimmune hepatitis (AIH) is characterized by portal tract inflammation and interface hepatitis; however, the spatial distribution of immune cells and the local microenvironment surrounding Treg cells remain poorly understood. This study aimed to use CosMx 6K spatial transcriptomics to define spatial immune niches in AIH liver and characterize niche-associated Treg alterations and candidate intercellular communication programs. **Methods:** We analyzed four AIH liver biopsy samples using the CosMx Spatial Molecular Imaging with Human 6K Discovery panel. After quality control and normalization in AtoMx pipeline, downstream analysis was conducted in Seurat. For spatial niche analysis, cells were classified into immune-enriched niches and immune-sparse niches based on local cellular composition. Using SpatialCellChat v3, spatial ligand–receptor interactions were estimated across all samples. **Results:** The median age of the four patients was 73 years, 3 patients were female (75%), and the median AST and ALT levels were 99 and 124 U/L, respectively. 85,678 cells were clustered and annotated into T cells, B cells, Kupffer cells, monocyte-derived macrophages (MoMFs), hepatic stellate cells (HSCs), and endothelial/LSEC subsets. Treg cells within immune-enriched niches showed elevated IFNγ-related pathway activity compared with those in immune-sparse niches. Conversely, TGF-β signaling and FOXP3 and ENTPD1 expression were reduced, suggesting altered suppressive or homeostatic features in inflammatory regions. SpatialCellChat analysis identified candidate communication programs contributing to immune-enriched niche organization. MHC-II signaling suggested antigen-presentation-related interactions from MoMFs and B cells toward the Treg/T-cell compartment. ICAM signaling was prominent around a portal-region endothelial cell-like EC/LSEC subset via ICAM1–integrin interactions, suggesting endothelial adhesion-mediated retention of inflammatory cells. CCL/CXCL signaling was enriched within T-cell compartments, suggesting localized chemokine-dependent T-cell clustering or retention. COLLAGEN signaling suggested an HSC-centered stromal/ECM network involving B cells, cytotoxic T cells, and MoMFs through the collagen–SDC1/CD44 axis. **Conclusion:** Spatial transcriptomics revealed that Treg cells residing within immune-enriched niches in AIH exhibit enhanced IFNγ-related inflammatory signaling and reduced FOXP3, ENTPD1, and TGF-β signaling. Cell-cell interaction analysis further identified candidate intercellular communication programs involved in antigen presentation, endothelial adhesion, chemokine-dependent T-cell clustering, and HSC-centered stromal remodeling. This study spatially links the immune microenvironment surrounding interface hepatitis with Treg alterations in AIH.

Background: Studies suggest recompensation may be achieved in patients with PBC decompensated cirrhosis. However, PBC-specific criteria for recompensation and its prognostic impact remain unclear. We aimed to investigate (i) potential defining criteria, (ii) its predictors, and (iii) the prognostic significance of recompensation in two independent international cohort of patients with decompensated PBC cirrhosis. **Methods:** We performed parallel landmark analyses of decompensated PBC patients from the Global PBC cohort (16 centres, 4 continents; n = 348) and the Baveno Cooperation (3 centres, 2 continents, n = 173). Adult PBC patients with index decompensation (ID) were included, with identical definition and analytic methods applied in both cohorts. Patients with hepatocellular carcinoma, prior liver transplantation, or PBC-AIH overlap were excluded. Recompensation was defined at the 12-month after ID as: UDCA treatment, free of new decompensating events, and without diuretics or HE prophylaxis, and synthetic function recovery (MELD 3.0 < 10).Expanded recompensation criteria without requiring cessation of ascites/HE treatment requirement were investigated. Primary outcome was transplant-free survival (TFS) 12 months after ID according to recompensation status. **Results:** A total of 521 patients with decompensated PBC were included. The Global PBC Study Group cohorts included 348 patients (86% female, mean age 54 (SD: ± 13) years, mean MELD 3.0 of 15 (SD ± 6). Recompensation occurred in 12 (3.4%) with strict definition and in 45 (12.9%) by expanded criteria. Over median follow-up of 46 [IQR: 23-92] months, recompensation by expanded criteria was independently associated with longer transplant-free survival (TFS) (HR 0.43, 95% CI: 0.25-0.75) compared to patients without recompensation (*Fig 1A*).The Baveno cohort included 173 patients (85% female, mean age 64 (SD ± 12) years, mean MELD 3.0 of 14 (SD ± 5) months. Of 106 patients eligible at 12 months, recompensation occurred in 16 (9.2%) and in 47 (27.2%) by extended criteria. Over median follow-up of 58.2 (36.2-89.5) months, recompensation defined by expanded criteria was associated with improved TFS (HR 0.28, 95%CI: 0.13-0.58) (*Fig 1B*).Across both cohorts, strict or expanded recompensation criteria yielded comparable long-term TFS. Common predictors for recompensation were better baseline liver function (lower MELD 3.0) and achieving Paris-II biochemical response to UDCA ($p < 0.05$ for all). **Conclusion:** Expanded recompensation criteria (MELD 3.0 < 10 and event-free at 1 year) identifies 1-in-3 decompensated PBC patients, which translate into substantially better transplant-free survival. These findings establish recompensation as clinically meaningful endpoints in decompensated PBC.

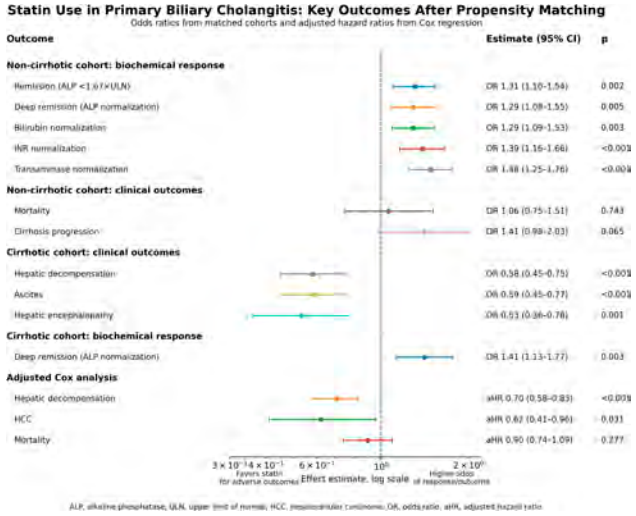
1214 | BEYOND LIPIDS: STATIN THERAPY IS ASSOCIATED WITH IMPROVED LIVER OUTCOMES IN PRIMARY BILIARY CHOLANGITIS



Nimish Thakral[1] Bipneet Singh[2] Suvishesh Pothuraju[3] Fatima Elmustafa[4] Mangesh Pagadala[5] Sajid Jalil[6] Ashwani Singal[3], [1]University of Kentucky Medical Center, [2]University of Kentucky, [3]University of Louisville, [4]Henry Ford Warren, [5]Methodist Health System Dallas, [6]Stanford University

Background: Statin use in primary biliary cholangitis (PBC) remains controversial due to concerns regarding hepatotoxicity in chronic liver disease, although emerging data suggest hepatoprotective effects in cholestatic diseases and cirrhosis. We evaluated the association of statin therapy with biochemical and clinical outcomes in patients with PBC receiving ursodeoxycholic acid (UDCA) stratified by cirrhosis stage. **Methods:** A retrospective cohort study was done via TrinetX database of adults aged 18–85 years with PBC receiving UDCA (> 3 prescriptions) & statins were included as exposures. Patients with viral & autoimmune hepatitis, alcohol-related liver disease, hemochromatosis, and alpha-1 antitrypsin deficiency were excluded. Propensity score matching was performed for demographics, comorbidities, laboratory variables, and medication exposure. Outcomes were assessed from 180 days to 7 years post-index and included mortality, hepatic decompensation, ascites, hepatic encephalopathy (HE), hepatocellular carcinoma (HCC), remission (alkaline phosphatase [ALP] < 1.67× ULN), and deep remission (normalization of ALP). Multivariable Cox regression analysis was performed to evaluate independent predictors of mortality, decompensation, and HCC. **Results:** In the non-cirrhotic cohort, 1,085 statin-treated patients were matched to 1,085 controls (not on statins). Statin use was associated with higher remission (55.5 % vs 48.4%;OR 1.32, 95% CI: 1.13-1.56 p = 0.002), bilirubin normalization (62.1% vs 54.7%;OR 1.29 95% CI: 1.15–1.60, p = 0.003), INR normalization (37.7% vs 30.3%; OR 1.39, p < 0.001), and transaminase normalization (60.6% vs 50.9%;OR 1.48,

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

p < 0.001). Deep remission was higher in statin users. Rate of cirrhosis development and mortality were comparable to controls (7.4% vs 5.4%;OR 1.41, p = 0.065) and (5.9% vs 5.6%; p = 0.743), respectively. In the cirrhotic cohort, 718 statin-treated patients were matched to 718 controls. Statin use was associated with lower decompensation (17.4% vs 26.6%;OR 0.58, p < 0.001), ascites (14.9% vs 23.0%;OR 0.59, p < 0.001), and HE (5.7% vs 10.3%;OR 0.53, p = 0.001). Deep remission was higher with statin use (35.0% vs 27.6%;OR 1.41, p = 0.003). On multivariable Cox analysis, statin use independently reduced risk of hepatic decompensation (aHR 0.70, p < 0.001) and HCC (aHR 0.62, p = 0.031). Male sex independently predicted increased mortality, decompensation, and HCC. **Conclusion:** Among patients with PBC receiving UDCA, statin use was associated with improved biochemical remission in non-cirrhotic patients and reduced hepatic decompensation and HCC risk in cirrhotics. The observed mortality benefit did not persist after multivariable adjustment, potentially reflecting the relatively short follow-up period and favorable baseline transplant-free survival in UDCA-treated PBC cohorts. These findings support the safety and potential hepatoprotective effects of statins in PBC.

1215 | BURDEN OF DISEASE IN ADULTS WITH ALAGILLE SYNDROME: FINDINGS FROM THE ALGS ADULT PATIENT REGISTRY

Morgan Faist[1] Quinn Rabenau-McDonnell[1] Roberta Smith[2] Cher Bork[2] Desiree Vaz[3] Stephanie Mullett[2] Binita Kamath[4], [1]Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, [2]Alagille Syndrome Alliance, [3]The Hospital for Sick Children, Toronto, Canada, [4]Children's Hospital of Philadelphia and the University of Pennsylvania Perelman School of Medicine

Background: Alagille syndrome (ALGS) is a rare, autosomal dominant disorder associated with cholestatic liver disease and extrahepatic manifestations. While studies to date have focused on childhood, long-term outcomes in adults with ALGS remain poorly understood. We aimed to characterize the disease burden, health-related quality of life and functional outcomes in adults with ALGS. **Methods:** The ALGS Adult Patient Registry is a cross-sectional survey of adults with ALGS, developed by the investigators in collaboration with the Alagille Syndrome Alliance, a family-advocacy group. Participants completed an online disease-specific questionnaire and the Patient-Reported Outcomes Measurement Information System-29 (PROMIS-29) to evaluate burden of disease. PROMIS domain scores were converted to T-scores normalized to the U.S. general population (mean = 50, SD = 10). **Results:** 95 adults (age ≥ 18) with ALGS completed the survey; 76.6% identified as female and 75.6% were born in North America. 43.4% age 25 and older had a bachelor's degree or higher and 69.1% were employed and/or students. 69.6% required no assistance with their own care, and 26.6% were actively providing care to others.24.5% received liver transplantation (LT) at a median age of 13 (IQR 4-22) years. Of these, 21.7% required kidney transplantation a median of 22 (IQR 11-23) years post-LT, compared to only 4.3% of those with native liver (NL).LT and NL PROMIS scores were compared (Table 1). Both groups scored worse than the general population on 6 of 7 domains. Ability to Participate in Social Roles and Activities scores were better than the general population in both groups. Fatigue was the only domain with a significant between-group difference, with the NL group reporting greater mean fatigue (57.8 vs. 51.2; p = 0.01). The NL group also had higher rates of severe fatigue (8.7% vs. 0%) and severe anxiety (17.6% vs. 0%). Among 38 respondents (40.9%) who reported pregnancies, 14 (36.8%) experienced ≥1 miscarriage(s). Of 114 total pregnancies, 35 (30.7%) were miscarriages. **Conclusion:** Preliminary analysis of the ALGS Adult Patient Registry reveals that, despite significant symptom burden, adults with ALGS are engaged in

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

employment, education, and caregiving. Severity distributions of the PROMIS anxiety and fatigue scores suggest a subset of the NL group experience higher symptom burden than those with LT, but further study is needed to identify risk factors in this population. LT recipients were more likely to require kidney transplantation post-LT compared to the NL group, highlighting the need for continued investigation into long-term renal outcomes in this population. Fertility challenges were prevalent, with nearly a third of pregnancies ending in miscarriage, estimated to be double the rate in the general population. Future enrollment will expand this registry's power to characterize the adult ALGS experience and guide future research priorities and clinical care.

Table 1. PROMIS-29 domain scores and severity distribution in adults with Alagille Syndrome by liver transplant status

PROMIS-29 Domains Mean (SD) or N (%)	Liver Transplant	Native Liver	p-value
	n=22*	n=69*	
Physical Function T-score	48.8 (7.7)	46.1 (9.6)	0.18
	n=22	n=69	
Ability to Participate in Social Roles and Activities T-score	53.7 (8.5)	50.4 (11.2)	0.15
	n=22	n=70	
Cognitive Function T-score	50.5 (9.0)	46.7 (8.5)	0.08
	n=22	n=68	
Anxiety, T-score	58.3 (7.6)	57.8 (10.6)	0.79
Severe (T-score >70)	0 (0.0%)	12 (17.6%)	
	n=21	n=68	
Depression T-score	54.5 (9.2)	55.1 (10.0)	0.98
	n=22	n=69	
Fatigue T-score	51.2 (9.1)	57.8 (10.6)	**0.01**
Severe (T-score >70)	0 (0.0%)	6 (8.7%)	
	n=22	n=69	
Sleep Disturbance T-score	56.4 (2.5)	56.7 (4.2)	0.60
	n=22	n=69	
Pain Interference T-score	51.4 (9.1)	53.0 (10.7)	0.51

1216 | COMPARATIVE EFFECTIVENESS OF AZATHIOPRINE, MYCOPHENOLATE MOFETIL, AND BUDESONIDE-AZATHIOPRINE THERAPY IN AUTOIMMUNE HEPATITIS

Jayati Anand[1] Ana Marenco-Flores[1] Victoria Abadi-Ron[1] Natalia Rojas-Amaris[1] Fernando Munguia[1] Behnam Saberi[1] Vilas Patwardan[1] Alan Bonder[1], [1]Beth Israel Deaconess Medical Center

Background: Induction therapy for autoimmune hepatitis (AIH) involves prednisone plus azathioprine (AZA), with a transition to maintenance therapy with steroid taper; budesonide may replace prednisone in non-cirrhotic patients, and mycophenolate mofetil (MMF) is used when first-line therapy is not tolerated or effective. Steroid-sparing strategies can minimize toxicity and preserve disease control. Optimal maintenance therapy for AIH with steroid-sparing regimens remains uncertain, particularly regarding remission durability and relapse risk. This study aims to compare long-term remission and active disease/relapse among AIH patients treated with AZA monotherapy, MMF monotherapy, or budesonide-AZA combination therapy. **Methods:** We conducted a retrospective cohort study at a tertiary center in Boston, including >550 adults with AIH. Exclusion criteria included age <18 at diagnosis, <2 follow-up visits, overlap with other autoimmune liver diseases, or incomplete clinical or medication data, leaving 155 patients. Primary analysis focused on 63 patients receiving AZA (n = 52), MMF (n = 6), or budesonide-AZA combination therapy (n = 5). Biochemical remission was defined as normalization of liver chemistries; relapse was defined as the first episode of non-remission after initial remission. Outcomes were assessed at 12, 24, and 36 months and compared using chi-square/Fisher's exact tests for categorical variables. Analyses and data visualization were performed using Stata and Python. **Results:** The baseline characteristics of the patient population by treatment category were similar with no statistically significant differences in demographics or biochemistry. Throughout the study period, there were no statistically significant differences between rates of remission and active disease/relapse between any of the treatment groups. At 12 months, remission rates were: AZA 67%, MMF 50%, budesonide–AZA 20%. At 24 months, remission rates improved in the MMF (67%) and budesonide-AZA groups (60%) and remained stable for AZA alone (65%). At 36 months, remission declined across all groups: AZA 56%, MMF 50%, budesonide–AZA 40%. Active disease/relapse rates were highest in the budesonide-AZA group throughout all three time points. At 12 months: AZA 23%, MMF 33%, budesonide–AZA 60%. At 24 months: AZA 13%, MMF 33%, and budesonide-AZA 40%. At 36 months: AZA 17%, MMF 33%, and budesonide-AZA 60%. **Conclusion:** AZA, MMF, and budesonide–AZA achieved comparable short-term remission with no significant differences in remission or active disease/relapse through 36 months. AZA showed a trend toward more durable remission, while budesonide–AZA had higher late relapse. Limitations of this study include the relatively modest sample sizes, particularly within the MMF and budesonide-AZA groups. Larger studies are needed to define optimal steroid sparing maintenance therapy in AIH.

1217 | INTEGRATED GENE MODULE ANALYSIS LINKS TNF-SUPERFAMILY SIGNALING TO INFLAMMATORY AND FIBROTIC INJURY IN AUTOIMMUNE LIVER DISEASE

Xiangya Wang[1], [1]University of Cincinnati

Background: Autoimmune liver diseases, including primary sclerosing cholangitis (PSC) and autoimmune hepatitis (AIH), show heterogeneous histologic injury. TNF-superfamily signaling participates in liver inflammation and immune activation, but how specific TNFSF/TNFRSF members relate to inflammatory/fibrotic gene programs and pathology features remains unclear. **Methods:** We analyzed 67 liver transcriptomes with matched diagnostic H&E images using an integrated systems biology pipeline combining WGCNA, GSEA, CIBERSORT immune deconvolution, and cross-modal correlation analysis of TNF-superfamily genes, pathology traits, and image features. **Results:** Using WGCNA, we identified seven disease-relevant gene modules associated with pathologist-annotated fibrosis/inflammation/AILD features. Modules ME3, ME9, ME13, and ME16 were associated with inflammatory activity; ME9 and ME16 were also linked to AIH, whereas ME3 was inflammation-positive but PSC-negative. These modules were enriched in immune activation pathways, including antigen presentation and T/B-cell signaling, and were associated with increased CD8 T cells, Tfh cells, B-cell fractions, and M1 macrophages. Several TNFSF/TNFRSF genes mapped to these modules, including TNFSF12, TNFSF13B, TNFRSF1B, and TNFRSF13B. Fibrosis-linked modules ME4, ME18, and ME21 were associated with fibrosis traits, with ME18 also linked to AIH. These modules were enriched in metabolic, complement/coagulation, bile acid, and tissue-remodeling pathways, and ME21 showed a macrophage-associated pattern, especially M0 macrophages. Fibrosis-associated TNFSF/TNFRSF genes included TNFSF11, TNFRSF10B, and TNFRSF12A. Cross-modal analysis showed that TNFSF genes were broadly correlated with portal/lobular inflammation, total modified HAI, periportal interface activity, and H&E intensity features. Fibrosis traits showed a more restricted receptor-dominant pattern involving TNFRSF11B, TNFRSF10B, and TNFRSF12A, with fewer TNFSF associations. **Conclusion:** These results show that fibrosis, inflammation, PSC-related injury, and AIH are associated with distinct co-expression modules and TNFSF/TNFRSF programs, linking immune signaling to coordinated inflammatory and fibrotic gene programs reflected in tissue morphology.

Disclosures: Xiangya Wang:Nothing to Disclose.

1218 | PRIMARY SCLEROSING CHOLANGITIS (PSC) IS ASSOCIATED WITH GREATER FAMILIAL HISTORY OF INFLAMMATORY BOWEL DISEASE (IBD) THAN IBD ALONE

S. Fernanda Quevedo[1] Brian Thorsen[1] Rachel Gomel[1] Sharon Nanz[1] Stephen Rossi[1], [1]PSC Partners Seeking a Cure

Background: Primary sclerosing cholangitis (PSC) is a rare cholestatic disease of largely unknown etiology with both genetic and environmental factors. Previous studies estimate that 1-2% of people with PSC have a family history of PSC. Approximately 70% of people with PSC also have inflammatory bowel disease (IBD). In people with IBD alone, previous data shows 8-12% have familial IBD, more frequently in Crohn's disease (CD) than ulcerative colitis (UC). The rates of IBD familial history in people with PSC-IBD or PSC alone is not currently known. We present familial PSC and IBD rates in a large PSC registry cohort and compare these to established familial rates in IBD alone to further characterize the gut-liver axis in PSC. **Methods:** The PSC Partners Patient Registry collects patient-reported data from people living with PSC worldwide, including

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

longitudinal clinical data, family history, and other disease-pertinent information. Most recent survey data was analyzed for rates of familial PSC and IBD. Z-tests were used to compare differences in proportions across groups. **Results:** The registry had complete data for 2472 respondents. The cohort included 72% with IBD (69% UC, 23% CD, 8% indeterminate IBD); 51% were female and 89% were Caucasian. The median age of respondents was 42 years, with a median 5 years duration of PSC and 13 years duration of IBD when present.In the overall registry cohort, familial IBD was reported in 29%, 15% with first-degree relatives with IBD. Both rates were higher than the 12% upper limit previously reported in IBD alone ($p < 0.001$). In respondents with PSC-IBD, 34% reported familial IBD with 20% reporting familial IBD in first-degree relatives. In respondents with PSC alone, 16% had familial IBD, 12% with first-degree relatives, both lower than in PSC-IBD ($p < 0.001$). CD was reported in 26% of PSC-IBD respondents with familial IBD, marginally higher than the 22% CD in PSC-IBD without familial IBD ($p = 0.06$). Consistent with other studies, familial PSC history was reported in 91 (3.5%) respondents, with 52 reporting first-degree relatives, 32 extended, and 7 with both. No significant differences were seen in IBD rates or types in respondents with familial versus sporadic PSC. In respondents with familial PSC, 59% had familial IBD, mainly due to PSC-IBD in the same relative. **Conclusion:** This large cohort reveals familial IBD rates in PSC, both with and without IBD, are higher than in IBD alone. Familial PSC rates are largely consistent with previous studies in PSC. CD was only slightly more common in those with familial IBD, contrary to the several-fold higher inheritability of CD versus UC in the IBD-alone general population. Validation in a cohort containing PSC, PSC-IBD, and IBD without PSC is needed to further investigate the relationship between disease type, genetic inheritability, and environmental exposures.

1219 | ALLOGENEIC MESENCHYMAL STROMAL CELL INFUSION MODULATES REGULATORY T-CELL AND MONOCYTE RESPONSES IN PRIMARY SCLEROSING CHOLANGITIS AND AUTOIMMUNE HEPATITIS: THE MERLIN PHASE II BASKET TRIAL

Julian Yeh[1] Victora Homer[2] Nguyet Luu[3] Sarah Mahgoub[4] Sheeba Khan[4] Annabelle Smith[5] John Cole[6] Rhian Glover[2] Helen Coulthard[2] Anna Rowe[2] Steve Elliman[7] Ye Oo[8] Palak Trivedi[9] Gideon Hirschfield[10] Philip Newsome[11], [1]The Shrewsbury and Telford Hospital Nhs Trust, [2]Cancer Research UK Clinical Trials Unit, University of Birmingham, Birmingham, UK, [3]Centre for Liver & Gastrointestinal Research, Institute of Immunology and Immunotherapy, Universi, [4]University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK., [5]University of Glasgow, [6]Medical, veterinary and life sciences shared research facilities, University of Glasgow, Glasgow, UK, [7]Orbsen Therapeutics, [8]NIHR Biomedical Research Centre, University Hospitals Birmingham & University of Birmingham, UK, [9]University of Birmingham, [10]Toronto General Hospital, [11]King's College London

Background: Primary sclerosing cholangitis (PSC) lacks any licensed disease-modifying therapy and autoimmune hepatitis (AIH) treatment is constrained by corticosteroid toxicity. Mesenchymal stromal cells (MSC) possess immunomodulatory properties relevant to both. MERLIN is an open-label, dose-finding phase II adaptive basket trial of single-dose allogeneic MSC infusion in PSC and AIH. **Methods:** Allogeneic umbilical cord-derived, $CD362^+$ MSC (ORBCEL-C^{TM}) were administered at two doses: 1×10^6 (dose A) and 2.5×10^6 cells/kg (dose B). The Highest Safe Dose (HSD) was determined by dose-limiting toxicity (DLT) within 14 days. Primary clinical outcomes were safety, HSD ascertainment and biochemical change (ALP in PSC; ALT in AIH), with Fibroscan and ELF as exploratory measures. The principal mechanistic outcome was change in circulating regulatory T cells (Treg) across both cohorts; mechanism was further explored by flow cytometry and bulk RNA-seq. **Results:** Eighteen patients were enrolled: AIH ($n = 6$, mean age 48 [28–77]) and PSC ($n = 12$, mean age 41 [27–73], 75% with colitis). The HSD in PSC and AIH was 2.5×10^6 cells/kg; DLTs comprised an ALT/AST rise >10×ULN at dose A and COVID-19–associated viral myocarditis at dose B. In pooled repeated-measures analysis ($n = 18$), the principal mechanistic endpoint was met: circulating $CD25^{HI}$ Tregs increased from 3.12% to 3.84% of $CD4^+$ cells at day 14 ($p = 0.0085$). A subsequent reduction in $CD25{-}CD127^{HI}$ T effectors was observed, from a day-3 peak of 5.06% (SD 3.38) to 4.04% (SD 2.66) by day 28. At the HSD ($n = 3$), AIH patients showed a 42% reduction in ALT by day 28 (95% CI: −70.7 to −12.4). Across the full PSC cohort ($n = 12$), ALP was unchanged while monocyte M1:M2 ratio fell from 5.85 to 4.17 by day 14 ($p = 0.043$); no change was seen in AIH. This paralleled a monocyte- and granulocyte-driven innate response on bulk RNA-seq at 4 hours post-infusion (132 significant gene signatures in PSC; 75 in AIH), with ligand–receptor analysis implicating IL-10, TLR and integrin

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

pathways. **Conclusion:** MERLIN established the Highest Safe Dose of allogeneic MSC infusion (2.5×10^6 cells/kg) in both disease cohorts, with relevant immunological changes including expansion of circulating $CD25^{HI}$ Tregs, a subsequent reduction in $CD25{-}CD127^{HI}$ T effectors, and a fall in monocyte M1:M2 ratio in PSC. Biochemical (ALT reduction in AIH) and transcriptomic signals (innate-immune; IL-10, TLR, integrin) support further evaluation of MSC therapy in autoimmune liver disease.

MERLIN: Key Clinical and Mechanistic Findings

Domain	Population	Timepoint	Finding	Statistic / Detail
Safety / HSD	PSC and AIH	Within 14 days	Highest safe dose established	2.5×10^6 cells/kg; DLTs: ALT/AST rise >10×ULN at dose A; suspected viral myocarditis at dose B
Tregs	Pooled cohorts	Day 14	Circulating CD25HI Tregs increased	3.12% to 3.84% of CD4+ cells; p=0.0085
T effectors	Pooled cohorts	Day 3 to Day 28	CD25⁻CD127hi T effectors decreased after peak	Peak 5.06% (SD 3.38) to 4.04% (SD 2.66)
ALT	AIH at HSD	Day 28	ALT reduced	42% reduction; 95% CI −70.7 to −12.4
ALP	PSC	Day 28	No biochemical change detected	ALP unchanged
Bulk RNA-seq	PSC / AIH	4 hours post-infusion	Peak transcriptomic response	132 significant gene signatures in PSC; 75 in AIH

Abbreviations: HSD, highest safe dose; DLT, dose-limiting toxicity; PSC, primary sclerosing cholangitis; AIH, autoimmune hepatitis.

1220 | FXR AGONISTS VS. PPAR AGONISTS: A REAL-WORLD COMPARISON OF SECOND LINE TREATMENT EFFECTIVENESS IN PRIMARY BILIARY CHOLANGITIS

Ngan Nguyen[1] Kelly Mei[1] Jimyeong Son[1] Sanjaya Satapathy[1] James Park[1], [1]Northwell Health - North Shore University Hospital

Background: Second-line treatment options for primary biliary cholangitis (PBC) historically included the farnesoid X receptor (FXR) agonist obeticholic acid (OCA) and peroxisome proliferator-activated receptor (PPAR) agonists such as fenofibrate prior to the recent approval of elafibranor and seladelpar. Comparative real-world effectiveness data between FXR- and PPAR-based therapies remain limited. **Methods:** We conducted a retrospective cohort study of adults with PBC treated at a tertiary care center between May 2016 and June 2025. Patients received either FXR agonist therapy or PPAR agonist therapy (fenofibrate, elafibranor, or seladelpar), with or without ursodeoxycholic acid. Baseline demographics, liver biochemistries, and liver stiffness measurements were collected. The primary endpoint was biochemical response at 12 months, defined as alkaline phosphatase (ALP) $<1.67\times$ the upper limit of normal (ULN), $>15\%$ ALP reduction from baseline, and normal total bilirubin. Secondary outcomes included ALP normalization, complete biochemical response, liver stiffness changes, and adverse events. **Results:** A total of 114 patients were included. The cohort was predominantly female (91.2%) with a mean age of 59.6 years. Fibrosis stages ranged from F0–F4, including 10.5% with advanced fibrosis (F4). Treatment distribution included 48 patients (42.1%) receiving FXR agonists and 66 patients (57.9%) receiving PPAR agonists, including fenofibrate (60.6%), elafibranor (18.1%), and seladelpar (21.2%). At 12 months, treatment persistence was 56.3% in the FXR group and 63.6% in the PPAR group.PPAR agonists demonstrated significantly higher biochemical response rates at 3 months (56.6% vs. 19.4%; $p<0.0001$), 6 months (50.0% vs. 25.0%; $p=0.0002$), and 12 months (43.6% vs. 24.4%; $p=0.0042$) compared with FXR agonists. PPAR agonists were also associated with greater reductions in alanine aminotransferase levels and higher rates of ALP normalization ($p=0.0006$) and complete biochemical response ($p=0.0003$). FXR agonists reduced liver stiffness ($p=0.028$), but this did not significantly impact fibrosis staging. FXR agonists yielded a higher proportion of patients with bilirubin $<0.6\times$ ULN; however, this effect was attenuated after baseline adjustment. Pruritus was the most frequently reported adverse event and occurred more commonly with FXR agonists. **Conclusion:** In this real-world cohort of patients with PBC, PPAR agonists demonstrated superior biochemical response rates, greater reductions in cholestatic liver enzymes, and improved tolerability. FXR agonists may retain potential benefit in select patients through effects on bilirubin and liver stiffness. These findings support the evolving role of PPAR-based therapies in PBC management and highlight the need for prospective studies evaluating individualized

treatment sequencing and combination strategies, including potential triple-therapy approaches.

Table 1. Comparative Biochemical and Liver Outcomes Between FXR and PPAR Agonist Therapy in Primary Biliary Cholangitis

Outcome	FXR Agonist (n=48)	PPAR Agonists (n=66)	P-value
Primary Endpoint			
Biochemical response at 3 months, %	19.4	56.6	<0.0001
Biochemical response at 6 months, %	25.0	50.0	0.0002
Biochemical response at 12 months, %	24.4	43.6	0.0042
Secondary Endpoints			
ALP <1.67× ULN, n (%)	17/41 (41.5)	24/39 (61.5)	0.005
>15% ALP reduction from baseline, n (%)	24/41 (58.5)	27/39 (69.2)	0.115
Normalization of total bilirubin, n (%)	34/41 (82.9)	32/39 (82.1)	0.882
Bilirubin normalization in patients with baseline bilirubin ≥1 mg/dL, n (%)	2/7 (28.6)	3/9 (33.3)	0.472
Total bilirubin <0.6× ULN, n (%)	31/41 (75.6)	23/39 (59.0)	0.012
Total bilirubin <0.6× ULN in patients with baseline bilirubin ≥0.6× ULN, n (%)	3/20 (15.0)	7/33 (21.2)	0.255
Relative ALP reduction, median [IQR]	−20.0% [30.6]	−35.0% [38.7]	<0.0001
Absolute ALP reduction (U/L), median [IQR]	−46 [127]	−64 [91]	<0.0001
ALP normalization achieved, n (%)	2/41 (4.9)	14/39 (35.9)	0.0006
Complete biochemical response achieved, n (%)	1/41 (2.4)	13/39 (33.3)	0.0003
Relative ALT reduction, median [IQR]	−26.4% [42.8]	−12.0% [41.1]	0.005
Absolute ALT reduction (U/L), median [IQR]	−14 [25]	−3 [17]	0.0005
Change in fibrosis stage, median [IQR]	0 [2.3]	0 [1.7]	0.515
Relative reduction in liver stiffness, median [IQR]	−48.4% [34.2]	−10.6% [36.7]	0.028
Absolute reduction in liver stiffness (kPa), median [IQR]	−5.6 [4.8]	−0.8 [2.6]	0.028

1221 | RISK FACTORS FOR PROGRESSION IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS WHO ARE ELIGIBLE FOR SECOND-LINE TREATMENT: EVIDENCE FROM A REAL-WORLD STUDY

Ira Jacobson[1] Robert Gish[2] Gideon Hirschfield[3] Marvin Rock[4] Chong Hoon Kim[4] Caroline Burk[4] Hayley Wallinger[5] William Johnson[5] Emily Green[5] David Jones[6] Robert Wong[7], [1]NYU Langone Health, New York, NY, USA, [2]Hepatitis B Foundation, Doylestown, PA, USA, [3]UHN's Francis Family Liver Clinic and Toronto Centre for Liver Disease, Toronto, ON, Canada, [4]Gilead Sciences, Inc., Foster City, CA, USA, [5]Adelphi Real World, Bollington, United Kingdom, [6]Newcastle University, Newcastle Upon Tyne, United Kingdom, [7]Stanford University School of Medicine, Palo Alto, CA, USA

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune disease that progressively damages the liver. A major indicator of PBC progression is elevated levels of alkaline phosphatase (ALP). Second-line (2L) treatments such as seladelpar, elafibranor, and fibrates work by reducing cholestasis measured by ALP and other markers. This abstract aims to characterize patients that are eligible for 2L treatment but not on 2L to emphasize the need for more timely escalation to 2L treatment to prevent PBC progression. **Methods:** Data were drawn from the Adelphi Real World PBC Disease Specific Programme, a cross-sectional survey, with retrospective data collection in France, Germany, Italy, Spain, United Kingdom, and United States between November 2024 to May 2026. Physicians completed surveys for their patients with PBC including demographics, clinical characteristics and treatment status. Patients were considered eligible for 2L treatment if they were currently receiving ursodeoxycholic acid (UDCA) monotherapy for ≥12 months, had a most recent ALP result of >1 × upper limit of normal (ULN), and had not received 2L treatment previously. Patients with decompensated cirrhosis were excluded from analysis. Analyses performed were descriptive. **Results:** Data for 146 patients were available (91% female, mean [SD] age of 54.5 [12.2], mean [SD] years diagnosed with PBC 4.7 [4.7] and years on UDCA 4.1 [4.5]). Fatigue (49%) and pruritus/itch (48%) were the most common current symptoms. Of those with pruritus/itch, 46% experienced moderate/severe itch. The majority of most recent biochemical liver test results showed poor levels of control with mean ALP (223.6 U/L [292.4]), gamma-glutamyl transferase (139.6 U/L [370.5]), alanine transaminase (64.2 U/L [177.4]), and aspartate aminotransferase (72.6 U/L [303.8]). A third of patients (32%) had an ALP >1.67 × ULN. 89% of patients had risk factors indicative of poorer prognosis including 75% aged <62 years old, 19% with PBC stage 3 or 4, 10% with a vibration-controlled transient elastography score of >10 kPa and 30% with associated comorbidities. **Conclusion:** Many patients eligible for 2L treatment but not on 2L continue to remain on UDCA monotherapy despite presenting with poor biochemical blood markers, risk factors indicative of poorer prognosis, and persistent symptoms. This data highlights the need for more timely escalation to 2L treatment for these patients to alleviate symptoms and prevent disease progression.

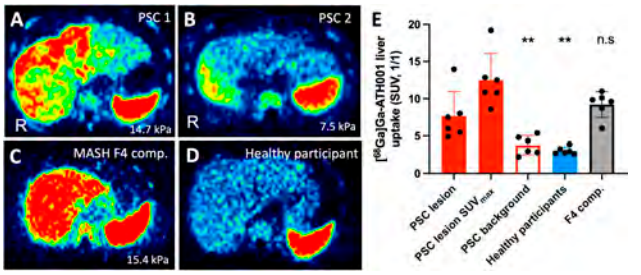
1222 | POSITRON EMISSION TOMOGRAPHY IMAGING OF ACTIVE LIVER FIBROGENESIS IN PRIMARY SCLEROSING CHOLANGITIS



Olof Eriksson[1] Fredrik Rorsman[2] Talakad Lohith[3] Cyrille Sur[4] Zoltan Derdak[5] Paresh Thakker[4] Thuy Tran[6] Lennart Nedar[6] Håkan Ahlström[7] Ayman Abouzayed[8] Edvin Johansson[7] Lars Johansson[7] Håkan Wennbo[4] Johan Vessby[2], [1]Antaros Tracer, [2]Uppsala University Hospital, [3]Takeda, [4]Takeda Development Center Americas, [5]Takeda Pharmaceuticals, [6]Karolinska Institutet, [7]Antaros Medical AB, [8]Antaros Tracer AB

Background: Primary Sclerosing Cholangitis (PSC) is a severe, chronic, progressive fibroinflammatory disease leading to strictures of the bile ducts, ultimately leading to liver cirrhosis. The condition is associated with an increased risk of cholangiocellular carcinoma. There is a lack of non-invasive tests (NITs) to assess disease activity and liver fibrogenesis. Here, we present [^{68} Ga]Ga-ATH001, a novel Platelet Derived Growth Factor Receptor β (PDGFRβ)-targeting Positron Emission Tomography (PET) tracer, for imaging of active liver fibrogenesis, in participants with PSC and healthy controls. **Methods:** Study cohorts recruited were healthy participants without history of liver disease (n = 6), and participants diagnosed with PSC (n = 6), with large-duct intrahepatic involvement according to Magnetic Resonance Cholangiopancreatography (MRCP)). Participants were administered 2.5 MBq/kg [^{68} Ga]Ga-ATH001 (corresponding to < 1µg/kg peptide mass) and examined by PET/ Magnetic Resonance Imaging (MRI) for up to 2 hours. Assessments also included Transient Elastography (TE, FibroScan). PET uptake in liver lesions and liver regions with background uptake was reported as mean and maximum Standardized Uptake Values (SUVs). A cohort of participants with advanced chronic liver disease with non-PSC etiology (n = 6) were also examined with the same PET/MR protocol as part of the study (NCT06562361). **Results:** The uptake of [^{68} Ga]Ga-ATH001 in liver in participants with PSC was highly

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

heterogenous (Figure 1A-B and E, SUV scale 0-12), where the high uptake regions exhibited intense tracer uptake (SUV_{mean} 7.6 ± 3.3, SUV_{max}12.5 ± 3.4) compared to liver of healthy participants (3.0 ± 0.5, $p < 0.001$, but comparable to that seen in advanced liver fibrosis (Figure 1C) (SUV_{mean} 9.2 ± 1.7). Low uptake regions in PSC liver (SUV_{mean} 3.8 ± 1.3) were comparable to the intensity of healthy livers (Figure 1D). No adverse events related to administration of [68 Ga]Ga-ATH001 was observed. **Conclusion:** [68 Ga]Ga-ATH001 is a novel PET based NIT for regional assessment of active liver fibrogenesis in participants with PSC. [68 Ga]Ga-ATH001 demonstrates strong heterogenous uptake in affected liver segments in subjects with PSC, while uptake in unaffected liver is low. Further analyses will focus on correlation of PET uptake to established NITs such as Magnetic Resonance Elastography (MRE), Proton Density Fat Fraction (PDFF) and plasma biomarkers.

1223 | PRURITUS IS ASSOCIATED WITH INCREASED BIOCHEMICAL DISEASE ACTIVITY AND SYMPTOM BURDEN IN PRIMARY BILIARY CHOLANGITIS: FINDINGS FROM THE GLOBAL LIVER REGISTRY

Saleh Alqahtani[1] Saad Alghamdi[1] Mohammad Mawardi[2] Dana Attar[2] Shadan AlMuhaidib[3] Feras Altunusi[3] Basmah Khoja[1] Amwaj Alanazi[1] Reem Alahmed[1] Abdullah Alkhenizan[1] Abdullah Alfhaid[1] Khalid Alswat[4] Fatema Nader[5] Faisal Abaalkhail[1] Zobair Younossi[6] Waleed Alhazzani[3], [1]King Faisal Specialist Hospital & Research Center, Riyadh, Saudi Arabia, [2]King Faisal Specialist Hospital & Research Center, Jeddah, Saudi Arabia, [3]Ministry of Defense Health Services, Riyadh, Saudi Arabia, [4]King Saud University/KKUH, [5]Center for Outcomes Research in Liver Diseases, CORLD, [6]The Global NASH/MASH Council

Background: Pruritus is among the most common and impactful symptoms in primary biliary cholangitis (PBC), yet its association with biochemical disease activity and accompanying symptom burden in real-world cohorts remains incompletely characterized. We aimed to evaluate the association of self-reported pruritus with biochemical disease severity and clinical symptom burden among patients with PBC enrolled in the Global Liver Registry. **Methods:** We performed a cross-sectional analysis of patients with PBC enrolled in the Global Liver Registry between July 2025 and October 2025. Participants were stratified according to the presence or absence of pruritus. Clinical characteristics, liver biochemistries, treatment patterns, and symptom profiles were compared between patients with and without pruritus. **Results:** A total of 102 patients with PBC were included (mean age 51.0 ± 10.8 years; 92.2% female), of whom 45 (44.1%) reported pruritus. Female sex was comparable between patients with and without pruritus (95.6% vs. 89.5%, P = 0.461). Patients with pruritus demonstrated significantly greater biochemical disease activity compared with those without pruritus, including higher alkaline phosphatase levels (median 230.0 vs. 135.0 U/L, P = 0.005), total bilirubin (13.6 vs 9.5 µmol/L, P = 0.029), alanine aminotransferase (29.5 vs 22.0 U/L, P = 0.004), aspartate aminotransferase (36.0 vs 27.0 U/L, P = 0.001), and gamma-glutamyl transferase levels (113.0 vs 47.5 U/L, P = 0.013). Fatigue was more frequently reported among patients with pruritus compared with those without pruritus (68.9% vs. 47.4%, P = 0.029), as was sleep disturbance (64.4% vs. 31.6%, P < 0.001). Rates of ursodeoxycholic acid use and second-line therapy use were similar between groups. **Conclusion:** Pruritus in PBC was associated with greater biochemical disease activity and higher symptom burden, including fatigue and sleep disturbance, in this real-world cohort from the Global Liver Registry. These findings suggest that pruritus may make a clinically more burdensome disease profile and highlight the importance of comprehensive symptom assessment and management in patients with PBC.

1224 | DIAGNOSTIC AND PREDICTIVE VALUE OF THE ASPARTATE AMINOTRANSFERASE-TO-PLATELET RATIO INDEX IN INTRAHEPATIC CHOLESTASIS OF PREGNANCY: A SYSTEMATIC REVIEW AND META-ANALYSIS

EzzElDien A. Ibrahim[1] Yazan Alnairah[2] Mostafa Adel T. Mahmoud[3] Khalid Alsaadany[4] Khalid Taha[5] Nour Aldin T. Ahmed[6] Abdelrahman Mahmoud[7] Elsayed S. Moubarak[8] Naseem Alnadi[9] Mohamed Mansour[10] Mahmoud Alfardous Alazm[9] Meghna Badami[11] Abdulah Aboukaff[12] Omar Medhat Abdelaziz Farag[13] Nikki Duong[14], [1]University of Missouri-Columbia, [2]Jordanian Royal Medical Services, Amman, Jordan, [3]Faculty of medicine, Beni Suef university, Beni Suef, Egypt., [4]Faculty of Medicine, Mansoura University, Egypt., [5]Jordan university of science and technology, Jordan, [6]Faculty of Medicine, Beni-Suef university, Beni-Suef, Egypt, [7]Minia University, [8]Faculty of Medicine Cairo University, Cairo, Egypt, [9]Flushing Hospital Medical Center, NYC, [10]Menoufia University hospital, Menoufia, Egypt, [11]Mysore Medical College and Research Institute, Mysuru, Karnataka, India, [12]Alexandria Faculty of Medicine, [13]Cairo University, [14]Stanford University, Palo Alto, CA

Background: Intrahepatic cholestasis of pregnancy (ICP) is associated with significant fetal morbidity and mortality, while total bile acid testing may be delayed or unavailable in many settings. The aspartate aminotransferase-to-platelet ratio index (APRI) is an inexpensive biomarker derived from routine blood tests. We evaluated the diagnostic, predictive, and severity-discriminating performance of APRI in ICP. **Methods:** We performed a PRISMA-DTA-guided systematic review and diagnostic test accuracy meta-analysis of studies assessing APRI in pregnant women with suspected or confirmed ICP. PubMed, Embase, Web of Science, and Scopus were searched from inception. Estimates were pooled using bivariate random-effects models. **Results:** Twelve studies encompassing 2,198 patients were included. For first-trimester prediction of ICP, the pooled sensitivity was 68.2% (95% CI 52.7%–80.5%), specificity was 81.8% (68.3%–90.4%), and AUC was 0.815, with moderate heterogeneity (I^2 = 54.2%). Preliminary second- and third-trimester prediction analyses, each limited to two studies, yielded supportive specificity estimates of 86.6% and 91.3%, respectively. For symptomatic diagnosis, the pooled sensitivity was 71.4% (63.0%–78.6%), specificity was 84.8% (77.6%–89.9%), positive likelihood ratio was 4.78, negative likelihood ratio was 0.34, AUC was 0.845, and heterogeneity was low (I^2 = 39.5%). In an exploratory analysis of severity discrimination based on two studies, APRI demonstrated a pooled sensitivity of 82.6% (73.1%–89.2%), specificity of 78.0% (64.3%–87.5%), diagnostic odds ratio of 18.50, AUC of 0.823, and minimal heterogeneity (I^2 = 2.7%). **Conclusion:** APRI demonstrates promising predictive and diagnostic utility in ICP, particularly for first-trimester prediction and symptomatic diagnosis. Preliminary data also suggest potential value in severity discrimination, though these findings require validation in larger studies. As a readily available and inexpensive biomarker, APRI may facilitate early triage and risk stratification in settings where bile acid testing is delayed or unavailable, though it should complement rather than replace standard bile acid measurement.

Figure 1. Summary Receiver Operating Characteristic (SROC) Curves for APRI in Intrahepatic Cholestasis of Pregnancy

APRI = aspartate aminotransferase-to-platelet ratio index; (A) First-trimester prediction of ICP; (B) Symptomatic diagnosis of ICP; AUC = area under the curve.

1225 | MALNUTRITION AS A PREDICTOR OF CLINICAL OUTCOMES IN HOSPITALIZED PATIENTS WITH PRIMARY BILIARY CHOLANGITIS(PBC) IN THE UNITED STATES

Tsegaye Gebreamlak[1] Mahader Wossene[1] Tamrat Petros Elias[2] Albert Gyato[1] Tamiru Dagnachew[3], [1]Loyola Medicine MacNeal Hospital, [2]King Faisal Hospital, University of Rwanda, [3]St. Paul's Hospital Millennium Medical College(SPHMMC)

Background: Malnutrition is a well-recognized complication among patient with primary biliary cholangitis (PBC). Yet the impact of malnutrition on outcomes in patients hospitalized with primary biliary cholangitis (PBC) is poorly characterized. This study aims to evaluate the association of malnutrition on clinical outcomes in patients with primary biliary cholangitis (PBC) by utilizing a national representative cohort. **Methods:** We performed cross-sectional analysis using data collected from the nationwide Inpatient Sample (NIS) database from 2016 to 2022. Hospitalizations of adult patients ($\geq$18 years) with primary biliary cholangitis(PBC) were selected by using ICD10CM codes. Malnutrition was defined as mild/moderate or severe using validated ICD10CM codes. The primary outcome was in-hospital mortality. Secondary outcomes included ascites, hepatic encephalopathy (HE), variceal hemorrhage, spontaneous bacterial peritonitis (SBP), hepatorenal syndrome (HRS), sepsis. We utilized a weighted frequency and contingency table for descriptive statistics. Multivariable logistics and linear regression were utilized for analysis to adjust for confounders including demographics, payer, income quartile, comorbidity, hospital region, bed size, cirrhosis and Hepatocellular carcinoma. Stata was utilized for statistical analysis. **Results:** We identified an estimated 86,130 hospitalizations due to primary biliary cholangitis (PBC) in the nationwide inpatient sample (2016-2022). Roughly 14.3% carried a diagnosis of malnutrition. As expected, females were predominant in both the malnourished and non-malnourished group with more than half of patients aged 65 years or older. After adjusted for cofounders Malnutrition more than doubled the odds of in hospital mortality (aOR 2.40, 95% CI 2.04–2.83; $p < 0.001$). Malnutrition was independently associated with significantly higher odds of ascites (aOR 2.77, 95% CI 2.52–3.04; $p < 0.001$), Hepatic Encephalopathy (aOR 2.04, 95% CI 1.30–3.18; $p < 0.002$), spontaneous bacterial peritonitis (SBP) (aOR 2.88, 95% CI 2.31–3.60; $p < 0.001$), and Hepatorenal syndrome(HRS) (aOR 3.42, 95% CI 2.85–4.10; $p < 0.001$). With regards to Infectious outcome malnutrition was associated with two-fold increase in sepsis (aOR 2.00, 95% CI 1.79–2.24; $p < 0.001$). Similarly, malnutrition more than doubled the odd of AKI (aOR 2.02, 95% CI 1.85–2.21; $p < 0.001$) and intensive care unit (ICU) admission (aOR 2.38, 95% CI 2.02–2.80; $p < 0.001$). A dose-response relationship was observed on clinical outcomes with severity of malnutrition. Severe malnutrition was associated with nearly threefold increased odds of in hospital mortality (aOR 2.80, 95% CI 2.28–3.44; $p < 0.001$) which is higher as compared to mild/moderate malnutrition (aOR 1.77, 95% CI 1.38–2.25). Similarly, significant dose-response relationships were observed across clinical outcomes: ascites (mild/moderate malnutrition aOR 2.20; severe malnutrition aOR 2.78), hepatorenal syndrome (aOR 2.40; 3.40), sepsis (aOR 1.80; 1.98), spontaneous bacterial peritonitis (aOR 2.16; 2.74), acute kidney injury (aOR 1.66; 1.95), and ICU admission (aOR 2.03; 2.29; all $P < 0.001$). **Conclusion:** Malnutrition shows a strong, independent link with adverse clinical outcomes in patients hospitalized with primary biliary cholangitis. Early recognition of malnutrition through targeted nutritional evaluation and intervention may improve patient outcomes.

1226 | CARDIOMETABOLIC CARE GAPS IN PRIMARY BILIARY CHOLANGITIS: UNDER-SCREENING FOR HYPERLIPIDEMIA AND STATIN UNDERUTILIZATION IN A CONTEMPORARY COHORT

Eleanor Belilos[1] Amanda Rodriguez[1] Ana Maria Davila Morales[1] Nancy Reau[1], [1]Rush University Medical Center

Background: As metabolic dysfunction-associated steatotic liver disease (MASLD) and cardiometabolic comorbidities become increasingly prevalent, patients with primary biliary cholangitis (PBC) may face heightened cardiovascular risk. Despite evidence supporting statin safety in chronic liver disease, concerns regarding hepatotoxicity may contribute to undertreatment of dyslipidemia in PBC. We evaluated lipid screening practices and statin utilization in a contemporary cohort of antimitochondrial antibody-positive (AMA+) PBC patients. **Methods:** We performed a retrospective chart review of adults with confirmed AMA+ PBC evaluated in hepatology clinic at a single academic center between January 2017 and December 2022. Demographics, body mass index (BMI), cardiovascular comorbidities, fasting lipid panel (FLP) screening history, and statin use were collected through chart review. Statin

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

eligibility was determined using current United States Preventive Services Task Force recommendations. Descriptive statistics characterized screening and treatment patterns. **Results:** A total of 131 patients with confirmed AMA+ PBC were included. Median age was 63 years and median BMI was 27.7 kg/m²; 120/131 (91.6%) were female. Diabetes mellitus was present in 25/131 (19.0%) and 14/131 (10.6%) had documented atherosclerotic cardiovascular disease (ASCVD). Overall, 56/131 (42.7%) met guideline-based indications for statin therapy. Despite substantial cardiometabolic risk burden, 22/131 patients (16.8%) had no documented prior FLP screening. Among patients with at least one documented FLP (109/131), median age was 64 years and median BMI was 27.9 kg/m². Overall, 48/131 patients (36.6%) were prescribed statin therapy. Among statin-eligible patients, 19/56 (33.9%) were not receiving treatment. In untreated statin-eligible patients, chart documentation frequently cited elevated liver enzymes or underlying liver disease as reasons for withholding therapy. **Conclusion:** In this contemporary AMA+ PBC cohort, substantial gaps in cardiovascular risk assessment and preventive care were identified. Nearly one in six patients had never undergone lipid screening, and one-third of statin-eligible patients were untreated despite established indications. Provider concerns regarding hepatotoxicity appear to contribute to undertreatment despite evidence supporting statin safety in chronic liver disease. These findings highlight the growing overlap between PBC, MASLD, and metabolic dysfunction and support greater integration of hepatology and cardiovascular preventive care in PBC.

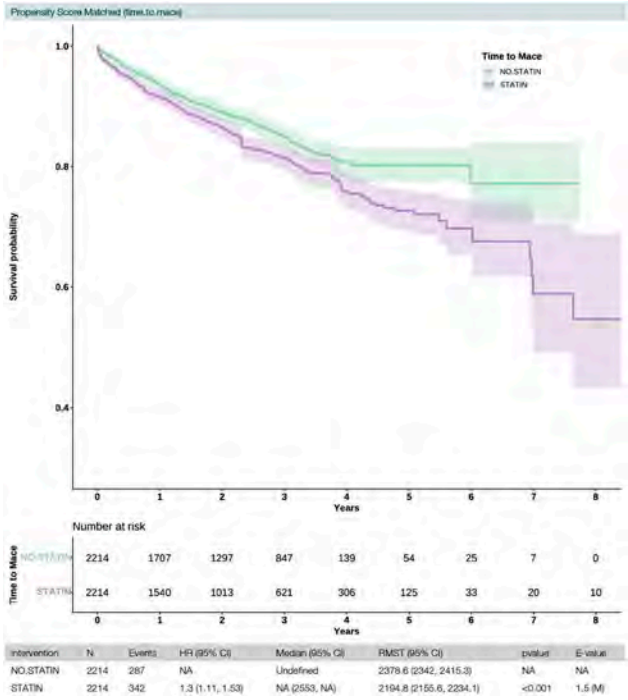
1227 | STATIN USE AND MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PRIMARY BILIARY CHOLANGITIS: A PROPENSITY SCORE–MATCHED COHORT STUDY



Remco Kersten[1] Honor Magon[2] Cheyne Hoke[2] Carlos Reina[2] Aparna Goel[1], [1]Stanford University Medical Center, [2]Atropos Health

Background: Primary biliary cholangitis (PBC) is characterized by distinctive dyslipidemia and incompletely understood cardiovascular risk. Statins are frequently withheld due to hepatotoxicity concerns and uncertainty surrounding major adverse cardiovascular events (MACE) outcome data in this population. With treatment advances prolonging survival, PBC patients face persistent MACE risk, highlighting the importance of better characterizing current ASCVD risk management practices in this population. **Methods:** This retrospective cohort study used the Apollo dataset (Atropos Health), a de-identified national EHR-claims database of more than 142 million U.S. patients. PBC and MACE were ascertained using ICD-9/10 codes; MACE encompassed MI, unstable angina, heart failure, ischemic and hemorrhagic stroke, TIA, subarachnoid hemorrhage, and cerebrovascular occlusion. Statin initiators were compared to statin-naïve controls with a 3-month washout. Index date was first statin prescription (intervention) or first office visit (controls) after PBC diagnosis. Time to MACE was analyzed via (1) unadjusted Cox regression, (2) basic demographic matching, and (3) propensity score (PS) matching augmented with time from PBC diagnosis to index date, diabetes history, and hypertension history. **Results:** 4,749 statin initiators and 4,661 statin-naïve controls were identified. Statin users were older (64.9 vs. 59.2 years) with higher rates of diabetes (36.0% vs. 16.3%) and hypertension (64.4% vs. 47.9%), confirming confounding by indication. Statin-naïve patients had higher rates of severe liver disease (21.5% vs. 14.4%). PS matching yielded 2,214 well-balanced pairs. MACE risk attenuated across matching steps: unadjusted (976 vs. 515 events; HR 1.54, 95%CI 1.38–1.72), basic matched (736 vs. 473 events; HR 1.30, 1.15–1.46), and PS-matched (342 vs. 287 events; HR 1.30, 1.11–1.53; all $p < 0.001$). An E-value of 1.5 suggests moderate confounding could explain the residual signal. **Conclusion:** Although statin users experienced more MACE in unadjusted analyses, attenuation across adjustment steps is consistent with residual confounding by indication rather than true drug toxicity. Residual associations may reflect dyslipidemia severity, PBC disease stage, and PBC-directed treatment. Higher severe liver disease prevalence among statin-naïve patients introduces competing risks, as advanced PBC may cause

hepatic decompensation before MACE, artificially improving cardiovascular survival in controls. These data highlight a clinically significant treatment gap: a substantial proportion statin-naïve PBC patients had diabetes and hypertension, conditions (likely) warranting lipid-lowering therapy. Studies incorporating competing-risk methodology and PBC-specific covariates are needed.

1228 | LOSS OF RESPONSE TO FIRST-LINE TREATMENT IMPACTS THE RISK AND TIME TO LONG-TERM OUTCOMES AMONG PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Seema Meloni[1] Gajinder Pal Singh[2] Allison Smither[2] Brian Juran[3] Christelle Pommie[4] Philip Troke[5] Konstantinos Lazaridis[3], [1]Ipsen, Cambridge, MA, USA, [2]nference, Cambridge, MA, USA, [3]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, USA, [4]Ipsen, Paris, France, [5]Ipsen, London, UK

Background: Ursodeoxycholic acid (UDCA) is the first-line (1L) treatment for patients (pts) with primary biliary cholangitis (PBC), and response to UDCA is typically defined using biomarkers such as alkaline phosphatase (ALP) levels. Pts with an adequate biochemical response at 12 months (M12) have better long-term outcomes than non-responders. To date, the proportion of patients who maintain adequate response beyond M12 and the impact of loss of response (LoR) to 1L treatment is not well characterized; better understanding of durability of response and impact of LoR may inform timing and urgency of escalation to second-line (2L) therapies. We evaluated the frequency and timing of LoR to UDCA, and its association with long-term liver outcomes. **Methods:** This observational study used electronic medical record data from the Mayo Clinic in the US. Pts with a PBC diagnosis were identified using structured (laboratory results and diagnostic codes) and unstructured (clinical notes) data. Eligible pts included those with PBC initiating UDCA between 1 January 1998−31 July 2024, with $\geq$12 months of UDCA treatment and without advanced liver disease or other predefined cholestatic conditions. Pts were followed from UDCA initiation until liver outcome, death, loss to follow-up, or the end of the study period (31 July 2025). Pts were classified as ALP responders (<1.67×upper limit of normal [ULN]) or non-responders ($\geq$1.67×ULN) at M12. Among responders, LoR was defined as any subsequent ALP $\geq$1.67×ULN after M12; a sensitivity analysis with a stricter definition of two consecutive ALP values $\geq$1.67×ULN was conducted. Long-term liver outcomes (decompensated liver disease, liver transplant, liver cancer, other liver outcomes, and death) were identified using International Classification of Diseases 9th and 10th revisions (ICD-9 and ICD-10) codes and unstructured data. **Results:** Among pts with adequate response to UDCA at M12 (n=265), LoR occurred in 9.1% by M24, 12.8% by M36, and 20.8% by M60. Higher proportions of pts with LoR progressed to adverse liver outcomes vs those without LoR at M24, M36 or M60 (**Figure A**), and survival probability free from any liver outcome was higher in pts without LoR vs with LoR (**Figure B**). Similarly, higher proportions of pts with LoR at M24, M36 and M60 underwent liver transplant (LT) vs those without LoR, with higher transplant-free survival probability observed in pts without LoR; median time to LT in those who had an LT was 5.6 years in pts without LoR vs 2.0 years in pts with LoR by M60 (**Figures C and D**). All findings were corroborated when the more stringent LoR definition of two consecutive ALP values $\geq$1.67×ULN after M12 was used. **Conclusion:** LoR to UDCA was associated with worse liver outcome-free survival than in pts without LoR. These findings highlight the importance

of ongoing biochemical response monitoring and timely consideration of switching to effective 2L therapy following LoR to improve long-term outcomes.

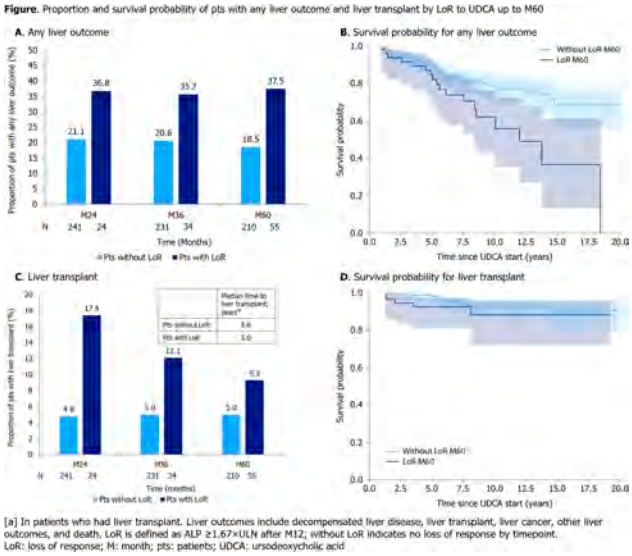

Figure. Proportion and survival probability of pts with any liver outcome and liver transplant by LoR to UDCA up to M60

[a] In patients who had liver transplant. Liver outcomes include decompensated liver disease, liver transplant, liver cancer, other liver outcomes, and death. LoR is defined as ALP ≥1.67×ULN after M12; without LoR indicates no loss of response by timepoint.
LoR: loss of response; M: month; pts: patients; UDCA: ursodeoxycholic acid

1229 | BONE LOSS TRAJECTORIES IN POSTMENOPAUSAL WOMEN WITH PBC COMPARED WITH MATCHED CONTROLS: A PROPENSITY-MATCHED ANALYSIS USING SERIAL DEXA SCANS

Leandro Sierra[1] Hussam Kawas[2] Qijun Yang[2] Sara Valencia[3] Rachel McNulty[2] Juan Armijos[2] John McMichael[2] Mohamad Alabbas[2] Li Tang[2] Kaylan Bhamidimarri[2] Bobby Zervos[2] Omar Sims[2] Dian Chiang[2], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic, [3]Department of Internal Medicine, University of Arizona, Tucson, AZ, USA

Background: Primary biliary cholangitis (PBC) is conventionally thought to accelerate postmenopausal bone loss, yet this assertion has not been rigorously tested against matched non-PBC women using serial DEXA scans. We aimed to quantify rapid bone disease progression in postmenopausal PBC women versus propensity-matched non-PBC controls using paired DEXA scans. **Methods:** We performed a retrospective cohort study of postmenopausal women at the Cleveland Clinic Ohio and Florida campuses. Female patients with PBC and non-PBC controls with at least one paired DEXA obtained 12–36 months apart were included. Propensity scores incorporated demographics, laboratory parameters, bone-active medication exposure, supplementation use, and osteoporosis-related comorbidities, followed by 3:1 nearest-neighbor matching. Co-primary outcomes were: (1) rapid progression of bone disease, defined as progression from osteopenia (T-score –1.0 to –2.5) to osteoporosis (T-score ≤–2.5) between paired DEXAs obtained 12–36 months apart, and (2) annualized change in lumbar T-score, lowest-site T-score, and lumbar BMD between serial DEXAs. Within PBC, UDCA biochemical response criteria (Paris-II, UK-PBC, and GLOBE low-risk) were evaluated as predictors of skeletal outcomes. **Results:** Among 551 postmenopausal women (229 PBC; 322 controls), 191 formed the propensity-matched cohort (127 PBC; 64 controls). Baseline osteoporosis prevalence at first DEXA was similar between groups (11.7% vs 11.8%, p = 0.84), as were baseline lumbar T-scores (–1.0 vs –0.9) and lowest-site T-scores (–1.8 vs –1.7). Rapid progression of bone disease between paired DEXAs did not differ between PBC and controls. Rapid lowest-site T-score progression occurred in 21.2% versus 25.0%, respectively (OR 0.18, 95% CI 0.02–1.37, p = 0.097). Similarly, annualized rates of bone loss were comparable between groups. Mean annualized change in lumbar T-score was +0.031/year in PBC versus –0.006/year in controls (β +0.039, p = 0.33), while annualized change in lowest-site T-score was –0.025/year versus –0.045/year, respectively (β +0.009, p = 0.81). Annualized lumbar BMD change was also similar between groups (p = 0.98). Within PBC, Paris-II responders showed improved lumbar T-score compared with non-responders (β +1.07, 95% CI +0.14 to +2.00, p = 0.024). Similarly, UK-PBC responders exhibited improved lowest-site T-score compared with non-responders (β +0.40, 95% CI +0.04 to +0.75, p = 0.028), same for GLOBE low-risk status (β +0.95, p = 0.048). **Conclusion:** Postmenopausal women with PBC did not exhibit accelerated bone loss or increased rapid progression to osteoporosis compared with propensity-matched non-PBC controls. However, biochemical response to UDCA was associated with significantly more favorable bone outcomes compared with non-responders. These findings suggest that PBC non-responders may represent a distinct skeletal risk phenotype.

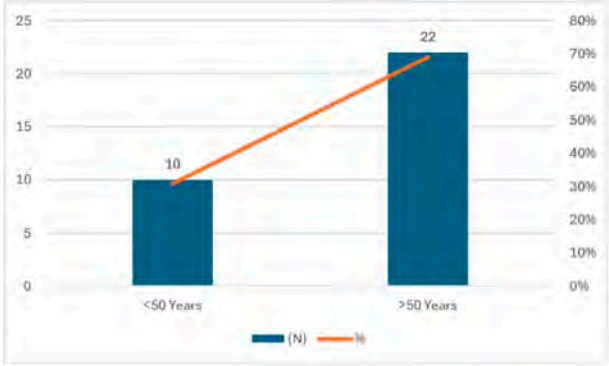
Table 1. Rapid bone disease progression and annualized change in bone density, matched cohort: PBC vs Controls

Outcome	PBC	Controls	Effect estimate (95% CI)	p
Binary rapid progression (12–36 mo paired DEXA)				
Rapid lumbar progressor, n (%)	2/22 (9.1)	1/8 (12.5)	OR 0.07 (0.005, 1.00)	0.05
Rapid lowest-site progressor, n (%)	7/33 (21.2)	3/12 (25.0)	OR 0.18 (0.02, 1.37)	0.097
Annualized change between paired DEXAs				
ΔT lumbar / year, mean	+0.031	−0.006	β +0.039 (−0.04, +0.12)	0.33
ΔT lowest-site / year, mean	−0.025	−0.045	β +0.009 (−0.06, +0.08)	0.81
ΔBMD lumbar (g/cm²) / year, mean	−0.002	−0.0015	β +0.0001 (−0.009, +0.009)	0.98

Binary outcomes restricted to patients with baseline osteopenia and paired DEXAs 12–36 months apart. Continuous outcomes use all available paired DEXAs in the matched cohort, with linear regression weighted by propensity matching weights. Negative ΔT and ΔBMD values indicate bone loss; positive values indicate bone gain.

Table 2. UDCA biochemical response status as a predictor of baseline bone density within PBC

Response definition	Outcome	n	β responder vs non (95% CI)	p
Paris-I	Lumbar T-score	146	+1.07 (+0.14, +2.00)	0.024
UK-PBC	Lowest T-score	141	+0.40 (+0.04, +0.75)	0.028
GLOBE low-risk	Lowest T-score	145	+0.95 (−0.003, +1.90)	0.048



Univariable linear regression of baseline bone outcome on UDCA biochemical response status (responder = 1, non-responder = 0), within PBC cases only. Positive β indicates higher T-score in responders. Three independent response definitions consistently identify responders as having superior baseline bone density.

1230 | MALE CHARACTERISTICS IN PRIMARY BILIARY CHOLANGITIS: A SINGLE-CENTER REAL-WORLD ANALYSIS

Abdullah Mubarak[1] Shagun Gupta[2] Shaun Meppidayil[2] Rayaan Malik[2], [1]Liver Center of Texas, PLLC, [2]IIVER CENTER OF TEXAS

Background: Primary Biliary Cholangitis (PBC) is a chronic autoimmune cholestatic liver disease, historically considered a condition of middle-aged women, that affects approximately 110 per million men — a figure likely underrecognized in clinical practice. Male patients may present at a later disease stage with a distinct comorbidity profile, yet sex-based differences remain understudied. This retrospective single-center analysis characterizes the demographic, clinical, and biochemical profile of male patients initiated on ursodeoxycholic acid (UDCA) for PBC or cholestatic liver disease, with a focus on fibrosis burden at presentation. **Methods:** Demographics, race, diagnoses, liver biopsy findings, baseline alkaline phosphatase (ALP), total bilirubin, and transient elastography (Fibroscan, kPa) values were collected and compared between male and female patients. Liver stiffness $\geq$ 9.6 kPa was used as a threshold associated with significantly worse clinical outcomes per AASLD guidance. **Results:** Males comprised one-third of the cohort (mean age 58.9 years vs. 61.0 years in females), with the 60–69 age group most represented and Caucasians comprising the majority of both groups. PBC was the most common diagnosis in males, followed by cirrhosis of various etiologies, with a subset carrying comorbid conditions including MASH, steatosis, and autoimmune cholangiopathy. Male patients had a lower mean baseline ALP compared to females (176.2 U/L vs. 204.1 U/L), though both groups exceeded normal limits. Mean Fibroscan values were notably higher in males, suggesting greater hepatic fibrosis burden at presentation. Most male patients were on UDCA 300 mg/day; notably, no male patient was documented on obeticholic acid (OCA), compared to four female patients, despite a proportion of males likely qualifying based on their fibrosis and ALP profiles. **Conclusion:** This analysis demonstrates that male PBC patients present with higher hepatic fibrosis burden despite similar ages at diagnosis, and reveals a potential gap in second-line therapy utilization. These findings are hypothesis-generating and limited by sample size; prospective studies are needed to better characterize sex-based differences in PBC presentation and management.

1231 | REAL-WORLD EFFECTIVENESS OF SELADELPAR IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS: EXPERIENCE FROM A COMMUNITY-BASED HEPATOLOGY PRACTICE

Rida Nadeem[1] Anita Kohli[1] Richard Manch[1] Ann Moore[1] Jana Mohamed[1] Cody Chen[1] Justin Reynolds[1] Phuong Nguyen[1] Jessica Omana Castaneda[1] Tessa Janovsky[1], [1]Arizona Liver Health

Background: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease associated with progressive fibrosis, cirrhosis, and liver-related morbidity. Despite standard therapy with ursodeoxycholic acid (UDCA), a substantial proportion of patients fail to achieve adequate biochemical response. Seladelpar, a peroxisome proliferator-activated receptor (PPAR)-delta agonist, has emerged as a novel therapeutic option for patients with inadequate response or intolerance to UDCA. Real-world data evaluating the effectiveness of seladelpar in routine clinical practice remain limited. **Methods:** We conducted a retrospective real-world analysis of adult patients with PBC treated with seladelpar at a single outpatient hepatology center for at least 12 months. Patients with available baseline and follow-up laboratory data were included. Primary efficacy outcomes included changes in alkaline phosphatase (ALP), total bilirubin normalization, improvement in liver transaminases, and patient reported outcomes following initiation of therapy. **Results:** A total of 37 patients with PBC were included in the final analysis (mean age 65 years; 95.2% females; mean BMI 28.2). Average time on ursodiol before starting a second-line agent was about 3.4 years. Following initiation of seladelpar therapy, patients demonstrated clinically meaningful reductions in ALP levels compared with baseline (mean reduction of 86 IU/L). Mean reduction in total bilirubin of 0.12 mg/dL. Improvements were also observed in cholestatic and hepatic biochemical parameters, including reductions in AST and GGT of 7.5 IU/L and 88.9 IU/L respectively. 13% reported improvement in pruritis. Elafibranor was generally well tolerated in this real-world cohort, with a 11.42% discontinuation rate overall. **Conclusion:** In this real-world community hepatology cohort, seladelpar treatment was associated with improvements in cholestatic liver biochemistries and fibrosis-related markers among patients with PBC. These findings support the effectiveness of seladelpar in routine clinical practice and reinforce its role as a promising therapeutic option for patients with inadequate biochemical response to standard therapy. Larger longitudinal studies are warranted to further evaluate long-term clinical outcomes and treatment durability.

1232 | MEAN REDUCTION IN ALKALINE PHOSPHATASE AT 6–9 MONTHS FOLLOWING URSODEOXYCHOLIC ACID INITIATION IN PRIMARY BILIARY CHOLANGITIS: A SINGLE-CENTER REAL-WORLD ANALYSIS

Abdullah Mubarak[1] Shagun Gupta[2] Rayaan Malik[2] Shaun Meppidayil[2], [1]Liver Center of Texas, PLLC, [2]Liver Center of Texas

Background: Ursodeoxycholic acid (UDCA) at 13 to 15 mg/kg/day is the established first-line therapy for Primary Biliary Cholangitis (PBC), a chronic cholestatic liver disease marked by progressive bile duct destruction and hepatic fibrosis. UDCA improves liver biochemistries and transplant-free survival, with alkaline phosphatase (ALP) reduction as the primary marker of treatment response. Per AASLD 2021 guidance, ALP assessment at 12 months identifies inadequate responders for second-line escalation; however, early trends at 6 to 9 months may identify non-responders sooner, enabling earlier intervention. **Methods:** This single-center retrospective analysis included 97 patients initiated on UDCA for PBC or cholestatic liver disease, of whom 36 had paired baseline and 6 to 9 month ALP values. Of 88 patients with documented baseline ALP, 27 had ALP above 200 U/L. Among the 36 with paired data, 9 had baseline ALP greater than 200 U/L, enabling assessment of early response in this higher-burden subgroup. **Results:** Mean ALP declined from 182.5 U/L

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

at baseline to 158.5 U/L at 6 to 9 months, a reduction of 24.0 U/L. Mean percent change was -1.0% and median was -6.4%, with individual changes ranging from -74.0% to +100.0%. Only 12 of 36 patients (33.3%) achieved the 15% or greater ALP reduction threshold; 24 (66.7%) did not. 31 of 36 (86.1%) achieved ALP below 2 times ULN at 6 to 9 months, and ALP continued declining at 12 months (mean 151.8 U/L), consistent with UDCA's gradual pharmacologic effect. Among 9 patients with baseline ALP greater than 200 U/L, only 2 reached that threshold or below by 6 to 9 months; 4 of 9 did so by 12 months. This suggests limited early response in higher-burden patients, with many remaining above 200 U/L even at 12 months, reinforcing the need for close monitoring and timely escalation in this subgroup. **Conclusion:** In conclusion, mean ALP declined 24.0 U/L at 6 to 9 months on UDCA, yet only 1/3 of patients met the responder threshold and those with baseline ALP greater than 200 U/L showed particularly limited early response. Patient-level monitoring is essential given the variability observed. Inadequate responders at 6 to 9 months, particularly those with ALP above 200 U/L, should be promptly considered for second-line therapy per AASLD 2021 guidance.

Metric	Value
Mean ALP Baseline	182.5 U/L
N baseline	88
Mean ALP at 6–9 Months	158.5 U/L
N 6-9 Months	36
N 12 Months	30
Mean Absolute Reduction	−24.0 U/L
Mean % Change	−1.0%
Median % Change	−6.4%
Responders (≥15% reduction)	12/36 (33.3%)
Non-Responders	24/36 (66.7%)
ALP <2× ULN at 6–9 mo	31/36 (86.1%)
Mean ALP at 12 Months	151.8 U/L

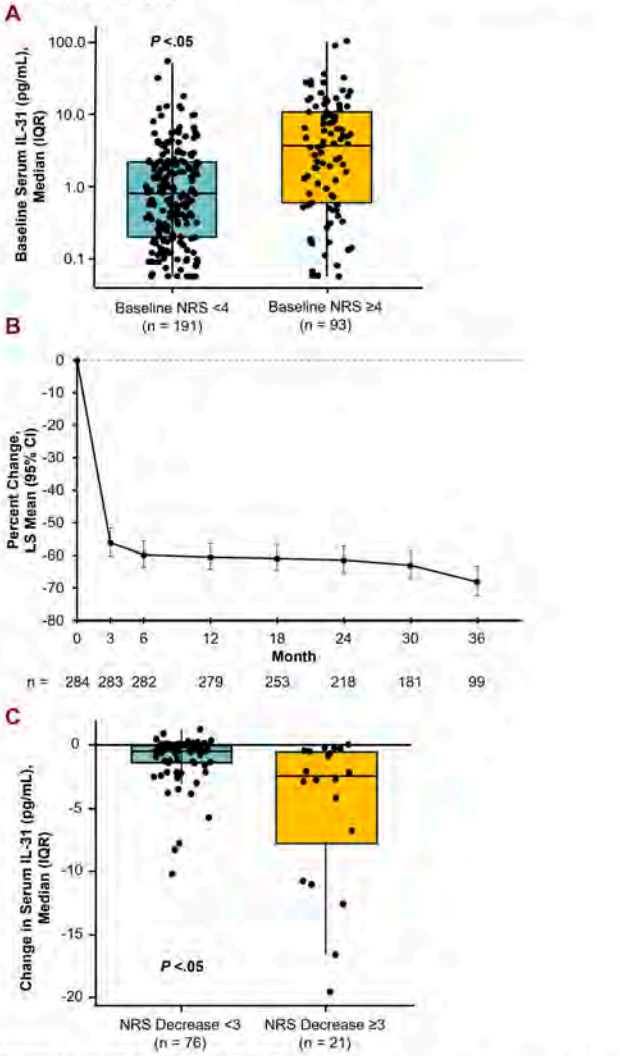
1233 | SELADELPAR LEADS TO DURABLE AND SIGNIFICANT DECREASE IN THE PRURITOGENIC CYTOKINE IL-31, ASSOCIATED WITH PRURITUS IMPROVEMENT: LONG-TERM DATA FROM THE ASSURE STUDY

Marlyn Mayo[1] Kyung min Kwon[2] Gideon Hirschfield[3] Yan Liang[2] Cynthia Levy[4] Christopher Bowlus[5] David Jones[6] Daria Crittenden[2] Peyvand Amini[2] Andreas Kremer[7], [1]University of Texas Southwestern Medical Center, Dallas, TX, USA, [2]Gilead Sciences, Inc., Foster City, CA, USA, [3]UHN's Francis Family Liver Clinic and Toronto Centre for Liver Disease, Toronto, ON, Canada, [4]Miller School of Medicine, University of Miami, Miami, FL, USA, [5]University of California Davis School of Medicine, Sacramento, CA, USA, [6]Newcastle University, Newcastle upon Tyne, United Kingdon, [7]University Hospital Zürich, University of Zürich, Zürich, Switzerland



Background: Pruritus affects up to 80% of patients (pts) with primary biliary cholangitis (PBC) and can impair quality of life. Seladelpar (SEL), a first-in-class delpar (selective peroxisome proliferator–activated receptor delta [PPARδ] agonist), is approved as a second-line treatment for PBC and demonstrated durable biochemical efficacy and pruritus improvement in clinical trials. Interleukin 31 (IL-31) is a pruritogenic cytokine elevated in pts with PBC. In the pivotal Phase 3 RESPONSE study (NCT04620733), SEL decreased IL-31 concentrations and reduced pruritus. Here, we present data on long-term changes in IL-31 and their association with pruritus and bile acids in pts with PBC treated with SEL up to 36 months (M) from an interim analysis of the ongoing Phase 3 open-label ASSURE study (NCT03301506). **Methods:** Pts from RESPONSE and legacy SEL studies enrolled in ASSURE and received open-label SEL 10 mg once daily. Pts were pooled at SEL initiation in either RESPONSE or ASSURE. Pts with baseline (BL) and ≥1 post-BL IL-31 concentrations were included in this post hoc analysis. BL pruritus with numerical rating score (NRS) ≥4 was used to define subgroups by pruritus severity. Serum IL-31 concentrations were determined using a single-molecule array ultrasensitive immunoassay (lower limit of quantitation of 0.024 pg/mL). IL-31 levels were assessed over time in the overall population. BL IL-31 levels were compared by BL NRS groups (≥4 vs <4). Changes in IL-31 by NRS improvement status (≥3 points decline vs less improvement) were also assessed. Correlations between IL-31 and NRS or total bile acids (TBAs) were evaluated using Spearman's rank correlation. Data cutoff: Jan 31, 2025. **Results:** Overall, 284 pts were included; 93 pts had BL NRS ≥4. BL median (IQR) IL-31 level was higher in pts with NRS ≥4 vs NRS <4 (3.70 [0.60, 11.00] pg/mL vs 0.81 [0.20, 2.20] pg/mL; Figure A). IL-31 reductions were rapid and sustained up to M36 in the overall population (least squares mean [95% CI], -68% [-63%, -73%]; Figure B) and in pts with BL NRS ≥4 (-74% [-66%, -80%]). At M36, pts with NRS improvement ≥3 points had greater median (IQR) reductions in IL-31 (-2.80 [-10.80, -0.52] pg/mL; n = 21) compared to pts with lower NRS improvement (-0.30 [-1.32, -0.04] pg/mL; n = 76; Figure C). BL IL-

31 levels were correlated with BL NRS (ρ = 0.39; P < 0.05), as were changes from BL to M36 in IL-31 and NRS (ρ = 0.37; P < 0.05). IL-31 and TBA were correlated at BL (ρ = 0.50; P < 0.05), as were changes from BL to M36 (ρ = 0.52; P < 0.05). **Conclusion:** SEL led to sustained IL-31 reductions through M36. IL-31, a pruritogenic biomarker, was higher in pts with greater pruritus burden, and greater reductions in IL-31 were observed among pts with meaningful improvement of NRS ($\geq$3). IL-31 was correlated with NRS and with TBA levels. Alongside existing evidence, these results—particularly the observed associations between IL-31 and NRS—suggest a mechanistic link between SEL treatment and pruritus improvement.

Figure. (A) Baseline IL-31 by Baseline NRS Subgroup, (B) Percent Change From Baseline in Serum IL-31, and (C) Changes in IL-31 by Decrease in Pruritus NRS at M36

P-values shown are from Wilcoxon rank-sum tests.
In panel B, the y-axis is log-scaled. In panel C, 1 outlier from the 'Decrease in NRS ≥3' group (change in IL-31 = −88.2 pg/mL) was removed for visualization purposes.
IL-31, interleukin 31; LS, least squares; M, Month; NRS, numerical rating score.

1234 | SEMAGLUTIDE AND LONG-TERM OUTCOMES IN UDCA-TREATED PRIMARY BILIARY CHOLANGITIS WITH OBESITY AND TYPE 2 DIABETES: A PROPENSITY-MATCHED ANALYSIS

Mohammad Alabbas[1] Akram Alnounou[2] Barish Eren[1] Riddhi Machchhar[3] Omar Sims[1] Dian Chiang[4], [1]Cleveland Clinic Foundation, [2]Department of Internal Medicine, Western Michigan University Homer Stryker M.D. School of Medicine, [3]Department of Internal Medicine, Hackensack Meridian Health Ocean University Medical Center, Brick, [4]Cleveland Clinic

Background: Primary biliary cholangitis (PBC) is frequently accompanied by metabolic comorbidity, including obesity and type 2 diabetes. The long-term hepatic and cardiovascular outcomes associated with semaglutide use in ursodeoxycholic acid (UDCA)-treated PBC remain uncertain. We evaluated outcomes associated with semaglutide exposure versus no GLP-1 receptor agonist exposure. **Methods:** Using the TriNetX Research Network of 111 healthcare organizations, we identified adults with PBC receiving UDCA. Semaglutide users, representing an obesity- and type 2 diabetes-enriched subgroup, were compared with UDCA-treated nonusers without GLP-1 receptor agonist exposure after 1:1 propensity-score matching on demographics, comorbidities, medications, and laboratory values. Patients with major competing liver diseases were excluded. Outcomes were assessed from day 1 after index through 3 and 5 years. The primary outcome was major adverse liver outcomes (MALO), a composite of liver-related events and death. Secondary outcomes included hospitalization, MACE, mortality, pruritus, fatigue, albumin $\leq$3.5 g/dL, ALP, and incident hepatic decompensation. **Results:** In the 3-year matched cohort, 482 semaglutide users were compared with 482 nonusers. Semaglutide was associated with lower MALO (22.6% vs 31.1%; RR 0.73, 95% CI 0.59–0.90), hospitalization (13.9% vs 24.9%; RR 0.56, 95% CI 0.43–0.73), MACE (21.0% vs 26.6%; RR 0.79, 95% CI 0.63–0.99), mortality (2.3% vs 8.7%; RR 0.26, 95% CI 0.14–0.50), and incident hepatic decompensation (5.8% vs 12.0%; RR 0.48, 95% CI 0.31–0.74). Pruritus, fatigue, albumin $\leq$3.5 g/dL, and ALP did not significantly differ. In the 5-year matched cohort, 531 semaglutide users were compared with 531 nonusers. Semaglutide remained associated with lower MALO (23.9% vs 36.3%; RR 0.66, 95% CI 0.55–0.80), hospitalization (15.3% vs 29.2%; RR 0.52, 95% CI 0.41–0.67), mortality (3.0% vs 6.6%; RR 0.46, 95% CI 0.26–0.82), albumin $\leq$3.5 g/dL (7.3% vs 17.1%; RR 0.43, 95% CI 0.27–0.69), and incident hepatic decompensation (6.2% vs 14.7%; RR 0.42, 95% CI 0.29–0.62). MACE was directionally lower by risk analysis and significant by survival analysis, while pruritus, fatigue, and ALP did not differ. **Conclusion:** In this propensity-matched cohort of UDCA-treated PBC enriched for obesity and type 2 diabetes, semaglutide exposure was associated with lower long-term MALO, hospitalization, mortality, incident hepatic decompensation, and hypoalbuminemia, without worsening ALP or symptom outcomes. These observational findings support prospective evaluation of semaglutide in metabolically selected patients with PBC.

Table 1. Outcomes after semaglutide vs no GLP-1 RA exposure in UDCA-treated PBC with obesity and T2DM

1:1 propensity-matched cohort, n=482 per group; 3-year outcomes

Outcome (3-year)	Sema, %	No GLP-1 RA, %	RR (95% CI)	P value
MALO (primary)	22.6	31.1	**0.73 (0.59–0.90)**	**0.003**
Hospitalization	13.9	24.9	**0.56 (0.43–0.73)**	**<0.001**
MACE	21.0	26.6	**0.79 (0.63–0.99)**	**0.041**
Mortality	2.3	8.7	**0.26 (0.14–0.50)**	**<0.001**
Incident hepatic decompensation	5.8	12.0	**0.48 (0.31–0.74)**	**0.001**
Pruritus	5.5	6.8	0.81 (0.47–1.40)	0.455
Albumin ≤3.5 g/dL	8.0	11.9	0.68 (0.41–1.12)	0.125
Fatigue	9.9	8.1	1.23 (0.76–1.99)	0.399
ALP (most recent value): mean 141.5 vs 159.8 U/L; p=0.075, NS				

Abbreviations: MALO, major adverse liver outcomes; MACE, major adverse cardiovascular events; PBC, primary biliary cholangitis; UDCA, ursodeoxycholic acid; ALP, alkaline phosphatase; NS, not significant.

P values are from risk-analysis testing in the propensity-matched cohort.

1235 | EFFECT OF UDP-GLUCURONOSYLTRANSFERASE (UGT) ENZYME POLYMORPHISMS ON SERUM ALKALINE PHOSPHATASE LEVELS IN PATIENTS WITH PBC RECEIVING ADJUNCT FENOFIBRATE THERAPY

Colleen Hayes[1] Christopher Hemme[1] Mahesh Krishna[2] Scott Roberts[1] Bonnie Chen[2] James Boyer[2] David Assis[2] Nisanne Ghonem[1], [1]University of Rhode Island, [2]Yale University

Background: PBC is characterized by the accumulation of toxic bile acids in the liver. Glucuronidation is a major pathway of bile acid detoxification in which UGT enzymes conjugate glucuronic acid to bile acids to enhance their elimination. Bile acid glucuronidation in humans is catalyzed by UGT1A1, -1A3, -1A4, -2B4, and -2B7 enzymes, which are predominantly regulated by the peroxisome proliferator-activated receptor alpha (PPARα). Importantly, polymorphisms in *UGT1A* and *-2B* genes may alter bile acid glucuronidation and subsequent treatment response to PPARα therapy. This study investigates the effect of UGT polymorphisms on serum alkaline phosphatase (ALP) levels in people with PBC who received treatment with ursodeoxycholic acid (UDCA) ± second-line therapy with fenofibrate (PPARα agonist). **Methods:** Genomic DNA was extracted from plasma samples obtained from de-identified PBC patients who received UDCA ± fenofibrate at the Yale Liver Center Biorepository. Genotyping was performed for *UGT1A1**28, *-1A3* -66T > C, *-1A3* 31T > C, *-2B4* 1374A > T, and *-2B7* 802T > C polymorphisms. Patients were stratified according to treatment response, defined as complete responders, e.g., serum ALP < upper limit of normal (ULN), or incomplete response (ALP > ULN). For paired data, linear regression was performed with samples pre- and post-fenofibrate. UGT genotypes were correlated with clinical variables. **Results:** Among people with PBC who received combination therapy (UDCA + fenofibrate, n = 23), both reference (wild-type) and alternate (heterozygote + homozygote mutant) genotypes were observed. For those who experienced an incomplete response after the addition of fenofibrate, a greater reduction in mean (± SD) serum ALP (-36%) was found with the reference *UGT2B7* 802T > C vs. alternate genotype (153 ± 47 vs. 209 ± 76 U/L, p = 0.24). Interestingly, greater reductions in mean serum ALP were found in those with the alternate *UGT1A3* -66T > C (-14%) and *UGT1A3* 31T > C (-18%) vs. reference genotypes (165 ± 41 vs. 191 ± 81 U/L, and 157 ± 40 vs.191 ± 81 U/L, p = 0.10, respectively). **Conclusion:** Our study identified several UGT polymorphisms in people with PBC, and all three genotypes (wild-type, heterozygous, homozygous mutant) were detected for *UGT1A1**28, *UGT1A3* -66T > C, *-1A3* 31T > C, and *-2B7* 802T > C. Patients who have the alternate *UGT2B7* 802T > C genotype may have a reduced response to second-line therapy with fenofibrate, while those with the alternate *UGT1A3* -66T > C or *-1A3* 31T > C genotype may have a greater response to fenofibrate. These data suggest that UGT polymorphisms may serve as indicators of treatment response to PPAR agonists and warrant further investigation.

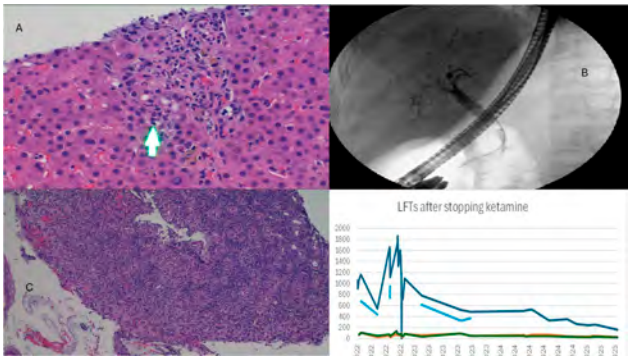
1236 | KETAMINE-INDUCED SCLEROSING CHOLANGIOPATHY MAY BE REVERSIBLE ON STOPPING TREATMENT



Gerond Lake-Bakaar[1], [1]PSLMC

Background: Chronic recreational ketamine misuse has been linked to severe complications, including ketamine-induced sclerosing cholangitis (KISC). We previously reported a case of KISC in a patient following chronic topical use of ketamine with lidocaine for neuropathic pain. We report a three-year follow-up of this single case study. **Methods:** Case Presentation: A 38-year-old woman with Alport syndrome, hearing impairment and two prior renal transplants (8/2019), first presented in 9/2021 with right upper quadrant pain and elevated levels of serum alkaline phosphatase (AlkP). US showed gallbladder stones. A successful laparoscopic cholecystectomy revealed cholelithiasis and cholecystitis. Between 9/2021 and 11/2022, she had multiple admissions for abdominal pain in the right upper quadrant, nausea, and vomiting, with elevated levels of AlkP (up to 1861 U/l) and normal serum bilirubin.A liver biopsy in 4/2022 showed portal and focal periportal fibrosis and patchy ductular proliferation with associated periductal neutrophils and portal edema consistent with large bile duct obstruction (A). MRCP showed no evidence of stones in the bile duct, but increased peribiliary T2 suggested mild cholangitis. Balloon cholangiography showed bile duct dilation of the left and right intrahepatic branches with peripheral pruning consistent with sclerosing cholangiopathy (B). In 11/2022, a colonoscopy was performed for hematochezia. Multiple ulcers, approximately 2 cm in

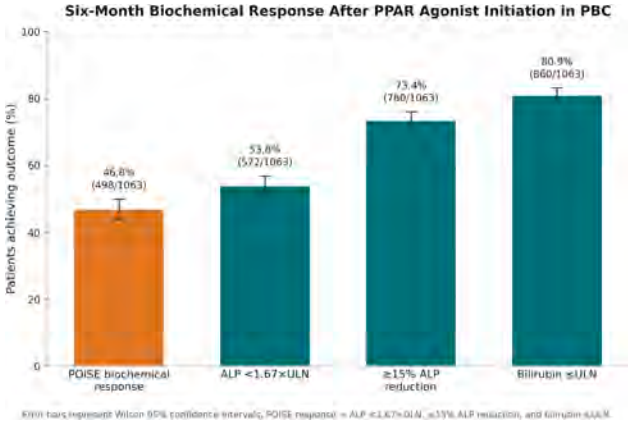
diameter were found in the proximal rectum and in the ascending colon. Smaller ulcers were also noted in the descending colon and scattered throughout the colon. Her RUQ pain was associated with a large ulcer at the hepatic flexure. The appendiceal orifice appeared normal. Histopathology revealed severe ulceration with abundant neutrophils, lymphocytes, and scattered eosinophils consistent with early inflammatory bowel disease (C). Immunohistochemical stain for cytomegalovirus was negative. She admitted to topical use of ketamine mixed with lidocaine for peripheral neuropathy. This was stopped in September 2022. The course of her AlkP levels were followed through the renal transplant clinic at 3-monthly intervals. **Results:** Result: After stopping ketamine, she had no further ER admissions for RUQ pain or hematochezia documented for three years through to 8/2025. Her serum AlkP, monitored at 3-monthly intervals in the renal transplant clinic, fell slowly from a peak of 1861 U/l (Oct 2022) to a trough 131 U/l (Aug 2025) (D). **Conclusion:** Conclusion: Chronic topical ketamine use carries a risk of serious hepatobiliary injury, including KISC, and may be associated with colonic mucosal changes consistent with IBD. Long term follow-up after stopping the drug suggests that the effects of the drug on the liver, as determined by serum AlkP levels, may be directly related to drug exposure and reversible on stopping.



Disclosures: Gerond Lake-Bakaar:Nothing to Disclose.

1237 | REAL-WORLD BIOCHEMICAL RESPONSE TO SELADELPAR AND ELAFIBRANOR IN PRIMARY BILIARY CHOLANGITIS

Shiab Mussad[1] Anna Tylecki[1] Muhammad Ismail[1] Tushar Khanna[1] Mei Lu[1] Stuart Gordon[2], [1]Henry Ford Health, [2]Henry Ford Health System

Background: Seladelpar and elafibranor are newly available peroxisome proliferator-activated receptor (PPAR) agonists for patients with primary biliary cholangitis (PBC) and inadequate biochemical response to ursodeoxycholic acid. They have expanded available treatment options, but real-world outcomes after approval remain limited. We evaluated 6-month biochemical response among PPAR agonist initiators with PBC. **Methods:** We performed a retrospective cohort study using Epic Cosmos, a large multicenter electronic health record database representing more than 300 million patient records. Adults with PBC who initiated seladelpar or elafibranor on or after June 10, 2024, were identified, with the first active PPAR agonist order as the index date. Eligible patients had baseline alkaline phosphatase (ALP) and bilirubin within 6 months before index, repeat labs at 6 months ± 2 months, baseline ALP ≥ 1.67×ULN, and no fibrate fill within 90 days before index. The primary outcome was 6-month POISE biochemical response, defined as ALP < 1.67×ULN, ≥ 15% ALP reduction from baseline, and bilirubin ≤ ULN. **Results:** A total of 1,063 PPAR agonist initiators met inclusion criteria, including 728 treated with seladelpar (68.5%) and 335 treated with elafibranor (31.5%). Median age was 60 years, and most patients were female (89.9%) and White (71.8%); 16.7% were Hispanic or Latino. Median time from first PBC diagnosis to treatment initiation was 44.9 months. Prior obeticholic acid use was present in 21.0%, autoimmune hepatitis overlap in 20.9%, and pre-index evidence of cirrhosis, portal hypertension, or hepatic decompensation in 44.7%. Median baseline ALP was 284 U/L, and median baseline total bilirubin was 0.66 mg/dL. At 6 months, 498 patients achieved POISE biochemical response (46.8%; 95% CI, 43.8-49.8%). Individual response components were common: 572 patients achieved ALP < 1.67×ULN (53.8%), 780 had a ≥ 15% ALP reduction from baseline (73.4%), and 860 had total bilirubin ≤ ULN (80.9%). **Conclusion:** In this real-world cohort of patients with PBC and baseline ALP ≥ 1.67xULN, nearly half of PPAR agonist initiators achieved POISE biochemical response at 6 months, with most achieving meaningful ALP reduction and bilirubin normalization. These findings support real-world biochemical effectiveness of PPAR agonists. Ongoing analyses will evaluate comparative effectiveness versus long-term UDCA users and exploratory differences between seladelpar and elafibranor.

1238 | PRIMARY SCLEROSING CHOLANGITIS IN OLDER ADULTS: A DISTINCT CLINICAL PHENOTYPE? A COMPARATIVE ANALYSIS OF PRESENTATION BY AGE AT DIAGNOSIS

Deepika Suresh[1] Mary McGrath[1] Daniel Strand[1] Brian Wentworth[1], [1]University of Virginia

Background: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease commonly diagnosed in early to middle adulthood. The clinical course of PSC is heterogenous, but there is a distinct lack of data regarding patients diagnosed beyond the sixth decade of life. Therefore, we aimed to characterize differences in presentation between patients diagnosed with PSC at age ≥ 65 years compared with those diagnosed prior to age 65. **Methods:** We performed a retrospective cohort study of patients diagnosed with PSC within a single tertiary care / transplant referral center between January 2023 and October 2025. Patients were stratified by age at diagnosis (< 65 vs ≥ 65 years). Demographic characteristics, laboratory values and magnetic resonance cholangiopancreatography (MRCP) findings at presentation, and markers of advanced chronic liver disease were compared between groups. Continuous variables were non-parametric and reported as median [interquartile range]; between group comparisons utilized the Mann-Whitney U test. Categorical variables were presented as counts (%) and analyzed using Chi-square or Fisher's exact tests, as appropriate. **Results:** Forty-five patients met inclusion criteria, including 16 (33%) diagnosed at age ≥ 65. Median age at diagnosis was 32 years [IQR 24–47] in the younger cohort and 76 years [IQR 70–84] in the older cohort (p < 0.001). Sex distribution and race were similar between groups. Older patients demonstrated higher median cholestatic and hepatocellular liver enzyme values, including ALP (414 vs 179 U/L, p = 0.099) and AST (71 vs 41 U/L, p = 0.155), though differences did not reach statistical significance. Median CA 19-9 was significantly higher among patients diagnosed at ≥ 65 years (29.0 vs 4.0 U/mL, p = 0.036). Total bilirubin levels were comparable between groups. The pattern of biliary involvement did not differ significantly by group (p = 0.368). However, a plurality of younger patients had multifocal intrahepatic disease whereas older patients had more combined intra- and extrahepatic involvement. Older patients more frequently had cirrhosis at diagnosis (31% vs 7%, p = 0.079), while rates of portal hypertension were similar between groups (19% vs 17%, p = 1.000). Only one case of cholangiocarcinoma was observed, occurring in a patient aged ≥ 65 years (6% vs 0%, p = 0.356). **Conclusion:** Patients diagnosed with PSC at age ≥ 65 may present with features suggestive of greater disease burden, including higher CA 19-9 levels, cholestatic and hepatocellular liver enzyme values, and increased prevalence of cirrhosis at diagnosis. These findings raise the possibility that later-onset PSC represents a distinct clinical phenotype and/or reflects delayed recognition, warranting further investigation in larger cohorts.

Clinical and Biochemical Characteristics at PSC Diagnosis Stratified by Age

	All (n = 45)	Age <65 (n = 29)	Age ≥65 (n = 16)	p
Age, median [IQR]	47 [29-71]	32 [24-47]	76 [70-84]	<0.001
Male sex (%)	21 (47)	14 (48)	7 (44)	1.000
Caucasian (%)	43 (96)	28 (97)	15 (94)	0.590
AST (U/L), median [IQR]	51 [29-118]	41 [26-118]	71 [45-134]	0.155
ALT (U/L), median [IQR]	61 [24-145]	43 [23-159]	74 [53-114]	0.767
ALP (U/L), median [IQR]	245 [104-597]	179 [86-508]	414 [190-741]	0.099
Total bilirubin, median [IQR]	0.7 [0.5-1.3]	0.7 [0.5-1.0]	0.8 [0.5-2.1]	0.576
CA 19-9 (U/mL)	9.5 [4.0-46.0]	4.0 [4.0-8.0]	29.0 [6.0-77.0]	0.036
Disease burden by MRCP (%)				0.368

1239 | TARGETING FARNESOID X RECEPTOR WITH INT-787, A HYDROPHILIC BILE ACID-DERIVED AGONIST, INHIBITS EXPERIMENTAL PRIMARY SCLEROSING CHOLANGITIS

Raffaella Gadaleta[1] Maria Arconzo[1] Marica Cariello[1] Silvia Cultrera[1] Angela Tricase[1] Sanjay Kansra[2] Mary Erickson[2] Luciano Adorini[2] Antonio Moschetta[1], [1]University of Bari "Aldo Moro", Bari, Italy, [2]Intercept Pharmaceuticals, Inc. Morristown, New Jersey, USA

Background: Primary sclerosing cholangitis (PSC) is a progressive, immune-mediated cholestatic liver disease associated with increased HCC risk and limited therapeutic options. First-line PSC therapy relies on ursodeoxycholic acid, a hydrophilic secondary bile acid (BA) lacking farnesoid x receptor (FXR) agonistic activity that improves cholestatic liver enzymes and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

bile composition, but has no proven survival benefit and may be harmful at high doses. Obeticholic acid (OCA), a potent BA-derived FXR agonist, showed promising effects in PSC in a Phase 2 study; however, it was not further evaluated in Phase 3 clinical trials. The second-generation BA-derived FXR agonist INT-787 combines high FXR affinity with hydrophilic, non-cytotoxic properties and has demonstrated anti-inflammatory, anti-fibrotic, and metabolic benefits superior to OCA in several preclinical liver disease models, together with a favorable safety profile in healthy volunteers, making it a promising candidate for PSC treatment. **Methods:** We investigated the effects of an INT-787-enriched diet (30 mg/kg/day) in Mdr2-KO mice, a reproducible model of spontaneously progressive chronic biliary liver disease associated with fibrosis and characterized by histological lesions closely resembling human PSC. The study included 3 experimental settings: 2 preventive protocols, with INT-787 administration for 12 or 24 weeks (wk), and 1 therapeutic/curative protocol, in which PSC was established after 16 wk of chow diet before switching to an INT-787-enriched diet for an additional 12 wk. All animal procedures complied with institutional and national guidelines and were approved by relevant ethics committees. **Results:** To confirm pharmacological FXR activation, qRT-PCR analyses of intestinal and hepatic FXR target genes were performed across all 3 settings. INT-787 treatment induced the intestinal FXR target genes *Fgf15* and Ibabp, while hepatic FXR activation was confirmed by Bsep upregulation. In addition, the downstream effect of ileal *Fgf15* induction was reflected by suppression of *Cyp7a1*, the rate-limiting enzyme in BA synthesis. In both preventive settings, the INT-787-enriched diet prevented collagen deposition and fibrosis compared with chow diet (Sirius Red staining) and reduced hepatic cell proliferation (cyclin D1 staining). INT-787 prevented ALT elevation and reduced AST levels compared with chow-fed mice. In the therapeutic setting, INT-787 halted disease progression and reversed collagen deposition, fibrosis, hepatic cell proliferation, and liver transaminase elevations. **Conclusion:** INT-787 demonstrates robust preventive and therapeutic efficacy in experimental PSC, markedly attenuating liver fibrosis, hepatocellular injury, and disease progression. These findings identify INT-787 as a promising and well-tolerated FXR-based therapeutic candidate with the potential to address the substantial unmet clinical need in PSC.

1240 | REAL-WORLD PATIENT-REPORTED SYMPTOM RESPONSE AFTER ELAFIBRANOR OR SELADELPAR THERAPY IN PRIMARY BILIARY CHOLANGITIS

Hussein Harb[1] Fabian Rodas[2] Toluwalase Okubote[3] Ronnie Scarboro[3] Krishna Venkata[3], [1]Texas Institute of Graduate Medical Education (TIGMER), [2]University of Texas San Antonio / The Texas Liver Institute, [3]The Texas Liver Institute

Background: Pruritus and fatigue are major determinants of impaired quality of life in primary biliary cholangitis (PBC) and may persist despite biochemical improvement. Real-world patient-reported outcome (PRO) data after elafibranor or seladelpar remain limited. **Methods:** We performed a retrospective single-center study of adults with PBC treated with elafibranor or seladelpar after inadequate response to ursodeoxycholic acid. Chart data and a single recall-based phone PRO survey captured baseline, 3-6-month, and available 8-12-month WI-NRS and PROMIS Fatigue 7 responses. The primary PRO analysis compared baseline with 3-6 months; 8-12-month outcomes were analyzed when available using within-patient baseline-to-follow-up pairs. Clinically meaningful improvement was defined as $\geq$3-point WI-NRS decrease and >3-point PROMIS Fatigue T-score decrease. Wilcoxon, Fisher exact, and Spearman tests were used as appropriate. **Results:** Among 41 patients, 23 initiated elafibranor and 18 initiated seladelpar; median age was 59 years [IQR, 52-67.2], and 39/41 (95.1%) were female. Baseline ALP, AST, ALT, total bilirubin, and PRN antipruritic use were similar between groups. Baseline WI-NRS burden was higher with elafibranor, including a higher proportion with baseline WI-NRS >3, supporting sensitivity analysis for itch response. WI-NRS and PROMIS Fatigue T-score improved significantly at 3-6 and 8-12 months. Clinically meaningful improvement was common, with no significant between-therapy differences, including among patients with baseline WI-NRS >3. ALP change was not significantly correlated with WI-NRS or PROMIS Fatigue T-score change. Total bilirubin change was associated with PROMIS Fatigue T-score change at 3-6 months, and this association persisted after excluding patients with bilirubin >2.0 mg/dL. No significant biochemical-PRO correlations were observed at 8-12 months. **Conclusion:** In this small real-world PBC cohort, elafibranor and seladelpar were associated with significant improvements in patient-reported pruritus and fatigue, with symptom improvement evident by 3-6 months and maintained among patients with available 8-12-month data. No clear therapy-specific symptom advantage was observed, including in sensitivity analysis among

patients with baseline WI-NRS >3. Baseline itch imbalance and small subgroup sizes limit between-therapy comparisons. These findings support incorporating symptom-specific PROs alongside biochemical endpoints when evaluating second-line PPAR agonist therapy in PBC.

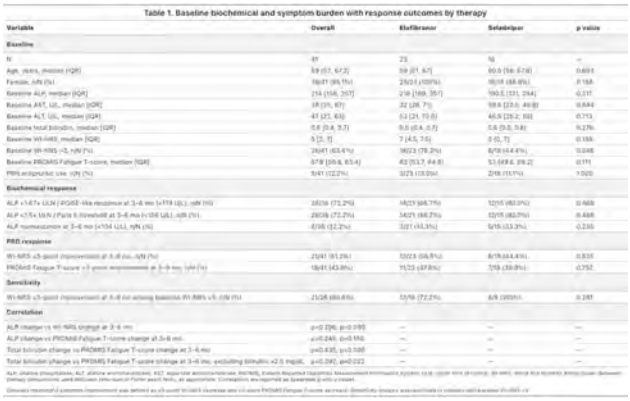

Table 1. Baseline biochemical and symptom burden with response outcomes by therapy

Variable	Overall	Elafibranor	Seladelpar	p value
Baseline				
N	41	21	20	—
Age, years, median (IQR)	59 (52, 67.2)	59 (51, 67)	60.5 (56, 67.8)	0.693

Baseline ALP, median (IQR)	214 (156, 297)	218 (169, 357)	190.5 (151, 264)	0.317
Baseline AST, ULN, median (IQR)	1.8 (1.5, 2.1)	2.2 (1.8, 2.7)	1.6 (1.3, 1.8)	0.004
Baseline ALT, ULN, median (IQR)	1.7 (1.2, 2.5)	2.1 (1.2, 2.7)	1.5 (1.2, 2.2)	0.173
Baseline total bilirubin, median (IQR)	0.6 (0.4, 0.7)	0.6 (0.4, 0.7)	0.6 (0.5, 0.8)	0.276
Baseline WI-NRS, median (IQR)	5 (3, 7)	7 (4.5, 7.5)	5 (3, 7)	0.188
Baseline WI-NRS >3, n/N (%)	29/41 (70.7%)	18/21 (85.7%)	11/20 (55%)	0.048
Baseline PROMIS-Fatigue T-score, median (IQR)	57.8 (55.6, 63.4)	62 (55.7, 64.8)	53.3 (49.4, 59.2)	0.011
PBC antipruritic use, n/N (%)	9/41 (22.0%)	3/21 (14.3%)	6/20 (30%)	0.429
Biochemical response				
ALP <1.67× ULN (POISE-like response) at 3–6 mo (<1.67× ULN), n/N (%)	28/39 (71.8%)	14/21 (66.7%)	12/18 (66.7%)	0.468
ALP <1.5× ULN (Paris II-like) at 3–6 mo (<1.5× ULN), n/N (%)	28/39 (71.8%)	14/21 (66.7%)	12/18 (66.7%)	0.468
ALP normalization at 3–6 mo (<1× ULN), n/N (%)	4/36 (11.1%)	2/21 (9.5%)	2/15 (13.3%)	0.636
PRO response				
WI-NRS ≥3-point improvement at 3–6 mo, n/N (%)	21/41 (51.2%)	12/21 (57.1%)	9/20 (45%)	0.405
PROMIS-Fatigue T-score ≥5-point improvement at 3–6 mo, n/N (%)	18/41 (43.9%)	11/21 (52.4%)	7/19 (36.8%)	0.352
Sensitivity				
WI-NRS ≥3-point improvement at 3–6 mo among baseline WI-NRS >3, n/N (%)	21/29 (72.4%)	12/18 (66.7%)	9/11 (81.8%)	0.641
Correlation				
ALP change vs WI-NRS change at 3–6 mo	ρ=0.296, p=0.070	—	—	—
ALP change vs PROMIS-Fatigue T-score change at 3–6 mo	ρ=0.240, p=0.150	—	—	—
Total bilirubin change vs PROMIS-Fatigue T-score change at 3–6 mo	ρ=0.420, p=0.008	—	—	—
Total bilirubin change vs PROMIS-Fatigue T-score change at 3–6 mo, excluding bilirubin >2.5 mg/dL	ρ=0.392, p=0.022	—	—	—

ALP, alkaline phosphatase; ALT, alanine aminotransferase; AST, aspartate aminotransferase; PROMIS, Patient-Reported Outcomes Measurement Information System; IQR, interquartile range; ULN, upper limit of normal; WI-NRS, worst-itch numerical rating scale; ρ, Spearman rank correlation coefficient. Between-therapy comparisons used Wilcoxon rank-sum or Fisher exact tests, as appropriate. Correlations are reported as Spearman ρ with p values.

Clinically meaningful symptom improvement was defined as ≥3-point WI-NRS decrease and ≥5-point PROMIS-Fatigue T-score decrease (bimodality analysis identified no natural cutoff between 0 and 10).

1241 | IMPACT OF MARALIXIBAT ON CAREGIVER BURDEN FOR PATIENTS WITH ALAGILLE SYNDROME OR PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS: 12-MONTH FOLLOW-UP

Natasha Dilwali[1] Fiona Coll[2] Robin Howard[3] Jolan Terner-Rosenthal[3] Douglas Mogul[3] Brandon Vu[4] Rachel Hallum-Montes[2] Wikrom Karnsakul[4], [1]Columbia University, [2]Motivo Insights, [3]Mirum Pharmaceuticals, Inc., [4]Johns Hopkins University

Background: Alagille syndrome (ALGS) and progressive familial intrahepatic cholestasis (PFIC) are rare cholestatic liver diseases (CLD) leading to end-stage liver failure. Patients experience significant pruritus, which impacts quality of life (QoL), sleep, and pruritus is a leading cause of transplant. Maralixibat (MRX) is approved to treat cholestatic pruritus in ALGS/PFIC with trials showing improvements in pruritus are linked to better patient sleep and QoL. We recently reported 6-month interim data demonstrating that MRX treatment may reduce caregiver sleep disruption, likely due to improvements in pruritus severity among patients. This study sought to extend these findings to 12-months of MRX treatment. **Methods:** Beginning in March 2024, caregivers of newly prescribed MRX for patients with ALGS/PFIC were invited to complete a survey assessing caregiver burden. Questions addressed the impact (0 to 10 scale where 0 = no impact, 10 = extreme impact) on sleep, pruritus, financial strain, and mood. Follow-up surveys were completed after 6- and 12-months. The focus of this analysis was on 12-month follow-up data. Data analysis included descriptive statistics. **Results:** A total of ten 12-month follow-up surveys were completed. The majority of respondents were parents of children with ALGS, mostly identified as White, and with a median age range of 30–39 years. 70% of caregivers reported a reduction in the number of hours (mean reduction = 7.3 hours from baseline [BL]) helping patients with activities of daily living. Impact of caregiving on mean productivity (4.3 vs 5.4 at BL), mood (3.9 vs 5.2 at BL), and sleep (6.1 vs 7.7 at BL) scores improved over the 12-month study period. Most (60%) caregivers showed improvements in hours of work missed since patients started MRX (mean reduction = 16 hours from BL). **Conclusion:** These findings demonstrate sustained improvement in caregiver QoL including improvements in sleep, daily activities and work productivity after 12-months of MRX treatment for patients with ALGS or PFIC. Generic instruments were used in this study to measure impact. Results indicate a need for more specific measurements in pediatric CLD to understand true caregiver impact.

1242 | FENOFIBRATE AS SECOND-LINE THERAPY FOR PRIMARY BILIARY CHOLANGITIS: EFFICACY AND SAFETY IN REAL-WORLD PRACTICE

Mikolas Holinka[1] Jan Šperl[1] Dusan Merta[1] Tomas Nesnidal[1] Tomas Hucl[1] Sona Frankova[1], [1]Institute for Clinical and Experimental Medicine

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Background: The first-line treatment for primary biliary cholangitis (PBC) is ursodeoxycholic acid (UDCA); however, approximately one-third of patients do not achieve an adequate biochemical response. Treatment with fibrates improves ALP activity, the strongest predictor of long-term prognosis; however, data supporting the use of fenofibrate, the only available second-line treatment (SLT) in the Czech Republic after the withdrawal of obeticholic acid, are limited to small, uncontrolled series. The aim of the study was to evaluate the efficacy and safety of fenofibrate as an SLT of PBC. **Methods:** We retrospectively analysed a cohort of 87 patients with PBC treated with fenofibrate (145 mg daily, NanoTab formulation). Eighty patients reached at least 12 months follow-up and could be evaluated for treatment response according to the Toronto criteria (decrease in ALP after 12 months of therapy to less than 1.67xULN; Toronto + group; no response: Toronto - group). The cohort included 72 (91.2%) women; the median age was 56 years (34–82), and the median liver stiffness was 8.8 kPa (4–57). UDCA was concomitantly administered to 78 patients (97.5%). ALP activity and bilirubin concentrations were assessed before treatment and at three-month intervals, as well as the occurrence of adverse events. **Results:** Forty-three patients (53.8%) met the Toronto criteria. Of the remaining 37 patients, 24 (30%) did not meet the Toronto criteria due to an insufficient decrease in ALP, and the remaining 13 (16.2%) due to premature discontinuation of treatment because of adverse events (myopathy 7, hepatotoxicity 2, pruritus 2, GIT complaints 2, self-discontinuation 1). The Toronto + group had significantly lower ALP activity at baseline (2.2x ULN; 0.63–4.4) than the Toronto - group (3.7x ULN; 0.67–11.9; $p < 0.0001$). Initial bilirubin concentrations did not differ significantly between the groups at baseline (0.64 vs. 0.75 mg/dL; N.S.), but during treatment, bilirubin was lower in the Toronto + group at both six and twelve months of treatment (0.57 vs. 0.84 mg/dL; $p = 0.03$, and 0.60 vs. 0.80 mg/dL; $p = 0.006$, respectively). Independent predictors of achieving Toronto + were older age (OR 1.1, 95% CI 1.00–1.20, $p = 0.05$) and baseline ALP activity (OR 0.27, 95% CI 0.11–0.49, $p = 0.0004$). The number of patients who underwent liver transplantation (LTx) did not differ between groups, 4/43 (9.3%) and 3/37 (8.1%) in the Toronto + and Toronto -, respectively (N.S.); none of the patients died. **Conclusion:** 53.8% of patients responded to fenofibrate therapy and met the Toronto criteria at month twelve. Baseline ALP levels and older age were independent predictors of treatment response. The data suggest that the biochemical response to fenofibrate is comparable to that of bezafibrate as SLT PBC therapy; however, there is so far insufficient evidence regarding its effect on survival and the need for LTx.

1243 | SINGLE CENTER RETROSPECTIVE STUDY OF CLINICOPATHOLOGICAL FEATURES OF HEPATIC SARCOIDOSIS

Rehan Razzaq[1] Shreya Shah[2] Alexis Kim[2] Matthew Ambrosio[2] Le Kang[2] Thomas Iden[3] Dana Alderson[3] Jessica McLaughlin[3] Huzaefah Syed[3] Neha Gupta[3] Ryan Canissario[3] Jordana Kron[3] Vikram Brar[3] Duaa AbdelHameid[3] Aamer Syed[3] Vaishali Patel[2], [1]VCU Health System, [2]Virginia Commonwealth University, [3]Virginia Commonwealth University Health System

Background: Hepatic sarcoidosis (HS), a rare manifestation of sarcoidosis, can lead to portal hypertension and hepatic decompensation. Most studies presume HS in all patients with sarcoidosis and elevated liver enzymes, leading to variable findings across studies. **Methods:** We performed a retrospective analysis of patients with known systemic sarcoidosis who underwent liver biopsy for unexplained elevated liver enzymes at our multidisciplinary clinic and had a follow up in the last 5 years. We defined Hepatic Sarcoidosis (HS) as noncaseating granulomas on liver biopsy whereas the remainder were classified as Presumed Hepatic Sarcoidosis (pHS). Clinical characteristics were compared using t-tests, chi-square tests, or Fisher's exact tests as appropriate. **Results:** 114 patients with systemic sarcoidosis underwent liver biopsy for unexplained elevated liver enzymes. 68% were female and 78% were Black. 78(68%) had biopsy proven HS and the mean Alkaline Phosphatase (ALP) was significantly elevated in HS compared to pHS (271. 06 vs 177.83, $p = 0.028$). 17% of patients with pHS had hepatic sarcoid nodules on imaging. Of the 16 patients with HS who underwent transjugular liver biopsy, 44% had non-cirrhotic portal hypertension (NCPH). Liver fibrosis was more common in HS vs pHS group (71% vs 56%), and patients with HS were more likely to have advanced fibrosis (F3-4) (29% vs 20%); due to small sample size this was not statistically significant. 2 patients with HS underwent liver transplantation (LT). Black patients with HS had significantly higher incidence of concomitant lung sarcoidosis ($p = 0.026$), however having HS did not

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

correspond to severity of lung fibrosis as calculated by Composite Physiological Index (CPI) (p = 0.2). **Conclusion:** Liver biopsy is diagnostic in 68% of patients with HS. ALP and imaging can improve diagnostic probability. Black patients with HS should be assessed for lung sarcoidosis. Given its rarity, developing consensus disease definition followed by multicenter trials are needed for improving patient outcomes.

1244 | THE BIPHASIC CLINICAL TRAJECTORY OF IGG4-ASSOCIATED AUTOIMMUNE HEPATITIS: RAPID REMISSION AND LATE CONVERGENCE

Chun Hsun Liao[1] Hsu-Hua Tseng[1] Tai-Chung Tseng[1] Hung-Chih Yang[1] Jia-Horng Kao[1] Chun Jen Liu[1],
[1]National Taiwan University Hospital

Background: IgG4-associated autoimmune hepatitis (IgG4-AIH) is an emerging entity bridging classical AIH and IgG4-related disease, yet its true clinical trajectory and classification remain debated. We aimed to characterize the dynamic biochemical response and long-term remission durability of IgG4-AIH to establish its unique clinico-pathological identity, ultimately guiding precision-driven therapeutic strategies and personalized long-term management.

Methods: This retrospective cohort study at a tertiary medical center evaluated patients with biopsy-proven AIH. All liver specimens were re-stained for IgG/IgG4 expression and reviewed by two pathologists. Patients were stratified into classic AIH (< 10 IgG4+ cells/high power field [HPF]) and IgG4-AIH (≥ 10 IgG4+ cells/HPF). Baseline clinico-serological profiles and 24-month longitudinal biochemical responses were analyzed. ALT normalization trajectories were mapped using a linear mixed-effects model (LMM), and long-term treatment durability was evaluated using Kaplan-Meier survival analysis. **Results:** Among 54 evaluated AIH patients, baseline sex distribution was comparable between the two cohorts. However, the IgG4-AIH group (N = 13, 24%) was older (median age 70 vs. 60 years), exhibited higher baseline serum IgG4 levels (median 208 vs. 58 mg/dL), and presented with a higher rate of baseline cirrhosis (31% vs. 12%). Despite this potentially more advanced baseline profile, longitudinal LMM analysis revealed a rapid and profound sensitivity to immunosuppression. The IgG4-AIH cohort maintained significantly lower ALT levels throughout the entire treatment trajectory, achieving faster and deeper biochemical remission at both Month 3 (p = 0.006) and Month 24 (p = 0.018). Survival analysis highlighted a prolonged initial remission in IgG4-AIH patients, whereas classic AIH exhibited early and continuous relapses. However, late-onset relapses still occurred in the IgG4-AIH group, leading to a gradual convergence of the survival curves over extended follow-up. **Conclusion:** IgG4-AIH constitutes a unique clinico-pathological entity marked by severe baseline fibrosis and a contrasting rapid response to early immunosuppression. Although IgG4-AIH patients achieve an exceptionally prolonged initial remission compared to classic AIH, they remain susceptible to late-onset relapses that ultimately bridge the long-term prognostic gap. These findings highlight the critical need for early biopsy-driven diagnosis and emphasize that despite a highly favorable initial treatment response, continuous clinical monitoring is essential for long-term management.

1245 | MECHANISTIC INSIGHTS INTO THE PROTECTIVE EFFECTS OF FAECALIBACTERIUM PRAUSNITZII AND ITS METABOLITE SHORT CHAIN FATTY ACIDS ON BILIARY INJURY IN PRIMARY BILIARY CHOLANGITIS

Qi Wang[1] Xi Wang[1] Chunyang Huang[2] Minghui Li[1] Ronghua Jin[1], [1]Beijing Ditan hospital, [2]Beijing You an hospital

Background: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease that primarily affects middle-aged women. Studies suggest that alterations in the gut microbiome are closely associated with the pathogenesis and treatment of PBC, but the underlying mechanisms remain unclear. **Methods:** This study first conducted gut microbiota analysis of fecal samples from PBC patients and healthy controls using metagenomic sequencing, with LEfSe and other methods employed to identify differential microbial taxa. Subsequently, a bile duct ligation (BDL) mouse model was established and treated with *F. prausnitzii* (1×10^9 CFU/day), while ductular reaction and liver fibrosis were evaluated through histopathological staining. For in vitro experiments, a GCDC-induced injury model using human primary biliary epithelial cells (HiBECs) was developed, followed by treatment with varying concentrations of short-chain fatty acids (SCFAs). Furthermore, ChIP assays were performed to detect H3K27ac modification levels, elucidating the specific mechanism by which SCFAs exert their effects through epigenetic regulation of the ELF3/PI3K-Akt pathway. All data were statistically analyzed using two-tailed t-tests/ANOVA with FDR correction ($P < 0.05$ considered statistically significant). **Results:** We found that *F. prausnitzii* was significantly reduced in the gut microbiota of PBC patients. Supplementation with *F.prausnitzii* markedly improved BDL-induced biliary injury, including cholangitis, bile duct hyperplasia, and liver fibrosis, while also restoring gut microbial balance and intestinal barrier function. These beneficial effects were linked to short-chain fatty acids (SCFAs) produced by *F. prausnitzii*. Mechanistic studies revealed that *F. prausnitzii*-derived SCFAs enhanced histone H3K27 acetylation, upregulating the transcription factor ELF3 and subsequently activating the PI3K-Akt signaling pathway to promote bile duct cell repair. **Conclusion:** This study demonstrates that *F. prausnitzii* exerts protective effects in PBC. Its depletion in PBC patients and its therapeutic potential in alleviating cholangitis and liver fibrosis, along with restoring gut function, highlight its promising clinical application for PBC treatment.

1246 | REAL-WORLD EXPERIENCE OF ODEVIXIBAT IN ADULTS WITH PERSISTENT HEPATOCELLULAR SECRETORY FAILURE

Mauro Viganò[1] Francesca Colapietro[1] Maria Iascone[2] Filippo Leonardi[1] Luisa Pasulo[1] Alessandro Loglio[1] Lisa Licini[3] Lorenzo D'Antiga[4] Stefano Fagiuoli[1], [1]ASST Papa Giovanni XXIII, Department of Gastroenterology, [2]ASST Papa Giovanni XXIII, Department of Genetics, [3]ASST Papa Giovanni XXIII, Department of Pathology, [4]ASST Papa Giovanni XXIII, Department of Pediactrics

Background: Persistent hepatocellular secretory failure (PHSF) [van Dijk R, et al. Liver Int. 2015] is a rare but potentially life-threatening condition characterized by sustained impairment of hepatocellular bile secretion, resulting in prolonged cholestasis, jaundice, and hyperbilirubinemia that may persist for months after withdrawal of the offending trigger including drugs, toxins, or transient biliary obstruction. Differential diagnosis with genetic cholestatic disorders remains particularly challenging in adults. We herein describe a case series of five consecutive adult patients presenting with persistent non-mechanical cholestasis at the Hepatology and Liver Transplant Unit, ASST Papa Giovanni XXIII, Bergamo, Italy, between 2024 and 2025. **Methods:** Clinical data, including the severity of pruritus, laboratory parameters [alanine aminotransferase (ALT), bilirubin and serum bile acids (sBAs)], genetic testing and imaging findings were assessed. All patients underwent liver biopsy and were consequently treated with Odevixibat (40 mcg/Kg/day), an Ileal Bile Acid Transporter (IBAT) inhibitor. **Results:** All patients were male, with a median age of 35 years (range 32-60) and exhibited cholestatic abnormalities persisting for at least 30 days (range 25-67 days) after resolution of biliary tract obstruction obtained

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

with endoscopic retrograde cholangiopancreatography (ERCP) and antibiotic treatment. Severe pruritus was present in all cases, significantly impairing sleep and quality of life. Mean bilirubin levels at first evaluation were 27.4 mg/dL (SD 7.3 mg/dL), while mean sBAs and median ALT levels were 355.6 ± 125.2 mmol/L and 61 U/L (29-224), respectively. Gamma glutamyl transferase (gGT) levels were completely normal in two patients whereas only mildly elevated in the remaining cases (lower than 2xULN). Magnetic resonance- colangiography excluded biliary obstruction in all patients. Liver histology demonstrated canalicular cholestasis, biliary metaplasia, and variable degrees of ductopenia, initially suggestive of drug-induced-livery injury (DILI), but evolving in some cases toward features consistent with genetic cholangiopathy and ultimately BRIC-like phenotype. Genetic analysis identified ATP8B1 variants in only one patient. During a mean treatment time of 65 days (range 40-120), odevixibat induced rapid normalization of both sBAs and bilirubin levels, accompanied by marked improvement in pruritus, which completely resolved in all patients at the last follow-up. No major safety concerns emerged; only one patient experiencing mild diarrhea, which resolved after dosage adjustment. **Conclusion:** PHSF may represent an overlap condition between DILI and genetic cholestatic disorders. IBAT inhibitors may play a relevant therapeutic role in this setting by effectively reducing both sBAs and bilirubin levels thus improving cholestatic pruritus.

1247 | HISTOLOGICAL SEVERITY PREDICTS CLINICAL PHENOTYPE AND OUTCOMES IN PEDIATRIC AUTOIMMUNE HEPATITIS

Aditya Soni[1] Rajeev Khanna[1] Seema Alam[2] Bikrant Biharilal Raghuvanshi[1] Vikrant Sood[1], [1]Institute of Liver and Biliary Science, New Delhi, [2]Institute of Liver and Biliary Sciences

Background: Pediatric autoimmune hepatitis (AIH) shows a heterogeneous spectrum ranging from acute liver failure to chronic liver disease. The association between histological severity, clinical phenotype, and outcomes remains incompletely understood. We evaluated histological correlates of presentation and outcome in pediatric AIH. **Methods:** We retrospectively analyzed prospectively collected data of children diagnosed with AIH between January 2010 and November 2025. Diagnosis was based on clinical and biochemical profile, compatible histology, elevated IgG, simplified AIH score ≥ 6, and exclusion of other liver diseases. Histological features were compared across presentations: acute liver failure/acute-on-chronic liver failure (ALF/ACLF), decompensated chronic liver disease (DCLD), and acute/chronic hepatitis or compensated chronic liver disease (AH/CH/CCLD). Outcomes assessed included death/liver transplantation (LT) and difficult-to-treat disease (DTT). **Results:** Among 232 children, median age was 10 years (IQR 7–13.3) with female predominance; 17% had AIH-overlap and 28% were seronegative. Presentations included ALF/ACLF in 42 (18%), DCLD in 76 (33%), and AH/CH/CCLD in 114 (49%). Concurrent extrahepatic autoimmune disorders were present in 35%. Median IgG was 24 g/L (IQR 19–29.9), and 5% had normal immunoglobulin levels. ALF/ACLF had higher histological activity index [10 (IQR 7–14)] with more multiacinar necrosis (45.2%) and central perivenulitis (26.2%), whereas DCLD showed advanced fibrosis [Ishak stage 4 (IQR 2–6)] ($p < 0.001$). Seronegative and seropositive AIH had comparable histology and presentation, although fibrosis was lower in seronegative AIH. Type-1 and type-2 AIH showed no significant differences. Among 179 patients with ≥ 12 months follow-up, 33 had poor outcomes (14 deaths, 19 LT) and 43 developed DTT disease. Independent predictors of poor outcomes were ALF/ACLF presentation (OR 4.65, 95%CI 1.57–13.72; $p = 0.005$), elevated INR (OR 1.64, 95% CI 1.00–2.69; $p = 0.049$), and histological cholestasis (OR 2.45, 95%CI 1.00–5.98; $p = 0.050$), while pseudorosettes were protective (OR 0.29, 95%CI 0.11–0.77; $p = 0.012$).Younger age, thrombocytopenia, and elevated GGT independently predicted DTT disease. **Conclusion:** Pediatric AIH demonstrates a heterogeneous clinical and histological spectrum. Histological severity correlates with clinical presentation and independently predicts outcomes. Histological cholestasis and elevated INR identify children at risk of poor outcomes, while younger age, thrombocytopenia, and elevated GGT predict difficult-to-treat disease. Histological assessment provides important prognostic information beyond conventional clinical and biochemical parameters.

1248 | CHARACTERISTICS OF DRUG-INDUCED AUTOIMMUNE-LIKE HEPATITIS: REPORT FROM A REGISTRY OF 535 PATIENTS WITH AIH

Divya Minnaganti[1] Marwan Ghabril[1] Raj Vuppalanchi[1] Naga Chalasani[1] Craig Lammert[1], [1]Indiana University School of Medicine

Background: Drug-induced autoimmune-like hepatitis (DIALH) shares clinical, serological, and histological features with *de novo* autoimmune hepatitis (AIH). Prior case series suggest most DIALH patients discontinue all immunosuppression within 6–12 months of diagnosis. We interrogated a large single-center prospective AIH registry, and characterized clinical differences between DIALH and AIH, as well as treatment trajectory and biochemical response. **Methods:** We analyzed AIH cases from the Genetic Repository of Autoimmune Liver Disease and Contributing Exposures (GRACE) registry (N = 535 patients 2014-2024). DIALH (n = 27, 5.0%) was defined by temporally associated drug exposure with confirmed autoimmune-like liver injury. AIH treatment was captured at intervals: 0–3, 3–6, 6–12, 12–24 months following the diagnosis, and most recent visit. **Results:** There were 27 DIALH cases (5%). Antimicrobials (44%) and statins (26%) were the most common implicated drug classes; nitrofurantoin (26%) was the most frequently identified agent, followed by atorvastatin (15%) and minocycline (7%). They had higher transaminases (ALT 354 vs 113 U/L, p = 0.002) and bilirubin (3.2 vs 1.2 mg/dL, p = 0.01) compared to AIH at onset (Table 1). ANA (68% vs 72%), ASMA (68% vs 64%), biopsy AIH-compatibility (96% vs 98%), and HLA-DR3/DR4 carrier rates were not different between groups. Despite higher at diagnosis, bilirubin normalized more rapidly in DIALH (94% vs 76% in 6 months, p = 0.04), yet rates of transaminase decline were similar through the first year compared to AIH. ALT level by year 2 (ALT 15 vs 25 U/L, p = 0.04) and most recent visit (p = 0.01) was lower in DIALH. DIAIH cases received more budesonide early (33% vs 12% at 0–3 months, p = 0.005; 26% vs 11% at 3–6 months, p = 0.03). Only 33% of DIALH patients were off all treatment at most recent visit at a median 3.9 years, not significantly different from AIH (19%, p = 0.08). Zero post-withdrawal relapses occurred in DIALH versus 18% in AIH. Five-year survival was 90% and 93%, respectively (log-rank p = 0.8). **Conclusion:** DIALH constitutes 5% of a large prospective AIH registry and is indistinguishable from de novo AIH clinically, serologically, and genetically. Our experience indicates

complete withdrawal of immunosuppression was feasible only in 3rd of DIAIH cases during follow-up.

Table 1. Baseline Characteristics, Biochemical Recovery, and Treatment Trajectory between DIALH vs De Novo AIH in the GRACE Registry

Variable	DIALH (n=27)	De Novo AIH (n=508)	P-value

1249 | AUTOIMMUNE HEPATITIS IN MEN: WORSE TRANSPLANT-FREE SURVIVAL AND A SUGGESTIVE *HLA-DR3* *SEX INTERACTION

Craig Lammert[1] Tae-Hwi Schwantes-An[1] Eduardo Vilar-Gomez[1] Kelsey Green[1] Divya Minnaganti[1] Nadia Blessing[1] Naga Chalasani[1], [1]Indiana University School of Medicine

Background: Autoimmune hepatitis (AIH) predominantly affects women, leaving male-specific disease behavior poorly characterized. HLA-DR3, the principal AIH susceptibility allele, may interact with sex to modify disease risk, but this has not been evaluated in a robust cohort. We used a large single-center registry to define how men differ from women in clinical course, outcomes, and genetic susceptibility. **Methods:** We analyzed 514 adults with AIH from the GRACE registry. Transplant-free survival (TFS) was time from diagnosis to composite endpoint (liver transplant, death) or last clinical follow-up. 474 patients with available diagnosis dates were included in survival analysis. Multivariate Cox regression estimated the sex-based hazard ratio adjusted for age, cirrhosis, log-bilirubin, and race; loss-of-remission and post-withdrawal relapse were compared by Fisher's exact test. In a genetic sub-cohort (n = 222; 43 men, 179 women), a Cox model with HLA-DR3 strata (ref: female DR3−) assessed gene-sex interaction on TFS. **Results:** Of 109 men and 405 women, fibrosis and synthetic function were equivalent at diagnosis: F3/F4 fibrosis (33.3% vs 34%, p = 1.0), albumin (3.7 vs 3.8 g/dL, p = 0.99), INR (1.2 vs 1.1, p = 0.48) (Table). Men had higher bilirubin (1.4 vs 1.0 mg/dL, p = 0.04) and ALT (152 vs 109 U/L, p = 0.02). Biochemical remission at 6 months (42.9% vs 55.4%, p = 0.25) and 12 months (60.5% vs 63.0%, p = 0.85) did not differ. Men had twice the composite event rate (27.5% vs 14.8%, p = 0.003) and worse 10-year TFS (79.6% vs 87.1%, p = 0.009). Male sex independently predicted worse TFS (HR 2.04, 95% CI 1.17–3.54, p = 0.01). Loss-of-remission was identical (15.9% vs 19.8%, p = 0.45), yet relapse was twice as frequent in men (64.3% vs 31.2%, p = 0.03). *HLA-DR3* was enriched in men (55.8% vs 31.3%, p = 0.004). When the combined effect of sex and DR3 positivity on outcomes was interrogated, there was a significant increasing trend in composite outcome rates across ordered sex/DR3 groups, with male DR3 + subgroups carrying the highest risk (Cochran–Armitage trend test, Z = 3.04, two-sided P = 0.002)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

(Table 1). **Conclusion:** Men with AIH have worse TFS despite presenting similarly to women. DR3 may identify a higher-risk subgroup among men, but this requires prospective validation in larger HLA-typed cohorts.

Table 1. Men vs Women with Autoimmune Hepatitis in the GRACE Registry

Variable	Men (n = 109)	Women (n = 405)	P
Demographics			
Age at diagnosis, mean ± SD (yrs)	45.1 ± 17.0	47.6 ± 17.4	0.2

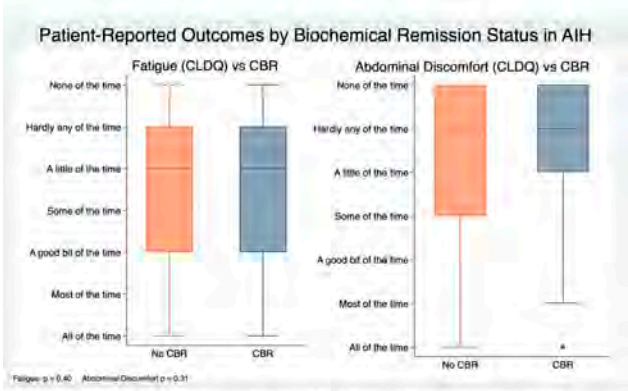
1250 | PERSISTENT PATIENT-REPORTED SYMPTOM BURDEN IN AUTOIMMUNE HEPATITIS REGARDLESS OF BIOCHEMICAL REMISSION OR MASLD OVERLAP

Victoria Abadi-Ron[1] Natalia Rojas Amaris[1] Ana Marenco-Flores[2] Fernando Munguia[1] Giuliana Arevalo[3] Romelia Barba[4] Daniela Goyes[5] Esli Medina Morales[6] Leandro Sierra[7] Behnam Saberi[1] Alan Bonder[1] Vilas Patwardhan[1], [1]Beth Israel Deaconess Medical Center, [2]Harvard Medical School, [3]Department of Internal Medicine, University of Miami / Jackson Memorial Hospital, [4]Texas Tech University, [5]Yale School of Medicine, New Haven, [6]Washington University in St Louis, [7]Cleveland Clinic Foundation



Background: In autoimmune hepatitis (AIH), treatment success is traditionally defined by biochemical remission. However, patient-reported outcomes (PROs) increasingly highlight aspects of disease burden not captured by laboratory markers. Metabolic dysfunction–associated steatotic liver disease (MASLD) frequently coexists with AIH and may contribute to symptom burden, but its role remains unclear. We aimed to evaluate PROs in AIH and assess whether biochemical remission or MASLD overlap reflects patient-reported symptom burden. **Methods:** A cross-sectional analysis was conducted within the Autoimmune Liver Diseases Registry at Beth Israel Deaconess Medical Center (Boston, MA, USA) from 2018 to 2025. Adult patients with a primary diagnosis of AIH who completed the Chronic Liver Disease Questionnaire (CLDQ) were included, regardless of overlap with primary biliary cholangitis, primary sclerosing cholangitis, or prior liver transplantation. MASLD was defined clinically as body mass index ≥ 25 kg/m² in combination with at least one cardiometabolic risk factor, including diabetes mellitus (with or without insulin therapy), hypertension, hyperlipidemia, or coronary artery disease. Complete biochemical remission (CBR) was defined as normalization of aminotransferases and immunoglobulin G. Group comparisons were performed using Fisher's exact test, and PROs were compared using the Mann–Whitney U test. Univariable logistic regression assessed the association between MASLD and CBR. **Results:** Among 178 patients with AIH, 55 (30.9%) met criteria for MASLD. CBR was achieved in 60.1% of the cohort and occurred at similar rates in AIH-only and AIH–MASLD patients (61.0% vs 58.2%, $p = 0.74$). MASLD was not associated with odds of achieving CBR (OR 0.89; 95% CI 0.47–1.70; $p = 0.73$). PROs demonstrated a substantial symptom burden across the cohort. Fatigue and abdominal symptoms were common and persisted even among patients who achieved CBR, with no significant differences by remission status or MASLD overlap (all $p > 0.20$). **Conclusion:** In AIH, patient-reported symptom burden persists despite complete biochemical remission and is not explained by metabolic overlap. These findings highlight a disconnect between enzymatic disease control and patient experience and underscore the importance of incorporating PROs into the assessment of treatment response in AIH.

Figure 1. **Baseline Characteristics, Complete Biochemical Remission, and Patient-Reported Outcomes in Autoimmune Hepatitis (n = 178)**

Characteristic	No CBR (n = 71)	CBR (n = 107)	P - Value
Age (years), median (IQR)	57 (40-64)	53 (42-60)	0.473
Female sex, n (%)	56 (76.71%)	79 (75.24%)	0.860
BMI (kg/ m²), IQR	27 (23-30.4)	27.4 (23-31.6)	0.583
MASLD overlap, n (%)	24 (32.88%)	31 (29.52%)	0.742
Cirrhosis, n (%)	26 (35.62%)	24 (22.86%)	0.089
ALT (IU/L), IQR	48 (30-94)	18 (13-23)	0.000
AST (IU/L), IQR	51 (34-98)	22 (17.5-27.5)	0.000
IgG (IU/L), IQR	1555 (1243-1911)	1034 (835-1266)	0.000
CLDQ Fatigue score, median (IQR)	5 (3-6)	5 (3-6)	0.788
CLDQ Abdominal discomfort score, median (IQR)	6 (4-7)	6 (5-7)	0.648

Values are presented as median (interquartile range) or number (%). Continuous variables were compared using the Wilcoxonrank-sum test and categorical variables using Fisher's exact test. CLDQ scores range from 1 (worst symptoms) to 7 (no symptoms). CBR = complete biochemical remission; BMI = Body Mass Index; MASLD = metabolic dysfunction–associated steatotic liver disease. Box plots show median, IQR, and range excluding outliers.

1251 | IMPACT OF LINERIXIBAT, AN ILEAL BILE ACID TRANSPORTER (IBAT) INHIBITOR, ON FAT-SOLUBLE VITAMIN (FSV) ABSORPTION IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS (PBC)

Gideon Hirschfield[1] Sadia Halim[2] Alexander Cobitz[3] Revathi Udayashankar[4] Linda Casillas[3] Ivana Lazic[2] Jennifer Shannon[5] Megan McLaughlin[6] Chester Bowen[3] Sanjay Kumar[3] Brandon Swift[5] Cynthia Levy[7] Christopher Bowlus[8], [1]Toronto General Hospital, Toronto, ON, Canada, [2]GSK, London, UK, [3]GSK, Collegeville, PA, USA, [4]GSK, Bangalore, India, [5]GSK, Durham, NC, USA, [6]GSK, Collegeville, PA, USA (at time of study conduct), [7]University of Miami Miller School of Medicine, Miami, FL, USA, [8]University of California Davis, Sacramento, CA, USA

Background: Bile acids act as digestive surfactants, assisting absorption of FSVs. IBAT inhibitors (IBATi) interrupt absorption of primary conjugated bile acids (while maintaining bile acid synthesis), which can potentially lead to FSV deficiencies, as observed with some IBATi in cholestatic diseases. Linerixibat is a minimally absorbed, twice-daily, oral IBATi recently approved in the US for the treatment of cholestatic pruritus in PBC. Here, we report FSV levels with linerixibat treatment in patients (pts) with PBC, and adverse events (AEs) associated with FSV deficiency. **Methods:** The Phase 3 GLISTEN (NCT04950127) and the Phase 2b GLIMMER (NCT02966834) trials were multicenter, randomized, placebo-controlled trials investigating the efficacy and safety of linerixibat in adults with PBC and pruritus. This abstract presents primary and post hoc analyses of FSV levels, and FSV-related AEs in the safety population of GLISTEN and GLIMMER (primary intervention periods). **Results:** The GLISTEN safety population included 237 pts (linerixibat n = 119; placebo n = 118). Most pts had FSV levels within normal range at baseline and throughout the study. No significant differences in absolute values were observed between linerixibat and placebo over 24 weeks. Analysis of covariance for the change from baseline in FSV levels at Week 24 showed no significant reductions with linerixibat vs placebo (**Table**). AEs of FSV decrease/deficiency were experienced in 4 (3%) pts receiving linerixibat and 2 (2%) pts receiving placebo, with no meaningful difference in incidence between groups. All were mild in intensity and not considered treatment-related. Eleven (9%) pts on linerixibat and 3 (3%) on placebo experienced hemorrhage. In these pts, no clinically significant differences were observed between groups in change from baseline in International Normalized Ratio and vitamin K. Fracture occurred in 2 (2%) pts receiving linerixibat (1 had a history of osteoporosis; both had vitamin A levels below lower limit of normal [LLN] at baseline and during the study) and 3 (3%) receiving placebo (1 pt had 2 fractures; 1 had vitamin D levels **Conclusion:** There was no clinical evidence suggestive of a causal association between linerixibat and FSV deficiency-related AEs, possibly due to its unique physicochemical properties that may not impact micellar formation and subsequent FSV absorption and its reversible inhibition compared to other IBATi. Most pts maintained vitamin A, D, E and K parameters within normal range, with no notable differences observed in change from baseline between linerixibat and placebo groups. **Funding:** GSK (212620/201000)

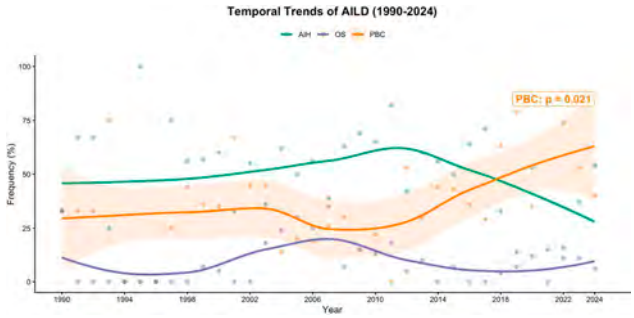
1252 | TEMPORAL TRENDS IN AUTOIMMUNE LIVER DISEASES OVER THE LAST THREE DECADES: IMPACT OF THE COVID-19/POST-COVID-19 PANDEMIC, RISING PRIMARY BILIARY CHOLANGITIS FREQUENCY, AND AGING AT DIAGNOSIS IN A MEXICAN REFERRAL CENTER



Linda Muñoz-Espinosa[1] Samuel Rivas-Lopez[2] Paula Cordero-Perez[2] Giselle Banda-Alvarez[2] Alexandra Costilla-Martinez[2] Ricardo Rodriguez-Macias[2] Liliana Torres-González[2] Fernando Iglesias-Hernandez[2] Emilia Sepulveda-Gutierrez[3], [1]University Hospital, UANL, [2]Hospital Universitario UANL, [3]Hospital Universitario, UANL

Background: The global impact of autoimmune liver diseases (AILD) poses a major diagnostic challenge. Mexico ranks first in cirrhosis-related mortality in Latin America. Cirrhosis is currently the fourth leading cause of death nationwide. The incidence of AILD, according to international diagnostic criteria, has increased in our center, particularly during the COVID-19 pandemic and post-pandemic periods. Therefore, we aimed to evaluate the distribution of autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and overlap syndromes (OS; mainly AIH/PBC) across two periods: pre-pandemic (historical cohort) and pandemic/post-pandemic (2020–2024). **Methods:** This analytical, observational, retrospective study included patients with AILD evaluated between 1990 and 2024 at a national referral center, with a minimum follow-up (FU) of 6 months. **Results:** This study represents the largest historical cohort of AILD reported in Mexico to date, including 519 patients: AIH (n = 259, 50%), PBC (n = 203, 39%), and OS (n = 57, 11%). Most patients were female (87%), with a median age at diagnosis of 52 years [IQR 39–59]. Median follow-up was 26 months [IQR 6–72]. At baseline, cirrhosis was present in 153 patients (30%), while an additional 91 patients (25%) who were initially non-cirrhotic developed cirrhosis during FU. Twenty-nine orthotopic liver transplants (OLT; 6%) were performed. Transplant-free survival for the entire cohort at 3, 5, 10, and 20 years was 88.5%, 84.8%, 82.5%, and 80.3%, respectively. AILD diagnoses increased by 48.6% during the last four years compared with the historical period (20.6 vs. 13.9 cases/year; $p < 0.001$), with the highest incidence observed during the COVID-19 pandemic and post-pandemic periods. Linear regression analysis demonstrated a significant upward trend in PBC frequency ($p = 0.021$) (Figure), unlike AIH and OS. Additionally, age at diagnosis progressively increased across the cohort ($p = 0.022$). Specifically, the probability of diagnosis at ≥ 60 years increased by 4% annually ($p = 0.003$; OR 1.04). **Conclusion:** A significant increase in AILD

diagnoses was observed, particularly during and after the COVID-19 pandemic. PBC showed the greatest increase in frequency in the last decade. These findings highlight the urgent need to improve epidemiological surveillance and reporting of AILD. Furthermore, our data demonstrate a shifting demographic pattern characterized by an increasing age at diagnosis across the cohort.

1253 | SWITCHING FROM OBETICHOLIC ACID TO NOVEL PPAR AGONISTS IN PRIMARY BILIARY CHOLANGITIS: EARLY MULTICENTER REAL-WORLD DATA FROM GERMANY

Universitätsklinik Düsseldorf[1] Smaranda Gliga[1] Carolin Angendohr[1] Paul Park[1] Tony Bruns[2] Karsten Grosse[2] Philipp Lutz[3] Johannes Chang[3] Hans Bock[1] Tom Luedde[1], [1]University Hospital Düsseldorf, Department for Gastroenterology, Hepatology and Infectious Diseases, [2]Department of Medicine III, University Hospital RWTH Aachen, [3]Department of Internal Medicine I, University of Bonn

Background: Primary biliary cholangitis (PBC) requires second-line therapy when response to ursodeoxycholic acid is insufficient. While bezafibrate has been used off-label for years, the recent withdrawal of obeticholic acid (OCA) from the European market resulted in a rapidly shifting treatment landscape. New PPAR agonists elafibranor and seladelpar are increasingly being introduced into clinical practice. Given limited real-world comparative data during this transition period, we evaluated treatment sequencing patterns and biochemical responses in a multicenter German cohort. **Methods:** PBC patients treated at Aachen, Bonn, and Düsseldorf were retrospectively included. Each initiation of OCA, bezafibrate, elafibranor, or seladelpar constituted a treatment episode. Baseline was defined as the closest laboratory value within −90/+14 days of start. Follow-up ended at switch, discontinuation, or last on-treatment test. Response was assessed at 3, 6, and 12 months using POISE-like criteria (AP $<1.67\times$ULN with $\geq 15\%$ reduction and normal bilirubin) and Paris-II criteria (AP $\leq 1.5\times$ULN, AST $\leq 1.5\times$ULN, bilirubin ≤ 1.0 mg/dL). **Results:** Forty-two patients (90% female, median age 56, 14% cirrhosis) contributed 76 episodes (bezafibrate 30, OCA 19, elafibranor 16, seladelpar 11).Response patterns varied by agent. Bezafibrate showed POISE/Paris-II responses of ~50% in early assessments and up to 75% Paris-II in later windows, with median AP reductions of −27.8% (early) and −44.0% (later). OCA responses were lower (POISE ~50% early, 20% later; Paris-II ~50% early, 22% later) with modest AP change (−8.6% to −15.7%). Elafibranor showed intermediate to favourable early responses (POISE 43%, Paris-II 50%) and higher later-window response (67% and 62%), with AP reductions of −17.3% to −19.9%. Seladelpar had limited follow-up but showed consistent biochemical improvement (POISE 17–25%, Paris-II 14–17%) with AP reductions of −22.5% to −20.4%.Overall, treatment sequencing was dominated by OCA → PPAR switching, and most elafibranor (75%) and seladelpar (82%) episodes occurred after prior therapy. Switch analyses suggested biochemical improvement after most OCA → PPAR transitions, although one patient showed progressive biochemical worsening across three therapies. Direct comparison between elafibranor and seladelpar is limited by differences in prior exposure and treatment time frames. **Conclusion:** In this real-world cohort, elafibranor and seladelpar were predominantly used after OCA exposure and were generally associated with biochemical improvement or response maintenance after switching. However, response magnitude and responder rates differed markedly by endpoint definition and treatment sequence. Comparative interpretation between agents is limited due to heterogeneous pretreatment and follow-up duration, and longer follow-up is needed for further analysis.

Therapy	n episodes	Median on-tx (days)	3 months			6 months			12 months				Cumulative on-treatment	
			POISE	Paris-II	Median ΔAP	POISE	Paris-II	Median ΔAP	POISE (on-tx)	POISE (ITT)	Paris-II	Median ΔAP	Best ΔAP	Ever AP ≤1.5×ULN
Bezafibrat	30	913	1/2 (50%)	2/4 (50%)	-27.8%	3/4 (75%)	4/9 (44%)	-44.0%	7/10 (70%)	7/18 (39%)	9/15 (60%)	-39.1%	-39.1%	10/15 (67%)
OCA	19	1096	1/2 (50%)	1/2 (50%)	-8.6%	1/5 (20%)	2/9 (22%)	-15.7%	1/4 (25%)	1/8 (12%)	2/7 (29%)	-30.4%	-33.4%	1/7 (14%)
Elafibranor	16	178	3/7 (43%)	5/10 (50%)	-17.3%	4/6 (67%)	5/8 (62%)	-19.9%	0/5 (0%)	0/16 (0%)	3/6 (50%)	-9.7%	-27.5%	8/13 (62%)
Seladelpar	11	163	1/6 (17%)	1/7 (14%)	-22.5%	1/4 (25%)	1/6 (17%)	-20.4%	-	0/11 (0%)	0/1 (0%)	-	-22.5%	2/8 (25%)

POISE-like response: AP <1.67×ULN AND ≥15% reduction from episode baseline AND total bilirubin ≤ULN.

Paris-II response: AP ≤1.5×ULN AND AST ≤1.5×ULN AND total bilirubin ≤1.0 mg/dL.

Intention-to-treat (ITT): episodes censored for switch or discontinuation before window upper bound were classified as non-responders.

Ever AP ≤1.5×ULN: proportion of episodes that achieved AP ≤1.5×ULN at any on-treatment laboratory.

– : not evaluable (no on-treatment laboratory within the corresponding window).

Across 76 second-line treatment episodes, biochemical response was assessed at three predefined on-treatment time-points using two complementary criteria: a POISE-like composite (AP <1.67×ULN with ≥15% reduction from episode baseline AND total bilirubin ≤ULN) and the Paris-II criteria (AP ≤1.5×ULN AND AST ≤1.5×ULN AND total bilirubin ≤1.0 mg/dL).

1254 | RECOMPENSATION FOLLOWING PBC-DIRECTED THERAPY IS ASSOCIATED WITH IMPROVED TRANSPLANT-FREE SURVIVAL IN DECOMPENSATED PRIMARY BILIARY CHOLANGITIS: A MULTINATIONAL SOUTHEAST ASIAN STUDY

Jimmy Che-To Lai[1] Junlong Dai[1] Jarell Jie-Rae Tan[2] Karen Hei-Tung Lai[1] Alyssa Shin Yee Sim[3] Ian Yang Liew[3] Kanokwan Pinyopornpanish[4] Chitchai Rattananukrom[5] Apichat Kaewdech[6] Wah Kheong Chan[7] Guan Wee Wong[8] Joyce Shin Han Seah[2] Senam Kaur[9] Terry Cheuk-Fung Yip[1] Yu Jun Wong[2],
[1]The Chinese University of Hong Kong, Hong Kong, [2]Changi General Hospital, Singapore, [3]Tan Tock Seng Hospital, Singapore, [4]Chiang Mai University, Thailand, [5]Khon Kaen University, Thailand, [6]Prince of Songkla University, Hat Yai, Thailand, [7]Universiti Malaya, Malaysia, [8]Ng Teng Fong General Hospital, Singapore, [9]Queen Elizabeth Hospital, Kota Kinabalu, Malaysia

Background: Clinical outcomes following hepatic recompensation in primary biliary cholangitis (PBC) have been predominantly characterized in Western population, with limited real-world data from Southeast Asia (SEA). The impact of PBC-directed treatment on recompensation in PBC remains unclear. We evaluated the incidence, predictors, and prognostic implications of clinical recompensation in a multinational Southeast Asian (SEA)-PBC cohort. **Methods:** This retrospective cohort study included adult with decompensated PBC cirrhosis from 9 tertiary centers within the SEA-PBC study group. The baseline was defined as the date of index decompensation. Patients were followed longitudinally until death, liver transplantation or last follow-up. Clinical recompensation was defined according to the Baveno VII criteria as the resolution of decompensation events for at least 12 months with discontinuation of medications for ascites and hepatic encephalopathy. The primary endpoint was transplant-free survival (TFS) beyond a 12-month landmark after index decompensation, stratified by recompensation status. Clinical recompensation was analyzed as a time-dependent covariate using cause-specific Cox regression models. **Results:** 160 decompensated PBC patients included (mean age 72.9 years, 81.9% female), 37 patients (23.1%) achieved clinical recompensation during a median follow-up of 16.6 (IQR: 5.6-41.0) months. Compared to those who remained decompensation, those with recompensation had a lower baseline Child-Pugh score and MELD ($p < 0.001$ for both). Clinical recompensation demonstrated a trend toward improved TFS compared with persistent decompensation (hazard ratio [HR] 0.55, 95% CI 0.30-1.02, $p = 0.057$) **(Figure 1A)** .Notably, patients who initiated ursodeoxycholic acid (UDCA) treatment after index decompensation and subsequently achieved recompensation had significantly superior TFS (HR 0.20, 95% CI 0.06-0.70, $p = 0.012$) **(Figure 1B)**, whereas no survival benefit was observed among patients already receiving UDCA prior to decompensation.Lower baseline MELD score (adjusted cause-specific HR 0.75, 95% CI 0.63-0.90, $p = 0.002$) and variceal hemorrhage as the index decompensation event (adjusted cause-specific HR 0.27 for ascites, 95% CI 0.11-0.67, $p = 0.005$) were independently associated with clinical recompensation. Among the established UDCA treatment response criteria, Rotterdam criteria best stratified TFS (HR 0.45, 95% CI 0.22-0.91, $p = 0.028$) **(Figure 1C)** . **Conclusion:** The association between post-decompensation UDCA initiation, recompensation, and improved outcomes highlights the importance of ongoing PBC-directed therapy even after hepatic decompensation. Rotterdam criteria may be used to define etiological control in PBC recompensation.

Background: Contemporary understanding of primary biliary cholangitis (PBC) has been largely derived from Western populations, while real-world outcomes and treatment patterns in the Asia Pacific region remain poorly characterized. We aimed to evaluate treatment response, long-term clinical outcomes, and unmet therapeutic needs in a large multinational Southeast Asian PBC cohort. **Methods:** The SEA-PBC cohort is a retrospective international multicenter cohort comprising patients with PBC from 19 tertiary centers across Asia-Pacific region. Patients with autoimmune hepatitis (AIH)-PBC overlap syndrome were excluded. Biochemical response to ursodeoxycholic acid (UDCA) at 12 months was assessed using established response criteria including ALP normalization, Paris-II, POISE, and deep response (normal alkaline phosphatase [ALP] with bilirubin $< 0.6 \times$ upper limit of normal [ULN]). Clinical outcomes included hepatic decompensation, hepatocellular carcinoma (HCC), liver transplantation (LT), and transplant-free survival (TFS). Multivariable logistic and Cox-regression analyses were performed to identify predictors of treatment response and long-term outcomes, respectively. **Results:** A total of 1,776 PBC patients were included. Patients were predominantly female (83.4%) and anti-mitochondrial antibody positive (87.1%), with median age at diagnosis of 65 (54-74) years; 16.1% had cirrhosis at diagnosis. At presentation, 28.5% were symptomatic, including pruritus (17.3%), fatigue (13.5%), or sicca symptoms (6.4%).UDCA was prescribed in 79.9% of patients. In these patients, ALP normalization was achieved in 21.2%, Paris-II in 39.1%, POISE in 49.4%, and deep response in 18.7% after 12 months. Despite inadequate biochemical response in a substantial proportion of patients, uptake rate of second-line therapy remained low (16.1% fibrates, 0.3% obeticholic acid). Over a mean follow-up of 6.5 ± 5.5 years, 13.1% experienced hepatic decompensation, 4.0% developed HCC, and 0.8% underwent LT. Five-year transplant-free survival rates were 80.3%. Higher baseline ALP (per unit of ULN increase; adjusted hazard ratio [aHR] 1.07, 95% CI 1.03 - 1.12; $p = 0.001$) and increasing fibrosis category by Fibrosis-4 index (aHR 1.96, CI 1.62 - 2.37, $p < 0.001$) were independently associated with death or LT. **Conclusion:** This study of a large multinational Southeast Asian PBC cohort demonstrates substantial residual disease burden. Despite UDCA therapy, biochemical remission and deep response rate remained modest, yet the uptake of second-line therapy remained strikingly low. Persistent adverse liver-related outcomes highlight important unmet needs in risk stratification, timely treatment escalation and equitable therapies for Asian patients with PBC.

1256 | BINATIONAL COMPARISON OF AUTOIMMUNE HEPATITIS ACROSS MEXICO CITY AND US REVEALS DISTINCT ENDOTYPES, EQUIVALENT TREATMENT RESPONSE, AND EARLY SURVIVAL DISADVANTAGE FOR HISPANIC PATIENTS WITH CIRRHOSIS

Neel Ravela[1] Daniela Marengo-Rodriguez[2] Oscar Manuel Fierro-Angulo[2] Astrid Ruiz Margain[2] Ricardo Macias Rodriguez[2] Marwan Ghabril[3] Eduardo Vilar-Gomez[3] Nadia Blessing[4] Naga Chalasani[3] Craig Lammert[3], [1]Texas Tech University Health Sciences Center, El Paso, [2]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, [3]Indiana University School of Medicine, [4]Indiana Universtiy School of Medicine

Background: Hispanic patients with autoimmune hepatitis (AIH) are reported to have increased prevalence of cirrhosis at presentation, yet whether this reflects biological differences, diagnostic delay, or limited care access remains unresolved. We tested this question by comparing phenotype, treatment response, and transplant-free survival (TFS) between Mexican (entirely Hispanic) and US (mostly non-Hispanic White) patients. **Methods:** We analyzed 699 AIH patients from Mexico City (MC, n = 185, 93% Hispanic) and Indiana University (IU, n = 514, 4% Hispanic) using multivariable Cox regression, landmark analyses at 6 months, and logistic regression for predictors of incomplete remission. To control for an average 7-year age difference between cohorts at diagnosis, we performed a 1:1 age- and sex-matched analysis (±5 years; n = 322) with time-split Cox models to assess an early survival gap among cirrhotic patients. **Results:** MC patients had a classic autoimmune phenotype: higher IgG (2,311 vs. 1,521 mg/dL), ANA positivity (99% vs. 67%), and anti-LKM positivity (14% vs. 2%) (Table 1). IU patients had a metabolic phenotype: higher BMI (28.4 vs. 26 kg/m²), ALT at diagnosis (170 vs. 69 U/L), and MASH features on biopsy (54% vs. 5%; all p < 0.001). MC patients remained on steroid treatment throughout follow-up (48% on prednisone at most recent visit vs. 17% at IU), while IU shifted maintenance to MMF (29% vs. 9%; all p < 0.001).Despite these differences, biochemical remission at 6 months was identical (50% MC vs. 53% IU, p = 0.64). Incomplete remission was predicted by cirrhosis at diagnosis (OR 5.1, 95% CI 1.87–13.92, p = 0.001), not site or ethnicity. In the full cohort, site did not independently predict TFS after adjustment for cirrhosis, albumin, and sex (HR 0.7, 95% CI 0.44–1.13, p = 0.15), with landmark analyses confirming no residual site effect at 6 months.In the matched cohort, overall TFS was similar (5-year: 85% MC vs. 93% IU; log-rank p = 0.18), but MC patients had a 2.6-fold higher hazard of transplant or death in the first 5 years (HR 2.58, 95% CI 1.14–5.86, p = 0.023), confined to those with cirrhosis at diagnosis (5-year TFS: 58% MC vs. 85% IU, log-rank p = 0.04). Non-cirrhotic patients had equivalent TFS at both sites (97% at 5 years each) and similar incident cirrhosis development (11% vs. 13%, p = 0.88). **Conclusion:** AIH patients present as two distinct endotypes in our cohorts; MC with classic autoimmune phenotype and IU with metabolic phenotype, yet both had equivalent outcomes. Cirrhosis, sex, and albumin are drivers of TFS, not treatment site or ethnicity. An early survival disadvantage of MC patients is confined to patients with cirrhosis.

Table 1. Comparison of AIH Across Mexico City (MC) and Indiana University (IU): Phenotype, Treatment, Response, and Outcomes

Variable	IU	MC	p-value
Demographics - FULL COHORT (IU n=514, MC n=185)			
N	514	185	—
Age at diagnosis, years, median (IQR)	50 (36–59)	41 (28–52)	**<0.001**
Female sex, n (%)	395 (78%)	143 (79%)	0.75
Cirrhosis at diagnosis, n (%)	111/452 (25%)	57/179 (32%)	0.08
Disease Phenotype - MATCHED COHORT (161 per site)†			
IgG, mg/dL, median (IQR)	1,521 (1,212–2,232)	2,311 (1,742–3,014)	**<0.001**
ANA positive, n (%)	88/131 (67%)	158/159 (99%)	**<0.001**
Anti-LKM positive, n (%)	1/55 (2%)	20/144 (14%)	**0.01**
BMI, kg/m², median (IQR)	28.4 (24.0–37.3)	26 (23.4–28.4)	**<0.001**
ALT at diagnosis, U/L, median (IQR)	170 (64–536)	69 (30–206)	**<0.001**
MASH features on biopsy, n (%)	71/132 (54%)	7/152 (5%)	**<0.001**
Cirrhosis at diagnosis, n (%)	36/145 (25%)	50/160 (31%)	0.26
Transplant-Free Survival — FULL COHORT (n=699)			
Adjusted HR, site — MC vs IU (95% CI)	Reference	0.7 (0.44–1.13)	0.15
Adjusted HR, cirrhosis at diagnosis (95% CI)	—	3.76 (2.34–6.03)	**<0.001**
Landmark HR at 6 months (95% CI)	Reference	1.33 (0.77–2.30)	0.31
Transplant-Free Survival — MATCHED COHORT† (161 per site)			
5-year TFS, overall	93%	85%	0.18†
5-year TFS — no cirrhosis at diagnosis	97%	97%	0.61†
5-year TFS — cirrhosis at diagnosis	85%	58%	**0.04†**
Adjusted HR, years 0–5 after diagnosis (95% CI)§	Reference	2.58 (1.14–5.86)	**0.02**
Adjusted HR, years >5 after diagnosis (95% CI)§	Reference	0.71 (0.26–1.91)	0.5
Incident cirrhosis (non-cirrhotic subgroup), n (%)	14/107 (13%)	12/110 (11%)	0.88†

Continuous variables: median (IQR), Mann–Whitney U test. Categorical: n (%), chi-square or Fisher's exact test.
† Matched cohort: 1:1 match on sex and age at diagnosis (±5 years). Total n=322.
§ Cox proportional hazards model restricted to years 0–5 or >5, adjusted for cirrhosis at diagnosis. Time-split analysis pre-specified.

1257 | ADULT TYPE 2 AUTOIMMUNE HEPATITIS: AN IMPORTANT CLASSIFIER OF DISEASE COURSE TO RECOGNISE

Natassia Tan[1] Ilkay Ergenç[2] Abhishek Rao[3] Shagani Thisairajah[4] Eliza Flanagan[1] Inbal Houri[1] Claire Gage[1] Madeline Cameron[1] Michael Heneghan[2] Palak Trivedi[3] Aldo Montano-Loza[4] Aliya Gulamhusein[1] Gideon Hirschfield[1], [1]The Autoimmune and Rare Liver Disease Programme, Toronto General Hospital, Toronto, Canada, [2]Department of Hepatology, King's College Hospital, London, United Kingdom, [3]Department of Hepatology, University Hospital Birmingham, Birmingham, United Kingdom, [4]Division of Gastroenterology and Liver Unit, University of Alberta, Edmonton, Canada

Background: Data on adults living with type two autoimmune hepatitis (AIH-2) is infrequent, given how rare it is. Recent international guidelines advise against classifying adult patients (pts) with AIH based on autoantibody profiles. We sought to describe the clinical characteristics and outcomes of adult pts with AIH-2. **Methods:** We performed a multi-centre (4 centres, 2 countries) retrospective cohort study including pts from 1st January 2017 to 1st May 2026, with a clinical diagnosis of AIH and strongly positive liver-kidney microsomal-1 (LKM-1) and/or liver-cytosol 1 (LC-1) antibodies. **Results:** One hundred and one pts with AIH-2 were identified. Ninety-three (92%) were female, with a median age of 20 (IQR 12-31) years at diagnosis and 34 (IQR 25-52) years at last follow-up. Seventy-six (76%) pts were LKM-1 positive, 33 (33%) were LC-1 positive, and 9 pts had both autoantibodies. The most common clinical presentation was chronic hepatitis (n = 54, 53%), followed by acute hepatitis (n = 22, 23%). Thirty-five (35%) patients had other autoimmune conditions. Twenty-one (21%) pts had relapses at a median of 3.7 (3-5.4) years from diagnosis, and 56 (55%) were on prednisone at last follow-up. Forty-one (41%) pts were on azathioprine and 24 (24%) on mycophenolate maintenance therapy. Twenty-one (21%) pts required third-line therapies (tacrolimus n = 17, cyclosporin n = 2, sirolimus = 1, rituximab n = 1) and three (3%) were on ursodeoxycholic acid. Fifty-nine (58%) pts were diagnosed in adulthood; there were no significant differences in baseline demographics and clinical characteristics between pts with pediatric and adult-onset disease. Adult-onset disease was characterized by a trend toward higher alanine transaminase (145 vs 40 IU/L, p = 0.06) at presentation, a shorter time to first episode of relapse (3.1 vs 4.2 years, p = 0.02), and a higher proportion of cirrhosis at diagnosis and last follow-up (p = 0.01). Eighteen (18%) pts received a liver transplant. **Conclusion:** As AIH-2 is so rare, limited adult data is available. In our large cohort study, we observe a more severe disease phenotype in adult-onset disease and high corticosteroid dependence in the entire cohort. These distinctions, identified by serologic classification, are important for guiding patient care.

Table: Demographics and clinical characteristics of AIH-2 stratified by pediatric or adult-onset disease

Variables	Pediatric onset (n=39)	Adult onset (n=59)	p-value
Age at diagnosis, years, median (IQR)	11 (6.5-15)	28 (21-42)	<0.001
Follow up, years, median (IQR)	17 (9-23)	10 (5-17)	0.04
Female, n (%)	37 (95)	53 (90)	0.60

1258 | LARGE-SCALE UNTARGETED PLASMA METABOLOMICS REVEALS SYSTEMIC DISEASE-ASSOCIATED METABOLIC SIGNATURES IN PRIMARY SCLEROSING CHOLANGITIS AND PRIMARY BILIARY CHOLANGITIS

Marios Nikolaidis[1] Brian Juran[1] Bryan Mccauley[2] Erik Schlicht[1] Jackie Bianchi[1] Ahmad Ali[3] Elizabeth Atkinson[2] Garry Miller[4] Dean Jones[5] Grigorios Amoutzias[6] Konstantinos Lazaridis[1], [1]Division of Gastroenterology and Hepatology, Mayo Clinic, Rochester, MN, [2]Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, MN, [3]Division of Gastroenterology and Hepatology, School of Medicine, University of Missouri,Columbia,MO, [4]Department of Environmental Health Sciences, Mailman School of Public Health, Columbia University,NY, [5]Division of Pulmonary,Allergy,and Critical Care Medicine, Department of Medicine,Emory University,GA, [6]Bioinformatics Laboratory,Department of Biochemistry and Biotechnology,University of Thessaly,Greece

Background: Primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC) are rare immune-mediated cholestatic liver diseases with incompletely understood pathogenesis and limited therapeutic options. Environmental, microbial, and metabolic factors are increasingly recognized as potential contributors to cholestatic liver disease biology. We aimed to define plasma metabolic alterations associated with PSC and PBC by performing a large, comprehensive, untargeted-metabolomic analysis of PSC and PBC patients and matched controls. **Methods:** Plasma samples from patients with PSC (n = 800), PBC (n = 600), and matched controls (PSC controls n = 800, PBC controls n = 600) underwent untargeted metabolomics analysis using ultra-high-resolution liquid chromatography coupled with high-resolution accurate mass spectrometry to profile thousands of small-molecule metabolic features. The dataset was split into exploration and validation cohorts. Metabolic features were extracted with ASARI and annotated using khipu, HMDB, LipidMaps, and microbial metabolite database MIMEDB. Feature-level comparisons between disease and control groups were performed with age- and sex-adjusted linear models. Differentially abundant features were prioritized based on reproducibility across cohorts, annotation confidence, and evidence for microbial or host metabolic origin. **Results:** Both PSC and PBC showed extensive plasma metabolic differences compared with matched controls across HILIC and C18 chromatography columns. Age- and sex-adjusted models identified thousands of differentially abundant features in the exploration cohort, including hundreds of putatively annotated signals in each disease group. Similar disease-associated signals were observed in the validation cohort, supporting reproducibility across independent analytical subsets. Across study, disease, and chromatographic mode comparisons, more than 100 common differentially abundant annotations were recurrently detected, with both increased and decreased abundance in patients. These signals mapped to metabolic processes relevant to cholestatic liver disease, including bile acid and lipid-related metabolism, and putative microbial-derived metabolites supporting a link between these diseases and systemic host-microbial metabolic perturbation. **Conclusion:** PSC and PBC are associated with substantial alterations in the plasma metabolome compared with matched controls, including signals consistent with host metabolic dysregulation and host-microbial co-metabolism. A subset of differentially abundant features mapped to microbial metabolites through MIMEDB, supporting a potential contribution of gut microbial metabolism to systemic metabolic changes in cholestatic liver disease. This large-scale untargeted metabolomics study identifies reproducible disease-associated metabolic signatures and provides a foundation for discovering novel biomarkers and biological pathways relevant to PSC and PBC pathogenesis.

1259 | BASELINE SYMPTOMS PREDICT WORSE SURVIVAL IN NON-CIRRHOTIC AUTOIMMUNE HEPATITIS DESPITE SIMILAR DISEASE SEVERITY: A REAL-WORLD COHORT STUDY

Christos Triantos[1] Konstantinos Papantoniou[1] Vasileios Lekakis[2] Ioanna Aggeletopoulou[1] Maria Bali[1] Odyssefs Ampazis[1] Georgia Diamantopoulou[1] Konstantinos Thomopoulos[1], [1]Division of Gastroenterology, Department of Internal Medicine, University of Patras, 26504, Patras, [2]First Academic Department of Gastroenterology, Medical School of National, Laiko General Hospital,

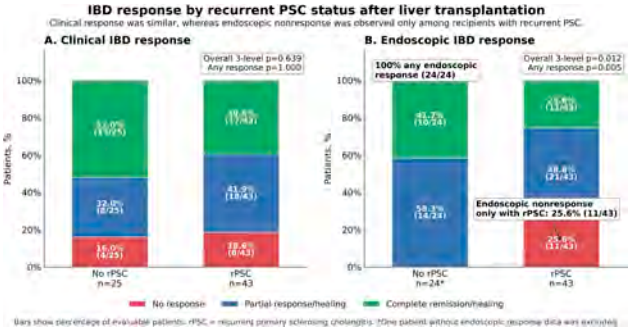
Background: The prognostic significance of symptomatic presentation in autoimmune hepatitis (AIH) remains unclear. While asymptomatic patients are often considered to have milder disease, available evidence is inconsistent (DOI: 10.1016/j.cgh.2025.04.034). We evaluated whether symptom status at diagnosis is

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

associated with disease severity, disease progression, and survival in AIH. **Methods:** We retrospectively analyzed 116 patients with AIH followed at a tertiary referral center. Patients were classified as symptomatic or asymptomatic at diagnosis. Baseline cirrhosis, hepatic decompensation, hepatocellular carcinoma (HCC), and disease progression during follow-up were compared between groups. Overall survival was evaluated using Kaplan–Meier analysis and Cox regression models. **Results:** The cohort included 116 patients (81.9% female) with a median age of 54 years (IQR 42–65); 58.8% were symptomatic at diagnosis. Median follow-up was 48 months (IQR 10–108), and overall mortality was 21.2%. Baseline cirrhosis (22.4% vs 17.0%, p = 0.482), hepatic decompensation (18.8% vs 12.5%, p = 0.699), and HCC (1.5% vs 0%, p = 0.400) were similar between symptomatic and asymptomatic patients. During follow-up, no differences were observed in cirrhosis progression (25.4% vs 21.7%, p = 0.656), hepatic decompensation (41.2% vs 40.0%, p = 0.952), or HCC development (3.0% vs 0%, p = 0.439). Survival was analyzed according to baseline cirrhosis status. Among patients with cirrhosis at diagnosis, symptom status was not associated with survival (log-rank p = 0.142). In 93 patients without cirrhosis at first visit, 53 (60.2%) had symptoms at baseline. Jaundice was the most commonly reported symptom (35.5%), followed by fatigue (9.7%), non-specific symptoms (9.7%) and arthralgias (2.2%). Among non-cirrhotic patients, symptomatic presentation was associated with significantly worse survival (log-rank p = 0.037). In Cox regression analysis, baseline symptoms were independently associated with poorer survival (HR 2.62, 95%CI 1.03–6.69, p = 0.044). **Conclusion:** Symptom status at diagnosis was not associated with baseline disease severity or disease progression in AIH. However, among non-cirrhotic patients, symptomatic presentation was associated with worse overall survival. These findings suggest that symptoms at presentation may identify non-cirrhotic patients at increased risk for adverse long-term outcomes.

Disclosures: Christos Triantos:Nothing to Disclose, Konstantinos Papantoniou:Nothing to Disclose, Vasileios Lekakis:Nothing to Disclose, Ioanna Aggeletopoulou:Nothing to Disclose, Maria Bali:Nothing to Disclose, Odyssefs Ampazis:Nothing to Disclose, Georgia Diamantopoulou:Nothing to Disclose, Konstantinos Thomopoulos:Nothing to Disclose.

1260 | RECURRENT PRIMARY SCLEROSING CHOLANGITIS AFTER LIVER TRANSPLANTATION IS ASSOCIATED WITH PERSISTENT ENDOSCOPIC INFLAMMATORY BOWEL DISEASE ACTIVITY INDEPENDENT OF COLECTOMY: THE ERA OF ADVANCED THERAPY



Hala Nabulsi[1] Jana Hashash[1] Andrew Keaveny[1] Darrell Pardi[2] Kymberly Watt[2] Elizabeth Carey[3] Denise Harnois[1] Omar Mousa[1], [1]Mayo Clinic Florida, [2]Mayo Clinic Rochester, [3]Mayo Clinic Arizona

Background: Recurrent primary sclerosing cholangitis (rPSC) after liver transplantation (LT) compromises allograft and patient survival. The gut-liver axis implicates intestinal inflammation in rPSC pathogenesis, and pretransplant colectomy has been reported to be protective. The relationship between post-LT inflammatory bowel disease (IBD) clinical and endoscopic (mucosal) activity and risk of rPSC in the era of advanced IBD therapy remains poorly defined. We examined associations among post-LT response to IBD therapy, colectomy status, and risk of rPSC. **Methods:** We performed a retrospective 3-center cohort study of LT recipients between 1992-2022 who received a LT for PSC and who had associated IBD for which they received advanced IBD therapy after LT. rPSC was defined by established cholangiographic and/or histologic criteria after exclusion of secondary causes. Post-LT IBD activity was categorized by clinical disease activity based on symptoms (none/partial/complete remission) and endoscopic remission based on disappearance of ulcerations in Crohn's disease (CD) and Mayo endoscopic subscore ≤ 1 in ulcerative colitis (UC) (none/partial mucosal healing/complete remission). Colectomy status, type and timing relative to LT were recorded. Patients with and without rPSC were compared using Fisher exact and Wilcoxon rank-sum tests. **Results:** Among 68 patients (UC 64.7%, CD 33.8%, IC 1.5%; 66.1% male; mean age 39.5 ± 12.8 years; mean MELD at transplant 20.9), rPSC developed in 63.2% (43/68) over similar follow-up time compared to patients without rPSC (median 5.7 vs 4.5 years; p = 0.28). Endoscopic response to therapy strongly separated the groups: every patient without rPSC achieved an

endoscopic response (24/24, 100%) versus 74% (32/43) with rPSC (p = 0.005), and absence of any endoscopic response occurred only in the rPSC group (11/43, 26% vs 0/24, 0%; p = 0.012). In contrast, clinical IBD response did not predict PSC recurrence: any clinical response occurred in 35/43 (81.4%) with rPSC and 21/25 (84.0%) without rPSC (p = 1.0); complete clinical remission occurred in 17/43 (39.5%) and 13/25 (52.0%), respectively (p = 0.639). Colectomy was not associated with rPSC (any colectomy 56% vs 52%; p = 0.81), irrespective of timing relevant to LT (pre-LT 28% vs 24%; post-LT 28% vs 28%) or surgical type (proctocolectomy with IPAA vs. proctocolectomy with end ileostomy vs. partial colectomy or no colectomy) (p = 0.969). **Conclusion:** In LT recipients with PSC-IBD who received advanced IBD therapy, persistent endoscopic mucosal inflammation, but not clinical symptoms or colectomy status, was associated with the risk of rPSC. This finding suggests that ongoing mucosal inflammation drives the gut-liver axis and that colectomy alone may not be sufficient to mitigate risk, supporting continued aggressive control of mucosal inflammation after LT to protect the liver allograft and warranting prospective study.

1261 | GLP-1 RECEPTOR AGONISTS IN A VULNERABLE BILIARY TREE: REAL-WORLD BILIARY AND LIVER OUTCOMES IN PRIMARY SCLEROSING CHOLANGITIS WITH TYPE 2 DIABETES

Chimezirim Ezeano[1] Sarpong Boateng[2] Ihunanya Kanu[3] Guy Loic Nguefang Tchoukeu[4] Emeka Stanley Obi[5] Ifelunwa Osanakpo[6] Cherechi Nwabueze[7] Onyinyechukwu Ozumba[0] Goodness Joseph[9] David Narvaez-De los Rios[10] Samuel Ayedun[11] Chimezie Madu[12] Angel Umahi[13], [1]Advocate Aurora Healthcare, [2]Yale New Haven Health, Bridgeport Hospital, [3]Baptist Memorial Hospital- Golden Triangle, [4]Texas Tech University Health Science Center, Permian Basin, [5]Brookdale University Hospital and Medical Center, [6]Carle Foundation Hospital, [7]John H. Stroger Jr. Hospital of Cook County, [0]Dept of Internal medicine Cape fear valley North Carolina , [9]Nnamdi Azikiwe University Teaching Hospital, [10]Universidad Icesi, [11]Montefiore Medical Center, Bronx NY, [12]Department of General Practice, Bradford Teaching Hospitals , NHS Foundation Trust, UK, [13]University of Lancashire School of medicine and dentistry

Background: The biliary safety of glucagon-like peptide-1 receptor agonists (GLP-1 RAs) in primary sclerosing cholangitis (PSC) is uncertain. We evaluated ERCP utilization, bile duct obstruction, and incident cirrhosis among adults with PSC and type 2 diabetes treated with GLP-1 RA/GLP-1-GIP therapy versus no documented GLP-1 exposure. **Methods:** We performed a retrospective TriNetX cohort study of adults with PSC and type 2 diabetes. GLP-1 exposure included GLP-1 analogues, semaglutide, liraglutide, dulaglutide, lixisenatide, or tirzepatide. The comparator cohort had no documented GLP-1 RA/GLP-1-GIP exposure. Outcomes began 1 day after the medication were started. Propensity-score matching yielded 103 patients per group from 115 exposed and 695 unexposed patients. Patients with the outcome before follow-up were excluded from that outcome analysis. Outcomes were analyzed using risk estimates, Kaplan-Meier analysis, hazard ratios (HRs), log-rank testing, and number of outcome instances. **Results:** After matching, mean follow-up was 1192.4 ± 1098.9 days in the GLP-1 group and 1243.7 ± 1231.4 days in the non-GLP-1 group. ERCP utilization occurred in 13/86 GLP-1-exposed patients versus 18/77 unexposed patients (15.1% vs 23.4%; risk difference [RD] -8.3%, 95% CI -20.4% to 3.9%, p = 0.18; risk ratio [RR] 0.647, 95% CI 0.34-1.23; HR 0.63, 95% CI 0.31-1.28; log-rank p = 0.2). Bile duct obstruction occurred in 12/78 versus 16/61 patients (15.4% vs 26.2%; RD -10.8%, 95% CI -24.5% to 2.8%, p = 0.11; RR 0.6, 95% CI 0.3-1.15; HR 0.6, 95% CI 0.23-1.25; log-rank p = 0.16). Incident cirrhosis rates were similar: 13/64 versus 12/55 patients (20.3% vs 21.8%;

RD -1.5%, 95% CI -16.2% to 13.2%, p = 0.84; RR 0.93, 95% CI 0.46-1.87; HR 1.14, 95% CI 0.51-2.55; log-rank p = 0.76). Mean ERCP instances were similar (3.15 vs 3.17, p = 0.98). **Conclusion:** In this propensity-matched real-world cohort, GLP-1 RA/GLP-1-GIP exposure was associated with numerically lower ERCP utilization and bile duct obstruction, but differences were not statistically significant, and incident cirrhosis was similar. Findings require cautious interpretation given observational design, coding-based ascertainment, residual confounding, and limited granular data on PSC severity, dose, and treatment duration.

1262 | PBC.CARE WEB APPS: TETHERED PATIENT-PROVIDER TOOLS TO SUPPORT SHARED DECISION-MAKING AND TREATMENT OPTIMIZATION IN PRIMARY BILIARY CHOLANGITIS

Robert Gish[1] Ibiagbani Max-Harry[2] Chelsie Anderson Chadha[2] Jeffrey Carter[2] Megan McLafferty[2] Jennifer Balmer[2] Leah Molloy[2] Laura Simone[2] Cherilyn Heggen[2], [1]Robert G Gish Consultants LLC, [2]PRIME Education

Background: The treatment landscape for primary biliary cholangitis (PBC) has advanced significantly with recent approvals of second-line therapies targeting disease progression and symptoms; however, optimal outcomes remain contingent on effective patient-provider communication and timely treatment escalation. To address the ongoing need for education and shared decision-making, we developed and evaluated companion patient-provider web apps hosted at https://pbc.care/. **Methods:** Patients and providers accessed PBC-focused learning modules and opt-in survey assessments evaluating perceptions, behaviors and clinical practices. Web apps were disseminated nationwide and implemented at 5 hepatology/gastroenterology clinics through workshops, with a follow-up survey conducted post-implementation to evaluate impact. **Results:** Between December 2025 and April 2026, 1430 providers and 749 patients/caregivers accessed the web apps, and surveys were completed by 738 providers (37% physician, 20% NP/PA, 43% other) and 365 patients/caregivers (51% patient, 49% caregiver). Among patients/caregivers, 77% reported moderate-to-extreme impact of PBC on quality of life (QoL). Although 64% reported confidence in discussing symptoms with their provider, only 27% reported doing so regularly. Key barriers included perceptions that symptoms were not taken seriously (22%), insufficient appointment time (18%), and uncertainty describing symptoms (15%). Only 34% of patients felt knowledgeable on when to consider second-line therapy. At baseline, only 46% of providers regularly assessed the impact of PBC symptoms on QoL, and 36% did not consider patient goals/preferences essential to improving outcomes. Web app engagement increased the proportion of providers with confidence in PBC diagnosis and symptom assessment (49% to 78%, p < .0001; figure) and evaluating response to first-line therapy (51% to 65%, p < .0001). Additionally, 60% of providers reported intent to regularly assess the QoL impact of PBC symptoms. The top action providers intended to take after using the web app was providing patients with PBC resources to support shared-decision making. Specialty clinics implementing web apps reported improvement in patient education, symptom control, and QoL. **Conclusion:** Persistent gaps in patient-provider communication, symptom assessment, and treatment escalation remain, however, digital educational tools have potential to improve communication, confidence, and patient-centered PBC care.

Figure. Changes in Provider Confidence in PBC Diagnosis and Symptom Assessment Following Web App Engagement

1263 | IBD STATUS MODIFIES ETHNIC DIFFERENCES IN RECURRENT CLINICAL EVENTS IN PRIMARY SCLEROSING CHOLANGITIS

Andrew John Cruz[1] Paul Yoon[1] Gevork Salmastyan[1] Mohamed Mahmoud[1] Jeffrey Kahn[2] Saro Khemichian[2] Damie Odufalu[2] Lily Dara[2], [1]USC/LAG, [2]University of Southern California

Background: Longitudinal PSC data come mostly from transplant registries, capturing endpoints but missing preceding disease activity. PSC-IBD is a phenotype distinct from PSC-alone, yet whether ethnic differences in event rates depend on IBD status is unknown. We compared recurrent hepatobiliary and IBD events in Hispanic vs non-Hispanic White (NHW) PSC patients, stratified by IBD at diagnosis. **Methods:** Retrospective cohort of patients diagnosed May 2001–Feb 2021, followed through May 2026 with 5-year follow-up at dual institutions (Table 1). PSC required cholestatic biochemistry, characteristic cholangiography, and exclusion of secondary causes. Event outcomes: cholangitis, decompensation, IBD flares, ERCP, stricture interventions. Hard outcomes: liver-related death, transplantation, cholangiocarcinoma. Rates per 100 person-years (PY) were compared by Poisson regression with offset, stratified by IBD; ethnicity×IBD interaction tested by likelihood ratio. **Results:** 67 patients (NHW = 33, Hispanic = 34) contributed 291 PY: 27 PSC-alone (105 PY), 40 PSC-IBD (186 PY). In PSC-alone, Hispanic patients had lower cholangitis rates (IRR 0.16, 95% CI 0.07–0.35; $p < 0.001$); decompensation, ERCP, and stricture intervention rates were similar (Figure A). In PSC-IBD, Hispanic ethnicity was associated with lower rates across all outcomes: cholangitis 0.33 ($p < 0.001$), decompensation 0.27 ($p < 0.001$), IBD flares 0.13 ($p < 0.001$), stricture interventions 0.15 ($p = 0.002$), ERCP 0.34 ($p = 0.004$) (Figure B). Ethnicity×IBD interaction was significant for decompensation ($p = 0.002$) and stricture interventions ($p = 0.020$). Any composite hard outcome (death, transplantation, or cholangiocarcinoma; Table 2) was less frequent in Hispanic patients (7/34 vs 15/33, $p = 0.039$). **Conclusion:** Ethnic differences in PSC burden appear phenotype-specific: lower recurrent-event burden in Hispanic PSC-IBD, and limited differences in PSC-alone. The significant ethnicity×IBD interaction—particularly for decompensation and stricture interventions—suggests against access or ascertainment bias alone, which would affect both similarly. The disparity extended to composite hard outcomes, beyond recurrent activity to clinically meaningful endpoints. These findings raise the possibility that gut-liver immune interactions, microbiome composition, dietary factors, or environmental exposures contribute to ethnic heterogeneity in PSC. Multicenter studies with immune and microbiome phenotyping are needed; IBD stratification should be routine in PSC outcome studies.

Background: Studies on primary biliary cholangitis (PBC) have focused on alkaline phosphatase (ALP) as surrogate marker for long-term clinical outcome, while aspartate aminotransferase (AST) is associated with disease progression as well. The aim of this study was to compare long-term outcome between subgroups of AST and ALP after 1 year of ursodeoxycholic acid (UDCA) initiation based on PARIS-II cut-offs (1.5x upper limit of normal [ULN]) among people with PBC. **Methods:** The retrospective Dutch PBC Cohort Study includes every identifiable patient with PBC from 1990 up to last data collection (2019-2023) from all 71 hospitals in the Netherlands. Patients were included in case of >1 year follow-up after start of UDCA and without auto-immune hepatitis, second-line therapy or immunosuppressants. Where feasible, laboratory values were imputed using joint model multiple imputation. Kaplan-Meier curves were constructed to analyze liver-transplant (LT)-free survival and liver disease progression (decompensation, LT, or liver-related death). **Results:** In total, 3139 patients were included. At the start of UDCA, median age was 58.0 years (IQR 49.7–67.2), 2745 (87.4%) were female and 203 (6.5%) had cirrhosis. At 1 year UDCA, median ALP was 1.2xULN (IQR 0.9-1.7), median AST was 0.9xULN (IQR 0.6-1.2) and median total bilirubin was 0.5xULN (IQR 0.3-0.7). During a median follow-up of 8.0 years (IQR 3.8–13.3), 295 patients developed decompensated cirrhosis, 78 patients underwent LT, and 584 patients died (152 [26%] liver-related). Overall, at 10 years the LT-free survival was 83.5% (95%CI 81.9-85.2) and the cumulative incidence of liver disease progression was 10.1% (95%CI 8.9-11.3). Among the 2029 patients with an ALP ≤1.5xULN, the 10y LT-free survival was 89.5% (95%CI 87.6-91.5), 84.5% (95%CI 80.1-89.0), and 56.6% (95%CI 45.8-70.0) in those with AST ≤1xULN (n=1501, 74.0%), AST 1-1.5xULN (n=431, 21.2%) and AST >1.5xULN (n=97, 4.8%), respectively (p<.001) (Fig. 1A). For liver disease progression the 10y cumulative incidence was 1.8% (95%CI 1.0-2.6), 7.4% (95% 4.0-10.6), and 32.7% (95% CI 20.6-44.8) in those with an AST ≤1xULN/1-1.5 xULN/ >1.5xULN (p<.001). In contrast, among the 2552 patients with AST ≤1.5xULN, the 10y LT-free survival was 88.3% (95%CI 85.8-90.9), 88.5% (95%CI 86.0-91.0), and 84.3% (95%CI 80.9-87.9) (p=0.239) in those with ALP ≤1 xULN (n=955, 37.4%), ALP 1-1.5 xULN (n=977, 38.3%) and ALP>1.5xULN (n=620, 24.3%) (Fig. 1B). The cumulative incidence of liver disease progression were 2.7% (95%CI 1.4-3.9), 3.2% (95%CI 1.9-4.5), and 6.0% (95%CI 3.8-8.2) in those with ALP ≤1/ 1-1.5/>1.5xULN (p<.001). Similar results were found in the subgroups without cirrhosis at baseline. **Conclusion:** During UDCA monotherapy, an AST level >1.5xULN is infrequent among those with low ALP levels (≤1.5xULN), but represents an unfavorable prognosis. In contrast, high ALP in people with low AST is more common, but has a more limited risk implication.

1265 | THE PROGNOSTIC IMPLICATIONS OF THE HEPATIC AMINOTRANSAMINASES DURING SECOND-LINE THERAPY FOR PRIMARY BILIARY CHOLANGITIS DIFFER: AST IS A STRONGER PREDICTOR

Gemma H.X. Weijsters[1] Vincenzo Ronca[2] Charlotte Hijzen[1] Antonio De Vincentis[3] Atsushi Tanaka[4] Christophe Corpechot[5] Palak Trivedi[6] Francesca Terracciani[7] Laura Cristoferi[8] Guilherme Cancado[9] Miki Scaravaglio[8] Nora Cazzagon[10] Nadir Abbas[6] Kathryn Olsen[6] Sergio Rodriguez-Tajes[11] Adrielly Martins[12] Francesca Colapietro[2] Maria Carlota Londono[11] Nikolaos Gatselis[13] Vasiliki Lygoura[13] Elina Lytvyak[14] Aldo Montano-Loza[14] Alessio Gerussi[15] Vincenza Calvaruso[16] Leandro Sierra[17] Romelia Barba[17] Alan Bonder[17] Alejandra Villamil[18] Xavier Verhelst[19] Cynthia Levy[20] Henriette Ytting[21] Raffaella Vigano[22] Mauro Viganò[23] Ana Lleo[2] Pietro Invernizzi[15] Umberto Vespasiani-Gentilucci[3] Yu Jun Wong[24] Gideon Hirschfield[25] Marco Carbone[26] Bettina Hansen[27] Adriaan Van der Meer[1], [1]Erasmus University Medical Center, [2]Humanitas University Milan, IRCCS Humanitas Research Hospital, [3]University Campus Bio-Medico of Rome, [4]Teikyo University School of Medicine, [5]Saint-Antoine Hospital, [6]Birmingham Biomedical Research Centre, University Hospitals Birmingham NHS Foundation Trust, [7]Internal Medicine and Hepatology, University Campus Bio-Medico of Rome, [8]University of Milano-Bicocca, [9]Hospital das Clínicas da Universidade Federal de Minas Gerais, Belo Horizonte, Minas Gerai, [10]University of Padua, [11]Hospital Clinic, [12]Schiff Center for Liver Diseases, University of Miami Miller School of Medicine, [13]National Expertise Center of Greece in Autoimmune Liver Diseases, [14]University of Alberta, Edmonton, [15]Center for Autoimmune Liver Diseases, University of Milano-Bicocca, [16]University of Palermo, [17]Beth Israel Deaconess Medical Center, Harvard Medical School, [18]Hospital Italiano de Buenos Aires, [19]Ghent University Hospital, [20]Schiff Center for Liver Diseases, University of Miami Miller School of Medicine, [21]Faculty of Health Sciences, University of Copenhagen, [22]ASST Grande Ospedale Metropolitano Niguarda, Milan, [23]ASST Papa Giovanni XXIII, Bergamo, [24]Changi General Hospital, [25]Toronto General Hospital, [26]ASST Grande Ospedale Metropolitano Niguarda, University of Milano-Bicocca, [27]Erasmus MC Rotterdam

Background: Aspartate aminotransferase (AST) and alanine aminotransferase (ALT) are associated with clinical outcomes during ursodeoxycholic acid therapy. The second-line treatment (SLT) options for primary biliary cholangitis (PBC) have shown different biochemical response patterns with respect to the hepatic transaminases. We aimed to assess the association between AST and ALT after one year of SLT with clinical outcomes in people with PBC. **Methods:** We performed an international, retrospective cohort study within the Global PBC database, including 20 centres from 12 countries in Europe, Asia, North America and South America, among patients with PBC treated with either obeticholic acid (OCA) or fibrates. Patients were excluded in case of <1 year of follow-up after the start of SLT or in case of overlap with auto-immune hepatitis. Cumulative liver-transplant (LT)-free survival was assessed with Kaplan-Meier analyses. Cox regression models were used to study the association between AST and ALT with LT-free survival. Continuous variables were fitted as restricted cubic splines in case of non-linearity. **Results:** In total, 1422 patients were included. OCA was started in 816 (57%) patients, and fibrates in 614 (43%) patients. Median age at start of SLT was 57 years (IQR 50-65), 1268 (89%) were female and 225 (25%) had cirrhosis. During a median follow-up of 36 months (IQR 24.0, 60.0), 64 (4.5%) individuals died and 22 (1.5%) underwent LT. At baseline, median AST was 1.13xULN (IQR 0.83-1.67) and median ALT was 1.08 xULN (IQR 0.73-1.73). After 1 year of SLT, these were 0.93 (IQR 0.73-1.29) and 0.79 (IQR 0.54-1.15), respectively. Median percentual change for ALT and AST after 1 year were -21.7% (IQR -45.4; 0.0%) and -11.1% (IQR -33.9; 8.2%), respectively; -28.6 (IQR -49.1; -6.3) and -18.4% (IQR -38.8; 0.0) for OCA and -14.9% (IQR -38.8; 10.0) and -3.8% (IQR -23.3; 14.4) for fibrates. Normalization of AST occurred in 285 (69.9%) of patients receiving OCA and 178 (48.1%) of patients receiving fibrates, which was 396 (69.7%) and 313 (65.5%) for ALT, respectively. OCA was associated with higher odds of normalization of AST (aOR 6.6, 95%CI 3.6-12.8) and ALT (aOR 3.7, 95%CI 2.1-6.5) ($p<0.001$). Patients with an AST $>1.5\times$ULN after 1 year of SLT had a 10 year LT-free survival of 74%, compared to 90% in those with AST $\leq 1.5\times$ULN ($p<0.001$). In contrast, the 10 year LT-free survival was 84.3% for ALT >1.5xULN and 85.1% for ALT ≤ 1.5x ULN ($p=0.03$). While AST showed a log-linear relationship with the risk for LT or death, this relation was non-linear for ALT. In univariable analysis, AST showed a stronger association with the risk of LT or death than ALT (Figure). **Conclusion:** In this large international cohort of patients with PBC treated with SLT, the decline in AST and ALT differed for OCA and fibrates. Both AST and ALT at one year of SLT were associated with risk of LT or death, but AST appeared to be a stronger predictor of outcome.

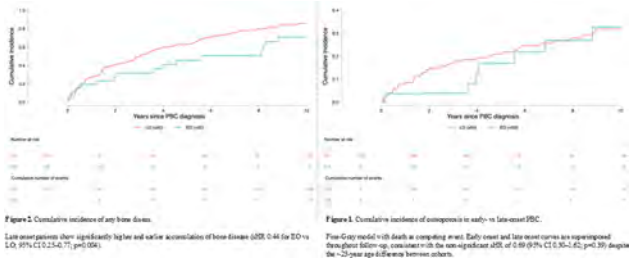
1266 | RISK-FACTORS AND INCIDENCE OF BONE DISEASE IN EARLY- VS. LATE-ONSET PRIMARY BILIARY CHOLANGITIS: A PROPENSITY SCORE–WEIGHTED RETROSPECTIVE COHORT STUDY



Leandro Sierra[1] Hussam Kawas[2] Qijun Yang[2] Sara Valencia[3] Rachel McNulty[2] Juan Armijos[2] John McMichael[2] Mohamad Alabbas[2] Li Tang[2] Kaylan Bhamidimarri[2] Bobby Zervos[2] Omar Sims[1] Dian Chiang[2], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic, [3]Department of Internal Medicine, University of Arizona, Tucson, AZ, USA

Background: Primary biliary cholangitis (PBC) carries substantial bone disease risk, but available evidence derives almost exclusively from postmenopausal women. The phenotype and risk-factor profile of bone disease in patients diagnosed before age 50 (early-onset PBC) remains poorly characterized. We aimed to compare cumulative incidence of osteoporosis and DEXA screening between early-onset and late-onset PBC, and to determine whether risk-factor profiles for osteoporosis differ between strata. **Methods:** Retrospective cohort study of PBC patients (2000–2024) from the Cleveland Clinic Ohio and Florida campuses. Cohort were classified based on age at PBC diagnosis: early-onset (< 50 years)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

vs late-onset (≥50 years). Primary outcome was time to first confirmed osteoporosis (T-score ≤ −2.5). Secondary outcomes were osteopenia/osteoporosis (T-score ≤ −1.0) and time to first DEXA. Fine-Gray subdistribution hazard models treated death as a competing risk. Inverse probability of treatment weighting (IPTW) balanced demographics (sex, calendar year of diagnosis, race, ethnicity, BMI). Within-stratum Fine–Gray models evaluated predictors; pooled cohort risk factor interaction models assessed risk profiles. **Results:** Of 678 PBC patients, 630 met inclusion criteria (110 early-onset [17.5%], 520 late-onset [82.5%]); 202 had ≥1 eligible DEXA. Early-onset patients had higher baseline alkaline phosphatase (median 192.5 vs 158 U/L, p = 0.07). Early-onset patients were less likely to undergo DEXA (24.5% vs 33.7%, p = 0.05) and significantly less likely to be screened within 2 years of diagnosis (10.0% vs 18.7%, p = 0.029), when compared to late-onset. In IPTW-weighted analyses, early-onset and late-onset had similar osteoporosis incidence (sHR 0.69, 95% CI 0.30–1.62; p = 0.39) despite the 23-year age difference. Early-onset had significantly lower incidence of any bone disease (sHR 0.44, 95% CI 0.25–0.77; p = 0.004) (**Figure**) and a 38% lower hazard of undergoing first DEXA (sHR 0.62, 95% CI 0.38–1.00; p = 0.049), when compared to late-onset. In stratum-specific univariable analyses, the effect of female sex on osteoporosis risk differed significantly between cohorts (p-interaction = 0.029). Baseline ALP, albumin, bilirubin, BMI, autoimmune comorbidities, UDCA exposure, vitamin D and calcium supplementation, smoking, and hormone therapy showed no significant differential effect (all p-interaction > 0.05). **Conclusion:** Patients with early-onset PBC are at risk of osteoporosis at rates comparable to those diagnosed later, while remaining significantly under-screened with DEXA. These findings support bone health screening in young PBC patients.

1267 | UTILITY OF ANTI-SP100 AND ANTI-GP210 ANTIBODY TEST IN PATIENTS WITH UNEXPLAINED CHOLESTATIC LIVER DISEASES

Jay Patel[1] Saurabh Agrawal[1] Arvind Murali[1],
[1]Orlando Health

Background: Anti-mitochondrial antibody (AMA) detection remains the cornerstone of diagnosis of PBC. Around 5 to 10% of patients with PBC are found to be AMA-negative, leading to diagnostic uncertainty, need for liver biopsy, and delay in treatment. Anti-SP100 and anti-GP210 antibodies have high specificity for PBC and provide a diagnostic alternative in AMA-negative patients. However, testing for anti-SP100 and anti-GP210 antibodies does not appear to be routinely performed. **Methods:** We identified all patients with cholestatic liver diseases referred to the Liver Center at Orlando Health, a large tertiary care center, from April 2023 to April 2026. Patients with cholestatic hepatitis from congestive hepatopathy, drug-induced liver injury, biliary obstruction, and infiltrative conditions were excluded. All patients received evaluation for PBC (AMA, if AMA negative then anti-SP100, anti-GP210 antibodies) and PSC (MRI-MRCP). Liver biopsy was performed whenever deemed necessary. We have reported data on demographics, biochemistry, and response to therapy in AMA negative PBC patients with positive anti-SP100 and anti-GP210 antibodies. **Results:** A total of 123 patients with cholestatic liver diseases were identified. Of these, 68 patients were diagnosed with PBC based on AMA-positivity, 27 patients had PSC, and 28 patients had neither AMA positivity nor evidence of PSC. Among the 28 patients with unexplained cholestatic disease, 5 (18%) had either anti-SP100 (n = 3) or anti-GP210 antibodies (n = 2) suggestive of PBC. Another two of the 28 patients had PBC diagnosed with liver biopsy, and these two patients did not have AMA, anti-SP100, or anti-GP210 antibodies. Thus, among all patients diagnosed with PBC (n = 75), AMA negative PBC was noted in 7 (9.3%) patients, and 5 (71%) of these 7 patients had anti-SP 100 or anti-GP 210 antibodies. Mean age of the five patients was 52, and four were females. The average peak ALP was 261U/L (Table 1). Only one of the five patients had liver biopsy, and findings were typical of PBC. All five patients were started on ursodiol with significant improvement in alkaline phosphatase noted in 4 out of the 5 patients thus far. **Conclusion:** AMA-negative cholestatic liver disease presents a diagnostic dilemma, with liver biopsy traditionally being utilized to clarify underlying disease pathology. Anti-SP100 and anti-GP210 present a diagnostic opportunity to identify PBC in AMA-negative patients and preclude the use of liver

biopsy which is invasive and has its inherent risks. In our study, anti-GP210 and anti-SP100 antibody helped provide a diagnosis without the need for a liver biopsy in 71% of patients with AMA negative PBC and 18% of all patients with unexplained cholestatic liver disease. We recommend that clinicians incorporate anti-SP100 and anti-GP210 antibodies routinely into their diagnostic algorithm for evaluating AMA-negative cholestatic liver disease prior to proceeding with liver biopsy.

Table 1: Characteristics of patients with AMA negative, anti-SP100 or anti-GP210 positive patients with PBC.

Patient	Age	Gender	Peak Alkaline Phosphatase (U/L)	Anti-SP100 or Anti-GP210 positivity	Liver Biopsy	Fibrosis stage	Response to Ursodiol
1	44	Female	491	Anti-GP210	Yes	F2	Yes
2	32	Female	347	Anti-SP100	No	F4	Yes
3	59	Female	225	Anti-GP210	No	F0-F1	No
4	66	Male	201	Anti-SP100	No	F4	Yes
5	59	Female	118	Anti-SP100	No	F0-F1	Yes

1268 | PRIMARY SCLEROSING CHOLANGITIS AND DELIVERY HOSPITALIZATION OUTCOMES IN THE UNITED STATES: A CONTEMPORARY NATIONAL INPATIENT SAMPLE ANALYSIS

Anas Al Mardini[1] Harika Dadigiri[1] Sabah Kulsum[1] Sowmya Mainog[2] Edward Barbarito[3], [1]NYMC, [2]NYMC-St Clare/St Mary hospital, [3]St Clare hospital

Background: Primary sclerosing cholangitis (PSC) affects reproductive aged individuals and is frequently associated with inflammatory bowel disease (IBD), yet contemporary U.S. data on delivery hospitalization outcomes are limited. We evaluated the prevalence, delivery outcomes, and resource utilization associated with PSC among U.S. delivery hospitalizations **Methods:** We performed a retrospective cross sectional analysis of delivery hospitalizations among patients aged 12-55 years in the 2020-2022 National Inpatient Sample. PSC and IBD were identified using ICD-10-CM codes. Outcomes included severe maternal morbidity (SMM), cesarean delivery, length of stay (LOS), and total hospital charges. Analyses incorporated NIS discharge weights, strata, and hospital clusters. **Results:** Among 10,433,032 weighted delivery hospitalizations, 155 involved PSC, corresponding to 1.49 PSC delivery hospitalizations per 100,000 deliveries. Coexisting IBD was present in 58.1% of PSC delivery hospitalizations. No SMM events were observed among PSC delivery hospitalizations. Cesarean delivery occurred in 35.5% of PSC versus 32.3% of non-PSC delivery hospitalizations; after adjustment for age and IBD, PSC was not significantly associated with cesarean delivery (aOR 0.86, 95% CI 0.42-1.80; P = 0.698). Mean LOS was 3.03 days for PSC versus 2.55 days for non-PSC hospitalizations. Mean total hospital charges were $27,348 versus $24,925, respectively. **Conclusion:** PSC was exceedingly rare among U.S. delivery hospitalizations from 2020-2022, with most PSC delivery hospitalizations involving coexisting IBD. In this national sample, PSC was not associated with increased cesarean delivery, and no SMM events were observed among PSC delivery hospitalizations. Larger longitudinal datasets are needed to clarify rare maternal complications and postpartum outcomes in pregnant patients with PSC.

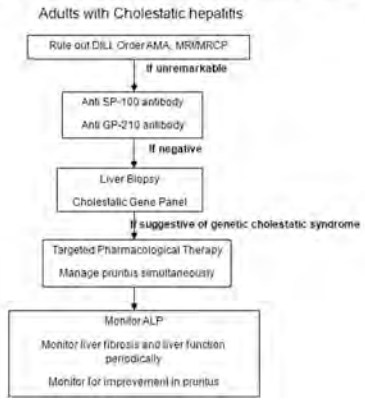
1269 | UTILITY OF CHOLESTATIC GENE PANEL TEST IN ADULTS WITH UNEXPLAINED CHOLESTATIC LIVER DISEASES: PROPOSED DIAGNOSTIC ALGORITHM

Arvind Murali[1] Saurabh Agrawal[1], [1]Orlando Health

Background: The gastroenterologist and hepatologist regularly provide care for a substantial cohort of adult patients with cholestatic liver diseases. A subset of these patients remains undiagnosed despite exhaustive serological, histopathological and imaging evaluations. Genetic cholestatic gene testing panel has been recommended for the evaluation of adult patients with cholestatic liver disease of unexplained etiology although there are currently no formal AASLD guidelines in this subject. We report our experience on the utility of cholestatic gene panel analysis in the diagnosis and management of adults with unexplained cholestatic liver diseases. **Methods:** We identified all patients with cholestatic liver disease referred to the liver center at Orlando Health, from April 2023 to April 2026. All patients received an exhaustive work up including for PBC (AMA, if AMA negative then anti-SP 100, anti-GP 210) and PSC (MRI-MRCP). Genetic cholestatic gene panel analysis was performed in patients with unexplained cholestatic liver disease. We collected and reported data on patient demography, biochemistry, genetic mutation identified on cholestatic gene panel test, treatment regimen, and response to treatment. Prevention genetics was used for cholestatic gene analysis. **Results:** A total of 123 patients with cholestatic hepatitis were identified. Of the 123 patients, 75 had PBC; 27 had PSC; and 21 had unexplained cholestatic liver disease on whom

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient



© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

cholestatic gene testing was performed. Of the 21 patients, 9 (43%) had a mutation implicated in the development of genetic cholestatic syndrome. Age ranged from 19 to 72 years, and 7 (78%) were females. Seven of 9 patients had liver biopsy without evidence of PBC, PSC, or infiltrative liver disease. One patient had homozygous ABCB4 variants, two had heterozygous ABCB4 variants, two had heterozygous Myo5B variants, and one patient each had heterozygous ATP8B1 variant, heterozygous ABCB11 variant, heterozygous Notch 2 variant, and heterozygous CFTR variant. All patients had pruritus, elevated alkaline phosphatase (ALP), and raised bile acids. All patients were initiated on ursodiol. In 5 (56%) patients, ALP improved to < 1.5*ULN, 3 (33%) had partial response, and one had no improvement. Improvement in pruritus and bile acids was seen in 4 (44%) of the 9 patients on ursodiol, while 5 (56%) had no improvement and started on alternate therapies. **Conclusion:** Personalized medicine has arrived as a defining paradigm in modern hepatology. Genetic cholestatic gene testing helps provide diagnosis in adult patients with unexplained cholestatic liver diseases. We thus recommend that adult patients with cholestatic liver diseases, in whom extensive evaluation has not revealed a diagnosis be tested for gene cholestatic syndromes such as PFIC (Progressive Familial Intrahepatic Cholestasis). We have provided simplified algorithm for evaluation of adult patients with cholestatic liver diseases.

Table 1 Characteristics of patients with genetic cholestatic disease

	Age	Sex	Peak ALP	Peak bile acids	Fibrosis stage	Liver biopsy performed	Genetic mutation identified	ALP after initiation of Ursodiol
1	26	M	500	263	F4	No	ABCB4 Homozygous	211
2	36	F	400	125	F1	Yes	ABCB4 Heterozygous	118
3	24	F	327	28	F0-F1	No	ABCB4 Heterozygous	183
4	41	F	503	261	F0	Yes	ATP8B1 Homozygous	129
5	19	F	329	N/A	F0	Yes	NOTCH2 Heterozygous	76
6	72	F	250	19	F3	Yes	CFTR Heterozygous	144
7	70	F	357	28	F1	Yes	Myo5B Heterozygous	190
8	30	M	190	22	F0	Yes	Myo5B heterozygous	138
9	42	F	897	193	F2	Yes	ABCB11 heterozygous	801

1270 | HIGH METABOLIC COMORBIDITY BURDEN IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS UNDERGOING LIVER TRANSPLANTATION

Dareen Chuy[1] Leandro Sierra[1] Sarah Alharfi[1] John McMichael[1] Dian Jung Chiang[1], [1]Cleveland Clinic Foundation

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease increasingly recognized to coexist with metabolic comorbidities. However, the characterization of this overlap and its effect on PBC outcomes, particularly in the context of liver transplantation, remain as areas of emerging research. We aimed to assess the prevalence of metabolic comorbidities in this population and their impact on post-transplant outcomes. **Methods:** Single-center retrospective cohort of 103 adult patients undergoing liver transplantation for PBC at the Cleveland Clinic, with a median follow up of 5.0 years. Metabolic comorbidities including overweight, hypertension, dyslipidemia, and diabetes were analyzed. The primary composite endpoint was re-transplantation or all-cause mortality. Secondary endpoints were re-transplantation, all-cause mortality, and PBC recurrence on biopsy (binary) analyzed as a competing-risks model with death as the competing event. Time-to-event analyses used Cox proportional hazards regression (composite endpoint, mortality) and Fine-Gray sub-distribution hazards (re-transplantation). PBC recurrence was modeled as a binary outcome with univariable logistic regression. Continuous pre-transplant HbA1c was analyzed in the subset with available values (n = 35) using Firth penalized logistic regression for PBC recurrence given sparse events. All analyses are univariable given the limited number of outcome events; no multivariable adjustment was performed. **Results:** The cohort was characterized by a high burden of metabolic comorbidities, with 63.1% having at least two of four components of metabolic syndrome. 24 patients (23.3%) reached the composite endpoint, 8 (7.8%) underwent re-transplantation, 20 (19.4%) died, and 18 (17.5%) developed PBC recurrence on biopsy. In univariable analyses, no metabolic comorbidity was significantly associated with the composite endpoint, re-transplantation, all-cause mortality, or biopsy-proven PBC recurrence. **Conclusion:** There is a high burden of metabolic comorbidities in PBC patients undergoing liver transplantation. No significant association was found between the presence of these comorbidities and post-transplant outcomes in this cohort. Our results nevertheless highlight the importance of a multidisciplinary approach in the management of these patients.

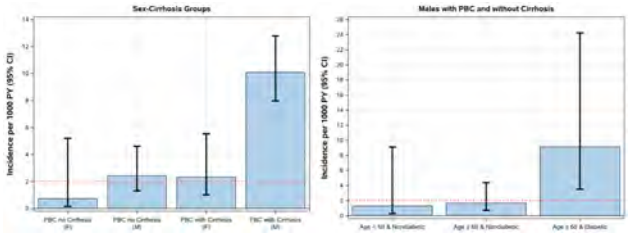
Table: Prevalence of metabolic comorbidities in PBC patients undergoing liver transplantation (N = 103)

Component	n (%)
BMI ≥ 25 kg/m²	61 (59.2)
Hypertension (coded diagnosis)	65 (63.1)
Dyslipidemia (coded diagnosis)	56 (54.4)
Diabetes Ever (coded diagnosis or HbA1c ≥ 6.5%)	35 (34.0)
Pre-Transplant Diabetes	15 (14.6)
New-Onset Diabetes After Transplant (NODAT)	20 (19.4)
Metabolic Burden Score, distribution	
0 components	6 (5.8)
1 component	32 (31.1)
2 components	27 (26.2)
3 components	21 (20.4)
4 components	17 (16.5)
High Burden (≥ 2 components)	65 (63.1)
Pre-Transplant HbA1c Available	35 (34.0)
Median (IQR), %	5.10 (4.50–5.95)
Post-Transplant HbA1c Available	30 (29.1)
Median (IQR), %	5.75 (4.93–6.00)



HbA1c values were available for a minority of patients in the chart, limiting power for HbA1c-based analyses.

1271 | DO MALE PATIENTS WITH PRIMARY BILIARY CHOLANGITIS WITHOUT CIRRHOSIS REQUIRE SURVEILLANCE FOR HEPATOCELLULAR CARCINOMA? RESULTS FROM A NATIONAL COHORT

Binu John[1] Samuel Soon[2] Bassam Dahman[3] Rithwick Terala[4] Kaley Levitt[5] Dustin Bastaich[2] Cynthia Levy[6] Amit Singal[7], [1]University of Miami and Miami VA, [2]Virginia Commonwealth University, [3]Virginia Conmonwealth University, [4]Jackson Memorial Hospital, [5]Florida International University, [6]University of Miami, [7]University of Texas Southwestern

Background: The AASLD recommends hepatocellular carcinoma (HCC) surveillance in male patients with primary biliary cholangitis (PBC) without cirrhosis, although there is limited data to support this practice. We examined HCC incidence rates in a large cohort of patients with PBC to identify subgroups without cirrhosis in whom annual HCC incidence rates exceed the cost-effective threshold of 0.2% per year (2 per 1000 person-years). **Methods:** This was a retrospective cohort of patients with PBC from the Veterans Health Administration recruited between January 2011 and December 2022 with follow up until December 2025. Patients with an overlap syndrome, hepatitis B or C, liver transplantation prior to HCC, or inadequate follow-up were excluded. The primary exposure was a four-level classification based on sex and cirrhosis status, and the outcome of interest was HCC. Patients were followed from the date of cirrhosis diagnosis or from the date of PBC diagnosis (in those without cirrhosis) up to the onset of HCC, and censored at liver transplantation, death, or the most recent date of follow up. Incidence rates (IR) in age and diabetic subgroups were modeled using Poisson regression. **Results:** We identified 1,788 patients with PBC, of whom 683 (28.2%) did not have cirrhosis during from time of enrolment until last follow up and evaluated in non-cirrhosis cohort, while 1105 individuals who had cirrhosis either at presentation or during the course of follow up, and were included and analyzed in the cirrhosis cohort. During a follow-up of 13,766.4 person-years (PY), 81 patients developed HCC. On multivariable analysis, predictors of HCC included male sex, presence of cirrhosis, older age, and harmful alcohol use, but not UDCA response. Annual HCC rates per 1000 PY were 0.74 (95%CI 0.10-4.66) in females without cirrhosis, 2.44 (95%CI 1.26-4.66) in males without cirrhosis, 2.32 (95%CI 0.97-5.58) in females with cirrhosis, and 10.08 (95%CI 7.92-12.83) among males with cirrhosis. Annual HCC incidences rates with non-cirrhotic PBC were 7.21(95%CI 2.71-19.21) in males with diabetes and 9.13 (95%CI 3.43-24.32) in older (>60 years) males with diabetes. **Conclusion:** HCC rates are elevated above the cost-effectiveness threshold for HCC surveillance in males with PBC without cirrhosis, but not among females without cirrhosis. HCC rates in non-cirrhotic males were as high as that in females with PBC cirrhosis, and older males and patients with diabetes had an even higher risk. Our data supports the AASLD guidance recommending HCC surveillance in males with non-cirrhotic PBC.

1272 | NON-TNF VERSUS ANTI-TNF BIOLOGIC INITIATION AND CODED CHOLANGITIS IN PSC-IBD

Nourhan Saleh[1] EzzElDien A. Ibrahim[1] Bjorn Rodriguez[1] Mahmoud Majed Mansour[1] Darian Fard[1] Khulood Ahmed[1], [1]University of Missouri

Background: Adults with primary sclerosing cholangitis and inflammatory bowel disease (PSC-IBD) often require biologic therapy while remaining at risk for recurrent cholangitis. Whether initial biologic class is associated with subsequent cholangitis in real-world practice is uncertain. **Methods:** We used TriNetX Global Collaborative to emulate an active-comparator new-user cohort. Adults with PSC-IBD initiating vedolizumab or ustekinumab after 365 days without advanced IBD therapy were compared with anti-TNF initiators. Follow-up began at first biologic initiation. We matched 1:1 on 24 demographic, liver, IBD, medication, utilization, and laboratory covariates. The primary outcome was exact diagnosis-coded cholangitis over days 1-1095. Sensitivities included analyses excluding earlier cholangitis, a shorter 180-day biologic-free baseline, serious infection, transplant/status, and attempted negative controls. **Results:** The 365-day biologic-free baseline identified 476 non-TNF and 454 anti-TNF initiators; 280 pairs were matched. Inclusive events were 67/280 versus 83/280 (RR 0.81, 95% CI 0.61-1.06; HR 0.81, 95% CI 0.58-1.11). After excluding patients with earlier cholangitis, events were 24/194 versus 39/192 (RR 0.61, 95% CI 0.38-0.97; HR 0.62, 95% CI 0.37-1.03). The 180-day biologic-free baseline sensitivity matched 381 pairs; among patients without earlier cholangitis, events were 35/269 versus 57/262 (RR 0.60, 95% CI 0.41-0.88; HR 0.60, 95% CI 0.40-0.92). Additional outcome checks showed near-null serious infection, higher liver transplant/status coding in non-TNF initiators, and small or suppressed negative-control cells. **Conclusion:** Non-TNF initiation was associated with lower subsequent coded cholangitis in analyses focused on patients without earlier cholangitis, with similar direction across 365- and 180-day biologic-free baseline designs. The transplant/status imbalance keeps residual PSC severity and specialty-care channeling in view, so the findings should not be read as proof that biologic class modifies PSC progression.

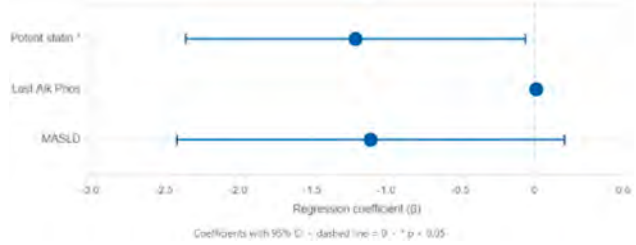
1273 | STATIN USE AND LIVER STIFFNESS PROGRESSION IN PRIMARY BILIARY CHOLANGITIS: A RETROSPECTIVE COHORT STUDY



Alexander Zhao[1] Hanna Abuhay[1] Russell Rosenblatt[2], [1]NewYork-Presbyterian Hospital/Weill Cornell, [2]Weill Cornell Medicine

Background: Primary biliary cholangitis (PBC) is a chronic, cholestatic liver disease characterized by immune-mediated destruction of small intrahepatic bile ducts that can lead to fibrosis and cirrhosis. Emerging data suggest statins may have antifibrotic properties in other chronic liver diseases, but evidence in PBC is limited. This is a critical question as most patients with PBC have hyperlipidemia (HL) because of the disease. We evaluated the association between statin use and changes in liver stiffness (LS) measured by transient elastography in patients with PBC. **Methods:** This was a single center

retrospective cohort study. Adult patients with PBC, confirmed by AASLD diagnostic criteria, were included if they had at least two separate transient elastography tests that were one year apart. Our primary outcome was LS change, which was the difference between the last LS measurement from the first. Subgroup analysis was performed to analyze potent statins vs either non-potent or no statin use. We also assessed the prevalence of metabolic dysfunction-associated steatotic liver disease (MASLD), as assessed by an elevated CAP score. We performed multivariable linear regression models controlling for the last alkaline phosphatase level (as a means to assess disease control) as well as MASLD. **Results:** There were 100 patients with PBC who were included (86% female, 67% with HL). All patients were on ursodeoxycholic acid, and 10% were on fenofibrate, 10% on seladelpar, and 9% on elafibranor. More than half of patients (54%) were taking a statin - 29 atorvastatin, 18 rosuvastatin, 4 simvastatin, 3 pravastatin. Median baseline LS was 5.4 kPa, with no significant difference between statin users and non-users (5.1 kPa vs. 5.7 kPa; $p = 0.33$). Median change in liver stiffness was 0.0 kPa overall, with no significant difference between groups ($p = 0.12$): statin users decreased by -0.15 kPa (IQR -1.1 to 0.3) while non-statin users increased by +0.55 kPa (IQR -0.7 to 1.5). Additionally, 60% met CAP criteria for hepatic steatosis, supporting inclusion of MASLD as a covariate. In multivariable linear regression, while controlling for the last alkaline phosphatase level and comorbid MASLD, statin use trended toward reduced liver stiffness (coefficient -1.11; 95% CI -2.25 to 0.03, $p = 0.056$), while potent statin use was associated with a significant reduction (-1.21; 95% CI -2.35 to -0.06, $p = 0.04$) (Fig. 1). **Conclusion:** In this PBC cohort, potent statin use was independently associated with reduced LS, with a similar trend for any statin use. These findings suggest a potential antifibrotic benefit of statins in PBC, warranting prospective studies to assess effects on long-term outcomes.

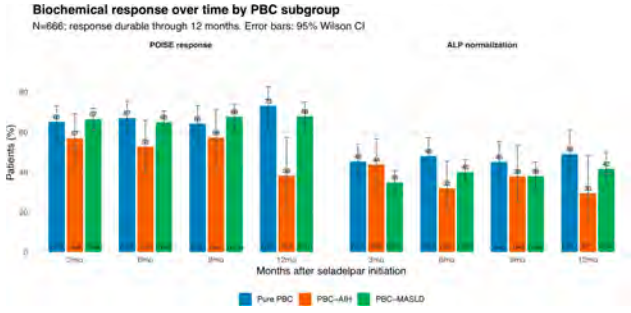
1274 | REAL-WORLD EFFECTIVENESS AND SAFETY OF SELADELPAR IN PRIMARY BILIARY CHOLANGITIS WITH AIH VARIANT SYNDROME AND MASLD: A NATIONWIDE ELECTRONIC HEALTH RECORD STUDY



Adrielly Martins[1] Cynthia Levy[2], [1]University of Miami, [2]Division of Digestive and Liver Diseases, University of Miami

Background: Seladelpar, a selective peroxisome proliferator-activated receptor delta (PPAR-δ) agonist, received United States Food and Drug Administration approval in August 2024 as second-line therapy for primary biliary cholangitis (PBC). However, patients with autoimmune hepatitis (AIH) variant syndrome and those with metabolic dysfunction-associated steatotic liver disease (MASLD) were either excluded or underrepresented in pivotal triais, leaving seladelpar's effectiveness in these subpopulations undefined. Real-world durability of response beyond 6 months is also unknown. We evaluated biochemical response through 12 months and safety across PBC subgroups. **Methods:** This retrospective cohort study used Epic Cosmos, a federated electronic health record platform. Adults with PBC prescribed seladelpar after approval were classified into mutually exclusive subgroups: PBC, PBC-AIH variant syndrome, and PBC-MASLD. AIH variant was identified by a validated administrative algorithm, MASLD by hepatic steatosis or metabolic syndrome with cardiometabolic risk factors, and cirrhosis by diagnostic codes and noninvasive criteria. The primary outcome was POISE biochemical response (alkaline phosphatase [ALP] $< 1.67\times$ULN, $\geq 15\%$ ALP reduction or normalization, and total bilirubin ≤ 1.2 mg/dL) at 6 months; secondary outcomes included POISE response at 3, 9, and 12 months, ALP normalization, and hepatotoxicity (ALT > 3 or $> 5\times$ULN), using laboratory-specific ULNs. Subgroups were compared by chi-square, and response was assessed by cirrhosis status. **Results:** Among 666 patients (209 PBC, 76 PBC-AIH, 381 PBC-MASLD; mean age 63.9 years, 89.8% female, 35.6% cirrhotic), POISE response at the primary 6-month endpoint was 64.2% ($n = 425$) and was durable across follow-up (65.1%, 65.6%, and 66.1% at 3, 9, and 12 months; Figure). Response did not differ between PBC-MASLD and PBC at any timepoint (6-month 65.2% vs 67.3%; $p = 0.70$), indicating MASLD did not attenuate response. Response in PBC-AIH was numerically lower throughout (6-month 52.9%; $p = 0.08$). Cirrhotic patients had significantly lower response than non-cirrhotic at every timepoint (6-month 54.8% vs 69.6%; $p = 0.002$), despite comparable baseline ALP (1.6 vs 1.6×ULN; $p = 0.72$). ALT elevations were infrequent and stable ($> 3\times$ULN $\leq 4.0\%$ at

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

all timepoints), with no progressive hepatotoxicity. **Conclusion:** In this nationwide real-world study, biochemical response to seladelpar was durable through 12 months and consistent with phase 3 trials. Coexisting MASLD did not attenuate response, whereas PBC-AIH variant syndrome and cirrhosis were associated with numerically and significantly lower response, respectively; the cirrhosis-associated difference was not explained by baseline biochemistry. Seladelpar demonstrated a stable hepatic safety profile across diverse PBC populations, supporting its real-world effectiveness in subgroups underrepresented in clinical trials.

1275 | RISK OF COMBINED HORMONAL CONTRACEPTIVES IN AUTOIMMUNE HEPATITIS: A RETROSPECTIVE COHORT STUDY

Isabella Hendrickson[1] Sahil Sethi[1] Jaime Perez[2] Sharon Danielson[2] Naemat Sandhu[1] Seth Sclair[1] Resham Ramkissoon[1], [1]University Hospitals Cleveland Medical Center, [2]University Hospitals Center for Clinical Research

Background: Autoimmune Hepatitis (AIH) is a chronic inflammatory liver disease driven by T-cell-mediated destruction of hepatic autoantigens. Defective regulatory T-cell function permits self-perpetuating hepatic inflammation, which can progress to cirrhosis and end-stage liver disease if untreated. Risk factors include female sex, genetic predisposition, concurrent autoimmune diseases, and environmental triggers. While exact mechanisms remain elusive, estrogen may influence AIH pathogenesis by promoting B-cell hyperactivity and autoantibody production (e.g., anti-SMA, anti-LKM1), inducing T-cell hypoactivity that disrupts T-cell/B-cell homeostasis, and interacting with X-linked genetic factors. Our study aims to examine the association between estrogen-containing combined hormonal contraceptives (CHC) and the risk of developing AIH. This could be informative in the management of these medications in patients with AIH. **Methods:** Data Source and Study Design Using a de-identified US health research network (TriNetX; 112 organizations; IRB-exempt; accessed April 27, 2026), we defined two adult female cohorts: (1) cases with ≥ 6 prescriptions for estrogen-containing contraceptives (estetrol, estradiol, or ethinyl estradiol), and (2) controls with no estrogen-containing medications, antineoplastic hormones, or gonadotropins. The primary outcome was occurrence of autoimmune hepatitis (ICD-10-CM K75.4) at least two months after the index event (contraceptive exposure or in-network gynecologic visit in the CHC and control groups, respectively). Statistical Analysis 1:1 propensity score matching was performed on demographics and comorbidities. Continuous variables were compared using independent t-tests, while categorical variables were analyzed using chi-square tests. Outcomes were evaluated using risk difference with 95% confidence intervals (CIs). All statistical tests were two-sided with a significance level of $\alpha = 0.05$. TriNetX rounds patient counts between 1 and 9 up to 10, which may impact estimates for rare outcomes. **Results:** After propensity score matching, 401,120 individuals were included. Risk of developing AIH was significantly higher in the CHC cohort compared to controls (0.058% vs. 0.045%; risk difference = 0.013%, 95% CI 0.0033%–0.0232%, p = 0.0079). **Conclusion:** Estrogen-containing combined hormonal contraceptive use is associated with a small but statistically significant increase in risk of developing autoimmune hepatitis. Further prospective studies are warranted to elucidate the underlying pathophysiologic mechanisms.

1276 | RELATIONSHIP BETWEEN UDCA TREATMENT RESPONSE AND CHANGE IN ALP AFTER 12 MONTHS OF THERAPY IMPACTS CLINICAL OUTCOMES AMONG PATIENTS WITH PRIMARY BILIARY CHOLANGITIS

Stuart Gordon[1] Amandeep Sahota[2] Trueman Wu[3] Sheri Trudeau[3] Christina Melkonian[3] Meng-Hua Tao[3] Mark Schmidt[4] Lora Rupp[1] Yihe Daida[5] Christopher Bowlus[6] Mei Lu[1], [1]Henry Ford Health System, [2]KPSC,

[3]Henry Ford Health, [4]KPNW, [5]KPHI, [6]University of California, Davis

Background: Ursodeoxycholic acid (UDCA) is the standard therapy for patients with primary biliary cholangitis (PBC); treatment response is typically defined by reduced alkaline phosphatase (ALP) after 12 months of treatment. Clinicians have noted that ALP levels may continue to increase over time, but the clinical impact of such increases is unknown. We used data from the US Fibrotic Liver Disease (FOLD) Consortium to evaluate ALP levels after 12 months of UDCA treatment and analyzed whether these levels were associated with liver transplantation (LT), all-cause mortality, and healthcare utilization. **Methods:** Patients from 6 FOLD sites were included if they: 1) received UDCA therapy for ≥ 6 months with gaps of < 3 months or treatment coverage $> 90\%$ for the first 12 months; and 2) had appropriate ALP testing at > 12 months. Inadequate UDCA treatment response (ITR) was defined by ALP measured at 9–14 months (levels $\geq 1.67\times$ULN or $< 15\%$ reduction from baseline). Rising ALP (ALP+) was defined as positive longitudinal slope (> 0) derived from subject-specific linear regression using available data for 1-6 years post-UDCA initiation. Generalized mixed spline regression was used to evaluate ALP trajectories across four groups defined by treatment response/ALP+ status. Wilcoxon tests for person-year outcomes and Cox time-to-event regression were used to evaluate their association with time to LT or death. **Results:** A total of 852 patients (6% Black; 10% AAPI; 11% male; 24% Hispanic) were included. At 12 months post-UDCA initiation, response categories were as follows: ITR/ALP+, 38 (5%); ITR, 436 (51%); ALP+, 140 (16%); adequate response, no ALP+ (full responders), 238 (29%). ALP+ was less common among ITR patients than responders (9% vs 25%, $p < 0.001$). ITR/ ALP+ patients were more likely to be men (21% vs 16% [ALP+] vs 9–12% in other groups) and demonstrated higher rates of hepatic decompensation within the first 12 months of UDCA therapy (21% vs 5–7% in other groups). We observed a significant interaction between ITR and ALP+ on longitudinal ALP trajectory ($p < 0.05$, Fig1a). ITR/ALP+ patients demonstrated persistently higher ALP, more frequent UDCA discontinuation, and higher rates of liver-related testing and hospitalization (all $p < 0.05$). No significant differences were observed among groups in rates of DILI, hypersensitivity reactions, or statin use. ALP+ was not associated with risk of LT/ death (aHR 1.16, 95%CI 0.63–2.02) among patients responding to UDCA, but significantly increased risk among patients with ITR (aHR 4.3, 95%CI 1.6–6.6; Fig 1b). **Conclusion:** ITR/ALP+ is associated with persistently elevated ALP, more healthcare utilization, and increased risk of liver transplantation or death. Consideration of longitudinal ALP trajectory may provide additional prognostic value beyond the standard 12-month assessment of UDCA response.

Background: Autoimmune hepatitis (AIH) accounts for 2–5% of liver transplant indications in Latin America. We aimed to identify prognostic factors associated with liver transplantation in a large Latin American AIH cohort. **Methods:** We analyzed data from 1,806 patients enrolled in the ALLATIN cohort, including demographic, clinical, laboratory, and histological variables. Univariable and multivariable Cox proportional hazards regression analyses were performed to identify predictors of liver transplantation. **Results:** Out of 1711 patients, 65 were submitted to liver transplant in a 6,6 years median follow-up. Patients with clinically significant portal hypertension had an approximately 2.2-fold higher risk of liver transplantation during follow-up (HR = 2.17; 95% CI: 1.04–4.55; p = 0.040). Higher albumin levels were associated with an approximately 52% reduction in transplantation risk (HR = 0.48; 95% CI: 0.35–0.66; p < 0.001), while higher platelet counts reduced the risk by approximately 24% for every increase of 50,000 platelets/mm³ (HR = 0.76; 95% CI: 0.61–0.93; p = 0.009). Insufficient biochemical response at 6 and 12 months was also associated with poorer transplantation-free survival; however, these variables were excluded from the final multivariable model due to the high proportion of missing data. **Conclusion:** Clinically significant portal hypertension, low albumin levels, and thrombocytopenia were independently associated with a higher risk of liver transplantation in Latin American patients with AIH.

1278 | ADHERENCE TO QUALITY INDICATORS IN PRIMARY SCLEROSING CHOLANGITIS AND INFLAMMATORY BOWEL DISEASE CARE

Megan van Niekerk[1] Caterina Prada[2] Mikesh Kansagra[3] Lily Wu[1] Laurence Vaitiekunas[2] Emma Davis[1] Michael Christmas[1] Lauren White[1] Sanchit Sharma[1] Richard Fernandes[3] Rohit Gupta[1], [1]Sunshine Coast University Hospital, [2]Gold Coast University Hospital, [3]Mater Research

Background: Primary sclerosing cholangitis (PSC) is a progressive cholestatic liver disease strongly associated with inflammatory bowel disease (IBD) and an elevated risk of malignancy. In the absence of effective disease-modifying therapies, optimal care depends on structured surveillance, disease monitoring and proactive symptom management. However, real-world adherence to guideline-recommended care in Australian practice remains poorly characterised. This study aimed to evaluate adherence to guideline-recommended quality indicators for patients with PSC and associated inflammatory bowel disease (PSC-IBD) across three tertiary centres in South East Queensland, Australia. **Methods:** We performed a retrospective cohort study of patients with PSC-IBD. Quality indicators were established through multidisciplinary stakeholder consensus involving hepatologists and IBD specialists. Adherence was assessed across five domains: colorectal dysplasia surveillance, hepatobiliary surveillance, disease monitoring, symptom assessment, and preventive care. **Results:** Eighty-nine patients were included across three tertiary centres. Adherence to colorectal dysplasia surveillance was as follows: annual colonoscopy in 84%,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

annual ileal pouchoscopy when indicated in 90%, and segmental biopsies during colonoscopy in 91%. Hepatobiliary surveillance adherence included annual MRCP in 95% of patients and annual gallbladder ultrasound in 70%. Disease monitoring included fibrosis assessment in 63% of patients and faecal calprotectin testing in 73%. Preventive care measures included vitamin D testing in 67% and bone mineral density assessment in 36%. Documentation of patient-reported symptoms included bowel frequency assessment in 99% and pruritus in 75% of cases (Table 1). **Conclusion:** While adherence to select quality indicators was high, there is substantial variability across other key domains of PSC-IBD care. These findings highlight gaps between guideline recommendations and routine clinical practice. Implementation of standardised care pathways, PSC-IBD care bundles, and shared multidisciplinary clinics may enhance adherence to quality indicators and improve patient outcomes.

Table 1: Adherence to PSC-IBD Quality Indicators

Domain	Quality Indicator	Adherence (%)
Symptoms	Pruritus assessment within 12 months	75
	Bowel frequency assessment within 12 months	99
Dysplasia surveillance	Surveillance colonoscopy within recommended interval	84
	Ileal pouchoscopy where applicable	90
	Segmental biopsies during surveillance colonoscopy	91
Hepatobiliary surveillance	Annual MRCP	95
	Annual gallbladder ultrasound	70
Disease monitoring	Fibrosis assessment within 2 years	63
	Faecal calprotectin within 9 months	73
	Treatment escalation in endoscopically active disease	98
Preventive care	Vitamin D assessment within 12 months	67
	Bone mineral density scan within 3 years	36

1279 | FROM LIVER TO BRAIN: INTRODUCING THE NEUROLOGICAL FOOTPRINT OF PBC

Natalia Rojas Amaris[1] Ana Marenco-Flores[2] Victoria Abadi-Ron[1] Hamza Khalil[3] Javier Polo-Ibarra[4] Fernando Munguia[1] Romelia Barba[5] Daniela Goyes[6] Esli Medina Morales[7] Behnam Saberi[8] Vilas Patwardhan[1] Alan Bonder[1], [1]Beth Israel Deaconess Medical Center, [2]Harvard Medical School, [3]Tufts Medical Center, [4]Boston Medical Center, [5]Texas Tech University, [6]Yale School of Medicine, [7]Washington University in St Louis, [8]BIDMC Harvard Medical School

Background: Patients with primary biliary cholangitis (PBC) frequently have concomitant extrahepatic autoimmune diseases. However, the prevalence and clinical relevance of neurological disorders in patients with PBC remain poorly characterized. This study aimed to evaluate the prevalence of neurological disorders among patients with PBC and assess their association with clinical outcomes. **Methods:** We conducted an analysis within a prospective cohort of patients with PBC enrolled in the Autoimmune Liver Diseases Registry at Beth Israel Deaconess Medical Center in Boston, MA, between January 2018 and May 2026. Medical records were reviewed to identify the presence and type of neurological disorders. Baseline demographic, clinical, and laboratory characteristics were compared between patients with and without neurological disorders. Univariable and multivariable logistic regression models were used, with multivariable models adjusted for age, sex, and cirrhosis. **Results:** Neurological disorders were present in 18% of patients with PBC. Movement disorders and migraine were the most prevalent conditions (28% each), followed by radiculopathy and epilepsy (22% and 17%, respectively). Biochemical response was similar regardless of neurological comorbidity. However, affected patients were more likely to require second-line therapy, including seladelpar or elafibranor ($p = 0.007$). Additionally, among affected patients, 44% developed their neurological condition several years after PBC diagnosis, with a median interval of 9.5 years. Psychiatric comorbidity was a strong predictor of neurological disorders (OR, 5.35; 95% CI, 1.58–18.07; $p = 0.007$). **Conclusion:** PBC's impact on brain function may extend beyond brain fog. PBC may precede the development of neurological disorders in some individuals, particularly those with concomitant psychiatric comorbidity. These findings highlight the importance of early recognition of neuropsychiatric manifestations during long-term follow-up of individuals with PBC.

1280 | STEROID-FREE BIOCHEMICAL REMISSION IN AUTOIMMUNE HEPATITIS WITHOUT OVERLAP: A REAL-WORLD PROSPECTIVE COHORT STUDY

Victoria Abadi-Ron[1] Ana Marenco-Flores[2] Natalia Rojas-Amaris[3] Fernando Munguia[3] Giuliana Arevalo[4] Aman Mohapatra[5] Romelia Barba[6] Daniela Goyes[7] Esli Medina Morales[8] Leandro Sierra[9] Behnam Saberi[10] Alan Bonder[3] Vilas Patwardhan[1], [1]Beth Israel Deaconess Medical Center, [2]Harvard Medical School, [3]Division of Gastroenterology, Hepatology, and Nutrition, Beth Israel Deaconess Medical Center, [4]University Of Miami Miller School of Medicine, [5]Department of Internal Medicine, Beth Israel Deaconess Medical Center, [6]Texas Tech University, [7]Division of Digestive Diseases, Yale School of Medicine, New Haven, [8]Washington University in St Louis, [9]Cleveland Clinic Foundation, [10]BIDMC Harvard Medical School

Background: Treatment for autoimmune hepatitis (AIH) often requires corticosteroids for long-term immunosuppression, yet some patients achieve long term biochemical remission (CBR) with steroid-sparing therapy. We aimed to identify AIH phenotypes where CBR can be maintained on minimal immune suppression including steroid free remission. **Methods:** We conducted a cross-sectional analysis of prospectively collected data from our institutional autoimmune liver disease registry and electronic medical record for patients with pure AIH (without overlap syndromes) followed at Beth Israel Deaconess Medical Center. Patients with available data on liver chemistries, current medications, and relevant clinical covariates were included. CBR was defined as normalization of aminotransferase, with IgG normalization required when available. The primary outcome was CBR without current steroid or off all immunosuppression. Categorical variables were compared using Fisher's exact test and continuous variables using the Mann–Whitney U test. Multivariable logistic regression evaluated factors associated with treatment-minimization CBR, including age, sex, race, alcohol use, smoking, autoimmune disease, and cirrhosis. **Results:** Among 167 classifiable patients, 114 maintained CBR overall. Of these, 48 were maintained on steroid-based therapy, 47 maintained steroid-free CB, and 19 maintained CBR off all immunosuppression. Overall, 56 (33.5%) maintained treatment-minimization CBR. Of the variables investigated there were no factors predictive of which patients maintained CBR without steroids. Cirrhosis was associated with a higher frequency of receiving steroids to maintain CBR on univariable analysis (20.5% vs. 37.5%; Fisher's exact $p = 0.028$) and remained independently associated with lower odds after multivariable adjustment (aOR 0.36, 95% CI 0.15–0.89; $p = 0.027$). Age, sex, race, alcohol use, smoking, and concomitant autoimmune disease were not significantly associated with the outcome. **Conclusion:** Treatment-minimization CBR was maintained in one-third of patients with pure AIH, supporting a rationale for steroid withdrawal strategies in AIH. Cirrhosis patients in our cohort had lower odds of receiving steroid-free immune suppression regimens. These data support a rationale for more aggressive steroid withdrawal strategies in AIH. Further investigation into which patients benefit most from steroid withdrawal strategies is a topic for further investigation.

FIGURE.

Figure1. Frequency of treatment-minimization complete biochemical response in the pure autoimmune hepatitis cohort. The pie chart shows the proportion of patients who maintained treatment-minimization complete biochemical response (CBR) versus those who did not. Treatment-minimization CBR was maintained in 33.5% of patients, while 66.5% did not maintain treatment-minimization CBR. CBR = complete biochemical response.

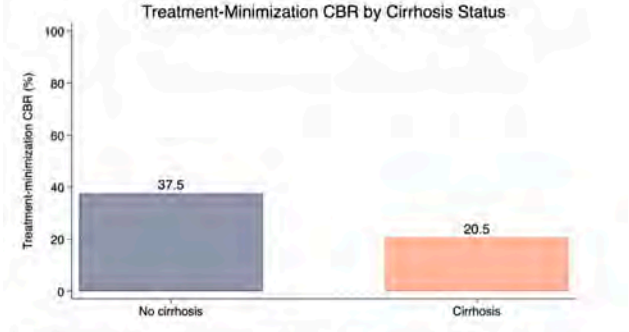

Figure 2. Treatment-minimization complete biochemical response by cirrhosis status. Bars show the proportion of patients achieving treatment-minimization complete biochemical response (CBR) among those without cirrhosis and those with cirrhosis. Treatment-minimization CBR was more frequent in patients without cirrhosis compared with those with cirrhosis (37.5% vs. 20.5%). CBR = complete biochemical response.

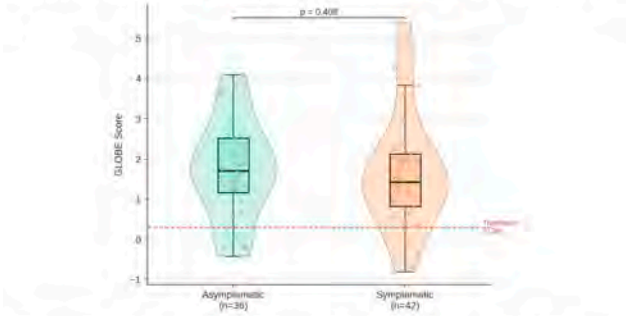
1281 | CLINICAL SYMPTOMS AT DIAGNOSIS AND RISK OF POOR BIOCHEMICAL RESPONSE IN PRIMARY BILIARY CHOLANGITIS: A U.S. COHORT STUDY

Ana Marenco-Flores[1] Natalia Rojas Amaris[2] Victoria Abadi-Ron[3] Fernando Munguia[2] Javier Polo-Ibarra[4] Romelia Barba[5] Daniela Goyes[6] Esli Medina Morales[7] Behnam Saberi[2] Vilas Patwardhan[2] Alan Bonder[2], [1]Harvard Medical School, [2]Beth Israel Deaconess Medical Center, [3]Beth Israel Deaconess Medical, [4]Boston Medical Center, [5]Texas Tech University, [6]Yale School of Medicine, [7]Washington University in St Louis



Background: The clinical presentation of primary biliary cholangitis (PBC) varies widely, with some patients presenting with cholestatic liver test abnormalities alone and others experiencing symptoms for months or years before being diagnosed. This study evaluated symptoms reported at diagnosis and its association with biochemical response to treatment in a real-world clinical setting. **Methods:** We analyzed data from patients with PBC or PBC-AIH overlap enrolled in a prospective cohort at Beth Israel Deaconess Medical Center in Boston, MA. Patients who reported fatigue, pruritus, sicca symptoms, abdominal pain, or jaundice at diagnosis were classified as symptomatic. Deep response was defined as normalization of alkaline phosphatase (ALP) and bilirubin, whereas standard (POISE) response was defined as ALP < 1.67× ULN. GLOBE scores were calculated to assess long-term prognosis and evaluate their association with symptoms at diagnosis and biochemical response. Univariable and multivariable logistic regression analyses were used to identify predictors of symptomatic presentation and biochemical response. Data analysis and visualization were performed using Stata and Python. **Results:** A total of 102 patients were included (median age 63 years, 88% female). Nearly half of participants reported symptoms at diagnosis (45%), with fatigue and pruritus being the most frequently reported symptoms (27% and 25%, respectively). Overall, 77% of patients achieved a biochemical response, including 36% deep responders and 41% standard responders, with either UDCA alone or second-line therapy. Among nonresponders, 72% were symptomatic at diagnosis ($p = 0.037$), and pruritus was the most prevalent symptom (61%; $p = 0.002$). Median GLOBE scores were elevated in both groups, suggesting a similarly increased predicted risk of liver transplantation or death. **Conclusion:** Symptomatic presentation at diagnosis was associated with poor biochemical response. Beyond serum biomarkers, symptom assessment at diagnosis may help identify patients who require more careful risk stratification, closer clinical monitoring, and individualized management, particularly among those reporting pruritus at diagnosis.

Figure 1. PBC Symptoms Reported at Diagnosis According to Biochemical Response

Percentages are shown above each bar. *p < 0.05; ** p < 0.01; ns = not significant; RUQ = right upper quadrant.

Figure 2. Distribution of GLOBE Scores by Symptom Presentation at Diagnosis in Patients with PBC

GLOBE score calculated using original formula: 0.044378 × Age + 0.93982 × ln(Bilirubin/ULN) + 0.335648 × ln(ALP/ULN) + 1.16009 × ln(ALT/ULN) − 1.04348 × ln(Platelets/ULN). ULN: bilirubin 1.0 mg/dL, ALP 120 U/L, ALT 35 U/L, platelets 250 K/μL. High-risk threshold: GLOBE > 0.30 (associated with 5-year liver-related mortality > 5%). GLOBE score available for patients with complete laboratory data.

1282 | SEVEN-YEAR LONGITUDINAL ASSESSMENT OF COGNITIVE SYMPTOMS IN PRIMARY BILIARY CHOLANGITIS: A U.S. COHORT STUDY

Natalia Rojas Amaris[1] Ana Marenco-Flores[2] Victoria Abadi-Ron[1] Javier Polo-Ibarra[3] Fernando Munguia[1] Romelia Barba[4] Daniela Goyes[5] Esli Medina Morales[6] Behnam Saberi[1] Vilas Patwardhan[1] Alan Bonder[1], [1]Beth Israel Deaconess Medical Center, [2]Harvard Medical School, [3]Boston Medical Center, [4]Texas Tech University, [5]Yale School of Medicine, [6]Washington University in St Louis

Background: Primary biliary cholangitis (PBC) is a chronic cholestatic disorder characterized by ongoing immune-mediated damage to the intrahepatic bile ducts. People living with PBC frequently report cognitive symptoms, typically involving memory impairment, reduced attention or concentration, and psychomotor slowing. Despite the high prevalence of these concerns, little is known about how cognitive symptoms evolve during routine follow-up. This study aimed to characterize longitudinal changes in patient-reported cognitive symptoms using the cognition domain of the PBC-40 questionnaire. **Methods:** We conducted a seven-year longitudinal analysis of a prospective PBC cohort enrolled in the Autoimmune Liver Diseases Registry at a U.S. tertiary medical center (2018–2025). Cognitive symptoms were assessed using the PBC-40 questionnaire, which evaluates self-reported cognitive impairment, with each item scored from 1 to 5 (higher scores indicating greater symptom burden). Patients were eligible if they completed more than one PBC-40 questionnaire and responded to all cognition-domain items. Scores from the first and last visits were compared using paired t-tests. Mean changes, correlation coefficients, and Cohen's d values were calculated. Statistical significance was defined as $p < 0.05$. **Results:** A total of 129 patients were included. The mean age was 54 years, most were female and caucasian, with a median of three visits. The mean cognition score decreased from 2.23 ± 1.18 at baseline to 1.95 ± 1.07 at the final visit, representing an average change of −0.28 ± 1.09 ($p = 0.0046$). This reflects a small but statistically significant improvement in reported cognitive symptoms over time. Among those with more than one assessment, 61 (47.3%) improved, 35 (27.1%) remained stable, and 33 (25.6%) showed worsening symptoms. The correlation between first and last scores was moderate ($r = 0.532$), indicating substantial individual variability in symptom trajectories. **Conclusion:** Self-reported cognitive symptoms and perceived cognitive impairment are common in PBC and demonstrate notable variability over time. Incorporating cognitive screening tools into routine clinical practice may help objectively characterize cognitive dysfunction in PBC. Given the fluctuating nature of symptoms, co-existing factors such as sleep and/or mood symptoms or disorders should also be considered when assessing cognitive function and interpreting longitudinal changes.

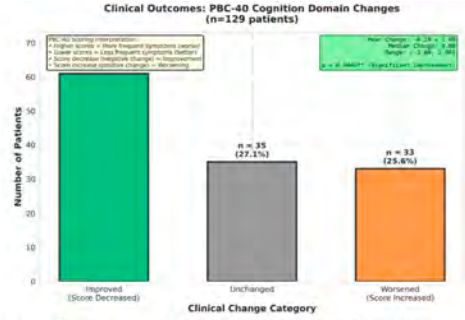

Figure 1. Distribution of cognitive symptom change categories based on PBC-40 cognition scores. Improved (n=61), unchanged (n=35), and worsened (n=33) categories are presented for 129 PBC patients. The average change in PBC-40 cognition scores was −0.28 ± 1.09 (median 0.00; range −3.00 to 3.00), indicating a significant overall improvement over time (p=0.0046). In the PBC-40 cognition domain, lower scores signify fewer cognitive symptoms.

1283 | EOSINOPHILIC CHOLANGITIS AS AN INDETERMINATE BILIARY MIMIC: A SYSTEMATIC REVIEW OF OUTCOMES

Thomas Stirrat[1] Shankar Thiru[2] Soham Apte[3] Maximilien Wilkey[2] Lovedeep Singh[2] Varat Ransibrahmanakul[2] Michael Flatley[4] Priyanka Kanth[5] Rachel Redfield[5] Amol Rangnekar[6], [1]University of California Los Angeles (UCLA), [2]Georgetown University School of Medicine, [3]Kentucky College of Osteopathic Medicine, [4]University of Colorado Internal Medicine Residency, [5]MedStar Georgetown University Hospital, [6]Georgetown University Hospital

Background: Eosinophilic cholangitis (EC) is a rare benign inflammatory biliary disorder that can mimic primary sclerosing cholangitis and cholangiocarcinoma. We systematically reviewed reported EC cases to define diagnostic features, treatment patterns, and outcomes relevant to indeterminate biliary strictures. **Methods:** Web of Science, PubMed, MEDLINE, Embase, Scopus, and CINAHL were searched from inception through December 31, 2025. Human case reports/series with extractable patient- level diagnostic, management, and outcome data were included. Data

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

were synthesized descriptively using available denominators. **Results:** Fifty-five studies describing 55 patients were included. Median age was 46.5 years (IQR, 29-65.8), and sex distribution was balanced among reported cases. Among cases with a preoperative impression (n = 39), malignancy was suspected in 19 (48.7%). Among cases with reported localization (n = 44), 22 (50.0%) had both intra- and extrahepatic involvement, 15 (34.1%) isolated extrahepatic disease, and 7 (15.9%) isolated intrahepatic disease. Tissue eosinophilic infiltration was reported in 52/53 (98.1%). Peripheral eosinophilia was common but not universal; serum IgE, when reported, was normal in 4/15 cases by author classification. Steroids were the primary therapy in 35/42 (83.3%); symptom resolution occurred in 36/37 (97.3%) and biochemical normalization in 39/39 (100%). Recurrence occurred in 8/18 (44.4%; median 2 months), and persistent stricture was reported in 7/11 (63.6%) when assessed. **Conclusion:** EC is a high-impact benign mimic of malignant and fibroinflammatory biliary disease. Recognition should pair guideline-concordant malignancy exclusion with targeted evaluation for eosinophilic/systemic disease and, when appropriate, closely monitored corticosteroid therapy with structured post-treatment surveillance.

Eosinophilic cholangitis: key abstract outcomes

Variable	Value
Studies / patients included	55 / 55
Malignancy suspected preoperatively	19/39 (48.7%)
Tissue eosinophilic infiltration	52/53 (98.1%)
Steroids as primary treatment	35/42 (83.3%)
Symptom resolution	36/37 (97.3%)
Biochemical normalization	39/39 (100%)
Recurrence	8/18 (44.4%)

1284 | SPECIFICITY OF ANTI-MITOCHONDRIAL ANTIBODY FOR PRIMARY BILIARY CHOLANGITIS: A LIVER EXPLANT-BASED STUDY

Rebecca Aquino[1] Christina Leyson[1], [1]University of Kentucky

Background: Primary biliary cholangitis (PBC) is a rare disease resulting from autoimmune destruction of intralobular bile ducts. Diagnosis is made when 2 of the following are present: elevation in alkaline phosphatase, presence of antimitochondrial antibody (AMA) or other PBC-specific autoantibodies, or histologic evidence of nonsuppurative destructive cholangitis and destruction of interlobular bile ducts. Anti-mitochondrial antibodies (AMAs) have a reported specificity of 96 to 98 percent for the diagnosis of PBC. However, it has been reported that positive AMAs can occasionally be present in other conditions such as systemic sclerosis and other autoimmune connective tissue diseases. Furthermore, research has shown that patients with positive AMAs who did not have PBC at the time of testing were unlikely to be diagnosed with PBC in the future. These findings bring the test's specificity into question. **Methods:** The University of Kentucky's electronic medical record, EPIC, was used to identify liver transplant recipients transplanted from July 1st 2021 to April 13th 2025 who had an abnormal AMA value documented. 30 patient charts were identified for review. Liver explant surgical pathology reports were reviewed and used to determine if explant tissue was compatible with a diagnosis of PBC. For those not consistent with PBC, the diagnosis suggested by the pathology was documented. Additional data recorded included patient age at transplant, sex, highest AMA level, highest alkaline phosphatase level, and presence of other autoimmune diseases. **Results:** This study consisted of 19 men and 11 women with an average age of 50.5 years. 20 percent of patients had liver explant tissue compatible with a diagnosis of PBC and 80 percent had explant tissue suggesting another disease. The average AMA level for the group with pathology consistent with PBC (PBC group) was 121 units (reference range 0 to 24.9 units) and in those with pathology inconsistent with PBC (non-PBC group) was 42 units. 83 percent of patients in the PBC group had other documented autoimmune diseases compared to 16.7 percent in the non-PBC group. The most common diagnoses suggested by explant pathology results were metabolic dysfunction-associated steatotic liver disease (23 percent) and alcohol-associated liver disease (23 percent). **Conclusion:** Despite the reported high specificity of AMA for the diagnosis of PBC, this study suggests that positive AMA levels may be associated with other chronic liver diseases. Our data suggests that there is a correlation between AMA level and the diagnosis, with higher levels being more likely to coincide with a confirmed diagnosis of PBC. The data highlights the prevalence of other autoimmune diseases in patients with PBC. The specificity of the AMA is important for guiding diagnosis which helps identify appropriate treatment. The diagnosis of PBC does not require liver biopsy, but tissue evaluation may be the only way to confirm diagnosis.

★ 1285 | SPATIAL TRANSCRIPTOMICS REVEALS A TLS-LIKE IMMUNE-FIBROTIC NICHE DRIVING BILIARY FIBROSIS IN PEDIATRIC PRIMARY SCLEROSING CHOLANGITIS

Yunguan Wang[1] David Adeleke[2] Alexander Miethke[2], [1]Cincinnati Children Hospital, [2]Cincinnati Children's Hospital Medical Center

Background: Pediatric-onset primary sclerosing cholangitis (PSC) is a cholestatic condition in which peribiliary inflammation and fibrosis progressively reorganize hepatic tissue into spatially distinct domains. The intercellular signals activating hepatic stellate cell (HSC) and driving fibrogenesis across spatial domains remain poorly characterized. **Methods:** We performed spatial transcriptomics on liver biopsies from 5 patients with PSC (median age 19 years, 3 males) and one healthy control. Spatial domains were identified using Novae, and cell-cell communications (CCC) were inferred using CellNest. Empirical CCC probability was estimated as the ratio of observed interactions to plausible. Differential communication was assessed using paired Wilcoxon signed-rank tests. **Results:** Novae identified four domains (D1-4) representing a continuum of disease progression. D1 occupied hepatocyte (Hep)-rich lobular regions (75% of cells) with relatively preserved architecture, D2 and D3 represented intermediate states characterized by reduced Hep (55%) and increased plasma cells, NK cells, T cells, and macrophages (MP), consistent with inflammatory infiltration at the portal-parenchymal interface. In contrast, D4 localized to portal and fibrotic periductal regions, was predominately (~85%) consisted of activated HSC, myofibroblasts, cholangiocytes, MP, and lymphoid cells.D4 emerged as the dominant fibrotic niche, with selective enrichment of TNFR2-associated signaling and tertiary lymphoid structure (TLS)-like chemokine programs, including CCL21-CCR7, CCL21-CXCR3, CXCL12-CXCR3, and CXCL12-CXCR4. Key interactions included cholangiocyte-derived SPP1–ITGB1, endothelial-derived CCL21 signaling to dendritic and T cells, and stromal CXCL12-CXCR4 signaling to plasma and T cells, consistent with a TLS-like immune-fibrotic microenvironment. D2 showed enhanced collagen-integrin and TNFSF14 signaling involving activated HSC, LSEC, MPs, and Kupffer cells, consistent with early stromal remodeling and leukocyte adhesion. D3 represented an interferon-γ-driven inflammatory niche dominated by CXCL9, CXCL10, and CXCL12 signaling through CXCR3 and CXCR4, consistent with recruitment of Th1 cells, NK cells, dendritic cells, and MPs. **Conclusion:** PSC progression is characterized by a structured spatial trajectory from disrupted matrix homeostasis to stromal remodeling, interferon-driven immune recruitment, and ultimately a cholangiocyte-centered TLS-like immune-fibrotic niche. The convergence of CCL21, CXCL12, SPP1, TNF, and LIGHT signaling implicates TLS as a central mechanism linking chronic immune activation to biliary fibrosis in pediatric PSC.

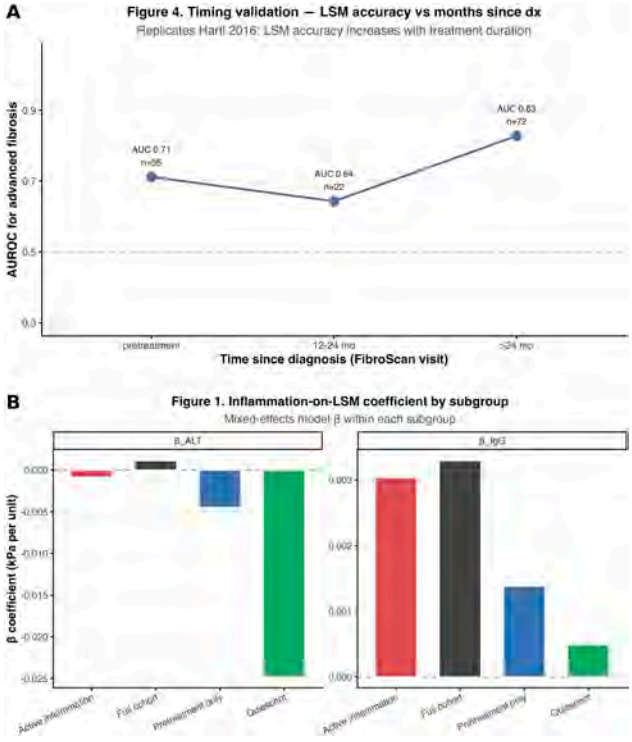
1286 | IMMUNOGLOBULIN G IS ASSOCIATED WITH HIGHER LIVER STIFFNESS IN AUTOIMMUNE HEPATITIS: TIMING MATTERS MORE THAN BIOCHEMICAL CORRECTION



Sebastian Niezen[1] Daniela Goyes[2] Victoria Abadi-Ron[1] Natalia Rojas Amaris[1] Fernando Munguia[1] Ana Marenco-Flores[1] Behnam Saberi[1] Vilas Patwardhan[1] Alan Bonder[1], [1]Beth Israel Deaconess Medical Center, [2]Yale University

Background: Transient elastography (TE) may overestimate fibrosis in autoimmune hepatitis (AIH) because hepatic inflammation can increase liver stiffness measurement (LSM) independently of fibrosis. Whether ALT, IgG, or both confound LSM, and whether a simple algebraic correction improves accuracy, remains undefined. We characterized the inflammation–LSM relationship in AIH and quantified when LSM is reliable for fibrosis staging. **Methods:** Single-center retrospective cohort of adult AIH patients with diagnostic liver biopsy (Metavir staging) and one or more FibroScan measurements with same-visit ALT and IgG. The diagnostic biopsy stage served as the patient-level fibrosis anchor. We fit a mixed-effects linear model with LSM as the outcome and biopsy stage, ALT, IgG, and time since diagnosis as fixed effects, with a patient-level random intercept. An

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

inflammation-adjusted LSM was computed by subtracting estimated ALT and IgG contributions centered at upper limits of normal. Spearman correlation with biopsy stage and DeLong-tested AUROC for advanced fibrosis (F3–F4 vs F0–F2) compared measured and adjusted LSM, overall and stratified by inflammation state (active vs quiescent) and by time since diagnosis. The IgG with timing interaction was formally tested. **Results:** We analyzed 208 FibroScan observations from 119 AIH patients with biopsy-defined fibrosis stage, including 49 observations with advanced fibrosis (F3–F4). In the mixed-effects model, IgG was independently associated with LSM (β = +0.003 kPa per mg/dL, p < 0.001), while ALT was not ($\beta \asymp 0$, p = 0.68). The IgG–LSM relationship varied significantly by treatment timing (IgG × 0–6 months interaction p = 0.001; IgG × 12–24 months p = 0.004). A simple ALT/IgG subtraction did not improve discrimination of advanced fibrosis (full-cohort AUROC measured 0.76 vs adjusted 0.72, DeLong p = 0.18). LSM accuracy varied by timing from diagnosis/treatment: AUROC for advanced fibrosis was 0.71 pretreatment (n = 35), 0.64 at 12–24 months (n = 22), and 0.83 beyond 24 months (n = 72). **Conclusion:** In this real-world AIH cohort, IgG was independently associated with higher LSM, with evidence of a time-dependent effect early after diagnosis. However, simple ALT/IgG-based correction did not improve fibrosis discrimination. LSM performed best beyond 24 months, suggesting that timing and biochemical context may be more useful than algebraic correction when interpreting FibroScan in AIH.

1287 | VARIANTS IN GENES KNOWN TO BE ASSOCIATED WITH PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS (PFIC) AND NON-PFIC CHOLESTATIC GENES ARE THE PRIMARY CAUSE FOR CHOLESTASIS OF UNKNOWN ETIOLOGY IN ADULTS

Mitchell Shiffman[1] Kimberly Taylor[1] Sarah Hubbard[1] Rebecca Rathburn[1] Jennifer Miller[1], [1]Bon Secours Mercy Health

Background: The etiology for cholestatic liver disease in adults encompasses a wide array of disorders. Despite extensive testing the etiology for chronic cholestasis remains undefined in many patients. Genetic causes for cholestasis such as PFIC and Alagille syndrome are well recognized in children and less severe forms of these diseases have recently been recognized in adults. We have hypothesized that variants in genes associated with cholestasis are the primary cause for cholestasis of undefined etiology in adults. **Methods:** A total of 81 patients with cholestasis of unknown etiology were evaluated. The definition of cholestasis in this cohort included at least 2 of the following: persistent or intermittent elevation in ALP for at least 6 months, an elevation in GGT, an elevation in serum bile acids (SBA), unexplained pruritus. All patients underwent extensive biochemical, serologic, radiologic (MRCP in all patients) and histologic evaluation (liver biopsy (54 patients) and/or VCTE (65 patients)) to exclude all known causes of cholestasis. Genetic testing was then performed with the Prevention Genetics Cholestsis panel which screens for variants in 70 genes involved in pathways associated with cholestasis and in the synthesis, uptake, intracellular transplant, and secretion of BA. **Results:** The mean age of the cohort was 55 years, 77% female. Mean liver chemistries were ALP 278 IU/L, TBILI 1.1 mg/dL, GGT 262 IU/L and SBA 40.9 µmol/L. Mild non-specific irregularities in bile ducts without significant inflammation was present in 19% of patients. Stage 0-1 fibrosis was present in 73% of patients but 15% had cirrhosis. A variant in at least one of the genes associated with cholestasis was present in 89% of patients. A variant in 1 or more genes known to be associated with PFIC or

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Alagille syndrome (1 patient) was present in 30% of patients. The mean number of genes with variants was 2.8 per patient. The mean duration of monitoring before genetic testing was 42 (6-198) months. Pruritus was present in 33% of all patients. The severity of pruritus was similar in patients with a known PFIC gene variant, patients with a non-PFIC gene variant and patients with no variants in any of the genes in the cholestatic genetic panel. A significant increase in ALP and ALT but not serum BA was present with increasing severity of pruritus ($p < 0.05$). Itching was severe and refractory to standard medicinal treatments in 20% of all patients but in 44% of patients with a variant in a known PFIC gene ($p < 0.05$). **Conclusion:** Variants in genes associated with cholestasis were present in 89% of patients and this appears to be the most common cause for cholestasis of unknown etiology in adults. 30% of patients with cholestasis of unknown etiology have a variant in a gene known to be associated with PFIC or Alagille syndrome. Patients with severe cholestatic pruritus are more likely to have a PFIC gene variant than a variant not currently recognized as a cause of PFIC.

1288 | PREVALENCE AND IMPACT OF MALNUTRITION ON CLINICAL OUTCOMES IN AUTOIMMUNE HEPATITIS: A PROPENSITY-MATCHED GLOBAL ANALYSIS

Prerna Ashok Kherajani[1] Savio John[1], [1]Suny Upstate Medical University

Background: Autoimmune hepatitis (AIH) is a chronic inflammatory liver disease characterized by progressive hepatocellular injury that can lead to cirrhosis, hepatic decompensation, and liver transplantation if untreated. Malnutrition is increasingly recognized as an important determinant of morbidity and mortality in chronic liver disease due to its association with sarcopenia, immune dysfunction and impaired hepatic regeneration. While the burden and prognostic impact of malnutrition have been extensively studied in cirrhosis and other chronic liver diseases, limited data exist evaluating its prevalence and clinical significance specifically in patients with AIH. We aimed to determine the prevalence of malnutrition in AIH and evaluate its association with adverse outcomes using a large multicenter database. **Methods:** We conducted a retrospective cohort study using the TriNetX global collaborative network. Adult patients with AIH were identified using ICD-10 codes and stratified into patients with concomitant malnutrition (AIH-Mal) and those without malnutrition (AIH). Propensity score matching (1:1) was performed for demographics, comorbidities, medications (Corticosteroids, Azathioprine and Mycophenolate mofetil), Liver function tests and serum IgG levels, yielding 2,924 patients in each cohort. Primary outcomes included all-cause hospitalization and mortality. Secondary outcomes included liver transplantation, ascites, esophageal varices, hepatic encephalopathy (HE), acute liver failure (ALF) and Hepatocellular carcinoma (HCC). **Results:** Among 38,570 patients with AIH, the prevalence of malnutrition was 7.7%. After propensity matching, patients with AIH-Mal had significantly worse outcomes compared to matched AIH controls. All-cause hospitalization occurred in 68.3% versus 32.5% of patients, respectively (OR 4.47, 95% CI 4.01–4.99, $p < 0.0001$). Mortality was significantly higher in the AIH-Mal cohort (14.3% vs 4.1%; OR 3.92, 95% CI 3.18–4.84, $p < 0.0001$). Malnutrition was additionally associated with increased risk of ascites (35.2% vs 8.1%; OR 6.19, 95% CI 5.31–7.22, $p < 0.0001$), esophageal varices (20.8% vs 5.6%; OR 4.39, 95% CI 3.66–5.26, $p < 0.0001$), hepatic encephalopathy (13.3% vs 2.1%; OR 7.22, 95% CI 5.49–9.51, $p < 0.0001$), and acute

liver failure (34.0% vs 8.4%; OR 5.60, 95% CI 4.81–6.51, p < 0.0001), liver transplantation (10.9% vs 1.6%; OR 7.76, 95% CI 5.62–10.71, p < 0.0001). No significant difference in hepatocellular carcinoma incidence was observed between groups. **Conclusion:** Malnutrition affects approximately 1 in 13 patients with autoimmune hepatitis and is associated with significantly increased mortality, hospitalization, hepatic decompensation, acute liver failure, and liver transplantation. Early nutritional assessment and intervention may represent an important modifiable target to improve outcomes in AIH.

1289 | DISTINCT PERIPHERAL IMMUNE SIGNATURES IN PRIMARY SCLEROSING CHOLANGITIS REVEALED BY STANDARDIZED IMMUNOPHENOTYPING

Shuhei Tanemura[1] Nobuhito Taniki[2] Haruka Okada[2] Ryosuke Kasuga[2] Yukie Nakadai[2] Makoto Ueno[2] Takaya Tabuchi[2] Shingo Usui[2] Keisuke Ojiro[2] Takanori Kanai[2] Nobuhiro Nakamoto[2], [1]Tanabe Pharma Corporation / Keio University School of Medicine, [2]Keio University

Background: Primary sclerosing cholangitis (PSC) is a chronic cholestatic liver disease in which reliable serological biomarkers have not been established, and diagnosis as well as disease assessment relies largely on imaging-based evaluation. To date, comprehensive and standardized characterization of systemic immune alterations in PSC remains limited. We aimed to characterize peripheral blood immune cell phenotypes in PSC using a standardized immunophenotyping framework and to identify PSC-specific immune signatures that may serve as a basis for future non-invasive biomarkers. **Methods:** This single-center observational study analyzed peripheral blood mononuclear cells (PBMCs) from patients with PSC (n = 61), with primary biliary cholangitis (PBC) included as a disease control and healthy controls (HC) as reference controls. Multiparameter flow cytometry was performed, and immune cell subsets were defined according to the Human Immunology Project Consortium (HIPC) standardized immunophenotyping guidelines (Maecker HT et al., Nat Rev Immunol 2012). Immune cell frequencies were Z-score normalized to enable cross-population comparison. Group differences were assessed using the Mann–Whitney U test. **Results:** Compared with HC, PSC patients showed a significant reduction in mucosal-associated invariant T (MAIT) cells ($CD3^+CD4^-CD161^+TCRV\alpha7.2^+$, $p < 0.001$), $CD45RA^-$ memory $CD8^+$ T cells ($p < 0.01$), and $HLA\text{-}DR^+CD11c^+$ myeloid dendritic cells ($p < 0.05$). Analysis of Th17-related populations demonstrated no significant difference in total $CCR6^+CD4^+$ T cells; however, activated Th1-like Th17 cells defined as $HLA\text{-}DR^+CXCR3^+CCR6^+CD4^+$ T cells were significantly increased in PSC ($p < 0.05$). Notably, the reduction in memory $CD8^+$ T cells was not observed in patients with primary biliary cholangitis (PBC), indicating a PSC-specific immune alteration distinct from other autoimmune cholestatic liver diseases. **Conclusion:** Using a standardized HIPC-based immunophenotyping approach, we demonstrated distinct systemic immune dysregulation in PSC, characterized by reduction of MAIT cells, memory $CD8^+$ T cells, and myeloid dendritic cells, together with a selective expansion of activated Th1-like Th17 cells. These PSC-associated peripheral immune signatures provide a rationale for the development of immunophenotype-based, non-invasive biomarkers for PSC diagnosis and disease activity assessment.

Background: The prevalence rates of primary biliary cholangitis (PBC) are estimated at between 19.1 and 40.2 cases per 100,000 people. Data on the prevalence and care pathway for these patients with PBC come from university hospitals in France, with a majority of second-line patients and/or those with advanced liver disease. No data are available or published on the prevalence and cascade of care for patients with PBC in non-teaching hospitals. **Methods:** It was a national multicentre study to describe the prevalence and care pathway of patients with PBC in hepatogastroenterology departments of general hospitals. **Results:** As of May 12, 2026, 156 patients (91% women) had been included in 19 centers: median age 64 years, 17% overlap syndrome, 4% family history. Liver fibrosis was mainly assessed by FIBROSCAN, both at diagnosis (66%) and at follow-up (89%); mean 7.3 Kpa, 23% of patients F3F4 at diagnosis and during follow-up. After initial treatment with UDCA (for 96%), 30% had a second-line treatment (fibrates 71%, obeticholic acid 29%). The average GLOBE score was -0.56. **Conclusion:** Conclusion : compared to the patients followed in university hospitals, patients followed in non-university hospitals are older, with more moderate liver fibrosis and more often on first-line treatment.

Background: Histological ductopenia and interface hepatitis predicts adverse outcomes in primary biliary cholangitis (PBC), yet the biochemical correlation and prognostic value of these features remained unknown. Using the multinational SEA-PBC cohort, we evaluated whether baseline biochemical phenotypes identify clinically distinct PBC subgroups associated with differential treatment response, symptom burden and clinical outcomes in an under-characterized cohort in Southeast Asia. **Methods:** From the multinational SEA-PBC consortium **,** we included PBC patients from 18 tertiary institutions. Patients with autoimmune hepatitis (AIH)-PBC overlap or under immunosuppression were excluded. Patients were classified into classical PBC, ductopenic phenotype (ALP > 3x ULN), or inflammatory phenotype (ALT > 3x ULN and ALP < 3x ULN). Biochemical response was assessed using ALP normalization, Paris-II, POISE, and deep response (i.e., normalization of ALP and bilirubin) at 12 months after ursodeoxycholic acid treatment. Clinical outcomes (hepatic decompensation, liver transplantation and death) were analyzed using Cox proportional hazard models, adjusted for age, sex, and baseline MELD. **Results:** Among 1,662 patients from SEA-PBC, 60.2% had classical PBC, 16.9% ductopenic phenotype, and 22.7% inflammatory phenotype. The ductopenic phenotype had significantly lower biochemical response rates than classical PBC across all criteria: ALP normalization 5.7% vs 25.6%, Paris-II response 20.3% vs 62.3%, POISE response 24.9% vs 44.9%, and deep response 3.3% vs 16.3% (all $p < 0.001$). In contrast, inflammatory phenotype showed similar rate of ALP normalization but higher POISE response than classical PBC.Symptom burden differed by phenotypes, with ductopenic PBC associated with more pruritus, fatigue, and sicca symptoms compared with classical PBC.Over median follow-up of 61 (IQR: 25-113) months, ductopenic phenotype was independently

associated with liver transplantation or death compared with classical PBC (adjusted hazard ratio [HR] 1.52, 95% CI 1.19–1.94; $p < 0.001$), whereas the apparent unadjusted survival advantage of inflammatory phenotype was attenuated after adjustment. Ductopenic phenotype was also consistently associated with incident hepatic decompensation across clinically relevant subgroups (AMA-positive, ANA-positive, cirrhosis and non-diabetic patients) ($p < 0.05$). **Conclusion:** In the large Southeast Asian PBC cohort of PBC patients, baseline biochemical patterns identified clinically meaningful subgroups with divergent treatment response and prognosis. The ductopenic phenotype represents a high-risk, treatment-refractory subgroup associated with poor biochemical response, higher symptom burden, and poorer clinical outcomes. These findings support phenotype-based risk stratification and earlier therapeutic escalation in PBC.

1292 | PROFILES OF VIRAL HEPATITIS MARKERS AND ASSOCIATED CLINICAL PHENOTYPES IN PRIMARY BILIARY CHOLANGITIS: A 10-YEAR REAL-WORLD COHORT FROM CHINA

Xiao Lin[1] Chunyang Huang[1] Bin Xu[1] Xue Yang[1],
[1]Beijing Youan Hospital, Capital Medical University

Background: Viral hepatitis markers are frequently detected in patients with primary biliary cholangitis (PBC). However, their positivity rates, combination patterns, and associated clinical phenotypes remain incompletely characterized in large real-world cohorts. We aimed to define viral hepatitis marker profiles and compare clinical features across viral marker-defined subgroups in patients with PBC. **Methods:** We retrospectively analyzed 3,688 patients with PBC treated at Beijing YouAn Hospital, Capital Medical University, from 2015 to 2024. Viral hepatitis markers for hepatitis A, B, C, and E viruses were extracted from clinical testing records. Patients with positive viral markers were categorized using a hierarchical, mutually exclusive approach: Group 1, HBsAg and/or HBV DNA positive; Group 2, anti-HCV and/or HCV RNA positive; Group 3, HEV IgM/HEV RNA and/or HAV IgM positive; and Group 4, isolated anti-HBc and/or HEV IgG positivity without markers suggestive of current infection. Demographics, liver biochemistry, immunoglobulins, and PBC-related autoantibodies were compared across groups. **Results:** Markers of previous viral exposure were common, whereas markers suggestive of current or potentially active infection were less frequently detected. Among tested patients, anti-HBc and HEV IgG were positive in 41.85% (945/2,258) and 21.50% (184/856), respectively. HBsAg, HBV DNA, anti-HCV, HCV RNA, HEV IgM, HEV RNA, and HAV IgM were detected in 3.34% (79/2,364), 11.62% (53/456), 3.01% (45/1,494), 15.38% (16/104), 1.64% (14/856), 6.90% (4/58), and 0.40% (3/753) of tested patients, respectively. Overall, 1,078 patients had positive viral markers, including 84 in Group 1, 48 in Group 2, 17 in Group 3, and 929 in Group 4. Age, ALT, ALP, GGT, albumin, and hemoglobin differed significantly across groups. Group 3 showed the most prominent hepatocellular injury, with the highest ALT level (257.6 ± 428.0 U/L). In contrast, Group 4 exhibited a more cholestatic phenotype, with the highest ALP (228.5 ± 191.6 U/L) and GGT (221.5 ± 288.6 U/L) levels and the lowest albumin level (36.6 ± 6.7 g/L). PBC-associated autoantibodies remained prevalent across all groups, while IgG, IgA, and IgM concentrations did not differ significantly. **Conclusion:** Previous HBV or HEV exposure was common in patients with PBC, whereas active viral hepatitis markers were uncommon. Distinct clinical phenotypes across viral marker-defined subgroups highlight the value of viral hepatitis marker assessment in PBC.

1293 | THE IMPACT OF VOLIXIBAT, AN IBAT INHIBITOR, ON FATIGUE AND SLEEP FOR PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS: DATA FROM VISTAS

Christopher Bowlus[1] Cynthia Levy[2] Mitchell Shiffman[3] Kris Kowdley[4] Marlyn Mayo[5] Palak Trivedi[6] Deepak Joshi[7] Adriaan Van der Meer[8] Verena Keitel[9] Alan Bonder[10] Ira Jacobson[11] Lisa Forman[12] Marco Carbone[13] David Bernstein[14] Walid Ayoub[15] Hallam Gugelmann[16] Erik Ness[16] David Sanchez-Ramos[16] Douglas Mogul[16] Jonathan Ieyoub[16] Jolan Terner-Rosenthal[16] Raul Aguilar[17] Lara Longpre[16] Pamela Vig[16] Joanne Quan[16] Gideon Hirschfield[18], [1]University of California, Davis, [2]University of Miami Miller School of Medicine, [3]Bon Secours Mercy Health, [4]Liver Institute Northwest, [5]University of Texas Southwestern Medical Center, [6]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom, [7]King's College Hospital NHS Foundation Trust, [8]Erasmus University Medical Center, [9]University Hospital Magdeburg, [10]Beth Israel Deaconess Medical Center, [11]NYU Grossman School of Medicine, [12]University of Colorado Anschutz Medical Campus, [13]University of Milano-Bicocca, ASST GOM Niguarda, [14]NYU Langone Health, [15]Cedars Sinai Medical Center, [16]Mirum Pharmaceuticals, Inc., [17]Mirum Pharmaceuticals, [18]Toronto General Hospital

Background: Primary sclerosing cholangitis (PSC) is a rare, progressive cholestatic liver disease that substantially impacts health-related quality of life (HRQoL). Pruritus, fatigue, and sleep disturbances are common symptoms in PSC whose burden may be severe and difficult to treat. Volixibat (VLX), a minimally absorbed ileal bile acid transporter inhibitor, blocks enterohepatic bile acid recirculation. Initial results from the VISTAS study demonstrated significant improvements in pruritus with VLX. Here, we present the effects of VLX on fatigue and sleep in participants from VISTAS. **Methods:** VISTAS is a 28-week randomized, multicenter, double-blind, placebo (PBO)-controlled Phase 2b study in adults with PSC and cholestatic pruritus. The primary endpoint, change in pruritus (Adult ItchRO score) from Baseline to Week 28, has been previously reported. Fatigue and sleep through Week 28 were assessed using the validated PROMIS HRQoL measures. Differences in fatigue and sleep between pruritus responders ($\geq$2-point reduction in Adult ItchRO; PR) and non-responders (NR) after treatment were also analyzed. Results were analyzed using a mixed model for repeated measures. **Results:** 111 participants with moderate-to-severe pruritus were randomized (VLX 20mg BID = 54; PBO BID = 57) in the primary cohort. Improvements (LS mean [SE]) favoring VLX treatment were observed in sleep (VLX: -6.47 [1.3], PBO: -0.78 [1.2]; P = 0.0011). Pruritus responders demonstrated greater improvements in fatigue and sleep versus NR, irrespective of treatment assignment (fatigue [mean, SD] PR: [-6.25, 7.8], NR: [-0.34, 6.3], P = 0.0004; sleep: [-7.48, 9,5], NR: [0.18, 6.6], P < 0.0001). However, the magnitude of improvement was greater in the VLX PR vs PBO PR group with significant differences observed with sleep (fatigue: VLX PR: -7.03 [8.7], PBO PR: -4.95 [6.0], P = 0.41; sleep: VLX PR: -10.20 [10.2], PBO PR: -2.93 [6.0], P = 0.0165). **Conclusion:** Initial results from the VISTAS trial in patients with PSC demonstrate that improvements in pruritus were associated with improvements in fatigue and sleep, with greater improvements observed following VLX treatment.

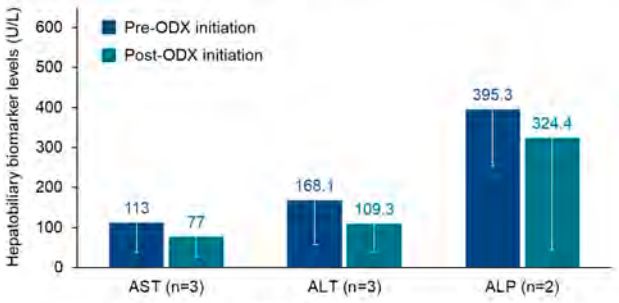
1294 | REAL-WORLD EFFECTIVENESS OF ODEVIXIBAT IN LATE-ONSET PROGRESSIVE FAMILIAL INTRAHEPATIC CHOLESTASIS (PFIC)

Tatyana Kushner[1] Seema Meloni[2] Omar Almudallal[2] Brian He[2] Hugo Gomes Da Silva[3] Wing-Kin Syn[4], [1]Division of Gastroenterology & Hepatology, Weill Cornell Medicine, New York, NY, US, [2]Ipsen, Cambridge, MA, US, [3]Ipsen, Paris, France, [4]Division of Gastroenterology & Hepatology, Saint Louis University School of Medicine, St Louis, MO,



Background: While symptoms for PFIC typically manifest in early childhood, increasing numbers of patients are being diagnosed with late-onset disease in adulthood. Older patients with PFIC often present with heterogeneous and atypical cholestatic phenotypes associated with progressive liver disease. Consequently, clinical management of late-onset PFIC remains poorly defined, and effectiveness of currently available therapies in this population is not well characterized. Odevixibat (ODX) is an ileal bile acid transporter inhibitor approved in the US for treatment of pruritus in patients with PFIC aged at least 3 months and in the EU for patients aged at least 6 months. However, data describing clinical outcomes with ODX in adults with late-onset PFIC remain limited, highlighting the need for additional evidence to support timely diagnosis and informed clinical decision-making. **Methods:** This non-interventional retrospective study focuses on 3 of 14 patients with late-onset PFIC (aged $\geq$18 years; International Classification of Diseases [ICD]-9: 576.8 and/or ICD-10: K76.8; confirmed by manual chart review) who were treated with ODX at Mayo Clinic or Duke Health; data for all 14 patients were characterized in a prior report (Meloni et al. AASLD 2025). The study period was July 20, 2021 to December 31, 2025. Change in pruritus from unstructured notes and change in measured hepatic parameters (aspartate aminotransferase [AST], alanine aminotransferase [ALT], serum bile acid [sBA], and alkaline phosphatase [ALP]) from structured fields were evaluated. To maintain patient confidentiality, only non-identifiable data are presented. **Results:** Mean age (SD) at first record of PFIC was 24.3 (9.7) years and at ODX initiation was 27.0 (11.5) years. Mean (SD) observed time on treatment was 12.3 (7.6) months. All 3 patients had physician interpretation of genetic testing and notable hepatocellular injury pre-ODX. Mean (SD) AST and ALT prior to ODX initiation was 113 (76) and 168.1 (110) U/L, respectively. All 3 patients reported improvements in pruritus within 3 months of ODX initiation and 1 noted resolution of symptoms. Temporary ODX interruption occurred in 2 patients; both reinitiated treatment and subsequently reported pruritus improvement. Of 2 patients with available sBA data, both had reductions while on ODX (by 140 µmol/L and 115 µmol/

L). Mean levels of AST, ALT, and ALP decreased following ODX initiation (**Figure**). **Conclusion:** Real-world use of ODX in patients with late-onset PFIC was accompanied by meaningful pruritus improvements and sBA reductions, and improvements in hepatobiliary biomarkers. Findings support potential ODX benefit in this understudied population, although further real-world studies are warranted to strengthen the evidence base and optimize management of late-onset PFIC.

Figure: Mean change in AST, ALT, and ALP levels pre- and post-ODX initiation in adults with late-onset PFIC (N=3)

Values shown as mean and SD.

1295 | MARALIXIBAT, AN IBAT INHIBITOR, IMPROVES CHOLESTATIC PRURITUS IN PFIC PATIENTS WITH COMPOUND HETEROZYGOUS VARIANTS

Mitchell Shiffman[1] Chaowapong Jarasvaraparn[2] Rene Romero[3] Adebowale Adeyemi[4] Marlyn Mayo[5], [1]Bon Secours Mercy Health, [2]Indiana University School of Medicine, [3]Emory University School of Medicine, [4]Nemours Children's Hospital, [5]University of Texas Southwestern Medical Center

Background: Progressive familial intrahepatic cholestasis (PFIC) is a group of rare autosomal recessive liver diseases distinguished by canalicular bile transport defects, which result in disrupted bile formation and progressive cholestasis. It is classically caused by biallelic pathogenic variants in genes such as *ATP8B1*, *ABCB11, ABCB4, TJP2, MYO5B* and *NR1H4*. Patients with PFIC often have elevations in serum bile acid (sBA) levels, abnormalities in liver function tests, and clinical manifestations of chronic cholestasis, including pruritus. Maralixibat (MRX), an ileal bile acid transporter (IBAT) inhibitor, is indicated for the treatment of cholestatic pruritus in patients with PFIC ≥1 year in the US, and for the treatment of PFIC in patients ≥3 months in the EU. Here we describe 5 real-world cases of PFIC with compound heterozygous variants who received MRX. **Methods:** Clinicians treating patients with a diagnosis of PFIC completed an electronic case report form including clinical and biochemical data. Pruritus was assessed with the Clinician Scratch Scale (CSS), a 0-4 scale where 0 = no evidence of pruritus and 4 = cutaneous mutilation, bleeding or scarring; ≥1-point reduction is considered clinically meaningful. Data are presented using medians and min/max, and categorical variables are as counts and percentages. **Results:** Data on 5 patients (3 males) from 5 centers with compound heterozygous variants in the following PFIC genes were included: 1 (20%) *ABCB11* and *MYO5B*, 2 (40%) *ABCB11*, 1 (20%) *FIC1*, and 1 (20%) *MYO5B*. Median age at initiation of treatment was 10 (range 1.25-70) years and duration of treatment was 12 (range 8-84) months with all patients still on MRX. Before treatment, 3 (60%) had CSS of 4, 1 (20%) had a CSS of 3, and 1 (20%) had CSS of 2. Following treatment, all had a clinically meaningful reduction in CSS, with 2 (40%) achieving complete resolution (CSS = 0). 3 of the 5 patients had both pre- and post-MRX sBA levels with all 3 (100%) patients having a substantial reduction in sBA levels (276 to 2, >300 to 4, and 212 to 14 µmol/L). Bilirubin and liver enzymes remained stable or decreased in the majority of patients. AEs were reported in 2 including diarrhea (n = 2; 40%), transaminase increase that normalized by last clinical follow-up (n = 1; 20%), increase in bilirubin (n = 1; 20%), and abdominal pain (n = 1; 20%). There were no discontinuations or severe liver events (e.g., decompensation). **Conclusion:** Patients with PFIC who had heterozygous variants in the same gene or across different genes all displayed similar clinical improvements, highlighting the effect of MRX across multiple PFIC genotypes.

1296 | REAL-WORLD OUTCOMES OF PATIENTS WITH PRIMARY BILIARY CHOLANGITIS IN CLINICALLY HIGH-RISK SUBGROUPS WHO INITIATED TREATMENT WITH ELAFIBRANOR

Channa Jayasekera[1] Cynthia Levy[2] Seema Meloni[3] Deborah Nikolla[3] Matthew Sobiesk[3] Christelle Pommie[4] Philip Troke[5] Christopher Bowlus[6], [1]Liver Transplant Program, Mayo Clinic Arizona, Pheonix, AZ, USA, [2]Schiff Center for Liver Diseases, University of Miami, Miami, FL, USA, [3]Ipsen, Cambridge, MA, USA, [4]Ipsen, Paris, France, [5]Ipsen, London, UK, [6]Division of Gastroenterology and Hepatology, UC Davis School of Medicine, Sacramento, CA, USA

Background: Primary biliary cholangitis (PBC), a chronic cholestatic liver disease, causes gradual liver dysfunction if untreated. Certain patient (pt) subgroups are at increased risk of disease progression and poor long-term clinical outcomes. Elafibranor, a peroxisome proliferator-activated receptor (PPAR)-α/δ agonist approved as a second-line treatment for PBC, demonstrated rapid and sustained biochemical efficacy in the phase III ELATIVE® trial. However, treatment effects in high-risk pts are less well established. Here, real-world (RW) data were used to assess early biochemical response following elafibranor initiation in pts with PBC within clinically relevant high-risk subgroups. **Methods:** This retrospective, observational study used RW data from the HealthVerity network. Adult pts with PBC who initiated elafibranor and had alkaline phosphatase (ALP) measurements both pre- and post-index were included; the index date was the date of first elafibranor exposure (baseline [BL]). Biochemical responses were assessed using laboratory data through 6 months (M) post-index for pts in high-risk subgroups: age < 40 years, male, those from underrepresented ethnic groups, decompensated cirrhosis 0–3 M before BL, BL ALP ≥ 3× the upper limit of normal (ULN), BL total bilirubin (TB) > ULN, and concomitant metabolic dysfunction-associated steatotic liver disease (MASLD). Results were analyzed using the Wilcoxon test. **Results:** Among 111 pts with PBC who initiated elafibranor with available BL and M6 data: 4 (3.6%) were aged < 40 years, 8 (7.2%) were male, 5 (4.5%) self-identified as Black, 41 (36.9%) self-identified as Latino/Hispanic, 9 (8.1%) had decompensated cirrhosis 0−3 M before BL, 8 (7.2%) had BL ALP ≥ 3× ULN, 12 (10.8%) had BL TB > ULN, and 12 (10.8%) had concomitant MASLD.While sample sizes were small, notable reductions in mean ALP levels were observed from BL to M6 in pts aged < 40 years (−23.9%), male pts (−32.2%), Latino/Hispanic pts (−15.9%), pts with decompensated cirrhosis (−25.0%), pts with BL ALP ≥ 3× ULN (−29.9%), pts with BL TB > ULN (−23.6%), and those with concomitant MASLD (−26.5%; **Figure A**). A smaller mean change from BL in ALP was observed in Black pts overall (−6.9%), however 3/5 (60.0%) of these pts had reductions ≥ 15% by M6. Among pts who had ALP > ULN at BL, ALP normalization was achieved in 2/3 pts aged < 40 years, 3/6 male pts, 13/34 Latino/Hispanic pts, 3/7 pts with decompensated cirrhosis, and 4/11 pts with concomitant MASLD (**Figure B**). **Conclusion:** Reductions in ALP were observed after 6M in high-risk subgroups of pts with PBC receiving elafibranor in RW settings. Given the limited published data, these key early findings suggest that elafibranor may improve liver biochemistry in high-risk pt populations that are not adequately responding to ursodeoxycholic acid.

Figure. ALP outcomes at M6 of elafibranor treatment in clinically high-risk pt subgroups

Error bars present SD. Decompensated cirrhosis recorded 0–3 months before BL. Percent with normalized ALP excludes those with normal ALP at BL. ALP: alkaline phosphatase; BL: baseline; CfB: change from baseline; MASLD: metabolic dysfunction-associated steatotic liver disease; M: Month; SD: standard deviation; ULN: upper limit of normal.

1297 | ADULT CHOLESTATIC DISEASE BEYOND PFIC: DIVERGENT RESPONSES TO MARALIXIBAT IN TWO COMPLEX ADULT CASES

Dimitrios Papanikolaou[1] Eleni Trifylli[1] Melanie Deutsch[1] Nikolaos Papadopoulos[2], [1]GI-Liver Unit, 2nd Department of Internal Medicine, General Hospital of Athens "Hippocratio", Nation, [2]National Organization for the Prevention and Treatment of Addictions (EOPAE), Athens, Greece

Background: Real-world adult experience with maralixibat (MRX), an ileal bile acid transport (IBAT) inhibitor, remains limited outside pediatric cholestatic disorders. We describe two adult cholestatic cases with divergent responses to IBAT inhibition. **Methods:** Retrospective chart review of clinical, biochemical, elastographic, histologic, and genetic data from two adult female patients treated with MRX for refractory cholestatic pruritus. Pruritus was assessed with the Clinician Scratch Scale (CSS: 0-4; 0 = no evidence of pruritus, 4 = cutaneous mutilation, bleeding, scarring); ≥ 1-point reduction is considered clinically meaningful. **Results:** Case 1 is a 41-year-old woman with Alagille syndrome (ALGS) and compensated cirrhosis (Child-Pugh A5, MELD-Na 8), presenting with severe refractory pruritus (CSS 4) causing major sleep disturbance despite relatively preserved liver biochemistry, albeit with elevated sBA (35 µmol/L). Following 1 year of MRX therapy, pruritus resolved completely (CSS 0) and sBA decreased to 2.2 µmol/L. Follow-up laboratory evaluation demonstrated stable compensated liver disease (Child-Pugh A5, MELD-Na 7). Liver stiffness measurement by transient elastography decreased from 14.5 to 10.2 kPa after approximately 18 months of MRX.Case 2 is a 59-year-old non-cirrhotic woman with severe (CSS 3) cholestatic pruritus, elevated sBA (31.3 µmol/L). Genetic testing identified two rare heterozygous *NPHP3* variants, including a novel likely pathogenic frameshift variant [c.1615_1619del p.(Leu539IlefsTer36)], suggesting a possible underlying ciliopathy-related cholangiopathic predisposition. Initial treatment with UDCA plus MRX resulted in partial biochemical improvement, but sBA increased to 41.3 µmol/L and pruritus persisted without clinical benefit. Liver biopsy subsequently demonstrated chronic cholangiopathy compatible with AMA-negative PBC. Following MRX discontinuation and initiation of fenofibrate in combination with UDCA, liver tests improved, although sBA increased to 82.8 µmol/L and pruritus remained severe. Reintroduction of MRX on background UDCA-fenofibrate therapy resulted in rapid and marked improvement of pruritus (CSS 1), with substantial symptomatic relief reported within weeks, while sBA decreased to 28.3 µmol/L after one month of MRX. **Conclusion:** Maralixibat was associated with marked improvement in pruritus, profound reduction in sBA, and reduction in liver stiffness in ALGS, while therapeutic benefit in AMA-negative PBC emerged after biochemical control with UDCA-fenofibrate. These findings support further evaluation of IBAT inhibition in complex adult cholestatic disease.

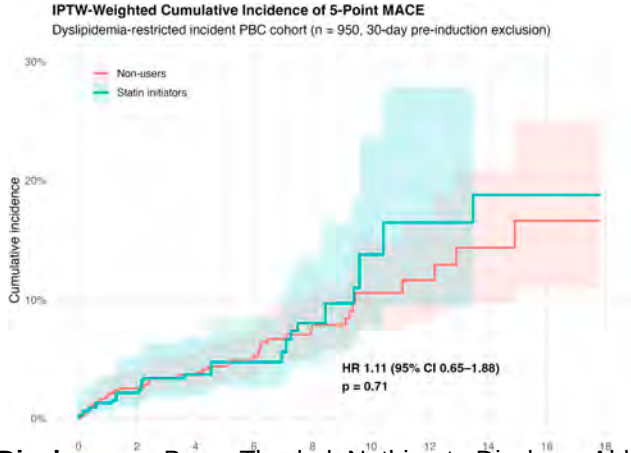
1298 | NEBOKITUG DOWN-REGULATES ECM CORE PROTEINS AND PATHWAYS IN PATIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

Revital Aricha[1] Tom Snir[1] Jack Lawler[1] Dave Weiner[1] Adi Mor[1], [1]Chemomab

Background: Primary sclerosing cholangitis (PSC) is an immune-mediated biliary disease, where the extracellular matrix (ECM) plays a critical role in the structural component of fibrosis. We aim to measure the effects of nebokitug, a CCL24-blocking monoclonal antibody currently in clinical development for PSC, on core ECM proteins and associated molecular pathways, using proteomic profiling of patients with PSC enrolled in the SPRING Phase 2 clinical study (NCT04595825). **Methods:** Serum proteins were quantified using the Olink proximity extension assay (PEA) in healthy

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



controls (n = 30) and patients with PSC enrolled in the SPRING study and treated with nebokitug 10 mg/kg (n = 21), nebokitug 20 mg/kg (n = 27), or placebo (n = 18) for 15 weeks. Linear regression was fitted to evaluate nebokitug's effect on patients with PSC and corrected for disease severity at baseline. Results were ranked based on a signed significance score and used as a basis for gene set enrichment analysis (GSEA). **Results:** Patients with PSC showed differential expression of ECM proteins, with multiple ECM proteins up regulated compared to healthy controls. Patients treated with nebokitug showed reduction of ECM proteins (collagens, proteoglycans, and glycoproteins) as compared to patients treated with placebo and overtime. This reduction was stronger in nebokitug treated patients with moderate to advanced disease. GSEA showed significant (<0.05 padj) down-regulation of ECM pathways, including ECM regulators, ECM organization, and several matrisome pathways. **Conclusion:** ECM proteins are differentially expressed in sera of PSC patients compared to healthy individuals, with multiple fibrosis driving proteins strongly up-regulated. Treatment with nebokitug resulted in suppression of ECM proteins and pathways, providing evidence of the pharmacological activities of nebokitug on fibrosis and inflammation.

1299 | STATIN INITIATION AND MAJOR ADVERSE CARDIOVASCULAR EVENTS IN INCIDENT PRIMARY BILIARY CHOLANGITIS: AN ACTIVE-INDICATION TARGET TRIAL EMULATION

Bryce Tkachuk[1] Aldo Montano-Loza[2] Juan Abraldes[2] Jason Jiang[3] Abdel-Aziz Shaheen[1], [1]University of Calgary, [2]University of Alberta, [3]Alberta Health Services

Background: Statins remain inconsistently prescribed in primary biliary cholangitis (PBC) because of potential hepatotoxicity concerns despite hepatoprotective benefits. Whether statin initiation alters major adverse cardiovascular event (MACE) risk in PBC is unknown. We emulated a target trial to estimate the association between statin initiation and MACE among incident PBC patients with dyslipidemia. **Methods:** We assembled 1,470 EMR-validated incident PBC patients in Alberta, Canada (2005-2024), linked to administrative and vital statistics data. After excluding prevalent MACE, early death, and baseline statin use, monthly eligibility windows were used in a single-entry target trial emulation from April 2005 to March 2025. New statin initiators entered at first dispensation and were compared with statin-naive non-users assigned one randomly sample eligible month to preserve temporal alignment. To approximate an active-indication trial, analyses were restricted to documented dyslipidemia (lab defined), and non-users were assigned a randomly sampled eligible trial month to preserve temporal alignment. Follow-up began after a 30-day induction period; early MACE or insufficient follow-up were excluded before propensity-score estimation. Stabilized inverse-probability-of-treatment weights, trimmed at the 1st/99th percentiles, balanced demographics, comorbidity, time since PBC diagnosis, ursodeoxycholic acid (UDCA) and cardiovascular medication use, LDL cholesterol, and calendar time. Weighted Cox models with robust standard errors estimated 5-point MACE (MI, stroke, CV death, heart failure, or revascularization); 3-point MACE was secondary. **Results:** Of 1,101 TTE-eligible patients, 964 had dyslipidemia. After induction exclusion, 950 were analyzed (255 statin initiators; 695 non-users). IPTW achieved excellent balance (all standardized mean differences <0.05): mean age 61 years, 11% male, mean LDL 3.2 mmol/L, and median follow-up 5.6 versus 5.5 years. During 5,906 person-years, 67 5-point MACE events occurred (22 statin, 45 non-user; rates 13.5 vs 10.5/1,000 person-years). Statin initiation was not associated with 5-point MACE (HR 1.11; 95% CI 0.65-1.88; p = 0.71, Figure 1) or 3-point MACE (44 events; HR 1.19; 95% CI 0.62-2.28; p = 0.61). MI was the most frequent event (n = 20), followed by heart failure (n = 18), stroke (n = 13), revascularization (n = 8), and CV death (n = 8). **Conclusion:** In this population-based, EMR-validated incident PBC cohort with dyslipidemia, sequential target trial emulation found no evidence that statin initiation affected MACE risk. These findings support statin prescribing for standard lipid indications, including dyslipidemia and for primary or secondary prevention of atherosclerotic cardiovascular disease.

1300 | REAL WORLD ANALYSIS OF PRIMARY BILIARY CHOLANGITIS SUBGROUPS AT RISK OF RAPID PROGRESSION

Brian Wentworth[1] Sonia Lee[2] Anusorn Thanataveerat[3] Christopher Adams[3] Stephanie Wall[3] Neil Shah[4], [1]University of Virginia School of Medicine, Charlottesville, VA, USA, [2]Ipsen, Cambridge, MA, USA, [3]Veradigm, Raleigh, NC, USA, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC, USA

Background: Primary biliary cholangitis (PBC) is a chronic cholestatic liver disease that can progress to cirrhosis, liver failure, and the need for liver transplant. Despite the availability of ursodeoxycholic acid as first-line treatment, some patients remain at increased risk of disease progression due to inadequate treatment response. This study used United States real-world data to describe demographics and clinical characteristics of high-risk PBC subgroups. **Methods:** This retrospective cohort study identified adults with newly diagnosed PBC and $\geq$6 months of prior continuous enrollment and documented activity in the Veradigm Network Electronic Health Records linked to Komodo Health claims data (Jan 2017–Dec 2025). Pre-defined high-risk subgroups included males, early-onset PBC (diagnosis $\leq$40 years), and markedly elevated baseline alkaline phosphatase (ALP; >2×upper limit of normal [ULN]). Exploratory subgroups of interest included Black and/or Hispanic patients, those with markedly elevated baseline total bilirubin (TB; >1×ULN), and concomitant metabolic dysfunction-associated steatotic liver disease (MASLD). Demographics and clinical characteristics were assessed during the 6-month baseline period. **Results:** The study included 21,406 patients. Among subgroups, 4,796 were males, 2,175 had early-onset PBC, 1,014 had markedly elevated baseline ALP, 2,940 were Black and/or Hispanic, 563 had markedly elevated baseline TB, and 4,414 had concomitant MASLD. Among males, mean (standard deviation [SD]) age was 61.4 (14.7) years and 18.1% had hepatic decompensation (cirrhosis/portal hypertension with diagnosed ascites), with a median (interquartile range [IQR]) ALP of 124.0 U/L (129.0), gamma-glutamyl transferase (GGT) of 151.0 U/L (251.3), and TB of 1.0 mg/dL (0.7). Despite only comprising 22.4% of the study population, males accounted for 41.0% of markedly elevated TB cases. Patients with early-onset PBC were mostly female (78.8%) with a mean (SD) age of 32.3 (6.1) years. This subgroup had the lowest proportion of hepatic decompensation (6.4% versus 9.9% overall). Patients with markedly elevated baseline TB had a median (IQR) platelet count of 165,000/mcL (139,000), the lowest across all subgroups. This subgroup had the highest proportions of portal hypertension (27.7%), hepatic decompensation (32.7%), and fatigue (35.9%) across subgroups (**Table**). **Conclusion:** Baseline disease severity at PBC diagnosis varied across subgroups and compared with the overall study population, with the proportions of hepatic decompensation ranging from 6.4% in early-onset patients to 32.7% in those with markedly elevated baseline TB. Elevated proportions of hepatic decompensation suggest many high-risk patients are beyond the benefit window of and/or may have contraindication for second-line therapy at diagnosis, underscoring the importance of earlier risk-based identification and intervention.

Table. Baseline demographic, clinical, and laboratory characteristics at PBC diagnosis

	All patients (N=21,406)		Males (N=4,796)		Early-onset PBC (N=2,175)		Elevated ALP levels at baseline* (N=1,014)		Elevated TB levels at baseline** (N=563)

1301 | PLATELET REACTIVITY AND PLATELET-IMMUNE CELL INTERACTIONS IN PBC ARE LINKED TO ALKALINE PHOSPHATASE LEVELS AND INCOMPLETE RESPONSE TO URSODIOL

Fallyn Kirlin[1] Subhasis Mohanty[1] Scott Roberts[1] Yasuko Iwakiri[2] David Assis[2] Matthew McConnell[2], [1]Yale School of Medicine, [2]Yale University

Background: Primary Biliary Cholangitis (PBC) is the most common autoimmune liver disease, and existing therapies still do not serve a substantial number of patients. New insights into disease pathogenesis are needed to identify novel therapeutic targets. Platelets can interact with immune cells in the setting of autoimmune disease, and this study aims to identify the pathological role of platelets in PBC. **Methods:** Platelet flow cytometry was performed from fresh whole blood (n = 10 patients). Banked PBMCs from PBC patients treated with UDCA and either normal (responder) or abnormal (non-responder) alkaline phosphatase (ALP) were included. Amnis Imagestream or CytoFlex LX flow cytometers were used. RNA was isolated from total PBMCs and analyzed with bulk RNAseq. **Results:** In PBC patients (n = 10), platelet reactivity measured by fold-change upregulation of platelet activation markers CD40L ($r2 = 0.48$, $p < 0.05$), CD62P ($r2 = 0.62$, $p < 0.01$), and PAC1 ($r2 = 0.73$, $p < 0.01$) upon collagen stimulation was significantly and positively correlated with ALP levels. Flow cytometry of PBMCs from responders (n = 10, mean ALP 94.2 U/L) vs. non-responders (n = 15, mean ALP 197.1 U/L) and co-staining for platelet marker CD41 identified significantly more platelet-interacting (CD41+) B cells in non-responders vs. responders (18.86%, 12.93%, $p = 0.03$). Platelet interactions in other populations (CD4 T cells, CD8 T cells, monocytes) were observed with no significant differences in non-responders vs. responders. Bulk RNAseq was done from non-responder (n = 10) and responder (n = 9) PBMCs, and deconvolution revealed a "platelet" cluster. This cluster expressed high proportions of T cell, B cell, and monocyte markers, suggesting it consists of platelet-immune cell aggregates. To visualize these aggregates, Amnis Imagestream was used to show discrete platelet (CD41+) events on the surface of lymphocytes in our PBMC samples, indicating cell-cell interactions. Within those aggregates, platelet activation pathways were found to be significantly upregulated in non-responders, suggesting immune cell interaction with more activated platelets in non-responders. Via deconvolution, we performed pathway analysis within total B cells showing upregulation(NES 1.4, FDR < 0.05) of the systemic lupus erythematosus pathway in non-responders. IL10 is a leading-edge gene within this pathway and can have a pathological role in autoimmunity. **Conclusion:** Increased platelet reactivity in PBC patients correlates with serum ALP levels. Platelet-B cell interactions are significantly increased in PBC patients who did not respond to UDCA. Bulk RNAseq and cell-type deconvolution also identify enhanced immune cell interactions with activated platelets, and upregulation of autoimmune signals in B cells, in non-responders. Platelet-B cell interactions may be a mechanism of disease pathogenesis in PBC and a novel candidate target for therapeutic interventions.

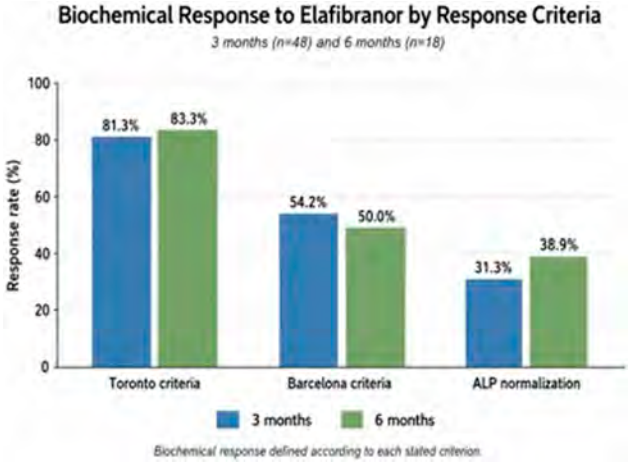
1302 | ASSESSING REAL-WORLD OUTCOMES IN PATIENTS WITH PRIMARY BILIARY CHOLANGITIS ON ELAFIBRANOR



Ibrahim Alomar[1], [1]Division of Gastroenterology and Hepatology, Western University & London Health Sciences Centre

Background: Primary biliary cholangitis is a chronic cholestatic liver disease that may progress to cirrhosis and liver failure. Elafibranor has shown biochemical efficacy in clinical trials, but real-world data remain limited. We aimed to evaluate the effectiveness and safety of elafibranor in patients with PBC treated in routine clinical practice. **Methods:** We conducted a single-center observational cohort study of adults with PBC treated with elafibranor. Clinical, biochemical, treatment, and safety data were collected from medical records. The primary outcome was biochemical response, defined as ALP $< 1.67 \times$ ULN and total bilirubin $\leq$ ULN. Descriptive statistics were used, and logistic regression estimated odds ratios for factors associated with response. **Results:** A total of 51 patients with PBC treated with elafibranor were included. Most patients were female (47/51, 92.2%), with a mean age at PBC diagnosis of 52.3 ± 12.5 years and a mean age at elafibranor initiation of 61.7 ± 10.9 years. Positive autoimmune markers were present in 45/51 patients (88.2%), and AMA positivity was observed in 38/51 (74.5%). At treatment initiation, 13/51 patients (25.5%) had cirrhosis, and baseline ALP was 240.8 ± 109.0. Coexisting liver disease was present in 31/51 patients (60.8%), most commonly MASLD (23/51, 45.1%),

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

followed by AIH overlap (8/51, 15.7%), MetALD (2/51, 3.9%), and ALD (1/51, 2.0%); no patients had coexisting PSC (0/51, 0%). All patients had previously received UDCA (51/51, 100%), and elafibranor was combined with UDCA in 47/51 (92.2%); the main indication for elafibranor was inadequate biochemical response (47/51, 92.2%). At 3 months, biochemical response according to Toronto criteria was achieved in 39/48 patients (81.3%), while 26/48 (54.2%) met Barcelona criteria and 15/48 (31.3%) achieved ALP normalization. At 6 months, mean ALP was 152.4 ± 54.7, and 15/18 patients (83.3%) met Toronto criteria, 9/18 (50.0%) met Barcelona criteria, and 7/18 (38.9%) achieved ALP normalization. Adverse events were reported in 11/50 patients (22.0%), most commonly nausea, and treatment discontinuation due to adverse events occurred in 3/51 patients (5.9%).In logistic regression, higher baseline ALP and ALT was associated with lower odds of biochemical response at 3 months (OR 0.99, 95% CI 0.98–1.00; p = 0.016 and OR 0.96, 95% CI 0.93–1.00; p = 0.030), while no significant associations were observed for age, sex, AMA positivity, coexisting MASLD or AIH, cirrhosis, or prior exposure to OCA or fibrates. **Conclusion:** Elafibranor was associated with a high biochemical response rate as early as 3 months in this real-world PBC cohort. Treatment discontinuation was infrequent, and higher baseline ALP and ALT were associated with lower odds of early response.

1303 | THE HEPATIC VENOUS PRESSURE GRADIENT IDENTIFIES HISTOLOGICAL ADVANCED FIBROSIS (F3–F4) IN AUTOIMMUNE HEPATITIS

Álvaro Urzúa[1] Víctor Henríquez-Auba[1] Daniela Simian[1] Diego Lizama[2] Jorge Chiong[2] Jaime Poniachik[2], [1]Hospital Clínico Universidad de Chile, [2]Universidad de Chile

Background: The hepatic venous pressure gradient (HVPG) correlates with fibrosis across several liver diseases, but evidence in autoimmune hepatitis (AIH) remains limited. The aim was to assess the association between HVPG and fibrosis, its performance for advanced fibrosis (AF), the optimal cutoff, and its relationship with 6-months biochemical response. **Methods:** Between January 2018 and July 2025, 208 hemodynamic procedures were performed. Of these, 77 had histology consistent with AIH. Overlap syndromes (n = 22), treatment at biopsy (n = 3), post–liver transplant AIH (n = 1), and uninterpretable HVPG due to communicating veins (n = 6) were excluded, yielding 47 treatment-naïve patients with AIH. Patients were classified as without AF (F0–F2) orwith AF (F3–F4). ROC analysis, the Liu method, and univariate logistic regression were performed. The association between HVPG and biochemical response was evaluated. **Results:** Median age was 59 years (17–79), and 74% were women. HVPG was higher in AF than in F0–F2 (15.5 vs 7.0 mmHg; p < 0.001). The AUROC for AF was 0.84 (95%CI 0.72–0.96). Each 1-mmHg increase in HVPG increased the odds of AF by 29% (OR 1.29;95%CI 1.11–1.50; p = 0.001). The optimal cutoff was 10.5 mmHg (sensitivity 0.85; specificity 0.76), above which the odds of AF were 17.6-fold higher. HVPG was not associated with biochemical response (p = 0.701). **Conclusion:** In treatment-naïve AIH, HVPG was associated with AF and showed good diagnostic accuracy. A 10.5-mmHg threshold may help identify AF. HVPG did not predict early 6-months biochemical response.

1304 | REAL-WORLD BIOCHEMICAL RESPONSES TO FIRST-LINE AZATHIOPRINE VERSUS MYCOPHENOLATE AND UPON SWITCHING FROM AZATHIOPRINE TO MYCOPHENOLATE IN AUTOIMMUNE HEPATITIS PATIENTS

Astrid Amador[1] Stephen Wong[1], [1]University of Santo Tomas Hospital

Background: Mycophenolate mofetil (MMF) has been found to be comparable to azathioprine (AZA) in achieving biochemical remission in autoimmune hepatitis (AIH). We aimed to compare real-world biochemical responses of first-line AZA and MMF, and responses after switching from AZA to MMF in AIH patients **Methods:** We analyzed a retrospective cohort of AIH patients treated with AZA or MMF. Patients received concomitant steroids 0-14 days prior to AZA or MMF. Biochemical responses were defined as: complete response(CR) = alanine aminotransferase (ALT) normalization; partial response(PR) = ≥50% ALT reduction but above normal upper limits (ULN); non-response(NR) = <50% ALT reduction or ALT increase. We analyzed a subset who switched from AZA to MMF. **Results:** Overall, 67(AZA) and 12(MMF) patients were included. CR progressively increased after 3 (AZA = 52% vs. MMF = 55.6%;p = 0.236), 6 (AZA = 61.7% vs. MMF = 100%;p = 0.760) and 12 months (AZA = 76.9% vs. MMF = 100%;p = 1.0) of treatment, with no difference in NR rates (AZA = 5.1% vs. MMF = 0%;p = 1.0) after 12 months. Despite similar response rates, AZA demonstrated greater median ALT reduction at 3 months vs. MMF (ΔALT −111.8 vs −1.0 U/L;p = 0.008). The reasons for AZA to MMF switch were AZA unavailability (n = 16;76.2%) and side effects to AZA (n = 5;23.8%). Following switching, most patients maintained biochemical stability after 6months (87.5%). However, biochemical flare (ALT ≥ 2×ULN) occurred in 3(14.3%) patients, prompting reversion to AZA. **Conclusion:** Our data support the effectiveness of MMF as first-line therapy. However, switching from AZA to MMF may be associated with biochemical flare in a subset of patients, highlighting the need for cautious use in clinical practice with close biochemical monitoring.

1305 | PREVALENCE AND CLINICAL OUTCOMES OF MASLD OVERLAP IN PATIENTS WITH AUTOIMMUNE LIVER DISEASE: A DESCRIPTIVE COHORT ANALYSIS

Victoria Abadi-Ron[1] Ana Marenco-Flores[2] Natalia Rojas Amaris[1] Fernando Munguia[1] Giuliana Arevalo[3] Romelia Barba[4] Daniela Goyes[5] Esli Medina Morales[6] Leandro Sierra[7] Behnam Saberi[8] Vilas Patwardhan[1] Alan Bonder[1], [1]Beth Israel Deaconess Medical Center, [2]Harvard Medical School, [3]Department of Internal Medicine, University of Miami / Jackson Memorial Hospital, [4]Texas Tech University, [5]Yale School of Medicine, New Haven, [6]Washington University in St Louis, [7]Cleveland Clinic Foundation, [8]BIDMC Harvard Medical School

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is increasingly recognized as a comorbidity in chronic liver disease, but its prevalence and clinical associations in autoimmune liver diseases (AILD) remain unclear. We evaluated MASLD overlap prevalence in autoimmune hepatitis (AIH), primary biliary cholangitis (PBC), and primary sclerosing cholangitis (PSC), and its association with clinical features and complete biochemical response (CBR). **Methods:** We performed a cross-sectional analysis using electronic medical records and prospectively collected data from our Autoimmune Liver Diseases Registry at Beth Israel Deaconess Medical Center. Patients with AIH, PBC, or PSC were included. MASLD was defined as body mass index ≥25 kg/m² plus ≥1 cardiometabolic risk factor, including diabetes mellitus, hypertension, hyperlipidemia, or coronary artery disease. CBR was disease-specific: POISE criteria for PBC, alkaline phosphatase below the upper limit of normal for PSC, and normalization of aminotransferases and immunoglobulin G for AIH. Laboratory values recorded as 0 were treated as missing. Continuous variables were compared using Mann–Whitney U tests and categorical variables using Fisher's exact tests. Multivariable logistic regression assessed the association between MASLD overlap and CBR, adjusting for age, sex, AILD subtype, and cirrhosis. **Results:** Among 343 patients with AILD, 103 (30.0%) had MASLD overlap. Prevalence was similar across subtypes: AIH 45/146 (30.8%), PBC 24/94 (25.5%), and PSC 34/103 (33.0%) (p = 0.501). Patients with MASLD overlap had higher BMI (31.0 [27.9–35.5] vs. 25.0 [22.6–28.9] kg/m²; p < 0.001), hyperlipidemia (42.0% vs. 18.7%; p < 0.001), and hypertension (59.4% vs. 24.6%; p < 0.001). Type 2 diabetes was numerically higher but not significant (10.3% vs. 4.7%; p = 0.109). Cirrhosis was less frequent with MASLD overlap (19.4% vs. 29.7%; p = 0.048). CBR was similar between groups (65.0% vs. 63.2%; p = 0.742). Baseline liver biochemistries did not significantly differ. In multivariable analysis, MASLD overlap was not independently associated with CBR (adjusted OR 0.96, 95% CI 0.57–1.63; p = 0.891). **Conclusion:** MASLD overlap was common in AILD, affecting nearly one-third of patients, with similar prevalence across AIH, PBC, and PSC. It was associated with higher BMI and greater metabolic comorbidity burden, but not with lower odds of CBR. These findings support routine metabolic risk assessment in AILD.

Interpretation is limited by the single-center design and modest cohort size, particularly within disease-specific subgroups; larger multicenter studies are needed to assess long-term outcomes.

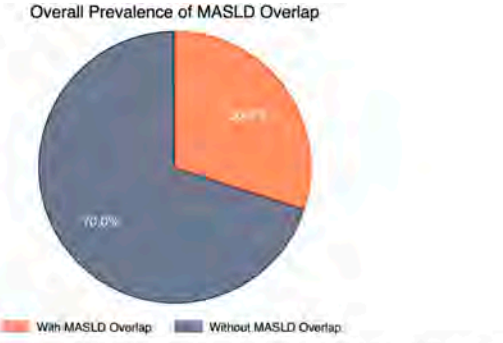

Figure 1. Overall prevalence of MASLD overlap in the autoimmune liver disease cohort. MASLD overlap was present in 103 of 343 patients (30.0%), while 240 of 343 patients (70.0%) had no MASLD overlap. MASLD = metabolic dysfunction-associated steatotic liver disease.

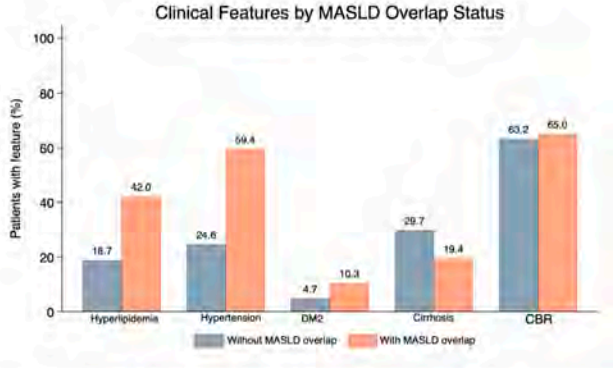

Figure 2. Clinical features by MASLD overlap status. Bars represent the percentage of patients with each feature among patients without MASLD overlap and those with MASLD overlap. Patients with MASLD overlap had higher prevalence of hyperlipidemia (42.0% vs. 18.7%, p<0.001) and hypertension (59.4% vs. 24.6%; p<0.001), while type 2 diabetes mellitus was numerically higher but not statistically significant (10.3% vs. 4.7%; p=0.109). Cirrhosis was less frequent in patients with MASLD overlap (19.4% vs. 29.7%; p=0.048), and complete biochemical response was similar between groups (65.0% vs. 63.2%; p=0.742). P values were calculated using Fisher's exact test. MASLD = metabolic dysfunction-associated steatotic liver disease; DM2 = type 2 diabetes mellitus; CBR = complete biochemical response.

1306 | TEMPORAL TRENDS, SOURCE-REGION DISTRIBUTION, AND CLINICAL PHENOTYPIC HETEROGENEITY OF PRIMARY BILIARY CHOLANGITIS: A 17-YEAR REAL-WORLD COHORT OF 4,646 PATIENTS FROM CHINA

Xiao Lin[1] Chunyang Huang[1] Bin Xu[1] Xue Yang[1],
[1]Beijing Youan Hospital, Capital Medical University

Background: Long-term real-world data on primary biliary cholangitis (PBC) in China remain limited, particularly regarding temporal trends, source-region distribution, and clinical phenotypic heterogeneity. We evaluated annual case volume, source-region composition, and clinical phenotypes in a tertiary liver-center cohort. **Methods:** We retrospectively included 4,646 PBC patients at Beijing YouAn Hospital, Capital Medical University, from January 1, 2008, to December 31, 2024. For repeated visits, the first qualifying record was used. Demographics, source region, liver biochemistry, immunoglobulins, autoantibodies, cirrhosis, histology, concomitant liver diseases, extrahepatic autoimmune diseases, and viral markers were collected. Beijing patients were compared with patients from the top eight non-Beijing source regions. **Results:** Annual PBC case volume showed an overall upward trend. Women accounted for 86.7% of the cohort; mean age was 56.5 ± 11.7 years. AMA, AMA-M2, anti-gp210, and anti-sp100 positivity rates were 87.3%, 89.8%, 30.4%, and 19.1%, respectively. Total bilirubin categories of ≤34, >34–102, >102–170, and >170 μmol/L accounted for 72.5%, 17.6%, 4.0%, and 5.9% of patients; cirrhosis was present in 888 patients (19.1%). Among 4,637 patients with source-region data, Beijing was the leading source region [1,515 (32.67%)], followed by Hebei [698 (15.05%)] and Inner Mongolia [652 (14.06%)]; these regions accounted for 61.79%. Other leading non-Beijing source regions included Heilongjiang, Shanxi, Shandong, Henan, Liaoning, and Jilin. North China and Northeast China accounted for 69.14% and 12.31%, respectively, comprising 81.45% of patients. Beijing patients were older than patients from the leading non-Beijing source regions (60.9 ± 11.7 vs. 54.5 ± 11.2 years, P < 0.001), but had lower ALT, AST, total bilirubin, GGT, ALP, and IgM levels. AMA positivity was lower in Beijing patients [84.3% (1,236/1,466) vs. 87.9% (2,143/2,438), P = 0.002], whereas AMA-M2 positivity was higher [89.8% (1,135/1,264) vs. 86.2% (1,977/2,294), P = 0.002]. Anti-sp100 positivity was slightly higher in Beijing patients [20.8% (266/1,276) vs. 18.0% (388/2,151), P = 0.048], while anti-gp210 positivity was similar (29.1% vs. 30.4%, P = 0.442). Cirrhosis prevalence was comparable [14.3% (217/1,515) vs. 15.5% (393/2,539), P = 0.342]. Overall, 21.1% had concomitant liver diseases, mainly autoimmune hepatitis, drug-induced liver injury, and steatotic liver disease; 311 patients (6.69%) had extrahepatic autoimmune diseases, mainly Sjögren's syndrome. **Conclusion:** In this 17-year real-world PBC cohort, annual recorded case volume showed an overall upward trend, and patient sources were concentrated in North and Northeast China. Differences in age, biochemical activity, and autoantibody profiles between Beijing and major non-Beijing source regions highlight clinical phenotypic heterogeneity in PBC.

1307 | ACCELERATED BIOLOGICAL AGING IN CHOLESTATIC LIVER DISEASE: TELOMERE ATTRITION AND ASSOCIATION WITH DISEASE SEVERITY

Saqr Alsakarneh[1] Biran Juran[1] Jenna Fernandez[1] Mrinal Patnaik[1] Gregory Gores[1] Nicholas LaRusso[1] Konstantinos Lazaridis[1], [1]Mayo Clinic

Background: Primary sclerosing cholangitis (PSC) and primary biliary cholangitis (PBC) are chronic cholestatic liver diseases associated with progressive fibrosis and hepatic complications. Emerging evidence suggests that accelerated biological aging may contribute to chronic inflammatory diseases. DNA methylation–derived telomere length (DNAmTL), a marker of replicative aging and cellular turnover, has not been characterized in PSC or PBC. We aimed to evaluate DNAmTL in PSC and PBC and assess its relationship with disease severity and epigenetic aging. **Methods:** We analyzed 1,540 individuals from a multicenter cohort with DNA methylation profiling, including PSC (n = 474), PSC controls (n = 484), PBC (n = 291), and PBC controls (n = 291). DNAmTL and age-adjusted DNAmTL were compared across groups. Associations with clinical outcomes were evaluated using nonparametric testing and multivariable logistic regression adjusting for age and sex. Correlations with the Primary Sclerosing Cholangitis Risk Estimate Tool (PRESTO) score and epigenetic age acceleration (AgeAccelGrim) were assessed using linear regression models. **Results:** PSC patients demonstrated significantly shorter age-adjusted DNAmTL compared with controls (median −0.036 vs 0.016; $p < 0.001$; Figure 1-A). Similarly, PBC patients exhibited reduced DNAmTL relative to controls (median 6.814 vs 6.885; $p < 0.001$; Figure 1-B). Within PSC, shorter DNAmTL was associated with cirrhosis and advanced disease, with associations persisting after age adjustment (both $p = 0.001$). In multivariable analyses, shorter DNAmTL independently associated with cirrhosis (OR 0.17, 95% CI 0.05–0.56, $p = 0.0039$) and advanced liver disease (OR 0.17, 95% CI 0.05–0.55, $p = 0.003$). Shorter DNAmTL was also observed in hepatic decompensation and hepatobiliary malignancy, including cholangiocarcinoma. DNAmTL inversely correlated with PRESTO score (Figure 1-C) and strongly correlated with AgeAccelGrim (Figure 1-D) in both PSC and PBC (all $p < 0.001$). **Conclusion:** PSC and PBC are associated with telomere shortening relative to controls, supporting accelerated biological aging in cholestatic liver disease. In PSC, telomere attrition independently associates with disease severity, suggesting DNAmTL may represent a clinically relevant biomarker of progressive disease biology. These findings identify telomere attrition as a clinically relevant and complementary dimension of biological aging in cholestatic liver disease.

Santamaría[7] Jose Manuel Sousa Martin[1] Javier Ampuero Herrojo[1], [1]Hospital Universitario Virgen del Rocío, [2]Hospital Universitario Virgen Macarena, [3]Hospital Universitario Regional de Málaga, [4]Hospital Universitario Virgen Valme, [5]Hospital Universitario Costa del Sol, [6]Hospital Universitario Torrecárdenas, [7]Hospital Universitario Puerto Real

Background: Despite the existence of national and international guidelines for primary biliary cholangitis (PBC), the management of this condition remains highly heterogeneous. Furthermore, data focusing on the PBC care cascade are limited. We characterized the different steps in the PBC care cascade, and evaluated adherence to the key recommendations of the international guidelines for PBC. **Methods:** This multicenter retrospective study included 387 PBC patients from seven hospitals. We collected data on: a) the care cascade (e.g., indications for testing PBC-specific autoantibodies, time to referral to a specialist, and time to PBC diagnosis); b) healthcare-related characteristics (e.g., the clinical unit responsible for patient management, the clinician's experience with PBC, and hospital characteristics); and c) adherence to guideline-recommended standards of care (e.g., comprehensive symptom assessment, evaluation of liver fibrosis, assessment of response to ursodeoxycholic acid and consideration of second-line therapy, and surveillance for complications of cirrhosis). **Results:** Up to 90% of patients were female, with a mean age of 55 years at the time of diagnosis. Advanced fibrosis (F3–F4) was observed in 11.8% of patients, while 9.4% had overlap with autoimmune hepatitis. In addition, 34.5% of patients were symptomatic at baseline. The number of visits required to establish the final diagnosis was 3.2 +/- 3.8.The main reason for assessing PBC-specific autoantibodies was cholestasis (58%), while a history of prior cholestasis was present in up to 87% of patients. Most patients (62.6%) were from urban areas, and 51.3% were treated at a referral center. A total of 51% of patients were diagnosed in Hepatology departments, while 45.9% were diagnosed in Gastroenterology departments. However, 85.9% were ultimately followed up by hepatologists. In addition, 74.6% of patients were managed by specialists with experience in treating more than 30 PBC patients.On the other hand, some adherence to the main recommendations differed significantly between clinicians managing more than 30 patients and those managing fewer than 30 patients (Figure). **Conclusion:** Nearly 90% of patients exhibited cholestasis prior to the diagnosis of PBC; however, cholestasis was the indication for testing PBC-specific autoantibodies in only 60% of cases. In addition, greater clinician experience was associated with better adherence to the key recommendations outlined in the guidelines.

1309 | 肠道微生物群和代谢的变化与PBC的严重程度相关。

Qi Wang[1] Chunyang Huang[1] Minghui Li[1] Ronghua Jin[1], [1]Beijing Ditan hospital

Background: 本研究旨在探讨原发性胆管炎(PBC)患者在代谢特征和肠道微生物群上的差异,这些患者在GP210抗体阳性(GP210_pos)和GP210抗体阴性(GP210_neg)患者之间存在差异。 **Methods:** 本研究采用非靶向代谢组学分析31名GP210抗体阴性患者与13名GP210抗体阳性患者间的血清代谢物差异。此外,还使用16S rRNA测序比较两组患者间肠道微生物群的组成。我们进一步利用桑基图和相关网络图探讨了不同代谢产物与不同细菌属之间的相关性。最后,对每种代谢物进行了ROC曲线分析,以评估其识别和预测GP210抗体阳性PBC的有效性。 **Results:** GP210_pos患者共鉴定出11个差异细菌属,其中4个属的相对丰度显著增加,7个属显著减少,同时发现9个差异代谢物。其中,增加的属如*Gemmiger*、*Faecalibacterium*、嗜血杆菌和巨型酵母属与1-过氧费罗酮类、类固醇O-硫酸盐呈显著负相关,与10,16-二羟基己腺酸呈显著正相关。相反,减少的链球菌属和沙门氏菌属与Synaptolepis K1因子、子甲酰胺F和Cassaidine呈显著负相关。此外,ROC曲线分析显示Chaksine的AUC值最高,达0.74,显示出强烈的预测能力。 **Conclusion:** 本研究发现GP210_pos PBC患者在代谢物谱和肠道微生物组成方面存在显著差异。单变量ROC分析结果特别强调Chaksine在其预测模型中具有强预测能力(AUC = 0.74)。

1310 | CLINICAL AND SEROLOGIC CHARACTERISTICS OF PRIMARY BILIARY CHOLANGITIS IN VIETNAM: A REAL-WORLD CASE SERIES

Khiem Pham[1] Khanh Vu Truong[1], [1]Tam Anh General Hospital

Background: Primary biliary cholangitis (PBC) is a chronic autoimmune cholestatic liver disease with heterogeneous clinical and serologic manifestations. Diagnosis may be challenging in patients with atypical biochemical patterns or negative anti-mitochondrial antibody (AMA). Data regarding PBC in Vietnam remain limited. This study aimed to describe the clinical, biochemical, and immunologic characteristics of patients with PBC in a real-world setting in Vietnam. **Methods:** We conducted a retrospective case series of patients diagnosed with PBC at Tam Anh General Hospital between 2022 and 2025. Diagnosis was established based on at least two of the following criteria: cholestatic liver biochemistry, AMA positivity or PBC-specific antinuclear antibodies (anti-Sp100 and/or anti-gp210), and compatible histology. Clinical, biochemical, and immunologic characteristics were analyzed descriptively. Liver injury patterns were classified using the R ratio. **Results:** Sixteen patients were included. Patients were predominantly female (93.8%), with a median age of 59.5 years (IQR 54–65.5). At diagnosis, 43.8% (7/16) were asymptomatic and identified incidentally through abnormal liver biochemistry. Among symptomatic patients, cirrhosis was present in 55.6%, while pruritus and jaundice were each observed in 44.4%.A cholestatic liver injury pattern was observed in 68.8% of patients, whereas hepatocellular and mixed patterns were identified in 18.8% and 12.5%, respectively. AMA positivity was detected in 68.8% (11/16) of patients, while 31.2% (5/16) were AMA-negative and required diagnosis based on PBC-specific antinuclear antibodies. Anti-gp210 and anti-Sp100 antibodies were positive in 43.8% and 26.7% of tested patients, respectively. Time from initial abnormalities to confirmed diagnosis varied substantially, with delays of up to 8 years. **Conclusion:** PBC in this Vietnamese cohort frequently presented with asymptomatic disease, atypical biochemical patterns, and AMA-negative serology, which may contribute to delayed diagnosis in clinical practice. PBC-specific antinuclear antibodies, particularly anti-gp210 and anti-Sp100, provided important diagnostic support in AMA-negative cases. Broader access to specialized autoantibody testing may facilitate earlier diagnosis of PBC in resource-limited settings.

1311 | SYMPTOM BURDEN IN PEOPLE WITH PSC-ASSOCIATED PRURITUS: A US-BASED SURVEY TO UNDERSTAND PATIENTS' LIVED EXPERIENCES WITH PSC

Jonathan Ieyoub[1] Brian Thorsen[2] Joanne Hatchett[2] Rachel Gomel[2] Mara Peters[1] Jolan Terner-Rosenthal[1] Lindsey Spelying[1] Brandon Gordon[3] Erika Sloan[3] Stephen Rossi[2] Robin Howard[1], [1]Mirum Pharmaceuticals, Inc., [2]PSC Partners Seeking a Cure, [3]Charles River Associates

Background: Primary sclerosing cholangitis (PSC) is a rare, chronic liver disease associated with progressive damage to hepatic bile ducts and cholestasis-related symptoms such as pruritus and fatigue, which have a significant impact on health-related quality of life (HRQoL). People with PSC often report symptom manifestation well before diagnosis, and pruritus and fatigue are largely independent of disease stage. This study aims to better understand and quantify people's experiences with pruritus and with other key symptoms of PSC. **Methods:** A 15-minute de-identified online survey and 45-minute follow-up qualitative interviews to understand the experiences and perspectives of people with PSC-associated pruritus living in the US were conducted in Fall 2025 through PSC Partners Seeking a Cure. Descriptive statistics were performed. Here we report results from the online questionnaire. **Results:** 89 individuals living with PSC all self-reported in screening some level of pruritus currently (52% male; mean [SD] age 42 [12.7] years old; 56% between 41-60 years old) were included. Pruritus was the most common first symptom before diagnosis (30%), more often in those with IBD than without ($P < 0.05$). Symptoms presented, on average, 22 months before diagnosis. 46% of patients have self-reported moderate-severe pruritus, 65% report damage/visible marks to skin, 57% have difficulty sleeping at night due to pruritus, 51% have difficulty sitting still or being comfortable, and 51% report others commenting or asking questions about itching. One-third reported itching is constantly present, but also flares/gets worse at times lasting days to weeks, with 26% of flares lasting ≥ 1 week. Common triggers for flares include heat, stress, clothing, and other PSC symptoms. The most common treatments for pruritus were antihistamines (70%), UDCA (65%), cholestyramine (40%), and rifampicin (25%).13% of patients discontinued ≥ 1 of these treatments at < 1 year of use due to lack of

symptom improvement. Besides pruritus, fatigue (56%) and difficulty sleeping (43%) were among the most common symptoms noted. Respondents reported pruritus or fatigue having the greatest impact (70% very/extremely impactful) on their HRQoL with it worsening over time and usually flaring together. **Conclusion:** For people with PSC-associated pruritus, initial findings demonstrate that pruritus, fatigue, and difficulty sleeping are some of the most high-impact HRQoL symptoms that people with PSC experience and continue to be a significant burden on their lives without adequate treatments available to provide relief.

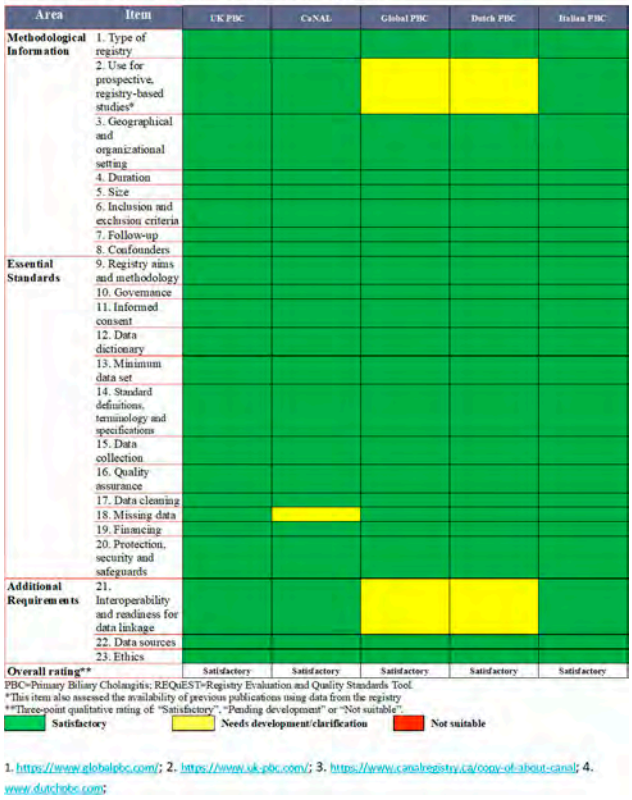
1312 | ASSESSING THE "FIT-FOR-USE" OF INTERNATIONAL PRIMARY BILIARY CHOLANGITIS (PBC) PATIENT REGISTRIES FOR REAL-WORLD EVIDENCE (RWE) STUDIES INTENDED TO SUPPORT REGULATORY DECISION MAKING

Sandrine Cure[1] Bettina Hansen[2] Adriaan Van der Meer[3] Gideon Hirschfield[4] George Mells[5] Pietro Invernizzi[6] Marco Carbone[7] Alessio Gerussi[8] Umberto Vespasiani-Gentilucci[9] Sandrine Cure[1] Nathalie Dunkel[1] Femi Adekunle[1] Nick Warwick[1] Madeline Cameron[10] Ellen Werner[11] Gemma Weijsters[12] Tiki Blom[11] Laura Cristoferi[13] Elisa Merelli[14] Samuel Igweokpala[15] Irene Pan[15], [1]ADVANZ PHARMA, [2]Erasmus MC Rotterdam, [3]Erasmus University Medical Center, [4]Toronto General Hospital, [5]Newcastle University, Newcastle, UK, [6]Fondazione IRCCS San Gerardo dei Tintori, [7]Liver Unit, ASST Grande Ospedale Metropolitano (GOM) Niguarda, Milan, Italy ;, [8]IRCCS San Gerardo dei Tintori, Monza, Italy;, [9]Department of Hepatology, University Campus Bio-Medico, Rome, Italy, [10]Toronto Centre for Liver Disease and TGHRI, University Health Network, Toronto, Ontario, Canada, [11]Departement of gastroenterology and hepatology, Erasmus University Medical Center, Rotterdam, [12]Departement of gastroenterology and hepatology, Erasmus University Medical Center, Rotterdam,, [13]ERN RARE-LIVER, Fondazione IRCCS San Gerardo dei Tintori, Monza, Italy, [14]IRCCS San Gerardo dei Tintori, Monza, Italy, [15]United BioSource LLC



Background: Randomized clinical trials (RCTs) remain the gold standard for regulatory decision-making in primary biliary cholangitis (PBC); however, real-world data may complement RCT evidence, particularly when RCTs are challenging to operationally execute. Regulatory-grade real-world evidence (RWE) requires "fit-for-use" data sources with reliable, reproducible, and well-documented data. No systematic feasibility assessment has previously evaluated PBC registries for this purpose. This study assessed their suitability for regulatory-grade RWE generation. **Methods:** Five registries — Global PBC[1], UK PBC[2], CaNAL[3], Dutch PBC[4], and Italian PBC — were evaluated. Selection of the cohorts was based on long-term follow-up, prior use in RWE studies, representativeness of the PBC population in the relevant country or region, and clinician-collected data supported by verifiable source records. A structured feasibility assessment, including a questionnaire incorporating REQueST (Registry Evaluation and Quality Standards Tool), was conducted to evaluate whether existing registries or cohorts could provide sufficient longitudinal, fit-for-use data from a regulatory perspective, including data accuracy, validity, variability, reliability, and provenance. Two independent reviewers assessed questionnaire responses and supporting documents and resolved discrepancies by consensus. They assigned item-level ratings based on REQueST's minimum standard and assessment criteria for each item (i.e., Methodological Information (8 items), Essential Standards (12 items), and Additional Requirements (3 items). Follow-up meetings with registry representatives were held as needed. Each registry was then assigned an overall rating of "Satisfactory," "Needs development/clarification," or "Not suitable" as a potential data source. **Results:** Across the 23 REQueST areas, all five registries were rated overall as satisfactory (**Table 1**). Identified limitations included restricted prospective use for Global PBC and Dutch PBC, incomplete documentation of missing data management in CaNAL, and restrictions on patient-level data sharing in some registries. The assessment reflected compliance with REQueST criteria rather than full alignment with the specific study research question. **Conclusion:** The qualitative assessment using REQueST found all five PBC registries to be of good quality and suitable for regulatory-grade research. The identified

limitations were considered manageable operational challenges rather than critical barriers. These findings support the feasibility of using international PBC registries for future regulatory-grade observational studies in PBC.

1313 | ASSOCIATION BETWEEN TREATMENT ADHERENCE AND HEALTHCARE UTILIZATION AMONG INDIVIDUALS WITH PRIMARY BILIARY CHOLANGITIS IN THE UNITED STATES

Robert Gish[1] Michel Mendler[2] Edward Mena[2] Chong Hoon Kim[3] Yi Pan[4] Lauren Do[4] Mihail Samnaliev[4] Diane Ito[4] Maria Agapova[3], [1]Robert G Gish Consultants LLC, [2]California Liver Research Institute, Pasadena, CA, [3]Gilead Sciences, Foster City, CA, USA, [4]Stratevi

Background: Primary biliary cholangitis (PBC) is a progressive, chronic autoimmune liver disease that can lead to significant burden for individuals, healthcare systems, and payers. Inadequate disease control, from poor adherence to PBC treatment, can contribute to worsening liver function and increased need for medical care. In previous analyses adherence predicted a lower risk of PBC disease progression and death. This study further evaluated the association between adherence and healthcare resource utilization (HCRU) among individuals with PBC in the United States. **Methods:** We conducted a retrospective cohort study using Komodo's Healthcare Map insurance claims data (January 1, 2016 - December 19, 2024). Adults aged ≥18 years diagnosed with PBC, with continuous health insurance coverage, initiating ursodeoxycholic acid (UDCA), obeticholic acid (OCA), or off-label fibrates following a treatment-free baseline of ≥12 months were included. The treatment initiation date was defined as the index, and individuals were followed until the end of the study window, discontinuation of insurance, or death. Adherence was measured by proportion of days covered (PDC) with continuous treatment with UDCA, OCA, and/or off-label fibrates. Longitudinal negative binomial models with annual intervals estimated associations between PDC ≥80% in the first 12 months post-index and the number of subsequent annualized all-cause HCRU events, including inpatient, outpatient, emergency, and any prescriptions (including PBC treatments) through the end of follow-up. The models controlled for demographics, PBC-related and other select baseline comorbidities, and PBC treatment type. **Results:** 54,034 individuals with PBC met the inclusion criteria. The mean age was 62 (±13) years; most were female (84.9%) and enrolled in Medicare (51.0%). During the 12-month baseline, the average Charlson Comorbidity Index score was 4.7 (±3.1); 18.9% were diagnosed with depression, 21.1% with anxiety, and 25.3% with fatigue. The percentage of individuals with PDC ≥80% was 50.2% in year 1 and decreased thereafter, ranging from 43.1% to 44.5% in years 2 to 7 post-index. Adjusted rate ratios associated with PDC ≥80% were 0.70 (95% CI,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

0.66–0.74) for inpatient, 0.95 (95% CI, 0.93–0.97) for outpatient, 0.75 (95% CI, 0.72–0.79) for emergency room, and 1.08 (95% CI, 1.06–1.10) for prescription counts (all $p < 0.001$). **Conclusion:** In this large real-world cohort of individuals with PBC, only half achieved adherence $\geq 80\%$ in the first year, with further declines over time. Adherence $\geq 80\%$ predicted lower inpatient, emergency department, and outpatient utilization, alongside increased prescription use. These findings highlight the importance of prioritizing access to therapies that support sustained adherence in the management of PBC.

1314 | CLINICAL IMPACT OF ALCOHOL USE DISORDER ON ONE-YEAR OUTCOMES IN PATIENTS WITH AUTOIMMUNE HEPATITIS: A PROPENSITY SCORE-MATCHED STUDY

Yasameen Muzahim[1] Abdullah Sohail[1] Antonio Sanchez[2] Marta Tejedor[1], [1]University of Iowa Health Care, [2]University of Iowa School of Medicine

Background: Alcohol use disorder (AUD) is associated with progressive liver injury and may worsen outcomes in chronic liver diseases. However, population-level data on the impact of AUD among patients with autoimmune hepatitis (AIH) remain limited. We evaluated one-year hepatic outcomes in patients with AIH with and without AUD using a large federated electronic health record network. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network, which includes data from 109 healthcare organizations. Adults aged 18–80 years with AIH were identified using ICD-10-CM code K75.4 and stratified by the presence or absence of AUD, identified using ICD-10-CM codes for alcohol abuse or dependence. Patients with viral hepatitis, hemochromatosis, Wilson disease, Budd-Chiari syndrome, non-HCC liver malignancy, unspecified liver disease, or baseline cirrhosis were excluded. Outcomes were assessed from 1 day through 365 days after the index event. Propensity score matching was performed for demographics, cardiometabolic comorbidities, nutritional status, nicotine dependence, and AIH-related immunosuppressive therapies. After matching, 717 patients were included in each cohort. **Results:** Before propensity score matching, 22,442 patients had AIH without AUD, and 723 had AIH with AUD. After matching, baseline characteristics were well balanced (Table 1). At 1 year, mortality was higher in the AIH+AUD cohort than in the AIH-alone cohort (8.8% vs 5.4%; risk difference −3.3%, 95% CI −6.0% to −0.7%; $p = 0.014$) (Table2). Kaplan-Meier analysis showed lower one-year survival in the AIH+AUD cohort (90.25% vs 93.83%; log-rank $p = 0.013$). Liver transplantation rates were not significantly different between AIH+AUD and AIH alone (4.3% vs 3.6%; $p = 0.499$). Acute/subacute liver failure was more frequent in the AIH+AUD cohort (5.7% vs 1.7%; risk difference −4.0%, 95% CI −6.0% to −2.1%; $p < 0.001$), with significant separation on Kaplan-Meier analysis (94.06% vs 98.18%; log-rank $p < 0.001$). There was no significant one-year difference in cirrhosis or hepatocellular carcinoma. **Conclusion:** This propensity score-matched real-world cohort showed that AUD is independently associated with significantly higher one-year mortality and acute/subacute liver failure in patients with AIH. These findings highlight that AUD acts as a major catalyst for adverse short-term outcomes and underscore the critical need for routine early alcohol screening, integrated addiction care, and enhanced surveillance in this high-risk population.

Table 1. Baseline Characteristics Before and After Propensity Score Matching

Characteristic	Before matching			After matching

1315 | 6-MERCAPTOPURINE VS. AZATHIOPRINE AS ADJUNCTIVE THERAPY DURING HIGH-DOSE CORTICOSTEROID INDUCTION IN AUTOIMMUNE HEPATITIS: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Bianca Patel[1] Jashanveer Johal[1] Archana Salek[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Abdallah Hussein[1] Jason Hyman[1] Yecheskel Schneider[1], [1]Virtua Health

Background: Azathioprine (AZA) is the guideline-standard steroid-sparing adjunct in autoimmune hepatitis (AIH), but 6-mercaptopurine (6-MP), its active metabolite, is used as an alternative in patients with AZA intolerance. Whether 6-MP provides equivalent disease control and safety during the high-dose induction phase of corticosteroid therapy has not been characterized in a real-world matched cohort. **Methods:** Using the TriNetX Global Collaborative Network, we identified AIH patients receiving prednisone (10–50 mg) with either 6-MP or AZA initiated within 1 month. Patients with cirrhosis, primary sclerosing cholangitis, liver transplant, or adrenal insufficiency were excluded. After 1:1 propensity score matching, 166 patients remained in each cohort. Outcomes included IV steroid use, biochemical remission, transition to low-dose prednisone ($\leq$7.5 mg), cytopenia, inpatient encounters, mortality, and incident cirrhosis. **Results:** No outcome differed significantly between groups. IV steroid use was similar (33.1% vs 30.7%; HR 1.00, p = 0.99). AZA showed numerically higher biochemical remission (86.1% vs 78.9%; HR 0.82, p = 0.098) and faster AST/ALT normalization (66 vs 105 days). Transition to low-dose prednisone was more frequent with AZA (53.0% vs 47.6%; HR 0.83, p = 0.24), with shorter time to taper (668 vs 1,311 days). Cytopenia occurred more often with 6-MP (59.0% vs 48.8%; HR 1.33, p = 0.055) and developed earlier (583 vs 1,988 days). Inpatient encounters, mortality, and cirrhosis rates were comparable. **Conclusion:** 6-MP and AZA demonstrated similar clinical outcomes during AIH induction therapy. AZA showed trends toward faster biochemical remission and steroid taper, whereas 6-MP was associated with earlier and more frequent cytopenia. These findings support 6-MP as an alternative for selected patients while underscoring the need for hematologic monitoring.

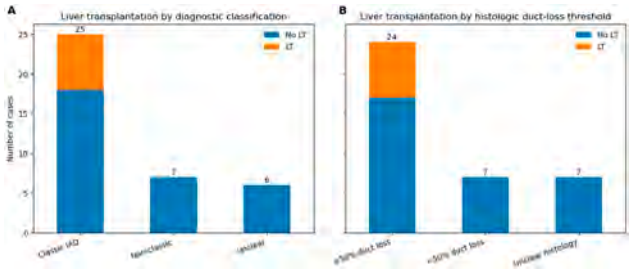
1316 | IDIOPATHIC ADULTHOOD DUCTOPENIA: DIAGNOSTIC HETEROGENEITY AND TRANSPLANT OUTCOMES ACROSS REPORTED CASES



Thomas Stirrat[1] Shankar Thiru[2] Priyanka Solanky[2] Michael Flatley[3] Soham Apte[4] Ashley Trinh[2] Rachel Redfield[5] Amol Rangnekar[6], [1]University of California Los Angeles (UCLA), [2]Georgetown University School of Medicine, [3]University of Colorado Internal Medicine Residency Program, [4]Kentucky College of Osteopathic Medicine, [5]MedStar Georgetown University Department of Transplant Hepatology, [6]Georgetown University Hospital

Background: Background: Idiopathic adulthood ductopenia (IAD) is a rare chronic cholestatic liver disease defined by adult-onset bile duct loss after exclusion of secondary causes. Published cases vary in diagnostic completeness, limiting interpretation of phenotype and outcomes. We reassessed reported cases using conservative case-level adjudication. **Methods:** Methods: Scopus, Web of Science, Embase, PubMed, and MEDLINE were searched from inception through December 31, 2025. Human reports with extractable patient-level data for IAD or closely related adult ductopenic cholestatic syndromes were included. Two reviewers screened studies, extracted data, assessed quality, and classified cases as classic IAD, non- classic, or unclear using Ludwig-based criteria. **Results:** Results: Thirty-eight extracted cases from 33 reports were included. Median age at diagnosis was 30 years (IQR, 20-43.3), and median age at symptom onset was 22 years (IQR, 16-34); 11/37 cases (29.7%) had symptom onset before age 18. Jaundice occurred in 23/32 cases (71.9%) and pruritus in 21/31 (67.7%). Twenty-four cases met the $\geq$50% bile duct-loss threshold. After adjudication, 25/38 cases (65.8%) were classic IAD, 7 (18.4%) non-classic, and 6 (15.8%) unclear. All 7 liver transplantations occurred among classic IAD cases and among cases meeting the $\geq$50% duct-loss threshold; no transplantations were reported among non- classic or unclear cases. Death was reported in 6/38 cases. **Conclusion:** Conclusion: Published IAD reports are diagnostically heterogeneous, and severe reported

outcomes cluster in conservatively defined classic IAD with substantial duct loss. Future IAD reports should standardize exclusion of mimics, cholangiographic characterization, portal-tract adequacy, duct-loss quantification, treatment response, and longitudinal follow-up.

1317 | CLINICAL PRESENTATION, CO-PREVALENCE, AND EXPRESSION OF AN IL-12 GENE SIGNATURE LINK PRIMARY BILIARY CHOLANGITIS AND AUTOIMMUNE HEPATITIS WITH ADDITIONAL AUTOIMMUNE DISEASES

Arielle Glatman Zaretsky[1] Stephen DiMartino[1] Kaitlyn Gayvert[1] Wenzhen Ge[1] Keran Moll[1] Dana Murdock[1] Elsa Au-Yeung[1] Rachna Shah[1] Veronica Mas Casullo[1] Wei Keat Lim[1] Andre Limnander[1] Jennifer Maloney[1] Jamie Orengo[1], [1]Regeneron

Background: It has long been recognized that patients with an autoimmune disease may exhibit clinical overlap with other distinct autoimmune diseases. For example, while dry mouth and dry eyes are defining clinical characteristics of Sjogren's disease, these symptoms are also observed in a notable proportion of patients with primary biliary cholangitis (PBC). In addition, PBC and autoimmune hepatitis (AIH) are known to exhibit co-prevalence at a much higher frequency than what would be expected by random chance. These observations highlight the likelihood of common etiologies that are not fully understood. We have recently linked 5 autoimmune conditions to the IL-12 signaling pathway. In this report, we explore common symptomatology, autoantibody profiles, co-prevalence, and gene expression among these diseases. **Methods:** A literature review was performed to determine the frequency of common clinical symptoms and autoantibody specificities in a subset of autoimmune diseases: PBC, AIH, Systemic Sclerosis/scleroderma (SSc), Sjogren's Disease (SjD), and Lupus (SLE). Co-prevalence of these diseases was evaluated in a cross-sectional study using the Komodo claims database. Luminex was performed to evaluate the concentration of inflammatory proteins in plasma from patients with PBC or SSc or healthy controls. An IL-12 gene signature was established using RNASeq analysis to identify differentially expressed genes (DEGs) in response to IL-12 signaling. The IL-12 signature was evaluated in gene expression datasets from relevant tissue sites from patients with PBC, AIH, SSc, SjD, and SLE to assess IL-12 signaling compared with healthy controls. **Results:** A literature review of clinical presentation highlights common symptoms and autoantibody reactivities across PBC, AIH, SSc, SLE and SjD. Komodo claims analysis revealed that the five conditions exhibited a high level of co-prevalence relative to the general population, but not observed with other inflammatory conditions such as psoriasis, type 1 diabetes, or rheumatoid arthritis.As previously reported, in plasma from patients with SSc or PBC, interferon-inducible chemokines, CXCL10, CXCL11, and CXCL13 were increased. Since IL-12 is the dominant upstream inducer of IFNg, an IL-12 signature was defined. This signature was discovered to be elevated in tissue from patients with PBC, AIH, SSc, SjD, and SLE. **Conclusion:** These data suggest common dysregulated pathways are shared across PBC, AIH, SSc, SjD, and SLE, despite disparate canonical presentation and organ involvement. These may indicate shared drivers of disease that could be targeted with therapeutic approaches.

[1]University of California, Irvine, [2]University of California, Los Angeles, [3]UCI Health

Background: Primary Biliary Cholangitis (PBC) is an autoimmune cholestatic liver disease with a strong female predominance, characterized by the serologic hallmark of antimitochondrial antibodies (AMA) and destruction of interlobular bile ducts leading to progression of liver disease, need for liver transplant, or shortening life without disease control. Extrahepatic manifestations include pruritus, and fatigue as most reported. While ursodeoxycholic acid (UDCA) is the first-line treatment, up to 50% of patients have an inadequate response. Peroxisome Proliferator-Activated Receptor (PPAR) agonists are newly FDA approved medications that are utilized in patients with inadequate response or intolerance to UCDA. Real world data for symptom and biochemical improvement is limited. We aim to report real world data of the newly approved PPAR agonists, including safety, efficacy, tolerability and effect on extrahepatic symptoms. **Methods:** We evaluated three patients with an established PBC diagnosis who demonstrated an inadequate response or intolerance to UDCA (13-15 mg/kg). Alternative liver diseases were ruled out via negative viral serologies and normal metabolic panels. Patients were initiated on Eafibranor 80 mg daily and followed with clinical and laboratory assessments conducted at baseline, 3 months, and 12 months. Serial data included symptom severity (Worst Itch Numeric Rating Scale [WI-NRS] and fatigue), liver enzymes, and non-invasive fibrosis markers. Primary outcomes were Alkaline Phosphatase (ALP) reduction, symptomatic improvement, and safety. **Results:** Three consecutive patients (1 male, 2 females; mean age 56.3 years) with inadequate response to UDCA for PBC were evaluated. Over 12 months of Elafibranor therapy, patients demonstrated a clinically significant biochemical and symptomatic response. Mean ALP decreased 58% from a baseline of 348 U/L to 144 U/L. Non-invasive fibrosis markers improved, with liver stiffness decreasing on transient elastography (mean -1.5 kPa). Mean WI-NRS score decreased from 5.3 to 2.0, and all reported improvement of debilitating daytime fatigue. Elafibranor was well-tolerated with no reported adverse events. **Conclusion:** Elafibranor shows positive safety, efficacy, side effect profile, improvement in extrahepatic manifestations including pruritus and fatigue in real world data. Improvement in fibrosis noted on transient elastography in all three patients. More studies are needed to evaluate long term fibrosis improvement, transplant free survival, mortality benefit and effect on extrahepatic manifestations.

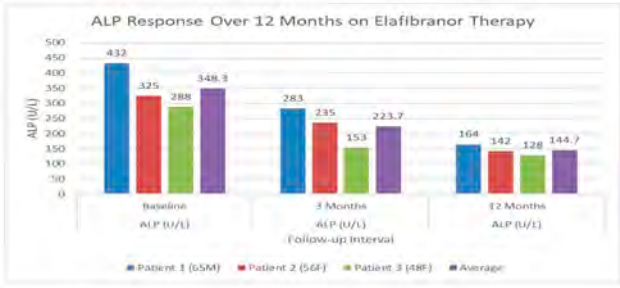

Figure 1: 12-month trajectory of ALP (U/L) in three patients with refractory PBC started on Elafibranor.

1319 | BASELINE LIVER STIFFNESS DOES NOT PREDICT COMPLETE BIOCHEMICAL RESPONSE IN TREATMENT-NAIVE AUTOIMMUNE HEPATITIS

Leonardo Calabrano[1] Alexis Guzmán[1] Sebastián Carrasco[2] Felipe Matus[2] Benjamín Chahuan[2] Miguel Guerra[3] Daniela Simian[1] Álvaro Urzúa[1], [1]Hospital Clínico Universidad de Chile, [2]Universidad de Chile, [3]Hospital San Borja Arriarán

Background: Liver elastography provides a non-invasive assessment of fibrosis in autoimmune hepatitis (AIH); however, its value for predicting biochemical response to treatment remains uncertain, especially in the presence of active inflammation. The aim was to evaluate whether baseline liver stiffness is associated with complete biochemical response and to assess its diagnostic accuracy for histological fibrosis in treatment-naive AIH patients. **Methods:** Retrospective cohort of 42 patients managed between 2017 and 2025 at a tertiary center, with baseline elastography and biochemical follow-up. Complete response was defined as normalization of AST, ALT, and immunoglobulin G at six months. Liver stiffness was compared according to measurement method and predefined fibrosis cutoffs. **Results:** Eighteen patients (43%) achieved complete biochemical response, whereas twenty-four (57%) did not. Baseline liver stiffness did not differ between groups: ARFI 10.65 versus 11.57 kPa ($p = 0.625$) and FibroScan 13.5 versus 19.3 kPa ($p = 0.565$). Baseline advanced

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

fibrosis was also similar: 14/18 (78%) versus 19/24 (79%) (p = 0.914). Elastography was associated with histologic F3–F4 fibrosis (OR 9.3), with sensitivity 92.3%, specificity 43.8%, PPV 73%, and NPV 78%. False-positive cases showed higher inflammatory activity than true positives: AST 581 versus 79 U/L (p = 0.006), ALT 703 versus 66 U/L (p = 0.002), and IgG 2440 versus 1975 mg/dL (p = 0.055). **Conclusion:** Baseline elastography did not predict complete biochemical response, but it identified advanced fibrosis with high sensitivity, although it tended to overestimate fibrosis in patients with greater baseline inflammatory activity.

Association between baseline liver stiffness levels and treatment response in patients with AIH

	Total N = 42	Complete response N = 18 (43%)	Partial response or no response N = 24 (57%)	p value
Method of fibrosis assessment				
ARFI	17 (40)	7 (39)	10 (42)	0.856

1320 | ◆ HUMAN HEPATOCYTE-BASED FUNCTIONAL ANNOTATION OF MASH-ASSOCIATED GENETIC RISK VARIANTS DEFINES DISTINCT STRESS STATES AND THERAPEUTIC RESPONSE

Takeshi Saito[1] Yein Woo[2] Jinyoung Ahn[2] Masashi Okawa[2] Meng Li[1] Garnik Arustamyan[2], [1]University of Southern California, [2]Keck School of Medicine, University of Southern California

Background: Genetic variants in TM6SF2, PNPLA3, MBOAT7, TRIB1, GPAM, ADH1B, FTO, APOB, MTTP, and other MASH-associated loci are thought to confer variable risks of steatosis, hepatocellular stress, fibrosis, and cirrhosis. However, this concept derives largely from clinical association studies; these variants have not been systematically compared at the cellular and molecular levels for direct effects on metabolic stress pathways or responses to hepatocyte-targeted therapeutics. This study establishes a physiologically relevant platform using our state-of-the-art primary human hepatocyte (HH) culture system to define how MASH-associated genetic risk signatures shape hepatocyte pathophysiology and drug responsiveness. **Methods:** HHs were perturbed using solid-phase siRNA transfection to model MASH-associated risk genes and exposed to a carbohydrate–fatty acid cocktail as the primary MASH-relevant metabolic challenge. Ethanol alone and combined carbohydrate–fatty acid/ethanol exposure were included as comparator and extension arms to test MASH-specific versus shared effects across ALD- and MetALD-like stress contexts. Effects on lipid accumulation, lipotoxicity, oxidative and ER stress, hepatocyte-intrinsic inflammatory signaling, and cell injury were assessed by high-content imaging, biochemical assays, and transcriptomic profiling. Therapeutic responsiveness was evaluated with resmetirom (THR-β agonist) and lanifibranor (pan-PPAR agonist). **Results:** Despite comparable lipid droplet accumulation, individual gene silencing produced distinct metabolic stress and injury signatures under MASH-like challenge and in MetALD/ALD extension arms. Silencing of PNPLA3, MBOAT7, TM6SF2, APOB, and MTTP was strongly associated with metabolic-oxidative stress and cytotoxicity, whereas silencing of GPAM, TRIB1, ADH1B, and FTO caused minimal stress or injury. Therapeutic responses were risk gene–dependent: resmetirom reduced steatosis and stress signaling in PNPLA3-, APOB-, and MTTP-silenced HHs, but the magnitude of lipid reduction, injury mitigation, and stress-gene suppression varied by genetic background. Lanifibranor modestly reduced lipid droplet burden across models but did not significantly reduce cell stress or injury. **Conclusion:** This study establishes a HH-based framework to functionally annotate MASH-associated genetic variants and link genetic risk to molecular pathophysiology and therapeutic response. These findings indicate that MASH risk genes define separable hepatocyte stress states with distinct drug-response profiles across metabolic and alcohol-associated stress contexts. This platform provides a functional approach to stratify MASH risk variants by mechanism and test therapeutic responsiveness in a bona fide human hepatocyte model system.

1321 | ◆ TARGETED DELETION OF HEPATOCYTE ERBB3 ATTENUATES MASLD PROGRESSION AND REPROGRAMS THE PPARΓ–HNF4A METABOLIC AXIS

Shehnaz Bano[1] Joseph Locker[1] Shirish Paranjpe[1] Rodrigo Florentino[1] Alejandro Soto-Gutierrez[1] George Michalopoulos[1] Bharat Bhushan[1], [1]University of Pittsburgh

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) can progress from steatosis to fibrosis and cirrhosis. A key feature of disease progression is hepatocyte reprogramming characterized by induction of PPARγ-dependent lipid storage programs and suppression of HNF4α-governed hepatocyte identity. In the murine fast-food diet (FFD) model, pan-ERBB inhibition reduces steatosis and fibrosis, whereas hepatocyte-specific EGFR deletion does not attenuate steatosis, increases fibrosis, and is associated with compensatory ERBB3 expression and persistent downstream signaling. In parallel, hepatocyte-specific PPARγ deletion has identified an antagonistic PPARγ-HNF4α axis as a key transcriptional regulator of MASLD progression. Here, we investigated whether hepatocyte ERBB3 (HER3) functions upstream of the PPARγ-HNF4α axis in MASLD. **Methods:** Hepatocyte-specific ErbB3 deletion (ERBB3-KO^{Hep}) was achieved in *Erbb3*$^{fl/fl}$ mice using AAV8-TBG-Cre. Mice were fed a fast-food diet (FFD) for 5 months to induce MASLD. Liver injury, lipid accumulation, and fibrosis were assessed by histology, biochemical assays, and western blotting. ERBB3–PI3K (p85) interactions were examined via immunoprecipitation. Therapeutic efficacy was evaluated using LNP-delivered siERBB3 *in vivo* and siRNA-driven knockdown in patient-derived primary human steatotichepatocytes. **Results:** NRG1 levels and ERBB3 expression/activation significantly increased in human and murine MASLD. ERBB3-KO^{Hep} mice were protected against FFD-induced steatosis, showing lower triglyceride content and improved glucose homeostasis compared to WT controls. Mechanistically, ERBB3 deletion attenuates PI3K–AKT–mTOR signaling, suppresses PPARγ, and restores HNF4α expression, thereby reprogramming the metabolic PPARγ–HNF4α axis. Transcriptomic and protein analyses revealed coordinated downregulation of de novo lipogenesis (ACC, SCD1, ACLY), lipid uptake (CD36), and droplet stabilization (PLIN2), alongside activation of autophagy/lipophagy pathways. ERBB3 loss also suppressed fibrogenic gene programs (Col1a1, Col3a1, Acta2) and reduced α-SMA and collagen deposition. Importantly, therapeutic ERBB3 silencing via LNP delivery in vivo, reversed already established MASLD and knockdown in human steatotic hepatocytes, consistently reduced lipid accumulation and reversed PPARγ–HNF4α transcriptional switch. **Conclusion:** Hepatocyte ERBB3 is a critical upstream driver of MASLD that regulates the PPARγ–HNF4α transcriptional switch. Targeted inhibition of ERBB3 restores metabolic homeostasis, induces lipophagy, and attenuates fibrosis, revealing an unexpected role for ERBB3 as a promising therapeutic target for MASLD.

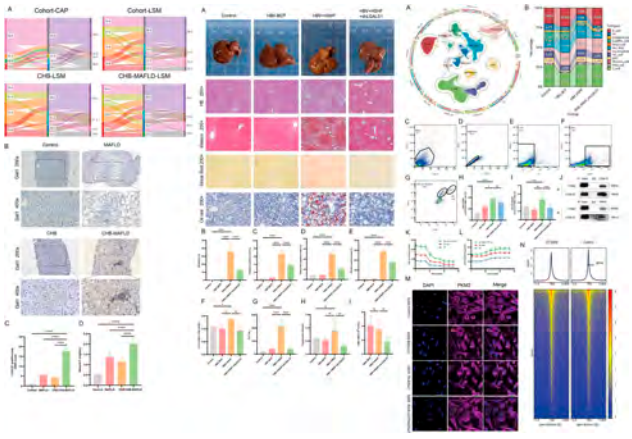
1322 | ◆ GALECTIN-1 DRIVES LIVER FIBROSIS IN CHB-MAFLD BY REMODELING THE IMMUNE-METABOLIC LANDSCAPE VIA PKM2-MEDIATED MACROPHAGE GLYCOLYSIS



Linlin Zheng[1] Qunyan Yao[2] Fangyuan Chen[2] Shengdi Wu[2] Jiangao Fan[3] Wei Jiang[2], [1]Zhongshan Hospital, [2]Zhongshan Hospital, Fudan University, [3]Xinhua Hospital Affiliated to Shanghai Jiao Tong University School of Medicine

Background: Chronic hepatitis B (CHB) remains a global health threat, and its increasing comorbidity with metabolic dysfunction-associated fatty liver disease (MAFLD) significantly accelerates progression to cirrhosis and hepatocellular carcinoma. Current antiviral therapies show limited efficacy in reversing advanced fibrosis in CHB-MAFLD patients compared to those with CHB alone, suggesting a complex pathogenic "cross-talk". Galectin 1 (Gal1, encoded by LGALS1) is a highly conserved glycan-binding protein involved in immune homeostasis and tissue fibrosis. However, its specific role and molecular mechanisms in CHB-MAFLD progression remain unclear. This study aimed to investigate the potential of Gal1 as a therapeutic target for the treatment of CHB-MAFLD. **Methods:** We analyzed 276 patients (MAFLD, CHB, and CHB-MAFLD) with a 5-year follow-up to identify unique clinicopathological features. Transcriptomic analysis of GEO datasets (GSE274114)

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and clinical validation were performed. In vivo, a CHB-MAFLD mouse model was established using HBV-BCP transgenic mice fed a high-sugar high-fat (HSHF) diet. Hepatic Lgals1 was specifically knocked down using AAV-shLGALS1. In vitro, mouse bone marrow-derived macrophages (BMDMs) were used to explore macrophage metabolism. Single-cell RNA sequencing (scRNA-seq) was employed to characterize the hepatic immune microenvironment. **Results:** CHB-MAFLD patients exhibited significantly higher serum Gal1 levels than CHB or MAFLD patients, which positively correlated with the severity of steatosis and fibrosis ($P < 0.05$). Standard antiviral therapy failed to significantly alleviate stage F3/F4 fibrosis in CHB-MAFLD patients over 5 years. HSHF diet significantly induced Gal1 expression in mouse liver tissues. Specific knockdown of hepatic Gal1 in CHB-MAFLD mice significantly reduced body weight, improved glucose tolerance, and ameliorated liver steatosis, inflammatory infiltration, and collagen deposition (Masson/Sirius Red staining, $P < 0.0001$). scRNA-seq and flow cytometry revealed that Gal1 knockdown remodeled the immune microenvironment by decreasing monocyte-derived macrophages (MoMFs) and promoting their polarization from a pro-inflammatory ($CD80^+$ $CD86^+$) to an anti-inflammatory ($CD163^+$ $CD206^+$) phenotype. Gal1 facilitated MoMFs recruitment by upregulating CCR2 expression. Gal1 directly interacted with PKM2, disrupting its tetrameric stability and promoting its transition to low-activity oligomers. This triggered the Warburg effect, mitochondrial dysfunction, and apoptosis. Nuclear translocation of PKM2 subsequently activated PRKAG2 and IP6K3 to drive metabolism remodeling. OTX008 (Gal1 inhibitor) or TEPP-46 (PKM2 activator) reversed these pro-fibrotic effects. **Conclusion:** Gal1 is a key driver of CHB-MAFLD progression. Targeting the Gal1-PKM2 axis offers a promising therapeutic strategy for liver fibrosis in CHB-MAFLD.

1323 | ◆ LOSS OF TET1 IN T CELLS EXACERBATES MASLD PROGRESSION

Muhammad Nisar[1] Xinjian Li[1] Cian-Ru Yang[1] Tomilola Olaolu[2] Ryan Huang[2] Ruiyu Zhang[1] Chiung-Kuei Huang[1], [1]Stony Brook University, [2]Tulane University School of Medicine

Background: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) progression is regulated by the inter-hepatic immune system. While T cells are known to play a key role in chronic hepatic inflammation, it is unknown how their regulation of population dynamics under metabolic conditions is regulated. Single-nucleus RNA sequencing (snRNA Seq) showed that DNA demethylation enzyme-TET1 changes across CD4, CD8 and regulatory T cells (Treg) in human MASLD patients closely related to the T cell subsets. Therefore, we aimed to determine the role of TET1 in T cells during MASLD progression. **Methods:** Human MASLD snRNA-seq datasets were used to assess the changes of DNA methylation enzymes in T cells. TET1 chromatin immunoprecipitation (ChIP-Seq) was adopted to investigate molecular regulations. T cell specific TET1 knockout (TKO) mice were used to evaluate how TET1 in T cells modulates MASLD. Transcriptomic analysis was performed in the liver and spleen samples to reveal the molecular regulations. In vitro assays were performed in human T cells using TET1 knockdown or pharmacological TET1 inhibitor to delineate molecular mechanisms. **Results:** TET1 loss in T cells significantly impacted liver injury in mice fed with an high fat diet (HFD). Surprisingly, TKO mice were lower in body weight after HFD, but body weights over liver, fat, and spleen weights were comparable to the control group. Hepatic triglyceride and cholesterol levels did not change between these mice. Histological and immune profiling indicated high F4/80 macrophage infiltration and high total immune cell infiltration in TKO mice. Despite elevated hepatic inflammation and injury, intrahepatic accumulation of CD4 and CD8 T cells was significantly reduced in TKO mice. Spleen RNA-seq suggests that systemic T cell activation, exhaustion markers, and standard surface trafficking receptors were virtually unchanged, suggesting the phenotype is a cell-intrinsic defect, and that cell proliferation or migration is likely involved. Transcriptomic analysis identified Rhou, a Rho GTPase crucial for cell movement, as one of the top robustly downregulated targets of TKO T cells. Simultaneously, TET1 knockdown or

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

chemical inhibition in Jurkat cells inhibited Rhou, suppressed cell growth, and reduced migration. Interestingly, the DNA methylation inhibitor, 5-Azacytidine treatment reversed Rhou expression in TET1 deficient T cells. Further, TET1 ChIP-seq confirmed that TET1 bound to the Rhou gene locus, thereby supporting direct epigenetic regulation through DNA methylation. Human MASLD sc/snRNA-seq also validated a significant positive relationship between TET1 and Rhou. **Conclusion:** In conclusion, TET1 deficiency in T cells promoted MALSD progression through targeting T cell mobility and growth. Although targeting hepatic TET1 improved MASLD, the long-term impact of targeting TET1 in MASLD patients with elevated CD4 and CD8 T cells should be monitored carefully.

1324 | ◆ RSPO3 PROMOTES LIVER METASTATIC GROWTH THROUGH MODULATION OF HEPATIC ZONATION AND IMMUNE REMODELING IN MASLD

Mustafa Karabicici[1] Jieun Kim[1] Ekihiro Seki[2], [1]CEDARS-SINAI Medical Center(CSMC), [2]Cedars-Sinai Medical Center

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is one of the most prevalent chronic liver diseases worldwide and is increasingly recognized as a major modifier of the hepatic tumor microenvironment. The liver is the most common site of metastasis for gastrointestinal malignancies, yet the mechanisms linking steatotic liver remodeling to metastatic progression remain poorly understood. Hepatic zonation creates distinct metabolic and immunologic niches along the porto-central axis, and these spatial programs become markedly altered in MASLD. R-spondin 3 (RSPO3), primarily expressed by endothelial cells and cytokine-producing hepatic stellate cells (HSCs), is a key regulator of hepatic zonation; however, its role in metastatic tumor progression remains controversial. **Methods:** Spatial transcriptomic, in vitro, and MC38 splenic injection liver metastasis models were used to evaluate RSPO3 regulation and function in steatotic livers under normal chow and high-fat diet conditions. **Results:** Here, we investigated the role of RSPO3 in colorectal cancer (CRC) liver metastasis under steatotic conditions. Our spatial transcriptomic analysis revealed that RSPO3 expression is increased in Zone 3 livers, mainly in endothelial cells and HSCs. As the RSPO3 promoter contains HIF-binding sites and Zone 3 is often hypoxic, RSPO3 may be regulated by hypoxia. Indeed, hypoxic challenge increased RSPO3 expression in HSCs. Furthermore, RSPO3 treatment significantly increased CRC cell proliferation. In vivo, we used the MC38 splenic injection liver metastasis model with high-fat diet (HFD) feeding, in which metastatic tumor growth is increased compared with normal chow (NC) feeding. Anti-RSPO3 treatment markedly reduced tumor burden, along with reduced hepatic lipid accumulation as demonstrated by decreased BODIPY staining. In addition, disruption of normal hepatic zonation patterns was observed following anti-RSPO3 treatment in both NC and HFD livers. The HFD condition also demonstrated increased CYP2E1 expression, consistent with MASLD-associated pericentral remodeling, which was reversed by anti-RSPO3 treatment. Immune profiling further revealed that although total CD3+ T-cell numbers were not significantly altered, the proportion of CD3+TIM3+ exhausted T cells was significantly reduced following anti-RSPO3 treatment in HFD mice. **Conclusion:** Collectively, these findings identify increased RSPO3 expression as an important regulator of the metastatic liver microenvironment in MASLD. RSPO3 may contribute to metastatic progression through alterations in hepatic zonation, lipid accumulation, and T-cell exhaustion. Targeting RSPO3 could therefore represent a potential therapeutic strategy for limiting liver metastasis in steatotic liver disease.

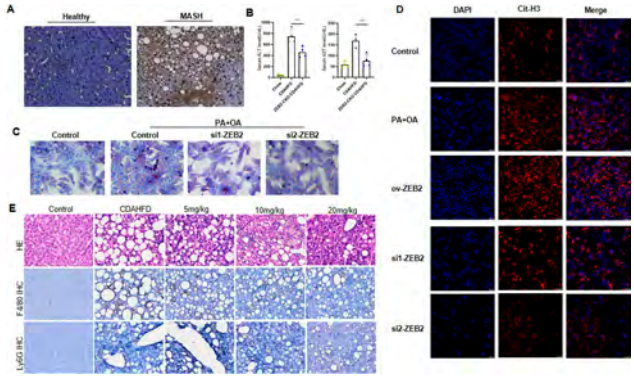
1325 | ◆ ZEB2 PROMOTES THE PROGRESSION OF MASLD BY INDUCING NEUTROPHIL EXTRACELLULAR TRAPS FORMATION



Guangqi Zhu[1] Qianwen Zhao[1] Jie Li[1], [1]Nanjing Drum Tower Hospital, Affiliated Hospital of Medical School, Nanjing University

Background: The transcription factor ZEB2 in hepatocytes has been implicated in metabolic dysfunction-associated steatotic liver disease (MASLD), yet its in vivo role and therapeutic potential remain undefined. This study aimed to determine whether hepatocyte ZEB2 drives MASLD via neutrophil extracellular traps (NETs) and whether pharmacological targeting of ZEB2 is feasible. **Methods:** ZEB2 expression was evaluated

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

by IHC and IF in MASH patients. Primary mouse hepatocytes were treated with palmitic/oleic acid (PA/OA) with ZEB2 siRNA or overexpression. Hepatocyte-specific ZEB2 knockout (ZEB2-CKO) mice were generated via Cre/LoxP, and hepatocyte-specific overexpression (ZEB2-HTG) via AAV8-TBG. MASLD was induced by high-fat high-fructose (HFFC) or choline-deficient, amino acid-defined high-fat diet (CDA-HFD). NETs formation was measured by serum MPO-DNA ELISA and IF co-staining of NE and Cit-H3. Anti-Ly6G monoclonal antibody or DNase I was administered intraperitoneally to deplete neutrophils or degrade NETs. Virtual screening identified Sitravatinib as a candidate, which was tested in vivo (HFFC and CDA-HFD models with three doses) and in vitro (PA/OA-stimulated hepatocytes). **Results:** ZEB2 was markedly upregulated in MASH livers. ZEB2 knockdown suppressed lipid accumulation and inflammation in vitro, whereas overexpression exacerbated them. In vivo, ZEB2-CKO significantly reduced hepatic steatosis, inflammatory cytokines (IL-1β, IL-6, TNF-α), lipogenic genes (Acc1, Fasn, CD36), serum ALT/AST, total cholesterol and triglycerides (both serum and liver), and improved pyruvate/glucose/insulin tolerance tests in both HFFC and CDA-HFD models. Opposite phenotypes were observed in ZEB2-HTG mice. Mechanistically, RNA-seq and co-culture experiments revealed that ZEB2 enhances hepatocyte-neutrophil adhesion and promotes NETs formation, as evidenced by increased MPO-DNA and NE/Cit-H3 colocalization. Both neutrophil depletion (anti-Ly6G) and NETs disruption (DNase) ameliorated steatosis, inflammation, and liver injury in both dietary models. Finally, Sitravatinib treatment dose-dependently reduced lipid accumulation, inflammatory markers, NETs formation, and hepatic damage in vitro and in vivo, mirroring the protective effects of ZEB2 inhibition. **Conclusion:** Hepatocyte ZEB2 drives MASLD progression by inducing NETs formation, and Sitravatinib represents a promising therapeutic agent targeting this pathogenic axis.

1326 | ◆ GENETIC AND PHARMACOLOGIC INHIBITION OF IL-21R ATTENUATES HEPATIC INFLAMMATION AND FIBROSIS IN MURINE MASH

Lucía Valenzuela-Pérez[1] Hyun Se Kim Lee[1] Rachel Bayer[1] Dina Manna[1] Ester Dohnalkova[1] Ivone Cristina Igreja Sa[1] Adebowale Bamidele[2] Petra Hirsova[2], [1]Mayo Clinic, Rochester, MN, [2]Mayo Clinic Rochester

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is a chronic liver disease in which persistent hepatic inflammation drives fibrosis, yet the immunological mechanisms linking these processes remain incompletely understood. Increasing evidence highlights a central role for $CD4^+$ T cells and cytokine signaling in disease progression. Activated $CD4^+$ T cells are a major source of interleukin 21 (IL-21) and also express IL-21 receptor (IL-21R), suggesting that IL-21 signaling may amplify $CD4^+$ T cell-mediated inflammation through autocrine and paracrine mechanisms and promote fibrotic remodeling in MASH. **Methods:** IL-21R transcript levels were quantified in liver tissue from patients with MASH and murine MASH models by RNA sequencing and qPCR, respectively, and plasma IL-21 levels were measured by ELISA. To define the role of IL-21 signaling, IL-21R-deficient mice were fed a choline-deficient high-fat diet (CD-HFD) for 6 weeks or a high-fat, fructose, and cholesterol (FFC) diet for 24 weeks. Pharmacologic IL-21R inhibition was evaluated using an anti-IL-21R antagonist antibody in FFC-fed mice with established MASH. At study endpoints, hepatic steatosis, injury, inflammation, and fibrosis were assessed, and intrahepatic leukocytes were immunophenotyped by mass cytometry (CyTOF) or flow cytometry. **Results:** Hepatic IL-21R expression was increased in both patients with MASH and mice fed CD-HFD or FFC diets. Plasma IL-21 levels were elevated in patients with MASH compared with obese controls with normal liver histology. In CD-HFD-fed mice, CyTOF analysis revealed reduced hepatic accumulation of monocyte-derived macrophages and overall macrophage abundance in IL-21R-deficient mice compared with wild-type controls. This was accompanied by reduced tissue fibrosis as assessed by Sirius Red staining and immunohistochemistry. IL-21R deficiency also attenuated fibrosis in the FFC model, where flow cytometric analysis showed reduced hepatic and splenic $CD4^+$ T cells, including $Eomes^+$ $CD4^+$ T cells, whereas $CD8^+$ T cells were unchanged. Finally, therapeutic IL-21R blockade in mice with established MASH reduced liver injury and inflammation and reversed fibrosis, indicating that IL-21R inhibition has therapeutic potential in MASH. **Conclusion:** The IL-21–IL-21R axis is upregulated in MASH and contributes to disease progression by amplifying

1327 | ◆ RAPID HUMANIZED MOUSE MODELS FOR LIVER FIBROSIS AND MASH

Clothilde Philouze[1] Omayra Martin-Rodriguez[1] Anaïs Meynet-Cordonnier[1] Sebastien Tabruyn[1] Dan Georgess[1], [1]TransCure bioServices

Background: The development of preclinical models integrating human immune components represents a key advance for the predictive evaluation of therapies targeting inflammation, fibrosis and metabolic dysfunction in liver diseases. In this study, we characterized two rapid induction approaches in humanized immune system NCG mice to establish distinct models of liver fibrosis and MASH. **Methods:** NCG mice engrafted with human $CD34^+$ hematopoietic stem cells (HIS-NCG) were exposed either to repeated carbon tetrachloride (CCl4) administration for 23 days or to a 14-day high-fat methionine- and choline-deficient (HFMCD) diet. Liver injury was assessed through clinical monitoring, circulating ALT and LGALS3 quantification, as well as histopathological fibrosis, steatosis and human macrophage infiltration assessment in the liver. **Results:** Both protocols induced rapid health deterioration associated with elevated serum ALT levels compared with control animals. However, the resulting pathological phenotypes differed substantially between models. CCl4-treated HIS-NCG mice developed severe liver fibrosis, with 88% of animals presenting bridging fibrosis (F3) or cirrhotic architecture, without associated steatosis or marked human macrophage infiltration. In contrast, the HFMCD diet induced a broader phenotype consistent with MASH, including advanced steatosis, a NAFLD activity score (NAS) of 6 and early-stage fibrosis (F0-F1), associated with infiltration by human $CD68^+$ macrophages. In both models, increased α-smooth muscle actin expression, indicative of hepatic stellate cell activation, together with elevated circulating galectin-3-binding protein levels, further supported the presence of active fibrotic processes. **Conclusion:** Together, these two HIS models provide well-defined liver phenotype platforms for the evaluation of therapeutic candidates targeting human immune-mediated pathways involved in liver disease.

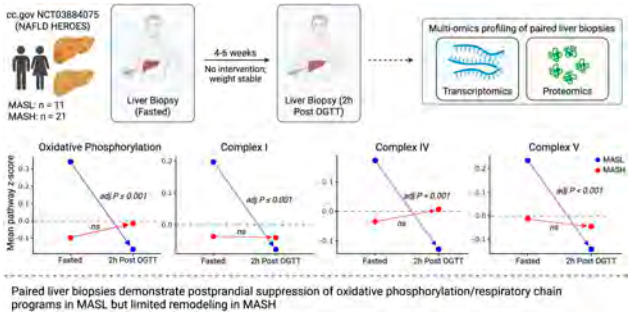
1328 | ◆ MULTIOMICS ON PAIRED FASTED AND FED HUMAN LIVER SAMPLES IDENTIFY IMPAIRED POSTPRANDIAL MITOCHONDRIAL FLEXIBILITY IN MASH



Haressh Sajiir[1] Harish Gopalakrishna[2] Elenita Rivera[3] Yaron Rotman[4], [1]National Institutes of Health/ NIDDK, [2]UTMB, [3]NIH/NIDDK, [4]National Institute of Diabetes and Digestive and Kidney Diseases; National Institutes of Health

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) ranges from simple steatosis (MASL) to steatohepatitis (MASH). MASH drives fibrosis, key to development of adverse clinical outcomes, yet drivers of MASH are not clear. Most human studies profile the fasting state, leaving hepatic adaptation to nutrient challenge poorly defined. We hypothesized that MASH reflects a defect in fasted-to-fed metabolic switching compared with MASL. **Methods:** Subjects with histology-defined MASL (n = 11) or MASH (n = 21) underwent two liver biopsies: one after an overnight fast and a second, 2 hrs after a 75g oral glucose load. Liver tissue was profiled by RNA-seq and proteomics and analyzed using paired, sex-adjusted differential expression/abundance models for fasting differences between groups, within-group post-glucose responses (2-hr post-glucose vs. fasting within MASL and MASH), and group-by-feeding interaction. Results were used for ranked pathway enrichment, with Hallmark pathways for global discovery and MitoCarta3.0 for mitochondrial module resolution. **Results:** Fasting MASH livers were transcriptionally distinct from MASL, with lower oxidative phosphorylation (OXPHOS) pathways compared to MASL but enrichment of protein secretion and cell-cycle pathways, suggesting a shift away from oxidative programs toward secretory/proliferative remodeling. Following oral glucose, MASL livers showed a significant decrease in OXPHOS pathways, whereas MASH had little change (FDR $q < 0.05$ for group-by-feeding interaction). MitoCarta analysis localized this effect to respiratory-chain pathways. MASL showed postprandial suppression of respiratory-chain subunit gene sets across Complexes I, IV, and V, whereas MASH showed limited remodeling from an already low-enrichment fasting state. This pattern was selective, as TCA cycle, fatty acid oxidation, amino acid

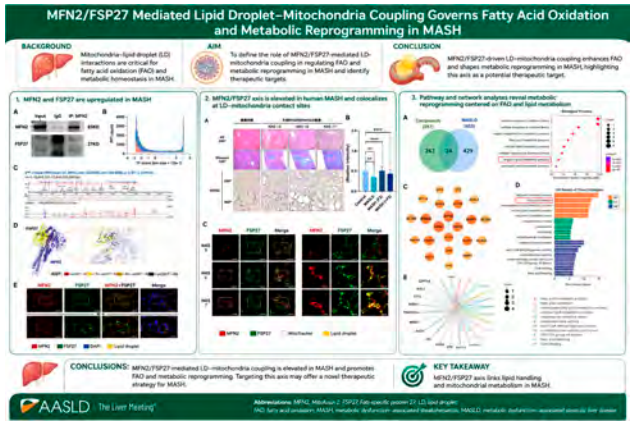
metabolism, carbohydrate metabolism, and small-molecule transport gene sets did not show comparable disease-specific effects. Liver tissue proteomics showed similar findings, with fasting MASH depleted for respiratory-chain proteins and a group-by-feeding signal concentrated in OXPHOS and OXPHOS-subunit proteins. **Conclusion:** In a paired fasted–fed human liver multiomic study of MASLD, we identified physiological postprandial suppression of hepatic respiratory-chain/OXPHOS programs in MASL, consistent with a mitochondrial component of catabolic-to-anabolic metabolic switching. This adaptive response was selectively lost in MASH, reflecting impaired hepatic mitochondrial flexibility. By moving beyond static fasting comparisons, these findings reveal failed adaptive hepatic remodeling after nutrient challenge.



Paired liver biopsies demonstrate postprandial suppression of oxidative phosphorylation/respiratory chain programs in MASL but limited remodeling in MASH

1329 | ◆ MFN2/FSP27 MEDIATED LIPID DROPLET-MITOCHONDRIA COUPLING GOVERNS FATTY ACID OXIDATION AND METABOLIC REPROGRAMMING IN MASH

Qianqian Zheng[1] Yuemin Nan[2] Chao Sun[3] Naoki Tanaka[4], [1]Third hospital of Hebei medical University, [2]Hebei Medical University Third Hospital, [3]The First Affiliated Hospital of Xi'an Medical University, [4]Shinshu University Graduate School of Medicine

Background: Disrupted lipid metabolism and mitochondrial dysfunction are central to metabolic dysfunction-associated steatohepatitis (MASH). However, the molecular mechanisms coordinating lipid droplet (LD)–mitochondria (MT) interactions remain poorly defined. We aimed to determine whether the MFN2–FSP27 complex regulates LD–MT coupling and thereby controls fatty acid oxidation and metabolic homeostasis in MASH. **Methods:** Human liver tissues from MASH patients and healthy controls were analyzed using immunofluorescence, confocal microscopy, and transmission electron microscopy to characterize LD–MT contact sites. MFN2 and FSP27 expression and interaction were assessed by Western blotting and co-immunoprecipitation. Gain- and loss-of-function approaches targeting MFN2 or FSP27 were performed in hepatocyte and adipocyte models to evaluate fatty acid oxidation, metabolic flux, and global metabolic reprogramming using metabolic assays and metabolomics. **Results:** MFN2 expression was markedly reduced in MASH livers, accompanied by decreased LD–MT contact formation and impaired MFN2–FSP27 complex assembly. Restoration of the MFN2–FSP27 axis enhanced LD–MT coupling, facilitated fatty acid trafficking to mitochondria, and significantly increased β-oxidation. In contrast, disruption of this complex led to defective fatty acid utilization, metabolic reprogramming toward lipogenic and pro-inflammatory pathways, and aggravated lipid accumulation and inflammatory responses. **Conclusion:** The MFN2–FSP27 complex is a critical regulator of LD–MT coupling that sustains fatty acid oxidation and metabolic homeostasis. Its dysfunction drives metabolic reprogramming and disease progression in MASH, highlighting a potential therapeutic target.

1330 | ◆ GUT MICROBIOTA-DERIVED PHENYLACETIC ACID PROMOTES MASH BY IMPAIRING MITOCHONDRIAL FUNCTION VIA SIRT3-REGULATED HSP60 PHENYLACETYLATION

Yidan Huang[1] Yufeng Li[1], [1]Shanghai Institute of Materia Medica, CAS

Background: Disturbances in the gut microbiota (GM) and their metabolites are pivotal in the

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

pathogenesis of metabolic dysfunction-associated steatohepatitis (MASH). These microbial metabolites often function as critical signaling molecules by serving as substrates for host protein post-translational modifications (PTMs), thereby orchestrating host-microbiota crosstalk. While short-chain fatty acid (SCFA)-driven PTMs are established, the capacity for other microbial products to reprogram the host proteome remains unrecognized. Specifically, although phenylacetic acid (PAA) promotes hepatic steatosis, its role as a bioactive acyl donor for protein PTMs is unknown. **Methods:** Kpaa identity was confirmed by HPLC-MS/MS and D_5-phenylacetate tracing. ACSF2/SIRT3 activities were screened using in vitro assays and gain/loss-of-function models. Mitochondrial function/mtUPR were assessed via Seahorse XFe96, TMRE/JC-1, TPE-MI imaging, ATF5 translocation, and HSP60-HSP10 assembly. K481 necessity was validated by K481A mutagenesis and mitochondria-targeted inhibitory peptides. Hepatic Kpaa/SIRT3 in MASH biopsies ($n = 30$) were quantified via multiplex immunohistochemistry (mIHC) and correlated with NAS scores. **Results:** Metaproteomics identified significant accumulation of fecal PAA in HFD-fed mice, associated with an increased abundance of *Clostridium asparagiforme*. Proteome-wide mapping identified 519 Kpaa sites on 236 hepatic proteins, with >75% localized to the mitochondria. Biochemical characterization established ACSF2 as the phenylacetyl-CoA synthetase driving Kpaa, while SIRT3 functioned as the primary mitochondrial dephenylacetylase. Mechanistically, PAA-induced Kpaa at Lys481 (K481) of HSP60 sterically disrupted its interaction with the co-chaperone HSP10. This disruption of the HSP60-HSP10 complex led to impaired mitochondrial proteostasis, as evidenced by ATF5 nuclear translocation and increased TPE-MI fluorescence, ultimately resulting in reduced oxygen consumption rate (OCR) and impaired mitochondrial membrane potential (MMP). These effects were abrogated by the K481A mutation or mitochondria-targeted competitive inhibitory peptides. In vivo, chronic PAA exposure or liver-specific SIRT3 knockdown significantly exacerbated hepatic steatosis and inflammatory infiltration. Clinically, hepatic Kpaa levels were markedly elevated in patients with MASH and showed a strong positive correlation with NAS ($r = 0.67$, $P < 0.001$) and a negative correlation with SIRT3 expression. **Conclusion:** We characterize Kpaa as a novel microbiota-derived PTM driving MASH. SIRT3/ACSF2-dependent HSP60-K481 phenylacetylation links gut-derived PAA to hepatic mitochondrial proteostasis failure, establishing the Kpaa-HSP60 signaling node as a viable therapeutic target for restoring mitochondrial function in MASH.

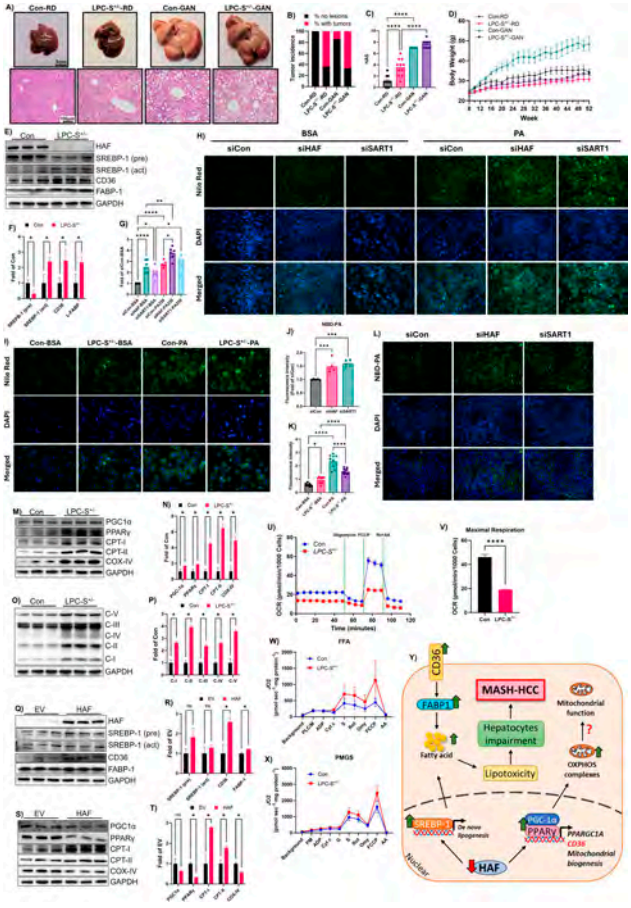
1331 | ◆ NOVEL ROLES OF HAF IN REGULATING LIPID METABOLISM IN METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE AND HEPATOCELLULAR CARCINOMA



Po-An Hu[1], [1]University of Utah

Background: Hypoxia-associated factor (HAF, *SART1*) has been shown to be an essential regulator of the NF-κB pathway, and loss of HAF in mouse hepatocytes results in increased apoptosis and spontaneous development of steatosis, leading to MASH and HCC. HAF is also decreased in steatotic human livers. However, the mechanisms by which HAF affects lipid metabolism in MASLD remain unknown. **Methods:** To determine the role of HAF in the pathogenesis of MASLD-HCC, we generated mouse models with hepatocyte-specific gain or loss of HAF. We used C57BL/6 mice with hepatocyte-specific *SART1* overexpression mediated by hydrodynamic tail-vein injection (HDTV, gain of HAF) and C57BL/6 mice bearing the floxed SART1 gene crossed with those expressing Alfp-Cre to generate liver-specific HAF knockdown (KD) mice (*LPC-S*$^{+/-}$, loss of HAF). Mouse models were fed the GAN diet for 1 year, then harvested and scored for NAFLD activity score (NAS) to investigate the impact of HAF modulation on MASLD progression. For in vitro experiments, primary hepatocytes from mouse models and the human hepatoma cell line Huh7 were used to support in vivo findings. **Results:** We observed increased tumor incidence and NAS in *LPC-S*$^{+/-}$ mice on a chow diet but no change in HDTVi mice, confirming our previous findings that HAF loss promotes MASH-HCC progression. However, feeding a GAN diet did not further exacerbate the liver pathology in *LPC-S*$^{+/-}$ mice. To characterize the impact of HAF loss, primary hepatocytes from *LPC-S*$^{+/-}$ mice were submitted for mRNA sequencing, which revealed significantly increased levels of genes involved in fatty acid (FA) metabolism. Following this finding, we observed elevated levels of FA uptake-related proteins CD36 and FABP-1, as well as the de novo lipogenesis-related protein SREBP-1 in primary hepatocytes from *LPC-S*$^{+/-}$ mice. Increased FA uptake and *de novo* lipogenesis were confirmed by fluorescence lipid staining and by treatment with a fluorescence probe-conjugated PA, demonstrating that HAF loss promotes FA uptake and lipogenesis. We also observed changes in PPARγ and PGC-1α, transcription factors associated with FA β-oxidation and mitochondrial biogenesis, as well as the mitochondrial marker COX-IV: PPARγ, PGC-1α, and COX-IV were elevated in *LPC-S*$^{+/-}$ hepatocytes and reduced in those from HDTV-HAF

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

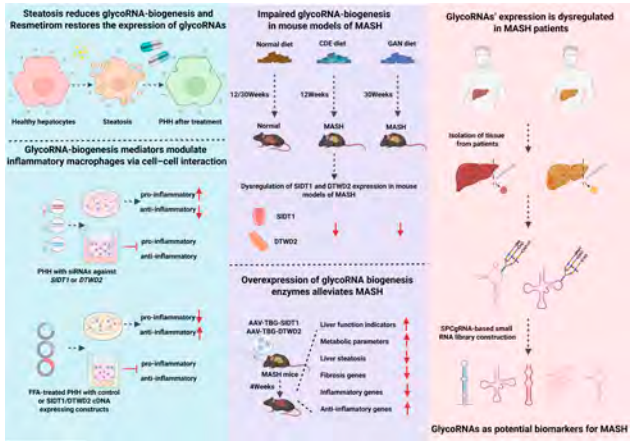
mice, suggesting that HAF may suppress the function of these proteins. Intriguingly, despite the elevation of these markers, we did not observe an increase in metabolic function using either the Seahorse analyzer or the Oroboros respirometry system. **Conclusion:** Our data suggest that decreased HAF levels may promote MASH-HCC progression, in part by increasing FA uptake and lipogenesis, leading to lipotoxicity. This may promote hepatocyte stress and generate a tumor-permissive environment that could potentiate progression to HCC. The potential mechanisms by which HAF regulates PPARγ and PGC-1α could provide new insights into the pathogenesis of MASH-HCC.



Disclosures: PO-AN HU:Nothing to Disclose.

★ 1332 | ◆ IMPAIRED GLYCORNA BIOGENESIS IN METABOLIC-DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE

Chengji Dong[1], [1]*Hannover Medical School*

Background: Glycosylated proteins and lipids regulate multiple cellular processes and play key roles in organ damage and regeneration. Recently, glycosylated non-coding small RNAs (glycoRNA) have been identified, however, their expression in the liver and their involvement in hepatic pathology has not yet been reported. **Methods:** We detected the presence of glycoRNAs by northern blot and a second method using an imaging approach called sialic acid aptamer and RNA in situ hybridization-mediated proximity ligation assay that enables the direct visualization of glycoRNAs. The in vivo restoration of key mediators of glycoRNA biosynthesis was achieved via adeno-asscoiated viral vectors. **Results:** Here, we show that glycoRNAs are synthesized in human liver tissue, primary hepatocytes and hepatic tumor cells. In tissues from patients with key features of metabolic dysfunction-associated steatotic liver diseases (MASLD), the most prevalent liver disease worldwide, expression of most glycoRNAs was reduced. Mechanistically, we found that the reduced expression of SID1 transmembrane family member 1 (SIDT1) and DTW domain containing 2 (DTWD2), two key mediators of glycoRNA biosynthesis, contribute to loss of glycoRNAs in MASLD. Inhibition of SIDT1 and DTWD2 increased fatty acid load in primary human hepatocytes and enhanced inflammation signals upon co-culture with macrophages. Importantly, adeno-associated viral vector mediated in vivo restoration of SIDT1 and DTWD2 attenuated MASH in a pre-clinical mouse model of MASH. Furthermore, sequencing of enriched glycoRNA samples identified six glycosylated piRNAs and two tRNAs, which were downregulated in steatotic human liver and hepatocytes. **Conclusion:** Collectively, our study demonstrates the presence of glycoRNAs in human hepatocytes and human liver tissues as well as dysregulated expression in experimental steatosis and in MASLD patients.

1333 | ◆ SPATIAL BREAKDOWN OF HEPATIC NITROGEN METABOLISM DRIVES MAFLD PROGRESSION

Feifan Yao[1] Xiaofeng Tie[1] Xuehao Wang[1] Qing Li[1], [1]Nanjing medical university

Background: MAFLD affects approximately 1.7 billion people globally, ranking among the fastest-growing chronic liver diseases. WHO recently recognized it as a rapidly escalating NCD, emphasizing its profound population health hazards. Emerging omics reveal aberrant ammonia metabolism as an independent driver of MAFLD. Physiologically, ammonia detoxification relies on precise spatial zonation: periportal hepatocytes utilize the high-capacity urea cycle, while perivenous hepatocytes employ high-affinity glutamine synthetase. We hypothesize the MAFLD microenvironment disrupts this zonation, causing an occult decline in ammonia clearance that fuels a pathogenic cycle. **Methods:** We integrated human MAFLD/MASH biopsies with a temporal HFCD-HF/G murine model. Systemic ammonia metabolic capacity was quantified via Acute and Chronic Ammonia Tolerance Tests (AATT/CATT). Spatial metabolic architecture was mapped using bidirectional in situ hepatic perfusion. Nessler's staining visualized intrahepatic ammonia. Mass spectrometry evaluated post-translational modifications. In vitro primary and passaged hepatocytes alongside hepatic stellate cells were utilized to assess the pro-pathogenic effects of ammonia. **Results:** In early steatosis, baseline intrahepatic ammonia appeared morphologically normal. However, AATT unmasked a profound, occult deficit in acute clearance capacity. Bidirectional perfusion revealed the precise spatial sequence of this breakdown: lipid accumulation initially targets the PV zone, severely suppressing GS activity. Subsequently, the dysregulated spatial architecture and oxidative stress downregulate PP CPS1 activity. Mass spectrometry revealed that while early-stage protein expression remains stable, aberrant PTMs—specifically palmitoylation and oxidation—significantly impair enzyme functions, precipitating a pan-lobular collapse of nitrogen processing zones. MASH progression triggers massive localized ammonia sequestration. CATT and in vitro assays confirmed this accumulated ammonia acts as a potent secondary hit, exacerbating lipotoxic mitochondrial damage and driving HSC activation and fibrogenesis. This establishes a pathogenic positive feedback loop where early PV-centric clearance impairment promotes ammonia accumulation, reciprocally accelerating MAFLD progression. **Conclusion:** MAFLD is inherently characterized by a progressive, occult downregulation of spatially distributed ammonia detoxification. The pathogenic cascade initiates with lipid-driven palmitoylation suppressing PV GS, precipitating a pan-lobular collapse of nitrogen metabolism. The resulting intrahepatic hyperammonemic microenvironment is a critical concomitant disorder, driving a pleiotropic pathogenic positive feedback loop. Targeting this spatial breakdown to restore zonal ammonia clearance represents a novel therapeutic strategy for halting MAFLD.

1334 | ◆ A+T RICH INTERACTION DOMAIN PROTEIN 3A (ARID3A) IN MACROPHAGES IMPAIRS PROTECTIVE TH17-MEDIATED GUT HOMEOSTASIS IN MASLD

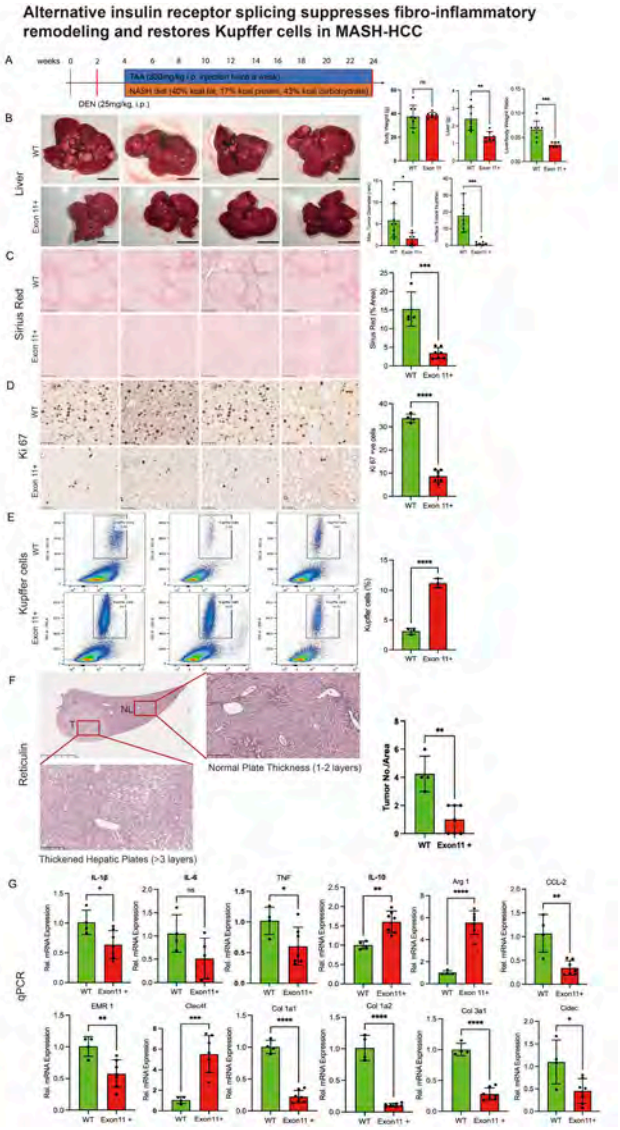
Ruiling Chen[1] Xiong Ma[1], [1]Renji Hospital, Shanghai Jiao Tong University, School of Medicine

Background: Macrophages play a critical role in metabolic dysfunction-associated steatotic liver disease (MASLD). We have previously demonstrated that macrophage Arid3a promotes cholestatic liver injury by impairing Mertk-mediated efferocytosis. However, the role of macrophage Arid3a in MASLD remains unclear. **Methods:** Myeloid-specific Arid3a knockout mice were generated as previously described. Arid3a-deficient mice and control littermates were fed a high-fat diet and housed either separately or in co-housing conditions. Mice were subjected to either oral gavage of Desulfovibrio or its metabolites, or administration of monoclonal antibodies against IL-23p19, IL-17A or IL-22. Metabolic status was assessed using intraperitoneal glucose

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

tolerance tests. Serum liver enzyme levels were measured, and the degree of hepatic steatosis was evaluated by H&E staining and oil red O staining. Fecal samples were collected for 16S ribosomal RNA gene sequencing-based microbiome analysis. Flow cytometry was employed to analyze in vitro co-cultured immune cells or primary intestinal immune cells. The accessibility of promoter regions was assessed by ChIP-seq targeting Arid3a. **Results:** Myeloid-specific deletion of Arid3a significantly improved metabolic parameters and alleviated high-fat diet-induced hepatic steatosis. Co-housing Arid3a-deficient mice with control littermates led to the convergence of gut microbiota composition and abolished the phenotypic differences in liver steatosis. Desulfovibrio abundance was positively correlated with metabolic indices, including body weight gain and serum alanine aminotransferase levels. Administration of Desulfovibrio or its metabolites exacerbated liver steatosis in Arid3a-deficient mice. Mechanistically, under high-fat diet conditions, Arid3a-deficient mice exhibited an increased frequency of intestinal Th17 cells expressing IL-17A and IL-22, along with improved gut permeability. In addition, intestinal macrophages from Arid3a-deficient mice showed upregulated expression of IL-23p19 and directly promoted Th17 cell differentiation in vitro. ChIP-seq analysis further demonstrated a direct interaction between Arid3a and the Il23a (IL-23p19) gene promoter in macrophages. Critically, targeting the IL-23-Th17 axis in vivo reversed the protective effect of macrophage-specific Arid3a deficiency against liver steatosis. **Conclusion:** Macrophage Arid3a drives hepatic steatosis by disrupting gut homeostasis through the IL-23-Th17 axis. This study identifies macrophage Arid3a as a critical link between the gut-liver axis and the pathogenesis of MASLD, positioning it as a potential novel therapeutic target for the disease.

Disclosures: RUILING CHEN:Nothing to Disclose, Xiong Ma:Nothing to Disclose.



1335 | ◆ ALTERNATIVE INSULIN RECEPTOR SPLICING GOVERNS IMMUNE NICHE REMODELING DURING MASH-DRIVEN HEPATOCARCINOGENESIS

Yanting Wang[1] Manasi Das[1] Yunpeng Yang[1] Isabella Maranan[1] Liping Zeng[1] Nicholas Webster[1], [1]University of California, San Diego

Background: Metabolic dysfunction-associated steatohepatitis (MASH) promotes hepatocellular carcinoma (HCC) through poorly defined mechanisms linking hepatocyte dysfunction to fibro-inflammatory immune remodeling. Loss of the splicing factor SRSF3 induces insulin receptor (INSR) exon 11 skipping, shifting expression from the metabolic IR-B isoform to the mitogenic IR-A isoform and establishing a pathogenic signaling state. We investigated whether restoration of INSR splicing fidelity could reprogram the hepatic immune niche and interrupt progression from chronic metabolic liver injury to hepatocarcinogenesis. **Methods:** We utilized hepatocyte-specific Exon11+ mice, in which Insr exon 11 inclusion is genetically enforced to prevent formation of the mitogenic IR-A isoform. Exon11+ and wild-type littermates underwent DEN plus Western diet/TAA-induced MASH-HCC for 24 weeks. Hepatocarcinogenesis, fibrosis, inflammatory signaling, and hepatic immune niche composition were assessed using histopathology, RT-qPCR, and high-dimensional flow cytometry. **Results:** Restoring INSR splicing fidelity markedly suppressed MASH-driven hepatocarcinogenesis. Compared with wild-type mice, Exon11+ mice exhibited an > 80% reduction in tumor burden ($p < 0.001$) and significantly attenuated hepatic fibrosis by Sirius Red staining and reduced Col1a1 expression (both $p < 0.001$). Exon11+ livers further demonstrated reduced Ki67+ hepatocyte proliferation together with coordinated suppression of inflammatory gene programs, including Il1b, Tnf, Ccl2, and Emr1.High-dimensional flow cytometry revealed remodeling of the hepatic immune niche in Exon11+ livers. Resident F4/80high Kupffer cell populations were markedly restored (~3-fold increase vs WT, $p < 0.0001$), while neutrophil accumulation was reduced, consistent with attenuation of the pro-inflammatory myeloid compartment. Increased expression of the reparative marker Arg1 and the anti-inflammatory cytokine Il10, together with restoration of the Kupffer cell identity marker Clec4f, further supported re-establishment of a Kupffer cell-enriched hepatic microenvironment. **Conclusion:** The SRSF3-INSR splicing axis mechanistically links hepatocyte dysfunction to fibro-inflammatory remodeling and immune dysregulation during MASH-HCC progression. These findings identify hepatocyte-specific alternative splicing as an upstream regulator of hepatic immune niche composition during hepatocarcinogenesis. Blocking the pathogenic IR-A isoform switch restores a tumor-suppressive hepatic immune microenvironment and positions the INSR splicing axis as a mechanistically targetable pathway linking metabolic injury, immune remodeling, and hepatocarcinogenesis.

1336 | ◆ GALECTIN-3 DEFICIENCY REVEALS SEX-SPECIFIC DIVERGENCE IN AGING-ASSOCIATED MASLD

Astrid Ardon-Lopez[1] Fernando Flores Guzman[1] Ella Nagaraj[2] Mia Panlilio[1] Clara Eugenia Moreno-Ramirez[3] Osvely Méndez-Guerrero[4] Yuhuan Luo[1] Christene Huang[1] Nalu Navarro-Alvarez[5], [1]University of Colorado Anschutz Medical Campus, [2]University of Colorado Anschutz Medical Campus, [3]Centro Universitario de la Costa, University of Guadalajara, [4]Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubiran, [5]University of Colorado Anschutz Medical Campus/ Instituto Nacional de Ciencias Médicas y Nutrición

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most common chronic liver disease worldwide and shows clear differences by age and sex. Although males have a higher burden earlier in life, disease risk rises in females after menopause, indicating that aging can reshape susceptibility to hepatic steatosis and injury. Galectin-3 (Gal-3), a β-galactoside-binding lectin linked to hepatic steatosis and inflammation, may contribute to this process, but its role in aging-associated MASLD in males and females remains unclear. We examined whether Gal-3 deficiency modifies the development of MASLD in aged male and female mice. **Methods:** Young (1-month-old) and aged (18-month-old) wild-type (WT) and Gal-3 knockout (KO) male and female mice were maintained on standard chow throughout life as a spontaneous aging model. Metabolic parameters, liver weight, clinical chemistry markers (ALT, AST, triglycerides, cholesterol), blood counts, and liver histology were assessed. Liver pathology was scored by H&E staining using NAFLD Activity Score (NAS) analysis by a pathologist blinded to experimental groups. Immunohistochemistry was performed to evaluate hepatic Gal-3 expression and F4/80+ macrophage accumulation. **Results:** Aging increased hepatic Gal-3 expression in WT mice, most prominently in females, and increased body weight and liver weight in both sexes. However, the liver phenotype was strongly male-biased. Aged males had the highest liver weight, higher plasma cholesterol than aged females ($p < 0.01$), and the most severe histologic injury, with increased NAS, steatosis, lobular inflammation, and hepatocellular ballooning compared with young controls. In aged males, Gal-3 deficiency reduced liver weight and was associated with lower steatosis and ballooning degeneration. Steatosis decreased from 51% in aged WT males to 21% in aged Gal-3 KO males, and liver weight positively correlated with steatosis severity.In females, the effect of Gal-3 deficiency was different. Aged females remained largely protected from hepatic fat accumulation, with steatosis below 12% regardless of genotype. Despite this low-steatosis phenotype, aged Gal-3 KO females had higher lobular inflammatory activity than aged WT females. F4/80+ macrophage accumulation was also greater in females than males ($p < 0.01$), independent of age or Gal-3 status. **Conclusion:** Gal-3 deficiency separated two distinct aging-associated liver responses. In aged males, loss of Gal-3 was associated with less steatosis, lower liver weight, and reduced hepatocyte injury. In aged females, low steatosis persisted, but inflammatory activity and macrophage accumulation remained prominent. This sex-dependent divergence places Gal-3 at the intersection of lipid accumulation and hepatic

inflammation during aging-associated MASLD. Thus, sex and age should be considered when evaluating Galectin-3-targeted therapies for MASLD.

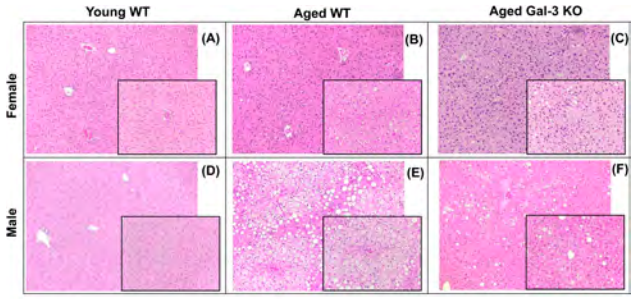

Figure 1. Reduced steatosis in aged Gal-3 KO males compared to aged WT males. Representative liver H&E images of: (A) female WT young, (B) female WT aged, (C) female Gal-3 KO aged, (D) male WT young, (E) male WT aged, and (F) male Gal-3 KO aged.

★ 1337 | ◆ TIME-RESTRICTED FEEDING (TRF) ATTENUATES FATTY-LIVER DISEASE AND POTENTIATES THE EFFICACY OF RESMETIROM FOR METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH) RESOLUTION

Shaunak Deota[1] Terry Lin[1] Kelsey Fierro[1] Krushali Powale[1] Ramesh Ramasamy[1] Hiep Le[1] Satchidananda Panda[1], [1]Salk Institute for Biological Studies

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is characterized by liver steatosis, inflammation, and fibrosis, which, if left untreated, can progress to cirrhosis, hepatic decompensation, and cancer (HCC). While exercise, weight loss, and dietary interventions are recommended for managing MASH, two drugs recently received accelerated FDA approval: Resmetirom (a liver-directed Thyroid receptor beta agonist) and Semaglutide (a glucagon-like peptide-1 receptor agonist). However, only 30-50% of patients on these drugs show a reduction in MASH progression and fibrosis, indicating that alternative molecular targets or combination therapies are needed to improve treatment outcomes and reduce disease burden. Time-restricted feeding/eating (TRF/TRE) involves restricting caloric intake to a consistent daily schedule during the active phase. While TRF reduces adiposity, dyslipidemia, and type 2 diabetes and improves liver steatosis in obese mouse models, its role in modulating MASH pathogenesis remains unexplored. **Methods:** We used a mouse model of high-fat, high-cholesterol diet (GAN diet) induced MASH that closely resembles human disease progression and pathophysiology. To test the preventive effect of TRF on MASH pathogenesis, we subjected male and female mice to ad libitum feeding (ALF) of GAN diet for 36 weeks, and the other group was subjected to iso-caloric feeding of the same diet for 9 hours during the dark phase (ZT13-ZT22). To test the therapeutic effect of TRF and resmetirom, we subjected male and female mice to ad libitum feeding (ALF) of GAN diet for 52 weeks to induce MASH, and then divided them into 4 groups: vehicle-treated ALF, resmetirom-treated ALF, vehicle-treated TRF, and resmetirom-treated TRF. Resmetirom treatment was performed by oral gavage for 5 days/week for 8 weeks at 3 mg/kg dose. We performed liver histology, serum and liver biochemical tests, and bulk and single-nuclei RNA sequencing of the liver to identify molecular mechanisms mediating beneficial effects. **Results:** TRF prevented the development of MASH symptoms, including liver steatosis, inflammation, and fibrosis, as assessed by histology, metabolic, and molecular analyses. Furthermore, in mice with established MASH and fibrosis, TRF enhanced the efficacy of resmetirom in resolving MASH and improved the associated metabolic syndrome in both male and female mice. Mechanistically, we observed that TRF and resmetirom increased the expression of genes involved in cholesterol and bile acid synthesis in the liver and reduced FXR-FGF15/19 signaling in the ileum, thus remodeling the gut-liver bile acid axis. **Conclusion:** Together, these results indicate that lifestyle interventions, such as TRF, can prevent the development of MASH and potentiate the effects of approved pharmacotherapies, such as resmetirom, thereby reducing disease progression and improving health.

1338 | ◆ INTEGRATING AI-BASED FIBROSIS STAGING AND PATTERN ANALYSIS IN A TRANSLATIONAL MOUSE MODEL OF MASH

Henrik Hansen[1] Denise Oró Bozzini[1] Monika Lewinska[1] Asbjørn Petersen[1] Kristoffer Voldum-Clausen[1], [1]Gubra A/S

Background: Histopathological fibrosis staging is a key endpoint in metabolic dysfunction-associated steatohepatitis (MASH) research and preclinical drug development. Conventional assessment using the MASH CRN (Kleiner) scoring system assigns a single global fibrosis stage per biopsy and may not adequately capture fibrosis remodeling or spatial heterogeneity within the tissue. This limitation is particularly relevant in treatment studies, where antifibrotic effects may occur without substantial changes in overall fibrosis stage. To address this challenge, we developed GHOST, an AI-based digital pathology platform that integrates clinically relevant fibrosis staging with quantitative analysis of fibrosis patterns from liver histology images. **Methods:** Picrosirius red (PSR)-stained liver sections from 2,321 GAN DIO-MASH mouse liver samples were scanned at 20×. Following AI-based tissue detection, individual biopsies were subdivided into small image regions ("tiles") for analysis. Three convolutional neural networks were trained for fibrosis pattern detection, bridging classification, and PSR-positive fiber segmentation. Tile-level outputs from the trained networks were aggregated into quantitative biopsy-level fibrosis pattern distributions and PSR fraction measurements. These features were integrated into a Random Forest classifier trained to predict fibrosis stage according to the Kleiner scoring system. **Results:** The GHOST platform predicted Kleiner fibrosis stage with a Kappa of 0.85, demonstrating high concordance to manual scoring. Misclassifications were limited to adjacent fibrosis stages, with no major discordant predictions observed. In addition, the platform generated quantitative fibrosis pattern distributions across biopsies, enabling assessment of fibrosis architecture and treatment-associated remodeling. The approach was further evaluated across multiple treatment studies in GAN DIO-MASH mice. In several studies, fibrosis pattern analysis identified treatment-associated remodeling patterns and changes in PSR-positive area despite limited or absent changes in global fibrosis score, including changes consistent with fibrosis improvement following semaglutide treatment. **Conclusion:** GHOST provides clinically interpretable fibrosis staging together with fibrosis pattern analysis from liver histology images. Beyond predicting the Kleiner fibrosis score, the AI-assisted approach enables characterization of dynamic changes in fibrosis architecture across biopsies, supporting sensitive treatment-response assessment in preclinical MASH studies.

1339 | ◆ ROLE OF SKELETAL MUSCLE THEM2 IN THE EXTRACELLULAR VESICLE-MEDIATED REGULATION OF HEPATIC LIPID METABOLISM

Sepideh Mikaeeli[1] Ayisha Bushra[1] David Cohen[1],
[1]Cedars-Sinai Medical Center

Background: We previously demonstrated that skeletal muscle-specific deletion of thioesterase superfamily member 2 (Them2) protects against metabolic dysfunction-associated steatotic liver disease (MASLD). The fatty acyl-CoA thioesterase activity of Them2 in skeletal muscle promotes insulin resistance, at least in part, through p38 MAPK signaling. Them2 also controls hepatic lipid metabolism, an effect that may be mediated through extracellular vesicle (EV) signaling from skeletal muscle to the liver. This study explored regulation by Them2 of skeletal muscle-derived EV production, cargo composition, and effects on hepatic lipid metabolism. **Methods:** Global Them2 knockout (*Them2*$^{-/-}$) mice and skeletal muscle-specific Them2 knockout (*S-Them2*$^{-/-}$) mice, generated by intramuscular injection of MCK-AAV8-Cre into *Them2*$^{fl/fl}$ mice, were fed a chow diet. EV were isolated from plasma and media from cultured myotubes. Purified EV were characterized and quantified by transmission electron microscopy (TEM) and nanoparticle tracking analysis (NTA). Functional effects were assessed by treating fatty acid-treated primary hepatocytes with equal concentrations of EV, followed by BODIPY staining to measure lipid droplet (LD) accumulation. To identify bioactive components, EV were sonicated to release their cargo, size-fractionated by microfiltration, and selectively depleted of RNA or lipids. EV cargo composition and skeletal muscle EV biogenesis pathways were analyzed by small RNA sequencing and qPCR. **Results:** Them2 deletion increased plasma EV concentrations, with a similar trend for myotube-derived EV. *Them2*$^{-/-}$ myotube-derived EV significantly reduced LD accumulation in primary hepatocytes relative to EV from wild type myotubes. The absence of Them2 in both *Them2*$^{-/-}$ and *S-Them2*$^{-/-}$ mice was associated with increased skeletal muscle expression of genes involved in EV biogenesis and release, including Rab27a. Small RNA sequencing of skeletal muscle EV revealed significant alterations in the expression of several microRNAs implicated in hepatic lipid accumulation, including downregulation of miR-21, a target of MKP-1-dependent inhibition of p38 MAPK signaling. The lipid-lowering activity of EV from Them2-deficient myotubes on primary hepatocytes was abolished by RNA depletion and by removal of cargo larger than 3 kDa, but not 10 kDa, indicating that active EV components reside within the 3-10 kDa molecular weight range. **Conclusion:** Them2 regulates skeletal muscle EV production, cargo composition, and EV-mediated control of LD accumulation in hepatocytes. Them2 deletion alters pathways of EV biogenesis, conferring protective effects against hepatocyte lipid

accumulation through specific bioactive cargo, likely microRNAs. We speculate that skeletal muscle EV might be leveraged as a potential therapeutic strategy for the management of MASLD.

1340 | ◆ SENESCENCE MEDIATED HEPATOCYTE INJURY DRIVES MASLD PROGRESSION

Sadam Bhat[1] Mustafa Karabicici[1] Takashi Tsuchiya[1] Vijay Pandyarajan[2] Rie Seki[1] Tiantian Chang[1] Jieun Kim[1] Keiya Watakabe[1] So Yeon Kim[3] Yoon-Seok Roh[4], [1]Cedars Sinai Medical Center, [2]Cedars Sinai Medical Center Hepatology, [3]Cedars-Sinai Medical Center, [4]Chungbuk National University College of Pharmacy

Background: Senescence of hepatocytes is a central driver of MASLD progression, but the mechanisms that initiate and sustain this senescent state remain unclear. Senescence-associated DNA damage, mitochondrial dysfunction, and metabolic reprogramming may contribute to persistent liver injury. In this study, we investigated whether loss of Ubc13, a K63-linked ubiquitin-conjugating enzyme involved in DNA repair and mitochondrial homeostasis, contributes to senescent hepatocyte accumulation and accelerates MASLD progression. **Methods:** Senescence was studied in mice with the conditional deletion of Ubc13 in hepatocytes ($Ubc13^{\Delta hep}$) and littermate WT controls ($Ubc13^{fl/fl}$) fed normal and high-fat diets (HFD). Senescent cells were targeted using dasatinib plus quercetin (D+Q). Liver injury, steatosis, senescence, and regeneration were assessed by ALT/AST, histology, γH2AX, p21, p16, PCNA, transcriptomics, and proteomics. Senescence-associated glutaminolysis was evaluated using CB-839, a glutaminase-1 inhibitor, in human hepatocyte organoids and mice. **Results:** In aged/MASLD human and mouse liver samples, we found an increased expression of senescence markers p21 and p16, while Ubc13 expression was reduced ($p < 0.05$). Senescent hepatocytes were significantly increased in HFD-fed $Ubc13^{\Delta hep}$ mice, with elevated γH2AX and p21, steatosis, and higher ALT/AST compared with HFD-fed WT controls ($p < 0.01$–0.05). Senolytic treatment with D+Q reduced steatosis, ALT/AST, and p21-positive hepatocytes ($p < 0.05$–0.01), supporting senescence as a functional mediator of disease severity. Liver transcriptomic analyses revealed a pro-senescent shift with increased anti-apoptotic genes (Bcl2, Mcl1) and reduced proliferation and ubiquitination pathways ($p < 0.05$), along with increased SASP expression. Pathway analysis showed activation of p53 signaling and cell cycle arrest, with suppression of DNA replication and metabolic pathways. Senescence-associated mitochondrial dysfunction was confirmed by proteomics, with reduced MFN2, OPA1, TOMM20, and TOMM70 under HFD (FD > 1.5, FDR < 0.05); these changes were improved by D+Q and further worsened in $Ubc13^{\Delta hep}$ mice ($p < 0.05$–0.01). Senescence-associated glutaminolysis inhibition by CB-839 reduced lipid accumulation ($p < 0.05$) and p21-positive senescent cell populations ($p < 0.05$) in human hepatocyte organoids and mice. **Conclusion:** Senescence is a major driver of MASLD progression and is further amplified by reduced hepatocyte Ubc13. This promotes a self-sustaining senescent state characterized by DNA damage, mitochondrial dysfunction, and glutaminolytic reprogramming, leading to steatotic liver injury. Senolytic therapy and GLS1 inhibition attenuate these disease features, identifying a senescence-centered Ubc13–mitochondria–glutaminolysis axis as a therapeutically actionable pathway in MASLD.

★ 1341 | ◆ DIETARY SUBSTRATE COMPOSITION UNCOUPLES STEATOSIS FROM INFLAMMATION IN PRIMARY HUMAN HEPATOCYTES

Alireza Ramandi[1] Mohammad Kabbani[1] Aditya Upadhyay[1] Leon Seifert[2] Chenhui Zou[1] Corrine Quirk[2] Yichen Zhou[1] Mano Maurya[3] Shankar Subramaniam[3] Luis Chiriboga[4] Clifton Fulmer[4] Eleftherios Michailidis[5] Vijay Soni[1] Ype De Jong[1], [1]Weill Cornell Medicine, [2]Rockefeller University, [3]university of california san diego, [4]new york university, [5]Emory University

Background: Hepatic steatosis is conventionally viewed as the substrate upon which MASLD-associated hepatocellular injury develops. Using human hepatocyte-chimeric huFNRG mice, we tested whether specific dietary macronutrients direct primary human hepatocytes toward distinct steatotic versus inflammatory states in vivo. **Methods:** huFNRG mice were fed for 4 weeks on one of nine dietary conditions: chow, Western diet (WD), WD with 10% sucrose water (WD+10%S), high-fat/low-sugar diet (HFD), high-sugar/low-fat diet (HSD), or chow supplemented with 10% sucrose (10%S), glucose (10%G), fructose (10%F), or high-fructose corn syrup (10%H). Human hepatocyte responses were characterized by histopathology, human-specific RNA-seq, ER stress/qPCR profiling, inflammation secretome analysis, and LC-MS lipidomics. Transcriptional signatures were benchmarked against liver RNA-seq from patients with

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

MASL and MASH. **Results:** WD and 10%S each induced steatosis in approximately 50% of human hepatocytes, with no additive effect in the WD+10%S combination, yet each engaged distinct transcriptional programs. HFD produced robust steatosis with limited inflammatory activation, while HSD caused hepatocyte ballooning with minimal lipid accumulation, demonstrating that steatosis and hepatocellular injury are dissociable phenotypes. Among liquid sugar conditions, 10%G, 10%S, and 10%H were consumed in excess and produced moderate steatosis, whereas 10%F was consumed sparingly yet generated comparable ballooning. Multi-omic integration identified fructose-containing diets, particularly 10%S and 10% H, as the principal drivers of inflammatory, ER stress, and immune secretory programs, transcriptionally most closely resembling human MASH. HFD and 10%G, by contrast, recapitulated low-inflammation MASL-like states. Lipidomics revealed that inflammatory states were defined not by total lipid burden but by selective enrichment of saturated and monounsaturated short- to medium-chain triglyceride species, while HFD preferentially expanded long-chain triglycerides consistent with neutral lipid storage. **Conclusion:** Steatosis and inflammatory injury in primary human hepatocytes are nutritionally uncoupled. Dietary fat expands lipid stores with limited inflammatory consequence, whereas fructose-containing sugars selectively engage pathways that phenocopy human MASH. These findings challenge hepatic fat burden as a sufficient proxy for pathogenic MASLD biology and position dietary substrate composition as an important determinant of human hepatocyte injury.

★ 1342 | MITOCHONDRIAL OXYSTEROLS AND THEIR SULFATES ESTABLISH A NUCLEAR 25HC/25HC3S AXIS CONTROLLING DNMT1 IN MASLD

Yaping Wang[1] Kevin Ren[2] Shunlin Ren[3], [1]Virginia Commonwealth University; Stravitz-Sanyal Institute for Liver Disease and Metabolic Health, [2]3. Mclean High School, Mclean, VA 22101, [3]Virginia Commonwealth University

Background: Epigenetic dysregulation, including altered DNA methylation, contributes to metabolic dysfunction–associated steatotic liver disease (MASLD). Prior work shows that mitochondrial oxysterols regulate DNA methyltransferase 1 (DNMT1) in vitro: 25-hydroxycholesterol (25HC) and 27-hydroxycholesterol (27HC) activate DNMT1, whereas cholestenoic acid (CA) is biphasic Their 3-sulfates—25HC-3-sulfate (25HC3S; larsucosterol), 27HC-3-sulfate (27HC3S), and 3-sulfate-cholestenoic acid (3SCA)—inhibit DNMT1. However, cellular metabolism and nuclear access integrate these opposing activities is unknown. We hypothesized that nuclear partitioning of oxysterols and their sulfates form a counter-regulatory axis that control DNMT1 activities. **Methods:** Huh-7 hepatocytes were exposed to exogenous 25HC, 27HC, or CA and harvested at 0, 1.5, 3, 6, 12, and 24 h. Oxysterols in culture media, whole-cell lysates, and nuclear fractions were isolated with a commercial nuclear extraction kit, using isotope-labeled internal standards. Oxysterols and their 3-sulfates in each fraction were quantified by liquid chromatography–tandem mass spectrometry (LC–MS/MS). DNMT1 modulation was evaluated by enzyme-kinetic assays with 25HC3S ± physiological 25HC (3.7 μM). Experiments were performed in 3 independent replicates. **Results:** 25HC rapidly accumulated intracellularly (detectable by 1.5 h) and ~4% localized to nuclei. Under identical conditions, 27HC and CA were not detected in nuclear fractions despite cellular uptake. All three oxysterols underwent extensive sulfation; predominant metabolites were 25HC3S, 27HC3S, and 3SCA. Notably, 27HC was preferentially converted to 3SCA rather than 27HC3S. Among sulfates, only 25HC3S was measurable in nuclei, whereas 3SCA was largely released to the medium, indicating differential nuclear retention/export. Biochemical assays revealed functional coupling: The presence of 25HC increased 25HC3S (larsucosterol) potency against DNMT1 (IC_{50}, from ~4 μM to 0.35 μM). At a 10:1 25HC:25HC3S ratio, 0.35 μM of 25HC3S suppressed DNMT1 activity by ~50%. **Conclusion:** Although 25HC, 27HC, and CA can modulate DNMT1 in vitro, only 25HC is able to enter nuclei, and only its sulfate, 25HC3S, accumulates in nuclei. Together these establish a nuclear 25HC/25HC3S rheostat—25HC (activator) versus 25HC3S (inhibitor)—that likely governs DNMT1-dependent promoter methylation in hepatocytes. In contrast, 27HC and CA appear to act predominantly via exported 3SCA rather than direct nuclear mechanisms. These findings provide a mechanistic framework for epigenetic remodeling in MASLD and nominate the nuclear 25HC:25HC3S ratio as a modifiable target for therapeutic intervention.

1343 | SIMULTANEOUS LOSS OF LAP2α ATTENUATES HEPATOCYTE-AUTONOMOUS STEATOHEPATITIS CAUSED BY LAMIN A/C DEFICIENCY THROUGH METABOLIC AND EPIGENETIC REPROGRAMMING

Kapil Upadhyay[1] Yunshu Yang[1] Chenguang Wang[1] Ryan Wilcox[1] Roland Foisner[2] M. Bishr Omary[3] Graham Brady[1], [1]University of Michigan, Ann Arbor, Michigan, [2]Max Perutz Labs, Medical University of Vienna, Vienna Biocenter Campus, Vienna, Austria, [3]Rutgers University, Piscataway, New Jersey

Background: Hepatocyte-specific *Lmna* deficiency disrupts nuclear lamina function and promotes liver injury characterized by lipid accumulation and steatohepatitis. We previously showed that hepatocyte-specific *Lap2*α deletion protected against diet-induced steatosis and liver injury, identifying LAP2α as a regulator of hepatic lipid metabolism. Because LAP2α binds to and regulates mobility of lamin A/C in the nuclear interior but also regulates other intranuclear proteins including transcription factors and chromatin state modifiers, we investigated whether hepatocyte-specific *Lap2*α deletion could modulate *Lmna* deficiency-induced liver injury and steatohepatitis. **Methods:** Hepatocyte-specific *Lmna/Lap2*α-double knockout (DKO), *Lmna*-knockout ($Lmna^{\Delta Hep}$), and wild-type (WT) littermate C57BL/6j male mice were fed standard chow or a high-fat diet with fructose (40% fat calories, 20 kcal% fructose, 2% cholesterol) for 8 or 16 weeks. Liver injury and steatosis were assessed via histopathology and measurement of serum chemistries and hepatic lipid content. Mechanisms of injury were examined using RNA-seq, RT-qPCR, and western blot. **Results:** DKO mice showed significantly reduced liver injury and hepatic steatosis compared with $Lmna^{\Delta Hep}$ mice, as evidenced by lower serum ALT and hepatic triglyceride levels, and reduced steatosis on H&E-stained liver sections (**Figure 1A**). RNA-seq analysis of liver RNA from young (7-8 weeks of age) chow-fed mice revealed that, while global transcriptomic profiles of $Lmna^{\Delta Hep}$ and DKO livers were similar, DKO livers showed reversion to WT-like expression of a defined gene subset (**Figure 1B**), which included genes related to lipid uptake and *de novo* lipogenesis (*Cd36*, *Srebf1*, *Thrsp*), inflammation (*Mpeg1*, *Ctse*), and mitochondrial and endoplasmic reticulum lipid metabolism (*Acss3*, *Insig2*). Mechanistically, $Lmna^{\Delta Hep}$ livers exhibited increased histone H3K9 acetylation compared to WT, which was prevented in DKO livers. **Conclusion:** DKO mice were protected from *Lmna* deficiency-induced liver injury and steatosis, with transcriptomic data showing locus-specific suppression of pro-steatotic and pro-inflammatory programs rather than global transcriptomic normalization in DKO livers. Reduced H3K9 acetylation in DKO livers points to altered histone acetylation as a potential mechanism underlying the selective protective transcriptional reprogramming in DKO hepatocytes. Together, these data identify transcriptional and metabolic reprogramming and epigenetic regulation as mechanisms by which simultaneous loss of LAP2α attenuates *Lmna* deficiency-induced steatohepatitis and liver injury in DKO mice.

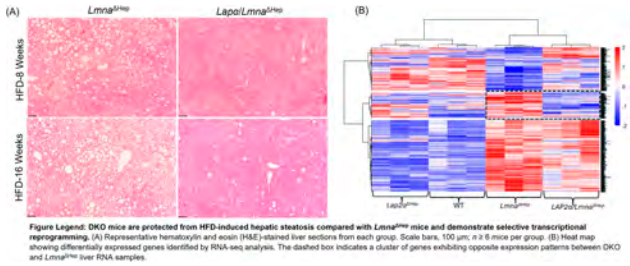

Figure Legend: DKO mice are protected from HFD-induced hepatic steatosis compared with $Lmna^{\Delta Hep}$ mice and demonstrate selective transcriptional reprogramming. (A) Representative hematoxylin and eosin (H&E)-stained liver sections from each group. Scale bars, 100 μm; *n* ≥ 6 mice per group. (B) Heat map showing differentially expressed genes identified by RNA-seq analysis. The dashed box indicates a cluster of genes exhibiting opposite expression patterns between DKO and $Lmna^{\Delta Hep}$ liver RNA samples.

[2]College of Pharmacy, Sookmyung Women's University, Seoul, Korea

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by hepatic lipid accumulation and extrahepatic complications. Lysophosphatidylcholine (LPC) is implicated in metabolic and inflammatory responses. Diet-induced gut microbiota dysbiosis may alter LPC-related glycerophospholipid metabolism, linking diet, microbiome, and lysophospholipid metabolism. However, tissue-specific LPC profiles across MASLD-related mouse models have not been systematically compared. We focused on LPC(18:1), a major C18 LPC species, and compared its distribution across liver, plasma, and kidney in distinct dietary and age-associated MASLD-related models. **Methods:** Male C57BL/6J mice were fed normal diet (ND), high-fat diet (HFD), western diet (WD), or choline-deficient, L-amino acid-defined, high-fat diet (CDAHFD). A separate group of 70-week-old male C57BL/6J mice was divided into four groups by body weight. LPC species in liver, plasma, and kidney were quantified by LC-MS using LPA(17:0) as an internal standard. Hepatic triacylglycerol (TAG) and blood chemistry parameters were measured. **Results:** Hepatic TAG levels were elevated in HFD- and WD-fed mice with the highest levels in WD-fed mice. LPC(18:1) was markedly elevated in liver, plasma and kidney of WD-fed mice. Other unsaturated C18 LPC species varied by tissue and dietary model; hepatic LPC(18:2) and LPC(18:3) were decreased in HFD- and WD-fed mice. CDAHFD-fed mice showed a distinct hepatic LPC pattern, with increased in LPC(18:1) and several other LPC species despite no apparent hepatic TAG increase. In body weight-stratified aged mice, hepatic TAG levels were elevated, whereas ALT, AST, and hepatic LPC species showed no marked group-dependent differences. Overall, LPC(18:1) alterations were most prominent in WD-fed mice. **Conclusion:** LPC(18:1) levels showed tissue- and model-dependent differences across MASLD-related mouse models. These differences were not fully explained by hepatic TAG accumulation, as aged mice exhibited elevated hepatic TAG without comparable LPC changes. Our data provide a targeted multi-tissue analysis of selected LPC species across diet-induced and age-associated MASLD-related contexts. Further analyses of FADS1/2 and SCD1 may determine whether alterations in selected unsaturated C18 LPC species are linked to double bond-dependent changes in hepatic lipid metabolism. In parallel, microbiome-related lipid changes, including odd-chain lysophospholipid species, warrant consideration in future studies.

1345 | APPLICATION OF MULTILINEAGE HUMAN LIVER ORGANOIDS IN DISEASE MODELING, DRUG TESTING AND GENETIC INTERVENTION

Qichao Ge[1] Qingqing Zhang[1] Yufei Yang[2] Ling Zhang[3] Ying Luo[3] Lungen Lu[1], [1]Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, [2]Shanghai General Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China bShangh, [3]Continent Pharmaceuticals Co. ,Ltd., Beijing, China

Background: Animal models have limitations in predicting human clinical outcomes, highlighting the need for advanced human-relevant models. We aimed to establish multilineage human liver organoids (hLOs) for modeling fibrosis and metabolic dysfunction–associated steatotic liver disease (MASLD), and for evaluating pharmacological and genetic interventions. **Methods:** hLOs were generated from human induced pluripotent stem cells by stepwise co-differentiation. Fibrosis was induced by transforming growth factor-β (TGF-β), and steatotic injury by free fatty acids. Hydronidone and resmetirom were used for pharmacological studies. Lentiviral knockdown of YB1 in hepatocytes and STAT3 in hepatic stellate cells was used for lineage-restricted genetic perturbation. **Results:** TGF-β induced a fibrotic phenotype in hLOs, with stellate cell activation, increased extracellular matrix secretion, and Sirius Red–positive matrix deposition. Free fatty acid treatment induced an acute lipotoxic MASLD-like phenotype characterized by steatosis, hepatocyte apoptosis, inflammatory activation, and fibrotic remodeling. Hydronidone attenuated fibrotic responses, whereas resmetirom reduced steatosis, inflammation, hepatocyte injury, and fibrosis-associated changes. In parallel, YB1 knockdown in hepatocytes and STAT3 knockdown in stellate cells ameliorated steatotic and fibrogenic phenotypes, respectively. **Conclusion:** Multilineage hLOs provide a human-relevant platform for modeling fibrosis and MASLD and for evaluating therapeutic and genetic interventions in a multicellular liver context.

1346 | FUNCTIONALLY CONSERVED LONG NONCODING RNA MOTIFS RESTRAIN PROTEIN KINASE R SIGNALING IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE

Shuangdi Duan[1] Haiming Cao[1], [1]NIH

Background: Long noncoding RNAs (lncRNAs) have emerged as regulators of metabolic dysfunction-associated steatotic liver disease (MASLD), but limited cross-species conservation hampers mechanistic validation and translation. We aimed to identify functionally conserved lncRNAs (FCLs) that control hepatic metabolism and define their mechanism. **Methods:** Human nonalcoholic fatty liver disease (NAFLD) liver transcriptomes were integrated with long-read nanopore transcriptomes from fasted/refed humanized mouse livers to prioritize metabolically responsive FCLs. Candidate function was tested in lipid-loaded hepatocytes, adenoviral and AAV-mediated hepatic knockdown/rescue models, high-fat diet models, metabolic phenotyping, RNA sequencing, phosphoproteomics, RNA pulldown-mass spectrometry, RNA immunoprecipitation, competitive binding assays, and viral or tri-N-acetylgalactosamine (tri-GalNAc) delivery of minimal RNA motifs. **Results:** This strategy identified a syntenic FCL pair, human FCL (hFCL) and mouse FCL (mFCL), whose expression was suppressed in patient livers, high-fat diet-fed mice, refed liver, and lipid-loaded hepatocytes. mFCL depletion worsened hepatic steatosis, dyslipidemia, glucose intolerance, insulin resistance, and transcriptional programs favoring lipogenesis, gluconeogenesis, and cholesterol synthesis, whereas hFCL restoration reversed these defects and improved oxygen consumption and energy expenditure. Mechanistically, hFCL/mFCL directly bound protein kinase R (PKR; EIF2AK2), reduced PKR interaction with PACT, limited PKR-stress granule colocalization, and suppressed PKR/eIF2α phosphorylation. Minimal human and mouse FCL motifs retained PKR binding, inhibited PKR activity and triglyceride accumulation, and ameliorated steatosis and systemic metabolic dysfunction after AAV or hepatocyte-targeted tri-GalNAc delivery in high-fat diet-fed mice. **Conclusion:** hFCL/mFCL define a conserved lncRNA-PKR signaling axis that protects against metabolic fatty liver disease. Compact FCL-derived motifs may provide a practical RNA-therapeutic strategy for MASLD.

Functionally Conserved Long Noncoding RNA Motifs Restrain Protein Kinase R Signaling in Metabolic Dysfunction-Associated Steatotic Liver Disease

1347 | PATIENT-LEVEL METABOLIC FLUX MODELING IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) REVEALS DIFFERENTIAL REPROGRAMMING OF HEPATIC METABOLISM IN MACROPHAGE-ENRICHED VERSUS DEPLETED FIBROTIC STATES

Stephen Hoang[1] Justin Taylor[2] Arun Sanyal[1], [1]Virginia Commonwealth University, [2]Genentech

Background: Progressive MASLD is characterized by hepatic metabo-inflammation and fibrosis. The inflammatory link to fibrosis is captured by the macrophage-fibroblast cell circuit theory that defines two stable states: “hot” (macrophage-rich) and “cold” (macrophage-depleted) (Zhou et al. 2018, Alder et al. 2020). The metabolic link to these inflammatory-fibrogenic states is unknown. The aim of this study is to define the metabolic reprogramming associated with hot vs cold fibrosis. **Methods:** We obtained bulk RNA-seq from 78 human MASLD liver biopsies spanning the disease activity and fibrosis spectrum (Hoang et al. 2019). Each sample was analyzed by two parallel pipelines on the same expression data (Figure A). First, cell-type deconvolution against the Guilliams et al. (2022) human liver atlas was used to estimate the proportion of lipid-associated macrophages (LAM) for each sample. This value was used as an operational proxy for fibrogenic temperature (hot to cold). Next, a transcriptomics-constrained flux balance analysis algorithm was applied to a genome-scale human metabolic network. The algorithm fits absolute reaction fluxes to continuous per-reaction targets derived from gene expression data, weighted by differential expression scores. This yielded per-patient flux predictions across all reactions. Predicted fluxes were correlated with fibrosis temperature while controlling for fibrosis stage. **Results:** Fibrosis temperature correlated positively with both NAFLD activity score (rho = 0.4, p = 0.0003) and fibrosis stage (rho = 0.33, p = 0.003), confirming that the temperature proxy generally tracks histologic severity. After controlling for fibrosis stage, the predicted flux of 138 reactions was significantly associated with fibrosis temperature (5% FDR, Figure B). The strongest associations were in reactions mediated by hepatic organic anion transporters (OATPs), consistent with their known regulation under cholestasis, inflammation, and regeneration. Phospholipid metabolism was also significantly altered, converging with independent evidence linking PE / PC ratio to membrane integrity in steatotic liver disease. In addition, over twenty boundary reactions correlated with temperature, defining a candidate serum biomarker list. **Conclusion:** Hepatic metabolism reorganizes systematically along the hot/cold fibrosis axis in human MASLD. Top predictions converge on pathways that have been previously implicated in hepatic injury and disease, providing biological validation. This patient-level metabolic phenotyping approach extends the hot/cold framework with a metabolic dimension and nominates candidate biomarkers for distinguishing fibrosis endotypes.

1348 | *DOREA LONGICATENA* ATTENUATES METABOLIC DYSFUNCTION-ASSOCIATED STEATOTIC LIVER DISEASE VIA ACTIVATING THE OVARIAN STEROIDOGENESIS PATHWAY AND MODULATING THE INTESTINAL MICROBIOTA

Xin Ai[1] Xin Wang[1] Zilong Wang[1] Haiying Zhang[1] Xiaoxiao Wang[1] Feng Liu[1] Huiying Rao[1], [1]Peking University People's Hospital

Background: The most prevalent chronic liver disease worldwide is metabolic dysfunction-associated steatotic liver disease(MASLD). The gut microbiota plays a crucial role in its pathogenesis, yet the therapeutic potential of specific microbial species and metabolites remains largely unexplored. **Methods:** We investigated the role of *Dorea longicatena* in MASLD using human stool samples, western diet with fructose/CCl_4 mouse model, and multi-omics approaches. Liver injury was evaluated by biochemical, histological, and molecular analyses. Gut microbiota composition was assessed by 16S rRNA sequencing, while transcriptomics identified functional pathways. **Results:** *Dorea longicatena* abundance was increased in MASLD patients and MASLD mice. Supplementation with *Dorea longicatena* in MASLD mice significantly attenuated hepatic steatosis, inflammation, and fibrosis. Mechanistically, *Dorea longicatena* activating the ovarian steroidogenesis pathway and restoring metabolic homeostasis. Inhibition the ovarian steroidogenesis pathway abolished *Dorea*

longicatena mediated protection. Furthermore, *Dorea longicatena* promoted the proliferation of well-characterized probiotics and improved gut barrier integrity. **Conclusion:** This study identifies *Dorea longicatena* as a commensal with hepatoprotective effects in MASLD, acting through the ovarian steroidogenesis pathway and gut microbiota modulation. These findings highlight *Dorea longicatena* holds potential as a probiotic for the prevention of MASLD.

1349 | ACTIVATION OF BILE ACID RECEPTOR FXR CHANGES TRANSCRIPTIONAL PROGRAM IN VISCERAL ADIPOCYTES OF OBESE INDIVIDUALS WITH MASLD

Lena Voško[1] Lukas Gulden[1] Judith Sommer[1] Dagmar Silbert-Wagner[1] Emilian Jungwirth[2] Antonio Molinaro[3] Katrin Panzitt[1] Martin Wagner[1], [1]Medical University of Graz, Austria, [2]Center for Biomarker Research in Medicine, Graz, Austria, [3]University of Gothenburg, Sweden

Background: Signaling via the bile acid-sensing farnesoid X receptor (FXR) undergoes adaptive changes in response to the metabolic disturbance in obesity, which is associated with metabolic dysfunction-associated steatotic liver disease. Our previous work showed that metabolic pressure in obesity alters FXR binding and transcriptional activity in the liver, which results in enhanced substrate utilization following ligand activation. Adipose tissue (AT) functions both as energy store and endocrine organ. In obesity, lipid storage capacity and release of fatty acids via lipolysis becomes impaired in adipocytes, which contributes to systemic inflammation. Although hepatic FXR signaling has been extensively investigated, its role in human AT remains poorly understood. Therefore, this study aimed, for the first time in humans, to define the cellular and transcriptional consequences of FXR activation in visceral adipose tissue (VAT) in metabolic disease. **Methods:** We performed single-nuclei RNA sequencing on VAT biopsies derived from non-obese and morbidly obese (BMI > 35 kg/ m2) individuals treated with the FXR agonist obeticholic acid (OCA; 25 mg/ d for 3 weeks) or placebo in a randomized double-blind trial. **Results:** 14 VAT samples (non-obese: 2 OCA, 2 placebo; obese: 5 OCA, 5 placebo) yielded a total of 24,526 quality-filtered nuclei. Adipocytes accounted for 12% and adipose-derived stromal and progenitor cells (ASPCs) for 16% of nuclei. Obesity resulted in increased mitochondrial respiration and lipolytic gene signatures. OCA treatment reversed these effects. Gene set enrichment analysis showed downregulated mitochondrial respiration, oxidative phosphorylation, and ATP synthesis in adipocytes and ASPCs from obese OCA-treated individuals. Additionally, lysosomal pathways and pathways involved in lipid turnover were downregulated in adipocytes in this group, accompanied by lower expression of lipolytic genes. Interestingly, NR1H4/FXR and GPBAR1/TGR5 expression levels were low or absent in most samples, suggesting that adipose tissue may be affected indirectly. The metabolic findings in VAT are much more pronounced than findings in comparable subcutaneous AT where anti-inflammatory events were predominant. **Conclusion:** In obese individuals, transcriptional profiling suggest that FXR activation reduces lipid turnover and mitochondrial oxidation across multiple VAT subpopulations. This contrasts the FXR activating effects in the livers of the same individuals. Minimal local FXR expression suggests that OCA mediated effects are indirect, supporting the existence of a liver-adipose (or intestine-adipose) signaling axis modulating energy production in adipocytes and progenitors.

1350 | THYMIDINE PHOSPHORYLASE RESTRAINS PPARA-DEPENDENT FATTY ACID OXIDATION IN MASLD

Wei Li[1] Hong Yue[1] Adam Belcher[2] Kelli Vaughan[3] Julie Mattison[3] Krista Denning[1] Angela Li[4] Yongke Lu[1] Zander Pinson[1], [1]Joan C. Edwards School of Medicine at Marshall University, [2]Vandalia Health, [3]NIA, [4]Ohio State University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by impaired hepatic fuel selection and suppression of fatty acid oxidation (FAO). However, the mechanisms linking metabolic stress to persistent repression of FAO programs remain incompletely understood. We investigated whether thymidine phosphorylase (TYMP) contributes to MASLD through regulation of PPARα-dependent metabolic programs. **Methods:** Wild-type (WT), *Tymp*$^{-/-}$, and *Ppar*$\alpha^{-/-}$ mice were subjected to Western diet (WD) or high-fat diet feeding. Metabolic phenotyping, histology, and molecular analyses were performed. Pharmacologic TYMP inhibition was achieved using tipiracil (TPI). Translational relevance

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

was evaluated using obese rhesus monkeys and human liver datasets. **Results:** TYMP expression was markedly increased in the livers of obese mice, rhesus monkeys, and humans with steatotic liver disease. Genetic deletion or pharmacologic inhibition of TYMP attenuated diet-induced obesity, hepatic steatosis, dyslipidemia, and insulin resistance without altering food intake or energy expenditure. TYMP deficiency reduced respiratory exchange ratio, indicating enhanced FAO. Mechanistically, TYMP deficiency increased hepatic PPARα expression and activity under dietary stress, whereas TYMP expression was elevated in *Pparα*$^{-/-}$ livers, demonstrating reciprocal regulation. Importantly, TPI-mediated metabolic protection was abolished in *Pparα*$^{-/-}$ mice. In obese rhesus monkeys, TPI treatment improved metabolic parameters and enhanced hepatic PPARα activity signatures. **Conclusion:** TYMP is a previously unrecognized regulator of hepatic fuel selection that restrains PPARα-dependent FAO programs during MASLD progression. Pharmacologic TYMP inhibition using the clinically approved agent tipiracil may represent a novel therapeutic strategy for MASLD.

1351 | 4-HYDROXYNONENAL PROMOTES HEPATIC FIBROSIS IN MASLD VIA FORMATION OF HEPATIC MACROPHAGE AGGREGATES

Masahiro Yanagi[1] Hidenori Kido[1] Eishiro Mizukoshi[2] Taro Yamashita[1], [1]Kanazawa University Hospital, [2]Kanazawa Medical University Hospital

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the leading cause of chronic liver disease, and fibrosis severity determines long-term prognosis. Oxidative stress and lipid peroxidation are key drivers of disease progression, generating reactive aldehydes such as 4-hydroxynonenal (HNE) that covalently modify cellular proteins. Hepatic macrophages critically orchestrate inflammation and fibrogenesis, but the pathogenic role of HNE-modified macrophages remains undefined. We previously reported that MASLD patients with marked hepatic HNE deposition exhibit advanced inflammation and fibrosis. Here, we investigated how HNE deposition on hepatic macrophages drives fibrosis in MASLD. **Methods:** (1) Liver tissues from MASLD patients and from mice fed a choline-deficient L-amino acid-defined (CDAA) or atherogenic high-fat (AHF) diet were stained for HNE, CD68 (F4/80), α-SMA, and Sirius Red to evaluate HNE deposition on hepatic macrophages and fibrosis. (2) In 60 MASLD patients, hepatic HNE deposition was graded (HNE score: 0–2), and its association with hepatic macrophage aggregates (HMA) number and fibrosis was analyzed. (3) Mice received daily intraperitoneal HNE (10 mg/kg) or vehicle (NC) for 8 weeks; an additional group received HNE plus clodronate liposome (CL) to deplete macrophages. (4) An HNE + Alda-1 group received Alda-1 (ALDH2 agonist, 20 mg/kg, three times weekly) to test the effect of HNE detoxification. (5) CD45+ cells from NC and HNE-treated livers (n = 1 each) underwent single-cell RNA sequencing (scRNA-seq) with macrophage sub-clustering. **Results:** (1) Numerous HMAs were observed in livers from MASLD patients and CDAA- and AHF-fed mice, with strong HNE deposition within HMAs. α-SMA was positive around HMAs, and fibrosis progressed along these aggregates. (2) Higher HNE scores were associated with significantly more HMAs and greater fibrosis. (3) Versus NC, HNE-treated mice showed significantly increased HMA formation with strong HNE deposition, peri-HMA α-SMA expression, and significantly larger α-SMA-positive and fibrotic areas. HMA formation was abolished in the HNE + CL group, with α-SMA-positive and fibrotic areas significantly reduced versus HNE. (4) In the HNE + Alda-1 group, HMA number, α-SMA-positive area, and fibrotic area were all significantly reduced versus HNE. (5) scRNA-seq revealed an *Spp1*+ macrophage subset emerging in HNE-treated mice, with elevated expression of *Trem2*, *Cd9*, *Fabp5*, *Arg1*, *Fn1*, *Olr1*, and *Cd63* — a signature consistent with the scar-associated/lipid-associated macrophage populations previously reported to drive hepatic fibrosis. **Conclusion:** HNE drives the formation of profibrogenic HMAs and hepatic fibrosis progression in MASLD. HNE detoxification may represent a novel therapeutic strategy.

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is the most prevalent chronic liver disease and has emerged as a global health problem. Accumulating clinical evidence has demonstrated that MASLD is independently associated with an increased risk of chronic kidney disease (CKD). This study aimed to explore the role of the lysophosphatidylcholine (LPC)-autotaxin (ATX)-lysophosphatidic acid (LPA) axis in MASLD-associated kidney injury. **Methods:** A murine model and a human cohort were used to investigate MASLD-associated kidney injury and accompanying circulating metabolic alterations. Male C57BL/6J mice were fed a high-fat, high-cholesterol, and high-fructose diet (HFCFD) for 12, 18, or 24 weeks to recapitulate the temporal progression of MASLD. At each disease stage, mice underwent comprehensive phenotyping, including serum biochemistry, serum cystatin C quantification, hepatic lipid measurement, urinary albumin measurement, and urinary hydrogen peroxide quantification. Histological analyses were performed using liver and kidney tissue sections, and renal ultrastructural changes were further examined by transmission electron microscopy. In parallel, patients were enrolled and stratified according to biopsy-defined MASLD stage, and serum samples were collected for lipidomic profiling. Serum ATX and LPA levels were quantified. Two pharmacological inhibitors were used: the ATX inhibitor PF-8380 and the LPA receptor antagonist Ki16425. After 18 weeks of HFCFD feeding, mice received daily intraperitoneal injections of PF-8380, Ki16425, or vehicle for 6 weeks. **Results:** With the progression of diet-induced MASLD, mice developed progressively worsening kidney injury. Serum cystatin C, urinary albumin, urinary albumin-to-creatinine ratio (UACR), and urinary hydrogen peroxide-to-creatinine ratio were significantly increased across disease stages. Histological analysis showed enlargement of glomerular cross-sectional area. Transmission electron microscopy further revealed segmental podocyte foot process effacement, glomerular basement membrane thickening, and mitochondrial abnormalities in renal tubular epithelial cells. These structural and functional alterations worsened with advancing disease severity. LC-MS-based untargeted serum lipidomic profiling of patients with biopsy-confirmed MASLD revealed that LPCs were the most prominently altered lipid class, with LPC 18:1 and LPC 18:2 progressively decreasing as MASLD advanced. Serum ATX and LPA levels also increased with MASLD progression. Compared with vehicle-treated HFCFD mice, UACR was significantly reduced in PF-8380- and Ki16425-treated mice. **Conclusion:** Our findings indicate that the LPC-ATX-LPA axis is markedly dysregulated during MASLD progression. Pharmacological inhibition of ATX-LPA signaling attenuated MASLD-associated kidney injury.

1353 | CERS6-DEPENDENT HEPATOCYTE-DERIVED EXTRACELLULAR VESICLES INDUCE MACROPHAGE INFLAMMATORY RESPONSES

Joseph Dempsey[1] Carole Smith[1] Benjamin Pryce[1] Christopher Savard[2] Aimee Wu[1] Aletta Li[1] Autumn York[1] Sum Lee[1] George Ioannou[1] Rotonya Carr[3], [1]University of Washington, [2]University of Washington; Veterans Affairs Puget Sound Health Care System, [3]University of Washington Medical Center

Background: The drivers for the transition from metabolic dysfunction-associated steatotic liver disease (MASLD) to metabolic dysfunction-associated steatohepatitis (MASH) remain incompletely understood. Ceramide synthase 6 (CERS6) produces long-chain ceramides (primarily C16:0), which we and others have linked to lipotoxicity and inflammation. C16:0 ceramide is increased in MASLD patients and is present in extracellular vesicles (EVs) in murine and human MASLD. We hypothesize that the accumulation of CERS6-derived C16:0 ceramides and EVs promotes proinflammatory macrophages in the transition from MASLD to MASH. **Methods:** Wild-type (WT) and CERS6 knockout (KO) mice were fed a normal chow or high fat, fructose, and cholesterol (FFC) diet for 4 weeks. EVs were isolated from the serum, liver histology was scored for steatosis and inflammation, and hepatic RNA was sequenced. Hepatocyte-specific EVs were isolated from the media of HepG2 WT and KO cells exposed to control (ctrl) or C16:0 ceramide (C16) for 48 hours. EV particle concentration and size was evaluated by a NanoSight NS300. Bone marrow-derived macrophages (BMDMs) were exposed to EVs for 6 hours. RT-qPCR was performed on RNA from

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

HepG2 cells and BMDMs. **Results:** Histologically, compared to normal chow mice, all FFC-fed mice were steatotic, but only FFC-fed WT mice had increased inflammation and a trend toward increased *Cers6* gene expression. In these mice, hepatic RNA expression of the EV biogenesis gene *Rab8* and the EV biogenesis and ceramide synthesis gene *Smpd3* was increased, suggesting a role for EVs and ceramides. *RAB8* and *SMPD3* were also expressed *in vitro* in HepG2 WT and KO cells. In general, EVs isolated from KO cells were larger than their respective controls, and particle size distribution was right-skewed in a CERS6-dependent manner. Compared to WT-ctrl EVs, the mean particle size of KO-ctrl EVs was larger (135 nm vs 148 nm, $p = 0.029$). There was no response by BMDMs to mouse serum-derived EVs, but compared to BMDMs exposed to HepG2 WT-ctrl EVs, BMDMs exposed to WT-C16 EVs had increased RNA expression of the inflammatory markers *Cxcl2* and *Cxcl10*. Compared to WT-C16, BMDMs exposed to KO-C16 EVs had decreased RNA expression of *Cxcl2* and *Il6*, suggesting a CERS6-dependent macrophage inflammatory response. **Conclusion:** In the absence of CERS6, C16 does not overcome the reduced macrophage inflammatory response to EVs. This study suggests that CERS6 may be required for macrophage inflammation in MASLD.

1354 | PATIENT-DERIVED IPSC LIVER ORGANOIDS EXHIBIT DONOR-SPECIFIC SUSCEPTIBILITY TO MASH AND DRUG-INDUCED TOXICITY

Ekta Minocha[1] Ashwani Kumar Gupta[1] Nate Schmidt[2] Ivan Sarabia[3] John Purdy[2] Jason Wertheim[2], [1]The University of Arizona, College of Medicine, Tucson, AZ, USA., [2]The University of Arizona, College of Medicine, Tucson, AZ, USA, [3]The University of Arizona, Tucson, AZ, USA

Background: Patient-derived induced pluripotent stem cells (iPSCs) have emerged as a powerful platform for modeling human liver disease by capturing donor-specific genetic backgrounds. As translational applications expand, there is a need for stable, reproducible human-relevant organoid systems that support reproducible analysis of metabolic dysfunction associated steatohepatitis (MASH) and drug-induced toxicity across diverse donors. Reliance on xenogeneic matrices, such as Matrigel introduces variability, underscoring the need for developing Matrigel-free methods for generating liver organoids suitable for disease modeling and toxicity assessment. **Methods:** De-identified control and MASH donor-derived iPSCs were obtained from CDI-CIRM stem cell repository and induced to differentiate into hepatic progenitors. These progenitors were spotted at an air-liquid interface (ALI) to generate highly vascularized, multicellular liver organoids. This 3D organotypic culture condition eliminated the need for Matrigel embedding. Phenotypic and functional analysis were conducted using specific markers and various functional assays. To model MASH, organoids were exposed to free-fatty acids and evaluated using transcriptomics, ELISA, lipidomics and stiffness measurements via nano-indentation as a read-out of fibrosis severity. Drug-induced hepatotoxicity was assessed following acetaminophen (APAP) treatment through apoptotic, transcriptional, and mitochondrial dysfunction analysis. **Results:** Control and MASH donor-derived liver organoids exhibited major hepatic cell types, including hepatocytes, cholangiocytes, stellate cells, sinusoidal endothelial cells, and Kupffer-like cells, confirmed by phenotypic analysis and functional assays. Following free-fatty acid exposure, MASH-donor derived liver organoids exhibited increased susceptibility to steatosis (BODIPY staining), inflammation (elevated expression and secretion of inflammatory cytokines like TNFα, IL-23 and IL-8), and fibrosis (increased COL1A1, TGFβ, and ACTA2 at transcript and protein levels). Lipidomic profiling showed global lipidomic shifts that closely resembled those observed in MASH liver biopsies, and organoid stiffness increased significantly reflecting enhanced fibrotic remodeling. APAP treatment induced a dose-dependent increase in apoptosis, inflammation and mitochondrial oxidative stress, accompanied by reduced ATP levels and downregulation of antioxidant pathways, with MASH-derived organoids exhibiting increased sensitivity to APAP toxicity. **Conclusion:** This study presents a robust, Matrigel-free approach for generating vascularized, multicellular liver organoids and demonstrates their utility for personalized disease modeling, and drug-toxicity assessment.

1355 | IDENTIFICATION OF FIBRILLIN-1 AS A DRIVER OF FIBROGENESIS AND PATHOLOGICAL ELASTIC FIBERS ACCUMULATION IN MASH FIBROSIS

Hiroaki Yashiro[1] Lisa Longato[2] Saman Farahmand[1] Maria Paraskevopoulou[3] Satoru Matsumoto[1] Athiva Shankar[2] Nafia Guljar[2] Ifigeneia Bardi[2] Gareth Muirhead[4] Tu Vinh Luong[5] Andrew Hall[5] Chris Stevenson[2] Giuseppe Mazza[5] Bernard Allan[1], [1]Takeda Pharmaceuticals International Co, [2]Engitix Therapeutics, London, United Kingdom, [3]Takeda Pharmaceuticals, [4]Engitix Therapeutics, London, United Kingdom,, [5]Department of Cellular Pathology, Royal Free London NHS Foundation Trust

Background: The fibrotic extracellular matrix (ECM) is a complex microenvironment of structural proteins, proteoglycans, glycoproteins, ECM regulators and growth factors. Among the ECM components demonstrated to promote resistance to degradation and limiting reversibility of liver fibrosis are elastic fibres, consisting of a scaffold of microfibrillar proteins, interacting with microfibrils-binding proteins and an inner core of elastin. This study aimed to identify and functionally validate regulators of liver fibrosis with emphasis on microfibril biology. **Methods:** Decellularized ECM from healthy and MASH F4 livers was generated and analyzed by tandem-mass-tag proteomics (n = 3/group). Proteins related to microfibrils and elastin fibers biology that were upregulated in the MASH F4 matrisome compared with healthy livers were prioritized for further assessment. Expression and spatial localization were validated using bulk and spatial transcriptomics in independent MASH patients. Target knockdown (KD) was performed in *in vitro* assay with primary human hepatic stellate cells (HSCs) as well as in CDHFD rats of liver fibrosis with robust features of elastin accumulation. **Results:** Proteomics identified enrichment of ECM and elastic fiber proteins in MASH. Fibrillin-1 (*FBN1*), the most upregulated ECM (~15-fold, $P < 0.0001$), was prioritized for assessment as potential regulator of fibrosis based on its structural and regulatory roles. Independent datasets confirmed *FBN1* mRNA upregulation (1.75-fold in F3, n = 16; 2.36-fold in F4, n = 32 vs controls n = 30; $P < 0.05$). *FBN1* mRNA expression was localized to the non-parenchymal component of healthy livers, and its overexpression and localization in the septa in MASH F4 livers was confirmed by singleplex in-situ hybridization and spatial transcriptomics analysis. Gene network analysis of F0 to F4 liver revealed that the disease module with *FBN1* as centre regulates ECM organization and type I/III collagens. In HSCs, *FBN1* KD reduced collagen production and disrupted ECM organization. In CDHFD rats, an advanced liver fibrosis model, progressive elastin deposition correlated with increased *FBN1* expression and LNP-mediated *Fbn1* siRNA KD achieved 74% target reduction ($P < 0.0001$) resulting in 60% reduction in collagen (Picrosirius red staining) and 58% reduction in elastin (Victoria blue) deposition. **Conclusion:** FBN1 is upregulated in MASH fibrosis in humans and its KD in HSCs prevents deposition of key ECM components *in vitro*. Further, using an appropriate *in vivo* model for mechanistic studies aimed at assessing the contribution of elastic fibers to liver fibrosis, we found that FBN1 plays a key role in elastic deposition in liver fibrosis.v

★ 1356 | FXR SIGNALING REWIRES CERAMIDE HOMEOSTASIS AND FERROPTOTIC VULNERABILITY IN MASH

Yasmeen Attia[1] Basma Abdelrahman[2] Rasha Tawfiq[2] Olfat Hammam[3], [1]Faculty of Pharmacy, The British University in Egypt, [2]The British University in Egypt, [3]Theodor Bilharz Research Institute

Background: Metabolic dysfunction-associated steatohepatitis (MASH) emerges when hepatocytes are forced to navigate a hostile landscape of distorted bile acid signaling and lipid overload. Among the most injurious lipid species, ceramides carve a pro-death metabolic signature that destabilizes membranes and primes the liver for ferroptosis, an iron-driven collapse of lipid integrity. Farnesoid X receptor (FXR) activation has been proposed to counter this trajectory, yet whether it intersects with ceramide biogenesis and ferroptotic susceptibility in a MASH setting remains obscure. Here, we explore whether the FXR agonist obeticholic acid (OCA) can recalibrate ceramide synthesis and blunt ferroptotic drive in experimental MASH. **Methods:** A dietary high-fat diet (HFD) model was used to establish experimental MASH. Male C57BL/6 mice were assigned to three groups: a normal chow group, an HFD control group receiving vehicle, and an OCA-treated group maintained on HFD and administered obeticholic acid (5 mg/kg/day, p.o.) starting week 8 for a duration of 4 weeks. Livers were collected for histopathology and molecular analyses. FXR downstream

signaling was assessed by quantifying hepatic SHP-1 expression *via* qRT-PCR and CYP7A1 protein levels by ELISA. Ceramide metabolism was examined by measuring sphingosine-1-phosphate (S1P) and acid sphingomyelinase (ASMase) to capture catabolic and salvage pathways. Ferroptotic stress was evaluated through GPX4 protein quantification and 4-hydroxynonenal (4-HNE) levels using ELISA, reflecting antioxidant defense status and lipid peroxidation, respectively. **Results:** Histopathological assessment revealed that OCA mitigated key features of MASH in HFD-fed mice, markedly reducing macrovesicular steatosis and lymphocytic infiltration, reflecting an overall reduction in hepatocellular injury and inflammatory burden. Consistent with FXR engagement, OCA treatment induced a clear upregulation of SHP-1 and produced a notable suppression of CYP7A1, which fell by 79% relative to the HFD group, indicating effective restoration of bile acid regulatory signaling. Perturbations in ceramide metabolism were also corrected, as shown by pronounced reductions in hepatic S1P and ASMase levels (63.5% and 49.1%, respectively), suggesting alleviation of ceramide-driven metabolic stress. Ferroptotic drive was similarly attenuated, with GPX4 increasing almost 2-fold and 4-HNE concentrations declining by approximately 37% compared to untreated HFD mice, consistent with strengthened antioxidant capacity and reduced lipid-peroxidation burden. **Conclusion:** Through limiting ceramide buildup and reinforcing anti-ferroptotic defenses, OCA steers the steatotic liver toward a more resilient metabolic trajectory, defining how FXR activation coordinates ceramide remodeling and ferroptotic stress within the integrated landscape of MASH.

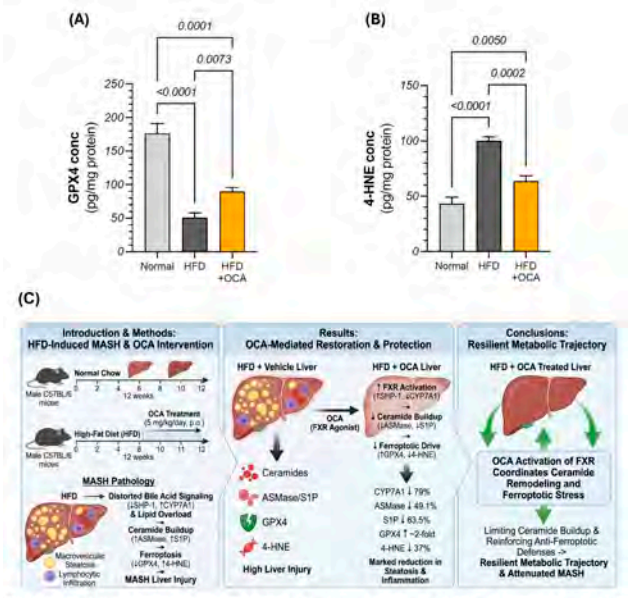

Fig. 1. Protein levels of **(A)** GPX4 and **(B)** 4-HNE in liver tissues from normal, HFD, and HFD+OCA groups. **(C)** Graphical summary demonstrating the proposed mechanism by which FXR recalibrates ceramide synthesis and blunts ferroptotic drive in experimental MASH. Data are presented as mean ± SD. Statistical analysis was performed using one-way ANOVA followed by Tukey's post hoc test for multiple comparisons. P values < 0.05 were considered statistically significant.

1357 | A HUMAN HIPSC-DERIVED LIVER ORGANOID PLATFORM FOR DILI PREDICTION AND DRUG SCREENING IN METABOLIC DYSFUNCTION-ASSOCIATED STEATOHEPATITIS (MASH)

Yedam Yoo[1] Jihye Choi[1] Jiseon Kim[1] Sewon Park[1] Joon Chul Kim[1] Seungwoo Cho[1] Yoonhee Jin[1], [1]Cellartgen Inc.

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is driven by lipotoxic stress, inflammatory activation, and hepatic stellate cell-mediated fibrogenesis. Drug-induced liver injury (DILI) also remains a major cause of drug attrition and post-marketing withdrawal. Conventional 2D hepatocyte models, including HepG2 cells, have limited predictive capacity because they lack key non-parenchymal cell components such as hepatic stellate cells (HSCs) and Kupffer cells (KCs). To address these limitations, we established a human induced pluripotent stem cell (hiPSC)-derived multicellular liver organoid platform for DILI prediction and MASH-associated drug screening. **Methods:** Human hiPSC-derived liver organoids containing hepatocyte-like cells, HSCs, and KCs were generated and characterized. Platform reproducibility was assessed by comparing intra- and inter-batch transcriptomic profiles using bulk RNA sequencing. For DILI prediction, organoids were exposed to reference DILI-positive compounds and structurally related DILI-negative analogs, followed by assessment of cell viability and AST leakage. To model MASH-associated liver injury and fibrosis, organoids were treated with free fatty acids and TGF-β. Therapeutic responses were evaluated after treatment with Resmetirom, Semaglutide, or Efruxifermin. Changes in lipid accumulation, fibrosis, lipogenesis, and inflammatory markers were assessed by triglyceride measurement, immunostaining, qRT-PCR, and collagen secretion analysis. **Results:** The differentiated liver organoids reproducibly incorporated hepatocyte-like cells, HSCs, and KCs, with higher expression of liver lineage and non-parenchymal cell markers than HepG2 cells. Transcriptomic analysis demonstrated low intra-batch variability and consistent inter-batch profiles, supporting platform reproducibility. In DILI prediction assays, the organoids selectively detected toxicity of DILI-positive compounds, as shown by reduced cell viability, increased AST leakage, whereas structurally related DILI-negative analogs showed minimal toxicity.FFA and TGF-β treatment induced MASH-associated phenotypes, including lipid droplet accumulation, increased triglyceride content, and upregulation of

fibrotic and inflammatory markers. In the MASH-induced organoids, Resmetirom, Semaglutide, and Efruxifermin reduced lipid accumulation and attenuated fibrotic and inflammatory responses, as indicated by decreased fibrotic gene expression and collagen secretion. **Conclusion:** This human hiPSC-derived multicellular liver organoid platform recapitulates key cellular and pathological features relevant to DILI and MASH-associated fibrosis. The platform may provide a reproducible and physiologically relevant in vitro system for hepatotoxicity prediction and therapeutic screening in MASH.

1358 | PRENATAL SYNTHETIC GLUCOCORTICOID EXPOSURE PROGRAMS SEX-SPECIFIC HEPATIC LIPID ACCUMULATION AND AGE-DEPENDENT LIVER TRANSCRIPTOMIC REMODELING IN BABOONS

Bowen Yang[1] Chen Zhang[2] Feiyang Zhao[2] Hillary Huber[3] Cun Li[4] Peter Nathanielsz[4] Laura Cox[5] Geoffrey Clarke[2] Lu Wang[2], [1]University of Texas Health Science Center at Houston, [2]University of Texas Health Science Center at San Antonio, [3]Texas Biomedical Research Institute, [4]University of Wyoming, [5]Wake Forest University School of Medicine

Background: Developmental programming posits that fetal exposures, including preterm antenatal synthetic glucocorticoid (sGC) therapy for reducing neonatal morbidity, can shape lifelong health risks. This project studied gene regulation in fetal (F) and aged (A) liver tissues obtained from a sGC baboon model and control (CTR) group. In-vivo hepatic lipid content (HLC) was also measured using 3T magnetic resonance spectroscopy (MRS) in the aged subjects. **Methods:** sGC pregnancies received clinically equivalent betamethasone (175 µg/kg/day x2 days at 0.60, 0.64, 0.68 gestation); CTR received saline. Groups were studied by treatment, age, and sex: F-sGC (165 d, 4M/4F), F-CTR (165 d, 4M/4F), A-sGC (4M:16.9 ± 0.8Y; 4F:15.9 ± 0.2Y), and A-CTR (4M:17.4 ± 0.8Y; 4F:15.4 ± 0.9Y). RNA-seq assessed differentially expressed genes (DEGs), pathways, alternative splicing, and RNA-binding protein (RBP) motifs in right-lobe F and A liver samples. Data are reported as mean ± SD. **Results:** Aged GC males had higher HLC by MRS than A-CTR males ($p = 0.04$) but no HLC differences were found in females. Aged liver RNA-seq mirrored this phenotype: A-sGC vs A-CTR males had more DEGs than females (55:37 up/18 down vs 15:9 up/6 down; up/down in A-sGC). Sex differences were minimal in A-CTR (7 DEGs:3 up/4 down in males) but prominent in A-sGC (104 DEGs:42 up/62 down in males). In A-sGC males, downregulated genes involved AMPK/insulin signaling (FBP2, IRS2), whereas upregulated genes involved fatty acid/steroid metabolism (ACSL4, HSD17 family). Cross-sectional fetal-to-aged RNA-seq showed greater age-associated downregulation in sGC than CTR animals, especially in males, with suppression of developmental regulators (ZEB2, SRF, TCF4). Shared sGC-associated changes involved extracellular matrix pathways. Female-specific changes involved inflammatory genes (NLRC4, ZBTB16, IRF8). Fetal-to-aged splicing analyses identified sGC-associated skipped-exon events in males with RBP motif enrichment and retained-intron events in genes enriched for catabolic/metabolic processes (SLC27A5, STAT6) in males and JNK/MAPK/stress-kinase pathways in females. **Conclusion:** Prenatal sGC exposure programs sex-specific hepatic metabolic deviations in baboons, with lipid accumulation in males and disruption of insulin signaling, lipid/steroid metabolism, developmental regulation, and alternative splicing. Cross-sectional fetal-to-aged analyses suggest antenatal sGC reshapes liver development programs creating latent metabolic vulnerability that emerges with aging.

Prenatal sGC exposure is associated with male-predominant hepatic lipid accumulation and altered liver developmental/aging programs. A. Representative hepatic ^1H-MRS voxel placement and lipid spectrum. B. Hepatic lipid content by ^1H-MRS in aged A-CTR and A-sGC males and females; A-sGC males showed increased lipid content, while females showed no significant exposure effect. C. Volcano plot of aged male A-sGC vs A-CTR liver DEGs; positive log2FC indicates upregulation in A-sGC. D. Volcano plot of aged A-sGC males vs females; positive log2FC indicates higher expression in males. E. GO enrichment of downregulated genes in aged A-sGC males. F. Fetal-to-aged alternative splicing event types and counts. G. Fetal-to-aged downregulated gene overlap across sex and exposure groups, identifying GC male-specific genes. H. GO enrichment of GC male-specific downregulated genes, implicating developmental regulation and liver remodeling. Volcano y-axes show −log10(FDR). Abbreviations: sGC, synthetic glucocorticoid; MRS, magnetic resonance spectroscopy; CTR, control; DN, downregulated; UP, upregulated; NS, nonsignificant; DEG, differentially expressed gene; GO, gene ontology.

1359 | LOSS OF LIVER HSD17B13 IMPROVES WHOLE BODY AND MUSCLE INSULIN SENSITIVITY IN OBESE MICE

Allison Wing[1] Yanling Ma[2] Yaron Rotman[3], [1]National Institutes of Health, [2]NIH Clinical Center, [3]National Institute of Diabetes and Digestive and Kidney Diseases; National Institutes of Health

Background: Loss-of-function variants in *HSD17B13* protect against metabolic dysfunction-associated steatotic liver disease (MASLD) progression, and clinical trials targeting HSD17B13 appear promising. HSD17B13 is mostly expressed in the liver, with low expression in the duodenum and pancreas. As MASLD and diabetes are closely associated, we aim to assess the role of HSD17B13 in insulin and glucose homeostasis. **Methods:** Obesity and diabetes were induced in *Hsd17b13*-knockout (KO) mice and littermate controls (WT) by feeding high-fat diet (HFD) for 12 weeks. Glucose and insulin homeostasis were assessed using glucose tolerance test (GTT), glucose-stimulated insulin secretion (GSIS) test, insulin tolerance test (ITT) and hyperinsulinemic euglycemic clamp. Knockdown of hepatocyte *Hsd17b13* was conducted by administering AAV8 containing control (scRNA) or *Hsd17b13*-shRNA (shHsd) via tail vein injection. Conditioned media (CM) was harvested from primary hepatocytes and administered to differentiated L6 skeletal muscle myotubes expressing GLUT4-Myc. Cells were treated with or without insulin and immunostained to quantify GLUT4 translocation. **Results:** After 12 weeks of HFD, obese KO mice demonstrated improved insulin sensitivity by ITT (27%, $p = 0.02$) and hyperinsulinemic euglycemic clamp compared to obese WT controls, with increased glucose uptake into muscle and brain, which lack *Hsd17b13* expression. KO mice also demonstrated decreased GSIS (46%, $p = 0.0002$) and decreased fasting insulin (51%, $p = 0.001$). Interestingly, these opposing phenotypes resulted in no difference in GTT.To determine if improved insulin sensitivity in whole body KO is driven by hepatocyte HSD17B13, we performed hepatocyte-specific knockdown. After 12 weeks of HFD, shHsd mice had improved ITT (20%, $p = 0.01$) and GTT (18%, $p = 0.04$). sh-Hsd mice also had decreased fasting insulin relative to control (38%, $p = 0.04$) but did not have a significant difference in GSIS.Muscle is a major glucose uptake tissue. After treating differentiated L6 muscle cells with CM from primary WT and KO hepatocytes, insulin-induced GLUT4 translocation was increased in L6 cells receiving KO CM, relative to WT (55%, $p = 0.04$). **Conclusion:** Our findings suggests that hepatocyte HSD17B13 modulates whole body and muscle insulin sensitivity in other tissues, likely through circulating mediators. While targeting HSD17B13 appears promising in clinical trials, our data suggest it may also benefit diabetes.

1360 | REDUCTION IN HEPATIC PC BIOSYNTHESIS PROMOTES MASH THROUGH COPPER DEFICIENCY

Jaclyn Welles[1] Michael Gonzalez[2] James Garifallou[3] David Li[4] Rebecca Wells[4] Dominic Santoleri[4] Gina DeNicola[5] Feroza Choudhury[5] Chang Jiang[5] Ryan Martin[5] Gen Li[6] Christopher Chang[6] Donita Brady[4] Paul Titchenell[4], [1]Northeast Ohio Medical University, [2]University of Pennsylvania - Perlman School of Medicine, [3]Children's Hospital of Pennsylvania, [4]University of Pennsylvania - Perelman School of Medicine, [5]Moffitt Cancer Center, [6]Princeton University

Background: PCYT1A encodes CTP: phosphocholine cytidyltransferase, alpha (CCT-α), a rate-limiting enzyme for ~70% of Phosphatidylcholine (PC) production via the Kennedy pathway. Notably, hepatic PC production is significantly decreased in patients with Metabolic-dysfunction associated steatohepatitis (MASH), a severe disorder affecting a subset of MASLD and T2D patients. MASLD is clinically characterized by hepatic lipid accumulation, while MASH includes hepatic fibrosis, scarring, and inflammation. Interestingly, several variants associated with impairments in PC biosynthesis or homeostasis have emerged in MASLD/MASH patients (e.g., PNPLA3; TM6SF2; HSD17β13). It remains unknown however, how the reduction of hepatic PC biosynthesis, promotes the fibrosis and inflammation observed in MASH patients. **Methods:** We used 10X Single Nuclei RNA-Seq to investigate the functional role of PC in MASH using two models, a genetic model using AAV8-TBG-CRE to KO *PCYT1A* in hepatocytes, and a dietary model where C57BL/6J mice were fed a low methionine choline-deficient HFD (LMCD-HFD) for 4-wks. ICP-MS was also used to perform metallomics

analysis and quantitatively measure tissue and serum metal abundance. For in vitro studies, human-derived cell lines, HUH-7 and LX-2, along with fluorescent-based reporters, were used for mechanistic studies. **Results:** SEURAT cluster analysis and KEGG pathway analysis revealed DEGs enriched in hepatocytes in mouse MASH models, associated with metal ion binding and signaling. Interestingly, ICP-MS showed a significant decrease in copper content in MASH livers, while serum showed an accumulation, suggesting liver-specific perturbations in copper transport. *In vitro* studies using HUH-7 cells showed that knockdown of *PCYT1A*/CCT inhibited *SLC31A1*/CTR1 localization to the plasma membrane, reducing copper import as confirmed by a fluorescent Cu+2 probe. In LX-2 cells, while copper ($CuSO_4$) alone drove fibrogenesis, $CuSO_4$ with h-TGFß showed a synergistic effect, increasing matrice formations. KO of PM-mediated copper import (siRNA-*SLC31A1*/CTR1) or mitochondria-mediated copper import (siRNA-*SLC25A3*) also inhibited fibronectin deposition in LX-2 cells. *In vivo* studies using the cell-impermeable copper chelator BCS protected against MASH-associated fibrogenesis in both genetic and dietary models. Reductions in fibrosis were observed through decreased Sirius red-positive liver areas (collagen deposition) and pro-fibrogenic gene expression. **Conclusion:** This data supports that MASH-associated lipid remodeling impairs copper transporter localization, causing copper deficiency. Given that the FDA has approved copper chelators for cancer, our work suggests that chelators could be repurposed to treat MASH in the future. This work highlights a gap in our understanding of fibrogenesis and the need for targeted, liver-specific, and cell-type-specific copper therapeutics against MASH.

1361 | 2-AAA DRIVES LIVER REGENERATION IN MASLD BY ENHANCING NEUTROPHIL GLYCOLYSIS AND HIF-1A-DEPENDENT HGF EXPRESSION

Bo Wang[1], [1]Zhongshan Hospital, Fudan University

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is characterized by impaired liver regeneration, which contributes to disease progression and poor outcomes following hepatic resection. The molecular mechanisms underlying this regenerative deficit remain poorly understood, and no targeted therapies are currently available. 2-Aminoadipic acid (2-AAA), an intermediate of lysine metabolism, has recently emerged as a potential metabolic regulator of tissue repair. Our previous studies revealed that 2-AAA is significantly upregulated during physiological liver regeneration but fails to increase in MASLD. Exogenous 2-AAA supplementation restored regenerative capacity in MASLD mice, an effect dependent on neutrophils. However, the mechanistic basis for 2-AAA-mediated liver regeneration remains to be fully elucidated. **Methods:** To investigate 2-AAA's role in liver regeneration, we used a MASLD mouse model subjected to 70% partial hepatectomy. Hepatic and serum 2-AAA levels were measured via LC-MS/MS. We modulated endogenous 2-AAA by knocking down its synthetic enzyme AASS with AAV-shRNA and administered exogenous 2-AAA to assess therapeutic effects. Neutrophil glycolysis and lactate production were analyzed, and HIF-1α lactylation and stability were examined. Neutrophil involvement was validated via anti-Ly6G depletion, and hepatocyte proliferation was evaluated by Ki67 and Cyclin A2 staining. **Results:** We found that 2-AAA levels increased significantly in the liver and serum of control mice after PHx, whereas this response was blunted in MASLD mice. Hepatic AASS expression was downregulated in MASLD, and AASS knockdown in normal mice recapitulated the regenerative defect observed in MASLD. Exogenous 2-AAA supplementation improved survival, liver weight recovery, and hepatocyte proliferation in MASLD mice. Mechanistically, 2-AAA enhanced neutrophil glycolysis and lactate production, leading to increased HIF-1α lactylation and protein stabilization. HIF-1α transcriptional activity upregulated HGF expression in neutrophils. Neutrophil depletion abolished the pro-regenerative effect of 2-AAA. In MASLD mice, impaired 2-AAA synthesis resulted in reduced neutrophil recruitment, diminished glycolysis, and disrupted HGF expression, ultimately compromising liver regeneration. **Conclusion:** This study identifies 2-AAA as a critical metabolic signal that promotes liver regeneration by enhancing neutrophil glycolysis and HIF-1α-dependent HGF expression. Impaired 2-AAA synthesis in MASLD contributes to regenerative failure, highlighting the therapeutic potential of targeting the 2-AAA-neutrophil-HGF axis to improve outcomes in patients with MASLD undergoing liver resection.

1362 | LOSS OF BATF3 REPROGRAMS ADIPOSE–LIVER METABOLIC COMMUNICATION TO ACCELERATE STEATOSIS-TO-FIBROSIS TRANSITION IN HIGH-FAT DIET INDUCED MASLD

Haibo Dong[1] Wei Guo[1] Xinguo Sun[1] Zhanxiang Zhou[1], [1]University of North Carolina at Greensboro

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is driven by complex inter-organ communication, particularly between adipose tissue and liver. BATF3, a transcription factor essential for dendritic cell differentiation and immune regulation, has recently been implicated in metabolic processes; however, its role in coordinating adipose–liver homeostasis during MASLD progression remains unclear. **Methods:** To investigate the metabolic function of BATF3, we utilized Batf3$^{-/-}$ mice subjected to a high-fat diet (HFD). Hepatic steatosis, inflammation, and fibrosis were assessed by histological and biochemical analyses. Adipose tissue lipolysis, hepatic lipid uptake, and systemic insulin signaling were evaluated using metabolic assays and immunoblotting. Transcriptomic profiling highlited angiopoietin-like protein 8 (ANGPTL8), a hepatokine involved in inter-organ communication, which was subsequently subjected to functional analysis. **Results:** BATF3 deficiency markedly exacerbated HFD-induced liver pathology, including increased steatosis, inflammatory responses, and fibrotic remodeling. These changes were accompanied by enhanced adipose tissue lipolysis, elevated hepatic fatty acid influx, and impaired insulin–AKT signaling, indicating systemic metabolic imbalance. Mechanistically, we identified ANGPTL8 emerged as a key mediator linked to metabolic alterations in Batf3$^{-/-}$ mice . ANGPTL8 expression was significantly reduced in Batf3$^{-/-}$ mice, suggesting disrupted endocrine regulation between adipose tissue and liver. Functional analyses demonstrated that ANGPTL8 exerts protective effects by suppressing inflammation-induced hepatic stellate cell activation and by differentially regulating lipid metabolism across tissues, reducing hepatic lipid accumulation while limiting adipose tissue lipolysis. **Conclusion:** Our findings reveal a previously unappreciated role of BATF3 in maintaining adipose–liver metabolic homeostasis and identify the BATF3–ANGPTL8 axis as a critical regulator of steatosis-to-fibrosis progression in MASLD. Targeting this pathway may offer a novel therapeutic strategy to prevent disease progression.

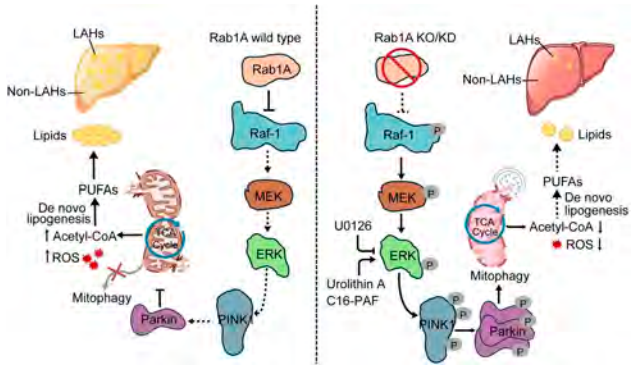
1363 | RAB1A PROMOTES HEPATIC STEATOSIS BY SUPPRESSING MITOPHAGY VIA THE RAF-1/ERK1/2/PINK1 SIGNALING AXIS



Xin Zhang[1] Li Zhang[2] Jianhua Li[3] Huilu Zhang[4] Qi Qin[5] Xiaofan Tian[6] Yichen Huang[5] Zhengxin Wang[7], [1]Institute of Translational Medicine, [2]Institute for Biomedical Sciences and School of Life Sciences, East China Normal University, [3]Institute of Organ Transplantation, Huashan Hospital, Fudan University, [4]Huashan Hospital, Fudan University, [5]Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, [6]Ernst Mario School of Pharmacy, Rutgers, The State University of New Jersey, [7]Huashan Hospital & Institute of Organ Transplantation, Fudan University

Background: Driven by the Western diet, metabolic dysfunction-associated steatotic liver disease (MASLD) has become a global health crisis, progressing from hepatic triglyceride accumulation to MASH, cirrhosis, and hepatocellular carcinoma. Although the liver displays marked zonation between periportal and pericentral hepatocytes, how the hepatic microenvironment shapes disease progression remains unclear, and the organellar mechanisms driving initial hepatocyte lipid overload during overnutrition are incompletely defined. **Methods:** We integrated single-cell RNA sequencing (scRNA-seq) data from murine and human MASLD cohorts to resolve hepatocyte heterogeneity and nominate candidate regulators. Findings were validated in global Rab1A knockout mice and in adult mice with AAV-mediated, hepatocyte-specific Rab1A knockdown, fed a Western diet or high-fat diet (HFD). Mechanistic dissection combined co-

immunoprecipitation, in vitro kinase assays, site-directed mutagenesis of PINK1, and pharmacological perturbation with U0126, Urolithin A, and C16-PAF. Clinical relevance was assessed in human MASLD liver specimens. **Results:** scRNA-seq identified a lipid-associated hepatocytes (LAHs) population enriched in MASLD livers, with Rab1A as a prominent driver. Both global Rab1A knockout and liver-specific Rab1A knockdown mitigated diet-induced hepatic steatosis. Mechanistically, Rab1A depletion attenuated lipid accumulation by inducing excessive mitophagy: Rab1A restrains Raf-1 activation and thereby suppresses MEK/ERK1/2 signaling, and U0126 reversed both the lipid-lowering and mitophagy phenotypes of Rab1A-deficient cells. ERK1/2 directly bound and phosphorylated PINK1 at Ser228, triggering PINK1–Parkin-dependent mitophagy. Pharmacological activation of this axis with Urolithin A or C16-PAF alleviated HFD-induced steatosis and attenuated MASLD progression in mice. In human MASLD samples, Rab1A expression inversely correlated with activation of the Raf-1/ERK1/2/PINK1 pathway. **Conclusion:** We identify the Rab1A/Raf-1/ERK1/2/PINK1 axis as a key regulator of hepatocyte mitophagy and MASLD pathogenesis, linking a small GTPase to mitochondrial quality control via MAPK signaling and nominating this pathway as a promising therapeutic target.

1364 | SIGLEC-H DEFICIENCY LICENSES PATHOGENIC PDC–MACROPHAGE CROSSTALK TO DRIVE FIBROSIS AND HCC IN MASH

James Ahodantin[1] Jiapeng Wu[2] Masaya Funaki[3] Xu Wang[2] Pan Zheng[4] Yang Liu[4] Lishan Su[5], [1]University of Nebraska Medical Center, [2]University of Maryland Baltimore, [3]Kanazawa University, [4]OncoC4, Inc, [5]Institute of Human Virology, University of Maryland School of Medicine

Background: Metabolic dysfunction–associated steatohepatitis (MASH) is driven by chronic immune activation, fibrogenesis, and progressive metabolic injury that culminate in hepatocellular carcinoma (HCC). Although macrophage-mediated inflammation is central to disease progression, the immunoregulatory role of plasmacytoid dendritic cells (pDCs) in MASH remains poorly defined. Siglec-H is a pDC-restricted inhibitory receptor that constrains innate immune activation; however, its contribution to metabolic liver disease is unknown. We investigated whether Siglec-H signaling regulates pDC-driven inflammatory and fibrogenic responses during MASH progression and hepatocarcinogenesis. **Methods:** The functional role of pDCs was evaluated using antibody-mediated pDC depletion and Siglec-H knockout (Siglec-H$^{-/-}$) mice subjected to Western diet (WD) feeding or the STAM model of MASH-associated HCC. Liver injury, steatosis, fibrosis, tumor burden, metabolic parameters, immune composition, and lipidomic remodeling were assessed by histopathology, flow cytometry, metabolic phenotyping, and transcriptomic/lipidomic analyses. Mechanistic studies examined free fatty acid–induced activation of pDCs and macrophages and their downstream effects on hepatic stellate cell activation. **Results:** pDC depletion markedly attenuated hepatic steatosis, inflammatory injury, and fibrosis in WD-fed mice, identifying pDCs as pathogenic mediators of MASH progression. In contrast, Siglec-H deficiency profoundly exacerbated obesity, insulin resistance, hepatic lipid accumulation, fibrosis, and MASH-associated HCC development. Mechanistically, loss of Siglec-H induced broad metabolic reprogramming characterized by enhanced lipogenesis, impaired fatty acid oxidation, and substantial alterations in hepatic and circulating lipid species. Siglec-H$^{-/-}$ pDCs displayed heightened responsiveness to palmitic acid stimulation, producing increased levels of CCL3 and TGF-β that promoted macrophage recruitment and activation. This pDC-macrophage crosstalk amplified profibrotic signaling and induced hepatic stellate cell activation, whereas direct exposure of macrophages and stellate cells to CCL3 and TGF-β recapitulated key inflammatory and fibrogenic phenotypes in vitro. **Conclusion:** Siglec-H functions as a critical immunometabolic checkpoint that restrains pDC-driven inflammatory and fibrogenic remodeling in MASH. Loss of Siglec-H licenses pathogenic pDC-macrophage communication through a CCL3/TGF-β signaling axis, accelerating fibrosis and hepatocarcinogenesis. These findings identify pDCs as central orchestrators of MASH progression and nominate Siglec-H signaling and pDC-macrophage

1365 | S-ADENOSYLHOMOCYSTEINE DRIVES LIVER–BRAIN AXIS DYSFUNCTION THROUNG MICROGLIAL ACTIVATION IN METABOLIC DYSFUNCTION–ASSOCIATED FATTY LIVER DISEASE

Han Wang[1], [1]Tongji Hospital, Tongji Medical College, Huazhong University

Background: Metabolic dysfunction–associated fatty liver disease (MAFLD) is increasingly linked to neuropsychiatric comorbidities, including depression, yet underlying mechanisms remain unclear. The hypothalamus integrates peripheral metabolic signals with central regulation, and microglia are highly responsive to metabolic stress, contributing to neuroinflammation and behavioral dysfunction. We hypothesized that MAFLD progression induces hypothalamic microglial activation via circulating metabolites, driving liver–brain axis dysfunction. **Methods:** Two diet-induced MAFLD models (high-fat diet, HFD; Western diet, WD) were established, each spanning steatosis to MASH. Behavioral assays were performed longitudinally. Hypothalamic microglia ($CD45^{+}CD11b^{+}$) were isolated and analyzed by SMART RNA sequencing. Untargeted metabolomics was conducted in hypothalamus and liver to identify shared metabolites. Functional validation included in vitro metabolite treatment and in vivo S-adenosylmethionine (SAMe) intervention via central and intraperitoneal administration to modulate S-adenosylhomocysteine (SAH). **Results:** Behavioral abnormalities, including anxiety-like behavior and impaired social interaction and memory, emerged at the steatosis stage and worsened in MASH. Microglial transcriptomics revealed a pro-inflammatory, interferon-responsive activation state, with upregulation of innate immune genes (cd300lb, ifitm3, ifi47, cxcr2, ifitm1, ifi211, clec4a1, ccr1) and downregulation of immunoregulatory genes (parg, cirbp, mef2a, hpgds). Metabolomics identified 60 metabolites elevated in both liver and hypothalamus, among which SAH was prominent. In vitro, SAH induced microglial activation, increasing Il1b, Il6, and Tnf while suppressing Arg1, Mrc1, Il10, and Tgfb1. In vivo, central modulation of SAH using SAMe reduced hypothalamic microglial activation and attenuated liver injury, indicating a brain-to-liver regulatory effect. Systemic SAMe administration similarly decreased hypothalamic SAH levels, suppressed microglial inflammation, and improved behavioral abnormalities. These interventions collectively support a bidirectional liver–brain axis mediated by SAH. **Conclusion:** Neurobehavioral dysfunction emerges early in MAFLD and worsens with progression to MASH, in parallel with hypothalamic microglial activation. We identify S-Adenosylhomocysteine as a key metabolic mediator linking liver pathology to brain inflammation. Modulating SAH levels alleviates microglial activation, improves behavioral phenotypes, and attenuates liver injury, supporting a bidirectional liver–brain axis. These findings provide mechanistic insight into the neuropsychiatric burden of MAFLD and highlight SAH metabolism as a potential therapeutic target for both hepatic and neurobehavioral complications.

1366 | NON-CANONICAL MLKL SIGNALING DRIVES HCC PROGRESSION IN OBESITY-ASSOCIATED MASLD

Deepa Sathyaseelan[1], [1]University of Oklahoma Health Campus

Background: MASLD affects over 1 billion people and is the fastest-growing cause of HCC, driven by obesity. No approved targeted therapies exist for MASLD-associated HCC. MLKL, the necroptosis effector, is consistently upregulated in human and experimental MASLD. We hypothesized that under lipotoxic stress, hepatocyte MLKL drives MASLD-to-HCC progression via non-necroptotic mechanisms. **Methods:** Hepatocyte-specific Mlkl knockout ($Mlkl^{HepKO}$) mice were generated using AAV8-TBG-Cre in $Mlkl^{fl/fl}$ mice and fed a Western diet (WD,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

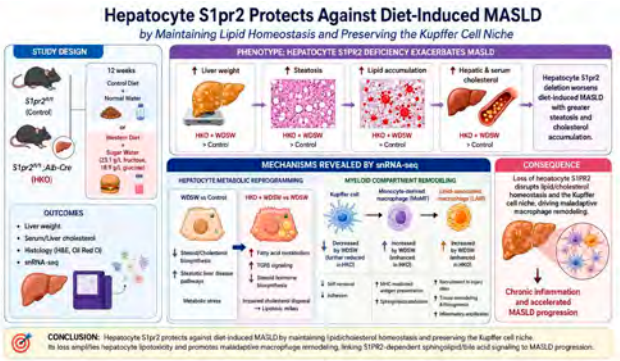
43.7% fat, 0.203% cholesterol) or control diet for 15 months. Endpoints included tumor incidence/burden, histology (H&E, Oil Red O, Sirius Red), necroptosis markers (p-MLKL, MLKL oligomers, RIPK3), liver injury (ALT, AST), RNA-seq, Seahorse MitoStress assay, and stemness/mitochondrial protein expression (Western blot, IHC, qPCR). MLKL knockdown (siRNA) and inhibition (necrosulfonamide, NSA) were tested in AML12, HepG2, and primary hepatocytes. NSA efficacy was assessed in HepG2 xenografts in nude mice. TCGA datasets and tissue microarrays were analyzed for MLKL expression and survival. **Results:** WD induced hepatic MLKL, yet necroptosis markers were undetectable, confirming a non-necroptotic context. *Mlkl*^{HepKO} mice developed significantly fewer and smaller tumors without differences in obesity, fibrosis, or liver injury, demonstrating hepatocyte MLKL promotes HCC independently of existing liver pathology. *Mlkl*^{HepKO} livers showed increased lipid droplets but reduced stemness markers DCLK1 and OCT4. RNA-seq revealed upregulation of mitochondrial OXPHOS and translation pathways. WD suppressed the tumor suppressor Mitofusin 2 (MFN2), and MLKL deficiency restored MFN2, linking MLKL to mitochondrial dysfunction. MLKL knockdown or inhibition reduced HepG2 proliferation, clonogenicity, and enhanced OXPHOS. NSA significantly reduced xenograft tumor volume and weight in vivo. In human HCC, MLKL was upregulated in tumor vs. adjacent tissue and correlated with poor survival. **Conclusion:** Hepatocyte MLKL drives MASLD-HCC via a novel non-necroptotic mechanism: suppression of MFN2 impairs mitochondrial OXPHOS and sustains tumor stemness, defining a new metabolic-oncogenic axis. NSA reduced xenograft tumor growth in vivo, providing proof-of-concept for MLKL as a druggable target. MLKL overexpression predicts poor survival in human HCC. Critically, MLKL loss reduces tumor burden without worsening liver injury or inflammation, establishing a favorable therapeutic window for MLKL inhibition in MASLD-driven HCC.

Disclosures: Deepa Sathyaseelan:Nothing to Disclose.

1367 | HEPATOCYTE S1PR2 PROTECTS AGAINST DIET-INDUCED MASLD BY MAINTAINING LIPID HOMEOSTASIS AND KUPFFER CELL NICHE INTEGRITY



Meiyi Song[1] Grayson Way[1] Chen Chen[1] Nan Wu[1] Lianyong Su[1] Derrick Zhao[1] Yunling Tai[1] Hongkun Lu[1] Hui LI[1] Sareh Bayatpour[1] Xuan Wang[1] Emily Gurley[1] Phillip Hylemon[1] Arun Sanyal[2] Huiping Zhou[1], [1]Virginia Commonwealth University and Richmond Veterans Affairs Medical Center, [2]Virginia Commonwealth University

Background: Sphingosine-1-phosphate receptor 2 (S1PR2), a bile acid-responsive GPCR, regulates hepatic lipid metabolism. Our previous study showed that global S1pr2 knockout significantly accelerated high-fat diet-induced steatohepatitis in mice. Here, we investigated whether hepatocyte S1pr2 protects against diet-induced MASLD by maintaining hepatic lipid homeostasis and preserving the macrophage niche. **Methods:** S1pr2fl/fl and hepatocyte-specific S1pr2 knockout mice (S1pr2fl/fl;Alb-Cre, HKO) were fed control diet/normal water or Western diet plus sugar water (WDSW; 23.1 g/L fructose, 18.9 g/L glucose) for 12 weeks. Steatosis and lipid accumulation were assessed by liver weight, serum/liver cholesterol, H&E, and Oil Red O staining. Whole-liver snRNA-seq was performed to define cell type-specific transcriptional responses and explore potential intercellular communication. **Results:** WDSW increased liver weight and circulating cholesterol in S1pr2fl/fl mice. Hepatocyte S1pr2 deletion exacerbated MASLD, with higher liver weight, more severe histologic steatosis and lipid droplet accumulation, and greater hepatic and serum cholesterol levels. In hepatocytes, WDSW induced broad metabolic reprogramming, including suppression of steroid/cholesterol biosynthesis and enrichment of steatotic liver disease pathways. Under WDSW, HKO hepatocytes showed additional pathway remodeling, with reactivation of fatty acid metabolism, increased TGFβ signaling, and reduced steroid hormone biosynthesis, consistent with impaired cholesterol disposal and a lipotoxic hepatic milieu. snRNA-seq also identified diet- and genotype-dependent remodeling of the myeloid compartment. WDSW was associated with reduced resident Kupffer cells and increased monocyte-derived macrophage and lipid-associated macrophage populations. In HKO mice, Kupffer cells showed reduced self-renewal/adhesion programs, whereas lipid-associated macrophages were enriched for recruitment, tissue remodeling, and fibrogenic programs; monocyte-derived macrophages displayed enhanced MHC-dependent antigen presentation and sphingolipid catabolism. **Conclusion:** Hepatocyte S1pr2 protects against WDSW-induced MASLD by maintaining lipid/cholesterol homeostasis and preserving the Kupffer cell niche. Its loss amplifies hepatocyte lipotoxicity and promotes maladaptive macrophage remodeling, linking S1PR2-dependent sphingolipid/bile acid signaling to inflam-

1368 | AMELIORATIVE EFFECTS OF COMBINATION THERAPY WITH RESMETIROM, TIRZEPATIDE, AND ROFLUMILAST ON A GAN DIET-MASH MOUSE MODEL

Takumi Sugawara[1] Mitsuharu Matsumoto[1] Sayuri Nakamura[1] Ryotaro Hori[1] Yasunori Nio[1], [1]Axcelead Drug Discovery Partners, Inc.

Background: Metabolic dysfunction–associated steatohepatitis (MASH) is driven by complex interactions between metabolic dysregulation and inflammation. Recently, thyroid hormone receptor-β (THR-β) agonist and glucagon-like peptide-1 receptor (GLP-1R) agonist have been approved for the treatment of MASH. In addition, phosphodiesterase-4 (PDE-4) inhibitors, which have a mechanism distinct from these therapeutic approaches, have been reported to exert ameliorative effects on inflammation and fibrosis in liver of MASH models. The aim of present study is to confirm the combination effects on them using Gubra Amylin (GAN) diet-induced MASH model mouse. **Methods:** To induce disease conditions, male C57BL/6J mice were fed the GAN diet for 43 weeks before treatment. Animals were treated for 16 weeks with a THR-β agonist (Resmetirom, 3 mg/kg, q.d., p.o.), a dual GLP-1/glucose-dependent insulinotropic polypeptide (GIP) receptor agonist (Tirzepatide, 0.1 mg/kg, b.i.w., s.c.), and a PDE-4 inhibitor (Roflumilast, 1 mg/kg, q.d., p.o.), either as monotherapy, dual combinations, or triple therapy. The body composition was measured using Magnetic Resonance Imaging. Energy expenditure was analyzed using Oxymax system. Then, mice were anesthetized and then blood was collected, and the liver was harvested. Plasma and liver were used for biochemical and pathological analyses. **Results:** All monotherapies reduced liver weight and improved metabolic and hepatic injury parameters. Liver weight was further reduced by all combination therapies compared with respective monotherapies and reached levels comparable to the control group. Plasma liver injury markers, such as AST, ALT, were additively reduced by dual combination therapies compared with the respective monotherapies. As reported previously, the GLP-1 analog significantly reduced energy expenditure, and co-treatment with resmetirom tended to recover energy expenditure. Triple therapy did not provide additional benefits beyond dual combinations therapies, suggesting a plateau in therapeutic efficacy. Further analyses of liver pathology, including fibrosis and nonalcoholic fatty liver disease activity score (NAS), will be presented at the conference. **Conclusion:** These findings indicate that simultaneous targeting of two distinct pathways might be sufficient to achieve maximal therapeutic effects in experimental MASH. Triple therapy provided limited additional benefit, supporting the concept that optimized dual combination strategies may represent a rational and clinically relevant therapeutic approach.

★ 1369 | METABOLIC FERROPTOSIS AS TARGETABLE SIGNATURE FOR THE GENETIC SUBTYPE OF MASLD

Erika Paolini[1] Marica Meroni[2] Miriam Longo[3] Sara Badiali[4] Marco Maggioni[5] Anna Ludovica Fracanzani[6] Paola Dongiovanni[2], [1]Medicine and Metabolic Diseases, Fondazione IRCCS Cà Granda, [2]Medicine and Metabolic Diseases, Fondazione IRCCS Cà Granda, Ospedale Maggiore Policlinico, Milan, [3]Fondazione IRCCS Cà Granda Ospedale Maggiore Policlinico Milano, [4]Department of Surgery, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [5]Department of Pathology, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy, [6]University of Milan

Background: The co-presence of the I148M-PNPLA3, rs641738-MBOAT7 and E167K-TM6SF2 polymorphisms enhances the risk of severe MASLD. Emerging evidence highlighted that ferroptosis is essential for developing MASLD/MASH since it promotes oxidative stress, lipid peroxidation and inflammation although the underlying mechanisms are still unknown. Thus, this study investigated the possible crosslink between ferroptosis and the three mutations in hepatic biopsies of MASLD patients, through a spatial transcriptomic (ST) approach. **Methods:**

ST was performed by Visium CytAssist and data were analyzed using Spaceranger (10x Genomics). Patients, featured by a similar histological severity (NAS≥4) and comparable comorbidities (gender, age, BMI, absence of T2D), were wild type (WT), homozygous for PNPLA3, MBOAT7, TM6SF2 polymorphisms and carriers of the 3 at-risk variants (3NRV) (n = 2/group). **Results:** All samples were integrated and clustered at 0.5 resolution allowing the identification of 7 clusters (cl), annotated as follows: cl0 enriched in periportal HEPs; cl1 in immune cells; cl2 in pericentral HEPs; cl3 in cholangiocytes; cl4 in endothelial cells (ENDOs); cl5 in immune cells; cl6 in NPCs (HSCs, immune cells and ENDOs); cl7 in HEPs. Firstly, we observed that cl4 was more abundant in PNPLA3, MBOAT7, TM6SF2 and 3NRV samples compared to WT, whereas cl6 was mainly enriched in patients carrying the 3 at-risk variants *vs* all. Then, we conducted a Pathway-enrichment analysis by considering differentially expressed genes (DEGs; Log2FC > 0.5 and padj FDR < 0.05) of 3NRV in all clusters *vs* the other samples. The former exhibited increased lipid metabolism, oxidative damage, inflammation, fibrosis, and ferroptosis reflecting a worse clinical *scenario*. By focusing on the ferroptosis pathway, we found that in patients carrying TM6SF2 and MBOAT7 variants, it was mainly espressed in immune cells whereas in *PNPLA3* and 3NRV, also in HEPs. Moreover, cl6 showed the strongest upregulation of a "metabolic" ferroptosis, driven by lipid buildup and mitocondrial dysfunction. It was designed by a signature of 53 unique genes, which was uregulated only in 3NRV patients, thus rappresenting a pathognonomic feature of the "genetic" subtype of MASLD. **Conclusion:** The co-presence of *PNPLA3*, *MBOAT7*, and *TM6SF2* variants may accelerate liver injury by triggering a lipid-metabolism and mitochondrial ferroptosis. Thus, ferroptosis could be a potential druggable signature to tackle 3NRV MASLD patients.

1370 | IN VITRO ASSESSMENT OF SKELETAL MUSCLE CONTRACTILITY IN A MOUSE MODEL OF ACUTE ALCOHOL EXPOSURE: A PLATFORM FOR STUDYING SARCOPENIA IN STEATOTIC LIVER DISEASE

Alexander Kusnik[1] Hwi Young Kim[1] Fedja Rochling[1] Gwenael Layec[2] Dongwoo Hahn[2], [1]University of Nebraska Medical Center, [2]University of Nebraska at Omaha

Background: Steatotic liver disease (SLD) reflects a dual burden of metabolic dysfunction and alcohol-associated liver disease (ALD), with sarcopenia and frailty emerging as prognostically significant complications. Our group's prior preclinical work demonstrated impairment in mitochondrial respiratory function by high-resolution respirometry and vascular function by pressure myography in skeletal muscle, suggesting a plausible mechanistic pathway to muscle weakness in SLD. Despite these findings, preclinical platforms capable of directly assessing skeletal muscle contractile dysfunction in an SLD-relevant context remain underdeveloped. We aimed to establish an in vitro methodology for reproducible assessment of skeletal muscle contractile function in mice following acute alcohol exposure as a foundational step toward etiologic burden-specific mechanistic studies of sarcopenia in SLD. **Methods:** C57BL/6J mice at young (21 ± 4 weeks) and old (88 ± 1 weeks) ages were assigned to vehicle or 20% ethanol solution ad libitum for 24 hours (n = 10/group; 5M/5F). Soleus muscles were dissected and mounted in an in vitro apparatus (Krebs solution, 32° C, oxygenated) to assess force-frequency relationships (absolute force, mN; specific force, N/cm²) across 10 to 200 Hz. Body weight, weight change, liquid consumption, and muscle mass were recorded. Two-way ANOVA evaluated the effects of age, treatment, and their interaction. **Results:** Liquid consumption trended higher in alcohol-exposed groups without reaching significance (treatment $P = 0.076$). Acute alcohol exposure did not significantly alter absolute force, specific force, or soleus muscle mass in young or old mice (treatment $P > 0.05$ for all contractile parameters; soleus weight: age $P = 0.405$, treatment $P = 0.733$). Age significantly affected body weight ($P < 0.05$) and was associated with a treatment-related weight change (treatment $P \leq 0.05$). Force-frequency curves were visually comparable between vehicle and alcohol groups in both age cohorts. **Conclusion:** This study establishes a reproducible preclinical methodology for in vitro assessment of skeletal muscle contractile function in mice that can be incorporated into translational studies of sarcopenia in the SLD spectrum. Despite mitochondrial and vascular dysfunction in the same model, absence of measurable contractile impairment suggests potential dissociation between subcellular and functional endpoints at acute exposure setting. This platform provides a foundation for future investigation of more clinically relevant models incorporating combined alcohol and metabolic burden, sustained exposure, and liver-muscle cross-talk.

1371 | EXERCISE-ASSOCIATED HEPATIC TRANSCRIPTOMIC REMODELING OCCURS INDEPENDENT OF LIVER FAT REDUCTION

Hannah Mohr[1] Liuyang Wang[2] Rajesh Dutta[3] Kuo Du[4] Anna Mae Diehl[5] Rajesh Dutta[3] Jonathan Stine[1], [1]Penn State College of Medicine, [2]Department of Molecular Genetics and Microbiology, Duke University; Durham, NC, USA, [3]Division of Gastroenterology & Hepatology, Duke University, Durham NC, USA, [4]University of Kansas Medical Center, [5]Duke University

Background: Aerobic exercise (AEx) is a foundational component of management for MASH, yet the hepatic molecular pathways mediating benefit remain poorly defined. To better characterize exercise-associated hepatic biology, we conducted an exploratory sub-study to assess whether AEx is associated with transcriptomic changes important to MASH and fibrogenesis. **Methods:** A total of 30 patients with fibrotic MASH were randomized to 16 weeks of supervised AEx or standard of care (SOC) (Fig 1A). RNA sequencing was performed on pre- and post-treatment liver biopsies in a subset [AEx n = 3, SOC n = 3]. Differential gene expression was evaluated pre- and post-intervention using a paired intent-to-treat framework comparing AEx versus SOC. Pathway enrichment analyses focused *a priori* on signatures previously associated with MASH severity, including aging-related pathways, cellular senescence, and ferroptosis. **Results:** AEx was associated with a greater number of differentially expressed genes (DEGs) than SOC (214 vs 4 DEGs) (Fig. 1B). In exercisers, post-intervention liver transcriptomes demonstrated consistent down-regulation of pathways previously correlated with fibrosis severity, including GO cellular senescence (NES = -1.85, p < 0.0001), MSigDB interferon alpha response (NES = -2.2, p = 0.025), and ferroptosis marker signature (p = 0.032) (Figs. 1C-E). Exercise was also associated with up-regulation of multiple metallothionein (MT) genes involved in intracellular metal handling and redox homeostasis, and down-regulation of targets MTs are known to suppress, including collagen (data not shown). These transcriptomic changes were not consistently associated with reductions in MRI-PDFF, as the latter occurred in one SOC subject and two AEx subjects (Fig. 1A). Transcriptomic profiles of MRI-PDFF responders demonstrated partial convergence across intervention groups (Fig. 1C), consistent with biologic heterogeneity of treatment response with AEx. In addition, transcriptomic changes were not associated with significant weight loss (Fig. 1A); two AEx subjects and one SOC subject reached the clinically significant threshold of ≥7% total body weight loss. **Conclusion:** In this exploratory sub-study, AEx was associated with favorable hepatic transcriptomic remodeling involving pathways related to biological aging, senescence, ferroptosis, and fibrogenesis, effects not captured by liver fat reduction alone. Notably, these molecular changes were observed despite no significant differences in body weight loss or MRI-PDFF change between SOC and AEx, suggesting that the effects of AEx on hepatic fibrogenic biology may be at least partly independent of weight loss. These findings support a role for exercise in modifying molecular pathways relevant to MASH progression and emphasize the importance of integrative, mechanism-informed endpoints when evaluating lifestyle-based interventions.

1372 | HARNESSING ENDOGENOUS LIVER REGENERATION FOR MULTIDIMENSIONAL MASH REGRESSION

Tianliang Sun[1] Yizhou Dong[2] Huiping Zhou[3] Federico Di Tullio[4] Sue Yang[2] Lida Yang[5] Bruno Cogliati[2] Shamsa Roshan[2] Kaiyuan Guo[2] Abigail Glezer[2] Lilian Li[2] Marina Barcena-Varela[2] Emily Bramel[2] Anthony Lozano[2] Siddarth Vinod Kumar[2] Lianyong Su[3] Derrick Zhao[3] fanglin ma[2] Jonathan Conrad[2] Amaia Lujambio[2] Sai Ma[2], [1]Icahn School of Medicine at Mount Sanai, [2]Icahn School of Medicine at Mount Sinai, [3]Virginia Commonwealth University, [4]Sanford Burnham Prebys, [5]Icahn School of Medicine at Mount S

Background: Metabolic dysfunction-associated steatohepatitis (MASH) remains a leading cause of cirrhosis, hepatocellular carcinoma (HCC), and liver-related mortality, with limited therapies capable of reversing established disease. In physiologic acute liver injury, tightly regulated activation of WNT/β-catenin signaling orchestrates regenerative repair, metabolic adaptation, and restoration of tissue architecture. We hypothesized that controlled transient reactivation of this endogenous regenerative program in chronic MASH could drive coordinated multidimensional disease regression, offering a regenerative therapeutic strategy grounded in native liver biology. **Methods:** MASH was induced in murine models of fibrosis and tumorigenesis, followed by hepatocyte-specific modulation of ZNRF3/RNF43 using genetic deletion and therapeutic lipid nanoparticle (LNP)-siRNA approaches. Phenotypic regression was assessed by histologic, biochemical, transcriptomic, and immunologic analyses, including evaluation of steatosis, inflammation, fibrosis, bile acid metabolism, regenerative activation, immune remodeling, and tumor safety. **Results:** Hepatocyte-specific activation of the ZNRF3/RNF43-WNT/β-catenin regenerative axis induced rapid and multidimensional regression of established MASH. Regression was characterized by early and active immune remodeling, including marked reshaping of hepatic immune populations preceding structural fibrosis improvement, supporting an active tissue reprogramming process rather than passive disease resolution. Steatosis regression occurred independently and substantially earlier than fibrosis reversal, indicating mechanistically separable therapeutic trajectories. Mechanistically, lipid detoxification was associated with activation of alternative bile acid synthesis pathways, including CYP27A1/CYP7B1-dependent metabolic rewiring, facilitating hepatocellular lipid clearance. Importantly, transient therapeutic pathway engagement using LNP-siRNA provided proof-of-concept feasibility for translational intervention while maintaining a favorable safety profile without evidence of accelerated tumorigenesis under tested conditions. **Conclusion:** Controlled activation of endogenous liver regenerative programs induces coordinated metabolic, immune, and structural remodeling to reverse established MASH. These findings identify transient ZNRF3/RNF43 pathway modulation as a potentially safe and efficient regenerative therapeutic strategy, establishing a framework for multidimensional disease reversal rather than single-axis disease suppression.

1373 | AGING ACCELERATES METABOLIC AND ALCOHOL-ASSOCIATED LIVER DISEASE (METALD), LIVER FIBROSIS AND TUMOR DEVELOPMENT WITH INCREASED FRAILTY AND MORTALITY

Marti Ortega-Ribera[1] Alejandro Hionides-Gutierrez[1] Marcelle Ribeiro[2] Prashanth Thevkar Nagesh[3] Soham Sudhakaran[1] Bruna Santos[1] Scott Minchenberg[2] Allyson Flavin[1] Siddharth Ghosh Roy[1] Gyongyi Szabo[2], [1]BIDMC - Harvard Medical School, [2]Beth Israel Deaconess Medical Center, [3]Beth Israel Medical Center

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: MetALD defines patients with metabolic dysfunction-associated steatotic liver disease with simultaneous alcohol misuse. Both alcohol and metabolic syndrome are recognized as risk factors for hepatocellular cancer. With the increase in life expectancy and the rising prevalence in obesity, alcohol misuse and liver cancer, there is an unmet need for understanding MetALD pathophysiology in the context of aging using relevant preclinical models. **Methods:** Young (2 month) and aged (19 month) C57BL/6N mice (♀ & ♂) were fed with chow diet or high fat diet containing 10gm% cholesterol, 208g/Kg sucrose and 30.8g/Kg fructose (hereinafter MASH diet) for 12 weeks. A subgroup of the mice receiving MASH diet also received weekly alcohol binges (2.5g/Kg) plus 5% alcohol in the drinking water to mimic MetALD pathophysiology. At week 11, mice were scored for frailty and at week 12, tissues were harvested for analysis. **Results:** Young mice had a higher body weight gain compared to their diet-matched aged groups. However, aged mice on MASH diet exceeded chow-fed aged mice in final body weight. Importantly, alcohol consumption was not different between both MetALD groups.Aged MetALD mice showed the greatest liver dysfunction, as evidenced by: 1) elevated ALT levels, compared to young MetALD, aged chow and aged MASH groups, 2) decreased circulating albumin levels, 3) increased expression of fibrotic markers including *Col1a1*, *Tgfb1* mRNA levels and alpha smooth muscle actin protein levels compared to young MetALD group and 4) increased spleen-to-body weight ratio compared with young MetALD & aged MASH groups.Liver tumors were more frequent in aged MetALD mice (31%) followed by aged MASH (6%) and aged chow (11%) while none of the young animals showed tumor burden. The increase in the frequency of liver tumors in the aged MetALD group correlated with the upregulation of malignancy/proliferation markers including *cMyc, Ki67* and protein levels of PCNA. Aged MetALD mice also showed increased expression of epithelial-to-mesenchymal transition markers such as *Snai1* & *Vimentin* and higher levels of cancer stem cell markers including *Cd133* & *Epcam*. MetALD regime in aged mice resulted in decreased % of lean mass and increased % of fat mass compared to aged chow or young MetALD mice in EchoMRI analysis. Finally, age and MetALD diet increased frailty scores in both young and aged groups, with aged MetALD mice exhibiting significantly higher score than young MetALD mice. Consequently, aged MetALD mice exhibited the highest mortality (45%) followed by young MetALD and aged MASH groups (10% and 5% respectively) while all other groups had a 100% survival. **Conclusion:** Our preclinical model reveals that MetALD, is accelerated in aging with exacerbated liver damage, fibrosis and increased activation of tumorigenic pathways in the liver. The combination of age and MetALD also interact to reduce lean mass and increase fat mass, overall leading to higher frailty and mortality.

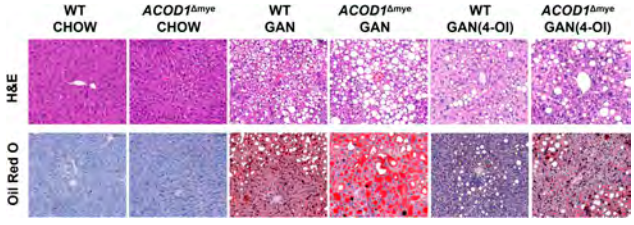
1374 | MACROPHAGE-DERIVED ITACONATE AMELIORATES MASH VIA NRF2-MEDIATED FERROPTOSIS INHIBITION



Shaoya Li[1] Qianqian Zheng[1] Jiawei Cui[1] Zhandong Lin[1] Yikang Song[1] Yue Shi[2] Yukai Chen[1] Congyue Zhang[1] Yaoyao Mao[1] Xiangxin Qin[1] Chao Sun[3] Yuemin Nan[1], [1]Hebei Medical University Third Hospital, [2]Hebei Medical University, [3]the First Affiliated Hospital of Xi'an Medical University

Background: Metabolic dysfunction–associated steatohepatitis (MASH), the progressive inflammatory and fibrotic subtype of metabolic dysfunction-associated steatotic liver disease (MASLD), lacks approved pharmacotherapy. Ferroptosis, an iron-dependent lipid peroxidation-driven cell death, critically drives MASH progression. Itaconate, an endogenous immunometabolite with anti-inflammatory and antioxidant properties, has emerged as a key regulator of oxidative stress; however, its role in ferroptosis-mediated MASH remains unclear. **Methods:** Wild-type (WT) and myeloid-specific ACOD1-knockout (KO) mice were fed a high-fat, high-sugar, high-cholesterol (GAN) diet for 21 weeks to establish a robust MASH model, with or without 4-octyl itaconate (4-OI) intervention. AML-12 hepatocytes were exposed to free fatty acids (FFA) to induce steatohepatitis in vitro. Hepatic steatosis, inflammation, fibrosis, oxidative stress, mitochondrial function, and ferroptosis were systematically evaluated. **Results:** Myeloid ACOD1-KO mice exhibited exacerbated hepatic steatosis, inflammation, and fibrosis,

accompanied by elevated malondialdehyde (MDA), reduced glutathione (GSH), and impaired mitochondrial respiration. Ferroptosis markers (downregulated GPX4, upregulated ACSL) were significantly increased, while Nrf2/HO-1 signaling was markedly suppressed in KO mice. 4-OI administration dose-dependently reduced hepatic triglycerides, inflammatory cytokines, and lipid peroxidation, restored mitochondrial membrane potential, and inhibited ferroptosis in WT mice. In FFA-treated AML-12 cells, 4-OI attenuated lipid accumulation, pro-inflammatory gene expression, and ferroptosis; Nrf2 silencing abrogated these protective effects. **Conclusion:** Itaconate confers hepatoprotection in MASH by activating Nrf2-dependent antioxidant signaling and suppressing ferroptosis, highlighting itaconate as a promising therapeutic target for MASH/MASLD.

1375 | BOVINE MILK-DERIVED EXTRACELLULAR VESICLES AMELIORATE STEATOHEPATITIS AND HEPATIC FIBROSIS THROUGH RESTORATION OF INTESTINAL BARRIER FUNCTION IN A MURINE MASH MODEL

Shinya Sato[1] Kosuke Kaji[1] Tadashi Namisaki[1] Hitoshi Yoshiji[1], [1]Nara Medical University

Background: Disruption of the gut-liver axis plays a critical role in the progression of metabolic dysfunction-associated steatohepatitis (MASH). Increased intestinal permeability promotes portal endotoxemia and hepatic inflammatory signaling, accelerating liver fibrosis. Bovine milk-derived extracellular vesicles (B-mEVs) contain bioactive microRNAs and have emerged as modulators of intestinal homeostasis. However, their effects on gut barrier dysfunction and liver fibrosis in MASH remain unclear. We investigated whether orally administered B-mEVs attenuate MASH progression through modulation of the gut-liver axis. **Methods:** MASH was induced in mice using a choline-deficient, L-amino acid-defined high-fat diet (CDA-HFD) for 8 weeks. Mice received oral administration of vehicle or B-mEVs. Hepatic injury, steatosis, and fibrosis were assessed by serum biochemistry, histology, hydroxyproline quantification, and fibrogenic gene expression. Intestinal barrier function was evaluated by FITC-dextran permeability assay and tight junction protein expression analyses. Portal lipopolysaccharide (LPS) levels and hepatic inflammatory signaling were examined. In vitro studies were performed using palmitic acid-treated Caco-2 cells. Fecal microbiota was analyzed by 16S rRNA sequencing, and small RNA sequencing of B-mEVs was performed. **Results:** B-mEV administration attenuated CDA-HFD-induced steatohepatitis, as demonstrated by reduced serum AST/ALT levels, hepatic lipid accumulation, and NAFLD activity scores. B-mEVs also suppressed hepatic fibrosis, accompanied by reductions in Sirius Red-positive areas, hepatic hydroxyproline content, and expression of fibrogenic markers, including Acta2, Col1a1, and Tgfb1.B-mEV treatment restored intestinal barrier integrity, evidenced by increased expression of tight junction proteins (ZO-1, Occludin, and Claudin-1) and reduced intestinal permeability. Portal LPS levels were decreased in B-mEV-treated mice, together with suppression of hepatic TLR4/NF-κB signaling and inflammatory cytokine expression. In Caco-2 cells, B-mEVs prevented palmitic acid-induced barrier dysfunction and MLCK upregulation.Microbiome analysis revealed partial restoration of gut dysbiosis without major shifts in microbial composition. Small RNA sequencing demonstrated that B-mEVs contained abundant miRNAs associated with epithelial barrier regulation and inflammatory signaling pathways. **Conclusion:** Orally administered B-mEVs attenuated steatohepatitis and hepatic fibrosis in CDA-HFD-fed mice by restoring intestinal barrier function and suppressing gut-derived endotoxin signaling. These findings identify milk-derived extracellular vesicles as a gut-liver axis-targeted therapeutic strategy for MASH.

Background: Colorectal cancer (CRC) and metabolic dysfunction-associated steatohepatitis (MASH) have been increasing worldwide in association with changes in dietary habits and lifestyle. Epidemiological studies have suggested that MASH is a risk factor for CRC. Although gut-derived metabolites are known to affect the liver, the influence of liver-derived metabolic alterations on intestinal immunity remains unclear. In this study, we investigated the effects of a MASH-inducing diet on colorectal tumor progression and intestinal immune responses. **Methods:** MASH model mice were generated by feeding a high-fat atherogenic diet. Murine colorectal cancer cells were orthotopically transplanted into the intestine, and tumor size and weight were evaluated. Mice fed a normal diet served as controls. Immune dynamics in intestinal and tumor tissues were analyzed by immunohistochemistry (IHC) and flow cytometry (FCM). Gene expression profiling of intestinal tissues was performed using DNA microarray analysis. In addition, fecal samples were collected longitudinally and analyzed by LC/MS-based metabolomics. **Results:** CRC tumors in MASH mice showed significantly greater maximum tumor diameter compared with controls (22.3 mm vs. 13.3 mm, $p = 0.037$). IHC demonstrated increased infiltration of CD8-positive cells in both intestinal and liver tissues during the course of high-fat atherogenic diet feeding. At 8 weeks, the number of CD8-positive cells in the intestine was significantly higher in MASH mice than in controls (16.0 vs. 1.33 cells/field, $p < 0.005$).FCM analysis revealed an increased proportion of effector memory T cells (emT) among intestinal CD8-positive T cells in MASH mice compared with controls (22.3% vs. 13.7%). PD-1 expression in intestinal CD8-positive emT cells also tended to increase (7.91% vs. 3.87%). In tumor tissues, both the proportion of CD8-positive T cells and CD8-positive emT cells were significantly increased in MASH mice (19.2% vs. 4.6% and 39.9% vs. 9.6%, respectively; both $p < 0.005$). PD-1 expression in tumor-infiltrating CD8-positive emT cells also showed an increasing trend in MASH mice (98.8% vs. 94.6%). Metabolomic analysis demonstrated reductions in taurine-conjugated bile acids, primary bile acids, secondary bile acids, and prostaglandins in feces from MASH mice. Gene expression analysis of intestinal tissues revealed downregulation of genes involved in bile acid and peptide transport, including Slc10a2 and Slc15a1. **Conclusion:** A MASH-inducing diet altered intestinal immune dynamics and promoted colorectal tumor progression. Changes in liver-related metabolic pathways, particularly bile acid metabolism, may contribute to a novel liver-gut axis involved in the colorectal tumor microenvironment.

1377 | EXTRACELLULAR ATP (EATP) AND INFLAMMASOME-RELATED PATHWAYS IN THE PROGRESSION OF METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE (MASLD)

Vanessa Garcia-Fernandez[1] Antonio Gil-Gómez[2] Rocío Muñoz Hernández[3] Sheila Gato-Zambrano[1] Rocio Aller[4] Angela Rojas[1] David Martí[5] Juan Manuel Pericas[6] Paloma Carrillo-Fernández[2] Carola Zurita[2] Isabel Fernandez[2] Rocio Gallego-Duran[7] Douglas Maya-Miles[2] Javier Ampuero[1] Manuel Romero Gómez[1], [1]SeLiver Group. Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocí, [2]SeLiver Group. Instituto de Biomedicina de Sevilla (IBiS), Hospital Universitario Virgen del Rocío, [3]Centro de Investigación Biomédica en Red, [4]Hospital Clinico Universitario de Valladolid, Valladolid, Spain,, [5]Digestive Disease Department, Clinic University Hospital, INCLIVA Health Research Institute, Vale, [6]Vall d'Hebron Institut de Recerca, Vall d'Hebron Barcelona Campus Hospitalari, Barcelona, Spain, [7]Ibis-Biomedicine Institute of Sevilla

Background: Extracellular ATP (eATP) is a damage-associated molecular pattern that promotes inflammation, leading to immune cell recruitment and cytokine release. Ectonucleoside Triphosphate Diphosphohydrolase 1 (ENTPD1) metabolizes eATP, reducing ATP levels and limiting inflammatory signaling. The purinergic receptor P2X7 (P2RX7) is activated by eATP and stimulates the NLR family pyrin domain containing 3 (NLRP3)/interleukin-1b pathway, amplifying liver inflammation. The aim of this study was to determine the role of eATP and the NLRP3 pathway in the progression of MASLD. **Methods:** The study was performed in 20 male C57BL/6J mice fed a High Fat High Carbohydrate and Cholesterol (HFHCC) ($n = 10$) or chow diet ($n = 10$). *Entpd1, P2rx7, Panx1 and Nlrp3* genes and Entpd1 and P2rx7 protein levels were assessed by PCR, IHC and Jess automated Western Blot. In addition, 654 patients were classified according to SAF and NAS Score and P2RX7-rs1718119 was analyzed. Serum ENTPD1 was measured in 170 patients. **Results:** Entpd1 was increased in HFHCC fed mice (fold change 1 ± 0.83 vs 1.97 ± 0.75; $p = 0.0005$). *P2rx7* (1 ± 0.62 vs 2.24 ± 0.58; $p < 0.0001$) and *Nlrp3* (1 ± 0.41 vs 2.28 ± 0.71; $p < 0.0001$) were also upregulated. *Panx1* expression was decreased (fold change 1 ± 0.53 vs 0.32 ± 0.14; $p = 0.0012$).In control mice, Entpd1 protein localized mainly around the central vein whereas in HFHCC fed

mice, it shifted towards the portal vein area. P2rx7 positive cells/area were higher in HFHCC fed mice (272.4 ± 79.8 *vs.* 391.8 ± 121.8; p = 0.0035).Jess automated Western Blot showed two Entpd1 bands: a 125kDa glycosylated, active form and a 36kDa non-glycosylated, inactive form. In HFHCC mice, the glycosylated Entpd1 form represented 16.8% ± 2.6 of total protein compared with 13.4% ± 1.8 in controls(p = 0.0077). Patients with MASH (1588 ± 1750pg/ml) had higher ENTPD1 levels than those with SS (1136 ± 808pg/ml, p = 0.03). ENTPD1 levels increased with inflammatory activity [none (n = 23), 1477 ± 1131pg/ml; mild (n = 99), 1113 ± 890pg/ml; moderate (n = 48), 1925 ± 2163pg/ml; p = 0.005], with significant difference between mild and moderate inflammation group (p = 0.015). ENTPD1 levels were not significantly associated with ballooning or fibrosis. In a multivariate analysis, adjusted for sex, age, diabetes mellitus, and Body Mass Index, P2RX7 rs1718119 polymorphism was significantly associated with presence of inflammation (n = 654; OR:0.50; IC 95%: 0.27-0.93; p = 0,028) and significant fibrosis (n = 654; OR = 0.58; IC 95%: 0.37-0.89; p = 0,013). **Conclusion:** To conclude, eATP-related pathways are implicated in MASLD progression. Upregulation of Entpd1, P2rx7, and Nlrp3, together with increased Entpd1 and P2rx7 protein levels, supports their role in inflammation-driven disease. Serum ENTPD1 reflects inflammatory activity and P2RX7 rs1718119 is independently associated with inflammation and significant fibrosis, highlighting the purinergic pathway as a potential therapeutic target in MASLD.

★ 1378 | PROBING METABOLIC-DYSFUNCTION ASSOCIATED STEATOTIC LIVER DISEASE (MASLD) INDUCED STRUCTURE-FUNCTION CHANGES IN HEPATIC ER-MITOCHONDRIA CONTACTS WITH A FOCUS ON INOSITOL-1,4,5-TRISPHOSPHATE (IP3) RECEPTORS

Arijita Ghosh[1] Prottoy Hasan[1] Marite Castromonte[1] Raghavendra Singh[1] Piyush Mishra[1] Rebecca Thomas[1] Gyorgy Hajnoczky[1], [1]Thomas Jefferson university

Background: MASLD is a widespread chronic liver disease affecting a third of the global population, with limited therapeutic cure demanding better comprehension and detection of early onset of identifiable biomarkers. Closely apposed membrane regions of ER and mitochondria, termed as ER-mitochondria contacts (ERMCs) participate in locally conveying Ca^{2+} signals, lipid exchange, ROS regulation among other essential functions governing cell metabolism. The key player mediating release of Ca^{2+} from ER is the inositol 1,4,5 trisphosphate receptor (IP3R). Dysregulated ER Ca^{2+} handling, IP3R linked Ca^{2+} transfer and mitochondrial dysfunction have been implicated in MASLD, but the mechanistic details are obscure. It is known from previous work that IP3R2 is the predominant IP3R isoform along with the other relevant isoform being IP3R1 in hepatocytes with no detectable IP3R3. IP3R2 has been reported to be the most effective in ER-mitochondria Ca^{2+} transfer in specific cell lines, by our group. IP3R isoform-specific impact on ERMCs and its relevance in MASLD is currently missing in literature. Our hypothesis is that IP3R contributes to ERMC structure-function in MASLD progression. **Methods:** In this work we studied the structure of ERMCs in MASLD in genetic models of control and IP3R knockdown (KD) mice. MASLD was induced with 60% High-fat choline-deficient diet (HFD) for 3- and 7-weeks mimicking inflammation and more severe steatohepatitis (MASH) in the form of fibrosis respectively. **Results:** Efficacy of the diet was validated with histological and biochemical marker measurements showing increased lipid droplet accumulation and higher triglyceride (TG) levels. The

IP3R triple knockdown (TKD), IP3R1 knockdown (R1KD) and IP3R2 knockdown (IP3R2KD) were validated at the level of expression and Ca^{2+} specific function with fluorometric measurements and imaging studies in hepatocytes derived from control and KD mice which together showed time-dependent abolition of IP3R expression and function. Electron microscopic (EM) analysis showed less tight contacts between ER and mitochondria in absence of IP3R in hepatocytes 0, 3 and 7 weeks of HFD. The HFD treatment induced an increase in tight contacts at 3- vs 7-weeks in mice liver tissue in majority of genotypic groups. The absence of IP3R2 prevented the increase in tight contacts, whereas IP3R1 deletion had no effect at 3-weeks of HFD. **Conclusion:** MASLD specific HFD induced structural reorganization of hepatic ERMCs. IP3R contribute to ERMC structure stabilization in control and MASLD liver. IP3R2 has an isoform specific leverage on MASLD induced liver. The functional relevance of IP3R isoforms and specific impact on ERMCs are being probed currently using multi omics and live cell imaging approaches.

1380 | CYTOSOLIC MITOCHONDRIAL RNA SIGNALING AS A DRIVER INFLAMMATION IN SENESCENCE AND MASH

Stella Victorelli[1], [1]Mayo Clinic

Background: Senescent cells contribute to age-related tissue dysfunction in part through induction of a chronic senescence-associated secretory phenotype (SASP). We have previously shown that mitochondria are key regulators of the SASP, suggesting that mitochondrial pathways may represent therapeutic targets to reduce senescence-driven inflammation in aging and age-related diseases. Mitochondrial double-stranded RNA (mtdsRNA), when released into the cytosol, is highly immunogenic and can trigger inflammatory signaling. Here, we investigated whether cytosolic mtdsRNA contributes to SASP induction in senescent cells and whether this pathway is activated in metabolic dysfunction-associated steatohepatitis (MASH), a disease associated with increased senescent cell burden. **Methods:** Senescent human fibroblasts and AML12 hepatocytes were used to assess cytosolic mitochondrial dsRNA accumulation, activation of RNA-sensing pathways, and SASP induction. To define the contribution of cytosolic RNA sensing to the SASP, RIG-I, MDA5, and MAVS were genetically manipulated. To determine whether mitochondrial outer membrane permeabilization contributes to mtdsRNA leakage, CRISPR-Cas9-mediated deletion of BAX and BAK was performed in senescent cells. In vivo, cytosolic RNA signaling was examined in a diet-induced model of MASH, and the impact of hepatocyte-specific BAX/BAK deletion was assessed by measuring hepatic RNA sensor expression, senescence markers, inflammation, immune infiltration, and fibrosis-associated endpoints. **Results:** Senescent cells exhibited increased levels of cytosolic mtdsRNA, which activated the RNA sensors RIG-I and MDA5 and promoted MAVS aggregation, leading to SASP induction. Inhibition of RIG-I and MDA5 significantly reduced the expression of SASP factors. Deletion of BAX and BAK, which regulate mitochondrial outer membrane permeability, suppressed mtdsRNA leakage and attenuated the SASP. In diet-induced MASH, a condition characterized by increased senescent cell burden, cytosolic RNA signaling was upregulated in the liver. Hepatocyte-specific deletion of BAX and BAK significantly reduced hepatic expression of RNA sensors, decreased expression of the senescence marker p21, diminished MASH-associated inflammation and immune infiltration, and improved markers of liver fibrosis. **Conclusion:** These findings identify cytosolic mtdsRNA as a major contributor to SASP induction in senescent cells and suggest that BAX/BAK-dependent mitochondrial RNA leakage promotes inflammatory signaling in MASH. Together, our results provide proof-of-concept evidence that targeting mechanisms involved in cytosolic mtdsRNA release may represent a novel therapeutic strategy to reduce senescence-associated inflammation and liver injury in MASH.

1381 | SEMAGLUTIDE REVERSES CLINICALLY RELEVANT BIOMARKER ALTERATIONS IN THE BIOPSY-CONFIRMED GAN DIO-MASH MOUSE MODEL

Henrik Hansen[1] Jacob Nøhr-Meldgaard[1] Jenny Norlin[2] Sanne Veidal[2] Kristian Bendtsen[2] Kristoffer Niss[2] Markus Latta[2] Susanne Pors[1] Mathilde Dalhoff[1] Kristoffer Voldum-Clausen[1], [1]Gubra A/S, [2]Novo Nordisk A/S

Background: The long-acting glucagon-like peptide-1 (GLP-1) receptor agonist semaglutide was recently approved as the first GLP-1–based therapy for people with metabolic dysfunction-associated steatohepatitis (MASH) and moderate-to-severe fibrosis. Clinical

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

studies show that semaglutide not only improves liver health but also reverses several biomarker alterations characteristic of the disease. In this study, we characterized metabolic, histological, and biomarker responses to semaglutide in the Gubra Amylin NASH (GAN) diet-induced obese, biopsy-confirmed mouse model of MASH, and compared these findings with clinical observations. **Methods:** Male C57BL/6 mice were fed GAN diet, high in fat, fructose and cholesterol for 38 weeks prior to study start. A liver pre-biopsy was collected 4 weeks before treatment start. Only GAN DIO-MASH mice with NAFLD Activity Score (NAS $\geq$ 5) and fibrosis stage F2-F3 were included and stratified into treatment groups. Semaglutide (30 nmol/kg) or vehicle was administered subcutaneously once daily for 12 weeks. Vehicle-dosed, chow-fed mice served as healthy controls. Endpoints included aptamer-based SomaScan plasma proteomics, blood/liver biochemistry, pre-to-post individual assessment of NAS and fibrosis stage, and quantitative histology. **Results:** Semaglutide promoted a weight loss of approx. 21% and improved hepatomegaly, plasma transaminases, plasma and hepatic lipid markers, NAS, and quantitative histological measures of steatosis and inflammation. Semaglutide also reduced fibrogenesis by histomorphometric analysis. Notably, the GAN DIO-MASH mouse model recapitulated key human MASH-associated circulating protein changes, including semaglutide-responsive biomarkers related to metabolism, inflammation, and fibrosis. **Conclusion:** The GAN DIO-MASH mouse model exhibits strong translational relevance across metabolic, histological, and molecular domains, offering a robust platform for advancing mechanistic understanding of semaglutide and supporting the development of next-generation MASH therapies.

1382 | SPT6 REGULATES HEPATIC STELLATE CELL FUNCTION TO PROMOTE LIVER FIBROSIS

Nahid Arghiani[1] Amel Ben Saad[1] Benjamin J Toles[1] Raza Ur Rahman[1] Arden Weilheimer[1] Alan Mullen[2], [1]Division of Gastroenterology, University of Massachusetts Chan Medical School, Worcester, MA, USA, [2]University of Massachusetts Medical School

Background: Chronic liver injury leads to fibrosis, which is characterized by excessive extracellular matrix (ECM) protein deposition. Hepatic stellate cells (HSCs) are the primary cell type responsible for ECM production, and inhibiting their fibrogenic activity has the potential to slow or reverse progression of liver fibrosis and development of end stage liver disease. We previously conducted a small interfering (si) RNA screen in primary human HSCs, which identified SPT6 (Suppressor of Ty Homologue-6, encoded by SUPT6H) as a putative regulator of the fibrogenic phenotype. Although SPT6 is known to function as a histone chaperone, regulating nucleosome remodeling and RNA splicing, its function in HSCs has not been explored. **Methods:** Chronic liver injury leads to fibrosis, which is characterized by excessive extracellular matrix (ECM) protein deposition. Hepatic stellate cells (HSCs) are the primary cell type responsible for ECM production, and inhibiting their fibrogenic activity has the potential to slow or reverse progression of liver fibrosis and development of end stage liver disease. We previously conducted a small interfering (si) RNA screen in primary human HSCs, which identified SPT6 (Suppressor of Ty Homologue-6, encoded by SUPT6H) as a putative regulator of the fibrogenic phenotype. Although SPT6 is known to function as a histone chaperone, regulating nucleosome remodeling and RNA splicing, its function in HSCs has not been explored. **Results:** We find that that SPT6 directly promotes gene expression programs to regulate ECM production, cell adhesion, and cell migration. Furthermore, depletion of SUTP6H reduces collagen and alpha-smooth muscle actin (α-SMA) production and cell migration, while promoting lipid droplet accumulation within HSCs, all phenotypic hallmarks of HSC inactivation. These effects are observed with SUPT6H depletion without reducing HSC viability. Furthermore, SPT6 promotes alternative splicing, providing a path to generate protein isoforms that increase the fibrogenic activity of HSCs. **Conclusion:** We find that that SPT6 directly promotes gene expression programs to regulate ECM production, cell adhesion, and cell migration. Furthermore, depletion of SUTP6H reduces collagen and alpha-smooth muscle actin (α-SMA) production and cell migration, while promoting lipid droplet accumulation within HSCs, all phenotypic hallmarks of HSC inactivation. 1383 | LEAN MAFLD IS NOT BENIGN: A SYSTEMATIC REVIEW OF LONG-TERM OUTCOMES

Namratha Vaghdevi Cherukuru[1] Nayanika Tummala[2] Puneet Gupta[3] Aditya Mansabdar[4], [1]New York medical College graduate medical education program, [2]New York Medical Graduate Medical Education Program, [3]New York Medical Graduate Medical Education, [4]NYMC

Background: Metabolic dysfunction-associated fatty liver disease (MAFLD) is increasingly identified in non-obese individuals but is still often presumed benign. Data on long-term cardiovascular and mortality outcomes in lean MAFLD are sparse, leaving its prognostic significance unclear. **Methods:** Following PRISMA 2020, we searched PubMed and the Cochrane Library from January 2016 to May 2026. We included studies of adults 18 years or older with lean MAFLD /MASLD (Metabolic dysfunction-Associated Steatotic Liver Disease) /NAFLD (Non-Alcoholic Fatty Liver Diseas) with a BMI < 25 kg/m2, or < 23 kg/m2 in Asians reporting at least one long-term outcome (fibrosis progression, cardiovascular events, hepatic decompensation, or all cause mortality) over a minimum 12 month follow-up. Cohorts, case-control studies, RCTs, and meta-analyses were eligible; pediatric populations, competing liver disease, and biochemical-only outcomes were excluded. Bias was assessed with the Newcastle-Ottawa Scale and Cochrane RoB (Risk of bias) 2.0. Of 91 records screened, 6 studies (398,599 participants) qualified; heterogeneity precluded meta-analysis, and findings were synthesized narratively following SWiM (Synthesis Without Meta-analysis) guidance. **Results:** In a propensity-matched cohort of 135,038 patients followed to 7 years (Al Ta'ani 2026), lean MASLD carried higher risks of new-onset heart failure (HR 1.23, 95%CI 1.16-1.31), composite cardiovascular events (HR 1.21, 1.13-1.30), cerebrovascular events (HR 1.33, 1.24-1.43), and all-cause mortality (HR 1.48, 1.38-1.59; all $p < 0.0001$) versus non-lean MASLD. In NHANES (Zou 2020, n = 14,365), 15-year all-cause mortality was 51.7% in lean versus 27.2% in non-lean NAFLD ($p < 0.001$), reaching 76.3% in lean patients. A Japanese cohort (Yoshitaka 2017, n = 1,647) found a 10.4-fold adjusted hazard for incident cardiovascular disease in lean NAFLD (95%CI 2.61-44.0, $p = 0.001$). In a 6-year RCT (Wong 2018, n = 154), lifestyle intervention achieved NAFLD remission in 67% of lean patients versus 18% of controls ($p < 0.001$), with ALT normalisation sustained at year 6 (46% vs 17%, $p = 0.013$). Across adjusted analyses, fibrosis and diabetes-not BMI-drove prognosis. **Conclusion:** Lean MAFLD is not benign. These patients face cardiovascular and mortality risks matching or exceeding non-lean counterparts yet respond well to lifestyle change. Clinicians should pursue active cardiometabolic risk stratification and early intervention rather than assuming low BMI is protective.

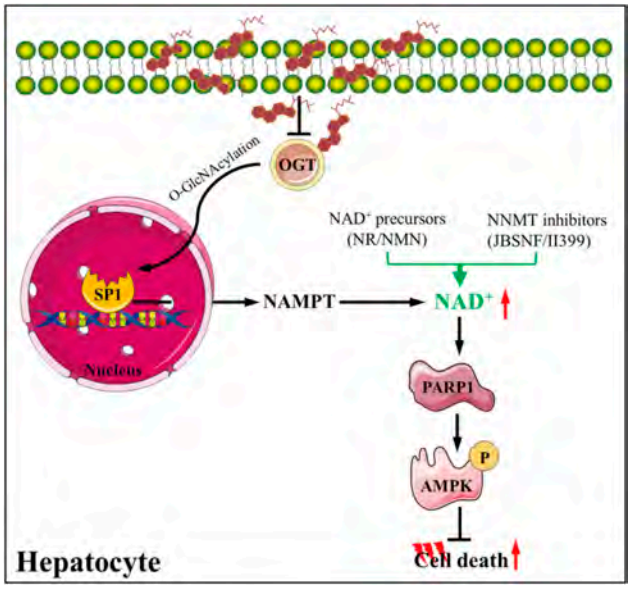
1384 | NAD+ DEPLETION MEDIATES CHOLESTEROL-INDUCED HEPATOTOXICITY THROUGH SP1 INACTIVATION AND PARP1-AMPK SUPPRESSION



Yanhui Li[1] Zhenyuan Song[1] Rui Guo[1] Izabela Hawro[2] Jose Cordoba Chacon[1], [1]University of Illinois Chicago, [2]University of Illinois at Chicago

Background: Cholesterol accumulation is a key pathogenic feature of metabolic dysfunction-associated steatotic liver disease (MASLD) and alcohol-related liver disease (ALD), yet the mechanisms linking cholesterol overload to hepatocellular injury remain unclear. This study aimed to elucidate how cholesterol perturbs hepatic NAD+ metabolism and contributes to hepatocellular injury. **Methods:** Cholesterol-loading models in hepatocytes and mice were used to assess changes in NAD+ metabolism, PARP1-AMPK signaling, and transcriptional regulation. Pharmacological and genetic approaches were applied to dissect the roles of SP1, OGT, PARP1, and SIRT1 in cholesterol-induced hepatotoxicity. **Results:** Cholesterol overload caused profound hepatic NAD+ depletion by down-regulating NAMPT, a key enzyme for NAD+ biosynthesis, accompanied by reduced PARP1 expression and global protein PARylation. NAD^+ restoration via either precursor supplementation or NNMT inhibition

and PARG blockade reinstated PARP1 activity, AMPK phosphorylation, and hepatocyte viability. Mechanistically, cholesterol suppressed OGT expression and protein O-GlcNAcylation, leading to SP1 inactivation and transcriptional repression of Nampt. Co-immunoprecipitation assay reveals that PARP1 is directly associated with and PARylates AMPK, and its inhibition diminished AMPK activation and metabolic stress resilience. Unlike palmitate-induced injury, cholesterol toxicity was independent of SIRT1 or mTORC1 signaling, underscoring a distinct form of lipotoxic stress driven by NAD+ depletion, impaired PARP1-AMPK signaling, and defective cellular adaptation to cholesterol overload. **Conclusion:** Our findings identify an unrecognized cholesterol-SP1-NAD+-PARP1-AMPK axis as a central mediator of cholesterol-induced hepatotoxicity. Restoration of NAD+ metabolism or activation of the OGT-SP1 pathway represents a promising therapeutic approach to counter cholesterol-driven liver injury, such as MASLD, ALD, and related metabolic disorders.

1385 | ADIPOSE FSP27 DEFICIENCY CAUSES A LOSS OF HEPATIC CEACAM1 TO DRIVE MASH AND HEPATIC FIBROSIS

Agnes Portuphy[1] Raziyeh Abdolahipour[1] Getachew Belew[1] Bijinu Balakrishnan[1] Vishwajeet Puri[1] Sonia Najjar[1], [1]Ohio University, Department of Biomedical Science, Heritage College of Osteopathic Medicine

Background: Dysregulated adipose lipolysis is a major contributor to MASH, which is reaching an epidemic rise and is a major cause of hepatic fibrosis and liver transplantation. In the liver, carcinoembryonic antigen-related cell adhesion molecule 1 (CEACAM1) promotes insulin clearance and mediates the inhibition of fatty acid synthesis in response to acute pulses of insulin release. Hepatic CEACAM1 levels progressively decline as fibrosis severity increases in patients with MASH. Free fatty acids (FFAs) suppress hepatic Ceacam1 transcription via a PPARα-dependent mechanism. In adipocytes, Fat-specific protein 27 (FSP27) interacts with adipose triglyceride lipase (ATGL) to prevent lipolytic flux. Thus, we hypothesized that adipocyte-specific loss of Fsp27 drives hepatic fibrosis via fatty acid-mediated repression of CEACAM1. **Methods:** We generated adipocyte-specific *Fsp27* knockout mice (*Adipo+Fsp27$^{fl/fl}$*) using adiponectin-Cre on a C57BL/6J background. To assess the protective role of CEACAM1, we crossed these *Adipo +Fsp27$^{fl/fl}$* mutants with L-CC1 mice with liver-specific overexpression of wild-type CEACAM1-L driven by the human Apolipoprotein A1 promoter to protect hepatic CEACAM1 expression. The metabolic function was assessed by glucose and insulin tolerance tests, and insulin clearance was evaluated using steady-state C-peptide/insulin molar ratio. Liver steatosis and fibrosis were evaluated by H&E and Sirius Red staining, respectively. Key markers of lipid metabolism, oxidative stress, inflammation, and fibrosis were also examined in plasma and liver tissues using RT-qPCR, Western blot, ELISA, and IHC analysis. **Results:** *Adipo +Fsp27$^{fl/fl}$* , but not *Adipo+Fsp27$^{fl/fl}$ LCC1* exhibited elevated plasma glycerol with lower epididymal WAT. Hepatocytic *Ceacam1* mRNA levels decreased as early as 2-3 months, preceding systemic insulin resistance. This was followed by a progressive decline of hepatic CEACAM1 protein levels starting at 6 months of age and reaching >60% loss by 8-9 months of age. Additionally, *Adipo+Fsp27$^{fl/fl}$* mice developed impairment of insulin clearance, hyperinsulinemia, glucose intolerance, and reduced plasma nitric oxide with increased plasma endothelin-1 levels at 8-9 months. Histology also revealed lipid deposition by 6 months and inflammatory infiltration by 8 months. This was followed by spontaneous chicken-wire pattern of interstitial and perivenular collagen deposition by 12 months. In contrast, these abnormalities were markedly attenuated in *Adipo+Fsp27$^{fl/fl}$ LCC1* mice. **Conclusion:** Elevated lipolysis led to an early decrease in hepatic *Ceacam1*, which preceded lipotoxicity, hyperinsulinemia, oxidative stress, and MASH progression to fibrosis. Restoring hepatic CEACAM1 uncoupled adipose lipolysis from liver injury, identifying CEACAM1 as a central mechanistic node and potential therapeutic target in MASH-associated fibrosis.

1386 | HEPATOCYTE-SPECIFIC VHL DELETION EXACERBATES HFHC-INDUCED STEATOHEPATITIS IN A SEX-DEPENDENT MANNER

Laura Fàbrega[1] Mariel Gorgon Manrique[2] Laura Conde de la Rosa[1] Susana Nuñez[3] Carmen Garcia-Ruiz[4] Jose Fernandez-Checa[1], [1]Institute of Biomedical Research of Barcelona, [2]Universitat de Barcelona - Universitat Rovira i Virgili, [3]CIBERehd, [4]Spanish National Research Council

Background: The Von Hippel–Lindau (VHL) tumor suppressor is a key regulator of hypoxia signaling and metabolic homeostasis. Although its role in cancer is well established, its contribution to metabolic dysfunction–associated steatotic liver disease (MASLD) and progression to steatohepatitis remains insufficiently defined, particularly in a sex-dependent context. We hypothesized that VHL deletion stabilizes HIF signaling, increasing STARD1-dependent mitochondrial cholesterol trafficking and promoting a self-amplifying loop of mitochondrial dysfunction and liver injury. **Methods:** Nine-week-old male and female Vhl-floxed mice were fed a high-fat high-cholesterol (HFHC) diet (Research Diets, D12011002) for 4 months. Hepatocyte-specific Vhl deletion was induced by tail-vein injection of AAV8-TBG-Cre, with AAV8-TBG-GFP as control. Mice remained on HFHC and were sacrificed one week post-injection. Liver injury, steatosis, fibrosis, cholesterol and bile acids levels, as well as metabolic gene and protein expression were assessed by histology, biochemical assays, immunostaining, qPCR and Western Blot analyses. **Results:** Vhl deletion exacerbated HFHC-induced liver injury in a sex-dependent manner. Vhl-deficient mice fed HFHC diet developed hepatomegaly, angiogenesis, steatosis, and fibrosis, with males showing higher serum transaminases and triglyceride accumulation compared to female mice. Vhl deletion increased hepatic cholesterol and STARD1 protein expression, supporting enhanced mitochondrial cholesterol trafficking. In parallel, mRNA expression of Cyp7a1, Cyp8b1, Cyp27a1, and Cyp7b1 was repressed, suggesting impaired bile acid synthesis. Despite reduced Cyp27a1 expression, residual Cyp27a1 activity and enhanced availability of mitochondrial cholesterol led to chenodeoxycholic acid (CDCA) generation and metabolism into muricholic and taurodeoxycholic acids. Mechanistically, CDCA was associated with reduced Fbp1 and increased Nrf2 expression in male vs female mice, linking bile acid remodeling to metabolic reprogramming and oxidative stress adaptation. Increased STARD1 expression relative to CYP27A1 favored mitochondrial free cholesterol accumulation, resulting in decreased GSH levels, increased ROS production, and inhibition of prolyl hydroxylases, thereby sustaining HIF-1α/HIF-2α stabilization and amplifying liver damage. **Conclusion:** Hepatocyte-specific Vhl deletion exacerbates HFHC-induced MASH in a sex-dependent manner involving hypoxia signaling, STARD1-associated mitochondrial cholesterol accumulation, bile acid remodeling, oxidative stress, and FBP1 repression. These findings identify VHL as a critical regulator of hepatic metabolic adaptation, supporting its role as a potential determinant of MASLD progression to HCC.

1387 | NOVEL ROLE OF NEURO-IMMUNOMETABOLISM IN THE PATHOGENESIS OF MASH

Miyako Tanaka[1] Takayoshi Suganami[1], [1]Nagoya University

Background: Metabolic dysfunction-associated steatohepatitis (MASH) is the liver phenotype of metabolic syndrome. The "multiple parallel hits hypothesis" proposes the pathological mechanism underlying MASH, emphasizing the significance of various metabolic disorders and inflammatory stimuli. However, the involvement of the central nervous system in the pathogenesis of MASH remains poorly understood. Within the liver, the β2-adrenergic receptor (Adrb2) is a primary receptor for the sympathetic nervous system, the dominant component of the autonomic nervous system. In this study, we focused on Adrb2 to investigate how the sympathetic nervous system regulates hepatic metabolism and inflammation during the development of MASH. **Methods:** We developed two types of MASH models in systemic Adrb2 knockout mice (KO). The first one was a genetic model generated by crossing Melanocortin 4 receptor-KO mice and Adrb2 KO mice, and the second one was a diet-induced model using a Gubra Amylin NASH (GAN) diet. To identify the cell type-specific roles , we created hepatocyte-specific Adrb2 KO mice, generated by crossing albumin-Cre mice with Adrb2 floxed mice, and immune cell-specific Adrb2 KO mice, generated by bone marrow transplantation, and both groups were fed a GAN diet. **Results:** In systemic Adrb2 KO mice, Adrb2 deficiency aggravated hepatic steatosis,

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

inflammation, and fibrosis in both genetic and diet-induced models, suggesting a protective role of the sympathetic nervous system during the development of MASH. Hepatocyte-specific Adrb2 KO mice showed similar hepatic phenotypes to those of systemic Adrb2 KO mice to a slightly lesser degree. Immune cell-specific Adrb2 KO mice exhibited enhanced inflammation and fibrosis in the liver without affecting hepatic lipid accumulation. As a potential underlying mechanism, Adrb2 deficiency in macrophages inhibited efferocytosis, and Adrb2 deficiency in hepatocytes increased the expression of genes involved in cholesterol metabolism. **Conclusion:** These findings suggest that Adrb2 plays an important role in cholesterol metabolism and efferocytosis in hepatocytes and macrophages, respectively, during the development of MASH. Our data suggest the involvement of the sympathetic nervous system in the pathogenesis of MASH, in addition to the previously recognized complicated interactions between metabolic disorders and inflammatory stimuli in the liver.

1388 | INTER-ORGAN GENE REGULATORY NETWORKS REVEAL ADIPOSE–AND MUSCLE–LIVER CROSSTALK UNDERLYING SEMAGLUTIDE-MEDIATED IMPROVEMENT OF MASH

Eveline Gart[1], [1]TNO

Background: Glucagon-like peptide-1 receptor agonists such as semaglutide improve obesity-related metabolic dysfunction including metabolic dysfunction-associated steatohepatitis (MASH). However, their effects extend beyond individual organs and involve coordinated inter-organ communication. Semaglutide-induced weight loss is accompanied by alterations in body composition, raising questions about the metabolic consequences of associated changes in skeletal muscle. Although tissue-level phenotypic effects have been well characterized, the molecular mechanisms underlying inter-organ crosstalk remain poorly understood. This study aimed to delineate cross-tissue regulatory networks linking adipose tissue and skeletal muscle to hepatic processes. **Methods:** Diet-induced obese Ldlr−/−.Leiden mice were treated with semaglutide alone or in combination with exercise. Transcriptomic datasets from liver, adipose tissue, and muscle were integrated using gene regulatory network analysis to identify inter-organ regulators and pathways. This approach enabled us to define how gene expression changes in adipose tissue and muscle drive hepatic molecular remodeling in the context of MASH. **Results:** Semaglutide reduced body weight, fat mass and lean body mass. Despite a reduction in absolute muscle mass, relative muscle mass increased as compared to high-fat diet controls as a result of changes in body composition. Gene regulatory network analysis identified distinct yet partially overlapping regulatory axes linking adipose tissue and muscle to the liver. Comparison of adipose- and muscle-derived networks revealed complementary modes of regulation: adipose tissue predominantly linked to inflammatory and immune signaling pathways, whereas muscle-derived signals were more strongly associated with mitochondrial and metabolic pathways. Importantly, the integration of these networks reveals that semaglutide-induced improvements in hepatic steatosis and inflammation are not solely driven by direct hepatic effects, but are mediated through multi-organ signaling axes. **Conclusion:** Integrated transcriptomic network analysis reveals that semaglutide induces coordinated transcriptional remodeling across adipose tissue, skeletal muscle, and liver. Adipose and muscle derived regulatory networks converge on hepatic pathways central to MASH pathogenesis, providing mechanistic insight into how these tissues specifically contribute to semaglutide-mediated improvements in liver disease.

multicellular human in vitro systems that capture immune–hepatic interactions. We developed a human induced pluripotent stem cell (iPSC)-derived macrophage-incorporated liver organoid (MILO) model to investigate HIV- and metabolic stress–induced inflammatory and fibrogenic signaling. **Methods:** Human liver organoids (HLOs) and functional CD14^{+} macrophages were generated from iPSCs and combined to generate MILO. HLOs, macrophages, and MILO were exposed to HIV, free fatty acids (FFA), or HIV+FFA. Hepatic function, inflammatory signaling, fibrogenic responses, and YAP-associated pathway activation were evaluated using immunofluorescence, flow cytometry, and qPCR. Pathway inhibition studies were performed to assess mechanistic signaling responses. **Results:** HLOs demonstrated hepatocyte-like functionality, including albumin secretion, indocyanine green uptake/release, and FFA-induced lipid accumulation. HIV and/or FFA exposure induced YAP-associated target genes (CTGF, CYR61, ANKRD1) together with fibrosis-associated genes (TIMP1, αSMA, COL1A1). Macrophages demonstrated activation of inflammatory and profibrotic polarization programs following HIV and/or FFA exposure, including induction of CD80, CD86, TLR4, IL1B, IL12, CD206, CD163, and ARG1. Compared with HLOs alone, MILO demonstrated coordinated induction of YAP-associated, inflammatory, metabolic, and fibrosis-related transcriptional programs following HIV +FFA exposure, including increased expression of CTGF (~3.2-fold), TIMP1 (~3.1-fold), and ARG1 (~5.5-fold), supporting a central role for immune–hepatic crosstalk in HIV-associated MASLD progression. Pathway inhibition suppressed treatment-induced YAP-associated signaling, macrophage activation, and fibrosis-related gene expression across macrophages, HLOs, and MILO. **Conclusion:** We established a multicellular human iPSC-derived macrophage-incorporated liver organoid platform that recapitulates HIV- and metabolic stress–associated inflammatory and fibrogenic signaling. These findings identify immune–hepatic crosstalk as a key driver of YAP-associated fibrogenic responses and establish MILO as a scalable platform for transcriptomic profiling and therapeutic testing in HIV-associated MASLD.

1390 | HEPATIC ARID5A IS INDUCED BY LIPOTOXIC ER STRESS THROUGH THE PERK PATHWAY AND ATTENUATES MURINE MASH

Takahito Nishihara[1] P. Vineeth Daniel[2] Amy Mauer[1] Jasmin Weninger[1] Hanna Erickson[1] Yeriel Yoon[1] Aditya Bhagwate[1] Cristina Correia[3] Harmeet Malhi[1], [1]Mayo Clinic Rochester, [2]SRM Medical College Hospital and Research Center, SRMIST, Kattankulathur, TN, India, [3]Department of Molecular Pharmacology and Experimental Therapeutics, Mayo Clinic, Rochester

Background: The endoplasmic reticulum (ER) is an essential hub of protein folding, lipid biosynthesis, and calcium homeostasis in hepatocytes. The metabolic significance of unfolded protein response (UPR) mediators and ER stress have become increasingly apparent in the context of lipid-overload in obesity and metabolic dysfunction-associated steatohepatitis (MASH). Yet significant gaps remain in our understanding of the full regulatory landscape that governs the ER stress response in MASH. **Methods:** Parallel bulk RNA sequencing (RNA-seq) and assay for transposase-accessible chromatin sequencing (ATAC-seq) were performed in tunicamycin-treated mouse liver tissue along with bulk RNA-seq in palmitate-treated primary mouse hepatocytes. ARID5A expression was measured by qPCR and western blotting. Steatohepatitis was induced by feeding mice a choline-deficient, amino acid-defined high-fat diet (CDAHFD) and MASH was induced by a high Fat, Fructose, and Cholesterol (FFC) diet. Hepatotropic adeno-associated virus (AAV) was injected via tail vein to overexpress ARID5A. **Results:** The integration of bulk RNA-seq and ATAC-seq identified *Arid5a* as one of the significantly upregulated transcripts in proteotoxic and lipotoxic ER stress. Analysis of publicly available human liver bulk RNA sequencing (GSE135251) and qPCR analysis of human steatosis (n = 4) and MASH (n = 4) samples demonstrated upregulation of *Arid5a* transcript in MASH. Murine MASH livers also demonstrated increased transcript and protein expression of ARID5A. Human and mouse hepatocyte-derived cell lines and primary mouse hepatocytes demonstrated palmitate-induced ARID5A upregulation at both transcript and protein level. Using a combination of immunofluorescence and subcellular fractionation, we found that ARID5A, though distributed in the cytosol and nucleus basally, was enriched in the nuclear compartment following palmitate treatment in hepatocytes. Cell lines deficient in each of the three UPR sensor pathways (IRE1α, PERK, and ATF6α) demonstrated palmitate-induced ARID5A upregulation was attenuated only in eIF2α phosphorylation-resistant cells, which is necessary for downstream responses in the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

PERK pathway. Using pharmacological inhibitors and PERK genetic knockdown, we observed that palmitate-induced ARID5A upregulation was attenuated when PERK was inhibited. Overexpression of ARID5A attenuated liver injury, inflammation, and fibrosis in murine models of steatohepatitis and MASH. **Conclusion:** We identified ARID5A as an ER stress-responsive transcript upregulated through the PERK pathway. Overexpression of ARID5A attenuated MASH supporting a protective role for ARID5A and suggesting that ARID5A could be a new therapeutic target in MASH.

1391 | CEACAM1 PROTECTS AGAINST DIET- INDUCED METABOLIC DYSFUNCTION AND HEPATIC FIBROSIS

Raziyeh Abdolahipour[1] Agnes Portuphy[1] Getachew Belew[1] Sonia Najjar[1], [1]Ohio University

Background: Carcinoembryonic Antigen-related Cell Adhesion Molecule 1 (CEACAM1) is a transmembrane glycoprotein highly expressed in hepatocytes, with lower expression in liver sinusoidal endothelial cells (LSECs) followed by hepatic stellate cells (HSCs). Lipolysis-derived non-esterified fatty acids (NEFA) stimulate PPARα activation to induce its interaction with the well-conserved PPRE-RXRα element in Ceacam1 promoter. This suppresses Ceacam1 transcription. Given that loss of hepatic CEACAM1 causes insulin resistance and hepatic steatosis, the current study investigated whether mutating PPRE-RXRα binding site within the Ceacam1 promoter could protect C57BL/6J mice against the metabolic and histological abnormalities caused by Gubra Amylin-NASH (GAN) diet. **Methods:** A knock-in (KI) mouse model carrying a mutation in the PPRE-RXRα binding site of the Ceacam1 promoter was generated. Male and female WT and KI mice were fed regular diet (RD), high-fat diet (HFD), or GAN diet for 4 and 6 months, respectively, to evaluate the metabolic and histological effects. **Results:** Relative to RD, feeding with HFD and GAN diet for up to 4 months suppressed hepatic CEACAM1 expression in wild-type (WT), but not KI males. Feeding males with HFD diet impaired insulin clearance to cause hyperinsulinemia-driven insulin resistance and hepatic steatosis in WT, but not KI mice. It also reduced energy expenditure and promoted hepatic fibrosis in WT, but not KI males. A parallel analysis was performed in female WT and KI mice fed with regular chow or GAN diet for 6 months. In female mice, GAN feeding similarly repressed CEACAM1 expression in WT but not KI mice, with the most pronounced loss observed in hepatocytes as compared to LSECs and HSCs. Despite the absence of insulin resistance, GAN-fed WT females developed greater steatosis, inflammation, apoptosis, and chicken-wire fibrosis, whereas KI females remained protected. Mechanistically, conditioned media from hepatocytes of GAN-fed WT mice activated HSCs and suppressed Ceacam1 expression, likely through inducing the release of fatty acids. Consistently, CEACAM1 expression was markedly reduced in hepatic stellate cells in patients with MASH, with progressive loss correlating with advanced fibrosis independent of sex or ethnicity. **Conclusion:** These findings identify CEACAM1 repression as a critical driver of MASH progression and hepatic fibrosis in response to GAN diet. Thus, preventing CEACAM1 repression constitutes a therapeutic target in protecting against diet-induced metabolic dysfunction, steatosis, inflammation and hepatic fibrosis.

1392 | PRECLINICAL CHARACTERIZATION OF ALG-037287 AS A LIVER-TARGETED SMALL MOLECULE INHIBITOR OF FATTY ACID SYNTHASE FOR THE POTENTIAL TREATMENT OF MASH

Jieun Song[1] Alexander Leung[1] Peter Althoff[1] Sarah Stevens[1] Sandra Chang[1] Kusum Gupta[1] Cheng Liu[1] Lillian Adame[1] Antitsa Stoycheva[1] Lawrence Blatt[2] David Smith[1] Julian Symons[1] Xuan Luong[1] Tongfei Wu[1], [1]Aligos Therapeutics, [2]Aligos Therapeutics, Inc.

Background: Fatty acid synthase (FASN) catalyzes the terminal, rate-limiting step in de novo lipogenesis (DNL). In metabolic dysfunction–associated steatohepatitis (MASH), hepatic FASN is upregulated, driving triglyceride accumulation and lipotoxicity. Although the FASN inhibitor denifanstat resulted in significant histological improvement in Phase 2b trials, it is associated with alopecia due to on-target skin effects. Here, we describe ALG-037287, a structurally novel, liver-targeted FASN inhibitor designed to retain efficacy in MASH while reducing skin exposure and other dermatologic side effects. **Methods:** Inhibition of beta-ketoacyl reductase (KR) activity was tested using the full-length human FASN protein in a biochemical assay and in vitro DNL inhibition was assessed in primary human hepatocytes. Antifibrotic effects were assessed by

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

quantification of *COL1A1* expression in TGF-β1-activated LX-2 human hepatic stellate cell line. In vitro ADME tox profile was profiled using standard assays. In rats, plasma exposure and liver/skin distribution were assessed after a single oral dose, PK study, and tissue-specific DNL inhibition was quantified in a single oral dose, PK/PD study. **Results:** ALG-037287 demonstrated potent inhibition of the FASN beta-ketoacyl reductase (KR) domain, with an IC50 value approximately 6-fold lower than that of denifanstat. *In vitro*, ALG-037287 showed comparable potency to denifanstat in suppressing *COL1A1* and inhibiting DNL. In a rat PK study, oral administration of ALG-037287 (15 mg/kg) yielded significantly superior liver-to-plasma concentration ratios compared to denifanstat (15 mg/kg) and it was undetectable in skin at 12 hours post-dose. In the rat PK/PD study, single oral doses of ALG-037287 (20 and 60 mg/kg) significantly inhibited hepatic DNL, whereas no significant inhibition was observed in Zymbal's glands and dorsal skin. Furthermore, ALG-037287 exhibited favorable liver microsomal stability across species, with no CYP-mediated drug-drug interactions and no in vitro cardiovascular (hERG, $Na_v1.5$ and Ca_v 1.2) or mutagenic (Ames) liabilities. **Conclusion:** ALG-037287 is a potent, orally bioavailable FASN inhibitor with a differentiated, liver-targeted profile. Its optimized tissue distribution is designed to potentially preserve therapeutic efficacy in MASH while reducing skin exposure and the risk of alopecia and other dermatologic side effects.

1393 | THE GCKR-CHREBP AXIS REGULATES LIPID AND GLYCOGEN LEVELS IN HUMAN HEPATOMA CELLS

Yue Chen[1] Rawdat Hussain[2] Prabhu Ponnandy[2] Elizabeth Speliotes[3], [1]University of Michigan, [2]University of Michigan Medical School, [3]University of Michigan Medical Center

Background: Human genetic studies have identified a missense variant GCKR P446L (rs1260326) which has been associated with metabolic dysfunction-associated steatotic liver disease (MASLD), hypertriglyceridemia, and diabetes. The exact mechanisms responsible for these phenotypes remain to be fully elucidated. **Methods:** We generated Huh7 cells stably by overexpressing WT or P446L GCKR gene as well as GCK, confirmed by immunoblotting. MLXIPL (ChREBP) was knocked out by CRISPR/Cas9. Cells were cultured under 2 mM glucose condition. Glucose-6-phosphate (G6P), glycogen and triglycerides (TG) levels were measured using biochemical assays. Expression of key genes involved in de novo lipogenesis (ACACA, ACLY, FASN, SCD1), MLXIPL and glycogen synthesis and breakdown (GYS1, GYS2, PYGL, STBD1) were determined with RT-qPCR. The levels of these key enzymes (ACC, FASN, ACLY and GYS1/2) as well as proteins involved in glycogen regulation (GSK-3β, PYGL and STBD1) were determined using immunoblotting. **Results:** GCKR P446L variant significantly increased intracellular glucose-6-phosphate (G6P) levels compared to wild-type GCKR, as well as elevated expression of MLXIPL and its target genes including ACC, ACLY, FASN, and SCD1. P446L cells exhibited increased triglyceride accumulation as well as enhanced glycogen content. Knocking out MLXIPL significantly decreased TG level in GCKR P446L cells as well as increased glycogen content in Huh7 and WT GCKR cells; there was a trending increase in glycogen in GCKR P446L cells. GCKR WT cells showed high levels of phospho-GYS1, the inactive form of the main enzyme that synthesizes glycogen, and low levels of phospho-GSK-3β, its upstream kinase regulator. MLXIPL KO increased phospho-GSK-3β regardless of GCKR background and decreased phospho-GYS1 in Huh7 and GCKR WT cells. **Conclusion:** P446L promotes higher G6P, triglyceride and glycogen levels whereas GCKR WT protects against these. MLXIPL deletion increased glycogen content. Differences in phospho-GYS1 and phospho-GSK-3β correlate with differences in glycogen content. Our results provide new information about how WT and P446L GCKR affect lipid and glycogen metabolism in human liver cells.

1394 | THE CELL SPECIFIC ROLE OF SYNDECAN-1 IN THE PATHOPHYSIOLOGY OF MASLD

Greg Callahan[1] Aaron Baker[1], [1]University of Texas at Austin

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Metabolic Dysfunction-Associated Steatotic Liver Disease (MASLD) is a progressive type of fatty liver disease characterized by fat accumulation in hepatic tissue that is not linked to excessive alcohol consumption. The disease encompasses early stages of metabolic dysfunction-associated fatty liver (MAFL) to more severe stages of metabolic dysfunction-associated steatohepatitis (MASH). It is currently the most common form of chronic liver disease worldwide, with a prevalence of approximately 25% in the general population (~1.8 billion people worldwide). While a few treatments have recently been approved by the FDA, the fundamental mechanisms of MASLD remain an area of active research. Syndecan-1 (SDC-1), a transmembrane protein that binds to heparan sulfate is one of the most important proteoglycans in the liver and its expression levels alter under various pathologies, including MASLD. The extracellular domain of SDC-1 has been detected in serum of patients with liver disease, shed during MASLD by either increased metalloproteinase activity or impaired SDC-1 sulfation. The literature on SDC-1's role in MASLD describe the complex interactions of both cell membrane bound and shed SDC-1 with cytokines and its impact on signaling pathways, lipid transport, and fibrosis. However, they are limited to *in vitro* studies involving one cell type, or *in vivo* studies that focus on hepatocyte syndecan-1. **Methods:** Using a tamoxifen inducible loxP-cre system, we generated cell-specific knockouts of SDC-1 in hepatic stellate cells or endothelial cells. We then fed mice possessing these knockouts a high fat methionine and choline deficient diet to induce inflammatory and fibrotic MASLD in the mice. Following the diet, we conudcted histological staining to study gross tissue morphology, inflammatory cell recrutiment / phenotype, stellate cell activation, and fibrogenesis. **Results:** From these *in vivo* experiments, we have determined that loss of hepatic stellate cell syndecan-1 increases stellate cell activation, indicated by a significant increase in aSMA area, while loss of SDC-1 in endothelial cells significantly decreases stellate cell activation. We also found that while both stellate cell and endothelial SDC-1 KO promoted macrophage recruitment to the liver (increased F4/80 area), only stellate cell SDC-1 promoted the activation of macrophages to pro-inflammatory morphologies such as a hepatic crown structure (forming around a steatotic hepatocyte). **Conclusion:** Taken together, our data suggests that stellate cell SDC-1 plays a key role in stellate cell activation while directing macrophage recruitment and phenotype, though the mechanisms behind some of these effects are still under investigation.

1395 | CANCER-ASSOCIATED FIBROBLAST-DERIVED ADAMTS7 FACILITATES HEPATOCELLULAR CARCINOMA VIA STAT3/CD36 SIGNALING AXIS

Tian Tian[1] Liya Pi[1], [1]Tulane University School of Medicine

Background: Clinical and genomic evidence links the aberrant activation of ADAMTS7 to the progression of hepatocellular carcinoma (HCC). **Methods:** In mouse models, metalloproteinase ADAMTS7 is markedly upregulated under hepatic stress induced by a high-fat diet (HFD) combined with chronic ethanol exposure or HFD alone, exhibiting strong pro-tumorigenic effects. **Results:** Based on these findings, we successfully generated *ADAMTS7* knockout (KO) mice. *In vivo* functional assays demonstrated that KO of *ADAMTS7* not only dramatically suppressed HFD-induced stromal remodeling, substantially reducing orthotopic liver tumor volume and nodule counts, but also exerted a robust inhibitory effect on distant lung metastasis. In vivo, genetic ablation of ADAMTS7 significantly decreased the infiltration and activation of this of $CD36^{+}$ cancer-associated fibroblast (CAF) population via the suppression of the STAT3 signaling pathway, effectively alleviating the immunosuppressive tumor microenvironment (TME). This stromal reprogramming subsequently enhanced $CD8^{+}$ T cell infiltration and restored their effector function, which remarkably potentiated the efficacy of anti-PD1 (aPD1) immunotherapy. **Conclusion:** Together, our study elucidates a novel microenvironmental mechanism whereby ADAMTS7 drives HCC malignancy and pulmonary metastasis via the STAT3/CD36 axis, highlighting stromal ADAMTS7 as a promising therapeutic vulnerability to overcome immunotherapy resistance in advanced liver cancer.

1396 | SEX-SPECIFIC EFFECTS OF MYELOID SMPDL3B DEFICIENCY ON DIET-INDUCED MASH AND HEPATOCELLULAR CARCINOMA PROGRESSION

Shuxia Wang[1] Taesik Gwag[1] Alla Mitrofanova[2] Alissia Fornoni[2] Steven Weinman[3], [1]University of Kentucky, [2]University of Miami, [3]University of Kansas

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) has become the most common chronic liver disease worldwide. Macrophage activation plays a critical role in the progression from

simple steatosis to metabolic dysfunction-associated steatohepatitis (MASH) and hepatocellular carcinoma (HCC). SMPDL3B (sphingomyelin phosphodiesterase acid-like 3B) is a GPI-anchored membrane protein that negatively regulates Toll-like receptor signaling in macrophages. However, whether SMPDL3B contributes to MASH progression and HCC development has not been determined. In this study, we investigated the in vivo role of myeloid-specific SMPDL3B deficiency in diet-induced MASH and HCC development, with particular attention to sex-specific effects. **Methods:** Both human liver samples and mouse models of diet-induced MASH and HCC were utilized in this study. SMPDL3B expression was examined in normal, MASLD, and MASH human liver samples by qPCR and immunohistochemical staining. For animal studies, myeloid-specific SMPDL3B knockout mice were generated by crossing Smpdl3b floxed mice with LysM-Cre mice. Both male and female knockout and littermate control mice were fed an AMLN diet for 16 or 32 weeks to induce MASLD and MASH, respectively. To accelerate HCC development, mice additionally received CCl4 injections during AMLN feeding. Liver steatosis, inflammation, fibrosis, and tumor development were assessed by histological and molecular analyses. **Results:** SMPDL3B expression was significantly reduced in human MASH liver samples compared with normal controls. In mouse models, myeloid-specific SMPDL3B deletion had minimal effects on diet-induced MASLD or MASH progression in male mice, with similar levels of hepatic lipid accumulation, inflammation, and fibrosis observed between knockout and control groups. In contrast, female myeloid-specific SMPDL3B knockout mice exhibited significantly increased liver inflammation and fibrosis despite showing similar levels of hepatic lipid accumulation compared with female control mice. Furthermore, female knockout mice developed substantially more HCC nodules in the AMLN/CCl4-induced HCC model compared with female control mice. **Conclusion:** These findings identify SMPDL3B as a previously unrecognized sex-dependent regulator of MASH and HCC progression. Myeloid SMPDL3B deficiency selectively exacerbates hepatic inflammation, fibrosis, and HCC development in female mice, while having minimal effects in males. Our study highlights the importance of macrophage lipid signaling pathways in regulating liver disease progression and suggests that sex-specific immune mechanisms may contribute to differential susceptibility to MASH-associated HCC. Targeting SMPDL3B-related pathways may therefore represent a novel therapeutic strategy for inflammation-driven liver disease, particularly in females.

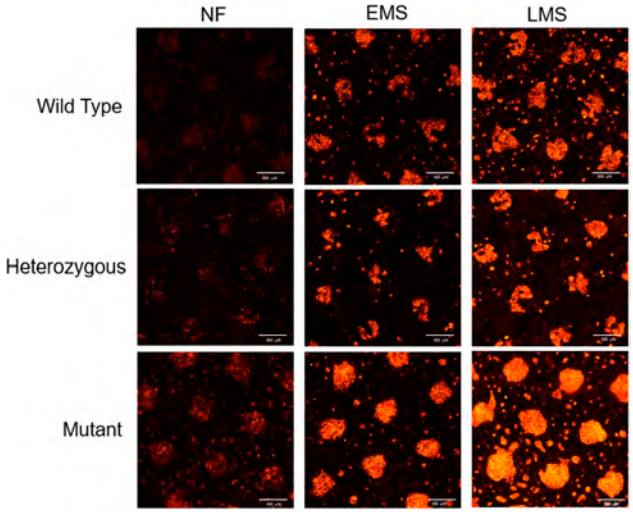
1397 | MODELING GENOTYPE-PHENOTYPE RELATIONSHIPS IN HUMAN MASLD USING A MICROPHYSIOLOGICAL SYSTEM



Nathan Shelton[1] Salman Khetani[2], [1]University of Illinois Chicago, [2]University of Illinois at Chicago

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) affects >30% of people worldwide. While MASLD development involves lifestyle factors, genetic susceptibility is increasingly recognized as a major contributor to disease onset and progression. However, the development of precision therapeutics for MASLD is hampered by a lack of physiologically relevant in vitro human models. To address this need, we utilized primary human hepatocytes (PHHs) genotyped for MASLD-associated variants in PNPLA3 rs738409 and GCKR rs1260326 to establish a model system for investigating genetic predisposition to disease and supporting preclinical therapeutic development. **Methods:** Commercially sourced PHH donors were genotyped for PNPLA3 rs738409 and GCKR rs1260326 using TaqMan SNP genotyping assays to select wild-type, heterozygous, and homozygous mutants. PHHs were then cultured in a well-established micropatterned co-culture (MPCC) model. Briefly, polydimethylsiloxane-based soft lithography was used to pattern collagen I into circular domains (500 μm diameter, 1200 μm spacing center-to-center) within multiwell plates. PHHs adhered to the collagen domains and were subsequently surrounded by stromal fibroblasts to stabilize functions for 3+ weeks. Cultures were then maintained in one of three different media: normal fasting (NF; 5 mM glucose, 500 pM insulin), early metabolic syndrome (EMS; 11 mM glucose, 500 μM fatty acid mixture, 10 nM insulin), or late metabolic syndrome (LMS; as EMS but with 22 mM glucose and 5 ng/mL TGF-β). Hepatic lipids were fluorescently stained with BODIPY, and metabolic-pathway genes were profiled by RT-qPCR. **Results:** The model reproduced human genetic risk in vitro. PHHs carrying risk variants showed greater lipid accumulation than wild-type controls across both EMS and LMS media perturbations, with the highest levels observed in homozygous mutant cells and increasing accumulation from NF to EMS to LMS media (Figure 1). Notably, heterozygous variants also displayed increased lipid accumulation compared to wild type, although to a lesser extent than homozygous risk variants, suggesting a genotype-dependent effect on steatotic burden. In addition to altered lipid accumulation, significant changes were observed in the expression of genes associated with lipid export, fatty acid oxidation, and broader metabolic dysregulation pathways; the direction and magnitude of these changes resolved how homozygous versus heterozygous

backgrounds reroute key pathways. **Conclusion:** Together, these findings establish a genetically stratified MASLD platform that captures gene-dose susceptibility and links genotype directly to mechanism in human cells. Ongoing work will map genotype-specific metabolic signatures and leverage the platform to test therapeutic responses across defined genetic backgrounds, positioning it as a tool for precision preclinical drug development.

1398 | IMEGLIMIN PROVIDES DUAL HEPATIC AND SKELETAL MUSCLE PROTECTION IN EXPERIMENTAL MASH-ASSOCIATED SARCOPENIA

Yui Osaki[1] Kosuke Kaji[1] Satoshi Iwai[1] Norihisa Nishimura[1] Hitoshi Yoshiji[1], [1]Nara Medical University

Background: Metabolic dysfunction-associated steatohepatitis (MASH), frequently complicated by sarcopenia, is partly driven by mitochondrial dysfunction and inflammatory catabolic signaling. The effects of imeglimin, an antidiabetic drug and mitochondrial modulator, against MASH-associated sarcopenia remain unclear. This study evaluated its effect on MASH-associated skeletal muscle atrophy in mice. **Methods:** MASH-associated sarcopenia was induced in mice using a choline-deficient, L-amino acid–defined high-fat diet. Imeglimin (200 mg/kg, b.i.d.) was administered for 6 weeks. Subsequently, muscle phenotype, mitochondrial function, and molecular signaling were assessed. Meanwhile, differentiated C2C12 myotubes were stimulated with interleukin-6 (IL-6). **Results:** Imeglimin alleviated steatohepatitis and restored mitochondrial regulators Ppargc1a and Tfam as well as hepatic and circulating insulin-like growth factor-1 levels. In skeletal muscle, imeglimin improved the psoas muscle index and grip strength; preserved the muscle fiber diameter; and reduced the expression of the atrogenes Fbxo32, Trim63, and Mstn. Mechanistically, imeglimin inhibited the nuclear localization of forkhead box O3 (FOXO3a), restored the phosphorylation of FOXO3a(Ser253), and reactivated AKT–mTOR signaling. Treatment reversed mitochondrial dysfunction, with increased complex I/IV activities alongside mitochondrial biogenesis. Moreover, imeglimin normalized autophagy–lysosome signaling by reducing p62 accumulation and normalizing Lamp2 expression. In C2C12 myotubes, imeglimin concentration-dependently reduced the IL-6–induced upregulation of Fbxo32 and Trim63, restored mitochondrial membrane potential, improved the oxygen consumption rate, and enhanced autophagic flux. **Conclusion:** Imeglimin exerts the protective effect on MASH-associated skeletal muscle atrophy by restoring mitochondrial homeostasis, suppressing FOXO3a-mediated proteolysis, and normalizing autophagy. These findings highlight the possibility of targeting mitochondria to treat MASH-associated sarcopenia.

1399 | DIFFERENTIAL STARD1-DEPENDENT MITOCHONDRIAL CHOLESTEROL-STRESS ADAPTATION PROGRAMS DRIVEN BY NRF2 AND FBP1 IN HCC SPHEROIDS

Fabian Arenas Rios[1] Yuanqing An[2] Susana Nuñez[1] Carmen Garcia-Ruiz[3] Jose Fernandez-Checa[4] Monica Barrios López[4], [1]Institute of Biomedical Research of Barcelona (IIBB) - CSIC, [2]Institute of Biomedical Research of Barcelona (IIBB)-CSIC, [3]Spanish National Research Council, [4]Institute of Biomedical Research of Barcelona

Background: Hepatocellular carcinoma (HCC) progression is strongly influenced by metabolic reprogramming and tumor-stroma interactions. The outer mitochondrial membrane resident protein STARD1 promotes mitochondrial cholesterol (mitChol) trafficking to the inner membrane and may influence metabolic adaptation and generation of oxysterols and primary bile acids (BA), including 27-hydroxycholesterol (27-HC) and chenodeoxycholic acid, respectively. Similarly, SAB is a mitochondrial outer membrane scaffold protein that amplifies stress

signaling, ROS production, and JNK activation. In addition, NRF2 is a master regulator of antioxidant/stress responses, whereas FBP1 is a gluconeogenic enzyme with tumor suppressor functions linked to metabolic restraint. We investigated how NRF2 and FBP1 modulate mitochondrial cholesterol handling, oxidative stress, and endoplasmic reticulum (ER) stress in 3D HCC spheroids. **Methods:** The HCC cell line HuH7 and the hepatic stellate LX2 cells were cultured under standard conditions. Stable HuH7-NRF2 and HuH7-FBP1 lines were generated by lentiviral transduction and puromycin selection. STARD1 and SAB knockdown models were generated by CRISPR lentiviral sgRNAs and GFP-based sorting. HCC spheroids (sph) were formed in 96-well ultra-low-attachment plates with or without LX2 cells, cultured for 5 days, and exposed to tunicamycin (Tn,10 µg/ml) during the last 24h. HCC-sph (10 sph/condition) were analyzed by 27-HC ELISA, RNA extraction, histology, and Seahorse XF analyses. **Results:** NRF2-sph showed increased STARD1 and SAB expression, higher mitChol, a stronger stress-responsive phenotype, and an imbalance of Tn-associated 27-HC levels. In contrast, FBP1-sph dysplayed a more heterogeneous profile, with partial suppression of basal ER stress markers, and stromal-sensitive changes in redox state, proliferation and stress-response genes. NRF2-sph showed enhanced GRP94 induction and TP53 responsiveness under ER stress, whereas FBP1-sph exhibited attenuated UPR activation. LX2 co-culture reduced oxidative stress in NRF2-sph and altered proliferation and stress markers in both models. Seahorse XF analysis suggests distinct metabolic adaptations, with NRF2-sph favoring glycolytic flexibility, while FBP1-sph retained a comparatively balanced energetic profile. STARD1 knockdown reduced mitChol loading, decreased 27-HC generation, and attenuated DHE/Ki67-associated phenotypes, particularly in NRF2 cells. SAB knockdown reduced ROS amplification and attenuated Tn-induced ER stress responses. **Conclusion:** These findings support that NRF2 and FBP1 differentially regulate mitochondrial stress adaptation and metabolic plasticity in HCC-sph, including microenvironment-dependent adaptation. Targeting STARD1/SAB-dependent pathways may represent a potential strategy to modulate ER stress tolerance and tumor-stromal adaptation in HCC.

1400 | LAMTOR1 LACTYLATION MEDIATES MECHANICAL FORCE-INDUCED MACROPHAGE EXTRACELLULAR TRAPS FORMATION AND LIVER FIBROSIS IN MASLD VIA MTORC1 SIGNALING

Jia-Shen Wu[1], [1]Dept. of Gastroenterology & Hepatology, Zhongshan Hospital

Background: Mechanical force acts as an emerging immunomodulator reshaping macrophage function in metabolic dysfunction-associated steatotic liver disease (MASLD), exacerbating liver fibrosis by perturbing hepatic regional immunity (HRI). Since mammalian target of rapamycin complex 1 (mTORC1) activation drives glycolytic reprogramming and lactic acid accumulation, this study investigates whether mechanical signals promote MASLD progression by driving macrophage extracellular traps (METs) formation via protein lactylation modification. **Methods:** Molecular targets were screened using single-cell transcriptomic analysis of liver tissues from MASLD mice. THP-1 cell models were established under conditions of (1) varying substrate stiffness, (2) mechanical force contact, and (3) high lactate exposure. Subsequently, immunofluorescence, co-immunoprecipitation, Western blotting, and qRT-PCR were employed to analyze mTORC1 signaling activation, lysosomal damage, and METs formation. **Results:** (1) Single-cell transcriptomic analysis of liver tissues from MASLD mice revealed increased mTORC1 signaling activation and glycolysis in macrophages, with significant enrichment of lysosomal damage and integrin signaling pathways. (2) Stiff substrates and increased mechanical force promoted mTORC1 signaling activation and lactic acid accumulation in THP-1 cells, inducing lysosomal damage and METs release; these effects were attenuated by integrin α4 knockout, but not PIEZO1 knockout. (3) Single-cell screening identified LAMTOR1 as a potential macrophage target. LAMTOR1 was downregulated in L-Leucyl-L-Leucine methyl ester hydrobromide (LLOMe)-induced lysosomal damage models, and inhibition of mTORC1 signaling with Torin 1 exacerbated this downregulation and promoted METs release. (4) In THP-1 cells cultured on stiff substrates or high lactate exposure, LAMTOR1 was downregulated and underwent lactylation modification. Inhibition of glycolysis with 2-DG reversed these effects and reduced METs release. **Conclusion:** This study elucidates that mechanical force triggers METs via integrin-mediated LAMTOR1 lactylation. We demonstrated that targeting this axis effectively blocks METs release and restores HRI homeostasis, providing a novel mechano-immunomodulatory strategy for the treatment of MASLD-associated liver fibrosis.

1401 | SEX DIFFERENCES IN EARLY MASH

Noah Wallace[1], [1]University of Memphis

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is currently the most common chronic liver disease affecting 38% of the global adult population. If left untreated, it has the potential to progress to the more severe form of MASLD called Metabolic dysfunction-associated steatohepatitis (MASH). MASH is characterized by not only steatosis, but also inflammation. MASH can eventually lead to fibrosis, cirrhosis, and/or hepatocellular carcinoma. It is well known that sexual dimorphism exists in the prevalence of various metabolic disorders including MASLD and MASH; however, few mouse studies utilize both male and female mice. Furthermore, investigate the effects of either a high fat (HF) or high sugar (HS) diet as separate components. This study aimed to investigate both. **Methods:** 30 male and female C57bl/6 mice were used for the study. Mice were placed on either control (CON), HF, or HS diets after one week of acclimation for 12 weeks. Bodyweight was measured during the duration of the study along with body composition using ECHO MRI. At sacrifice, portions of liver were frozen in liquid nitrogen or fixed in formalin. Masson's Trichrome stain was used to visualize liver fibrosis. F4/80 immunohistochemistry was used to investigate macrophage infiltration in the liver. qPCR was used to analyze gene expression of inflammatory and fibrotic genes associated with MASH. All data is represented as means ± SEM. Two-way ANOVA was used to investigate diet and sex while a three-way ANOVA was used for diet, sex, and time. GraphPad Prism 8 software was used for all statistical analysis with Tukey post hoc analysis used to examine interactions. Significance was set a $p \leq 0.05$. **Results:** Males on the HF diet showed significantly higher bodyweight than all groups. Males on a HF diet had a 45.36% increase in body weight compared to females on a HF diet gaining only n32.55%. Males on a CON and HS diet showed greater bodyweights when compared to female CON and HS. Males on a HF diet at the end of the study showed the greatest fat percentage when compared to all other groups with an average of 34.54%. While males on the HF diet exhibited some fibrosis, male on the HS diet showed the greatest amount. Males on the HS diet also had the greatest macrophage infiltration with the F4/80 stain. Females on both HF and HS diets did not show fibrosis; however, HF females did show some macrophage infiltration, but not the extend of the Male HS. Main effects of sex and diet and sex was shown for *Cd68* and *Tnf*α, respectively. **Conclusion:** The current study showed after 12 weeks of being on a HF or HS diet, male mice showed the presence of hepatic fibrosis and inflammatory infiltration. While female mice lacked fibrosis, a HS diet did induce macrophage infiltration. Future studies will need to consider duration of diet as well as the effects of young, healthy female mice on study outcomes when investigating diet induced MASH/ **Disclosures:** Noah Wallace:Nothing to Disclose.

1402 | CELL TYPE- AND ZONAL-SPECIFIC HEPATIC EXPRESSION OF THE ISC ASSEMBLY FACTOR *CCDC117*

Isaac Park[1] Kyu-Ho Lee[1] Matthew Savoca[1] John Lemasters[1] Don Rockey[1], [1]Medical University of South Carolina

Background: Coiled-coil domain containing 117 (*Ccdc117*) is part of a cytoplasmic iron-sulfur cluster (FeS) transfer complex that transfers FeS to enzymes critical for cell function. While its function in liver has yet to be defined, its potential modulation by microRNA populations has been previously in a rodent model of alcoholic steatohepatitis (ASH). In order to gain insight into the potential role of Ccdc117 in the liver, we examined the cell-type and spatial distribution of Ccdc117 expression in the liver. **Methods:** *Ccdc117* mRNA expression was determined by qRT-PCR in primary isolates of hepatocytes, Kupffer cells, endothelial cells, and quiescent and activated stellate cells isolated from wild-type C57BL/6 mice. Histological distribution of Ccdc117 protein expression in mouse liver was determined by immunohistochemistry (IHC) and its localization relative to expression of the pericentral marker, glutamine synthase, and to periportal MitoTracker Red staining. Subcellular localization of Ccdc117 under normal and nutrient-deprivation conditions was determined by super-resolution confocal microscopy of HepG2 hepatoma, mouse and human primary cells following vital staining with PK Mito Orange mitochondrial membrane dye and immunostaining for TOMM20A and further quantified by immunoblotting of different cellular compartments **Results:** qPCR analysis revealed that hepatocytes exhibited by far the greatest basal expression of Ccdc117 relative to that of other liver cell types. IHC microscopy and zonal studies revealed that Ccdc117 expression was distinctly enriched in pericentral hepatocytes. In HepG2 cells and primary hepatocytes, Ccdc117 was localized to nuclear, cytosolic and mitochondrial compartments. In hepatocyte mitochondria, Ccdc117 was found to be localized both on the inner and outer mitochondrial membrane compartments. Following nutrient deprivation via incubation with Krebs-Ringers Hepes (KRH) medium, which leads to mitophagy, enhanced Ccdc117 immunofluorescence signal was observed in mitochondria. Further, in HepG2 cells, following incubation with KRH medium, immunoblotting of subcellular fractions revealed increased mitochondrial localization of

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Ccdc117. **Conclusion:** The data suggest that the expression pattern of Ccdc117 in the liver is consistent with a role in the hepatocyte response to metabolic signaling and/or regulation. The shift in Ccdc117 localization to mitochondria induced by nutrient deprivation, while also being consistent with a role in modulation of mitochondrial metabolic function, may indicate a role in autophagic, mitophagic and/or mitochondrial quality control pathways.

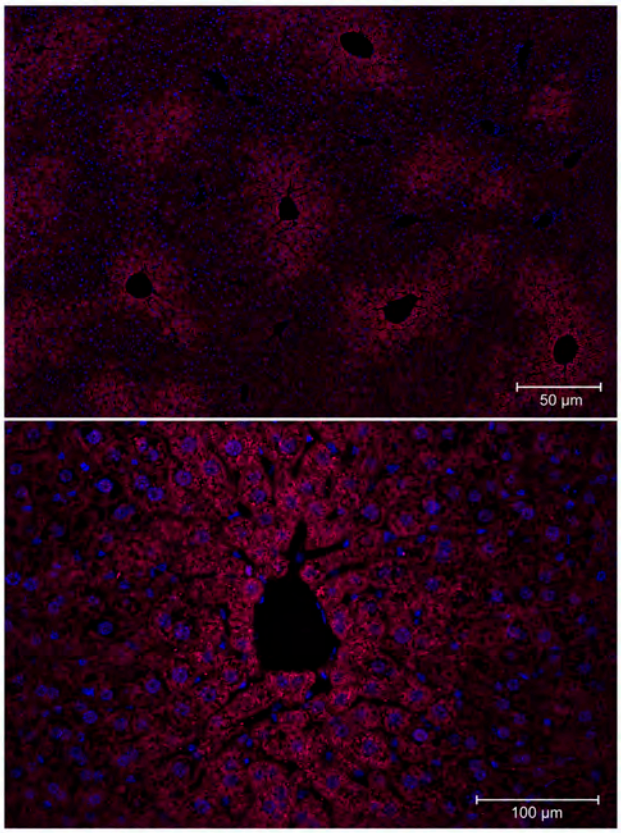

Figure 1. IF of functional liver lobule showing pronounced Ccdc117 expression (**pink**) in zone 3, vs. zones 1 & 2 Hoechst staining (**blue**) marks cell nuclei. Top panel, low magnification; bottom panel, high magnification.

★ 1403 | ASSOCIATION OF LOW VITAMIN D LEVELS WITH NON-ALCOHOLIC FATTY LIVER DISEASE IN LEAN INDIVIDUALS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Raja Khan[1] Nasir Hasan Luck[2] Abbas Ali Tasneem[2] Zain Majid[2] Syed Mudassir Laeeq[3], [1]Bahrain Specialist hospital, [2]Sindh Institute of Urology and Transplantation, [3]Khamis Mushait armed forces Hospital

Background: Non-alcoholic fatty liver disease (NAFLD) is a growing global health concern, affecting approximately 25% of the global population. While traditionally linked to obesity and metabolic syndrome, NAFLD is increasingly recognized in individuals with normal body mass index (BMI), termed 'lean NAFLD.' Identifying risk factors for lean NAFLD is vital, as these individuals often escape routine screening yet may still progress to advanced liver disease. Vitamin D, known for its immunomodulatory and anti-inflammatory effects, has been implicated in liver metabolism and fibrogenesis. Several observational studies have suggested a link between low serum vitamin D levels and NAFLD, but its association in the lean population remains underexplored. This meta-analysis aims to systematically assess the relationship between serum vitamin D levels and NAFLD in lean individuals. **Methods:** A comprehensive literature search was conducted using PubMed, Semantic Scholar, and Google Scholar from January 2002 to May 2025. A total of 276 studies were initially identified. After screening and eligibility assessment, 7 studies were included in the final analysis. Study designs included observational, cross-sectional, and cohort studies. The total number of patients across all studies was 258,354. The effect size was measured using both odds ratios (OR) with 95% confidence intervals (CI) and mean differences in serum vitamin D levels between NAFLD and non-NAFLD lean individuals. A random-effects model was applied to account for between-study heterogeneity. Statistical heterogeneity was assessed using the I^2 statistic, and publication bias was evaluated using funnel plots. **Results:** The pooled analysis demonstrated a significant association between low vitamin D levels and the presence of NAFLD in lean individuals. The mean difference in serum vitamin D levels between lean NAFLD and non-NAFLD groups was −4.28 ng/mL (95% CI: −6.52 to −2.04, $p < 0.001$), indicating significantly lower levels in NAFLD patients. The odds ratio for vitamin D deficiency (< 20 ng/mL) being associated with NAFLD was 1.47 (95% CI: 1.22–1.77). Substantial heterogeneity was observed among studies (I^2 = 91%), which could be attributed to differences in geographic regions, population demographics, and diagnostic thresholds. Funnel plot inspection suggested minimal publication bias. **Conclusion:** This meta-analysis indicates a significant association between low serum vitamin D levels and the risk of non-alcoholic fatty liver disease in lean individuals. Given the emerging prevalence of lean NAFLD and its potential progression to more severe liver diseases, screening for vitamin D deficiency may serve as a valuable adjunct in identifying at-risk individuals. Further prospective studies are warranted

1404 | A NEW FULLY AUTOMATED 3D LIVER ELASTOGRAPHY WORKFLOW IN MICE WITH SINGLE-CLICK ACQUISITION AND ANALYSIS

Thomas Kierski[1] Joseph Betthauser[1] Adam Aji[1] Juan Rojas[1] Ryan Gessner[1] Tomek Czernuszewicz[1], [1]Revvity, Inc.

Background: High-throughput ultrasound platforms such as Vega enable rapid longitudinal assessment of liver disease in preclinical models using shear wave elastography (SWE). However, SWE acquisition and analysis remain multi-step, requiring manual liver localization, region-of-interest (ROI) placement, and post hoc annotation. This study develops and evaluates a fully automated workflow combining AI-based liver localization with a robotic enabled agent-driven acquisition and analysis framework for single-click 3D elastography. **Methods:** A conventional workflow (scout B-mode, manual ROI placement, SWE acquisition, offline analysis) was replaced with a Python-based pipeline. An AI segmentation model identifies the liver from 3D scout scans and generates an organ mask to guide downstream actions. A modified U-Net was trained to delineate liver boundaries from 3D ultrasound datasets (training/validation/test: 536/72/108). Because high-resolution models did not generalize to lower-resolution SWE-paired B-mode images, a second model was developed. Training data were generated by down-sampling high-resolution scans and cropping to match SWE ROIs. An AI agent orchestrates the workflow by selecting optimal ROIs from scout segmentation, triggering acquisition, and refining segmentation on SWE data to compute stiffness metrics in 3D. The process can be executed with a single click or via natural language command. **Results:** The system reduced SWE acquisition and analysis to a single user interaction, enabling operators to prepare subsequent animals during scanning. Segmentation performance remained robust across imaging contexts. On held-out datasets, the high-resolution model achieved a Dice coefficient of 0.87 (R^2 = 0.93), while the SWE-paired model achieved 0.85 (R^2 = 0.96). The full workflow completes in < 4 minutes, including ~30 seconds for scout acquisition, 1-2 seconds each for localization and ROI selection, and ~3 minutes for 3D SWE across entire liver. A higher throughput 2D workflow can be completed in ~35 seconds if users wish to trade off comprehensive organ coverage for speed. **Conclusion:** This work demonstrates the feasibility of a fully automated, AI-driven workflow for 3D liver SWE acquisition and analysis in mice. By combining segmentation models tailored to specific imaging contexts with an agent-based orchestration framework, this approach reduces operator burden, improves reproducibility, and increases throughput. This capability has the potential to accelerate preclinical liver research and enable scalable longitudinal imaging studies.

1405 | HEPATIC THR-β EXPRESSION ACROSS FIBROSIS STAGES AND NAS SCORES IN MASLD/MASH: IMPLICATIONS FOR THR-β–TARGETED THERAPY

Esteban Arroyave[1] Omar Saldarriaga[1] Kellen Henning[1] Monique Ferguson[1] Deena Kapadia[2] Israa Ali[1] Michael Kueht[1] Heather Stevenson-Lerner[1], [1]University of Texas Medical Branch, [2]Asst Professor Clin Practice

Background: Thyroid hormone receptor beta (THR-β) is a key regulator of hepatic lipid metabolism and the therapeutic target of resmetirom, the first FDA-approved therapy for noncirrhotic metabolic dysfunction-associated steatohepatitis (MASH). Emerging transcriptomic studies suggest that hepatic THRB expression and transcriptional activity decline with fibrosis progression and are associated with adverse clinical outcomes. However, most evidence is derived from RNA-based studies, and protein-level characterization of THR-β across clinically relevant stages of MASLD/MASH remains limited. **Methods:** Archived liver biopsies from patients with MASLD/MASH representing distinct fibrosis stages and NAFLD Activity Scores (NAS) were analyzed using automated immunohistochemistry and multiplex immunofluorescence. THR-β protein expression was assessed using a validated anti-THR-β antibody (NR1A2; Novus Biologicals) on the Ventana platform (Roche Diagnostics) with OPAL 570 detection. Whole-slide multispectral imaging and fluorescence microscopy (Vectra 3, Akoya Biosystems) were used to evaluate THR-β staining patterns. Representative cases included patients with minimal fibrosis (F1/4, NAS 5/8) and advanced fibrosis (F4/4, NAS 5/8). **Results:** THR-β protein was detected predominantly in hepatocytes and demonstrated heterogeneous expression across fibrosis stages. Liver tissue with minimal fibrosis exhibited focal and less

extensive THR-β staining, whereas advanced fibrotic tissue displayed broader and more heterogeneous immunoreactivity. Differences in staining intensity and distribution were observed despite similar NAS scores, suggesting that fibrosis-associated changes may influence THR-β expression independently of histologic disease activity. The proposed workflow generated robust and reproducible signal with appropriate cellular localization, supporting its utility for systematic THR-β assessment in archived liver tissue. **Conclusion:** Hepatic THR-β expression exhibits substantial heterogeneity across fibrosis stages in MASLD/MASH. These preliminary findings support the concept that THR-β signaling varies across clinically relevant disease phenotypes and may contribute to disease heterogeneity. Reliable quantification of THR-β protein in routine liver biopsies provides a clinically scalable approach for evaluating this pathway and may support future biomarker-driven patient stratification for THR-β–targeted therapies.

1406 | LA-RELATED PROTEIN 1 (LARP1) AS A DRIVER OF METABOLIC DYSFUNCTION–ASSOCIATED STEATOTIC LIVER DISEASE

Komal Ramani[1] Chandana Thimme Gowda[1] sonal sinha[1] Mario Alba[1] Jose Mato[2] Shelly Lu[1], [1]Cedars-Sinai Medical Center, [2]CICBiogune

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) can progress from steatosis to MASH and hepatocellular carcinoma (HCC). Methionine adenosyltransferase 1A (*MAT1A*, encodes for MATα1) is responsible for the biosynthesis of S-adenosylmethionine (SAMe) in normal liver and its expression is reduced in human MASLD and HCC. Consistently, *Mat1a* knockout (KO) mice spontaneously develop MASH and HCC and their liver proteomics showed disruptions in mitochondrial, peroxisomal, and translational pathways. The translational regulator, La-related protein 1, LARP1, which binds 5′-terminal oligopyrimidine (TOP) mRNAs, was induced and hyperphosphorylated at T503/S471 (human T449/S471) in *Mat1a* KO, and reversed by SAMe treatment. We assessed the global effects of LARP1 on mRNA translation and expression in SAMe deficient systems and observed that apart from TOP mRNAs, LARP1 influenced non-TOP mRNAs involved in metabolic regulation. We hypothesize that LARP1 drives MASLD by reprogramming non TOP mRNAs and seek to define this axis in disease progression. **Methods:** Actively translated non-TOP mRNAs from LARP1-overexpressing Huh7 cells were detected by RNA seq. Bulk RNA seq detected non-TOP mRNA expression in advanced MASH *Mat1a* KOs with or without *Larp1* silencing (si*Larp1*). Liver steatosis, inflammation, and fibrosis were evaluated by BODIPY, F4/80, and Sirius Red staining. mRNA stability was assessed by actinomycin D chase assays. Metabolite alterations were identified by untargeted metabolomics of the liver. **Results:** LARP1 elevation in de-differentiated primary hepatocytes, diet induced MASH models and in human MASLD was associated with a fall in MATα1. S/T to A mutants of LARP1's SAMe sensitive phospho-sites destabilized the protein in SAMe-deficient cell lines. Beyond canonical TOP mRNAs, LARP1 altered numerous non TOP transcripts involved in hepatic metabolism, including *SIRT5* (peroxisomal β oxidation, PBO), *c-MYC* (aerobic glycolysis), and mitochondrial ribosomal proteins involved in oxidative phosphorylation or OXPHOS (*MRPL13*, *MRPL50*, *MRPL59*). CRISPR deletion of *Larp1* in Mat1a KOs normalized these transcripts and the metabolite profiles associated with these pathways, markedly reducing lipid accumulation, inflammation, and fibrosis. Conversely, LARP1 activation (via increased expression or phosphorylation) in normal liver and primary human hepatocytes increased lipid deposition and impaired mitochondrial respiration. Under SAMe deficiency, LARP1 destabilized *SIRT5* and *MRPLs* while stabilizing *c-MYC*; SAMe treatment reversed these effects. **Conclusion:** Our study reveals a previously unrecognized role for LARP1 activation as a driver of MASLD progression through perturbations in mRNA stability of its targets, disrupting hepatic metabolic homeostasis. Targeting LARP1 activation may offer a novel therapeutic strategy for MASLD.

Background: Prenatal and early environmental exposures enhance susceptibility to metabolic disease in later life. Polychlorinated biphenyls (PCBs) act as metabolism disrupting chemicals (MDCs) to promote metabolic dysfunction-associated steatotic liver disease (MASLD) in humans. Post-transcriptional chemical modification of mRNA regulates transcript stability, splicing, and translation. PCB-exposure in combination with a high fat diet (HFD) induced MASLD and progression to metabolic-associated steatohepatitis (MASH) in male mice and resulted in N-6-methyladenosine (m6A) mRNA modifications in differentially expressed genes (DEG) in pathways of MASLD pathogenesis. With the goal of using a tractable system to edit m6A sites in MASLD-related genes regulated by PCB exposure, we examined the impact of PCB exposure on m6A-modified DEG expression in two mouse hepatocyte cell lines. **Methods:** We evaluated the protein abundance of m6A writers, readers, and erasers in FL38B fetal and AML12 adult mouse hepatocyte cell lines by western blot. We compared the response of palmitic acid (as a HFD mimetic)-treated FL38B and AML12 mouse hepatocytes to vehicle control or after exposure to combined Aroclor1260 + PCB126. Integration of short-read Illumina RNA-seq and Nanopore direct long read RNA seq (DRS) identified DEG with site-specific m6A modifications. **Results:** The abundance of m6A writer proteins METTL3 and METTL14 was higher in FL83B whereas METLL16 and the m6A eraser proteins FTO and ALKBH5 were higher in AML12 cells. Cell-specific differences in the levels of specific m6A readers including IGF2BP2, YDHDC1, and YDHDC2 were observed. More DEG correlated with m6A-alterations were found in PCB-exposed FL83B (1,863, including Apob, Gstm2, Cpt1a, Hnf4a, Krt18, and Pparg) than AML12 (54, including Gsr and Gclc) cells. PCB exposure decreased Srebf1 in both cell lines. **Conclusion:** These data suggest that fetal liver may be more susceptible to PCB exposure-induced m6A alteration and downstream pathway changes associated with MASLD and its progression to MASH.

1408 | AWARENESS OF LIVER DISEASE TERMS BY SOURCES OF INFORMATION

Trenton White[1] Leire Agirre-Garrido[1] Lila Neal[1] Sonal Kumar[2] Melina Manolas[3] Scott Isaacs[4] Jeffrey Lazarus[5], [1]Barcelona Institute for Global Health (ISGlobal), [2]Department of Medicine, Division of Gastroenterology and Hepatology, Weill Cornell Medicine, [3]Weill Cornell, [4]Emory University School of Medicine, [5]City University of New York Graduate School of Public Health (CUNY SPH)

Background: Public awareness of liver disease remains limited, particularly as terminology evolves from widely recognised terms such as fatty liver disease to newer clinical nomenclature including MASLD and MASH. Understanding how familiarity with these terms relates to where individuals perceive they obtain valuable health information is important for informing effective communication strategies. This study therefore examines the association between self-reported health-information sources and awareness of key liver disease terms. **Methods:** We conducted a survey of n = 3,010 US adults using a stratified sampling frame on gender, age, race, and education according to the 2023 American Community Survey distributions. Weighting yielded n = 1,000 respondents who are living with obesity (BMI > 30) or diagnosed with diabetes. We examined the distribution of term awareness by information sources and applied chi-square tests to determine the strength of association between distributions. **Results:** Across the tested terms, there is a positive correlation between being familiar with the term and learning health information of value from any sources. Similarly, among those being unfamiliar with the terms, they tend not to have learned health information of value from any source. **Conclusion:** Familiarity with liver disease terminology varied substantially, with broader recognition of terms such as fatty liver disease and liver cirrhosis and much lower familiarity with newer terms such as MASLD and MASH. Respondents who reported learning valuable health information from sources such as healthcare providers, the internet, social media, and friends or family differed significantly in their familiarity with these terms. Public health practitioners should use clear, consistent terminology across trusted health-information channels and develop messaging that bridges familiar language with newer clinical terms.

1409 | LOBEGLITAZONE COMBINED WITH HGF ATTENUATES FFA-INDUCED HEPATIC STEATOSIS VIA COORDINATED AMPK–PPARα–PGC1α AXIS ACTIVATION IN HEPG2 CELLS

Yun Bin Lee[1] Se-Mi Jung[1] Jeayeon Park[2], [1]Seoul National University College of Medicine, [2]Ajou University School of Medicine

Background: Lobeglitazone, a dual peroxisome proliferator-activated receptor α/γ (PPARα/γ) agonist, improves metabolic parameters; however, its therapeutic role in hepatic steatosis remains incompletely characterized. Hepatocyte growth factor (HGF) regulates liver protection and lipid homeostasis through c-MET–AMPK signaling. We investigated the effects of lobeglitazone alone and in combination with HGF on free fatty acid (FFA)–induced hepatic steatosis in HepG2 cells and explored the underlying mechanisms. **Methods:** HepG2 cells were exposed to FFAs to induce intracellular lipid accumulation and subsequently treated with lobeglitazone, HGF, or their combination. Lipid accumulation was evaluated by Oil Red O staining. Mitochondrial function was assessed using mitochondrial DNA quantification and MitoTracker staining. Expression of genes and proteins involved in lipid metabolism and mitochondrial regulation was analyzed using quantitative real-time polymerase chain reaction and Western blotting. Oxidative stress and antioxidant capacity were evaluated by measuring intracellular reactive oxygen species (ROS), superoxide dismutase (SOD) activity, glutathione redox balance, and intracellular ATP levels. **Results:** Lobeglitazone treatment significantly reduced intracellular lipid accumulation in FFA-treated HepG2 cells, and this effect was further enhanced by co-treatment with HGF (Figure 1A). HGF co-treatment more effectively restored mitochondrial DNA content and mitochondrial integrity than either treatment alone (Figure 1B). At the molecular level, lobeglitazone treatment restored expression of PPARα, PGC1α, and CPT1A while attenuating FFA-induced upregulation of PPARγ, and these effects were further enhanced by co-treatment with HGF (Figure 1C). HGF significantly increased AMPK phosphorylation, and this effect was further amplified by lobeglitazone co-treatment. Combined treatment also more substantially improved redox homeostasis, reflected by lower ROS levels, enhanced SOD activity, higher GSH/GSSG ratio, and increased intracellular ATP compared with either monotherapy (Figure 1D). **Conclusion:** Lobeglitazone attenuated FFA-induced intracellular lipid accumulation and mitochondrial dysfunction in steatotic hepatocytes, and these effects were further enhanced by co-treatment with HGF. Combined treatment was associated with coordinated activation of the AMPK–PPARα–PGC1α axis and restoration of redox balance, suggesting a potential synergistic effect on hepatocellular lipid metabolism under lipotoxic conditions.

1410 | SEX DIFFERENCES IN MASH PROGRESSION ARE UNDERPINNED BY DIVERGENT HEPATIC PROTEOMIC SIGNATURES IN THE GAN DIO MOUSE MODEL

Isabella Simon[1] Samantha Emery-Corbin[2] Timothy Fitchett[2] Alannah Hunt[3] Avik Majumdar[4] Robert Widdop[2] Mark Del Borgo[2], [1]Monash Unviersity, [2]Monash University, [3]Monash Univeristy, [4]Austin Hospital

Background: MASH is the progressive and inflammatory form of steatotic liver disease. Premenopausal women exhibit lower MASH risk than men, but this protection is lost following menopause and underlying mechanisms remain poorly understood with preclinical research remaining predominantly male-biased. This study characterised sex-divergent proteomic and histological MASH trajectories in the GAN DIO mouse model. **Methods:** Male and female C57BL/6J mice were fed Gubra Amylin NASH (GAN) diet or chow for 26 or 40 weeks. Histopathology was assessed by MASH CRN scoring; fibrosis was quantified by picrosirius red staining and SHG imaging. Hepatic proteomes were characterised by DIA-MS on an Orbitrap Astral, processed in Spectronaut (v20.4) against the UniProt mouse proteome; differentially expressed proteins (DEPs) were defined at p.adj < 0.05 and $\log_2$FC ≥ 1. GO enrichment used clusterProfiler (v4.14.6) against 8,769 detected proteins (p.adj < 0.05, q < 0.2). **Results:** Histologically, 100% of males met MASH criteria (NAS ≥ 5) by 26 weeks with clinically significant fibrosis in all animals, versus 40% of females; consistent female MASH was not established until 40 weeks. Females showed lower NAS from 12 weeks, with reduced inflammation, ballooning, and collagen deposition (p < 0.05). By 40 weeks, all males reached F3-4 fibrosis versus 28% of females (p < 0.05). GAN diet induced 663 DEPs in males versus 145 in females at 26 weeks, expanding to 753 versus 205 at 40 weeks. Male GO enrichment at 26 weeks was dominated by ECM upregulation (collagen-containing ECM: 79 proteins; p.adj = 1.3×10^{-27}), innate immune activation (inflammatory response: 97 proteins; p.adj = 1.4×10^{-19}), and pro-inflammatory arachidonate metabolism via Cyp4a12b. Females demonstrated enrichment of anti-inflammatory EET biosynthesis, fatty acid oxidation, and estrogen receptor signalling, consistent with hepatoprotection. By 40 weeks, male ECM remodelling intensified (94 proteins; p.adj = 3.7×10^{-36}) with CYP450 suppression (arachidonate monooxygenase: FE = 28.4; p.adj = 9.8×10^{-13}). Females acquired a male-like immune-inflammatory signature (immune effector process: 40 proteins; p.adj = 5.1×10^{-14}) alongside downregulation of estrogen 16α-hydroxylase (FE = 62.1; p.adj = 2.8×10^{-7}) and arachidonate monooxygenase (FE = 32.8; p.adj = 5.0×10^{-7}). **Conclusion:** Males exhibit early ECM remodelling, innate immune activation, and pro-inflammatory arachidonate metabolism consistent with accelerated liver fibrosis. Females are protected by EET biosynthetic pathways, lipid oxidation, and estrogen signalling, but acquire a male-like inflammatory proteome by 40 weeks, providing a molecular basis for histological convergence. These findings identify CYP450-mediated eicosanoid and estrogen metabolism as critical checkpoints in sex-specific MASH pathogenesis, supporting inclusion of female cohorts across the full disease time-course in preclinical studies.

1411 | DISRUPTED MITOCHONDRIAL COPPER HOMEOSTASIS PROMOTES FERROPTOTIC STRESS, HEPATOCYTE SENESCENCE AND MASLD PROGRESSION

Kuo Du[1] Niansheng Ren[2] Liuyang Wang[2] Rajesh Dutta[2] David Umbaugh[2] Qiaojuan Zhang[1] Seh-Hoon Oh[3] Dennis Ko[2] Ming Song[4] Anna Mae Diehl[3], [1]University of Kansas Medical Center, [2]Duke University, [3]Duke University, [4]University of Louisville

Background: Systemic metabolic dysfunction promotes degenerative diseases in many organs, including liver and kidney. The liver is a master regulator of systemic metal ion homeostasis. Hepatic copper deficiency is increasingly observed in metabolic dysfunction associated steatotic liver disease (MASLD) and is associated with greater disease severity and poor outcomes. However, mechanisms linking copper dysregulation to MASLD and its comorbidities remain poorly defined. We investigated whether impaired mitochondrial copper homeostasis contributes to MASLD-related pathobiology and represents a modifiable therapeutic axis. **Methods:** We employed dietary mouse models of MASLD, in vitro hepatocyte systems, and integrated analyses of human transcriptomic cohorts to investigate the role of mitochondrial copper in disease progression and systemic outcomes **Results:** Using dietary mouse models of MASLD and *in vitro* systems, we found that dietary copper deficiency induces lipotoxicity and suppresses mitochondrial metabolic programs. MASLD livers exhibited marked depletion of copper, impaired cytochrome c oxidase integrity, and bioenergetic failure. Targeted restoration of mitochondrial copper with the copper ionophore normalized copper-handling programs, improved mitochondrial function, and suppressed ferroptotic stress, hepatocyte senescence, and fibroinflammatory remodeling. Mechanistically, reduced expression of the mitochondrial copper transporter *SLC25A3* and *MT-CO1* disrupted the SLC25A3–SCO1–MT-CO1–CTR1 axis, limited copper uptake and destabilized copper-iron balance, promoting maladaptive cell fate changes. Across multiple human cohorts and mouse models, copper-iron imbalance tracks with MASLD progression, clinical outcomes, and multiple extrahepatic comorbidities; restoring copper homeostasis in mice with MASLD attenuates both liver and kidney inflammation and fibrosis. **Conclusion:** Mitochondrial copper deficiency is a mechanistically actionable driver of MASLD that promotes bioenergetic failure, ferroptosis, senescence and fibroinflammatory damage in the liver and other organs. Targeting copper-centered mitochondrial regulation represents a novel biomarker and therapeutic strategy for MASLD and its systemic complications.

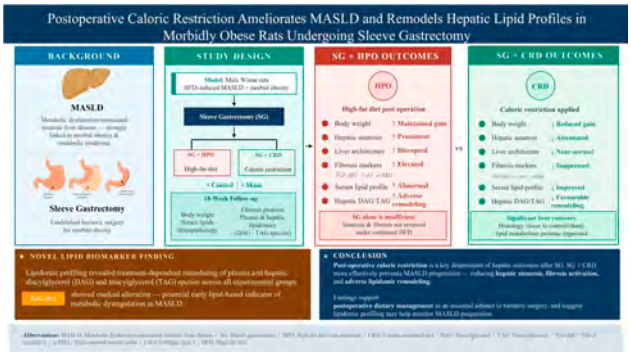
1412 | POSTOPERATIVE CALORIC RESTRICTION AMELIORATES MASLD AND REMODELS HEPATIC LIPID PROFILES IN MORBIDLY OBESE RATS UNDERGOING SLEEVE GASTRECTOMY



Wei-Yu Kao[1] Ching-Wen Chang[2] Chin-Ying Wu[3] Chun-Chao Chang[4] Shih-Yi Huang[2], [1]Taipei Medical University Hospital, [2]Graduate Institute of Metabolism and Obesity Sciences, Taipei Medical University, Taipei, Taiwan, [3]School of Nutrition and Health Sciences, Taipei Medical University, Taipei, Taiwan, [4]Division of Gastroenterology and Hepatology, Taipei Medical University Hospital

Background: Metabolic dysfunction–associated steatotic liver disease (MASLD) is strongly associated with morbid obesity and metabolic syndrome. Although sleeve gastrectomy (SG) is an established treatment for morbid obesity, whether its hepatic benefits are sustained without postoperative dietary control remains unclear. This study evaluated the effects of caloric restriction after SG on MASLD progression and lipidomic remodeling in morbidly obese rats. **Methods:** Male Wistar rats were used to establish morbid obesity with MASLD. After MASLD induction, rats underwent SG and received either a high-fat diet post-operation (HPO) or calorie-restricted diet (CRD) for 18 weeks. Control and sham-operated groups were included for

comparison. Body weight, caloric intake, serum biochemical variables, organ weights, hepatic cytokines, gross liver morphology, histopathology, fibrosis-related protein expression, lipid metabolism–related protein expression, and plasma/hepatic lipidomic profiles were assessed. **Results:** Continued HPO after SG maintained weight gain and MASLD-related liver injury, including pale enlarged liver morphology, prominent steatosis, disrupted lobular architecture, hepatic lipid accumulation, and increased fibrosis-related protein expression. SG alone partially improved metabolic parameters but did not sustainably reverse hepatic steatosis or fibrosis under continued HFD exposure. In contrast, CRD after SG reduced caloric intake and body weight gain, improved circulating lipid-related biochemical parameters, and attenuated hepatic lipid accumulation. Histology showed liver morphology and hepatic architecture closer to control/sham groups in CRD-treated rats. CRD also suppressed fibrosis-related markers, including transforming growth factor-β receptor 1, collagen I, and α-smooth muscle actin, and improved hepatic lipid metabolism–related protein expression. Lipidomic profiling demonstrated treatment-dependent remodeling of plasma and hepatic diacylglycerol and triacylglycerol species. Diacylglycerol 38:2 showed marked alteration across MASLD-related metabolic conditions, supporting its potential relevance as an early lipid-based indicator of metabolic dysregulation. **Conclusion:** Postoperative caloric restriction is a key determinant of hepatic outcomes after SG in morbidly obese rats with MASLD. SG combined with an 18-week CRD more effectively prevented MASLD progression than SG with continued HFD by reducing hepatic steatosis, inflammatory activity, fibrosis-related protein activation, and adverse lipidomic remodeling. These findings support postoperative dietary management as an essential adjunct to bariatric surgery and suggest that lipidomic profiling may help monitor MASLD progression.

1413 | HEPATOCYTE ADENOSINE KINASE SENSITIZES AGED MASLD TO KETOGENIC DIET–INDUCED HEPATOCELLULAR CARCINOMA IN MICE

Chaodong Wu[1] Honggui Li[1] Xiaojing Li[1] Miaoyun Chen[1], [1]Texas A&M University

Background: Aging is a major risk factor that is shown to significantly increases the incidence of hepatocellular carcinoma (HCC) in individuals with metabolic dysfunction–associated steatotic liver disease (MASLD) and steatohepatitis (MASH), the advanced form of MASLD. In the liver, adenosine kinase (ADK) is highly expressed and plays an important role in promoting steatosis and inflammation. While various studies have addressed the effect of ketogenic diet (KD) on metabolic dysfunction and MASLD, the effect of KD on aged MASLD remain unclear. Here, we examined the impact of KD on HCC development in aged MASLD, particularly in an ADK-high context. **Methods:** Human liver specimens from MASLD patients and healthy controls stratified by age (young vs aged) were analyzed by hematoxylin and eosin (H&E) staining and ADK immunohistochemistry. Aged and young mice were fed a MASLD-inducing diet, followed by liver histopathology and RNA sequencing with pathway enrichment analysis to identify aging-associated tumor-related transcriptional programs. To evaluate diet-triggered tumor susceptibility in an ADK-high context, 12-month-old hepatocyte-specific ADK overexpression (Hep-ADK^{Tg}) mice were fed KD for 6 months, with age-matched chow diet (CD)-fed Hep-ADK^{Tg} and KD-fed WT mice as controls, and liver phenotypes and HCC incidence were assessed. **Results:** In human liver specimens, ADK immunohistochemistry showed higher hepatic ADK expression in MASLD patients compared with healthy controls. ADK staining intensity increased with MASLD severity and was more pronounced in aged MASLD patients than in young MASLD patients. In mice, aged MASH exhibited more severe inflammation, hepatocellular ballooning, and steatosis than young MASH. RNA-seq analysis further revealed significant enrichment of tumor-related transcriptional programs in aged MASH livers, including pathways associated with hepatocellular carcinoma development. After 6 months of KD feeding in 12-month-aged mice, HCC incidence was significantly higher in Hep-ADK^{TG} mice, whereas no increase was observed in CD-fed Hep-ADK ^{Tg} mice or KD-fed aged MASLD WT mice. **Conclusion:** Hepatic ADK is elevated in MASLD and is further increased with aging. Aged MASH livers exhibit activation of tumor-related transcriptional programs, indicating a tumor-permissive molecular state. Under conditions of elevated

1414 | GMFB DRIVES MITOCHONDRIAL DYSFUNCTION AND PROMOTES MASH PROGRESSION VIA INHIBITION OF MITOPHAGY

Zhongquan Sun[1] Weilin Wang[2] Haotian Fu[2] Hongfan Ding[2], [1]Zhejiang University, [2]The Second Affiliated Hospital Zhejiang University School of Medicine

Background: MASH is a chronic inflammatory disease that can progress to cirrhosis and hepatocellular carcinoma (HCC). The key molecular mechanisms underlying this progression remain unclear. **Methods:** Protein expression was evaluated using immunohistochemistry and immunofluorescence. Co-immunoprecipitation (Co-IP), pull-down assays, and mass spectrometry were performed to identify GMFB-interacting proteins and phosphorylation sites. GMFB translocation and mitophagy were assessed by immunoblotting and immunofluorescence. A liver-specific GMFB knockout mouse model was generated to investigate its role in MASH progression in vivo. **Results:** GMFB expression was significantly elevated in MASH tissues. Free fatty acids (FFAs) induced phosphorylation of GMFB at T27 via the ERK signaling pathway, promoting its translocation from the cytoplasm to mitochondria. Mitochondrial GMFB competitively bound to PINK1, thereby impairing PARKIN recruitment and subsequent mitophagy, leading to mitochondrial dysfunction and hepatocyte injury. In vivo, liver-specific GMFB knockout alleviated mitochondrial damage and reduced steatosis, inflammation, and fibrosis in MASH models. Furthermore, in human MASH samples, GMFB expression positively correlated with disease severity and mitochondrial dysfunction. **Conclusion:** This study identifies a novel mechanism whereby FFA-induced phosphorylation and mitochondrial translocation of GMFB inhibit PINK1/PARKIN-mediated mitophagy, thereby contributing to MASH pathogenesis. Targeting GMFB may represent a promising therapeutic strategy for MASH.

1415 | GENETIC AND PHARMACOLOGIC MIR-92A INHIBITION PROVIDES HEPATIC PROTECTION IN EXPERIMENTAL MASH

Philipp Stephan Althaus[1] Eike Fürst[1] Sara Zarei[1] Robert Schierwagen[1] Maximilian Joseph Brol[2] Frank Erhard Uschner[1] Stefanie Dimmeler[3] Jonel Trebicka[1] Sabine Klein[1], [1]University Hospital Münster, Internal Medicine B, Germany, [2]University Hospital Münster, [3]Goethe-University Frankfurt a.M. Institute of Cardiovascular Regeneration, Germany

Background: Metabolic dysfunction-associated steatotic liver disease (MASLD) is an emerging cause of liver cirrhosis worldwide. Its progressive form, metabolic dysfunction-associated steatohepatitis (MASH), is a major driver of liver-related complications. Given the limited therapeutic options for MASH and the need for innovative biomarkers, this study aimed to define the role of miR-92a in disease progression and to evaluate its translational therapeutic potential through pharmacologic inhibition. **Methods:** miR-92a expression was analyzed in human MASH liver biopsies and in experimental MASH models, including Sprague Dawley (SD) rats and wild-type (wt) mice. Hepatic effects of miR-92a inhibition with LNA92a in wt mice and hepatocyte-specific deletion of miR-92a in Alb-Cre +miR-92a$^{fl/fl}$ (miR-92a$^{\Delta Hep}$) mice were evaluated and compared with wt controls. Hepatic profibrotic and inflammatory gene expression was assessed. Fibrosis was quantified by Sirius-Red (SR) and αSMA staining, hepatocyte injury by serum AST/ALT levels, and portal hypertension by *in-vivo* portal pressure (PP) measurement. **Results:** Hepatic miR-92a expression was upregulated in human MASH biopsies and in experimental MASH models compared to controls. The induction of MASH in miR-92a$^{\Delta Hep}$ and in LNA92a–treated wt mice showed reduced expression of hepatic profibrotic genes (TGFβ and Col1a1). Hepatic stellate cell (HSC) activation was attenuated, reflected by reduced αSMA and PDGF gene expression in LNA92a–treated wt mice with MASH. Subsequently, SR stainings demonstrated reduced collagen deposition while αSMA immunostaining confirmed decreased HSC activation. Markers of mitochondrial dysfunction (EMR1 and CCL2) were associated with decreased chemokine and cytokine release resulting in dampened inflammatory signaling. AST and ALT serum levels were reduced, indicating diminished necroinflammation and hepatocellular injury in miR-92a$^{\Delta Hep}$ mice compared to wt controls. In addition to decreased fibrosis, also PP was lower in both LNA92a–treated and miR-92a$^{\Delta Hep}$ mice. **Conclusion:** miR-92a is a key regulator and biomarker in MASH. Therefore, the inhibition of miR-92a using LNA92a represents a pioneering

1416 | CARDIOMETABOLIC AND ADIPOSE TISSUE ABNORMALITIES IN THE STAM MOUSE MODEL OF MASH: IMPLICATIONS FOR EXTRAHEPATIC CLINICAL OUTCOMES

Taishi Hashiguchi[1], [1]SMC Laboratories,Inc

Background: MASH is increasingly recognized as a systemic disease associated not only with liver-related events but also with cardiovascular events and multi-organ complications, which represent major determinants of clinical outcomes. However, preclinical MASH models are often evaluated mainly by hepatic histology and fibrosis endpoints. This study aimed to characterize cardiometabolic and adipose tissue-related features in the STAM mouse model, with a focus on endpoints relevant to extrahepatic clinical outcomes. **Methods:** STAM mice were evaluated for cardiometabolic parameters related to cardiovascular risk, including blood pressure and plasma lipid profiles such as triglycerides and HDL cholesterol. In addition, adipose tissue morphology and adipocytokine-related changes were assessed to determine whether systemic metabolic dysfunction accompanies MASH progression in this model. **Results:** STAM mice showed an increase in blood pressure, suggesting the development of a cardiovascular risk-related phenotype. Plasma lipid analysis demonstrated changes in lipid parameters, including triglycerides and HDL cholesterol, consistent with cardiometabolic dysregulation. Histological evaluation of adipose tissue revealed adipose tissue expansion and adipocyte hypertrophy. Furthermore, adiponectin expression was decreased, indicating impaired adipose tissue function and altered adipocytokine regulation. **Conclusion:** These findings indicate that the STAM mouse model recapitulates not only hepatic features of MASH but also extrahepatic abnormalities related to cardiovascular risk, dyslipidemia, adipose tissue dysfunction, and adipocytokine imbalance. Therefore, STAM may be useful as a translational platform to evaluate therapeutic strategies targeting clinical outcomes beyond liver histology, including cardiometabolic risk and multi-organ complications associated with MASH.

1417 | ◆ EFFICACY AND SAFETY OF FAZIRSIRAN TREATMENT IN ALPHA-1 ANTITRYPSIN DEFICIENCY-ASSOCIATED LIVER DISEASE: POOLED ANALYSES FROM TWO PHASE 2 CLINICAL TRIALS

Virginia Clark[1] Ying-Wooi Wan[2] Xinhua Hu[2] Seth Pixton[2] Jen-Chieh Chuang[2] Susana Gonzalez[2] Hong Li[2] Lisi Wang[2] Thomas Schluep[3] Rohit Loomba[4] Charlie Strange[5] Pavel Strnad[6], [1]University of Florida, Gainesville, FL, USA, [2]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [3]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, USA, [4]University of California San Diego, San Diego, CA, USA, [5]Medical University of South Carolina, Charleston, SC, USA, [6]University Hospital RWTH, Aachen, Germany

Background: Alpha-1 antitrypsin deficiency (AATD) is characterized by the presence of liver and/or lung disease. Patients (pts) with the protease inhibitor (Pi) *ZZ genotype are at high risk of AATD-associated liver disease (AATD-LD) due to hepatic accumulation of misfolded alpha-1 antitrypsin (Z-AAT). We report pooled safety and efficacy data from two phase 2 trials of fazirsiran, a small interfering RNA therapy, in pts with AATD and a Pi*ZZ genotype. **Methods:** Adults with the Pi*ZZ genotype received placebo (PBO) or fazirsiran 25/100/200 mg in AROAAT-2001 (NCT03945292), or fazirsiran 100/200 mg in AROAAT-2002 (NCT03946449). Dosing occurred on Day 1, Week (W) 4 and then every 12 weeks (Q12W) $\leq$ W48 (primary phase). In the open-label extension (OLE) phase, pts received fazirsiran 200 mg Q12W $\leq$ W196 in AROAAT-2001, and fazirsiran 100/200mg (depending on primary phase dose) Q12W $\leq$ W192 in AROAAT-2002. Liver biopsies were performed at W24 (AROAAT-2002 only), 48, 72 and/or 96. Endpoints included total intrahepatic Z-AAT burden (evaluated by periodic acid–Schiff staining with diastase [PAS-D] and LC-MS), serum Z-AAT, liver enzymes (ALT, AST, GGT), portal inflammation and fibrosis severity (METAVIR, FibroScan®), pulmonary function (FEV1, FVC, DLCO) and treatment-emergent adverse events (TEAEs). **Results:** The analyses included 56 pts (median age: 56 years; 57% male), of which 38 entered the OLE phase. During the primary study phase, a consistent improvement was observed with fazirsiran 200 mg vs PBO for total intrahepatic Z-AAT burden, serum Z-AAT, liver enzymes, portal inflammation and fibrosis severity (**Table**). Higher fazirsiran doses

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

(200 mg vs 25/100 mg) led to numerically greater median reductions from baseline (BL) in PAS-D (score change: −5.0 vs −3.5/−5.0, not significant [ns]) and total intrahepatic Z-AAT (% change: −90% vs −84/−88%, ns). In the OLE phase, switching to fazirsiran 200 mg led to geometric mean serum Z-AAT reductions from OLE BL to W24 (switching from PBO: −86%; from fazirsiran 25 mg: −54%; from fazirsiran 100 mg: −40%; all nominal $p < 0.05$ in mixed models for repeated measures); while maintenance of fazirsiran 200 mg led to continuous and sustained reductions in serum Z-AAT to ~W60, followed by a plateau ≤ W140. Liver enzymes broadly declined towards normal ranges and pulmonary function remained stable across all fazirsiran doses, with no evidence of pulmonary decline in the primary or OLE phases. During the OLE phase, 34 pts (90%) reported TEAEs; most were mild/moderate in severity and unrelated to the study drug. **Conclusion:** Fazirsiran 200 mg showed consistent efficacy for Z-AAT burden and other liver-/fibrosis-related endpoints in the primary and OLE phases of two phase 2 studies. Overall, fazirsiran was well tolerated with no safety signals or pulmonary decline. A phase 3 trial is ongoing to evaluate the benefits of fazirsiran 200 mg for AATD-LD further.Writing support provided by E Butcher, Oxford PharmaGenesis.

Table

Endpoint	Change from baseline to end of primary study phase[a]		
	Fazirsiran 200 mg (n = 19)	PBO (n = 9)	*p* value
Z-AAT burden			
Intrahepatic Z-AAT in nmol/g, % change	−89.6 (−94.5, −79.7)	25.5 (−35.4, 93.2)	< 0.001
PAS-D, composite score change	−5.0 (−5.5, −3.5)	0.0 (−1.0, 1.0)	< 0.001
Serum Z-AAT in mg/L, % change	−92.3 (−95.2, −87.0)	−6.9 (−13.1, 4.9)	< 0.001
Liver enzymes			
ALT in U/L, % change	−35.6 (−44.0, 10.0)	12.0 (0.3, 27.2)	0.023
AST in U/L, % change	−19.2 (−32.1, −1.1)	10.5 (1.5, 21.2)	0.008
GGT in U/L, % change	−33.3 (−41.6, −7.4)	8.0 (−1.1, 10.9)	0.003
Inflammation and fibrosis severity			
Portal inflammation score, score change	0.0 (−1.0, 0.0)	0.0 (0.0, 1.0)	0.003
METAVIR, score change	−1.0 (−1.0, 0.5)	0.0 (−1.0, 0.0)	0.74
FibroScan, change in kPa	−1.5 (−2.5, 0.9)	0.3 (−0.9, 1.0)	0.11

[a]All values are median (IQR) change from baseline to end of primary study phase.

ALT, alanine aminotransferase; AST, aspartate aminotransferase; GGT, gamma glutamyl transferase; IQR, interquartile range; METAVIR, Meta-analysis of Histological Data in Viral Hepatitis; PAS-D, periodic acid–Schiff staining with diastase; PBO, placebo; Pi, protease inhibitor; Z-AAT, misfolded alpha-1 antitrypsin produced by the Pi*ZZ *SERPINA1* allele.

Complejo Hospitalario Universitario Insular Materno-Infantil, Las Palmas, Spain, [8]Salem Medical Center, Department of Internal Medicine, Heidelberg, Germany, [9]Department of Gastroenterology, University Hospital Heidelberg, Heidelberg, Germany, [10]Children's Memorial Health Institute, Warsaw, Warsaw, Poland, [11]AKH Vienna, [12]Pediatric Liver GI and Nutrition Centre and Mowat Labs, King's College Hospital, London, United King, [13]Aarhus University Hospital, Aarhus University, Denmark, [14]Yale University Medical Center

Background: Wilson disease (WD) is a rare inherited disorder (1:30.000) with heterogeneous manifestations. We examined how age at diagnosis, sex, and year of diagnosis were associated with phenotypic presentation. **Methods:** In this cross-sectional study, nine registries contributed data on 3,338 patients with WD diagnosed over a 75-year period (1.1.1950-12.31.2024). Phenotypes could be categorized into three groups: Asymptomatic or hepatic (ASYMP/HEP) (without neurologic symptoms); neuropsychiatric (NEUROPSYC) (with or without hepatic disease); and acute liver failure (ALF). Logistic regression and sensitivity analyses were used to account for confounding, referral, and survivor bias. **Results:** The ASYMP/HEP phenotype decreased steadily from 87.0% at 0-19yr at diagnosis to 41.1% at ages 40-44yr and then rose to 52.9% for age >44yr. The median (IQR) age at diagnosis was 21yr (13-31yr) for all phenotypes, 17.5yr (11-27yr) for ASYMP/HEP and 28yr (20-39yr) for NEUROPSYC. Females more often presented with the ASYMP/HEP phenotypes (females 69.8%, males 63.6%; p = 0.001) or ALF (females 5.7%, males 1.9%, p = 0.001), in both cases mostly driven by individuals being 15–39yr at diagnosis. In contrast to expectations, the median age at diagnosis was relatively constant over the decades, with a modest rise at the end of the period, caused by an increased proportion of diagnoses in patients above 40yr of age from 1% of all diagnoses in 1980-84 to 24% in 2020-2024. In these "late-presenters", the ASYMP/HEP phenotype increased from 30% in 2000-2004 to 71% in 2020-2024, while the ratio between ASYMP/HEP and NEUROPSYC was surprisingly constant during the observation period in patients diagnosed before 39 years of age. **Conclusion:** In this largest-of-its-kind multicenter study, we confirmed that the ASYMP/HEP phenotype dominates in childhood while NEUROPSYC becomes steadily more important until age 44. Female preponderances of the ASYMP/HEP and ALF phenotypes were driven by the 15-39yr age groups, possibly related to hormonal changes. Over the last two decades, WD was more often diagnosed in patients above the age of 40, a subgroup that may have been grossly overlooked in the past and needs better characterization. Despite attempts to prevent development of the NEUROPSYC phenotype through earlier diagnosis, this did not show up in the data. Combining data from multiple registries for patients with WD enables better epidemiologic studies.

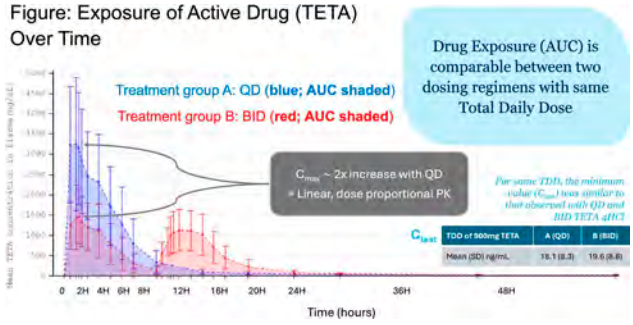
1419 | ◆ CAN A NOVEL INSTANT RELEASE TRIENTINE TETRAHYDROCHLORIDE FORMULATION BE EFFECTIVE WHEN ADMINISTERED ONCE-DAILY? RESULTS OF THE TRIUMPH-3 PHARMACOKINETIC STUDY



Michael Schilsky[1] Karl Heinz Weiss[2] Thomas Ashdown[3] Ulrike Lorch[3] Nichloas Manamley[4] Farah Lawrence-Wilde[4] C.Omar Kamlin[5], [1]Yale University Medical Center, [2]Krankenhaus Salem der Evang. Stadtmission Heidelberg GmbH, Heidelberg, Germany, [3]Richmond Pharmacology, [4]Orphalan SA, [5]Orphalan

Background: The therapeutic goal of Wilson Disease (WD) is to control copper levels and modify disease progression. Adherence to all approved anti-copper drugs is challenging; need for life-long medication

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

with at least twice-daily dosing, food-drug interactions make timing of intake critical. Efficacy of chelation, measured by urinary copper excretion, is determined by total exposure of active drug determined by pharmacokinetic (PK) measure of area under the curve (AUC) independent of dosing frequency[1] . This study describes and compares the PK profile of a novel trientine tetrahydrochloride (TETA 4HCl) administered once a day (QD) with approved TETA 4HCl formulation administered twice daily. **Methods:** A Phase 1 (NCT06128954), single center, randomized, open-label, cross-over study to compare the PK, safety and tolerability of a new 300mg trientine base TETA 4HCl formulation with EU approved 150mg trientine base. A total daily dose of 900mg trientine base was evaluated by comparing QD dosing (x3 tablets = 900mg) with 2 [BID] equally divided doses 8 hours apart (6x150mg trientine base) in a fasted state. Blood samples were taken prior to dosing and at prespecified intervals for 48 hours measuring peak concentration (C_{max}), last sampled concentration (C_{last}), time to C_{max} (T_{max}) followed by a 5–7-day washout period between cross-over. **Results:** 26 participants completed both sequences of the study. PK profiles of the two formulations were as expected, single peak and gradual decline in plasma levels with the QD formulation, and a bimodal pattern, with BID TETA 4HCl. Plasma concentrations of trientine increased to a geometric mean peak of 3436 and 1567 ng/mL, respectively [GMR 2.192, 90% CI 1.882-2.554]) reflecting dose-proportionally higher C_{max} between QD and BID dosing with median T_{max} values of 1h and 1.25h for QD and BID dosing respectively. Figure shows comparable systemic exposure of TETA AUC_{0-24}. The geometric mean ratios (GMR) of the new QD formulation relative to BID TETA 4HCl were the following: C_{max} (2.192), AUC_{0-24} (1.155) AUC_{0-48} (1.14) and AUC_{inf} (1.12). Mean (SD) final concentrations (C_{last}) sampled at 48h were 18.1 (8.3) and 19.6 (8.8) ng/mL for QD and BID dosing respectively. Five participants experienced a total of 8 adverse events (AE); 7 mild, 1 moderate (viral infection). **Conclusion:** The new QD TETA 4HCl with a TDD of 900mg was well tolerated and demonstrated dose proportional and linear pharmacokinetics with a doubling of C_{max} with comparable time to C_{max} with equally divided dose of 450mg of TETA 4HCl. Comparable AUC and values of the last sampled plasma concentration of TETA show that systemic exposure and excretion of TETA for the same TDD is independent of frequency of dosing and supports once daily dosing.Reference: 1. Cho *J Clin Pharmacol 2009* **Figure:** Mean linear TETA concentrations following QD and BID dosing of TDD of 900mg trientine tetrahydrochloride

1420 | NEUTRAL MOLYBDENUM BALANCE AND LACK OF MOLYBDENUM TOXICITY IN SUBJECTS TREATED WITH TIOMOLIBDATE CHOLINE SUPPORTS SAFETY PROFILE OF TMC

Aftab Ala[1] Valentina Medici[2] Karl Heinz Weiss[3] Chandler Robinson[4] Andrew Cittadine[4] Declan Tuffy[4] Thomas Sandahl[5] Frederick Askari[6], [1]Kings College Hospital, [2]University of California Davis Medical Center, [3]Krankenhaus Salem, [4]Monopar Therapeutics, [5]Aarhus University Hospital, [6]University of Michigan Medical Center

Background: Tiomolibdate choline (TMC; ALXN1840) is an oral, once-daily, novel mechanism albumin-tripartite-complex (ATC) activator in development for Wilson disease (WD). TMC contains tetrathiomolybdate, a molybdenum (Mo)-containing high affinity Cu-binding moiety intended for chronic administration. Because excess Mo exposure presents with hyperuricemia and gout-like symptoms, evaluation of progressive Mo accumulation and serum uric acid levels are important for assessing the safety of chronic TMC treatment. To address both, we present results from a Mo balance study (HV-108) conducted in healthy volunteers administered TMC along with long-term serum uric acid and adverse event (AE) data in WD patients from Phase 2&3 TMC trials. **Methods:** In HV-108, 17 healthy volunteers were admitted to a clinical

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

research unit and started on a Mo-controlled diet. Following a 4-day pretreatment period (baseline), volunteers received TMC 30 mg once daily for 15 days followed by a 15-day drug withdrawal period. All intake (food, drink, TMC) and output (urine, stool) during the study were collected and analyzed for Mo content. Daily Mo balances were calculated as Mo intake minus Mo output.In the Phase 3 trial, patients with WD were randomized to standard of care (SoC, n = 70) or TMC (n = 137; 15-30 mg daily) for 48 weeks. Serum uric acid concentrations were evaluated over the study duration and during long-term follow-up. Serum uric acid was also measured in the Phase 2 WTX101-201 trial and included in the analyses (n = 235). For AEs, data from the Phase 2 ALXN1840-WD-204 and ALXN1840-WD-205 trials were additionally included (n = 266). **Results:** At baseline in HV-108, mean daily Mo balance was approximately neutral. Following initiation of TMC, Mo balance increased transiently, then progressively declined as urinary and fecal Mo elimination increased. Neutral Mo balance was achieved by Day 13 even with continued TMC dosing (Figure 1A). After treatment withdrawal on Day 15, Mo elimination continued, primarily through fecal excretion.In the Phase 3 trial, mean serum uric acid remained stable and was similar between TMC and SoC through Week 48. Over 6 years of TMC treatment, mean serum uric acid levels across the 235 WD patients in the Phase 3 and WTX101-201 trials remained within normal limits (Figure 1B), and no AEs of hyperuricemia or gout-like symptoms were reported in 266 WD patients from the Phase 2&3 studies over the same period. **Conclusion:** In HV-108, Mo balance returned to neutral despite continued TMC administration and the overall pattern is consistent with the mechanism of ATC formation. Mean serum uric acid remained stable and within normal range over 6 years of treatment, with no hyperuricemia or gout-related AEs observed. Together, these findings show no evidence of progressive Mo accumulation and the absence of Mo-related toxicity during chronic TMC treatment. These findings contribute to the understanding of the safety of the novel mechanism of TMC.

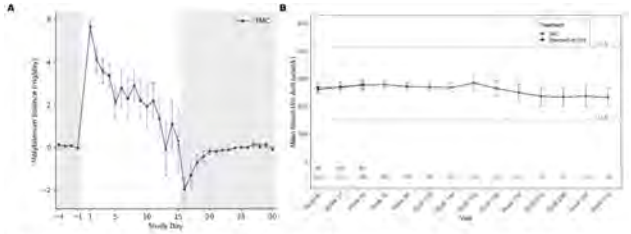

Figure 1A: daily mean Mo balance in healthy volunteers. Mean (± 95% CI) daily Mo balance in healthy volunteers (n=17) measured while on TMC (Days 1 to 15) and off TMC (Days -1 to -4, 16 to 30). Daily Mo balance reached neutral by Day 13 while subjects remained on drug. **Figure 1B: Mean serum uric acid by treatment arm in patients with WD.** Mean (± 95%) serum uric acid in patients with WD treated with TMC (n=235; purple line) and standard of care (n=70, red line). Patients were followed from Baseline through 48 weeks in the standard of care arm and 312 weeks in the TMC arm. Mean levels were within normal limits for both treatment arms at all visits.

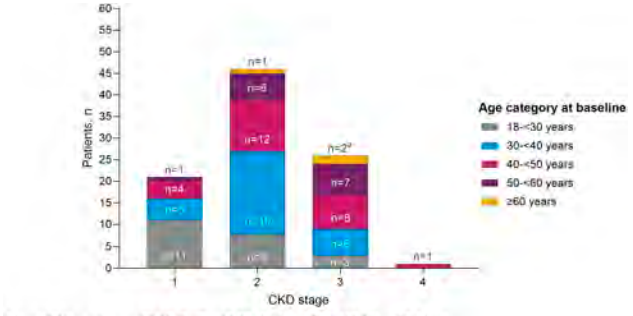
1421 | IMPAIRED BASELINE KIDNEY FUNCTION IN PATIENTS WITH ACUTE HEPATIC PORPHYRIA ENROLLED IN THE PHASE 3 ENVISION STUDY



Desmond Murphy[1] Akshata Moghe[2] Paolo Ventura[3] Rebecca Leaf[4] John Quigley[5] Penelope Stein[6] Weiming Du[1] Eliane Sardh[7] Bruce Wang[8] Roy Smith[9], [1]Alnylam Pharmaceuticals, Cambridge, MA, USA, [2]University of Texas Health Science Center at Houston, Houston, TX, USA, [3]Internal Medicine Unit, University of Modena and Reggio Emilia, Modena, Italy, [4]Center for Hematology, Mass General Brigham Cancer Institute, Boston, MA, [5]University of Illinois College of Medicine, Chicago, IL, USA, [6]Haematological Medicine, King's College Hospital, London, UK, [7]Centre for Inherited Metabolic Diseases, Karolinska University Hospital, Stockholm, Sweden, [8]University of California San Francisco, San Francisco, CA, USA, [9]University of Pittsburgh School of Medicine, Pittsburgh, PA, USA

Background: Acute hepatic porphyrias (AHPs) are rare disorders of hepatic heme synthesis that lead to elevated levels of neurotoxic δ-aminolevulinic acid (ALA) and porphobilinogen (PBG). Patients may present to hepatologists with recurrent AHP attacks of severe abdominal pain, nausea, and neuropsychiatric symptoms, and may experience chronic AHP symptoms and low quality of life. Over time, untreated or inadequately managed AHP may result in progressive renal dysfunction because of recurrent attacks and the nephrotoxic effects of ALA and PBG on the glomeruli. Monitoring renal function is recommended in patients with AHP, but the real-world burden of chronic kidney disease (CKD) as a long-term AHP complication has not been well characterized. The phase 3 ENVISION study of givosiran, an RNA interference therapeutic approved for treatment of AHP, included follow up on long-term complications of AHP, including CKD. The objective of this *post hoc* analysis was to characterize baseline CKD prevalence among patients with AHP who were enrolled in ENVISION. **Methods:** ENVISION (NCT03338816) was a multicenter, randomized,

double-blind, placebo-controlled study enrolling patients ≥12 years old with AHP who had ≥2 attacks requiring hospitalization, urgent care, or intravenous hemin at home in the 6 months before study entry. This *post hoc* descriptive analysis included all patients randomized to givosiran or placebo stratified by CKD stage at baseline (before treatment), as defined by estimated glomerular filtration rate (eGFR [mL/min/1.73m^2]): stage G1, eGFR ≥90; stage G2, eGFR 89-60; stage G3, eGFR 59-30; or stage G4, eGFR <30. **Results:** In total, 94 patients (89% female; mean age 37 years) were included in the analysis. Most patients had CKD stage G2 (n = 21, n = 46, n = 26, and n = 1 for CKD stages G1-4, respectively); 50% of patients (36/72) with CKD stage G2 or G3 were aged 18 to <40 years (**Figure**). Mean (standard deviation) time since diagnosis was 7.22 (9.22) years, 9.82 (10.73) years, 11.85 (9.10) years, and 17.45 (–) years for stages G1-4, respectively. Median (range) annualized attack rates at baseline were 6 (0-34), 10 (2-46), 6 (4-26), and 24 (–) attacks/year among patients with CKD stages G1-4, respectively. **Conclusion:** At baseline, patients with AHP exhibited considerable renal impairment, with the majority at CKD stage 2 or 3. Patients had kidney function below age-matched reference values (Wetzels JF *et al. Kidney Int* 2007;72:632-7), and those with longer disease duration presented with worsened kidney function at baseline. These results demonstrate the additional disease burden outside of AHP attacks and highlight CKD as a potential long-term complication of AHP with high clinical relevance. The findings support ongoing renal monitoring in patients with AHP to help prevent CKD progression, and suggest that AHP should be suspected in patients with unexplained recurrent abdominal pain and impaired kidney function.

1422 | GENETIC MODIFICATION OF WILSON DISEASE ATP7B GENE IN HUMAN CELLS USING RNA-BASED CRISPR/CAS9 TECHNOLOGY

Moritz Marciniak[1] Andree Zibert[1] Oksana Nadzemova[1] Phil-Robin Tepasse[1] Jonel Trebicka[1] Vanessa Sandfort[1], [1]University Hospital Münster, Medical Clinic B

Background: Wilson disease (WD) is a monogenic disorder of copper (Cu) metabolism caused by mutations in the Cu-transporting ATP7B protein and associated with hepatic Cu accumulation. H1069Q is the most frequently reported ATP7B variant in European and North American populations. A previous study by our group demonstrated the feasibility of H1069Q correction using plasmid-based CRISPR/Cas9 (Clustered Regularly Interspaced Short Palindromic Repeats / CRISPR-associated protein 9) molecules in WD-specific induced pluripotent stem cells (iPSCs). After differentiation into hepatocyte-like cells (HLCs), corrected cells showed improved resistance to high Cu concentrations (Iwan et al. 2026). Replacing plasmid-based delivery with transient RNA-based CRISPR/Cas9 molecules may further improve the translational relevance of this approach. **Methods:** A single-guide RNA (sgRNA) targeting the ATP7B H1069Q locus was designed and delivered together with Cas9 mRNA into HEK293 and HepG2 cells by lipofection. Individual clones from both cell lines were screened by Sanger sequencing to identify CRISPR/Cas9-induced deletions or insertions at the target locus. ATP7B expression was analysed by Western blotting (WB) and quantitative PCR (qPCR). Cellular tolerance to high Cu concentrations was assessed using MTT assays. **Results:** RNA-based CRISPR/Cas9 editing generated several ATP7B knockout (KO) clones in HEK293 and HepG2 cells. Sanger sequencing conformed distinct homozygous and heterozygous insertions and deletions at the H1069Q locus. WB analysis showed reduced ATP7B protein expression in KO clones from both cell lines. At the mRNA level, reduced ATP7B expression was observed most consistently in HEK293 clones. MTT assays indicated a functional impact of ATP7B disruption on the cellular response to high Cu concentrations. **Conclusion:** This study demonstrates that RNA-based delivery of Cas9 mRNA and sgRNA can successfully target the ATP7B H1069Q locus and generate

genetically defined ATP7B KO clones in both HEK293 and HepG2 cells. The combination of Sanger sequencing, ATP7B expression analyses and Cu-dependent viability assays provide molecular and functional evidence that ATP7B disruption effects cellular Cu tolerance. These findings establish an RNA-based CRISPR/Cas9 platform for ATP7B editing in vitro and provide a relevant intermediate step towards mutation-specific repair approaches in WD. Future work will focus on RNA-based correction of H1069Q in human cell lines and patient-derived iPSCs using previously validated repair template molecules (Iwan et al. 2026).

1423 | TWO PHASE 1 STUDIES TO CHARACTERIZE THE PHARMACOKINETICS, PHARMACODYNAMICS, AND SAFETY OF TWO PROLONGED-RELEASE VAMIFEPORT FORMULATIONS IN HEALTHY ADULTS AND TO ASSESS THE EFFECT OF FOOD ON THE FORMULATION SELECTED FOR FUTURE CLINICAL DEVELOPMENT

Sonya Abraham[1] Jens-Alexander Fuchs[2] Yulia Shalaeva[3] Deya Cherpokova[4] Gregory Kato[1], [1]CSL Behring, King of Prussia, Pennsylvania, USA, [2]CSL Behring, Glattbrugg, Switzerland, [3]CSL Vifor, Glattbrugg, Switzerland, [4]CSL Innovation GmbH, Marburg, Germany

Background: Vamifeport is an oral small-molecule hepcidin-mimetic that targets the ferroportin transporter. In two clinical studies in healthy volunteers and one study each in patients with non-transfusion-dependent thalassemia and sickle cell disease, vamifeport immediate-release (IR) formulation reduced circulating iron levels and was generally well tolerated. Here, we report the clinical development path that identified and characterized a new prolonged release (PR) formulation now being used in a phase 2 study in hereditary hemochromatosis (HH; Study CSL624_2001; "Ferroclear"). **Methods:** Two phase 1, open-label studies were conducted **(Figure 1)** . Study 1 included four treatment periods to characterize and compare the pharmacokinetic (PK), pharmacodynamic (PD) and safety of two vamifeport PR formulations ("PR1" and "PR2") across single- and multiple- dose regimens: Period 1 (single-arm; IR three times daily to steady-state); Period 2 (parallel-group; PR1 or PR2 twice daily to steady-state); Periods 3 and 4 (crossover; single dose of PR1 or PR2 in Period 3 and following washout, the alternate formulation in Period 4). Study 2 was a single-dose two-way, two-period crossover study to assess the effect of food on the oral bioavailability of the selected vamifeport PR formulation ("PR1"). In both studies, safety was evaluated, and the PD (serum iron and transferrin saturation [TSAT]) was determined. **Results:** Study 1 (N = 22): When compared with vamifeport IR, both PR formulations showed slower absorption, resulting in increased T_{max}, lower C_{max}, and lower systemic exposure (AUC) (dose-normalized exposures). The reduction of C_{max} was greater than the reduction in AUC, flattening the PK profile and making vamifeport PR favorable over IR. Further, absorption of PR1 was slower and lower compared with PR2, resulting in better safety margins while preserving comparable PD effects between these formulations. Study 2 (N = 28): A high-fat breakfast reduced C_{max} of vamifeport PR1 by 40.6% (fed:fasted ratio = 0.594; 90% CI: 0.522, 0.675) and delayed T_{max} by 2 h, but the ratio and 90% confidence interval for overall exposure ($AUC_{0\text{-last}}$ and $AUC_{0\text{-inf}}$) remained within the bioequivalence limits of 0.8 and 1.25. The observed changes in the absorption phase were within the range of inter-subject variability and did not impact the TSAT profiles, which were comparable between both states. In both studies, vamifeport was well tolerated. **Conclusion:** The selected vamifeport PR formulation provided a flatter PK and PD profile and increased C_{max}-based safety margins when compared with equal doses of vamifeport IR. Also, vamifeport PR can be administered with or without food, providing superior flexibility in studies involving patients compared with vamifeport IR. In both studies, vamifeport PR was well tolerated. Based on these results, vamifeport PR progressed to a phase 2 study in HH (NCT07332091).

1424 | CYSTIC FIBROSIS PATIENTS HAVE THE LOWEST TRANSPLANT ACCESS AND HIGHEST WAITLIST MORTALITY AMONG ADULTS LISTED FOR RARE LIVER DISEASES: A CONTEMPORARY UNOS ANALYSIS

Rebeca Sierra[1] Maria Saavedra-Martinez[1] Marcela Cuellar-Lobo[2] Butros Fakhoury[3] Pojsakorn Danpanichkul[4] Leandro Sierra[5], [1]Universidad De La Sabana, [2]Cardiovascular Division, Beth Israel Deaconess Medical Center, [3]Virginia Commonwealth University, [4]Texas Tech University Health Sciences Center, [5]Cleveland Clinic Foundation

Background: Efforts in liver transplant research have left rare liver diseases behind. There are currently no contemporary analyses of waitlist attrition, transplant access, and outcomes across rare liver diseases in the U.S. Understanding the risk profile of every liver condition, including those that are less common, is necessary to inform organ allocation decisions. **Methods:** Using the Scientific Registry of Transplant Recipients, we retrospectively analyzed adults listed for liver transplantation from 2010 to 2025. Rare liver diseases were selected based on U.S. prevalence below 200,000 (Rare Diseases Act of 2002) and the absence of a national-registry analysis published after 2015. Of seven plausible diseases, three were excluded: primary hyperoxaluria (insufficient sample size of 40 subjects), hepatic sarcoidosis (no dedicated OPTN diagnosis code), and congenital hepatic fibrosis/Caroli disease (national analysis published in 2021). The final cohort comprised Wilson disease (WD), alpha-1 antitrypsin deficiency (A1AT), Budd-Chiari syndrome (BCS), and cystic fibrosis (CF). Annual listing trends were assessed with the Cochran-Armitage test. Waitlist mortality or dropout and access to transplantation were evaluated using Kaplan-Meier estimation and adjusted Cox regression. **Results:** A total of 3,668 adults were included: A1AT (n = 2,399, 65.4%), BCS (n = 617, 16.8%), WD (n = 442, 12.1%), and CF (n = 210, 5.7%). Annual listing trends were stable across the study period for all four diseases. Transplant rates differed substantially across groups (A1AT 78.2%, WD 71.7%, BCS 51.7%, CF 29.0%; p < 0.001). Among CF patients not reaching transplantation (n = 149, 71.0%), 39 (26.2%) died on the waitlist and 38 (25.5%) were removed for clinical deterioration. Waitlist survival differed across groups (log-rank p < 0.001). CF had the lowest survival at every time point, falling to 90.4% at 3 months and 76.2% at 12 months, while BCS had the highest survival throughout (97.3% at 3 months, 96.5% at 12 months). Median waitlist time was shortest in WD (43 days; IQR 7-308) and longest in BCS (215 days; IQR 35-790). **Conclusion:** Among adults listed for transplantation with rare liver diseases, CF carries the lowest transplant access and the highest waitlist attrition, with one in four CF patients dying on the waitlist and another quarter removed for clinical deterioration. In contrast, Budd-Chiari syndrome carries the most favorable waitlist survival. The progressive extrahepatic disease in CF not captured by MELD 3.0 might be limiting its overall survival. Policies that apply exception pathways for CF patients must be considered.

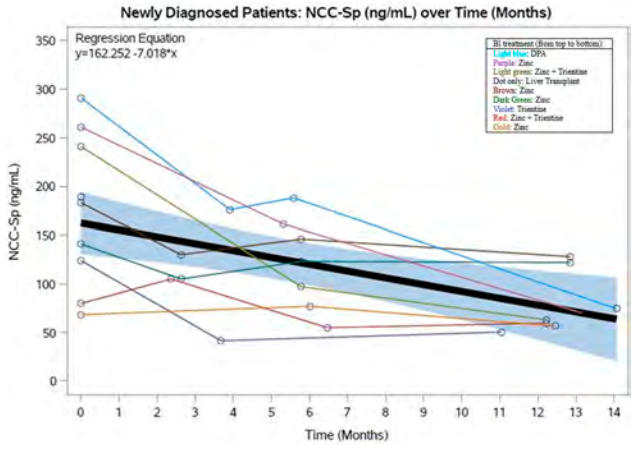
1425 | REAL WORLD EVIDENCE OF THERAPY IMPACT OF NON-CERULOPLASMIN BOUND COPPER BY SPECIATION AS A NOVEL MONITORING TOOL IN NEWLY DIAGNOSED WILSON DISEASE



Michael Schilsky[1] Regino Gonzalez-Peralta[2] Amanda Cheung[3] Valentina Medici[4] James Hamilton[5] Cynthia Levy[6] Kalyan Bhamidimarri[7] Steven Lobritto[8] Amy Brown[9] C.Omar Kamlin[10] Jamie Heise[11] Brenda Gorsett[10] Nick Manamley[10] Frederick Askari[12], [1]Yale University Medical Center, [2]AdventHealth for Children, [3]Northwestern Memorial Hospital/Northwestern University, [4]University of California Davis Medical Center, [5]Johns Hopkins University, [6]University of Miami, [7]Cleveland Clinic, [8]Columbia University, [9]Vanderbilt University, [10]Orphalan, [11]Orphalan Inc, [12]University of Michigan Medical Center

Background: Monitoring of treatment for Wilson disease (WD) remains challenging, underscoring a substantial unmet need for accurate and clinically practical biomarkers to assess treatment response. **Aim:** To describe the response of non-ceruloplasmin bound copper by speciation (NCC-Sp), a measurement of circulating bioavailable copper, at key time points in newly diagnosed WD in relation to therapy initiation and change . **Methods:** The REASON study (NCT05783687) was a non-interventional, prospective study conducted across 9 U.S. sites between June 2023 and October 2025. Blood samples for NCC-Sp measurement were collected at baseline (BL), during

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

standard of care (SOC) visits, and at end of study (EOS). NCC-Sp was analyzed following EOS visit, thus treating physicians were blinded to these values and clinical decision-making was independent of contemporaneous NCC-Sp values. NCC-Sp was evaluated at baseline, SOC visits and EOS or in association with therapy change. Findings were compared with liver enzyme (AST, ALT) changes and 24-hour urinary copper excretion (UCE) where available. **Results:** Of 9 newly diagnosed patients (2 asymptomatic), 1 underwent liver transplantation following enrollment and contributed baseline data only. Among the 8 treated patients, baseline therapies included zinc monotherapy (n = 4), combination zinc/trientine (n = 2), trientine monotherapy (n = 1), and D-penicillamine (n = 1). Two patients changed therapy during the 12-month follow-up: 1 initiated on zinc and added trientine at 5 months, and 1 on combination therapy discontinued zinc at 2 months. Therapy assignments are illustrated in the accompanying figure. NCC-Sp mean (SD) at BL was elevated to 175.32 (78.83) ng/ml and declined by 95.69 (85.59) ng/ml by EOS, aligned with previously reported values for chronically treated patients in the CHELATE trial (NCT03539952). Among patients with both BL and EOS liver enzymes, mean AST and ALT demonstrated slight reductions compared to the NCC-Sp trends. UCE data was limited; 4 patients with paired data, mean (SD) BL UCE of 523.72 (679.16) mcg/d increased by 83.0 (118.79) mcg/d at EOS. Clinical Global Impression of Change (CGIC) scale indicated improvement in all (5 much improved, 3 minimal). **Conclusion:** In treatment naïve WD patients, NCC-Sp declined consistently across all therapy groups with concurrent trends toward clinical stability and liver enzyme improvement, supporting NCC-Sp as a potential biomarker for monitoring copper-directed therapy. Larger studies are needed for validation.

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: The ratio of bioavailable Cu to the total Cu in the circulation can help discriminate Wilson disease (WD) from non-affected individuals. A highly accurate method for determining non-ceruloplasmin copper (ANCC) utilizing anion exchange chromatography linked to ICP mass spectrometry can provide information on the total and bioavailable Cu needed to calculate the ratio of bioavailable Cu to total serum copper, the RelANCC (Harrington et al *Clinical Chemistry and Laboratory Medicine* 2025) . RelANCC was able to distinguish acute liver failure (ALF) due to WD from ALF due to other causes of liver disease (Sandahl et al *Am J Gastroenterol*. 2025). Only limited data is available on RelANCC in WD outside of those with ALF due to WD. The Wilson disease registry (WDR) based at Yale is a multicenter, multinational registry of patients with WD coupled with a biorepository, allowing the correlation of specimen analysis with information related to patient treatment needed for exploring the RelANCC in the larger population of patients with WD. **STUDY AIM** : To determine the range of values for RelANCC in a large population of patients with a chronic presentation of WD, and if RelANCC is affected by copper directed treatment specific for WD. **Methods:** Total Cu and ANCC determined from serum obtained from patients in the WDR at time of study entry and at least annually thereafter was used to calculate RelANCC. The phases of treatment of WD for patients in the WDR include naïve patients (0-1 month (m) of treatment), patients treated from 1-3 m, from >3-18 m, and > 18 m. Control patients included those without liver disease from the laboratory. A total of 407 observations from 150 unique subjects with WD were included in the analysis. The cohort had a mean age of 35.5 ± 19.2 years (median 33.1; range 1.1–78.6), and 82 subjects (54.7%) were male. Cu-directed treatment with either Zn or chelation therapy was recorded at time of measurement. **Results:** Among controls without WD (n = 31), median RelANCC was 9.66% (IQR 6.09–12.5%). In treatment-naïve WD patients, median RelANCC was 24.9% (IQR 17.8–29.9%). The Youden-optimized cutoff distinguishing the two groups was 16.8%. Median RelANCC during Cu directed therapy for 1–3 m (n = 23) was 34.1% (IQR 25.4–63.6%); for 3–18 m (n = 45) 35.2% (IQR 23.4–56.1%) and for >18 m (n = 324) 31.4% (IQR 23.1–51.0%). The greatest number of RelANCC below 16.8% was found in patients treated >18m, and these individuals were older and treated predominantly with Zn. **Conclusion:** The predictive value of RelANCC is highest in untreated patients with WD. Cu directed treatment for WD reduces the discriminatory ability of RelANCC in some patients, and for those treated with Zn more so than on treatment with chelation. Further studies are needed to further validate RelANCC as a diagnostic test for WD and establish cut-off ranges that yield the highest predictive value for this test. Funding: NIDDK DK137861, Wilson Disease Association.

1427 | PSYCHOMETRIC DEVELOPMENT AND HEPATIC CORRELATION OF A BRIEF CROSS-DIAGNOSTIC MENTAL HEALTH ASSESSMENT FOR WILSON DISEASE USING ITEM RESPONSE THEORY

Hatice Maras[1] Asim Ulcay[1] Sefa Keserci[1] Paula Zimbrean[1] Susan Rubman[1] Regino Gonzalez-Peralta[2] Isabelle Mohr[3] Aftab Ala[4] Sanjiv Harpavat[5] Thomas Sandahl[6] Michael Schilsky[1], [1]Yale University School of Medicine, [2]AdventHealth for Children, [3]Universitats Klinikum Heidelberg, [4]Kings College Hospital, [5]Texas Children's Liver Center - Baylor College of Medicine, [6]Aarhus University Hospital

Background: Psychiatric symptoms have a lifetime occurrence of up to 71% in Wilson disease (WD) with 30–40% manifesting symptoms at diagnosis. Despite this, screening protocols to detect the need for formal mental health evaluation remain unstandardized, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

the relationship between psychiatric symptoms and hepatic disease severity undefined. **STUDY AIM:** to develop a screening instrument 'WD Mental Health Impact Battery (WD-MHIB)' using selected items from PHQ-9, GAD-7, and PSS-10 to evaluate longitudinal associations between mental health and liver disease in WD. **Methods:** Data from 164 participants from the WD Registry (85 female; mean age 39.3 y, range 18–75) included 591 survey responses for PHQ-9, GAD-7, and PSS-10 that were analyzed. Psychometric properties were evaluated using polychoric correlation matrices and Item Response Theory (IRT) graded response models (Reise SP, Rodriguez A. Psychol Med. 2016;46(10):2025-39). Items were selected based on discrimination (α) and threshold parameters. The resulting 9-item WD-MHIB comprised of top-performing items from PHQ-3 (1, 2, 9), GAD-3 (1, 2, 3), and PSS-3 (reverse-coded 5, 7, 8), was validated against the SF-12 Mental Component Summary (MCS) using Pearson correlation. Associations between mental health scores (WD-MHIB, PHQ-9, GAD-7, PSS-10) and hepatic variables including AST, ALT, FIB-4, and cirrhosis status were evaluated using linear mixed-effects models with patient-specific random intercepts and Mann–Whitney U tests (See Table). **Results:** Selected items demonstrated peak discrimination: GAD-3 (α = 3.21–5.39), PHQ-3 (α = 2.97–3.79), and PSS-3 (α = 2.16–3.41). WD-MHIB demonstrated robust convergent validity with SF-12 MCS (r = -0.78, p < 0.001). After adjustment for time, AST (p = 0.126) and ALT (p = 0.235) were not significantly associated with mental health scores. Elevated FIB-4 scores ($\geq$ 2.67) were associated with lower PHQ-9 (p = 0.002), GAD-7 (p = 0.004), and composite survey z-scores (p = 0.006), while WD-MHIB did not differ significantly (p = 0.072). Cross-sectional analyses demonstrated lower mental health scores in cirrhotics versus non-cirrhotics (median composite score 12.0 vs 19.0; p < 0.001), including WD-MHIB, PHQ-9, GAD-7 (all p < 0.001), and PSS-10 (p = 0.045). Longitudinal analyses demonstrated decline in WD-MHIB scores over time (β = −0.226 points/year; p = 0.003). **Conclusion:** WD-MHIB, can facilitate efficient mental health screening and the need for formal psychiatric consultation in WD as recommended by the recent AASLD guidance (Hepatology 2025). WD-MHIB scores appeared independent from the presence of advanced hepatic fibrosis. Validation of optimal cutoffs for clinical decision-making is needed for the use of WD-MHIIB as a screening instrument and for monitoring. Further work is needed to evaluate the association between liver disease severity and mental health concerns in WD. Funding: NIH DK137861, Wilson Disease Association.

Table 1. Associations Between Mental Health Survey Scores and Hepatic Disease Severity Measures in Wilson Disease

Measure	Analysis Type	WD-MHIB (p value)	N	PHQ-9 (p value)	N	GAD-7 (p value)	N	PSS-10 (p value)	N
SF-12 MCS	Pearson correlation	<0.001	591	—	—	—	—	—	—
AST	Linear mixed-effects model	0.126	574	0.126	574	0.126	574	0.126	574
ALT	Linear mixed-effects model	0.235	574	0.235	574	0.235	574	0.235	574

1428 | VIRTUAL CME SIMULATION IMPROVES MULTI-SPECIALTY PERFORMANCE IN THE DIAGNOSIS AND MANAGEMENT OF WILSON DISEASE

Margaret Harris[1] Jovana Lubarda[1] Karen Badal[1], [1]Medscape Education

Background: Wilson disease (WD) is a rare but treatable genetic disorder of copper metabolism that requires a high index of clinical suspicion for timely diagnosis. Clinical gaps exist regarding the recognition of varied presentations and the selection of evidence-based maintenance therapies. The objective of this educational initiative was to improve clinician awareness of clinical red flags and optimize the management and monitoring of patients with WD. **Methods:** This virtual medical simulation educational activity engaged learners in two objective-based interactive patient cases involving a treatment-naïve patient and a patient requiring maintenance therapy. Clinical competence was assessed using a pre-guidance vs. post-guidance methodology. Statistical significance was determined via McNemar's test. The activity launched on September 19, 2025, with data collected through February 2026. The analysis included n = 162 for Case 1 and n = 99 for Case 2. **Results:** A total of 9,061 learners participated.

Performance data for Gastroenterologists/Hepatologists (Gastros) and Neurologists demonstrated significant gains across core learning objectives (LO): **Diagnostic Workup (LO1):** In Case 1, Neurologists saw a 24% relative increase in diagnostic accuracy (P < .01) , while Gastros showed a 16% improvement (P < .001). Both groups saw significant lifts in recognizing extrahepatic cues, specifically requesting slit-lamp exams (Gastros: +18%; Neurologists: +24%). **Treatment Selection (LO2):** Sharpest gains were seen in this domain. In the setting of chelator intolerance (Case 1), Neurologists' selection of zinc salts rose by 56% (P < .001) compared to a 40% increase among Gastros (P < .001). In maintenance management (Case 2), adoption of trientine tetrahydrochloride increased by 21% for Neurologists and 19% for Gastros (P < .05 and P < .001, respectively). **Monitoring Success (LO3):** Gastros improved significantly in longitudinal care elements, including follow-up intensity (+16%) and patient education (+12%). Neurologists improved most in patient education (+11%). **Top Practice Changes & Barriers: Planned Changes:** 76% of learners plan to make one or more practice changes. **Primary Barriers:** Persistent obstacles to therapy adoption include unfamiliarity (reported up to 65%), cost (up to 42%), and insurance/access constraints. **Conclusion:** This online simulation effectively bridged gaps in WD clinical performance, yielding significant improvements in diagnostic workup and evidence-based treatment selection for both Gastroenterologists and Neurologists. With 97% of learners agreeing the education will impact their practice , this program potentially impacts 2,243 patient visits monthly.

1429 | WHOLE-BLOOD TRANSCRIPTOMIC PROFILING REVEALS DISTINCT FEATURES IN CIRRHOTIC PATIENTS CARRYING PI*MZ *SERPINA1* GENOTYPE

Mariia Lunova[1] Sona Frankova[2] Jan Kubovciak[3] Mikolas Holinka[2] Katerina Plchova[2] Tomas Nesnidal[2] Tomas Hucl[2] Milan Jirsa[2] Jan Sperl[2], [1]mariia.lunova@ikem.cz, [2]Institute for Clinical and Experimental Medicine, [3]Institute of Molecular Genetics of the Czech Academy of Sciences

Background: The *SERPINA1* Pi*MZ genotype is notably prevalent in the general population and is associated with an increased risk of liver disease and cirrhosis. While the role of the Pi*ZZ genotype in liver disease has been increasingly studied, little is known about blood-associated molecular changes linked to end-stage liver disease in Pi*MZ carriers. We aimed to determine whether whole-blood transcriptomic profiling identifies molecular signatures in Pi*MZ carriers with cirrhosis compared with Pi*MM cirrhotic patients and healthy Pi*MM controls. **Methods:** Whole-blood PAXgene RNA sequencing was performed in cirrhotic patients with alcoholic or metabolic dysfunction-associated liver disease carrying the Pi*MZ (n = 6) or cirrhotic patients with the same underlying liver disease carrying Pi*MM (n = 4) SERPINA1* genotype, and healthy Pi*MM controls (n = 2). Differential gene expression analysis was used to identify genotype-associated transcriptional changes, followed by gene set enrichment tests. We focused on the expression profiles of genes associated with inflammatory signaling (*LY96, IL1B, SOCS3, TNFAIP6, CKLF, GPR84*), cell stress and survival response (*BCL2A1, GADD45A, GADD45B, NAIP, SERPINB1, RAB20*), granulocyte inflammatory markers (*S100A8, S100A9, S100A12, MS4A3CLE 4D, AZU1, MPO, ELANE, PRTN3, CTSG*), and genes associated with acute-phase features (*B2M, ORM, LILRA5, MCEMP1*). Blood count parameters were evaluated to determine whether the observed signals reflected differences in circulating immune cell abundance. **Results:** Compared with Pi*MM cirrhotic patients, Pi*MZ carriers demonstrated a distinct blood transcriptomic profile characterized by increased expression of genes associated with neutrophil granules biology. The strongest signals included *AZU1* (log2 fold change (FC) 3.38, false discovery rate (FDR) < 0.05), *MPO* (log2 FC 1.18, FDR < 0.05), and *CTSG* (log2FC 1.32, FDR < 0.05). Evaluation of blood count parameters did not support a simple increase in total neutrophil counts, suggesting that the observed transcriptional changes may reflect altered immune-cell activation states or differences in cellular composition not captured by routine blood measurements. **Conclusion:** Cirrhotic Pi*MZ *SERPINA1* carriers present with a distinct whole-blood transcriptomic profile characterized by increased expression of genes associated with neutrophil granule biology in the absence of differences in total neutrophil count. These findings support the need for further investigation of immune-related alterations and blood-associated molecular signatures in alpha-1 antitrypsin–related liver disease.

1430 | UNDERSTANDING THE DRIVERS OF TREATMENT EXPERIENCE AND ADHERENCE IN WILSON DISEASE – WHAT DO PATIENT INTERVIEWS AND REPORTED OUTCOMES FROM A PHASE 2 STUDY EVALUATING A NEW TRIENTINE TETRAHYDROCHLORIDE FORMULATION TELL US?

C.Omar Kamlin[1] Courtney Hurt[2] Chelsea Perschon[2] John Peipert[3] Aftab Ala[4] Andrew Holt[5] Richard Parker[6] Joanna Moore[7] Elaine Kamara[8] Carla Bennett[8] Nick Manamley[8] Emmanuel Tsochatzis[9], [1]Orphalan, [2]Northwestern University, [3]University of Birmingham, [4]Kings College Hospital, [5]University Hospital Birmingham, [6]Leeds Teaching Hospitals NHS Trust, [7]Leeds University Hospital, [8]Orphalan SA, [9]Royal Free Hospital, London

Background: Wilson disease (WD) is a rare disorder of impaired copper transport requiring lifelong therapy with challenging circumstances (pharmacological and human factors) impacting medication adherence. Patient reported outcomes (PROs) are direct reports from patients without interpretation by a healthcare professional or anyone else, but no WD-specific treatment satisfaction PRO exists. The Food and Drug Administration (FDA) encourages the inclusion of the patient voice in medical product development. Following literature review and prior qualitative interviews, the objective of this study was to describe the patient experience following a switch from standard of care (SoC) to a novel trientine tetrahydrochloride formulation administered once-a-day (QD TETA4) using patient interviews and PRO responses. **Methods:** Phase 2 decentralized study (NCT07010575) of adults with WD (Leipzig score ≥ 4) on maintenance therapy prescribed at least twice daily either a chelator, zinc salts, or combination were switched to QD TETA4 (mg-for-mg rounded to nearest full tablet for chelators or 600mg [2 tablets] for zinc conversion) for 28-days followed by return to SoC for 28-days. Online interviews were conducted by PRO development experts. PROs included Treatment Satisfaction Questionnaire for Medication (TSQM-9 covering convenience, effectiveness, satisfaction domains) and Morisky Medication Adherence Scale (MMAS-8; less than 6 considered poorly adherent). **Results:** Ten (7 male) patients, mean (range) age 35.3 (21-55) years were enrolled with hepatic (2), neurologic (3), mixed (3), asymptomatic (2) phenotypes. SoC therapies were trientine (4), zinc (3), DPA (2) and combination trientine and zinc (1). All subjects were switched to either 2 or 3 QD TETA-4HCl tablets. Nine AEs (8 mild, 1 moderate) were reported in 7 subjects. In interviews, treatment satisfaction was high (5 patients selecting "Very much" and 3 "Quite a bit" to indicate level of satisfaction) with 80% of patients preferring QD TETA4, citing dosing schedule (n = 5), mental load (n = 3), adaptations/planning (n = 2), side effects (n = 2) as benefits over their SoC with a diversity of preference drivers (n = 11) documented. Of those participants asked, QD was rated as "much less challenging" for adherence and "much less disruptive" to daily life (7/9;[78%]). None reported treatment experience worsening. Responses from generic TSQM-9 convenience domain and MMAS-8 are shown in figure. **Conclusion:** Interview insights from people living with WD suggest that QD TETA-4HCl meaningfully reduces treatment burden through dosing simplification, reduced mental load, and fewer planning demands and were corroborated by self-reported improved convenience and adherence after 28 days of QD TETA-4HCl treatment compared to their SoC dosing regimen.

1431 | AGREEMENT BETWEEN MRI-PROTON DENSITY FAT FRACTION AND CONTROLLED ATTENUATION PARAMETER FOR DIAGNOSING HEPATIC STEATOSIS IN A COMMUNITY POPULATION

Linmei Yao[1] Minghui Li[2] Ruyu Liu[2], [1]Department of Hepatology Division 2, Beijing Ditan Hospital, [2]Department of Hepatology Division 2, Beijing Ditan Hospital, Capital Medical University

Background: Magnetic resonance imaging–proton density fat fraction (MRI-PDFF) is the noninvasive reference standard for quantifying hepatic steatosis. Controlled attenuation parameter (CAP) is increasingly used for population screening. We aimed to evaluate the diagnostic accuracy of CAP, determine its optimal cutoff, investigate the impact of age, BMI, and triglyceride (TG) on diagnostic consistency, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

quantify the agreement between CAP and MRI-PDFF in a large community-based population. **Methods:** A total of 1571 community participants were enrolled. Anthropometric, metabolic, and laboratory data were collected. Using MRI-PDFF ≥5% as the reference standard, receiver operating characteristic (ROC) analysis was performed to obtain the optimal CAP threshold. Stratified ROC analyses by age, BMI, and TG were conducted. Spearman correlation and κ statistics were used to assess correlation and agreement. **Results:** CAP was strongly correlated with MRI-PDFF (Spearman ρ = 0.727, 95% CI: 0.698–0.752, P < 0.001). The optimal CAP cutoff was 246 dB/m, with an AUC of 0.849 (95% CI: 0.831–0.868), sensitivity 74.9%, specificity 79.0%, positive predictive value 82.7%, and negative predictive value 70.3%. Stratified analyses showed higher diagnostic performance in participants aged < 60 years (AUC = 0.933), BMI 24–28 kg/m² (AUC = 0.912), and TG < 1.7 mmol/L (AUC = 0.921). Linear weighted κ for four-grade steatosis was 0.469, and binary κ was 0.532 (both P < 0.001), indicating moderate agreement. **Conclusion:** In a general community population, CAP shows good diagnostic accuracy for hepatic steatosis with an optimal cutoff of 246 dB/m. Age, BMI, and TG significantly influence CAP performance. CAP has moderate agreement with MRI-PDFF and is a valid noninvasive tool for population-level screening of hepatic steatosis.

1432 | EPIDEMIOLOGICAL TRENDS, TREATMENT MODALITIES, AND GENOTYPE-PHENOTYPE CORRELATIONS IN WILSON'S DISEASE: A COMBINED ANALYSIS OF A NATIONWIDE COHORT AND A MULTICENTER STUDY

Seong Hee Kang[1] Hyung Joon Yim[1] Young Kul Jung[1] Eun Ju Cho[2] Hye Won Lee[3] Young-Sun Lee[1] Hyo Jung Cho[4] Ji Hoon Kim[1] Jong Eun Yeon[1], [1]Korea University College of Medicine, [2]Seoul National University Hospital, [3]Yonsei University College of Medicine, [4]Ajou University College of Medicine

Background: This study aimed to investigate the nationwide epidemiological shifts, treatment patterns, and mortality risk factors of Wilson's disease (WD) in South Korea, while integrating a multicenter cohort to elucidate specific ATP7B genotype-phenotype correlations and long-term clinical outcomes. **Methods:** We analyzed data from a comprehensive nationwide registry cohort (2008–2022) alongside detailed clinical and genetic datasets from a multicenter cohort (5 centers) of 121 patients who underwent ATP7B mutation testing. Survival analyses and genotype-phenotype evaluations were performed. **Results:** Between 2008 and 2022, the nationwide registry cohort demonstrated that the age-standardized prevalence of WD steadily increased from 4.30 to 12.71 per 100,000 population, consistently showing a male predominance (14.81 vs. 10.61 per 100,000 in 2022). Genetic diagnoses dramatically escalated after 2014, peaking in 2021 (n = 472), and were primarily clustered in the 0–19 age group. Clinical complications significantly increased mortality, with liver cirrhosis (HR 7.99, p < 0.001) and hepatocellular carcinoma (HCC) (HR 1.53, p = 0.007) acting as major independent risk factors. Regarding pharmacotherapy, D-penicillamine and trientine combination therapy significantly reduced the mortality risk (HR 0.43).In the multicenter cohort, ATP7B mutational mapping identified compound heterozygotes (54.5%), heterozygotes (15.7%), homozygotes (13.2%), and wild-type cases (9.1%). Heterozygotes and compound heterozygotes presented at an earlier age (mean 12.9–15.7 years) with lower baseline ceruloplasmin levels. Crucially, homozygous Type 1 (1/1) patients exhibited an exceptionally high rate of liver cirrhosis (56.3%) and a correspondingly high liver transplantation rate (18.8%, p = 0.024). Wild-type patients experienced a significantly delayed diagnosis (mean age 24.8 years) and presented predominantly with neuropsychiatric symptoms (45.5%). **Conclusion:** The prevalence and genetic detection rates of WD are rising continuously in South Korea. Patient clinical trajectories and long-term prognoses are profoundly dictated by ATP7B mutation types. Genotype-stratified risk assessment, and optimal selection of combination pharmacotherapies are crucial to mitigate fatal outcomes driven by hepatic complications.

1433 | NON-INVASIVE ULTRASOUND AND PHOTOACOUSTIC IMAGING OF HEPATIC COMPOSITION AND BIOMECHANICS IN PRECLINICAL MODELS OF METABOLIC LIVER DISEASE USING THE VEVO F2XC AND LAZR-X20

Barry Campbell[1] Anna St. Lorenz[1] Laura Griffin[2] Steven Yeung[3] Sridhar Radhakrishnan[4] Kristiina Aasa[5] Stephen Buttars[1] Stephanie Ly[1] Sarah Burris[1], [1]Fujifilm

VisualSonics Inc., [2]Taconic, [3]Research Diets Inc., [4]Research Diets, [5]Fujifilm VisualSonics Inc

Background: Metabolic liver disease encompasses a spectrum of conditions from steatosis to inflammation, fibrosis, and liver failure. These stages involve changes in hepatic biochemical composition and mechanical properties. Traditional preclinical methods relying on terminal tissue collection, limit longitudinal monitoring of disease progression and therapeutic response in the same animal. To overcome this, our study applied a multimodal imaging approach to acquire anatomical and functional data using ultra-high frequency ultrasound, combined with photoacoustic imaging (PAI) to monitor disease progression. Employing a diet-induced obesity (DIO) mouse model (Taconic Biosciences) of metabolic dysfunction-associated steatohepatitis (MASH), we quantitatively assessed liver stiffness over time, enabling characterization with real-time, non-invasive imaging. **Methods:** Longitudinal imaging was performed on mice fed a high-fat diet (60% kcal fat, Research Diets) using the FUJIFILM VisualSonics Vevo F2xc LAZR-X20, capturing the model's progression from steatosis to fibrosis. Real-time shear wave elastography, a push button mode on the system, measured liver tissue stiffness, while PAI mapped lipid and theoretical collagen content based on distinct spectral signatures. **Results:** Distinct hepatic phenotypes emerged in the DIO model. Although no significant changes were seen with collagen, PAI revealed a strong correlation between liver lipid content and duration of high-fat diet feeding (R^2 = 0.8), indicating progressive fat accumulation. SWE detected early decrease in liver stiffness at 14 weeks, reflecting tissue softening due to increased lipid content, followed by a significant increase at 22 weeks ($p < 0.005$), consistent with presumed maturation of lipid droplets or remodeled extracellular matrix (ECM). These results demonstrate the ability of combined SWE and PAI to differentiate steatosis-associated softening from pre-fibrotic stiffening within the same tissue over time. **Conclusion:** The Vevo F2xc LAZR-X20 integrates shear wave elastography and PAI into a powerful, non-invasive platform for comprehensive, longitudinal liver phenotyping in preclinical models. These studies reveal a biphasic pattern driven by lipids as opposed to fibrosis. Early steatosis softens the liver tissue, consistent with lipid droplets acting to disrupt cytoskeletal tension. The subsequent liver stiffening at 22 weeks, absent of changes in collagen deposition, suggests a fibrosis-independent mechanism such as lipid droplet maturation or ECM remodeling. We plan to expand SWE and PAI applications to other metabolic and vascular models, including atherosclerosis and diet-induced MASH. This will leverage quantitative assessment of stiffness alongside molecular markers such as collagen, and lipids providing comprehensive multimodal insights into disease progression and treatment efficacy.

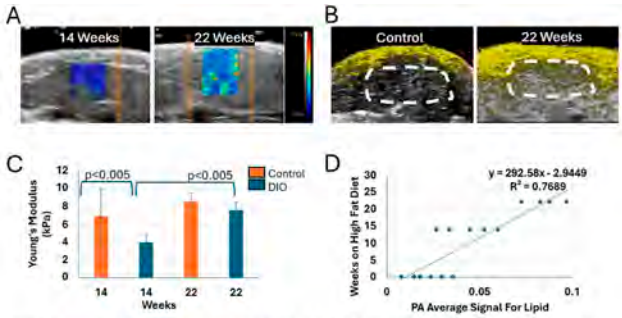

Figure 1. Combined SWE and photoacoustic imaging (PAI) capture lipid-driven, biphasic mechanical responses in pre-fibrotic DIO mice. (A) High-frequency ultrasound and real-time SWE imaging of livers from 14-week (left) and 22-week (right) DIO model mice. **(B)** Unmixed PAI images of lipid (yellow) in a 22-week DIO model mouse (right) and an age-matched control (left). Quantified data were obtained from the region of interest (ROI) within the liver tissue, beneath the fat pad. **(C)** DIO animals exhibited a significant decrease in liver stiffness at 14 weeks compared to age-matched controls, with no significant difference observed at 22 weeks. **(D)** A strong positive linear correlation exists between weeks on the high-fat diet and lipid deposition, as determined by PAI (R^2 = 0.769).

1434 | DE-CENTRALIZED CLINICAL TRIALS IN RARE DISEASE; INCORPORATING THE PATIENT VOICE IN THE EVALUATION OF TOLERABILITY, TREATMENT SATISFACTION AND ADHERENCE OF A NOVEL TRIENTINE TETRAHYDROCHLORIDE FORMULATION FOR THE TREATMENT OF WILSON DISEASE

Emmanuel Tsochatzis[1] Aftab Ala[2] Andrew Holt[3] Richard Parker[4] Joanna Moore[5] Elaine Kamara[6] Carla Bennett[6] Nick Manamley[6] C.Omar Kamlin[7], [1]Royal Free Hospital, [2]Kings College Hospital, [3]University Hospital, Birmingham, [4]Leeds Teaching Hospitals NHS Trust, [5]Leeds University Hospital, [6]Orphalan SA, [7]Orphalan

Background: Wilson disease (WD) is a rare disorder of impaired copper transport requiring lifelong therapy where suboptimal adherence is increasingly recognised. As per US Federal Drugs Agency (FDA)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

guidance, decentralized trials (DT) may reduce participant burden and improve trial efficiency and access to participants, important considerations for rare disease studies. To support the clinical development of a new trientine tetrahydrochloride formulation administered once daily (QD TETA4), a DT was designed to assess tolerability and patient perspective before and after a switch in therapy. **Methods:** Phase 2 DT (NCT07010575) approved by a single centralized ethics committee enrolled adults with WD (Leipzig score ≥ 4) in a single arm switch study identified and referred by 6 UK centres of excellence to a virtual clinical trial centre (VCTC, UK). Medications were dispensed and returned to a remote pharmacy. Assessments (blood draws, online study visits with investigators, completion of patient reported outcome (PRO) questionnaires and online semi-structure patient interviews) were conducted at participants' homes. Participants switched from their standard of care (SoC) maintenance therapy to QD TETA4 (mg-for-mg rounded to nearest full tablet for chelators or 600mg [2 tablets] for zinc conversion) for 28-days followed by return to SoC for 28-days. Adverse events (AEs) were collected. Paper PROs (treatment satisfaction questionnaire for medication [TSQM-9] and Morisky medication adherence score [MMAS-8]) were mailed and collected by courier on 5 fixed dates. **Results:** Ten (7 male) multi-ethnic (>4 groups) individuals, mean (range) age 35.3 (21-55) years were enrolled from 3 major cities in the UK (London, Birmingham, Leeds) with hepatic (2), neurologic (3), mixed (3), asymptomatic (2) phenotypes. SoC therapies were trientine (4), zinc (3), DPA (2) and combination trientine and zinc (1). Nine AEs (8 mild, 1 moderate) were reported in 7 subjects and all resolved. TSQM-9 convenience domain showed significant improvements; mean (90% CI) at baseline, 28d after QD TETA-4HCl and 28d after SoC was 43.1 (26.3, 59.9), 85.0 (78.4, 91.6) [p = 0.008], and 40.7 (26.9, 54.4), respectively. At the same timepoints, TSQM-9 Effectiveness did not change, TSQM-9 Satisfaction improved but not significantly. At same timepoints, adherence significantly improved; MMAS-8 score was 4.8 (3.7, 5.8), 7.7 (7.4, 8.0) [p = 0.002] and 5.0 (4.0, 5.9). A selection of study metrics is shown in the table. **Conclusion:** In the absence of benchmarking for DT trials in WD, our findings confirm the feasibility of successfully completing a DT in rare liver disease with nationwide enrollment, diverse ethnicities and phenotypes reflective of the national population, successful home blood collection with central laboratory analyses. All PROs were fully completed indicating positive impact on convenience and adherence after 28d of well tolerated QD TETA-4HCl treatment.

1435 | EFFICACY OF SEMAGLUTIDE AND RELATED DRUGS IN ANIMAL MODELS OF VARIOUS DISEASES

Yishuang Wei[1] Xingjuan Wang[2] Ping Chen[2] Lingling Chang[2] Danyi Zhu[2] Chenlin Su[2] Ming Ding[2] Yunhan Qiu[2] Liang Xiang[2] Beilei Cai[2] Runan Yin[2] Xin Li[2] Jeff Duan[2] Deming Xu[1], [1]PharmaLegacy Laboratory (Shanghai) Co., Ltd., [2]PharmaLegacy Laboratory (Shanghai) Co. Ltd.,

Background: The glucagon-like peptide-1 (GLP-1) receptor, GLP-1R, and its agonists have become the focal point in recent years, due to its novel mechanism, significant efficacy and broad potential in

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

treating various diseases. We sought to determine the efficacy of GLP-1 peptides and a GLP-1R agonist in animal (rodents and nonhuman primate, NHP) models of various diseases. **Methods:** We selected natural occurring obese cynomolgus monkeys to test semaglutide and orforglipron (small molecule GLP-1R agonist). Rodent models of diet-induced obesity (DIO) were used to test semaglutide, tirzepatide (dual GLP-1 and GIP agonist), bimagrumab (promoting muscle growth) and combination of semaglutide and bimagrumab. Humanized hGLP-1R transgenic mouse was tested for the efficacy of danulipron. Tirzepatide and semaglutide were tested in mouse models for type 2 diabetes (T2D) and MASH, respectively. In addition, rodent models for heart failure with preserved ejection fraction (HFpEF) and alcohol addiction were used to test tirzepatide and semaglutide, respectively. **Results:** 1) In the NHP study, the efficacy of both semaglutide and orforglipron was observed as determined by weight loss. However, the loss of fat mass was accompanied by the loss of lean mass, as seen in the clinics. 2) In a mouse model of DIO, weight loss was observed with tirzepatide, semaglutide + bimagrumab and semaglutide treatments. The level of weight loss correlated with loss of fat mass. The loss of lean mass was observed with tirzepatide and semaglutide, the latter of which was reserved by bimagrumab. Similar results were observed in rats. 3) When danuglipron was tested DIO hGLP-1R mouse, significant weight loss was observed, together with loss of both fat and lean mass. 4) The efficacy of tirzepatide was observed in db/db T2D models. 4) In a CDAHFD rat model for MASH, semaglutide significantly improved steatosis and fibrosis. In a HFD+CCL4 mouse MASH model, similar results were observed. We also performed RNA seq profiling of semaglutide and resmetirom and will share the results. 5) In an HFD+L-NAME induced DIO and HFpEF model, tirzepatide was shown to improve several heart failure-related cardio functions. 6) We are testing semaglutide in a mouse model of alcohol addiction and will share the results. **Conclusion:** The weight loss efficacy of semaglutide and other GLP-1R agonists was observed in DIO models in rodents and NHP. In all cases, weight loss was associated with loss of both fat and lean mass. Bimagrumab prevents loss of lean mass without impacting weight loss. These results are consistent with what has been observed in the clinics. Semaglutide and other agonists were efficacious in rodent models for diabetes, heart failure and MASH. Semaglutide is mechanistically different from resmetirom in treating MASH. We are currently exploring semaglutide in a rodent model for alcohol addiction.

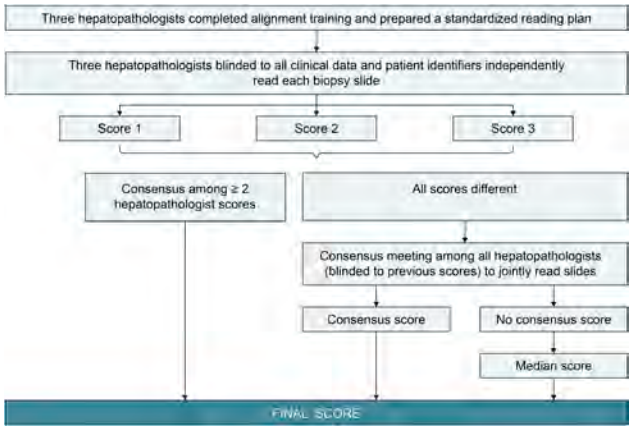
1436 | CONSENSUS PATHOLOGY PANEL READING FOR METAVIR FIBROSIS STAGING AND PAS+D SCORING IN ALPHA-1 ANTITRYPSIN DEFICIENCY CLINICAL TRIALS



Vandana Gupta[1] Seth Pixton[1] Chantal Beauchemin[1] Jen-Chieh Chuang[1] Natasha Darras[1] Jennifer Green[1] Susana Gonzalez[1] Hong Li[1] Divya Shakti[1] Tom Davis[2] Reema Kainth[2] Caitlin Langford[2] Thomas Schluep[3] Virginia Clark[4] Pavel Strnad[5] Cynthia Behling[6] Kay Washington[7] Romil Saxena[8], [1]Takeda Development Centre Americas, Inc., Cambridge, MA, USA, [2]Perspectum Limited, Oxford, UK, [3]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, USA, [4]University of Florida, Gainesville, FL, USA, [5]University Hospital RWTH Aachen, Aachen, Germany, [6]University of California San Diego, San Diego, CA, USA, [7]Vanderbilt University Medical Center, Nashville, TN, USA, [8]Emory University School of Medicine, Atlanta, GA, USA

Background: In alpha-1 antitrypsin deficiency-associated liver disease (AATD-LD), disease burden is determined using biopsy-based METAVIR fibrosis staging and assessment of hepatic accumulation of misfolded Z-alpha-1 antitrypsin by periodic acid–Schiff staining with diastase (PAS+D). However, these measures are subject to inter- and intra-reader variability. Regulatory guidance supports the use of histological endpoints in clinical trials if variability is minimized through standardization (reader training, calibration and consensus-based assessments). In AATD-LD clinical trials, harmonization of METAVIR and PAS+D-based scores ensure consistent and reliable biopsy interpretation. This study aimed to establish a consensus scoring method for METAVIR fibrosis staging and PAS+D. **Methods:** Archived liver biopsy samples from adults with AATD-LD, viral hepatitis or metabolic dysfunction-associated steatohepatitis were analyzed for METAVIR fibrosis stage and PAS+D burden (AATD-LD samples only). Slides stained with both Masson's trichrome and hematoxylin and eosin from 55 biopsy samples were used for METAVIR fibrosis staging, and 86 biopsy samples (across two batches) were analyzed for PAS+D burden. Digitized slides were assessed independently by three hepatopathologists who had previously completed alignment training and prepared a standardized reading plan. METAVIR fibrosis stage was scored from F0 to

F4, and PAS+D components (zonal location, percent portal tract involvement, percent of zone 1 periportal involvement and number of hepatocytes involved per high power field) were scored from 0 to 3 (least severe to most severe) for each component. The consensus method is shown in the **Figure** . **Results:** For METAVIR fibrosis staging (n = 55), consensus agreement (≥ 2 hepatopathologists) was 94.5% and inter-reader concordance (overall Krippendorff's alpha [K-a]: 0.71) was consistent with the literature for well harmonized readers. After a 4-week washout period, there was good intra-reader reproducibility following slide re-scoring (overall percent intra-reader agreement for each hepatopathologist ranged between 72.2% to 90.9% and K-a ranged from 0.81 to 0.94). Across two batches assessed for PAS+D burden, consensus across PAS+D components was 86.4% to 97.6%. When all readers assigned different scores, a consensus meeting resulted in an agreed score for METAVIR fibrosis stage and individual PAS+D components. **Conclusion:** This study demonstrated a robust and reproducible consensus multi-reader approach for METAVIR fibrosis staging and PAS+D burden. These data support the utility of longitudinal histological assessment in the ongoing phase 3 fazirsiran trial in AATD-LD.Writing support provided by R Tooze, Oxford PharmaGenesis.

1437 | LONG-TERM OUTCOMES OF ZINC THERAPY IN WILSON DISEASE: A 25-YEAR RETROSPECTIVE STUDY

Frederick Askari[1] Ashley Page[2] Graham Brady[2] Matthew Lorincz[2], [1]University of Michigan Medical Center, [2]University of Michigan

Background: Wilson Disease is a disorder of copper metabolism characterized by toxic copper accumulation in the liver and central nervous system, requiring lifelong treatment. Zinc monotherapy is widely utilized for maintenance therapy due to its ability to inhibit intestinal copper absorption. However, there is limited data at two decades of use on long-term clinical outcomes, real-world adherence, and tolerability. **Methods:** Retrospective chart review identified Wilson Disease patients managed primarily with zinc for 20 years or more at the University of Michigan. Medical charts assessed the availability and frequency of clinical data, including disease presentation, liver biochemistry, and non-invasive markers (APRI, MELD, FIB-4), and 24 hour urinary copper and zinc levels. Adherence and adverse effects were evaluated by urinary zinc levels and systematic review of clinical documentation. **Results:** The cohort included 21 patients (mean age 58, 60% female) with hepatic, and/or neuropsychiatric, as well as asymptomatic individuals. Hepatic function remained stable with long-term zinc therapy. Mean laboratory cumulative mean values included AST 39.5 IU/L, ALT 54.6 IU/L, albumin 4.3 g/dL, and INR 1.2. Noninvasive fibrosis markers were relatively stable, with mean APRI 0.81 (Δ -0.35), FIB-4 2.09 (Δ 0.17), and cumulative MELD score 9.17 (Δ 0.90); Δ values represent cumulative changes from baseline to most recent measurement. Adequate zinc therapy was associated with urinary copper excretion < 100 µg/24 hours. Approximately 71% of patients experienced periods of nonadherence, demonstrated by intermittent urinary copper elevations (> 100−200 µg/24 hours), fluctuating urinary zinc levels, and difficulty maintaining TID dosing regimens. Wide ranges of urine copper levels (6.1−942 µg/24 hours) were observed, with higher values partly explained by transient use of combination chelation therapy. Gastrointestinal adverse effects (nausea, vomiting, abdominal discomfort) were observed and necessitated antiemetics, zinc dose adjustments, or change in treatment. Five patients temporarily transitioned to chelation therapy, and two permanently discontinued zinc due to intolerance and adherence burden.Two deaths were observed: a 65-year-old male while carrying a diagnosis of cholangiocarcinoma and 84-year-old female in the setting of senescence, dementia, anxiety, and cholangiocarcinoma. **Conclusion:**

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

Long-term zinc therapy is effective and safe when adherence is maintained, supporting hepatic stability. However, real-world effectiveness is limited by challenges with adherence and gastrointestinal intolerance. These findings underscore the need for improved zinc formulations and drug delivery strategies to reduce treatment burden and optimize long-term outcomes.

Table 1: Cumulative Cohort Characteristics and Changes Over Time

Variable	Cumulative Mean ± SD	Cumulative Median (Range)	Δ Cumulative Mean (Baseline → Recent)	Δ Cumulative Median (Baseline → Recent)
Age (years)	58.0 ± 12.3	61.1 (35.7–82.7)	—	—
Urine Copper (µg/24h)	77.85 ± 60.43	67.50 (5.1–842)	-44.86 ± 182.33	-15.3 (-803.4 to 123.9)
Urine Zinc (µg/24h)	4639.49 ± 2620.06	4262.00 (117–21696)	-172.67 ± 3064.37	-1018 (-4360 to 6915)
AST (U/L)	39.50 ± 39.06	30.00 (10–440)	-17.14 ± 35.54	-3 (-84 to 34)
ALT (U/L)	54.67 ± 81.42	36.00 (4–644)	-31.62 ± 49.01	-17 (-126 to 51)
Albumin (g/dL)	4.31 ± 0.87	4.30 (1.60–9.95)	-0.22 ± 1.56	0.2 (-4.95 to 1.3)
INR	1.23 ± 0.46	1.10 (0.90–4.49)	0.01 ± 0.36	0 (-1 to 1.22)
APRI	0.81 ± 1.32	0.45 (0.14–13.61)	-0.35 ± 0.57	-0.06 (-1.65 to 0.40)
FIB-4 Score	2.09 ± 2.14	1.38 (0.22–25.56)	0.17 ± 1.72	0.20 (-3.07 to 4.69)
MELD Score	9.17 ± 3.79	8 (6–36)	0.90 ± 3.17	0 (-7 to 9)

* Δ cumulative mean and median values reflect the change within the cumulative cohort from baseline to the most recent measurement.

1438 | P.GLY1341SER AS A FREQUENT REGIONAL ATP7B VARIANT IN WILSON DISEASE: GENOTYPIC SPECTRUM AND AGE-STRATIFIED CLINICAL HETEROGENEITY FROM A SOUTH INDIAN REFERRAL CENTER

Rajat Prabhakar Pande[1] Vivek Ashokan[1] Blessline Sampath Kumar[2] MadhuSuriya M[1] Joeimon JL[1] PremKumar K[1] PremKumar K[1], [1]Madras Medical College & Rajiv Gandhi Government General Hospital, Chennai., [2]Madras Medical College & Rajiv Gandhi Government General Hospital, Chennai

Background: Wilson Disease is a rare autosomal recessive disorder of impaired copper metabolism. Despite a well characterized pathophysiology, genotype- phenotype heterogeneity persists across age groups. Mutational data from South India remain sparse; regional founder variants may distinctly alter the local phenotypic landscape. **Methods:** This is an ambispective single-center study involving Wilson disease patients aged >13 years with hepatic involvement (**pure neurological Wilson disease excluded**). Standard clinical, biochemical, and imaging parameters were recorded. Next-generation sequencing of *ATP7B* was performed. The patients were further **divided into three groups based on their age, Group A (13-17 years), Group B (18-25 years), Group C (> 25 years) to ascertain genotype- phenotype correlates and clinical outcomes. Results:** The study involved 86 cases with a mean age of 23.11 ± 8.07 including 52.3% males. Decompensated cirrhosis was the predominant presentation across all groups (42.9% vs 44.1% vs 32.6%), followed by neurohepatic disease (30.7% vs 23.5% vs35.2%) **ALF/ACLF was significantly high in adolescent age group (14.3% vs 2.9% vs 5.0%) Neuro-Hepatic phenotypes demonstrated delayed diagnosis and higher disability burden despite lower hepatic biochemical severity.** On a median follow up of 1358 days, the adolescent group recorded highest event burden (23.3% vs 11.7% vs 17.6%) although event-free survival did not differ significantly across age groups (log-rank p = 0.291) Genetic sequencing of 33 patients identified 18 distinct ATP7B variants, **Notably, p.Gly1341Ser (exon 19), identified in 15.2% of patients and infrequently reported from India, emerged as one of the most common mutations in our cohort surpassing established pan Indian variants** followed by c.813C > A (p.Cys271Ter) in 12.1% and c.3182G > A (p. Gly1061Glu) in 9.1% and other rare variants. **Missense mutations predominated (60%)** followed by frameshift (15%) and stop-gained variants (12.5%). **On genotype–phenotype correlation analysis, hepatic manifestations were more frequent among homozygous patients compared to neurohepatic disease (59.1% vs 40.9%) however, zygosity pattern was not significantly associated with clinical phenotype (p = 0.493).** Substantial **phenotypic heterogeneity persisted despite a high prevalence of homozygous mutations (60.6%) and consanguinity (42.2%) Conclusion:** Wilson disease demonstrates marked age-dependent phenotypic heterogeneity with **genotype-phenotype discordance transcending zygosity. The regional predominance of p.Gly1341Ser over the established pan-Indian variant p.Cys271Ter reinforces the necessity of comprehensive genetic analysis** in patients with Wilson disease. These findings underscore the need for **region-specific mutational registries to refine phenotypic correlation, risk stratification, and advance precision medicine-based management strategies** in South Asian populations.

1439 | EVALUATION OF DIGITIZED WHOLE SLIDE IMAGING FOR METAVIR LIVER FIBROSIS STAGING: CONCORDANCE WITH CONVENTIONAL GLASS SLIDE READING

Jennifer Green[1] Adam Tellier[1] Vandana Gupta[1] Jen-Chieh Chuang[1] Susana Gonzalez[1] Paresh Thakker[1] Tom Davis[2] Reema Kainth[2] Caitlin Langford[2] Thomas Schluep[3] Kay Washington[4], [1]Takeda Development Center Americas, Inc., Cambridge, MA, USA, [2]Perspectum Limited, Oxford, UK, [3]Arrowhead Pharmaceuticals, Inc., Pasadena, CA, USA, [4]Vanderbilt University Medical Center, Nashville, TN, USA

Background: Liver biopsy is the reference standard for fibrosis assessment in patients with alpha-1 antitrypsin deficiency-associated liver disease (AATD-LD). Histopathologist-assigned METAVIR fibrosis staging defines liver fibrosis severity and is a key regulatory endpoint for evaluating treatment efficacy in clinical trials. However, conventional glass slide review by histopathologists imposes substantial operational burden. Modernized digital pathology approaches that permit efficient and robust METAVIR fibrosis staging by multiple readers in parallel can streamline histopathologist scoring of clinical trial endpoints in fibrotic liver diseases, including AATD- LD. We evaluated agreement between review of digitized whole slide images (WSI) and conventional glass slides to support METAVIR fibrosis staging in clinical trials. **Methods:** Liver biopsy samples from patients with fibrosis (F0–F4) and/or metabolic dysfunction-associated steatohepatitis (MASH) were evaluated on stained slides (Masson's trichrome [MT; n = 60] or hematoxylin and eosin [H&E; n = 20]). Sample processing, sectioning and slide staining was performed in a central lab using standardized methods and slides were scanned at 40x magnification. Paired digitized WSI and glass slides were evaluated in a blinded, randomized manner by an expert hepatopathologist according to the College of American Pathologists' guidelines (sequential 1-week glass and WSI reads separated by a 2-week wash-out period with no reads performed). Agreement between digitized WSI and glass slides was evaluated for specimen quality, number of complete portal tracts (< 6 vs ≥ 6), METAVIR fibrosis stage and presence/absence of MASH. Overall percent agreement (OPA) and weighted Cohen's kappa (κ) statistics were calculated. **Results:** There was strong agreement between the 80 digitized WSI and glass slides for the number of portal tracts (< 6 or ≥ 6); OPA was 97.5%. Specimen quality showed 100% agreement, with 2/80 slides (one MT- and one H&E-stained) deemed unacceptable by both digitized WSI and glass slides. For the 59 MT-stained samples with acceptable quality, there was high agreement for METAVIR fibrosis staging with an OPA of 88.1% and weighted Cohen's κ of 0.97. For the samples with disagreement, all were within one stage difference. For the 19 H&E-stained samples with acceptable quality, there was complete agreement (100%) for the assessment of presence/absence of MASH. **Conclusion:** Digitized WSI demonstrated strong agreement with conventional glass slide reading for portal tract assessment, METAVIR fibrosis staging and MASH classification. These findings support the use of digital WSI as a robust method for histological assessment and highlight its potential as a scalable option for pathology evaluation in clinical trials requiring METAVIR fibrosis evaluation.Writing support provided by C Bartley, Oxford PharmaGenesis.

1440 | FROM INFANTILE HYPERTRIGLYCERIDEMIA TO HEPATOCELLULAR CARCINOMA AT AGE 46: THE FIRST REPORTED CASE OF GPD1 DEFICIENCY CAUSING CIRRHOSIS AND LIVER CANCER IN AN ADULT

HuiDan Sun[1] Dazhi Zhang[1] Yu Lei[1] Ying Huang[1], [1]The 2nd Affiliated Hospital of Chongqing Medical University

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Transient infantile hypertriglyceridemia (HTGTI) is a rare autosomal recessive disorder caused by mutations in the *GPD1* gene. Although HTGTI typically presents in early childhood with hepatomegaly, hepatic steatosis, and hypertriglyceridemia, adult presentation is exceedingly rare. Progression to cirrhosis and hepatocellular carcinoma (HCC) has rarely been described. **Methods:** A 46-year-old woman with short stature (height 144 cm, weight 45 kg, BMI 21.7 kg/m^2) and a history of hypertriglyceridemia presented with recurrent liver dysfunction for more than one year. Routine evaluation excluded common etiologies, including viral, alcoholic, drug-induced, liver parasitosis and cholestatic liver diseases. Transient elastography demonstrated significant steatosis (CAP 278 dB/m) and cirrhosis (LSM 21.7 kPa). Contrast-enhanced MRI/CT demonstrated a hypervascular nodule in segment II, concerning for HCC, and the patient subsequently underwent partial hepatectomy. Histopathology confirmed moderately differentiated HCC with underlying cirrhosis and macrovesicular steatosis. Given the cryptogenic nature of the liver disease, whole-exome sequencing was performed and identified a homozygous pathogenic variant in the *GPD1* gene. **Results:** Despite mildly elevated AMA-M2, histopathology revealed no evidence of autoimmune hepatitis, primary biliary cholangitis, or primary sclerosing cholangitis. Imaging revealed cirrhosis, steatosis, splenomegaly, portal hypertension, and a segment II hypervascular lesion. Pathology confirmed moderately differentiated HCC on a cirrhotic background. To further clarify the cause of the disease, genetic testing identified a homozygous splice-site variant in *GPD1*(chr12:50499329; c.220-2A > G), with parental and offspring testing confirming heterozygous carrier status. To our knowledge, this is the first reported case of genetically confirmed HTGTI caused by *GPD1* deficiency presenting with both cirrhosis and HCC in a 46-year-old adult. Following treatment with fenofibrate and ursodeoxycholic acid, triglyceride levels normalized, liver function improved, and liver stiffness decreased . **Conclusion:** We recommend that genetic testing for *GPD1* deficiency be performed routinely in all adults presenting with cryptogenic cirrhosis or HCC, as long as hypertriglyceridemia and short stature are present. Screening for HTGTI prevents misdiagnosis, minimizes therapeutic delays, and enables early intervention—including family counseling—prior to the onset of irreversible liver failure or malignancy.

1441 | PLASMA ZINC AS A MARKER OF ADHERENCE TO ZINC THERAPY IN WILSON DISEASE

Klara Marie Evensen[1] Camilla Lorenzen[1] Karen Boysen[1] Tea Laursen[1] Chris Harrington[2] Karl Heinz Weiss[3] Isabelle Mohr[3] Peter Ott[1] Asim Ulcay[4] Michael Schilsky[4] Thomas Sandahl[5], [1]Department of Hepatology and Gastroenterology, Aarhus University Hospital, ERN RARE-Liver, Aarhus, [2]SAS Trace Element Laboratory, Berkshire and Surrey Pathology Services, Royal Surrey Hospital, Guild, [3]Department of Gastroenterology and Hepatology, University Hospital Heidelberg, Heidelberg, Germany, [4]Yale School of Medicine, Yale University, New Haven (CT), US, [5]Department of Hepatology and Gastroenterology, Aarhus University Hospital, ERN RARE-Liver, Aarhus,

Background: Zinc is widely used for maintenance therapy in Wilson disease (WD), but poor adherence to the multiple daily dosing required for copper control remains a major challenge. Monitoring adherence to zinc therapy typically relies on 24-hour urinary zinc excretion (U-zinc), which reflects both zinc intake and absorption. Plasma zinc (P-zinc) offers an alternative that does not require 24-hour urine collection, but its clinical utility as an adherence marker remains unclear. We evaluated the relationship between P-zinc and U-zinc, and the performance of P-zinc for identifying adherence to zinc therapy in WD. **Methods:** In this retrospective multicentre study, patients with WD receiving zinc therapy at three tertiary referral centres were included if paired P-zinc and U-zinc measurements obtained within 30 days were available. Adherence thresholds were defined as > 19 µmol/L for P-zinc and > 18 µmol/24h for U-zinc, corresponding to the upper limit of normal (ULN) for both markers. U-zinc served as the reference standard for adherence classification as adherent or non-adherent. Patients were stratified by treatment regimen into zinc monotherapy or combination therapy with zinc and chelation therapy. Associations between P-zinc and U-zinc adherence classifications were evaluated using Fisher's exact test. **Results:** 74 patients were included: 53 on zinc monotherapy and 21 on combination therapy. In patients receiving monotherapy, P-zinc adherence classifications were significantly associated with U-zinc classifications ($p = 0.0001$). P-zinc identified adherence with 96 % sensitivity and a positive predictive value (PPV) of 93 % (Figure 1A). As expected with concomitant chelation therapy, no significant association between P-zinc and U-zinc classifications was observed in patients receiving combination therapy ($p = 0.2620$). Misclassifications were substantially more frequent in this group, particularly false negatives (Figure 1B). Median P-zinc concentrations were 27.6 µmol/L (IQR 22.0-31.4) during monotherapy and 15.0

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

µmol/L (IQR 13.2-20.0) during combination therapy. Median U-zinc concentrations were 45.7 µmol/24h (IQR 24.7-63.2) and 36.6 µmol/24h (IQR 18.6-63.7), respectively. **Conclusion:** P-zinc may serve as a practical rule-in marker of adherence in patients with WD receiving zinc monotherapy, with potential utility as a simplified monitoring tool in routine care. However, this measure may not be as useful for combination therapy. P-zinc should therefore be interpreted as a complementary marker of zinc intake and absorption rather than a standalone measure of treatment efficacy or copper control.

A

Zinc Monotherapy		U-zinc > 18 µmol/24h		
		Adherent	Non-Adherent	Total
P-zinc > 19 µmol/L	Adherent	42	3	45
	Non-Adherent	2	6	8
	Total	44	9	53

B

Zinc Combination Therapy		U-zinc > 18 µmol/24h		
		Adherent	Non-Adherent	Total
P-zinc > 19 µmol/L	Adherent	6	0	6
	Non-Adherent	10	5	15
	Total	16	5	21

Figure 1: *2x2 contingency tables of adherence classifications based on P-zinc versus U-zinc in patients receiving (A) zinc monotherapy and (B) zinc combination therapy. Thresholds for adherence were defined as > 19 µmol/L for P-zinc and > 18 µmol/24h for U-zinc. U-zinc was used as the reference standard for adherence classification.*

1442 | NEW SUBMISSION PHARMACOKINETIC DIFFERENCES BETWEEN TRIENTINE DIHYDROCHLORIDE CAPSULE FORMULATIONS: A RANDOMIZED CROSSOVER STUDY

Steffen Wahler[1] Karl Heinz Weiss[2], [1]St. Bernward GmbH, [2]Heidelberg University

Background: Trientine dihydrochloride is an established copper chelator for Wilson disease. Because treatment is lifelong, pharmacokinetic (PK) differences between formulations may be clinically relevant when products are initiated or switched. We compared a 250 mg test capsule with a 300 mg reference capsule. The products differed in marketed strength and capsule/formulation characteristics, providing a setting to assess formulation-specific PK behavior. **Methods:** This randomized, open-label, balanced, two-treatment, two-period crossover study enrolled 36 healthy adults under fasting conditions. Test and reference products were administered as single doses separated by a 7-day washout. Plasma trientine and N1-acetyl-triethylenetetramine were measured by validated LC-MS/MS up to 48 h. PK parameters were derived by non-compartmental analysis. Bioequivalence was assessed using log-transformed Cmax and AUC0-t. Exploratory pooled analyses across 70 PK observations evaluated associations between baseline characteristics and Cmax or AUC0-t. **Results:** Thirty-five subjects completed both periods and were included in PK analyses. Absorption was faster with the test product, with median Tmax 1.25 h versus 2.25 h for reference ($p < 0.0001$). Mean Cmax was 934.0+/-345.0 versus 832.3+/-370.9 ng/mL, AUC0-t 4,525.4+/-2,354.6 versus 3,503.7+/-1,898.0 h*ng/mL, and AUC0-inf 4,771.2+/-2,450.1 versus 3,684.7 +/-1,968.7 h*ng/mL. Half-life was comparable (11.3 +/-7.5 vs 9.5+/-5.8 h). Unadjusted test/reference ratios were 114.96% for Cmax and 109.36% for AUC0-t, with 90% CIs 104.40-126.60% and 98.40-121.55%; dose-normalized ratios increased to 137.95% and 131.24%. Metabolite exposure was similar (Cmax 610.5+/-248.5 vs 661.3+/-311.1 ng/mL; AUC0-t 6,367.0+/-2,308.0 vs 6,820.7+/-2,955.6 h*ng/mL).In exploratory analyses, higher AUC0-t was observed in males versus females (3,850.6 vs 2,606.9 h*ng/mL, $p = 0.040$), serum creatinine > 0.92 versus $<= 0.92$ mg/dL (4,295.6 vs 3,083.1, $p = 0.008$), urinary pH $<= 6$ versus > 6 (4,205.1 vs 3,036.3, $p = 0.010$), and epithelial cells 0-1 versus higher categories (4,829.5 vs 3,089.0/3,137.4, $p = 0.001$). Lower leukocytes were associated with higher Cmax and AUC0-t.Five mild, non-drug-related

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

adverse events occurred; no serious adverse events occurred. **Conclusion:** The 250 mg test capsule showed faster absorption and higher exposure per mg than the 300 mg reference product, while both formulations were well tolerated. Exploratory pooled analyses suggest that sex, creatinine, leukocyte count, urinary pH, and urinary epithelial cells may contribute to interindividual trientine exposure variability. These hypothesis-generating findings require confirmation in multivariable analyses and patient cohorts.

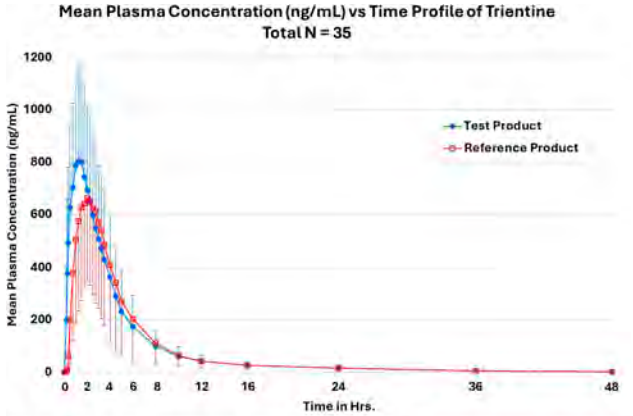

Figure. Mean plasma concentration-time profile of trientine after single oral administration of the 250 mg test and 300 mg reference formulations under fasting conditions (n=35). Error bars represent standard deviations.

1443 | MODERN PATIENT PERSPECTIVES IN ALPHA-1 ANTITRYPSIN DEFICIENCY

Sheryl Denker[1] Wes Anderson[1] Gina DeAngelo[1] Jon Hagstrom[2] Kitty Bogy[1] Collin Hovinga[1], [1]Critical Path Institute, [2]Alpha-1 Foundation

Background: Alpha-1 antitrypsin deficiency affects 3+ million people globally; there is no cure. For 30 years, augmentation therapy has been the only option for pulmonary disease, with no option other than liver transplant for hepatic disease. As innovations in molecular, oral, and chaperone therapies work their way through clinical trials, the imperative exists to update the patient perspective for modern times. This is particularly true for alpha-1 antitrypsin deficiency (AATD), where a Patient Focused Drug Development meeting was last held by the FDA in 2015. A 2025 workshop and survey held by the Critical Path Institute's alpha-1 consortium addressed current knowledge gaps. **Methods:** In September 2025 over 100 patients, clinicians, industry members and advocates convened in Washington, DC and virtually for the workshop, *Shaping the Future of AATD: Patient Perspectives to Drive the Next Decade of Innovation in Alpha-1 Antitrypsin Deficiency*. In parallel, an online patient/caregiver survey, C PA -1 P atient E xperience S urvey U pdate for iN novation (CAPESUN), was developed in partnership with CPA-1 member patient advocacy groups. Survey data were analyzed using R [4.5.2]. Categorical variables were compared using Chi-Squared analysis or Fischer's Exact test based on data frequency, with $p < 0.05$ as statistically significant. Key themes discussed during the workshop were determined by analysis of the de-identified transcript. **Results:** Workshop attendance included 46% alpha-1 patients/caregivers; thematic analysis identified seven categories of concerns emphasizing the multisystem nature of the disease with substantial burden beyond lung and liver. 713 self-identifying patients/caregivers responded to CAPESUN with 22 genotypes represented: ZZ (60%), MZ (22%), SZ (10%), and MS (1.7%). Half (55%) of ZZ respondents reported having liver elastography; 58% of MS indicated steatosis/fatty liver disease, and 13% of MZ indicated intrahepatic cholestasis of pregnancy. Across all genotypes, 22% participated in clinical trials. Oxygen use and liver transplant status were used to determine disease severity cohorts; cohort analysis revealed willingness to participate in placebo controlled clinical trials is influenced by lung but not liver disease severity. Both transcript and CAPESUN indicated patients with advanced liver disease have higher tolerance for uncertainty and risk when participating in clinical trials. **Conclusion:** This work captures a comprehensive view of the alpha-1 patient perspective in modern day drug development. Those with serious liver disease will accept more risk in clinical trials although biopsy is burdensome and limiting; patients want non-invasive testing. Patients indicate endpoints and biomarkers do not reflect their lived experience, and they describe a range of clinically meaningful benefit: maintain current liver function, prevent additional decline, or ultimately repair damage.

1444 | THE CONNECTION BETWEEN HEREDITARY HEMOCHROMATOSIS & PORPHYRIA CUTANEA TARDA: A SYSTEMATIC REVIEW AND META-ANALYSIS OF POPULATION-BASED STUDIES

Somtochukwu Abazu[1] Arif Qazi[2], [1]Howard University, [2]HCA Florida Healthcare Brandon Hospital

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Hereditary hemochromatosis (HH) is a prevalent autosomal recessive disorder caused primarily by HFE gene mutations, especially C282Y and H63D, resulting in systemic iron overload. Porphyria Cutanea Tarda (PCT), the most common porphyria and manifests photosensitivity and hepatic siderosis and is believed to be triggered by iron overload. This systematic review and meta-analysis assess the relationship between HFE gene mutations and the risk of PCT. **Methods:** A comprehensive literature search was conducted using PubMed, Scopus, and Web of Science databases through May 2025. Inclusion criteria were population-based or clinical cohort studies reporting the prevalence of HFE mutations in individuals with PCT. Ten studies met inclusion criteria, with over 800 PCT cases. Data extraction included study design, population demographics, genotype prevalence, and odds ratios (ORs). A random-effects model was used to calculate pooled odds ratios with 95% confidence intervals (CIs). **Results:** The pooled analysis demonstrated a significant association between HFE mutations and PCT with an odd's ratio of 2.85 with a confidence interval of 95%. The majority of the studies determined that the C282Y homozygosity conferred the highest predisposition to PCT. Additionally, most studies reported iron overload and hepatic siderosis among mutation carriers. Geographic differences were acknowledged, but the findings remained consistent across all diverse populations. **Conclusion:** There is a strong association between HFE mutations particularly C282Y and PCT. Genetic screening for hereditary hemochromatosis in patients with PCT should be considered to enable early detection and iron-reduction therapy, potentially preventing progression of disease. Future prospective studies should explore whether early intervention alters the clinical course of PCT.

1445 | ALPHA-1 FOUNDATION RESEARCH REGISTRY: LIVER AFFECTED ALPHA-1 ANTITRYPSIN DEFICIENCY PATIENTS AND WORKPLACE TOXIN EXPOSURE IN THE UNITED STATES

Nadine Nuchovich[1] Alison Keaveny[1] Jennifer Illarramendi[1] Randel Plant[1] Monica Goldklang[2] Jeanine D'Armiento[3], [1]Alpha-1 Foundation, [2]Columbia University Irving Medical Center, [3]Columbia University Irving Medical Center and Alpha-1 Foundation

Background: Alpha-1 Antitrypsin Deficiency (AATD) is a rare genetic condition that leads to increased risk of liver disease, particularly when compounded with workplace exposures to environmental hepatotoxins. Patients' career choices may cause long-term exposure to toxicants, and with millions of adults in industrial and agricultural professions, it is critical to examine a snapshot of liver-affected AATD patients and their workplace exposures. **Methods:** We looked at 1054 who reported yes to liver disease (fatty liver, cirrhosis, cholestasis and severe liver disease manifestations) and further examined 412 A1F Registry adult participants who reported yes to liver hepatotoxin workplace exposure including agricultural and organic dusts, combustion, smoke and exhaust, as well as metal fumes and industrial process particles. **Results:** Participants with liver disease and workplace exposures to liver toxicants reported a mean age of 54.95 (+/- 14.85), with a quarter of patients (32.5%) below the age of 50 (N = 412). Half were female (52.4%),predominantly PiZZ (38.8%) or PiMZ genotype (27.6%), and reported average age of AATD diagnosis 46.08 yrs (+/-16.01). Participants largely report being exposed to fire, smoke, or other combustion particles (63.1%), indoor fuel powered motors, compressors, or engines (45.4%), silica, sand, concrete and cement dust (36.7%), cadmium, batteries, or other metal dust or fumes (37.8%), and/or welding or flame cutting (27.2%). Lifestyle behaviors showed high rates of current drinking (45.1%) but low current smoking (10.6%). Patients largely reported fatty liver (64.8%), with 18.4% reporting cirrhosis, 5.6% with cholestasis and 27.7% report having symptoms of severe liver disease such as ascites (8.3%), variceal bleeding (2.9%) and bacterial peritonitis (1.7%). Patients also report high rates of lung disease including emphysema (33.2%), COPD (45.7%), bronchiectasis (24.3%) and adult asthma (39.5%) and are largely tested due to lung symptoms (43.4%). 8.2% of patients report having been to the hospital due to Alpha-1 in the previous 12 months an average of 2.28 times. Current AAT replacement therapy was noted in a third of the cohort (32.2%), and 22% required current supplemental oxygen. **Conclusion:** A significant number of liver affected A1F participants report exposure to workplace hepatotoxin particulates which may exacerbate AATD liver disease. In AATD, proactive counseling and patient education on minimizing environmental exposures, and lifestyle behavior risks, is crucial to guide occupation decisions that may affect disease progression. While there is currently no cure for AATD related liver disease, career choices can impact exposure to these toxins that can further impair liver health.

1446 | METABOLIC AND CIRCADIAN PATHWAY DYSREGULATION IN WILSON DISEASE: INSIGHTS FROM TRANSCRIPTOMIC ANALYSIS

Doyoon Kim[1] Jayden Trac[1] Nora Spuler[1] Marie Heffern[1] Noreene Shibata[1] Valentina Medici[1], [1]University of California Davis

Background: Wilson disease (WD) is an inherited disorder caused by pathogenic variants affecting the ATP7B gene, leading to impaired biliary copper excretion and progressive accumulation of copper in the liver, brain, and other tissues. WD demonstrates marked clinical heterogeneity, with hepatic, neurologic, and psychiatric manifestations that vary substantially in age of onset, severity, and progression. This phenotypic variability remains incompletely understood and cannot be fully explained by genotype alone. Sleep disturbances have been extensively described in WD and may have an impact on clinical outcomes as it has been proven in common metabolic liver diseases. Growing evidence indicates that an interplay between genetic and metabolic factors, including those regulated by the circadian cycle, may combine to affect the disease phenotype. We hypothesize that gene expression in WD is regulated through the circadian cycle with differential gene expression in the liver and in the intestine. **Methods:** Experiments were performed in female *Atp7b*$^{-/-}$ knockout mice, a model of genetic copper accumulation, and *Atp7b*$^{+/-}$ heterozygous mice with normal copper metabolism (n = 3/genotype and time point). Sixteen-week-old mice were euthanized at 12:00 pm (day) and 12:00 am (night). At the end of the experiment, livers and intestines were obtained for bulk RNA-sequencing. **Results:** RNA sequencing analysis identified 6,384 liver genes differentially expressed in *Atp7b*$^{-/-}$ vs *Atp7b*$^{+/-}$ during the day and 9,902 liver genes at night. In addition, a larger number of liver transcripts differentiated *Atp7b*$^{-/-}$ mice day vs night compared to *Atp7b*$^{+/-}$ mice day vs night. The analysis also identified 628 intestine genes differentially expressed in *Atp7b*$^{-/-}$ mice vs *Atp7b*$^{+/-}$ during the day and 665 intestine genes at night. A larger number of intestine transcripts also differentiated Atp7b$^{-/-}$ mice day vs night compared to intestine *Atp7b*$^{+/-}$ mice day vs night. Enrichment analyses identified pathways related to circadian rhythm regulation, lipid and fatty acid metabolism, mitochondrial energetics, oxidative phosphorylation, inflammatory signaling, and cellular stress responses. **Conclusion:** These findings support a model in which phenotypic presentation in WD may arise not only from ATP7B genetic variants but also from circadian cycle-regulated disturbances in metabolic and mitochondrial pathways.

1447 | NATURAL HISTORY OF PATIENTS WITH WILSON'S DISEASE: A SINGLE CENTER EXPERIENCE

Youseph Karouni[1] Clavia Ruth Wooton-Kee[1] Karim Adhem[1] Ximena Ramirez Morlaes[1] Mohamad Ali Ibrahim[1] Nagham Ramadan[1] Mazen Elsheikh[1] Prasun Jalal[1], [1]Baylor College of Medicine

Background: Wilson's Disease (WD) is a rare (about 1 in 30,000) autosomal recessive liver disease caused by mutations in the ATP7B gene, resulting in excess copper deposition in the eyes, liver, and brain. This can manifest in patients as acute liver failure, chronic liver disease and neuro-psychiatric disorder. Several Wilson's Centers of Excellence have been established to provide specialized medical care and community for these patients. The aim of this study was to outline the outcome of patients with WD at Baylor College of Medicine. **Methods:** We performed a retrospective chart review of patients identified in an electronic database search (search terms: penicillamine, trientine, zinc (any formulation); Wilson's Disease diagnosis code in the period between 2015-2026). A diagnosis of Wilson's disease was confirmed based on AASLD/EASL guidance: clinically via Leipzig score and/or copper quantification, a biopsy that returns > 55 mcg Cu, and/or any confirmatory genetic testing for a mutation in ATP7B). The outcome was transplant, death or clinical stability on follow-up. Adherence to clinic visit and copper-related tests were reviewed **Results:** The search returned 53 patients, and after review, 13 patients were found to have diagnoses other than Wilson's, such as PBC, MASLD Cirrhosis, or Hereditary Hemochromatosis. Out of 40 patients, 31 White non-Hispanic, 4 White Hispanic, 4 Asian and 1 African American. Patients were receiving maintenance therapy (n = 28) or had a liver transplant (n = 12). In the maintenance group, 24 received a biopsy as part of their workup, 13 had genetic testing done, and 8 were diagnosed through clinical work-up (symptoms, Labs with Leipzig score). In the maintenance therapy group, 10 were diagnosed with cirrhosis, and 13 were non-cirrhotic. All patients in the transplant group had cirrhosis prior to transplant, 9 were mixed etiology, and 3 had no competing etiology. 17 patients are on

trientine, 4 are on Zinc alone, 4 are on a combination of trientine and zinc, 1 on penicillamine. Six patients were lost to follow up. Monitored patients remain clinically stable without worsening. **Conclusion:** Wilson's disease therapy requires long term commitment to therapy and close monitoring. The care pathway in centers of excellence needs further optimization to improve outcome.

1448 | METABOLOMICS AND COPPER-FOCUSED PROTEOMICS IN DOGS WITH COPPER-ASSOCIATED AND IMMUNE-MEDIATED CHRONIC HEPATITIS

Tarini Ullal[1] Jacob Padilla[1] Marie Heffern[1] Sarah Shropshire[2] Cecilia Giulivi[1] Valentina Medici[3], [1]University of California, Davis, [2]Colorado State University, [3]University of California Davis Medical Center

Background: Copper-associated chronic hepatitis (CAH) in dogs causes excessive hepatic copper accumulation, analogous to Wilson Disease (WD) in humans, resulting in oxidative stress, mitochondrial injury, and necroinflammation. These derangements are apparent in metabolomic and proteomic analyses of WD patients, but have not been evaluated in dogs with CAH or immune-mediated chronic hepatitis (ICH). **Methods:** Serum samples were collected from dogs diagnosed and untreated for CAH (n = 14), immune-mediated chronic hepatitis (ICH) (n = 18), and healthy controls (n = 20). Metabolomic evaluation of primary metabolites, biogenic amines, and complex lipids was performed using gas chromatography/time-of-flight mass spectrometry and compared between groups using sparse partial least squares discriminant analysis, hierarchical clustering, and a limma framework adjusting for covariates (age, sex, clinical signs, liver values, hepatic copper) with random forest classification. Copper-focused proteomics was performed on a serum subset of 12 dogs per group. A copper(II) iminodiacetic acid immobilized metal affinity chromatography (Cu-IMAC) was paired with liquid chromatography tandem mass spectrometry to identify differentially abundant proteins. **Results:** Metabolomics showed no significant differences between CAH and ICH. Dogs with CAH relative to healthy controls showed significantly higher copper (2.15 fold increase), upregulation in amino acids (ornithine, phenylalanine, quinolonic acid), uracil, beta-alanine, and fatty acids (oleic and palmitoleic acids) (range: 0.7 to 1.4 fold increase), and downregulation in markers of phospholipid metabolism (O-phosphoethanolamine, glycerophosphoric acid), purine metabolism (inosine, guanosine), and hydroxyproline (range: -0.6 to -1.4 fold decrease). Cu-IMAC enriched a population of proteins with copper (II)-binding capacity in dogs with CAH, showing upregulation of immune response proteins (inter-alpha-trypsin inhibitor heavy chains (H3,H4), polymeric immunoglobulin receptor, galectin-3-binding protein, alpha-2-macroglobulin, and CD14) and a downregulation of hepatic function proteins (apolipoproteins, coagulation factor XIII A chain, transthyretin) relative to healthy controls. No significant proteomic differences were found between CAH and ICH. **Conclusion:** CAH in dogs was characterized by high hepatic copper, lipid and phospholipid dysregulation, oxidative stress and mitochondrial dysfunction, amino acid/purine turnover, necroinflammation, and impaired hepatic function relative to healthy controls, mirroring human WD. Similar pathways were altered in dogs with ICH. Upregulated metabolites and proteins identified in this study could represent potential biomarkers for canine chronic hepatitis, though might not reliably differentiate copper from auto-immune etiologies.

1449 | PERSISTENT BIOCHEMICAL ACTIVITY PREDICTS ADVERSE OUTCOMES IN WILSON DISEASE: DEVELOPMENT OF PROGNOSTIC INDICES

Esra Durmazer[1] Elvan Işık[2] Ilker Turan[2] Fulya Gunsar[2] Zeki Karasu[2] Ulus Akarca[2], [1]Ankara University Faculty of Medicine, [2]Ege University Faculty of Medicine

Background: Wilson disease (WD) is a rare but potentially fatal disorder of copper metabolism characterized by progressive hepatic and neurological injury. Although medical therapy is available, a subset of patients develops progressive liver disease requiring transplantation or resulting in death. Predictors of adverse outcomes in WD remain insufficiently

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

characterized. We aimed to identify factors associated with death or liver transplantation and to develop prognostic indices for poor outcomes in WD. **Methods:** In this retrospective longitudinal cohort study, consecutive patients with WD followed at Ege University Faculty of Medicine between January 2000 and August 2024 were evaluated. The primary endpoint was a composite of death or liver transplantation. Continuous laboratory variables were categorized using predefined clinically relevant thresholds. Multivariable logistic regression analyses were performed to identify independent predictors of adverse outcomes and to construct prognostic indices. Discriminative performance of the derived indices was internally evaluated using ROC curve analysis. **Results:** A total of 105 patients with WD were included, of whom 54 (51.4%) were male. Median age at diagnosis was 19 years (95% CI, 15–20). During follow-up, liver transplantation was performed in 9 patients (8.6%), while 8 patients (7.6%) died, including 2 following transplantation. Overall, 15 patients (14.3%) reached the composite endpoint of death or liver transplantation. In multivariable logistic regression analysis, lower baseline creatinine levels ($p = 0.02$) and lower white blood cell counts ($p = 0.004$) were independently associated with adverse outcomes. Continuous laboratory variables were categorized using predefined clinically relevant thresholds. Creatinine levels < 0.7 mg/dL ($p = 0.019$) and white blood cell counts $\leq 4000/\mu L$ ($p = 0.001$) were associated with poor outcomes. Prognostic indices derived from regression coefficients of significant variables demonstrated strong discriminative performance for adverse outcomes (AUC 0.816, 95% CI 0.713–0.894). Persistent biochemical activity, defined by AST elevation above the upper limit of normal and INR > 1.3 during follow-up, remained strongly associated with adverse outcomes (OR 17.7, 95% CI 1.86–168.7, $p = 0.0123$; OR 11.4, 95% CI 2.03–63.9, $p = 0.005$, respectively). A treatment-period prognostic index incorporating AST and INR demonstrated excellent discriminative performance (AUC 0.909, 95% CI 0.822–0.962). **Conclusion:** Persistent biochemical activity despite treatment is strongly associated with death or liver transplantation in Wilson disease. Our laboratory-based prognostic indices demonstrated strong discriminative ability for adverse outcomes and may improve early risk stratification in clinical practice. The association between lower creatinine levels and adverse outcomes warrants further investigation in patients with WD.

Disclosures: Esra Durmazer:Nothing to Disclose, Elvan Işık:Nothing to Disclose, ILKER TURAN:Nothing to Disclose, Fulya Gunsar:Nothing to Disclose, Zeki Karasu:Nothing to Disclose, Ulus Akarca:Nothing to Disclose.

1450 | ◆ CHOLANGIOCYTE YAP1-MEDIATED DUCTULAR REACTION EXACERBATES CIRRHOTIC PORTAL HYPERTENSION BY PROMOTING CCN1-REGULATED DISRUPTION OF HEPATIC MICROCIRCULATION

Jinbo Zhao[1] Zhenhao Wu[1] Guqing Luo[1] Mengting Li[1] Hongjie Li[1] Jiayun Lin[1] Chihao Zhang[1] Guangbo Wu[1] Meng Luo[1] Lei Zheng[1], [1]Ninth People's Hospital, School of Medicine, Shanghai Jiaotong University

Background: Portal hypertension (PHT) is a severe life-threatening complication of advanced chronic liver disease, primarily resulting from increased intrahepatic vascular resistance. Hepatic Microcirculation, including Liver sinusoidal dysfunction and pathological angiogenesis, was well recognized to play pivotal roles in the initiation and progression of cirrhotic PHT; however, their upstream regulatory molecular networks remain poorly defined. Emerging evidence indicates that ductular reaction (DR), which has been proven to impair the intrahepatic homeostasis microenvironment in various chronic liver diseases yet remained poorly investigated in cirrhotic PHT, may serve as a critical driver of disease progression. Herein, we combined clinical specimen analysis, in vivo animal models and in vitro cell experiments to explore the core pathological mechanism by which DR contributes to cirrhotic PHT, and to screen potential therapeutic targets. **Methods:** Clinical specimen and immunofluorescence analysis: Clinical samples from patients with cirrhosis and cirrhotic portal hypertension (PHT) were collected to analyze the correlation between ductular reaction (DR) and disease progression. Immunofluorescence staining was further performed to clarify the relationships of DR with pathological angiogenesis and liver sinusoidal dysfunction. Animal model construction and in vivo intervention: Three classic mouse PHT models were established via BDL surgery, DDC diet and CCl_4 injection. A Hnf1β-promoter-driven adeno-associated virus (AAV) was constructed to achieve specific knockout of YAP1 or Cyr61(CCN1) in cholangiocytes, so as to explore their functional roles in PHT. In addition, pharmacological inhibition of YAP1 was conducted in BDL and DDC models using Verteporfin. In vitro mechanistic experiments: YAP1 expression in cholangiocytes was genetically manipulated. Cell co-culture combined with supernatant mass spectrometry was applied to evaluate the effects of cholangiocyte-derived secretory factors on HUVEC tube formation and proliferation, as well as LSEC capillarization. In vitro rescue assays were used to validate the direct regulatory effect of cholangiocyte-secreted CCN1 on HUVEC and LSEC biological functions. Furthermore, blockade of the CCN1 receptor integrin αvβ3 on endothelial cells was performed to explore its mediating

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

role in CCN1-induced pro-pathological phenotypes. **Results:** Clinical specimen analysis revealed a significant correlation between DR and the progression of liver cirrhosis. Immunofluorescence staining further confirmed that DR was closely associated with the progression of pathological phenotypes, including pathological angiogenesis and liver sinusoidal dysfunction. YAP1 was identified as a core molecular regulator of DR. To further elucidate the biological function of YAP1 in cholangiocytes, we established an AAV-Virus driven by the Hnf1β-promoter to achieve cholangiocyte-specific YAP1 knockout in vivo. In BDL, DDC and CCl_4-induced PHT mouse models, Cholangiocyte-specific YAP1 ablation markedly attenuated liver injury, as evidenced by reduced portal pressure, alleviated DR, improved liver sinusoidal dysfunction and suppressed pathological angiogenesis. In addition, pharmacological inhibition of YAP1 with Verteporfin in BDL and DDC mice further validated that YAP1 suppression significantly alleviated the pathological phenotypes of cirrhotic PHT. Combined with the findings from clinical cirrhotic PHT samples, our results suggest that DR promotes pathological angiogenesis and liver sinusoidal dysfunction. In vitro experiments demonstrated that intervention of YAP1 expression in cholangiocytes, followed by cell co-culture and supernatant mass spectrometry analysis, revealed that cholangiocyte-derived secretory factors prominently promoted HUVEC tube formation and proliferation, as well as LSEC capillarization. CCN1 was subsequently identified as a key secreted protein. Consistently, Hnf1β-promoter-mediated cholangiocyte-specific CCN1 knockout recapitulated the protective effects observed upon cholangiocyte YAP1 ablation. Rescue experiments in vitro further verified that cholangiocyte-secreted CCN1 directly facilitated HUVEC tube formation and proliferation, as well as LSEC capillarization. Moreover, blockade of the predicted receptor integrin αvβ3 on HUVEC or LSEC substantially abrogated the pro-pathological effects of CCN1. **Conclusion:** In conclusion, our findings demonstrate that cholangiocyte YAP1 accelerates the progression of cirrhotic PHT by facilitating DR, and further induces pathological angiogenesis and LSEC capillarization via paracrine CCN1. This study provides novel mechanistic insights and a promising targeted therapeutic strategy for the treatment of cirrhotic PHT.

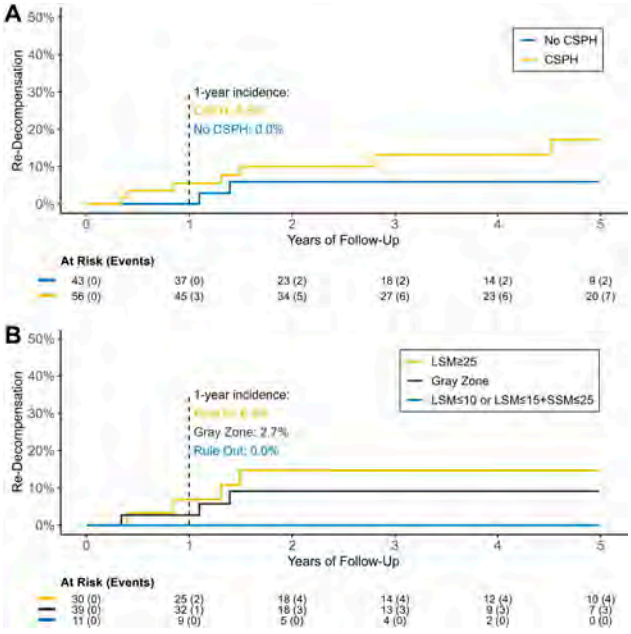
1451 | ◆ REGRESSION OF PORTAL HYPERTENSION IN RECOMPENSATED CIRRHOSIS, ITS PROGNOSTIC IMPLICATIONS, AND THE UTILITY OF NON-INVASIVE TESTS TO EVALUATE CSPH RESOLUTION



Benedikt Hofer[1] Georg Semmler[1] Dario Saltini[2] Luis Tellez[3] Anna Brujats[4] Angela Puente[5] Josune Cabello[6] Susana Rodrigues[7] Petra Fischer[8] Fernando Cao[9] Zouhir Gadi[10] Dominik Bettinger[11] Xiaofeng Zhang[12] Yu Wang[13] Vincenza Calvaruso[14] Jan Embacher[1] Mattias Mandorfer[1] Antonio Piscopo[2] Amparo Moscardó Ribes[4] Horia Stefanescu[8] Sven Francque[10] Salvatore Petta[14] Jidong Jia[15] Jinjun Chen[12] Wilhelmus Kwanten[10] Elba Llop[9] Bogdan Procopet[8] Annalisa Berzigotti[7] Jonel Trebicka[6] Jose Ignacio Fortea[5] Edilmar Alvarado[4] Agustin Albillos[3] Filippo Schepis[2] Thomas Reiberger[1], [1]Medical University of Vienna, [2]University of Modena and Reggio Emilia, [3]Hospital Universitario Ramón y Cajal, [4]Hospital de la Santa Creu i Sant Pau, [5]University Hospital Marqués de Valdecilla, [6]University of Münster, [7]Bern University Hospital, [8]Regional Institute of Gastroenterology and Hepatology Cluj-Napoca, [9]Hospital Universitario Puerta de Hierro Majadahonda, [10]Antwerp University Hospital, [11]University Medical Center Freiburg, [12]Southern Medical University, Guangzhou, [13]Beijing Friendship Hospital, Capital Medial University, [14]University of Palermo, [15]Beijing Friendship Hospital, Capital Medical University

Background: Aetiological therapy enables hepatic recompensation in decompensated cirrhosis. However, portal hypertension dynamics in recompensated cirrhosis, the utility of non-invasive tests (NITs) for clinically significant portal hypertension (CSPH) in this setting, and the prognostic implications of CSPH and of NITs after recompensation remain unclear. **Methods:** This Baveno-endorsed multicentre study included 102 patients undergoing hepatic venous pressure gradient (HVPG) measurement after achieving recompensation (Baveno VII criteria; all Child-Pugh A). Platelet count, liver (LSM; n = 83), and spleen (SSM; n = 46) stiffness measurements were collected at HVPG (±90 days). **Results:** Aetiologies included alcohol-related liver disease (ALD; 70.6%), hepatitis B (4.9%), hepatitis C (9.8%), or combined viral/ALD (14.7%). Median HVPG after recompensation was 11 (8-13) mmHg, and CSPH resolved in 43%.Fifty-two patients had paired pre-recompensation HVPG/NIT assessments available: HVPG decreased by -50% ([-57]-[-23]%; $p < 0.001$) from the decompensated stage. LSM also decreased significantly after recompensation (-57% [(-70)-(-36)%]; $p < 0.001$), yet changes in platelets were heterogeneous (+5% [(-21)-(+40)%]; $p = 0.777$), and thrombocytopenia persisted in 57% despite CSPH resolution.LSM

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and SSM showed high diagnostic accuracy for persistent CSPH in recompensated patients (AUROC: 0.890 / 0.911), whereas platelet count was uninformative (AUROC: 0.613). LSM ≥25 kPa reliably ruled in CSPH with 100% positive predictive value/specificity (CSPH n = 31/31). LSM ≤10 kPa and SSM ≤30 kPa both ruled out CSPH with 100% negative predictive value (NPV)/sensitivity (CSPH n = 0/6 and n = 0/13). SSM ≤25 kPa combined with LSM ≤15 kPa maintained 100% NPV/sensitivity (CSPH n = 0/5) and may provide an additional safety margin.After HVPG, 99 patients were followed for 36.5 (18.3-72.8) months. 13 patients returned to a decompensated state, with a 3-year cumulative incidence of 10%. Higher HVPG (SHR /mmHg: 1.178; 95%CI: 1.069-1.298; p < 0.001) and persistent CSPH (SHR: 3.996; 95%CI: 0.880-18.154; p = 0.073; Fig. 1A) at recompensation were linked to a higher re-decompensation risk. No patient with resolved CSPH re-decompensated within the first year. However, late re-decompensation occurred in 2 patients, related to recurrent liver disease (i.e., alcohol relapse) in one patient and presumably to portal vein thrombosis in the other. Importantly, no patient with LSM ≤10 kPa or SSM ≤25 kPa + LSM ≤15 kPa re-decompensated (Fig. 1B). **Conclusion:** CSPH may resolve in a considerable proportion of patients after recompensation, yet persistent CSPH is associated with a higher re-decompensation risk. LSM ≥25 kPa reliably rules in persistent CSPH after recompensation, while LSM ≤10 kPa or LSM ≤15 kPa plus SSM ≤25 kPa rule out CSPH and identify patients with negligible re-decompensation risk if the aetiology remains controlled.

1452 | ◆ MIDODRINE AND ALBUMIN IN PATIENTS WITH REFRACTORY ASCITES. A DOUBLE BLIND RANDOMISED CONTROLLED TRIAL

Virendra Singh[1] Amandeep Singh[1] Arka De[2] Sayan Malakar[1] Nitesh Bassi[1] Upasna Chauhan[1] Simrat Kaur[1] Jahnvi Dhar[1], [1]Punjab Institute of Liver and Biliary Sciences, [2]Post Graduate Institute of Medical Education and Research

Background: Long-term human albumin (HA) administration has shown inconsistent results in control of ascites and survival in patients with cirrhosis. Midodrine, an oral α1- adrenergic agonist has also been used in refractory ascites (RA) with variable results. The aim of this study was to evaluate the effects of long-term administration of HA and midodrine on control of ascites and survival at one year in patients with cirrhosis and refractory ascites. **Methods:** We studied 114 patients with RA in a randomised, double blind, placebo-controlled trial between January 2021 and March 2025. Group A (n = 38) received long-term midodrine and HA with Standard Medical therapy (SMT); group B (n = 38) received long-term HA along with placebo and group C (n = 38) received SMT with placebo. The group A and B received HA in 1.5 gm/kg/

weekly for 2 weeks along with Midodrine 7.5 mg three times a day and SMT. This was followed by HA 40 grams every 7days. The primary end point was the control of ascites at 1 year and secondary end points were survival at 1-year, mean arterial pressure, change in serum and 24-hour urinary sodium, incidence of AKI and hyponatremia. **Results:** At 12 months, control of ascites was achieved in 8 (21.1%) patients of group A, 2(5.3%) patients of group B and none in group C (p = 0.003). One year mortality was significantly lower in the group A as compared to group B and group C (57.9% vs 86.8% vs 97.4%) (p < 0.001). On multivariable logistic regression analysis, midodrine therapy independently predicted improved control of ascites (OR 16.84, 95% CI 2.41–117.62; p = 0.004). Higher mean arterial pressure (OR1.15, 95% CI 1.03–1.29; p = 0.014), increased 24-hour urinary sodium excretion (OR 1.09, 95% CI 1.02–1.17; p = 0.009), and urine volume (OR 1.003, 95% CI 1.001–1.005; p = 0.006) were also independently associated with sustained ascites control. In comparative analysis between albumin and SMT group, the control of ascites (p = 0.152) as well as survival (p = 0.168) was not significantly different. AKI developed in 31.5%, 55% and 68.4% of patients in group A, B and C, respectively (p = 0.014) and new onset hyponatremia in 23.6% vs 44.3% vs 63.2% of patients in group A, B and C, respectively (p = 0.04) during the follow up. **Conclusion:** Midodrine in combination with HA significantly improved control of ascites and one year mortality compared to long term albumin and SMT alone in patients with refractory ascites. However, long term HA did not improve control of ascites or survival in comparison to SMT. New onset hyponatremia and AKI were more common in SMT and albumin groups. (NCT:04621617)

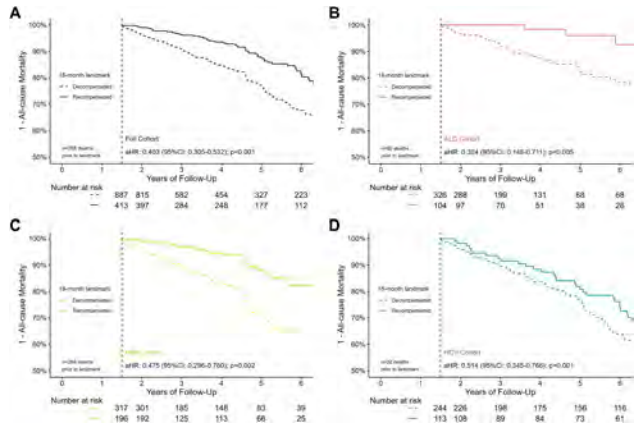
1453 | ◆ HEPATIC RECOMPENSATION OCCURS AT SIMILAR RATES IN ALCOHOL- AND VIRAL HEPATITIS-RELATED CIRRHOSIS AND IS CONSISTENTLY ASSOCIATED WITH REDUCED MORTALITY AND HCC RISK



Benedikt Hofer[1] Georg Semmler[1] Terry Cheuk-Fung Yip[2] Hong You[3] Wen Xie[3] Javier Ampuero Herrojo[4] Marta Tonon[5] Alberto Zanetto[5] Salvatore Piano[5] Sabela Lens[6] Inmaculada Fernandez[7] Sonia Alonso Lopez[8] Monica Pons[9] Benjamin Maasoumy[10] Dalila Costa[11] Elisa Pose[6] Paolo Caraceni[12] Celia Pérez-Estrada[4] Isabel Carmona[13] José Miguel Rosales[14] Horia Stefanescu[15] Hélène Larrue[16] Annalisa Berzigotti[17] Emmanuel Tsochatzis[18] Luis Tellez[19] Rafael Bañares[8] Joan Genesca[9] Marika Rudler[20] Alexander Zipprich[21] Jonel Trebicka[22] Zhiying He[3] You Deng[3] Bingqiong Wang[3] Xiaoning Wu[3] Jimmy Che-To Lai[2] Jidong Jia[3] Mattias Mandorfer[1] Thomas Reiberger[1], [1]Medical University of Vienna, [2]The Chinese University of Hong Kong, [3]Beijing Friendship Hospital, Capital Medical University, [4]Hospital Universitario Virgen del Rocío, [5]University of Padua, [6]Hospital Clínic de Barcelona, [7]Hospital Universitario 12 De Octubre, [8]Hospital General Universitario Gregorio Marañón, [9]Vall d'Hebron University Hospital, [10]Hannover Medical School, [11]Braga Hospital, [12]University of Bologna, [13]Hospital Universitario Virgen Macarena, [14]Hospital Universitario Costa del Sol, [15]Regional Institute of Gastroenterology and Hepatology Cluj-Napoca, [16]University Hospital and Toulouse III - Paul Sabatier University, [17]Bern University Hospital, [18]Royal Free Hospital and UCL, [19]Hospital Universitario Ramón y Cajal, [20]Sorbonne University, [21]Jena University Hospital, [22]University of Münster

Background: Aetiological cure enables hepatic recompensation in decompensated cirrhosis, yet reported rates and prognostic implications of recompensation were heterogeneous across aetiologies. This study assessed differences in recompensation incidence and subsequent risk of hepatocellular carcinoma (HCC) and liver-related mortality. **Methods:** This Baveno-endorsed multicentre study enrolled patients with decompensated cirrhosis at time of aetiological treatment until December 2022, i.e., start of abstinence in alcohol-related liver disease (ALD) or initiation of antiviral treatment in hepatitis B (HBV) or C (HCV). Recompensation was defined by Baveno VII criteria: (i) resolution of ascites and hepatic encephalopathy (off treatment), (ii) no variceal bleeding for 1 year, and (iii) improved hepatic function. Alcohol/viral recurrence and liver transplantation led to censoring. Multivariable models included age, sex, MELD, platelet count, alanine transaminase, and centre/cohort as random effect. **Results:** 1838 patients were included, with ALD in 34% (n = 633), HBV in 43% (n = 792), and HCV in 22% (n = 413). Baseline hepatic dysfunction was most pronounced in ALD (median MELD: 17), followed by HBV (14) and HCV (11; p < 0.001).During a median follow-up of 4.4 years, 674 patients achieved recompensation. After 3 years, the overall cumulative incidence of recompensation was 33%, being highest in HCV (37%), followed by HBV (35%), and ALD (29%). However, on adjusted analysis, recompensation probability did not differ between aetiologies (adjusted subdistribution hazard ratios (aSHRs): 0.987 (p = 0.963) for HBV vs. ALD, 1.149

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

(p = 0.759) for HCV vs. ALD, and 1.165 (p = 0.759) for HCV vs. HBV).During follow-up, 648 patients died; 59% from liver-related causes. Recompensation (time-dependent covariate) was independently associated with reduced all-cause mortality, with adjusted hazard ratios (aHR) of 0.403 (p < 0.001) in the full cohort, 0.324 (p = 0.005) in ALD, 0.475 (p = 0.002) in HBV, and 0.514 (p = 0.001) in HCV (Fig. 1). Similarly, recompensation reduced the risk of liver-related mortality in HBV (aHR: 0.222; p < 0.001) and HCV (aHR: 0.285; p < 0.001); no liver-related deaths occurred in recompensated ALD.De novo HCC was diagnosed in 257 patients, with a significantly higher risk in viral liver disease (HBV vs. ALD aSHR: 7.506; p < 0.001 / HCV vs. ALD aSHR: 6.457; p < 0.001). Recompensation was linked to a significantly reduced HCC risk in HBV (aHR: 0.528; p = 0.040) and HCV (aHR: 0.549; p = 0.040), and no recompensated ALD patient developed HCC. **Conclusion:** When accounting for baseline disease severity, the incidence of hepatic recompensation is comparable across ALD, HBV and HCV. Recompensation significantly improves survival and reduces the risk of HCC across all aetiologies. HCC risk in recompensated patients remains higher with viral hepatitis than in ALD.

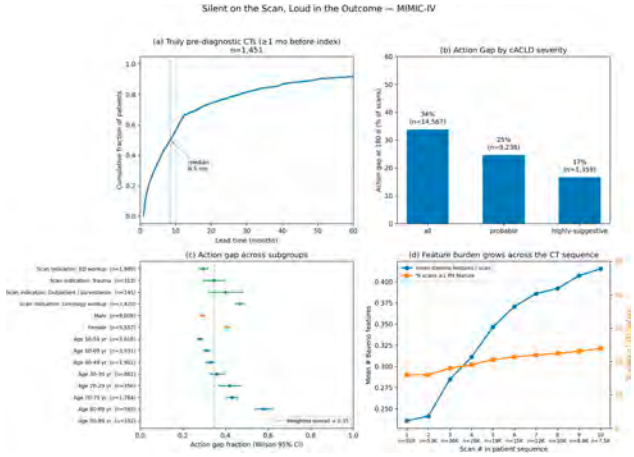
1454 | ◆ CIRRHOSIS HIDDEN IN PLAIN SIGHT: AN AGENTIC LLM PIPELINE OPERATIONALISES BAVENO VII CACLD/CSPH FROM FREE-TEXT CT REPORTS AND QUANTIFIES THE CARE ACTION GAP IN MIMIC-IV



Harika Dadigiri Srinivas Venkatanarayanan[1] Anas Al Mardini[2] Jeril Lasington[3] Edward Barbarito[4], [1]UCF, [2]NYMC, St Clare St Mary hospital, [3]NYMC Saint Clare's and Saint Mary's Health, [4]NYMC Saint Clare's Hospital

Background: The compensated phase of cirrhosis is often undiagnosed; routine cross-sectional imaging often visualises portal-hypertensive features long before cirrhosis is diagnosed in structured EHR data. It remains to be established whether free-text CT abdomen reports prior to the first cirrhosis ICD code contain operationalisable Baveno VII evidence of compensated advanced chronic liver disease (cACLD) and clinically significant portal hypertension (CSPH) at a population scale and whether that imaging signal results in clinician action. **Methods:** MIMIC-IV cirrhosis cohort (n = 7,874; index = earliest cirrhosis-coded discharge) and non-cirrhotic CT-control cohort (n = 87,439, matched on age/sex/race/scan year/indication). All 343,128 abdominal CT reports were processed via an agentic LLM pipeline (Gemini-2.5-Flash-Lite; 128-way concurrent; 98.9% extraction success) emitting a Baveno-VII-grounded schema with required supporting spans; a NegEx shadow extractor ran in parallel with a conservative downgrade on disagreement. Headline metrics are computed on the

case cohort; controls provide background PH-feature prevalence for specificity. Four outcomes: (1) Silent-CT fraction: PH-positive scans with no cirrhosis impression mention and no cirrhosis ICD within 90 days; (2) Care Action Gap: no hepatology referral, surveillance imaging, or NSBB within 180 days, stratified by cACLD severity; (3) lead time from earliest pre-index PH-positive CT to first cirrhosis ICD (scans ≥ 30 days pre-index); (4) action-gap disparities by sex, age band, and scan indication (Wilson 95% CIs). Sensitivity: IPTW target-trial emulation for 24-month decompensation. **Results:** 14,567 pre-index PH-positive CT reports identified. Silent-CT: 38% (5,497/14,567) had no cirrhosis impression mention and no cirrhosis ICD within 90 days. Care Action Gap at 180 days: overall 34% (n = 14,567) probable cACLD 25% (n = 9,238); highly suggestive 17% (n = 1,359). Lead time (n = 1,451 scans ≥ 30 days pre-index): median 8.5 months (IQR 3.2–21.0) 16% predated the first cirrhosis ICD by ≥ 1 year. Disparities: women 41% vs men 29% age 80–89 58% vs 50–59 28% Black 40% vs Hispanic/Latino 26% oncology 47% vs ED workup 30%. Largest absolute gaps in older adults, women, Black patients, and incidental oncology CTs. IPTW sensitivity confirmed indication-driven confounding (E-value 2.37) action-gap metrics were reported as care-delivery indicators, not causal estimates. **Conclusion:** An agentic LLM pipeline operationalises Baveno VII cACLD/CSPH from 343,128 free-text CT reports at full MIMIC-IV scale. More than one in three PH-positive CT scans had no documented hepatology evaluation within six months, with disproportionate gaps in women, older adults, Black patients, and oncology CTs. Deployable on a HIPAA-eligible endpoint for prospective referral flagging, the action-gap metric serves as an equity-sensitive system level quality indicator

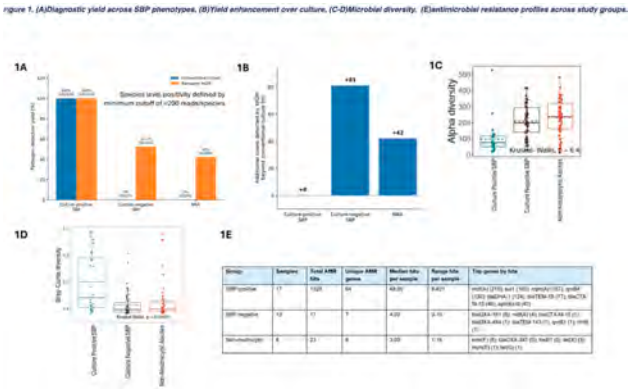
1455 | ◆ WHOLE-GENOME METAGENOMICS ENABLES RAPID PATHOGEN DETECTION, QUANTITATIVE BACTERIAL BURDEN, AND ANTIMICROBIAL RESISTANCE (AMR) ACROSS SPONTANEOUS BACTERIAL PERITONITIS PHENOTYPES



Chhagan Bihari[1] Rosmy Babu[2] Ramesh Prasad[2] Pratibha Kale[2] Vinod Arora[2] Sukriti Baweja[2] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences, [2]ILBS, New Delhi

Background: Spontaneous bacterial peritonitis (SBP) carries > 20% 30-day mortality in decompensated cirrhosis. Conventional culture detects pathogens in < 50% cases, requires 3-5 days, and cannot assess bacterial burden or antimicrobial resistance (AMR). We applied nanopore whole-genome metagenomics to quantify bacterial burden, identify mortality-associated taxa, and map AMR gene landscapes across culture-positive SBP, culture-negative SBP, and non-neutrocytic ascites (NNA). **Methods:** Treatment-naive adults with decompensated cirrhosis (culture-positive SBP n = 100, culture-negative SBP n = 155, NNA n = 100) underwent low-biomass DNA extraction and sequencing on Oxford Nanopore P2 Solo. Diversity metrics, bacterial burden, mortality associations, and AMR gene profiling were analysed (Kruskal-Wallis; Bray-Curtis PERMANOVA). **Results:** Among 355 patients (median age 51, male-predominant, alcohol/NASH etiology, MELD-Na 20/20/23), metagenomics detected bacterial DNA in 100/100 (100%) of culture-positive SBP, 81/155, (52.2%) of culture-negative SBP, and 42/100 (42%) of NNA, with a 10-hour turnaround vs. 5 days by culture. Alpha diversity was lowest in culture-positive SBP (p = 6.4x10-8); beta-diversity differed across groups (PERMANOVA p = 0.00037). Culture-positive SBP was dominated by *Escherichia coli*, *Stenotrophomonas maltophilia*, *Acinetobacter baumannii*, *Salmonella enterica*, and *Chryseobacterium indologenes*; culture-negative SBP harboured these pathogens at 4.8-fold lower read counts; NNA showed 6.8-fold lower burden. One-month septic shock mortality was 11%, 6.2%, and 4.8%; all fatal cases were enriched for *Stenotrophomonas maltophilia* (53,477 reads/sample, OR 9.90, 95% CI 8.71–11.25) establishing bacterial burden as a mortality biomarker. AMR profiling detected 1,363 resistance hits (69 unique genes), highest in culture-positive SBP (1,323 hits; 64 genes) vs. culture-negative SBP (17 hits) and NNA (23 hits). Key resistance genes-blaCTX-M-15, blaTEM-1B, qnrB4, mph (A), sul1, tet (B)-conferred resistance to beta-lactams, fluoroquinolones, aminoglycosides, and macrolides. **Conclusion:** In this metagenomics cohort of SBP phenotypes (n = 355), nanopore sequencing delivered rapid (10-hour) pathogen identification, bacterial burden stratification, and AMR profiling unattainable by culture. Stenotrophomonas maltophilia burden correlated with mortality. AMR gene profiles

1456 | ◆ SGLT2 INHIBITOR USE AND FUTURE PARACENTESIS BURDEN IN RECURRENT ASCITES: A RETROSPECTIVE MULTICENTER ANALYSIS

Ali Emre Bardak[1] Nazli Begum Ozturk[2] Gizem Teker[3] Kamran Qureshi[2], [1]Boston Medical Center - Brighton, Boston, MA, USA, [2]Saint Louis University School of Medicine, St. Louis, MO, USA, [3]Beth Israel Deaconess Medical Center, Boston, MA, USA

Background: Recurrent paracentesis-requiring ascites reflects advanced portal-hypertensive fluid dysregulation and remains a major unmet need in cirrhosis. SGLT2i promote osmotic diuresis and natriuresis, but whether they reduce future drainage burden in patients with established recurrent ascites is unknown. **Methods:** We performed a multicenter retrospective study using the TriNetX U.S. Collaborative Network. Adults with cirrhosis receiving furosemide and spironolactone were included if they had recurrent paracentesis-requiring ascites, defined as ≥2 abdominal paracenteses performed ≥14 days apart within 3 months between 2015 and 2024. CKD stage 5/ESRD, dialysis dependence, or hepatocellular carcinoma were excluded. SGLT2i plus standard diuretics was compared with standard diuretics alone using 1:1 PSM. Matching covariates included demographics, cirrhosis etiology/decompensation burden, MELD parameters, HF, CKD, DM, insulin use, and sarcopenia. The index date was when patients met recurrent paracentesis and medication-strategy assignment criteria. Outcomes were assessed from day 31 through day 365. The primary outcome was repeat paracentesis. Fluid-management failure was repeat paracentesis, TIPS, liver transplantation (LT), or death. Advanced liver decompensation was HRS, SBP, HE, variceal bleeding, TIPS, LT, or death. The safety composite included ketoacidosis, hypoglycemia, genitourinary infection, sepsis/bacteremia, or hypotension. **Results:** 1,749 pairs were analyzed after PSM. SGLT2i use was associated with lower risk of repeat paracentesis (777 vs 951 events; HR 0.71, 95% CI 0.65–0.78; p < 0.001), higher 1-year paracentesis-free survival (49.8% vs 36.9%, NNT 7.75), and fewer mean post-index paracentesis encounters (4.39 vs 5.22; p = 0.014). SGLT2i use was also associated with lower fluid-management failure (HR 0.68, 95% CI 0.62–0.74), advanced liver decompensation (HR 0.80, 95% CI 0.73–0.88), and LT or death (HR 0.82, 95% CI 0.73–0.94). HE was numerically higher but not significant (HR 1.09, 95% CI 0.95–1.25). TIPS was numerically decreased but not significantly (HR 0.74, 95% CI 0.54–1.02). The safety composite was not statistically significant (HR 0.93, 95% CI 0.83–1.05). Findings were directionally consistent across subgroups, in a ≥30-day separation sensitivity analysis, and in an exploratory 3-year follow-up for repeat paracentesis (HR 0.53, 95% CI 0.47–0.61). **Conclusion:** In patients with recurrent paracentesis-requiring cirrhotic ascites despite standard diuretics, SGLT2i use was associated with lower future paracentesis burden and fewer fluid-management failures without an increase in composite safety events. Although causal inference cannot be established from this analysis, findings support prospective evaluation of SGLT2i as a potential adjunctive fluid-management strategy for recurrent ascites.

Outcomes of SGLT2 Inhibitor Use in Recurrent Paracentesis-Requiring Cirrhotic Ascites

Panel A. Main outcomes, procedure burden, and safety

Outcome	Events/values (SGLT2i vs control)	HR/estimate (95% CI)	p-value
Primary outcome and procedure burden			
Repeat paracentesis	777/1,749 vs 951/1,749	0.710 (0.646–0.781)	<0.001
Paracentesis encounters, mean ± SD	4.392 ± 9.547 vs 5.220 ± 10.277	Mean difference -0.83	0.014
Key composite outcomes			
Fluid-management failure	929/1,749 vs 1,145/1,749	0.680 (0.623–0.743)	<0.001
Advanced liver decompensation	813/1,749 vs 930/1,748	0.800 (0.728–0.879)	<0.001
Renal decompensation	604/1,749 vs 891/1,749	0.842 (0.765–0.926)	<0.001
Liver transplantation or death	411/1,488 vs 529/1,533	0.824 (0.726–0.936)	0.003
Secondary individual outcomes			
All-cause hospitalization	822/1,749 vs 859/1,749	0.901 (0.819–0.991)	0.032
All-cause mortality	399/1,634 vs 504/1,570	0.738 (0.647–0.842)	<0.001
TIPS placement	66/1,749 vs 86/1,749	0.738 (0.535–1.017)	0.062
Spontaneous bacterial peritonitis	163/1,749 vs 187/1,749	0.837 (0.678–1.033)	0.096
Hepatorenal syndrome	151/1,749 vs 171/1,749	0.849 (0.682–1.057)	0.142
Hepatic encephalopathy	434/1,749 vs 386/1,749	1.093 (0.953–1.254)	0.203
Acute kidney injury	635/1,749 vs 664/1,749	0.915 (0.821–1.021)	0.111
Variceal bleeding	101/1,749 vs 132/1,748	0.735 (0.567–0.952)	0.019
Safety outcomes			
Safety composite	588/1,749 vs 607/1,749	0.934 (0.834–1.046)	0.235
Diabetic ketoacidosis	19/1,579 vs 16/1,579	1.149 (0.591–2.234)	0.682
Hypoglycemia	47/1,579 vs 47/1,579	0.961 (0.643–1.440)	0.846
UTI/pyelonephritis/genital candidiasis	162/1,579 vs 190/1,579	0.814 (0.660–1.003)	0.053
Sepsis/bacteremia	226/1,579 vs 255/1,579	0.848 (0.709–1.014)	0.071
Hypotension	363/1,579 vs 324/1,579	1.094 (0.942–1.271)	0.237

Panel B. Subgroup, sensitivity, and exploratory analyses

Subgroup/analysis	Pairs	Repeat paracentesis	Fluid-management failure	Advanced liver decompensation
Demographic subgroups				
Male	1,008	0.720 (0.635–0.816)	0.730 (0.652–0.819)	0.888 (0.782–1.008)
Female	573	0.727 (0.617–0.856)	0.686 (0.589–0.798)	0.789 (0.672–0.927)
Cardiometabolic subgroups				
Type 2 diabetes	1,116	0.795 (0.706–0.894)	0.759 (0.682–0.845)	0.844 (0.752–0.948)
No type 2 diabetes	387	0.698 (0.555–0.878)	0.651 (0.528–0.802)	0.716 (0.563–0.910)

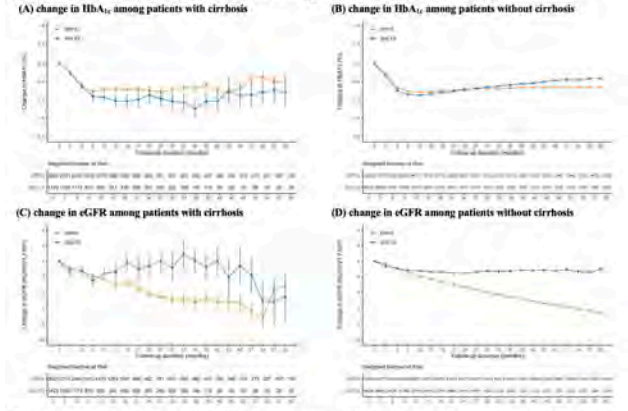
1457 | ◆ SAFETY OF SODIUM-GLUCOSE COTRANSPORTER 2 INHIBITORS IN PATIENTS WITH AND WITHOUT CIRRHOSIS: EMULATION OF A STRATIFIED TARGET TRIAL

Nana Peng[1] Guanlin Li[2] Yue Wang[3] Sherlot Juan Song[1] Grace Wong[1] Vincent Wong[1] Jimmy Che-To Lai[1] Terry Cheuk-Fung Yip[1], [1]The Chinese University of Hong Kong, [2]Zhujiang Hospital, Southern Medical University, China, [3]The Chinese Univeristy of Hong Kong



Background: Emerging evidence suggests that sodium-glucose cotransporter 2 inhibitors (SGLT2i) can improve steatohepatitis and liver-related outcomes. However, data on the safety of SGLT2i in patients with cirrhosis remains scarce. We examined the safety of SGLT2i vs dipeptidyl peptidase 4 inhibitors (DPP4i) in patients with type 2 diabetes mellitus (T2DM), with and without cirrhosis. **Methods:** Adults newly initiated on SGLT2i or DPP4i for T2DM between March 2015 and December 2023 were identified from clinics and hospitals in Hong Kong. Safety of SGLT2i vs DPP4i was estimated using a target trial emulation framework with randomisation stratified by cirrhosis status at treatment assignment. The primary outcome was acute kidney injury (AKI). Secondary outcomes were genito-urinary infections, diabetic ketoacidosis (DKA), fractures, and lower limb amputations. Long-term hemoglobin A_{1c} (HbA_{1c}) and estimated glomerular filtration rate (eGFR) changes were assessed. Inverse probability of treatment weighting was used to balance baseline characteristics between the SGLT2i and DPP4i groups within each cirrhosis stratum, and inverse probability of censoring weighting was applied to account for treatment discontinuation. Intention-to-treat and per-protocol effects were estimated using inverse probability-weighted marginal structural Cox models. **Results:** Overall, 193,794 patients with T2DM were included, 4,584 with cirrhosis (mean age, 73.5 ± 12.2 years; baseline eGFR 68.0 ± 23.8 mL/min/1.73 m²; 1,430 SGLT2i vs 3,154 DPP4i initiators) and 189,210 without cirrhosis (mean age, 65.6 ± 12.4 years; baseline eGFR 78.9 ± 23.3 mL/min/1.73 m²; 65,173 SGLT2i vs 124,037 DPP4i initiators). SGLT2i was associated with lower AKI risk than DPP4i use in patients with cirrhosis (adjusted hazard ratio [HR], 0.63; 95% CI, 0.50 to 0.80; adjusted rate difference, −49.72 per 1,000 person-years; 95% CI, −74.46 to −21.37), and without cirrhosis (adjusted HR, 0.71; 95% CI, 0.68 to 0.75; adjusted rate difference, −9.47 per 1,000 person-years; 95% CI, −10.93 to −8.09). No statistically significant interaction was observed between treatment and cirrhosis status for AKI risk (p for interaction = 0.456, Table 1). SGLT2i use was associated with no increased risks of genitourinary infections, diabetic ketoacidosis, fracture, or lower limb amputation in cirrhosis; treatment effect on adverse events did not differ by cirrhosis status (Table 1). Per-protocol analyses showed consistent results. SGLT2i was associated with more favourable long-term HbA_{1c} (Figure 1A and 1B) and eGFR trajectories (Figure 1C and 1D) than DPP4i in patients with and without cirrhosis. **Conclusion:** SGLT2i in adults with T2DM and cirrhosis was associated with a lower risk of AKI than DPP4i and no increase in genitourinary infections, DKA, fractures, and lower limb amputations. The safety of SGLT2i did not differ by cirrhosis status.

Table 1. Intention-to-treat analysis of the association between sodium-glucose co-transporter 2 inhibitor (SGLT2i) use and safety outcomes in patients with and without cirrhosis.

1458 | ◆ NOT ALL ACID SUPPRESSION IS EQUAL: PPIS ARE ASSOCIATED WITH HIGHER RISKS OF SPONTANEOUS BACTERIAL PERITONITIS AND HEPATIC ENCEPHALOPATHY THAN H2 RECEPTOR ANTAGONISTS IN DECOMPENSATED CIRRHOSIS

Shreya Sanghvi[1] FNU Deepali[1] Delano Carty[1] Nina Wanyin Hu[1] Laith Alomari[1] Ghideon Ezaz[1] Shanthi Sripathi[1], [1]Jefferson Einstein Philadelphia

Background: Proton pump inhibitors (PPIs) are prescribed in up to 60% of patients with cirrhosis, often without a clear indication. Emerging evidence suggests PPIs promote gut dysbiosis and bacterial translocation, potentially increasing the risk of spontaneous bacterial peritonitis (SBP) and hepatic encephalopathy (HE). Whether PPIs confer greater risk of these complications compared to H2 receptor antagonists (H2RAs), an alternative acid suppression strategy, remains unclear. We compared the cumulative risk of SBP and HE among patients with decompensated cirrhosis newly initiated on PPIs versus H2RAs. **Methods:** We performed a retrospective propensity score-matched cohort study using the TriNetX US Collaborative Network (66 healthcare organizations). Adults with decompensated cirrhosis newly initiated on a PPI or H2RA within one year of hepatic decompensation were included using an active-comparator, new-user design. Patients with concurrent use of both drug classes,or prior liver transplantation were excluded. Patients with prior SBP or HE were retained, with baseline history incorporated into propensity matching to evaluate both incident and recurrent events. Cohorts were matched 1:1 for demographics, liver disease severity, comorbidities, and concurrent medications. Primary outcomes were SBP and HE within 365 days. Risk ratios (RRs) with 95% confidence intervals (CIs) were calculated. **Results:** Before matching, 133,995 PPI users and 4,777 H2RA users were identified. After 1:1 propensity matching, 4,458 patients remained in each cohort with well-balanced baseline characteristics (standardized mean differences < 0.1). PPI use was associated with significantly higher cumulative risk of SBP compared with H2RA use (5.0% vs 2.6%; RR 1.96, 95% CI 1.57–2.44; p < 0.001), corresponding to an absolute risk increase of 2.4%. Similarly, PPI users had higher cumulative risk of HE (13.5% vs 7.9%; RR 1.72, 95% CI 1.52–1.94; p < 0.001), with an absolute risk increase of 5.6%. Kaplan-Meier analysis demonstrated lower SBP-free survival among PPI users compared with H2RA users at 365 days (93.6% vs 97.0%; log-rank p < 0.001). **Conclusion:** In this large propensity score-matched real-world cohort study, PPI use in patients with decompensated cirrhosis was associated with significantly increased risks of both SBP and HE compared with H2RA use. Given the frequent use of PPIs without clear indication in this population, these findings support careful reassessment of acid suppression strategies in patients with decompensated cirrhosis. Prospective studies are needed to confirm causality and define optimal approaches to gastric acid suppression in this vulnerable population.

1459 | ◆ NEW SUBMISSION CIRRHOTIC CARDIOMYOPATHY INCREASES THE RISK OF DEATH ON THE LIVER TRANSPLANT WAITLIST

Andre Hall[1] Murray Coetzee[2] Rawia Aburumman[2] Christopher Slaughter[2] Ashley Spann[2] Deepak Gupta[2] Anthony Dreher[3] Manhal Izzy[2], [1]Vanderbilt University School of Medicine, [2]Vanderbilt University Medical Center, [3]Vanderbilt Center for Transplant Science

Background: Cirrhotic cardiomyopathy (CCM) is chronic cardiac dysfunction arising from cirrhotic

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

physiology in patients with end-stage liver disease. Patients with CCM may have increased rates of adverse outcomes after transplantation, largely due to cardiac comorbidities. However, the impact of CCM on mortality while on the liver transplant waitlist has yet to be studied. We aim to define the association between the diagnosis of CCM and liver transplant waitlist mortality. **Methods:** We performed a retrospective cohort study of adult patients with cirrhosis listed for liver transplant at a large academic center in North America between 11/1/2020 and 4/1/2025. Out of 878 patients on the liver transplant waitlist, 617 met inclusion criteria, from which 453 had sufficient data to determine CCM diagnosis. Patients with primary cardiac pathology were excluded. We adjusted for age and MELD-3.0 using a Fine-Gray model, with transplant and delisting as competing events. **Results:** A total of 81 patients met criteria for CCM and 372 did not meet CCM criteria. In our age and MELD 3.0 adjusted model, CCM was independently associated with an increased risk of death while on the waitlist (HR 2.59; 95% CI 1.23-5.46; p = 0.013). However, when treating waitlist death and delisting for being too sick as a composite outcome, CCM was no longer associated with an increased risk of waitlist mortality (HR 1.73, 95% CI 0.94-3.20, p = 0.078). The one-year cumulative incidence of waitlist death was 4.7% for no CCM versus 9.7% for CCM (p = 0.007), whereas the one-year cumulative incidence of death or delisting for being too sick was 7.9% for no CCM and 14% for CCM (p = 0.062). Of the four diastolic dysfunction echo parameters composing CCM criteria, only peak early septal diastolic velocity (septal e') of < 7 cm/s was associated with increased waitlist mortality and delisting for being too sick (HR 2.80, 95% CI 1.47-5.36, p = 0.002). **Conclusion:** Cirrhotic cardiomyopathy is associated with increased rates of death while on the liver transplant waitlist. However, when also accounting for patients who are delisted for being too sick for transplant, a diagnosis of CCM is not significantly associated with increased waitlist mortality. Importantly, abnormally low septal e' was the most predictive echocardiographic parameter of waitlist mortality.

Table 1
Association of CCM Across Competing Transplant Waitlist Outcomes

Outcome	Events (n = 452)	Hazard Ratio (95% CI)	P-value
Transplant	347	0.92 (0.64-1.33)	0.657
Composite: Waitlist Death + Delisted Too Sick	53	1.73 (0.94-3.20)	0.078
Waitlist Death	30	2.59 (1.23–5.46)	**0.013**
Delisted Too Sick	23	0.78 (0.23-2.61)	0.687
Delisted Too Well	16	0.00 (0.00-0.00)	**<0.001**

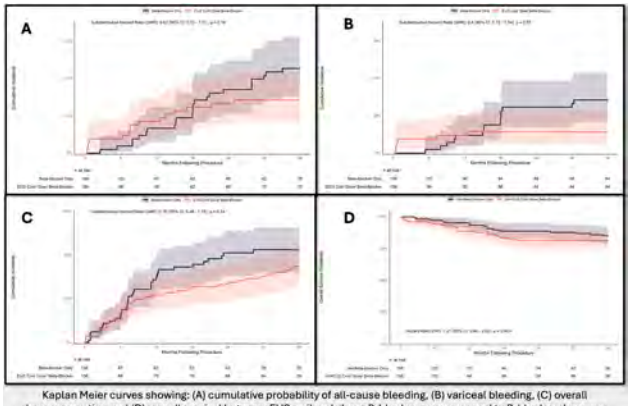
1460 | ◆ EUS-GUIDED COIL AND GLUE INJECTION IN ADDITION TO ß-BLOCKERS LEADS TO LOWER RATES OF GASTRIC VARICEAL BLEEDING COMPARED TO ß-BLOCKERS ALONE FOR PRIMARY PROPHYLAXIS OF GASTRIC VARICES IN CIRRHOSIS – A MULTICENTRE PROPENSITY MATCHED ANALYSIS FROM INDIA



Shubham Mehta[1] Arka De[2] Jimil Shah[3] Pawan Khatri[4] D. Vignesh[5] Shrihari Anikhindi[6] Hitesh Panchal[7] Nikhil Sonthalia[8] Pankaj Gupta[7] Ankit Agarwal[9] Ashish Agarwal[9] Aditya Vikram Pachisia[10] Chalapathi Rao Achanta[11] pawan rawal[7] Sunil Taneja[2] Rajesh Puri[7], [1]MEDANTA-THE MEDICITY, [2]Post Graduate Institute of Medical Education and Research, Chandigarh, India, [3]Post Graduate Institute of Medical Education and Research, Chandigarh, [4]Deenanath Mangeshwar Hospital and Research Center, Pune India, [5]E.S.I.C Medical College and Hospital, Chennai, India, [6]Sir Gangaram hospital, Delhi, India, [7]Medanta- the Medicity, Gurugram, India, [8]Apollo Gleneagles Hospital, Kolkata, India, [9]All India Institute of Medical Sciences, Jodhpur, India, [10]Command hospital, Bangalore, India, [11]KIMS Hospital, Hyderabad

Background: Gastric variceal bleeding (GVB) is associated with high morbidity and mortality. EUS-guided coil and cyanoacrylate injection (EUS-CG) has been shown to be an effective therapy for bleeding gastric varices and secondary prophylaxis, however, there is a paucity of data on primary prophylaxis of gastric varices. We compared the efficacy of addition of EUS-CG to ß-blockers against ß-blockers alone for primary prophylaxis of gastric variceal bleeding. **Methods:** This multi-centre observational study included patients across 11 tertiary care centres in India. Adult patients with cirrhosis and large gastric varices (F2 or F3) without prior bleeding were included. Baseline demographics, prior non-bleeding decompensating events and clinical outcomes including bleeding, hepatic decompensation and mortality were reviewed. Patients ß-blockers undergoing EUS-CG (EUS-CG + ß-

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

blocker arm) were compared with propensity-matched (PSM) patients on ß-blockers alone (ß-blocker arm). Competing risk analysis was performed to assess the risk of bleeding and hepatic decompensation, with mortality and liver transplantation as competing events. The primary outcome was to compare the incidence of first gastric variceal (GV) bleeding. **Results:** Of 366 patients, 106 who underwent EUS-CG and received ß-blockers were compared with 106 propensity-matched cases who received ß-blockers alone. Patients who underwent EUS-CG and received ß-blockers had significantly lower incidence of GV bleeding at 3 years compared to patients who received ß-blockers alone (5.7% vs 14.2%; p = 0.04). There was no significant difference in the probability of being free from overall bleeding (sHR: 0.63, 95% CI:0.33-1.21;p = 0.17), freedom from hepatic decompensation (sHR:0.76, 95% CI:0.49-1.20 ;p = 0.24) and overall survival (sHR: 1.31, 95% CI: 0.68-2.52; p = 0.43) between the 2 groups. On sub-group analysis, lower rates of GV bleeding were observed in the EUS-CG and ß-blocker arm in patients with IGV1 varices (sHR: 014, 95% CI: 0.03-0.67; p = 0.01), F3 varices (sHR: 0.27, 95% CI: 0.10-0.74; p = 0.01) and patients with red colour sign (RCS) on endoscopy (sHR: 019, 95% CI: 0.06-0.63; p = 0.01). On multivariate regression analysis, higher MELD-Na score alone was a significant predictor of bleeding (aOR:1.12,95%CI:1.06-1.19;p = 0.03) and mortality (aOR: 1.23,95%CI:1.11-1.34;p = 0.02). **Conclusion:** In patients with cirrhosis and large gastric varices, addition of EUS-coil and glue injection to ß-blockers was superior to ß-blockers alone for the prevention of first GV bleeding. Lower rates of GV bleeding were specifically noted in patients with IGV1 varices, F3 varices and patients with RCS on endoscopy.

Kaplan Meier curves showing: (A) cumulative probability of all-cause bleeding, (B) variceal bleeding, (C) overall decompensation and (D) overall survival between EUS-coil and glue + B-blocker arm compared to B-blocker alone arm

1461 | ◆ REMIMAZOLAM VERSUS PROPOFOL FOR PROCEDURAL SEDATION DURING UPPER ENDOSCOPY IN PATIENTS WITH CIRRHOSIS: A SYSTEMATIC NARRATIVE REVIEW OF SAFETY EVIDENCE ACROSS CHILD-PUGH SUBGROUPS

Neev Mehta Ishan Antony[1], [1]Lahey Clinic

Background: Patients with cirrhosis require repeated EGD for variceal surveillance amid portal hypertension, low vascular resistance, and hepatic encephalopathy (HE). Propofol has replaced midazolam as preferred sedative because it does not worsen subclinical HE. Remimazolam, metabolized by tissue esterases rather than CYP450, offers hemodynamic stability and flumazenil reversibility, but raises concerns in advanced cirrhosis where esterase activity is substantially reduced. **Methods:** We conducted a PRISMA-compliant systematic narrative review. PubMed, Embase, and Cochrane Library were searched through March 2024 using MeSH terms: “remimazolam,” “propofol,” “liver cirrhosis,” “endoscopy,” and “hepatic encephalopathy.” Two authors independently screened records; disagreements resolved by consensus. Eligible studies were RCTs or systematic reviews reporting sedation safety, or pharmacokinetic studies in hepatic impairment; studies lacking a comparator were excluded. Risk of bias was assessed using Cochrane RoB2 (RCTs) and AMSTAR-2 (meta-analyses). Outcomes including respiratory depression, hypoxemia, hypotension, HE worsening, and recovery time, were stratified by Child-Pugh class. No primary data accessed. **Results:** Across 26 RCTs (n = 3,641), remimazolam reduced respiratory depression (RR 0.40), hypoxemia (RR 0.34), hypotension (RR 0.36), and bradycardia (RR 0.34) vs. propofol (all $p < 0.01$, GRADE High for most; Table 1). The advantages amplified in cirrhosis, where low vascular resistance heightens susceptibility to propofol-induced compromise. Child-Pugh stratification revealed a key gradient (Table 2). In Child-Pugh A, clearance is preserved. In Child-Pugh B, esterase activity falls ~38%, extending recovery to ~12–14 minutes. In Child-Pugh C, clearance drops ~75% and recovery doubles to ~16.7 minutes, making flumazenil a clinical necessity. On HE, evidence favors propofol (Table 3): multiple RCTs confirm no worsening of subclinical HE across cirrhosis

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

subgroups. Remimazolam's HE data are limited to one underpowered RCT; a GABA-ergic class effect in Child-Pugh C cannot be excluded. **Conclusion:** Remimazolam offers a meaningful hemodynamic and respiratory advantage in Child-Pugh A and B cirrhosis. In Child-Pugh C, impaired clearance and unresolved HE risk favor propofol for HE prevention. A prospective RCT in decompensated cirrhosis with neuropsychometric and hemodynamic endpoints is needed. Until then, remimazolam in Child-Pugh C warrants dose reduction, flumazenil availability, and extended monitoring.

Table 1. *Remimazolam vs. propofol: pooled safety outcomes (Zhao et al., Int J Surg 2023; 26 RCTs, n = 3,641)*

Safety outcome	Remimazolam	Propofol	Risk ratio (95% CI)	p-value	GRADE
Respiratory depression	~8%	~20%	0.40 (0.28–0.57)	< 0.01	High
Hypoxemia	~6%	~17%	0.34 (0.23–0.49)	< 0.01	High
Hypotension	~7%	~19%	0.36 (0.26–0.48)	< 0.01	Low
Bradycardia	~5%	~14%	0.34 (0.23–0.51)	< 0.01	High
Injection site pain	< 1%	~16%	0.06 (0.03–0.13)	< 0.01	High

RR < 1.0 favors remimazolam. GRADE ratings from source meta-analysis. Source: Zhao et al., Int J Surg 2023;109(11):3566–77.

Table 2. *Remimazolam pharmacokinetics and clinical implications by Child-Pugh class*

Child-Pugh class	Esterase clearance vs. healthy	Recovery time	Remimazolam considerations	Propofol considerations
A — compensated	Normal	~8 min	Standard dosing; predictable offset; flumazenil available	Preferred; does not worsen HE; rapid recovery
B — moderate	↓ ~38%	~12–14 min	Dose reduction advised; extended monitoring; flumazenil an advantage	Hemodynamic vigilance; hypotension risk in moderate decompensation
C — decompensated	↓ ~75%	~16.7 min	Prolonged sedation; accumulation risk; flumazenil reversal critical; use with caution	Severe hypotension risk; low SVR amplifies vasodepressor effect

Recovery time: ~16.7 min (severe hepatic impairment) vs. 8.0 min (healthy). Sources: Murrell & Hartleroad; Eur J Drug Metab Pharmacokinet 2025; Frontiers in Medicine 2026.

Table 3. *Post-procedural HE worsening: key evidence by sedative agent*

Study	Agent	n	HE assessment	Key finding
Riphaus et al., J Hepatol 2010	Propofol vs. midazolam	61	NCT pre/post EGD	Propofol: no HE worsening; midazolam: NCT delayed
Suh et al., Korean J Hepatol 2013	Propofol (deep sedation)	20	PHES + CFF	No overt HE; CFF unchanged in non-MHE patients
Nishizawa et al., J Hepatol 2014	Propofol vs. + midazolam	132	NCT at 2 h post-EGD	Propofol alone safe; midazolam regimens: NCT worsened
Cao et al., Med Sci Monit 2022	Remimazolam tosylate	Cirrh*	AE monitoring	No HE events reported; favorable hemodynamics
Moraru et al., Am J Ther 2025	Review: remimazolam in HE	N/A	Narrative synthesis	Flumazenil key advantage; CP-C HE risk unresolved

**Cirrhosis patients; not stratified by Child-Pugh. NCT, number connection test; CFF, critical flicker frequency; MHE, minimal HE; AE, adverse event.*

1462 | ◆ ADVANCED LIVER FIBROSIS IS ASSOCIATED WITH SKELETAL MUSCLE DISRUPTED HOMEOSTASIS AND INCREASED INFLAMMATION

Enis Kostallari[1] Kate Kurotani[2] Charles Cox[2] Peng Xu[3] Marion Tanguy[4] Zeba Firdaus[3] Alexander Washington[3] Timucin Taner[1] Julie Heimbach[1] Patrick Starlinger[3] Pierre-Emmanuel Rautou[5] Meng Yin[3] Enis Kostallari[1], [1]Mayo Clinic Rochester, [2]Mayo Clinic, University of Minnesota Rochester, [3]Mayo Clinic, [4]4Centre de recherche sur l'inflammation, Université Paris-Cité, Inserm, UMR 1149, Paris, France, [5]Centre de recherche sur l'inflammation, Université Paris-Cité, Inserm, UMR 1149, Paris, France

Background: The loss of skeletal muscle mass, or sarcopenia, is a common finding in patients with cirrhosis and observed in 50% of patients assessed for liver transplantation. Sarcopenia is associated with mortality pre- and post-liver transplantation, a higher rate of infection, hepatic encephalopathy, poor quality of life, and increased healthcare cost. However, the characterization of the skeletal muscles remains elusive and is the scope of this study. **Methods:** Livers and dorsal skeletal muscles of 62 healthy individuals or patients with metabolic-associated steatotic liver disease (MASLD) liver fibrosis were imaged using magnetic resonance (MRI). Individuals were sex, age and BMI-matched. Skeletal muscle area was normalized to the thoracic cage surface (Mu-Tho ratio). Human skeletal muscles were characterized by H&E and bulk RNA-seq. Large extracellular vesicles (lEVs) from human sera were analyzed by mass spectrometry. Liver fibrosis in C57Bl/6 or Alb-Cre mice was induced by carbon tetrachloride (CCl_4) and mouse skeletal muscles were characterized by H&E, BODIPY staining and immunostaining. **Results:** Mu-Tho ratio decreased in patients with stage F2-F3 liver fibrosis (3.5 kPa < liver stiffness < 5 kPa) and F4 liver fibrosis (liver stiffness > 5 kPa) compared to patients with F0-F1 liver fibrosis (liver stiffness < 3.5 kPa) (4.2, 4.2, 5.1, respectively, $p < 0.05$). Utilizing the Spearman correlation, Mu-Tho ratio positively correlated with muscle stiffness and negatively correlated with muscle fat fraction and liver stiffness, suggesting that muscle loss is associated with liver fibrosis and muscle fat. RNA-seq of human skeletal muscles revealed that patients with liver cirrhosis (liver stiffness > 5 kPa) had increased expression of inflammatory genes such as CCL2 (112-fold) and IL6 (47-fold) compared to healthy individuals ($p < 0.05$). Infiltrating cells were present in these muscles, suggesting that skeletal muscles from individuals with cirrhosis are inflamed. Circulating lEVs from patients with Child-Pugh C cirrhosis were enriched with liver-specific proteins such as SerpinA7 and ApoA5, suggesting that liver might affect skeletal muscles through lEVs. In mice, Alb-Cre mice with liver fibrosis and injected with AAV8-GFP (green hepatocytes) contained green vesicles in the tibialis anterior muscle as compared to olive oil controls, suggesting that fibrotic liver-derived EVs are taken up by skeletal muscles. In addition, mice with liver fibrosis had sarcopenia as attested by a 10% reduction of gastrocnemius muscle weight ($p < 0.05$) and 2-fold decrease of myofiber diameter ($p < 0.001$), suggesting that this model recapitulates sarcopenia. **Conclusion:** These results suggest that liver fibrosis is associated with skeletal muscle inflammation and dysregulated homeostasis and EVs might be involved in liver-skeletal muscle axis.

1463 | ◆ CANNABIS USE AND DECOMPENSATION OUTCOMES IN CIRRHOSIS: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Brandon Cunha[1] Jashanveer Johal[1] Archana Salek[1] Bianca Patel[1] Mahmoud Al-Bataineh[1] Abdallah Hussein[1] Jason Hyman[2] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Background:: Cannabinoid receptor signaling exerts divergent effects in cirrhosis: CB1 activation promotes portal vasodilatation, splanchnic pooling, and stellate cell activation, whereas CB2 signaling may exert anti-inflammatory and antineoplastic effects. However, the impact of cannabis use on decompensation, HCC incidence, and mortality in cirrhosis remains poorly characterized despite increasing cannabis use prevalence. **Methods: Methods::** We performed a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 included adults with non-alcoholic, non-viral cirrhosis (K74.6) and cannabis use disorder (F12.10, F12.20, F12.90). Cohort 2 included matched cirrhotic patients without cannabis use. Patients with alcoholic liver disease/cirrhosis, alcohol or opioid dependence, and chronic hepatitis B/C were excluded. Cohorts were balanced via 1:1 PSM yielding 9,464 patients per arm over a 6–120 month follow-up window. Prespecified outcomes included new or progressive ascites, hepatic encephalopathy (HE), esophageal varices (EV), spontaneous bacterial peritonitis (SBP), incident HCC, all-cause mortality, and inpatient encounters. **Results: Results::** Post-PSM cohorts were well-balanced across matched covariates. Cannabis use was associated with significantly higher rates of portal hypertensive decompensation. HE occurred more frequently in cannabis users on both MOA (18.8% vs. 15.3%; RR 1.23; $p < 0.001$) and KM analysis (HR 1.28, 95% CI 1.20–1.37; $p < 0.001$). EV incidence was higher in the cannabis cohort (11.1% vs. 10.0%; HR 1.14, 95% CI 1.04–1.24; $p = 0.004$), as was SBP (4.0% vs. 3.1%; HR 1.34, 95% CI 1.15–1.56; $p = 0.0002$). Ascites rates were similar on time-to-event analysis (HR 1.05, 95% CI 1.00–1.11; $p = 0.053$). Incident HCC was significantly lower among cannabis users (2.0% vs. 2.8%; HR 0.76, 95% CI 0.63–0.92; $p = 0.005$), as well as all-cause mortality (23.8% vs. 29.6%; HR 0.82, 95% CI 0.78–0.87; $p < 0.001$). Median survival was not reached in the cannabis cohort versus 2,758 days in controls. Inpatient encounter burden was higher in the cannabis arm (58.3% vs. 50.8%; HR 1.29, 95% CI 1.24–1.34; $p < 0.001$), with a shorter median time to first encounter (241 vs. 564 days). **Conclusion: Conclusion::** In this propensity-matched real-world cohort, cannabis use in cirrhosis was associated with higher rates of portal hypertensive complications, including HE, EV, and SBP, but lower HCC incidence and all-cause mortality. These findings suggest divergent hepatic associations of cannabis use in cirrhosis. The observed reduction in mortality despite increased decompensation events may reflect residual confounding by age, physiologic reserve, and unmeasured liver disease severity, including lack of MELD stratification. Prospective fibrosis stage–stratified studies are needed to clarify the net hepatic impact of cannabis use.

1464 | ◆ THE OBESITY PARADOX IN SPONTANEOUS BACTERIAL PERITONITIS: ASSESSING OUTCOMES IN PATIENTS WITH CIRRHOSIS

Arti Patel[1] Sujay Singh[1] Homan Abdollahzadeh[1], [1]Eisenhower Medical Center

Background: Spontaneous bacterial peritonitis (SBP) is a serious complication of cirrhosis associated with substantial morbidity and mortality. Obesity has traditionally been linked to adverse health outcomes; however, emerging evidence suggests the presence of an obesity paradox, where higher body mass index may be associated with improved outcomes. We evaluated the impact of obesity on clinical characteristics and outcomes among hospitalized patients with cirrhosis and SBP. **Methods:** This retrospective cohort study used the National Inpatient Sample (NIS) to identify adults between 2019 and 2022 with cirrhosis and SBP, comparing patients with obesity to those without obesity. Demographics, comorbidities, inpatient complications, and hospitalization outcomes were analyzed. Univariate analyses were performed using STATA software. **Results:** Of the 105,405 patients who met the inclusion criteria, 62.2% were male and the mean age was similar between groups (60.0 vs 57.3 years, $P \geq 0.05$); however, females were more likely to be obese ($P < 0.05$). White patients were more

likely (OR 1.236, 95% CI 1.128-1.353), while Black (OR 0.659, 95% CI 0.554-0.783), Asian (OR 0.517, 95% CI 0.365-0.732), and patients of other races (OR 0.724, 95% CI 0.563-0.931) were less likely to be obese; no significant differences were seen among Hispanic and Native American patients ($P \geq 0.05$). Chronic obstructive pulmonary disease, congestive heart failure, diabetes, and hypertension were more common among obese patients, whereas alcohol use, cancer, malnutrition, and smoking were less common ($P < 0.05$). No significant differences were observed in dementia and end-stage renal disease ($P \geq 0.05$). Obese patients had lower odds of variceal bleeding (OR 0.824, 95% CI 0.706-0.962), hepatocellular carcinoma (OR 0.814, 95% CI 0.683-0.970), and inpatient mortality (OR 0.846, 95% CI 0.752-0.952), but higher odds of acute kidney injury (OR 1.116, 95% CI 1.031-1.208). No differences were seen in rates of paracentesis, hepatic encephalopathy, acute liver failure, liver transplantation, ICU admission, length of stay, and total hospitalization charges ($P \geq 0.05$). **Conclusion:** Among patients with cirrhosis and SBP, obesity was associated with higher risk of acute kidney injury. However, it was found to be protective for variceal bleeding and associated with lower overall mortality. Our finding of an obesity paradox in cirrhosis may reflect differences in patients' nutritional status; further studies are necessary to better understand this association.

Table 1: Demographics

1465 | ◆ LONGITUDINAL TRAJECTORIES OF IL-6 AND VWF PREDICT CLINICAL OUTCOMES IN ADVANCED CHRONIC LIVER DISEASE INDEPENDENT OF LIVER FUNCTION

Georg Kramer[1] Dalila Costa[2] Benedikt Hofer[3] Benedikt Simbrunner[1] Ana Frias[2] Ricardo Silvestre[2] Joana Camoes Neves[2] João Belmiro Martins[2] Kerstin Zinober[3] Vlad Taru[3] Christian Sebesta[3] Paul Thöne[3] Marlene Hintersteininger[3] Lorenz Balcar[3] Lukas Hartl[3] Mathias Jachs[3] Georg Semmler[1] Michael Trauner[3] Carla Rolanda[3] Thomas Reiberger[1], [1]Medical University of Vienna, [2]Life and Health Sciences Research Institute (ICVS), University of Minho, [3]Medical University of Vienna, Vienna, Austria

Background: Systemic inflammation (SI) and portal hypertension (PH) are drivers of disease progression in cirrhosis. We investigated longitudinal, stage-dependent patterns of Interleukin-6 (IL-6), a surrogate for SI, and von Willebrand factor antigen (vWF), a surrogate of PH, across compensated (cACLD), decompensated (dACLD), and recompensated advanced chronic liver disease (ACLD), and assessed their association with subsequent clinical transitions. **Methods:** In this prospective two-center cohort study (Vienna/Braga, 2017-2024), ACLD patients were enrolled at their first combined IL-6 and vWF assessment. Inclusion required at least two longitudinal measurements of IL-6, vWF, and MELD, with a minimum interval of 6 months between the first and last assessment. Clinical disease evolution was modeled using a 5-state multi-state model (cACLD, first and further decompensation, clinical recompensation, liver-related death [LRD]). Bayesian joint models linked biomarker trajectories to transition-specific hazards, adjusted for time-updated MELD. **Results:** This study included 472 patients (273 cACLD, 199 dACLD, mean age 53.5 ± 12.8 years, 67.1% steatotic liver disease, median MELD 11 [IQR: 8-15]) contributing 3,954 vWF and 2,918 IL-6 measurements. Over a median follow-up of 35.5 months, 138 transitions to first decompensation, 124 to further decompensation, 56 to clinical recompensation, and 35 to LRD occurred. Rising IL-6 independently predicted the transition to first decompensation, further decompensation, and LRD, with adjusted hazard ratios (aHR) per 20% increase of 1.21, 1.17, and 1.15, respectively (all $p < 0.001$). Conversely, decreasing IL-6 was associated with transition to clinical recompensation from first and further decompensation, with aHR per 20% decrease of 1.17 ($p = 0.007$) and 1.18 ($p < 0.001$), respectively. Increasing vWF predicted first and further decompensation, with aHR per 20% increase of 1.39

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

and 1.19 (both p < 0.001), respectively, while declining vWF levels were not significantly associated with recompensation or lower risk of LRD. **Conclusion:** Longitudinal modeling shows that dynamics in biomarkers of systemic inflammation (IL-6) and portal hypertension (vWF) are associated with ACLD progression independently of MELD. Rising vWF was most strongly linked to progression toward first decompensation, whereas IL-6 trajectories also reflected course in dACLD, predicting further decompensation and liver-related death when increasing, and clinical recompensation when decreasing.

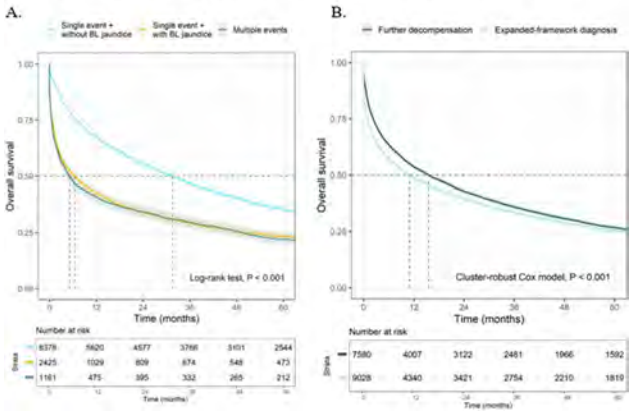
★ 1466 | ◆ IMPLICATION OF MULTIPLE FIRST DECOMPENSATION EVENTS ON THE DEFINITION OF FURTHER DECOMPENSATION

Jimmy Che-To Lai[1] Junlong DAI[1] Vincent Wong[1] Grace Wong[1] Terry Cheuk-Fung Yip[1], [1]The Chinese University of Hong Kong



Background: The upcoming Baveno VIII proposes an expansion of the definition of further decompensation by including multiple first decompensation events and/or jaundice. However, there is a lack of evidence to support this proposal. We aimed to assess the clinical implication of the proposed expanded definition. **Methods:** This was a retrospective cohort study on patients with decompensated cirrhosis between 2000 and 2020 in Hong Kong. Patients were classified into three groups, namely “single event without jaundice” (Group A), “single event with jaundice” (Group B) and “multiple events” (Group C), where jaundice was defined as bilirubin ≥ 85μmol/L at the time of first decompensation. Groups B and C were further classified as further decompensation according to the expanded definition and compared to those fulfilling the original Baveno VII definition using a cluster-robust Cox model. The primary endpoint was all-cause mortality. **Results:** 11,964 patients (Group A: 8,378; Group B: 2,425; Group C: 1,161) with decompensated cirrhosis were identified. Most had chronic hepatitis B and were male. The mean age ranged from 61.0-67.0 years. Patients in group B and C had poorer liver function (Child-Pugh scores 9, 11 and 12, respectively for Groups A-C, p < 0.001; median Model for End-stage Liver Disease [MELD] scores 12.0, 19.1 and 16.9, respectively, p < 0.001). The 1-year cumulative incidences of all-cause mortality were 32.7% (95% CI 31.6-33.6%), 57.5% (55.4-59.4%) and 58.9% (56.0-61.7%) for Groups A-C, respectively (p < 0.001) **(Figure 1A)** . Compared to single event without jaundice, single event with jaundice (adjusted hazard ratio [aHR] 1.27, 95% CI 1.20-1.35) and multiple events (aHR 1.37, 95% CI 1.28-1.48) were independent risk factors for mortality. An additional 1,448 patients with multiple decompensation events were classified as further decompensation based on the expanded definition (mean Child-Pugh score 11, median MELD score 25.1). The 1-year cumulative incidences of all-cause mortality were not different between the expanded definition and the Baveno VII definition (51.3% [95% CI 50.2-52.3%] vs 46.4% [45.3-47.5%] respectively, p = 0.208) **(Figure 1B)** . Adopting the expanded definition allowed an earlier identification of further decompensation by a median 1.8 (IQR 0.3-19.3)

Symbols: ◆, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

months. The sensitivity analysis yielded similar results when jaundice was defined as bilirubin ≥50μmol/L. **Conclusion:** Patients with multiple decompensation events and/or jaundice had worse clinical outcomes than those with single decompensation event. Expanding the definition of further decompensation to these patients led to an earlier identification of the at-risk population, validating the use of the Baveno VIII-proposed definition of further decompensation. **Financial support:** This study is supported by the Health and Medical Research Fund of Health Bureau of HKSAR Government (Reference number: 11222426) to Jimmy Lai.

Figure 1. Cumulative incidence of mortality, (A) among Groups A-C and (B) among patients fulfilling the Baveno VII and expanded definition for further decompensation.

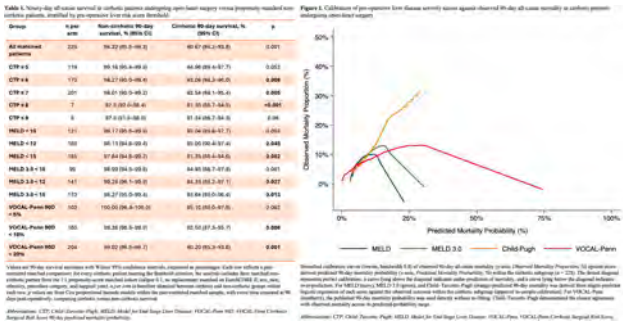
1467 | ◆ CALIBRATION AND THRESHOLD PERFORMANCE OF LIVER DISEASE SEVERITY SCORES IN OPEN-HEART SURGERY: A PROPENSITY-MATCHED MULTICENTRIC ANALYSIS



Leandro Sierra[1] Zainab Ifthikar[1] Walaa Mahmoud[2] Nicholas Ruthman[2] John McMichael[2] Tang Li[2] Omar Sims[1] William Carey[2], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic

Background: Many tools have been developed to risk-stratify (RS) those with cirrhosis (C) in need of surgery. We have recently shown limitations of Mayo Clinic, and Vocal-Penn Scores in the context of open-heart surgery (OHS) (1). Aim: In patients with C undergoing OHS to 1) compare the fidelity of various RS tools in predicting mortality; 2) ascertain optimal time horizon to capture risk. **Methods:** MELD, MELD 3.0, CTP, and VOCAL-Penn (VPS) predictors of mortality were compared. We conducted a multicenter retrospective cohort study comparing adults with and without cirrhosis (C versus NoC) undergoing OHS at Cleveland Clinic Main Campus and Cleveland Clinic Florida (2014–2024). Patients on therapeutic anticoagulation without standardized washout and those with incomplete preoperative laboratories were excluded. 1:1 propensity-score matching (caliper 0.1, no replacement) on EuroSCORE II, sex, race, ethnicity, procedure category, and surgical year yielded 225 cirrhotic and 225 non-cirrhotic patients. For each score, we identified the threshold at which 30 and 90-day mortality in C diverged from matched NoC patients using Kaplan–Meier and Cox proportional hazards analyses. Score calibration was assessed graphically within the cirrhotic subgroup by lowess smoothing of observed against predicted 90-day mortality. **Results:** Thirty-day mortality did not differ significantly between C and matched NoC patients (2.22% vs 1.33%; HR 2.59, 95% CI 0.50–13.35, P = 0.26) but diverged sharply by 90 days (9.33% vs 1.78%; HR 7.48, 95% CI 2.23–25.07, P = 0.001). C patients with CTP score =5, MELD or MELD 3.0 < 10, or VPS 90 day prediction < 5% did not experience higher 90 day mortality.(Table 1) Ninety-day mortality increased with CTP score, with a threshold transition at CTP 6: CTP 5, 5.04% (HR 3.95, P = 0.052); CTP 6, 11.11% (HR 9.29, P = 0.002); CTP 7, 10.71% (HR 8.82, P = 0.008); CTP 8, 42.86% (HR 34.64, P < 0.001). On calibration (Figure 1), CTP closely tracked observed mortality across the full predicted range; MELD and MELD 3.0 over-estimated risk above predicted values of approximately 10%; VOCAL-Penn 90D showed the most pronounced miscalibration, with observed mortality plateauing near 13% despite predicted values

reaching 75%. **Conclusion:** Cirrhosis-attributable mortality after OHS is not apparent at 30 days but emerges clearly by 90-days. OHS in C confers no added mortality risk when CTP = 5, MELD, MELD 3.0 < 10, or VPS 90 day risk < 5%. Among current RS scores, CTP had the best agreement between predicted and observed 90-day mortality; VPS, MELD, and MELD 3.0 substantially over-estimated mortality risk. These findings validate continued use of CTP as a primary means of RS in cirrhotics undergoing OHS. Development of a dedicated cardiac-surgery–specific hepatic risk score is needed.[1] **Jenkins H** et al H. JTCVS Open. 2026 Mar 6;30:101718. doi: 10.1016/j.xjon.2026.101718. eCollection 2026 Apr.PMID: 42079952

1468 | ◆ ULTRASOUND LOCALIZATION MICROSCOPY FOR DIAGNOSIS OF CLINICALLY SIGNIFICANT PORTAL HYPERTENSION: A PROSPECTIVE MULTICENTER STUDY

Wei Zhang[1] Chuan Liu[2] Xinde Gong[3] Yingchun Yuan[4] Jiahao Han[5] Xia Chen[6] Su Wu[7] Xiangwu Wang[8] Jie Ren[9] Xiaolong Qi[10], [1]Department of Ultrasound, The Third Affiliated Hospital of Sun Yat-sen University, [2]Zhongda Hospital, Medical School, Southeast University, [3]TaiHe Hospital (Affiliated Hospital Of HuBei University Of Medicine), [4]General Hospital of Ningxia Medical University, [5]Department of Ultrasound, Zhongda Hospital Southeast University, [6]The First Affiliated Hospital of USTC, Division of Life Sciences and Medicine, University of Science, [7]Xingtai People's Hospital, [8]Department of Ultrasound in Medicine, Tangdu Hospital, Air force Medical University, [9]Department of Ultrasound, The Third Affiliated Hospital of Sun Yat-sen University, [10]Department of Radiology, Zhongda Hospital, Medical School, Southeast University

Background: Hepatic venous pressure gradient (HVPG) is the gold standard for diagnosing clinically significant portal hypertension (CSPH), but its invasive nature limits routine use. Existing noninvasive methods mostly rely on indirect indicators such as liver stiffness and have diagnostic “grey zones”. Ultrasound localization microscopy (ULM) can noninvasively visualize microvascular perfusion and morphology in the liver with super-resolution. This study aimed to assess the feasibility and accuracy of ULM for noninvasive diagnosis of CSPH. **Methods:** This prospective, multicenter diagnostic study enrolled patients with chronic liver disease from eight hospitals between October 2024 and May 2026. CSPH was defined as HVPG ≥ 10 mmHg. ULM images were acquired to extract perfusion and morphological parameters, including vessel density (VD) and flow-weighted vessel density (FWVD). LASSO regression was used for feature selection, and a logistic regression prediction model was developed and internally validated in an independent validation cohort. The performance of the ULM-based model was compared with the Baveno VII criteria, APRI, and FIB-4. **Results:** A total of 147 patients (median age 52 years) were enrolled, with a CSPH prevalence of 68.0%. ULM parameters showed that, compared with the non-CSPH group, the CSPH group had significantly lower VD, FWVD, perfusion index, directional variance, and velocity entropy (all $P < 0.01$), but significantly higher velocity variance and coefficient of variation of velocity ($P < 0.01$), indicating reduced microvascular perfusion, disturbed flow, and increased vascular tortuosity in CSPH patients. The final prediction model included six variables: hemoglobin, platelet count, albumin (ALB), international normalized ratio (INR), VD, and FWVD. In the derivation cohort, the model achieved an AUC of 0.971 (95% CI: 0.931–0.996) for predicting CSPH, significantly outperforming other noninvasive scores. In the validation cohort, the AUC was 0.963 (95% CI: 0.901–0.999), with good calibration and significant net clinical benefit. The model also showed the best performance for diagnosing HVPG ≥ 12 mmHg and HVPG ≥ 20 mmHg. **Conclusion:** The ULM-based prediction models accurately diagnose HVPG ≥ 10 mmHg (CSPH), HVPG ≥ 12 mmHg, and HVPG ≥ 20 mmHg, reflecting portal pressure changes from the perspectives of microvascular perfusion and morphology. It offers excellent discrimination, calibration, and clinical utility, providing a novel imaging tool for noninvasive assessment and dynamic monitoring of portal hypertension in cirrhosis.

1469 | ◆ ASSOCIATION OF MIDODRINE USE WITH RENAL AND TRANSPLANT OUTCOMES IN PATIENTS WITH HEPATORENAL SYNDROME–CHRONIC KIDNEY DISEASE: A PROPENSITY SCORE-MATCHED ANALYSIS

Abdullah Sohail[1] Sara Naimimohasses[1] Jackson Snyder[2], [1]The University of Iowa Hospitals and Clinics, [2]Roy J. and Lucille A. Carver College of Medicine

Background: Midodrine is frequently used as an oral vasoconstrictor in patients with cirrhosis and hepatorenal syndrome–chronic kidney disease (HRS-CKD), particularly when intravenous vasopressors or terlipressin are not feasible. However, real-world data evaluating its association with renal outcomes in this population remain limited. We assessed whether midodrine use was associated with differences in clinical outcomes at 6 months and 1 year. **Methods:** We conducted a retrospective cohort study using data from the TriNetX Research Network, which encompasses data from 109 healthcare organizations. Adults aged ≥18 years with HRS-CKD were identified using ICD-10-CM codes. The treatment cohort included patients who received midodrine; the control cohort included patients without midodrine exposure. Patients with pre-existing acute kidney failure, end-stage kidney disease, dialysis dependence, dialysis-related encounters, or prior kidney transplant were excluded. Outcomes were assessed from 1 day after the index event through 180 and 365 days. Propensity score matching was performed on demographics, liver disease diagnoses, cardiovascular comorbidities, and relevant medications, including diuretics, beta-blockers, albumin, octreotide, and terlipressin. After matching, 1,625 patients were included in each cohort. **Results:** At 180 days, mortality was similar between the control and midodrine cohorts (34.2% vs. 33.0%; OR 1.06, 95% CI 0.91–1.22; p = 0.458). Dialysis initiation occurred less frequently in the midodrine cohort (2.4% vs. 3.9%; OR 1.64, 95% CI 1.09–2.46; p = 0.016), with time-to-event analysis confirming a lower dialysis risk (HR 1.58, 95% CI 1.06–2.36; log-rank p = 0.023). Kidney transplantation (1.0% vs. 1.6%; p = 0.167) and liver transplantation (11.2% vs. 12.0%; p = 0.476) did not differ significantly between groups.At 365 days, mortality remained similar (37.1% vs. 36.0%; OR 1.05, 95% CI 0.91–1.21; p = 0.512). Dialysis initiation remained less frequent in the midodrine cohort (2.8% vs. 4.5%; OR 1.62, 95% CI 1.11–2.35; p = 0.012), with consistent findings on time-to-event analysis (HR 1.55, 95% CI 1.08–2.25; log-rank p = 0.018). Kidney transplantation and liver transplantation rates did not differ significantly between groups at 1 year. **Conclusion:** In this large propensity score-matched cohort of patients with HRS-CKD, midodrine use was associated with a significantly lower risk of dialysis initiation at both 6 months and 1 year, while mortality, kidney transplantation, and liver transplantation rates did not differ significantly. These findings suggest that midodrine may confer a renal-protective benefit in HRS-CKD, although prospective trials are required to validate these findings.

1470 | ◆ PULMONARY HEMODYNAMIC RESPONSE TO PORTOSYSTEMIC SHUNT OCCLUSION IN PORTAL HYPERTENSION: IMPACT OF SHUNT CHARACTERISTICS ON BRTO RESPONSE

Tsuyoshi Ishikawa[1] Aika Kirihara[1] Maho Egusa[1] Natsuko Nishiyama[1] Daiki Kawamoto[1] Ryo Sasaki[1] Tatsuro Nishimura[1] Taro Takami[1], [1]Yamaguchi University Graduate School of Medicine

Background: Spontaneous portosystemic shunts (PSSs) may contribute to pulmonary hemodynamic abnormalities in portal hypertension by promoting hyperdynamic circulation and systemic exposure to vasoactive mediators. However, the effects of PSS occlusion on pulmonary hemodynamics and predictors of treatment response remain unclear. This study evaluated cardiopulmonary hemodynamic changes after balloon-occluded retrograde transvenous obliteration (BRTO) and factors associated with treatment response. **Methods:** This single-center retrospective study included 28 patients with portal hypertension and spontaneous PSSs who underwent transthoracic echocardiography both before and 1 month after initial BRTO between January 2020 and December 2025. Tricuspid regurgitation pressure gradient (TRPG), cardiac output (CO), endothelin-1 (ET-1), and 5-hydroxytryptamine (5-HT) levels were evaluated. PSS characteristics and portal-splenic hemodynamics were assessed using contrast-enhanced CT and indirect portography. **Results:** Compared with patients with lower baseline TRPG, those with high baseline TRPG ($\geq$22.0 mmHg; cohort median) more frequently had splenic vein (SpV)-derived shunts (100.0% vs 69.2%, p = 0.0203) and hepatofugal SpV flow (66.7% vs 23.1%, p = 0.0211), whereas PSS size was not associated with baseline TRPG. BRTO significantly reduced TRPG (23.8 ± 7.3 to 21.6 ± 6.5 mmHg, p = 0.0050), accompanied by significant reductions in CO (p = 0.0030), ET-1 (p = 0.0458), and 5-HT (p = 0.0248). TRPG reduction was observed in 75.0% of patients. In contrast to factors associated with baseline TRPG, PSS size, namely maximum shunt diameter, was the only factor significantly associated with TRPG reduction after BRTO (17.3 ± 4.9 vs 12.1 ± 4.4 mm, p = 0.0204). The optimal cutoff value was 12.5 mm (AUROC 0.7959, sensitivity 71.4%, specificity 81.0%). Patients with large PSSs ($\geq$12.5 mm) showed significant improvements in cardiopulmonary hemodynamics and hepatic functional reserve after BRTO, whereas those with smaller shunts showed no significant changes. **Conclusion:** PSS occlusion by BRTO improved cardiopulmonary hemodynamics in patients with portal hypertension. Larger PSS diameter was associated with greater hemodynamic response to BRTO. Imaging assessment of spontaneous PSS characteristics may help identify patients most likely to benefit from BRTO-induced cardiopulmonary hemodynamic modulation.

Kookwan Sawadpanich[1] Apichat Sangchan[1] Pisaln Mairiang[1] Wattana Sukeepaisarnjaroen[1], [1]Division of Gastroenterology and Hepatology

Background: Portal hypertension drives hepatic decompensation and mortality in liver cirrhosis, yet effective pharmacological prevention remains an unmet need. Statins' pleiotropic effects on intrahepatic vascular resistance and portal pressure offer compelling biological rationale, but prospective evidence supporting atorvastatin for preventing first decompensation in compensated cirrhosis is strikingly scarce. We conducted the first randomized controlled trial in an Asian cohort to rigorously evaluate atorvastatin 20 mg daily on dynamic liver stiffness and hepatic decompensation incidence. **Methods:** This prospective, single-center, double-blind, placebo-controlled trial enrolled adults (18–65 years) with compensated cirrhosis (CTP score ≤ 6) and ≥ 1 high-risk feature: LSM ≥ 20 kPa, platelets $\leq 150\times10^9$/L, esophageal varices, or portosystemic collaterals. Participants were randomized 1:1 to atorvastatin 20 mg or matching placebo for 96 weeks. The primary endpoint was LSM response ($\geq 30\%$ reduction or LSM < 20 kPa) at 12, 24, and 48 weeks by VCTE. Secondary endpoints included time to first hepatic decompensation and safety outcomes. Analyses used intention-to-treat MMRM and multivariable logistic regression. **Results:** Sixty-four patients were randomized (atorvastatin n = 32; placebo n = 32) with well-matched baseline LSM (23.6 vs. 23.8 kPa; P = 0.88). At 24 weeks, LSM response was achieved in 40.9% vs. 33.3% (adj.OR 2.07; 95%CI 0.46–9.39; P = 0.345). Critically, LSM trajectories diverged after week 12—the atorvastatin group demonstrated sustained decline (−16.2%) while the placebo group stabilized (−0.3%), suggesting an emerging biological effect. Within-group analysis confirmed a significant and durable LSM reduction only in the atorvastatin arm at 24 weeks (−4.71 kPa; P = 0.048). At 24 weeks, one patient (4.8%) in the placebo group developed ascites, while one patient (4.3%) in the atorvastatin group developed HCC. No additional liver-related complications or deaths were observed during follow-up. Atorvastatin was associated with modestly higher ALT at 24 weeks (+11.10 U/L; P = 0.038) and greater aminotransferase elevation $> 3\times$ULN (30.4% vs. 4.8%; P = 0.048); however, no CTCAE Grade ≥ 3 hepatotoxicity, rhabdomyolysis, or clinically significant myopathy occurred. Creatine kinase remained comparable throughout. **Conclusion:** At this 24-week interim analysis, atorvastatin 20 mg demonstrated an acceptable safety profile in high-risk compensated cirrhosis without severe hepatotoxicity or muscle injury. Although the primary endpoint did not reach statistical significance, diverging LSM trajectories and sustained within-group LSM reduction represent encouraging early biological signals. Completion of the full 96-week follow-up is essential to establish whether atorvastatin prevents hepatic decompensation in this underrepresented Asian population.

1472 | ◆ U-SHAPED ASSOCIATION BETWEEN PORTAL PRESSURE REDUCTION AND POST-TIPS OUTCOMES SUGGESTS A RELATIVE LOW-RISK INTERVAL FOR POST-TIPS COMPLICATIONS

Zhiling Zhou[1] Dazhi Zhang[2] Qiongfang Zhang[1] Chang Shu[1] YuanKang Luo[1] HuiMin Fan[1] ZhiHan Zhang[1] Yang Lv[1], [1]Chongqing Medical University, [2]Chongqing Medical University

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is an effective treatment for complications of portal hypertension, but hepatic encephalopathy (HE) remains a major limitation. Portal pressure gradient (PPG)-based targets, derived largely from the bare-stent era, remain the standard framework for procedural guidance. However, clinically relevant complications continue to occur even when target PPG reduction is achieved, suggesting that static pressure thresholds may not fully capture individual hemodynamic responses in contemporary covered-stent TIPS. Portal venous pressure (PVP) provides a direct measure of intra-procedural pressure change and may offer complementary information to PPG-based assessment. We therefore evaluated the association between portal pressure reduction and post-TIPS outcomes, with particular emphasis on hepatic encephalopathy (HE), to investigate a relative low-risk decompression range. **Methods:** We retrospectively analyzed 175 patients who underwent

covered-stent TIPS between 2018 and 2025. Portal venous pressure (PVP) was measured before and after the procedure. Absolute (ΔPVP) and relative (ΔPVP%) pressure reductions were calculated. Post-TIPS complications included HE, variceal rebleeding, new-onset ascites or pleural effusion, and shunt dysfunction. Restricted cubic spline, Kaplan–Meier, and multivariable Cox regression analyses were performed. **Results:** During follow-up, 71 patients (40.6%) developed post-TIPS complications, including HE in 38 (21.7%). ΔPVP demonstrated significant U-shaped associations with both overall complications and HE. A relative low-risk interval for overall complications was observed at approximately 11–19 mmHg, within which HE risk was lowest at approximately 13–17 mmHg. Kaplan–Meier analyses showed significant differences across ΔPVP groups ($P = 0.043$ for overall complications; $P = 0.032$ for HE). Both lower and higher ΔPVP were independently associated with increased HE risk (both $P < 0.05$). In contrast, post-TIPS PVP was not significantly associated with outcomes, while ΔPVP% showed similar but non-significant nonlinear trends. **Conclusion:** Portal pressure reduction after covered-stent TIPS demonstrated a U-shaped association with post-procedural outcomes, suggesting a non-linear and structured relationship between decompression magnitude and clinical risk. A relative low-risk interval was identified for overall complications, within which HE risk followed a narrower distribution. These findings suggest that ΔPVP may serve as a complementary hemodynamic parameter to conventional PPG-based assessment, potentially aiding individualized risk stratification and helping to reduce post-TIPS complications in clinical practice.

1473 | INTEGRATED CLINICAL AND EXPERIMENTAL CHARACTERIZATION OF CARDIAC REMODELING IN CHRONIC LIVER DISEASE

Hyo-Jin Park[1] Shoma Bommena[2] Ege Kacira[3] Nickolaus Lorson[1] Amaya Bruner[1] Marjan Aghajani[3] Steven Kawut[4] Tobias Jakobi[3] Shirin Doroudgar[3] Michael Fallon[5], [1]University of Arizona, College of Medicine-Phoenix, [2]Banner University Medical Center-Tucson, University of Arizona, College of Medicine-Tucson, [3]Translational Cardiovascular Research Center, University of Arizona, College of Medicine-Phoenix, [4]Perelman School of Medicine, University of Pennsylvania, [5]Banner University Medical Center-Phoenix, University of Arizona, College of Medicine-Phoenix

Background: Cardiac dysfunction in chronic liver disease is a major contributor to morbidity and mortality despite the absence of overt cardiovascular disease. Although 30-70% of patients with advanced liver disease develop cardiac abnormalities, the mechanisms linking liver fibrosis to myocardial remodeling remain poorly defined. We hypothesized that liver fibrosis generates a distinct circulating milieu that drives cardiac structural and functional adaption. This study aimed to define myocardial phenogroups in cirrhosis and identify liver-derived mediators associated with cardiac remodeling and dysfunction. **Methods:** We performed unbiased clinical and echocardiographic phenotyping analysis in 454 adults with cirrhosis from the Pulmonary Vascular Complications of Liver Disease 2 cohort. Unsupervised machine learning integrated cardiac and clinical variables to identify myocardial phenogroups associated with liver disease severity and outcomes. Circulating mediators were assessed using targeted plasma biomarker analysis. Complementary animal studies utilized common bile duct ligation (CBDL)-induced liver fibrosis and partial portal vein ligation (PPVL)-induced portal hypertension mouse models. Advanced echocardiography assessed cardiac structure and function, and plasma endostatin levels were quantified by ELISA. **Results:** Three myocardial phenogroups were identified in cirrhosis. Group 1 “Reductive” demonstrated the lowest left ventricular mass index (LVMI), preserved ejection fraction (EF), low stroke volume, and compensatory increased heart rates, despite the lowest MELD scores, indicating uncoupling of mortality from liver disease severity. Group 2 “Concentric Remodeling” exhibited increased LVMI and metabolic dysregulation, while Group 3 “Hyperdynamic/Eccentric” demonstrated the highest MELD scores, frailty, and eccentric remodeling. Distict circulating factor signatures differentiated each phenogroup. Notably, Group 1 patients exhibited significantly elevated circulating endostatin, a collagen XVIII-derived factor, compared with other groups. In experimental studies, CBDL mice developed reduced LVMI and preserved EF, recapitulating key features of human Group 1 phenotype. Both CBDL and PPVL models exhibited diastolic dysfunction, although dysfunction was more severe in CBDL mice. Consistent with human findings, circulating endostatin levels were significantly elevated in CBDL but not PPVL mice, supporting a fibrosis-dependent mechanism linking liver injury to myocardial remodeling. **Conclusion:** Cardiac dysfunction in chronic liver disease comprises distinct

myocardial phenogroups associated with unique circulating factor profiles and clinical outcomes. Identification of fibrosis-associated liver factors provides a mechanistic framework for liver-heart crosstalk and highlights endostatin signaling as a potential therapeutic target.

1474 | MUSCLE QUALITY, RATHER THAN MUSCLE MASS ALONE, IS INDEPENDENTLY ASSOCIATED WITH FRAILTY SEVERITY AND FRAILTY PROGRESSION IN CIRRHOSIS

Avesh Thuluvath[1] Nghiem Ha[2] Wei Shen[3] Jennifer Lai[2] Elizabeth Verna[1], [1]Columbia University Medical Center, [2]University of California, San Francisco, [3]Columbia University Irving Medical Center

Background: Frailty is associated with increased mortality in cirrhosis. Although frailty is linked to sarcopenia, there is poor correlation between the Liver Frailty Index (LFI) and the Skeletal Muscle Index (SMI), the imaging gold standard measure of sarcopenia. Myosteatosis, characterized by intra/intermuscular fat deposition, has emerged as a predictor of mortality in cirrhosis and may better reflect impaired muscle function than muscle quantity alone. We hypothesized that poor muscle quality is a driver of frailty in cirrhosis. **Methods:** We performed a retrospective single center study of adults with cirrhosis who underwent abdominal CT within 6 months of LFI assessment, with ≥ 1 follow-up LFI. Muscle composition was assessed at the L3 vertebral level. Sarcopenia was measured using SMI. Intramuscular fat was measured by muscle density (Hounsfield units) and intermuscular fat by height-adjusted intermuscular adipose tissue (IMATI). Composite measures of muscle quality and quantity included the "myosteatosis-adjusted SMI," defined as SMI x muscle density, and "adverse muscle composition," defined as concomitant sarcopenia and myosteatosis using established sex-specific cutoffs. Frailty progression was assessed by longitudinal change in LFI (ΔLFI - change in LFI between frailty assessments adjusted for time). Multivariable linear and logistic regression analyses evaluated associations between body composition parameters and frailty outcomes. **Results:** Among 177 patients (68% male, mean age 60 ± 8 years, mean MELD 13 ± 5), 49% had ascites, 43% hepatic encephalopathy (HE) and 72% hepatocellular carcinoma (HCC). Mean baseline LFI was 3.7 ± 0.8: 24% were frail, 64% pre-frail and 12% robust. On baseline CT, 41% were sarcopenic, 26% had myosteatosis and 14% met criteria for adverse muscle composition (Figure 1A). On multivariable analysis adjusting for age, sex, MELD, ascites, HE and HCC, lower muscle density (greater intramuscular fat) (estimate [est] -0.02, $p = 0.002$) and adverse muscle composition (est 0.31, $p = 0.03$) were associated with greater frailty (higher LFI). Higher myosteatosis-adjusted SMI (est -0.0003, $p = 0.003$) was associated with less frailty (lower LFI), whereas standard SMI was not associated with frailty (est -0.007, $p = 0.34$) (Figure 1B). Among robust patients, IMATI (est 0.01, $p = 0.005$), myosteatosis-adjusted SMI (est -6.84 x 10^{-5}, $p = 0.04$) and adverse muscle composition (est 0.19, $p = 0.004$)—but not sarcopenia alone—were associated with ΔLFI (Figure 1C). **Conclusion:** Muscle impairment, reflected by myosteatosis and adverse muscle composition, is independently associated with frailty and progression of frailty in cirrhosis. These findings support the incorporation of muscle composition assessment into frailty evaluation and identify robust patients with adverse muscle composition as high-yield targets for early preventative frailty interventions.

1475 | STROOP-DEFINED MINIMAL HEPATIC ENCEPHALOPATHY IS STABLE AND RESPONSIVE TO CLINICAL EVENTS IN A MULTI-CENTER CIRRHOSIS COHORT

Vinay Jahagirdar[1] Scott Silvey[2] Dan Park[1] Ali Khan[1] K Rajender Reddy[3] Puneeta Tandon[4] Jennifer Lai[5] Jacqueline O'Leary[6] Florence Wong[7] Guadalupe Garcia-Tsao[8] Hugo Vargas[9] Philip Vutien[10] Scott Biggins[11] Brian Bush[1] Jasmohan Bajaj[12], [1]Virginia Commonwealth University, Richmond, VA, [2]Virginia Commonwealth Universtiy, Richmond, VA, [3]University of Pennsylvania, Philadelphia, PA, [4]University of Alberta, [5]University of California, San Francisco, CA, [6]UT Southwestern Medical Center, North Texas VA Health Care System, Dallas, TX, [7]University of Toronto, [8]Yale School of Medicine, New Haven, CT, [9]Mayo Clinic Arizona, Scottsdale, AZ, [10]University of Washington, Seattle, WA, [11]University of Pittsburgh, Pittsburgh, PA, [12]Virginia Commonwealth University

Background: Background: Minimal hepatic encephalopathy (MHE) is a neurocognitive complication of cirrhosis that precedes overt HE (OHE), hospitalizations & death. With longer timeframes needed for hard endpoints to occur in clinical trials, considering Stroop-defined MHE as a potential surrogate endpoint may be possible. However, the stability of MHE and responsiveness of this diagnosis to important clinical events. Aim: To define MHE stability using Stroop & determine if it changes over time in those with and without subsequent clinical events. **Methods:** Outpatients with cirrhosis from two tertiary centers and the separate NACSELD3 cohort, all of who underwent Stroop testing at ≥ 2 time points. US-based norms defined MHE and intermediate clinical events (hospitalizations, OHE with new lactulose/rifaximin) were collected. Intraclass correlation coefficients (ICCs) assessed within-patient stability. Generalized linear mixed-effects models with logit link and patient-specific random intercepts evaluated associations between MHE and subsequent events, and between interval events and Stroop-MHE at the next test. The latter outcome was persistent MHE or progression from no-MHE to MHE **Results:** The cohort included 696 patients who underwent ≥ 2 Stroop tests (Fig A). Median age was 61 years, 50% men, 37% alcohol-related cirrhosis & median MELD 11. At baseline 49% had MHE, who persisted with MHE throughout (ICC: 0.76); none went from MHE to no-MHE. Median intervals between tests were 6 months. Of the 352 no-MHE patients,32% developed MHE on the second test, and 26% developed MHE after the second test. Clinical events occurred in 25.5% between tests 1 & 2 and 23.3% after test 2. MHE patients were more likely to develop a clinical event vs those without MHE (30.5% vs 16.1%, $p < 0.001$). Across repeated intervals, clinical events were associated with higher odds of Stroop-MHE (OR 2.10, 95% CI 1.58–2.79; $p < 0.001$). Clinical events were also associated with persistence of previously detected MHE or progression to MHE from no-MHE at the next assessment (OR 1.82, 1.03–3.22; $p = 0.039$). **Conclusion:** In a multi-center cohort, Stroop-defined MHE was present in almost half of patients and did not regress. With clinical events, a quarter of patients without MHE developed MHE over time. Stroop-defined MHE is stable when patients are stable and responsive to clinical events, and with prior studies indicating prediction of OHE could be a potential surrogate.

1476 | MUCH ADO ABOUT HEART RATE: REASSESSING BETA-BLOCKER TOLERABILITY IN PATIENTS WITH CIRRHOSIS

Avesh Thuluvath[1] Kamaryn Tanner[2] Jessica Siguencia[3] Olivia Blocker[3] Joel Castro[1] Nayda Pichardo-Fernandez[1] Robert Brown[3] Alan Cohen[2] Adam Buckholz[4] Elizabeth Verna[1], [1]Columbia University Medical Center, [2]Mailman School of Public Health, Columbia University, [3]Weill Cornell Medicine, [4]New York Presbyterian Hospital Program

Background: Non-selective beta blockers (NSBB) are a cornerstone of cirrhosis management and increasingly used to prevent hepatic decompensation. The benefits of NSBBs are well-established but their true effect on resting heart rate (RHR) remains unclear, as RHR data are limited to intermittent clinic visits. Moreover, clinicians may underutilize NSBBs given concerns over fatigue or bradycardia. We used digital wearables (Oura Rings) to assess the association between NSBBs, RHR and physical activity in cirrhosis. **Methods:** Adults (≥18 years) with cirrhosis were prospectively enrolled at two centers from 8/2023-11/2025. Those on selective beta-blockers were excluded. Patients completed the Chronic Liver Disease Questionnaire (CLDQ) and were provided Oura rings to measure RHR and daily steps for 6 months. Linear mixed effects models estimated the association between NSBBs and primary outcomes (RHR, daily steps and baseline CLDQ activity/fatigue scores). **Results:** Of the 96 patients (Figure 1A) included, 49% were on a NSBB (carvedilol/nadolol/propranolol). Those on a NSBB had a higher mean MELD (11.2 vs. 9.3, p = 0.04) and were more likely to have a history of variceal hemorrhage (25 vs 6%, p = 0.03) than those not on a NSBB. Overall, the mean RHR was 69.2 (± 8.6) beats/min and median daily steps was 7401 (IQR 4651-9652) steps/day. Compared to those not on a NSBB, those on a NSBB had a similar mean RHR (69.7 vs 69.7 beats/min, p = 0.98), median daily step count (6997 vs 7904 steps/day, p = 0.13), CLDQ fatigue score (4.2 vs 4.1, p = 0.61) and CLDQ activity score (4.4 vs 4.2, p = 0.57) (Figure 1B,C). The mean RHR was higher (72.2 vs. 66.7 beats/min, p = 0.001) in those with CP B/C cirrhosis compared to those with CP A cirrhosis. The median daily step count (6403 vs. 8219 steps/day, p = 0.001), mean CLDQ activity score (3.9 vs 4.7, p = 0.02) and CLDQ activity score (3.8 vs 4.4, p = 0.02) were lower in those with CP B/C cirrhosis compared to those with CP A cirrhosis. After adjusting for age, sex, CP status and weekday/weekend status (given changes in physical activity on weekends), NSBB use was not associated with the log of daily steps (estimate [est] -0.12, p = 0.22), RHR (estimate -0.14, p = 0.93), CLDQ fatigue score (est 0.18, p = 0.55) or CLDQ activity score (est 0.25, p = 0.46). CT B/C status was associated with a higher RHR (est 5.92, p < 0.001) and lower log daily step count (est -0.37, p < 0.001), CLDQ fatigue (est -0.90, p = 0.003) and CLDQ activity (est -1.13, p = 0.001) scores on multivariable analysis. **Conclusion:** NSBB use is not associated with lower RHR or activity levels in cirrhosis. Non-adherence cannot be excluded, but our findings suggest that clinicians are not optimizing NSBB dose and should not be overly concerned that NSBBs will cause symptomatic bradycardia or decreased physical activity. Use of digital wearables offers the ability to monitor and maximize NSBB use while minimizing potential toxicity.

FIGURE 1A: Clinical Characteristics, Stratified by NSBB Use

Clinical Characteristics	Total n=96	No NSBB n=47	NSBB n=49	P-value
Age, mean (SD)	54.9 (11.1)	54.0 (11.9)	55.7 (10.3)	0.47
Female, N (%)	46 (47.9)	26 (53.3)	20 (40.8)	0.22
MELD 3.0, mean (SD)	10.3 (4.6)	9.3 (4.3)	11.2 (4.8)	**0.04**
CP Category, n (%)				0.21
CP A	52 (54.2)	29 (61.7)	23 (46.9)	
CP B/C	44 (45.8)	18 (38.3)	26 (53.1)	
Decompensated, n (%)	64 (66.1)	25 (54.3)	39 (81.2)	**0.01**
History of HE, n (%)	37 (39.4)	17 (37.0)	20 (41.7)	0.80
History of Ascites, n (%)	34 (35.4)	12 (25.5)	22 (44.9)	0.08
History of Variceal Hemorrhage, n (%)	15 (15.8)	3 (6.4)	12 (25.0)	**0.03**

1477 | COMMERCIAL WEARABLES RAPIDLY ESTABLISH RELIABLE DEEP SLEEP HRV BASELINES THAT REFLECT LIVER DISEASE SEVERITY

Adam Buckholz[1] Himel Mallick[1] Avesh Thuluvath[2] Alec Chang[1] Jayden Maramis[1] Lara Phipps[1] Ana Krieger[3] Robert Brown[4], [1]NewYork-Presbyterian/Weill Cornell Medical Center, [2]Columbia University Irving Medical Center, [3]NewYork-Prebyterian/Weill Cornell Medical Center, [4]Weill Cornell Medicine

Background: Heart rate variability (HRV) is a non-invasive marker of autonomic dysfunction associated with cirrhosis, but its use as a longitudinal biomarker is limited by circadian variability and physiologic fluctuation during wakefulness. Sleep may provide an ideal window for assessment because HRV can be measured repeatedly and passively under largely stable conditions. We evaluated whether sleep-stage specific nocturnal HRV identifies disease-related abnormalities and establishes stable individualized baselines for longitudinal monitoring. **Methods:** We analyzed longitudinal wearable data from 104 participants with cirrhosis using the Oura Ring and ≥14 valid wear days with ≥80% wear time and analyzable sleep-stage HRV. HRV was calculated as RMSSD from 30-second sleep-stage epochs and summarized across deep, light, REM, and awake periods. Mixed-effects models evaluated associations between MELD 3.0 or Child-Turcotte-Pugh (CTP) score and sleep-stage specific HRV after adjustment for age, sex, and beta blocker use. Night-to-night HRV variability was compared between compensated and decompensated cirrhosis. Within-individual reliability of nightly HRV was assessed using the single-night intraclass correlation (ICC) and the Spearman-Brown projection of the number of nights required for a reliable per-person average; the stabilization of each participant's running median was summarized as the proportion within 10% of their final value by a given number of tracking days. **Results:** Across 12,221 analyzed nights, higher MELD 3.0 was associated with lower nocturnal HRV overall (-0.84 ms RMSSD per MELD point, 95% CI -1.27, -0.41). The strongest association was observed during deep sleep, where a 1-SD increase in MELD corresponded to a 4.29 ms reduction in RMSSD (95% CI -6.49, -2.09), with similar directional effects across sleep stages (A). CTP score demonstrated a similar stage-specific pattern. Decompensated disease was associated with significantly greater night-to-night instability in deep sleep HRV, including increased within-subject variability on rolling 7-day analyses (adjusted fold-change in SD 1.16, adjusted p = 0.023). Reliable individualized HRV estimates were achieved rapidly (deep-sleep single-night ICC 0.55; reliability ≥0.80 within 4 nights, while within-individual medians stabilized quickly, 75% within 10% of stable values by day 14 (B-D). **Conclusion:** Advanced cirrhosis was associated with progressive impairment and greater instability of deep sleep HRV, suggesting that restorative sleep may represent a vulnerable physiologic state in progressive liver disease with associated autonomic dysfunction. Commercial wearables captured longitudinal HRV abnormalities and suggest deep-sleep HRV may represent a scalable digital biomarker capable of establishing both stable individualized baselines and detecting physiologic deterioration before clinically apparent decompensation.

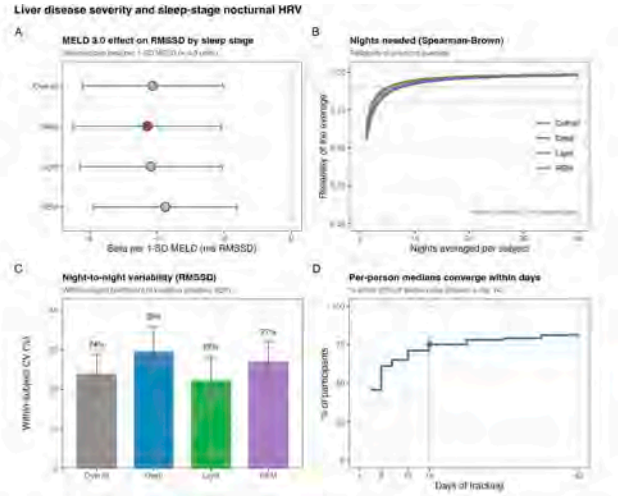

Figure 1. Sleep-stage nocturnal HRV and liver disease severity. (A) Standardized MELD 3.0 effect on mean nightly RMSSD by sleep stage and overall: beta (95% Wald confidence interval) per 1-SD increase in MELD 3.0 (1 SD = 4.9 units); negative coefficients across strata indicate lower HRV at higher disease severity. Linear mixed-effects models with subject random intercept, adjusted for age and beta-blocker use. (B) Spearman-Brown reliability of a k-night per-subject average by stage, derived from single-night intraclass correlations. Reference lines mark reliability 0.8 (dotted) and 0.9 (dashed); annotation gives the median nights collected per subject. (C) Within-subject coefficient of variation of nightly RMSSD by stage, shown as median (bar) and IQR (error bars) across subjects with at least 5 valid nights per stratum. (D) Within-individual establishment of a personal deep-sleep HRV baseline: percentage of participants whose cumulative running median of nightly RMSSD falls within 10% of their final value by elapsed day of tracking (final value anchored on subjects with at least 14 valid nights). Rapid convergence supports the use of wearable nocturnal HRV for remote monitoring, where a stable individual baseline is the reference against which clinically meaningful change is detected. Vertical line at day 14.

Mumtaz[8] Paul Kwo[9] Maiying Kong[2] Ashwani Singal[2], [1]University of Louisville School of Medicine, [2]University of Louisville, [3]The Ohio State University Wexner Medical Center, [4]Stanford University/Phyathai Hospital, Bangkok, Thailand, [5]Aga Khan University,, [6]Eastridge Primecare, Lahore, Pakistan, [7]Stanford University, [8]Ohio State University, [9]Stanford University Medical Center

Background: Transjugular intrahepatic portosystemic shunt (TIPS), commonly performed in appropriate patients with refractory ascites and/or variceal bleeding, has been associated with improvement in liver disease severity. Recompensation, an emerging entity in the natural history of liver disease, is defined as per Baveno VII consensus as resolution of ascites without diuretics, hepatic encephalopathy without lactulose or rifaximin, and absence of recurrent variceal hemorrhage for at least 12 months, along with stable improvement in liver function tests. Although recompensation is defined in the setting of removal, suppression, or cure of the primary etiology of cirrhosis, recompensation has been observed after TIPS. However, the data on this are limited. **Methods:** We conducted a multicenter retrospective study of adults with cirrhosis who underwent TIPS at three tertiary academic institutions. The following outcomes were examined at 1 year: patient survival, improvement in MELD score and in renal function, hepatic recompensation as per Baveno VII consensus definition, and clinical (modified) recompensation, defined as resolution of decompensation events (absence of ascites, hepatic encephalopathy, or variceal bleeding), bilirubin ≤ 1.1, INR ≤ 1.1, and albumin ≥ 3.5. Collected variables included procedure date, indication, cirrhosis etiology, bilirubin, creatinine, sodium, albumin, INR, MELD score, age, sex, ethnicity, survival status, recompensation date, and last follow-up. **Results:** Among 644 patients (mean age 57.9 yrs., 56.4% male), 78.8% survived by 1 year after TIPS (59.6% for refractory ascites and 38.4% for variceal bleeding). A total of 32 liver transplants (LT) were performed within 12 months, with LT-free survival of 73.9%. MELD score worsened or decreased by < 3 in 36%, decreased by 3 to 5 points in 3.5%, and decreased by ≥ 5 in 4.2%, while this was indeterminate in 56.2% of cases. Using a cutoff of 10, 23% had MELD ≥ 10, 22% had MELD < 10, and 55% were indeterminate. Among 77 patients with pre-TIPS creatinine > 1.5 mg/dL, 17% improved to < 1.5 mg/dL, 24.7% improved but remained ≥ 1.5 mg/dL, and 58.3% were indeterminate. In a subgroup of 251 patients, 87 (34.7%) achieved recompensation, while 10 patients (4% of the subgroup) achieved clinical (modified) recompensation. The data were indeterminate in 50.2% patients. **Conclusion:** In this multicenter cohort, about 79% of patients survived at 1 year, with about 74% surviving without LT. Liver disease improved in a significant proportion of patients, with over a third of patients achieving recompensation. Clinical modified recompensation was observed in 4% of patients. Future prospective studies are needed to longitudinally assess liver function, renal function, and control of cirrhosis etiology to better identify independent predictors and effects of recompensation in patients with decompensated cirrhosis who undergo placement of TIPS.

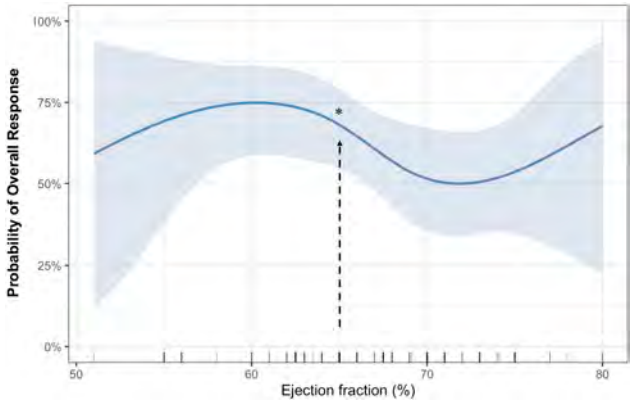
1479 | ASSOCIATION OF LEFT VENTRICULAR EJECTION FRACTION WITH TERLIPRESSIN RESPONSE AND SAFETY IN HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY: RESULTS FROM THE HRS-HARMONY CONSORTIUM



Sanad Dawod[1] Neev Patel[2] Andrew Allegretti[3] Manhal Izzy[4] Tianqi Ouyang[3] Sydney Whittaker[5] Jevon Robinson[3] J. Pedro Teixeira[6] Adam Dossaji[7] Xingxing

Cheng[8] Kavish Patidar[9], [1]Houston Methodist, [2]Stanford University, [3]Massachusetts General Hospital, [4]Vanderbilt University Medical Center, [5]Massachussets General Hospital, [6]University of New Mexico, [7]Virginia Commonwealth University, [8]Stanford University Medical Center, [9]Houston Methodist Hospital

Background: Response to terlipressin in hepatorenal syndrome-acute kidney injury (HRS-AKI) is variable, and practical predictors of non-response or intolerance are limited. Hyperdynamic circulatory physiology may influence response and cardiopulmonary safety in HRS-AKI. We tested whether left ventricular ejection fraction (EF), a routinely reported marker of hyperdynamic circulation, was associated with overall response, terlipressin-associated cardiopulmonary decompensation, and 90-day mortality. **Methods:** We analyzed consecutive HRS-AKI patients treated with terlipressin in the HRS-HARMONY registry (n = 243) who had transthoracic echocardiography (TTE) prior to or on the day of terlipressin initiation (n = 107). The primary outcome was overall response, defined as complete or partial response. Secondary outcomes were terlipressin-associated cardiopulmonary decompensation (respiratory failure and/or volume overload) and 90-day mortality. The relationship between EF and Overall Response was evaluated using cubic spline logistic regression. Youden's index identified an optimal EF threshold, and outcomes were compared above and below this threshold. **Results:** Median age was 58 years, 61% were male, 63% had alcohol-associated cirrhosis, 53% had refractory ascites, median MELD 3.0 was 31 (IQR 26–36), and 43% had ACLF grade 3. Median EF was 66% (IQR 63–71), and no patient had EF < 50%. Overall response occurred in 67 patients (63%), cardiopulmonary decompensation in 10 (9.3%), and 90-day mortality in 41 (38%). Cubic spline modeling suggested lower predicted response probabilities at higher EF values, with a potential inflection near 65% (**Figure**). Youden's index identified 64.5% as the optimal EF threshold; using 65% as a clinically interpretable cutoff, 71 patients had EF ≥ 65% and 36 had EF < 65%. EF < 65% was more common among responders than non-responders (43.3% vs 17.5%; p = 0.012), whereas EF ≥ 65% was more common among non-responders (82.5% vs 56.7%). Cardiopulmonary decompensation also clustered at higher EF: affected patients had higher median EF (69.5% vs 66.0%; p = 0.025), and all events occurred in patients with EF ≥ 65% (10/10; p = 0.044). EF was not significantly associated with 90-day mortality; EF ≥ 65% was present in 70.7% of patients who died and 63.6% of survivors (p = 0.586). **Conclusion:** In this multicenter real-world cohort of terlipressin-treated HRS-AKI, EF ≥ 65% was associated with lower overall response and terlipressin-associated cardiopulmonary decompensation, but not 90-day mortality. These findings raise the possibility that a hyperdynamic circulatory phenotype contributes to terlipressin non-response and cardiopulmonary intolerance. Prospective echocardiographic studies are needed to validate EF as a pragmatic risk marker and define which cardiac parameters best predict terlipressin response and safety.

Background: Patients with cirrhosis and type 2 diabetes mellitus (T2DM) are at increased risk for hepatocellular carcinoma (HCC), hepatic decompensation, and mortality. While glucagon-like peptide-1 receptor agonists (GLP-1 RAs) and sodium-glucose cotransporter-2 (SGLT2) inhibitors improve cardiometabolic outcomes, their comparative hepatic benefits in patients with cirrhosis remain poorly defined. **Methods:** We conducted a retrospective cohort study using the TriNetX U.S. Collaborative Network. Adults ≥18 years with T2DM and cirrhosis were included, excluding those with prior HCC or liver transplantation. Patients were categorized into GLP-1 RA, SGLT2 inhibitor, or control (other antidiabetic therapies without GLP-1 or SGLT2 exposure) groups, with mutual exposure excluded. Outcomes assessed ≥30 days after the index event and included HCC, hepatic decompensation, all-cause mortality, liver transplantation, and ICU admission. One-to-one propensity score matching adjusted for demographics, comorbidities, medications, and laboratory values. Adjusted hazard ratios (aHRs) with 95% confidence intervals (CIs) were reported. **Results:** After matching, 22,362 patients per group were included in the GLP-1 RA versus SGLT2 comparison. GLP-1 RA use was associated with lower risks of HCC (6.5% vs 7.3%; aHR 0.80, 95% CI 0.74–0.85), hepatic decompensation (21.1% vs 23.6%; aHR 0.78, 95% CI 0.75–0.81), all-cause mortality (aHR 0.87, 95% CI 0.83–0.92), and ICU admission (13.8% vs 15.1%; aHR 0.78, 95% CI 0.74–0.81) (all $p < 0.001$). Liver transplantation rates were low and did not differ significantly.Compared with matched controls, GLP-1 users had a significantly lower risk of HCC (aHR 0.74, 95% CI 0.69–0.78; $p < 0.001$), all-cause mortality (aHR 0.59, 95% CI 0.56–0.61; $p < 0.001$), and hepatic decompensation (aHR 0.61, 95% CI 0.59–0.63; $p < 0.001$). LT rates were lower in the GLP-1 cohort (aHR 0.71, 95% CI 0.60–0.83; $p < 0.001$) and ICU admissions (aHR 0.65, 95% CI 0.63–0.68; $p < 0.001$). Compared to matched controls, HCC was lower in the SGLT2 cohort (aHR 0.94, 95% CI 0.89–1.00; $p = 0.04$), in addition to all-cause mortality (aHR 0.70, 95% CI 0.68–0.72; $p < 0.001$), hepatic decompensation (aHR 0.82, 95% CI 0.80–0.85; $p < 0.001$), and ICU admission (aHR 0.92, 95% CI 0.89–0.95; $p < 0.001$). LT was infrequent and did not differ significantly between groups (aHR 0.89, 95% CI 0.75–1.06; $p = 0.19$). **Conclusion:** In patients with cirrhosis and T2DM, GLP-1 receptor agonists and SGLT2 inhibitors are associated with significantly improved hepatic outcomes and survival compared with other antidiabetic therapies. GLP-1 RAs demonstrated the greatest overall benefit, including reduced risks of HCC, hepatic decompensation, and mortality. These findings support preferential use of incretin-based and SGLT2 therapies in this high-risk population.

Characteristic	After Matching GLP-1 (n = 22,362)	After Matching SGLT2 (n = 22,362)
Age, mean ± SD (years)	63.3 ± 10.5	63.3 ± 10.9
Female sex, n (%)	10,366 (46.4)	10,224 (45.7)
White race, n (%)	16,368 (73.2)	16,427 (73.5)
Black race, n (%)	2,547 (11.4)	2,467 (11.0)
Hispanic ethnicity, n (%)	2,453 (11.0)	2,775 (12.4)
Hypertension, n (%)	17,728 (79.3)	17,842 (79.8)
Ischemic heart disease, n (%)	8,639 (38.6)	8,652 (38.7)
Heart failure, n (%)	5,937 (26.5)	5,950 (26.6)
Chronic kidney disease, n (%)	6,920 (30.9)	6,951 (31.1)
BMI, mean ± SD (kg/m²)	35.2 ± 7.9	31.6 ± 7.4
Albumin, mean ± SD (g/dL)	3.8 ± 0.6	3.7 ± 0.7
Platelets, mean ± SD (×10³/μL)	188.9 ± 86.9	184.8 ± 94.0

Background: Sarcopenia is increasingly recognized as a prognostic factor in cirrhosis, but whether its impact differs by severity stage remains incompletely understood. We evaluated the association of sarcopenia severity with all-cause and liver cirrhosis-related mortality in patients with advanced liver fibrosis or cirrhosis. **Methods:** Using UK Biobank data, we identified participants with advanced liver fibrosis or cirrhosis at baseline, defined by FIB-4 index ≥ 2.67 or validated ICD codes, and excluded those with a history of malignancy. Sarcopenia was classified according to EWGSOP2 criteria as probable sarcopenia (low muscle strength alone), or confirmed/severe sarcopenia (low muscle strength plus low muscle mass and/or poor physical performance), based on grip strength, appendicular skeletal muscle mass estimated from bioimpedance analysis, and self-reported physical performance. Mortality data were identified through linked national death registries. Cox proportional hazards models were used to estimate hazard ratios (aHRs) and 95% confidence intervals (CIs), with adjustment for demographics, education level, BMI, smoking, and alcohol consumption. **Results:** Among 10,328 participants (mean age 64 years; 64.5% male), 1,400 (13.6%) had probable sarcopenia and 511 (4.9%) had confirmed/severe sarcopenia. During a median 10-year follow-up, 1,295 deaths occurred, including 126 liver cirrhosis-related deaths. Sarcopenia showed a graded association with mortality. For all-cause mortality, probable sarcopenia was associated with higher risk (aHR 1.44, 95% CI 1.24–1.67; $P < 0.001$), and confirmed/severe sarcopenia was associated with a greater risk (aHR 3.76, 3.18–4.44; $P < 0.001$). For liver cirrhosis-related mortality, the corresponding aHRs were 1.92 (1.22–3.02; $P = 0.005$) and 3.52 (2.10–5.92; $P < 0.001$), respectively. In sex-stratified analyses, the association with liver cirrhosis-related mortality was more pronounced in males, with significant associations for both probable sarcopenia (aHR 2.00, 1.15–3.48; $P = 0.015$) and confirmed/severe sarcopenia (aHR 4.46, 2.46–8.09; $P < 0.001$). In females, confirmed/severe sarcopenia remained associated with all-cause mortality (aHR 3.60, 2.63–4.93; $P < 0.001$), whereas neither probable nor confirmed/severe sarcopenia was significantly associated with liver cirrhosis-related mortality. Kaplan-Meier survival curves detailed in Figure 1. **Conclusion:** In patients with advanced liver fibrosis or cirrhosis, sarcopenia was associated with increasing mortality risk in a severity-dependent manner. The prognostic association was evident at the probable stage and strongest at the confirmed/severe stage. Sex-stratified analyses suggested that the association with liver cirrhosis-related mortality was more evident in males. These findings support routine sarcopenia assessment and severity-based risk stratification in advanced liver disease.

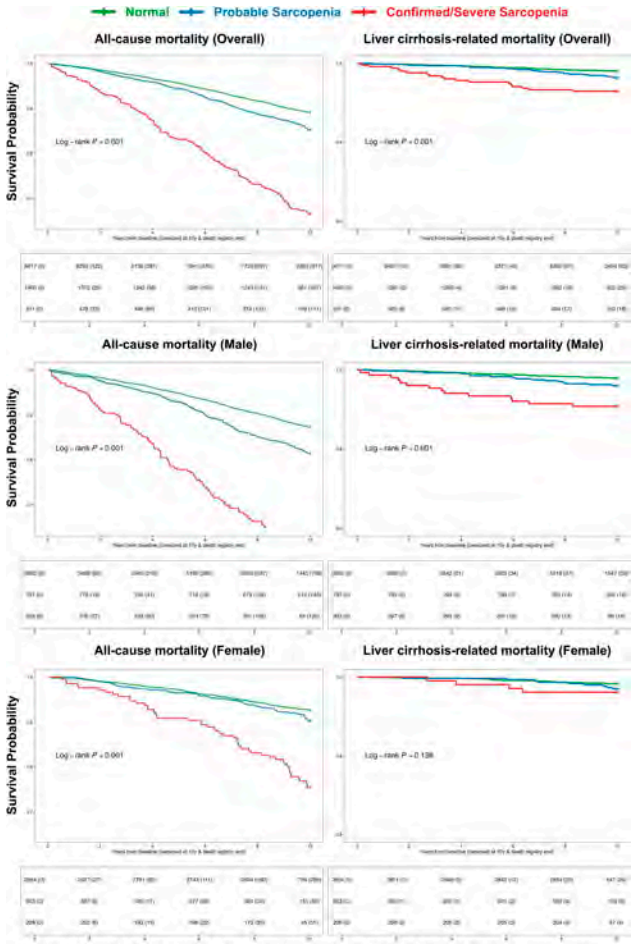

Figure 1. Kaplan–Meier curves for all-cause and liver cirrhosis-related mortality by sarcopenia severity in the overall cohort and by sex. Sarcopenia was classified as normal, probable sarcopenia, or confirmed/severe sarcopenia using EWGSOP2 criteria. Log-rank P values are shown in each panel. Numbers at risk are displayed below the curves.

Fudan University, [2]Department of Echocardiography, Zhongshan Hospital, Fudan University

Background: Porto-sinusoidal vascular disorder (PSVD) is a heterogeneous group of vascular liver diseases that generate portal hypertension (PH) in the absence of cirrhosis. In contrast to cirrhotic cardiomyopathy(CCM), cardiac involvement in PSVD remains poorly delineated. We aimed to compare structural and functional cardiac alterations in patients with PSVD versus cirrhosis, and to examine the association between PH severity and cardiac involvement. Because PSVD provides a clinical setting in which PH arises largely independently of advanced parenchymal injury, comparing PSVD with cirrhosis offers a unique opportunity to dissect the cardiac consequences attributable to portal hemodynamic perturbation per se. **Methods:** In this single-center retrospective cohort study (December 2019 to December 2020), consecutive patients with cirrhosis or PSVD scheduled for transjugular intrahepatic portosystemic shunt (TIPS) underwent a comprehensive echocardiographic evaluation within 48 hours preceding the procedure. Three-dimensional speckle-tracking echocardiography (3D-STE) parameters, including left ventricular ejection fraction, left ventricular global longitudinal strain (LVGLS), global circumferential strain, and systolic dyssynchrony index, were calculated using commercially available software. Patients were subsequently stratified by the severity of the invasive portal pressure gradient (PPG) obtained during the TIPS procedure, with a pre-specified cut-off of 20 mmHg. **Results:** A total of 92 patients were enrolled, including 22 in the PSVD group (mean age 48 ± 15 years; female 8/22, 36%) and 70 in the cirrhosis group (mean age 49 ± 9 years; female 23/70, 33%). Applying the 2019 Cirrhotic Cardiomyopathy Consortium criteria, the prevalence of CCM was comparable between groups (PSVD 31.8% vs. cirrhosis 32.9%; P = 0.928). Relative to the cirrhosis group, PSVD patients exhibited a lower left atrial volume index (LAVI, 34.08 ± 14.84 vs. 37.11 ± 10.47 mL/m²; P = 0.001) but demonstrated impaired right ventricular function, as reflected by RV global longitudinal strain. In PPG-stratified subgroup analyses, higher PPG was associated with more impaired 3D-LVGLS in both cohorts (PSVD: −16.78 ± 4.33% vs. −20.76 ± 3.36%, P = 0.028; cirrhosis: −18.48 ± 3.69% vs. −21.34 ± 5.53%, P = 0.004). 3D-LVGLS correlated with PPG in both cohorts (PSVD: r = −0.343, P = 0.049; cirrhosis: r = −0.235, P = 0.049). **Conclusion:** Patients with PSVD show a prevalence of CCM comparable to that in cirrhosis, despite differing patterns of chamber-specific involvement. Across both etiologies, the degree of subclinical myocardial dysfunction tracks the severity of portal hypertension, supporting a hemodynamically driven hepatic–cardiac axis.

1483 | METABOLIC AND RENAL COMORBIDITY PREDICT HEPATIC ENCEPHALOPATHY AND MORTALITY AFTER TIPS: A REAL-WORLD COHORT STUDY

Gloria Sanchez Antolín[1] Elena Velasco Martinez[2] Natalia Marcos Carrasco[2] Carolina Almohalla Alvarez[2] María Jordán de la Fuente[2] Pilar Hernandez Manchado[2] Laura Jimenez Gonzalez[2] Celia Portela Guerra[2] Maria Pina Pallin[2] Elena Villacastin-Ruiz[2] Rebeca Pintado Garrido[2], [1]Hepatology Unit. Hospital Universitario Rio Hortega, [2]Hospital Universitario Rio Hortega

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is an effective treatment for complications of portal hypertension, but post-TIPS hepatic encephalopathy (HE) remains a major limitation. The impact of metabolic and renal comorbidity on HE and survival after TIPS is incompletely defined **Methods:** We performed a retrospective observational study of 119 patients who underwent TIPS at a hepatology unit. Demographic characteristics, liver disease etiology, comorbidities, liver disease severity, indication for TIPS, clinical response, complications, HE, early HE ($\leq$30 days), and survival were analyzed. Overall survival was assessed using Kaplan-Meier methods. Factors associated with HE and mortality were evaluated by univariable and multivariable analyses. **Results:** Most patients were male (83.3%), with a median age of 64 years. Alcohol-related liver disease was the most frequent etiology (63.9%). The most common comorbidities were diabetes mellitus (42.9%) and chronic kidney disease (16.8%). Main indications for TIPS were variceal bleeding (50.4%) and refractory ascites (42.9%). Clinical efficacy was high, with recurrent ascites or bleeding observed in 13.7% of patients. Overall, 66.4% developed complications; HE was the most frequent event (48.7%), and TIPS reduction was required in 7.6%. HE was significantly associated with age $\geq$65 years (p = 0.003), diabetes mellitus (p = 0.023), chronic kidney disease (p = 0.010), and advanced liver functional stage (Child-Pugh B/C; p = 0.035), but not with etiology or MELD score. Median overall survival was 1,116 days. Survival was significantly worse in patients with MELD $\geq$15 (p = 0.007), advanced liver functional stage (p = 0.007), and chronic obstructive pulmonary disease (p = 0.003). In multivariable analysis, diabetes mellitus (HR 2.29, 95% IC;

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

p = 0.008) and chronic kidney disease (HR 2.15, 95% CI p = 0.042) were independently associated with increased mortality. Overall HE was not significantly associated with survival, although early HE showed a trend toward higher early mortality **Conclusion:** TIPS was highly effective in this real-world cohort, but post-procedure HE was frequent. Older age, diabetes, chronic kidney disease, and impaired liver functional reserve identified patients at increased risk of HE. Diabetes and chronic kidney disease were also independently associated with mortality, supporting the integration of metabolic and renal comorbidity into pre-TIPS risk stratification and post-TIPS monitoring.

1484 | TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT VS. REPEAT LARGE-VOLUME PARACENTESIS FOR CIRRHOTIC ASCITES: RENAL AND CLINICAL OUTCOMES IN A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Archana Salek[1] Jashanveer Johal[1] Bianca Patel[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Abdallah Hussein[1] Jason Hyman[2] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Refractory ascites in cirrhosis portends significant morbidity, and the choice between transjugular intrahepatic portosystemic shunt (TIPS) and repeat large-volume paracentesis (LVP) as definitive management carries important implications for renal function, hepatic decompensation, and survival. Real-world comparative data on renal-specific outcomes between these strategies remain limited. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised adult cirrhotic patients (K74.6) with ascites (R18) and portal hypertension (K76.6) who underwent TIPS placement. Cohort 2 comprised cirrhotic patients with ascites and portal hypertension who underwent repeat paracentesis without TIPS. Both cohorts excluded prior liver transplant, ESRD, heart failure, and hepatocellular carcinoma. Cohorts were balanced via 1:1 PSM yielding 3,934 patients per arm over a 6–120 month follow-up window. Pre-specified outcomes included acute kidney injury (AKI), progression to ESRD or dialysis initiation, development of hepatorenal syndrome (HRS), need for repeat paracentesis, development of hepatic encephalopathy (HE), liver transplant listing, ICU admission, and all-cause mortality. **Results:** Post-PSM cohorts were well-balanced across all matched covariates. TIPS was associated with significantly lower rates of AKI (27.4% vs. 36.3%; HR 0.63, 95% CI 0.57–0.70; p < 0.001), HRS (7.2% vs. 12.3%; HR 0.50, 95% CI 0.43–0.58; p < 0.001), and progression to ESRD or dialysis (6.3% vs. 6.5%; HR 0.84, 95% CI 0.70–1.00; p = 0.047). Need for repeat paracentesis was dramatically lower in the TIPS arm (39.0% vs. 64.7%; HR 0.44, 95% CI 0.41–0.47; p < 0.001), with a median time to repeat paracentesis of 32 days in the LVP-only arm. TIPS patients had significantly higher rates of new or worsened hepatic encephalopathy (52.6% vs. 41.2%; HR 1.28, 95% CI 1.15–1.42; p < 0.001), with a shorter median time to HE onset (366 vs. 680 days). Liver transplant listing rates were higher in the TIPS arm on MOA analysis (8.4% vs. 6.5%; RR 1.30; p = 0.002) but did not reach significance on time-to-event analysis (HR 1.11, 95% CI 0.93–1.32; p = 0.25). All-cause mortality was significantly lower in the TIPS arm (30.4% vs. 43.2%; HR 0.57, 95% CI 0.53–0.61; p < 0.001). **Conclusion:** In this large propensity-matched real-world cohort, TIPS was associated with substantially lower rates of AKI, HRS, ESRD progression, repeat paracentesis, and all-cause mortality compared to LVP-only management in cirrhotic ascites. These benefits came at the cost of significantly higher rates of hepatic encephalopathy, consistent with the known hemodynamic tradeoff of portal decompression. These findings support TIPS as the preferred strategy in eligible patients with refractory ascites and reinforce the need for proactive HE surveillance post-procedure.

Background: Management of ascites in cirrhosis remains challenging, and therapies that may reduce portal hypertensive and renal complications are needed. Sodium-glucose cotransporter-2 inhibitors have mild natriuretic and diuretic effects, but their association with clinical outcomes in patients with cirrhosis and ascites remains unclear. We evaluated whether SGLT2 inhibitor use was associated with improved outcomes among adults with cirrhosis and ascites. **Methods:** We conducted a retrospective cohort study using the TriNetX Research Network, which included 111 healthcare organizations. Adults aged ≥18 years with cirrhosis and ascites were identified. Patients receiving SGLT2 inhibitors were compared with patients with cirrhosis and ascites without SGLT2 inhibitor exposure. Outcomes were assessed beginning 90 days after the index event. The primary outcome was need for abdominal paracentesis. Secondary outcomes included spontaneous bacterial peritonitis, hepatorenal syndrome, hyponatremia, and all-cause mortality. Propensity score matching was performed for 43 demographic, comorbidity, procedure, and medication covariates, yielding 21,977 patients in each cohort. **Results:** After propensity matching, SGLT2 inhibitor use was associated with significantly lower risk of abdominal paracentesis compared with non-use: 12.2% vs 15.8%; risk ratio [RR] 0.772, 95% CI 0.737–0.809; hazard ratio [HR] 0.816, 95% CI 0.775–0.858. SGLT2 inhibitor use was also associated with lower risk of spontaneous bacterial peritonitis: 3.5% vs 5.2%; RR 0.677, 95% CI 0.620–0.740; HR 0.771, 95% CI 0.703–0.845. Hepatorenal syndrome occurred less frequently among SGLT2 inhibitor users: 3.8% vs 5.0%; RR 0.759, 95% CI 0.695–0.829; HR 0.890, 95% CI 0.813–0.975. Hyponatremia was modestly reduced: 17.8% vs 19.5%; RR 0.908, 95% CI 0.873–0.944, although time-to-event analysis did not demonstrate a significant difference. All-cause mortality was substantially lower among SGLT2 inhibitor users: 18.4% vs 31.5%; RR 0.584, 95% CI 0.564–0.604; HR 0.681, 95% CI 0.655–0.708. **Conclusion:** In this large propensity-matched multicenter cohort of patients with cirrhosis and ascites, SGLT2 inhibitor use was associated with lower risks of paracentesis, spontaneous bacterial peritonitis, hepatorenal syndrome, and mortality. These findings suggest a potential role for SGLT2 inhibitors in improving decompensation-related outcomes in cirrhosis with ascites. Prospective studies are warranted to validate these findings and clarify patient selection, safety, and mechanisms of benefit.

Study cohort: TriNetX Research Network; adults with cirrhosis and ascites. After propensity score matching, each cohort included 21,977 patients. Outcomes were assessed beginning 90 days after the index event.

Outcome	SGLT2i Cohort n/N (%)	Non-SGLT2i Cohort n/N (%)	Risk Ratio (95% CI)	Risk Difference	Hazard Ratio (95% CI)	P value
Abdominal paracentesis	2,680/21,977 (12.2%)	3,474/21,977 (15.8%)	0.772 (0.737–0.809)	-3.6%	0.816 (0.775–0.858)	<0.001
Spontaneous bacterial peritonitis	776/21,977 (3.5%)	1,150/21,977 (5.2%)	0.677 (0.620–0.740)	-1.7%	0.771 (0.703–0.845)	<0.001
Hepatorenal syndrome	833/21,977 (3.8%)	1,099/21,977 (5.0%)	0.759 (0.695–0.829)	-1.2%	0.890 (0.813–0.975)	0.012*
Hyponatremia	3,901/21,977 (17.8%)	4,296/21,977 (19.5%)	0.908 (0.873–0.944)	-1.8%	1.023 (0.979–1.069)	0.309*
All-cause mortality	4,041/21,977 (18.4%)	6,923/21,977 (31.5%)	0.584 (0.564–0.604)	-13.1%	0.681 (0.655–0.708)	<0.001

*P value reflects log-rank test for survival analysis where noted. Risk analysis p values were reported as 0.000 in TriNetX for all listed outcomes.

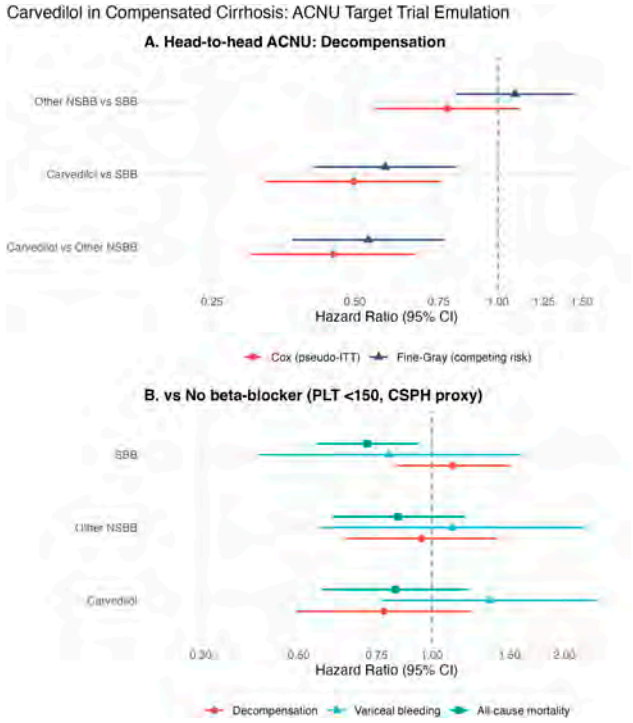
1486 | CARVEDILOL IS ASSOCIATED WITH LOWER HEPATIC DECOMPENSATION COMPARED WITH PROPRANOLOL/ NADOLOL AND SELECTIVE BETA-BLOCKERS IN COMPENSATED CIRRHOSIS: A POPULATION-BASED TARGET TRIAL EMULATION



Abdel-Aziz Shaheen[1] Mark Swain[1] Juan Abraldes[2], [1]University of Calgary, [2]University of Alberta

Background: Carvedilol may prevent decompensation in compensated cirrhosis, but comparative effectiveness versus propranolol/nadolol and selective beta-blockers (SBBs) remains uncertain. We compared beta-blocker strategies using a target trial emulation. **Methods:** Alberta administrative data (2012-2025) identified 8,093 adults with compensated cirrhosis. After a 12-month beta-blocker washout, new users of carvedilol (n = 618), propranolol/nadolol (n = 477), and SBBs (n = 808) entered single-entry active-comparator new-user trials at first dispensation. A 30-day pre-induction exclusion was applied. Stabilized inverse probability of treatment weighting (IPTW) balanced age, sex, alcohol etiology, Charlson index, platelets, MELD-Na, varices, rurality, and diagnosis year. Outcomes were hepatic decompensation, variceal bleeding, and mortality. IPTW-weighted Cox models were primary; Fine-Gray models addressed death/transplant. Follow-up was capped at 3 y. A secondary analysis compared each beta-blocker with no beta-blocker in patients with platelets < $150^{10\text{^}9}$ /L (n = 2,397), using random temporal assignment for non-users. **Results:** In the head-to-head beta-blocker cohort (n = 1,903), median age was 58 y (IQR 50-66), 57% were male, 68% had alcohol etiology, median platelets were 153 x 10^9/L, median MELD-Na was 10, and varices were detected in 32%. Carvedilol was associated with lower decompensation risk than propranolol/nadolol (HR 0.45, 95% CI 0.30-0.67; Fine-Gray SHR 0.53, 0.37-0.77; as-treated HR 0.50, 0.32-0.77) and SBBs (HR 0.50, 0.33-0.76; Fine-Gray SHR 0.58, 0.41-0.82; as-treated HR 0.49, 0.30-0.78). Propranolol/nadolol did not differ from SBBs for decompensation (HR 0.78, 0.55-1.11; Fine-Gray SHR 1.09, 0.82-1.44), Figure 1A. Carvedilol was not significantly associated with variceal bleeding (HR 0.78, 0.50-1.21) or mortality (HR 1.12, 0.82-1.52) versus propranolol/nadolol. Results were similar by alcohol etiology (HR 0.47, 0.29-0.74) and non-alcohol etiology (HR 0.44, 0.20-0.94), by platelets < 150 (HR 0.42, 0.26-0.68), and across induction

periods (30-180 days; HR range 0.40-0.48) and washout windows (6-24 months; HR range 0.44-0.45). Duration estimates versus propranolol/nadolol were HR 0.46 (0.29-0.73) for > = 365 days. The negative-control fracture outcome was not significant (HR 0.88, 0.46-1.68; p = 0.691). In the platelet-restricted analysis versus no beta-blocker, carvedilol was not significantly associated with decompensation, variceal bleeding, or mortality, Figure 1B. **Conclusion:** Carvedilol was associated with lower hepatic decompensation risk than propranolol/nadolol and SBBs, with consistent estimates across different sensitivity analyses. No significant differences in bleeding or mortality were observed.

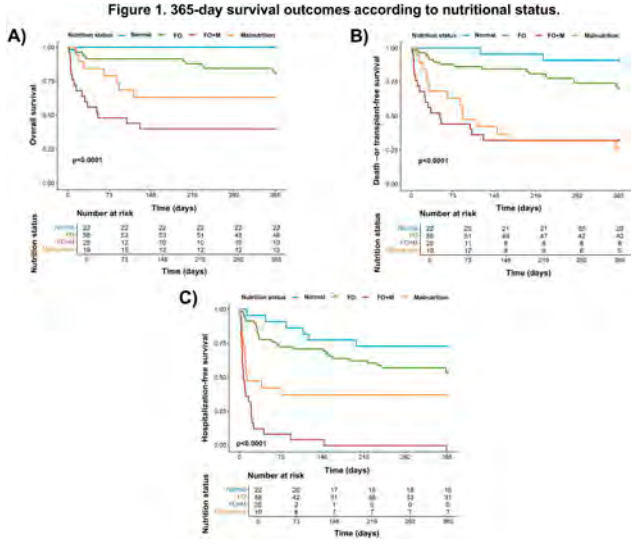
1487 | COMBINED FLUID OVERLOAD AND MALNUTRITION IDENTIFIES A HIGH-RISK PHENOTYPE WITH POORER 365-DAY OUTCOMES IN CIRRHOSIS

Anaisa Carranza-Carrasco[1] Osvely Méndez-Guerrero[2] Claudia López-López[1] Rodrigo Guerrero-Guerrero[1] Farid Tejeda-Dominguez[3] Graciela Castro-Narro[4] Lilia Castillo-Martínez[1] Nalu Navarro-Alvarez[5], [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, [2]Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubiran, [3]Panamerican University School of Medicine, [4]Hospital Médica Sur, Ciudad de México. Instituto Nacional de Ciencias Médicas y Nutrición, [5]University of Colorado Anschutz Medical Campus/Instituto Nacional de Ciencias Médicas y Nutrición



Background: Malnutrition and fluid overload frequently coexist in cirrhosis and are each associated with systemic inflammation and adverse outcomes, yet they are typically evaluated as separate complications. Whether their combination identifies a clinically distinct phenotype with added prognostic value remains unclear. We aimed to determine whether bioelectrical impedance vector analysis (BIVA)-defined nutritional and hydration phenotypes capture differences in systemic inflammation and clinical outcomes in cirrhosis. **Methods:** In this prospective cohort study, patients with cirrhosis were followed for 12 months. Nutritional and hydration status were assessed using BIVA and classified as normal, fluid overload (FO), malnutrition, or combined fluid overload and malnutrition (FO+M). Baseline liver disease severity was assessed using Child-Pugh and MELD-Na scores. Galectin-3 and neutrophil-to-lymphocyte ratio (NLR) were measured as markers of systemic inflammation. The discriminative ability of galectin-3 and NLR for identifying BIVA-defined phenotypes was evaluated using ROC curves. Overall survival, death- or transplant-free survival, and hospitalization-free survival were estimated using Kaplan-Meier curves and compared across phenotypes using log-rank tests. **Results:** A total of 124 patients were included. BIVA classified patients into four

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

nutritional/hydration phenotypes: normal status (n = 22, 17.74%), FO (n = 58, 46.77%), FO+M (n = 25, 20.16%), and malnutrition (n = 19, 15.32%). FO+M represented the highest-risk subgroup, characterized by more advanced liver disease, with most patients classified as Child-Pugh C (72%) and the highest MELD-Na scores (26 [18–30]). Alcohol-related and autoimmune liver disease were the most frequent etiologies within this group. This phenotype also showed the highest inflammatory burden, with higher galectin-3 (25.35 [20.08–39.87] ng/mL) and NLR (11.15 [5.85–18.27]) than other phenotypes ($p < 0.001$). Galectin-3 and NLR showed strong discriminative ability for identifying the combined phenotype (AUC: 0.893; 95% CI: 0.831–0.954). Over 365 days, FO+M consistently showed the poorest outcomes across all survival endpoints, including the lowest overall survival, death- or transplant-free survival, and hospitalization-free survival (log-rank $p < 0.001$ for all). The separation between groups was most pronounced for hospitalization-free survival, where FO+M declined early and remained the worst-performing phenotype throughout follow-up (**Figure 1**). **Conclusion:** The coexistence of fluid overload and malnutrition defines a clinically distinct, high-risk phenotype in cirrhosis that is not captured when these features are considered separately. This phenotype aligns with increased inflammatory burden and identifies patients with worse clinical outcomes.

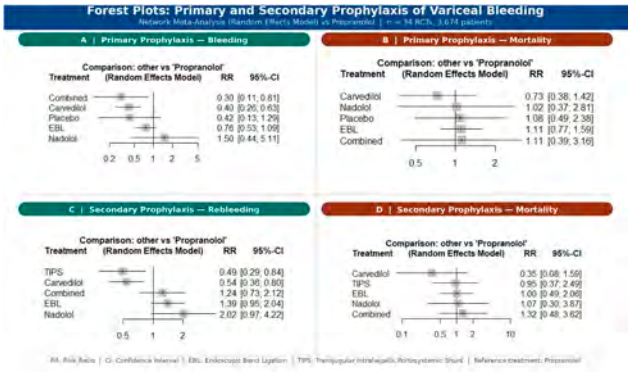
1488 | COMPARISON OF PHARMACOLOGICAL, ENDOSCOPIC, AND INTERVENTIONAL STRATEGIES FOR PRIMARY AND SECONDARY PROPHYLAXIS OF VARICEAL BLEEDING: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS



Mujtaba Moazzam[1] Hasnain Saqib[2] Rehman Bashir[2] Talha Khan[2] Mahad Ahmad[2] Marjan Haider[3] Michael Fine[3], [1]Corewell Health William Beaumont University Hospital, [2]Islamic International Medical College, Rawalpindi, Pakistan, [3]Trinity Health, Ann Arbor, Michigan, USA

Background: Gastroesophageal variceal bleeding carries significant morbidity and mortality in patients with portal hypertension. Multiple pharmacological, endoscopic, and interventional strategies have emerged for prophylaxis, yet no network meta-analysis has comprehensively compared the full treatment spectrum across both primary and secondary prophylaxis settings. We aimed to evaluate their relative efficacy within a single unified framework. **Methods:** We conducted a systematic review and frequentist random-effects NMA of RCTs comparing propranolol, nadolol, carvedilol, EBL, combination therapy (EBL plus beta-blocker), and TIPS. Databases searched included PubMed/MEDLINE, Embase, Cochrane CENTRAL, Scopus, and ClinicalTrials.gov through January 2026 (PROSPERO: CRD420261304355). Outcomes included bleeding/rebleeding risk and all-cause mortality. Risk of bias was assessed using Cochrane RoB 2. Treatment ranking used SUCRA values. Consistency was evaluated using design-by-treatment interaction models and TSA assessed conclusiveness of mortality evidence. **Results:** Thirty-four RCTs enrolling 3,674 patients were included. In primary prophylaxis, combination therapy (RR 0.30, 95% CI 0.11-0.81; SUCRA 0.86) and carvedilol (RR 0.40, 95% CI 0.26-0.63; SUCRA 0.76) significantly reduced first bleeding versus propranolol. In secondary prophylaxis, TIPS (RR 0.49, 95% CI 0.29-0.84; SUCRA 0.92) and carvedilol (RR 0.54, 95% CI 0.36-0.80; SUCRA 0.88) most effectively reduced rebleeding. No intervention demonstrated a statistically significant mortality benefit in either setting; carvedilol showed consistent directional trends toward lower mortality in both primary (RR 0.73, 95% CI 0.38-1.42) and secondary (RR 0.35, 95% CI 0.08-1.59) prophylaxis, though TSA confirmed evidence remains below the required information size. Sensitivity analyses were robust to exclusion of high-risk-of-bias studies. **Conclusion:** This first comprehensive NMA across the full prophylaxis spectrum demonstrates that combination therapy is the most effective strategy for

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

primary prophylaxis, while TIPS leads in secondary prophylaxis. Carvedilol's consistent directional mortality advantage warrants investigation in adequately powered trials. These findings provide a comparative framework to inform clinical practice and guideline development.

1489 | THE ALARM SCORE: DUAL RISK STRATIFICATION AFTER ALBUMIN INFUSION IN CIRRHOSIS

Nikhilesh Mazumder[1] John Rice[2] Laura Mariani[3] Kayvan Najarian[3] Anna Lok[4] Elliot Tapper[4], [1]University of Michigan Hospitals and Health Centers, [2]University of Michigan School of Public Health, [3]University of Michigan, [4]University of Michigan Medical Center

Background: Albumin infusion is first line therapy for patients with cirrhosis, ascites, and acute kidney injury (AKI). However, albumin therapy also may cause respiratory failure. Models to jointly predict AKI response and respiratory failure after albumin infusion are lacking. Herein, we develop and internally validate the ALARM score (ALbumin response And Respiratory Model). **Methods:** We retrospectively identified 1,096 hospitalized patients with cirrhosis who received IV 25% albumin from 2015–2025. Patients in shock, receiving positive pressure ventilation, hospitalized for < 48 hours, on dialysis, or with prior TIPS or liver transplantation were excluded. Respiratory failure and AKI response were assessed 48 hours after first albumin infusion. Separate LASSO-regularized logistic regression models for respiratory failure and AKI response were developed using clinical, vital sign, and laboratory data available at infusion and internally validated using 5-fold cross-validation. Model performance was compared with reduced models including MELD 3.0 variables alone. Because the primary clinical objective was high-sensitivity risk stratification, models were evaluated at thresholds corresponding to 90% sensitivity. **Results:** Patients had a median MELD 3.0 of 26, bilirubin 2.7 mg/dL, MAP 75 mmHg, and SpO2 97%; 888 (81.7%) were on room air at infusion. Among 381 patients with AKI at infusion, 70 (29.2%) experienced AKI response at 48 hours, while 101 patients (12.9%) developed respiratory failure. The ALARM respiratory failure model achieved an AUC of 0.71 versus 0.62 for MELD 3.0 and at 90% sensitivity threshold it significantly reclassified patients (NRI 0.3, $p < 0.01$) with a NPV of 0.94. For AKI response, the ALARM model achieved an AUC of 0.70 versus 0.60 for MELD 3.0 alone, with NPV 0.91but did not significantly reclassify patients. A combined risk model identified a subgroup with a 40% higher risk of respiratory failure and four times lower likelihood of AKI response (Figure). **Conclusion:** The ALARM model jointly predicts respiratory failure and AKI response following albumin infusion and may support high-sensitivity clinical risk stratification in patients with cirrhosis and AKI.

1490 | NIGHT MOVES: DELAYED NOCTURNAL ACTIVITY IS ASSOCIATED WITH HEPATIC ENCEPHALOPATHY WHEN MEASURED LONGITUDINALLY WITH COMMERCIAL FITNESS TRACKERS

Adam Buckholz[1] Sophie Silbert[2] Kamaryn Tanner[3] Avesh Thuluvath[4] Lara Phipps[2] Jayden Maramis[2] Elizabeth Verna[5] Edwin Kan[6] Ana Krieger[2] Robert Brown[7], [1]New York Presbyterian Hospital Program, [2]NewYork-Presbyterian/Weill Cornell Medical Center, [3]NewYork-Presbyterian/Columbia University Medical Center, [4]Columbia University Irving Medical Center, [5]Columbia University Medical Center, [6]Cornell University, [7]Weill Cornell Medicine

Background: Hepatic Encephalopathy (HE) is a complex complication of portal hypertension, with sleep disturbances and day-night reversal a commonly reported symptom. Despite this, longitudinal monitoring to detect and manage HE is understudied, leading to frequent hospitalizations and impaired outcomes. Commercial wearables permit passive, continuous assessment of nocturnal behavior in real-world settings. We evaluated whether commercially available fitness trackers detect altered nocturnal activity patterns associated with HE. **Methods:** We analyzed activity after sleep onset in 102 participants who were followed with an Oura fitness tracker a median of 177 days (range 40-180). Activity was assessed using its internal accelerometer and reported as metabolic equivalent of task (MET)-minutes, a continuous measure where <1 is considered rest; MET minutes, activity level, and sleep status were analyzed in 5-minute epochs. HE was defined as a previous episode of overt HE and active treatment with lactulose/rifaximin. Impaired cognition was defined as PHES $\leq$ -4 regardless of prior overt episode. Sleep onset was defined as initiation of the longest sleep period in each 24-hour epoch. Mixed-effects models accounting for repeated measurements evaluated associations between HE/cognition and weeknight nocturnal activity trajectories after adjustment for age, sex, and MELD score. **Results:** In 102 participants, 46.1% were female, 45.1% had CTP B/C cirrhosis, 39 had prior overt HE and 34 had PHES $\leq$-4. In mixed-effects models, HE was associated with greater odds of being active overnight (MET >1.0) compared to participants without HE (OR 1.19, $p=0.01$). Nocturnal activity trajectories were significantly different from normal/unimpaired in patients with both HE ($p = 0.01$) and/or cognitive impairment ($p = 0.04$). Participants with OHE demonstrated higher late-night activity intensity during the 4–8 hour post-sleep onset period (mean difference 0.024 in 75th percentile MET; 95% CI −0.002 to 0.051; $p=0.073$). **Conclusion:** Commercial wearable devices identified delayed nocturnal activity patterns consistent with digitally quantifiable day-night reversal in with HE and cognitive impairment in cirrhosis. These findings suggest wearable-derived longitudinal activity metrics may enable scalable, passive longitudinal monitoring of HE-related neurocognitive dysfunction between clinic visits. Such activity may also be one of the complex mechanisms by which sleep and HE are related to worsened daytime cognitive function. Future studies should consider whether shape and timing of nocturnal activity can adequately identify patients at risk for HE.

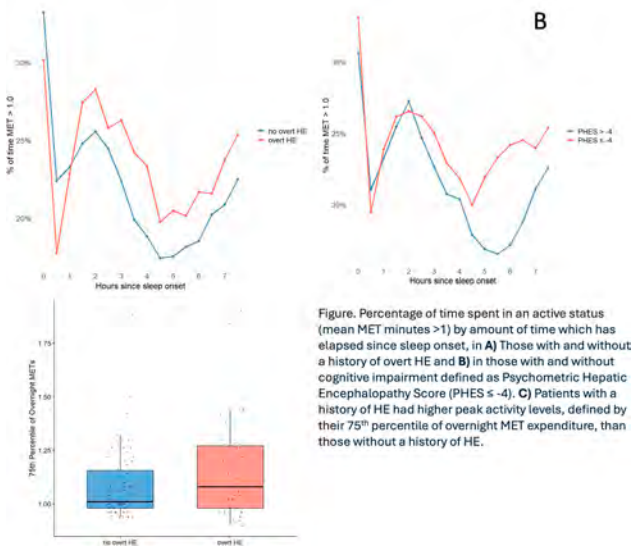

Figure. Percentage of time spent in an active status (mean MET minutes >1) by amount of time which has elapsed since sleep onset, in **A)** Those with and without a history of overt HE and **B)** in those with and without cognitive impairment defined as Psychometric Hepatic Encephalopathy Score (PHES ≤ -4). **C)** Patients with a history of HE had higher peak activity levels, defined by their 75th percentile of overnight MET expenditure, than those without a history of HE.

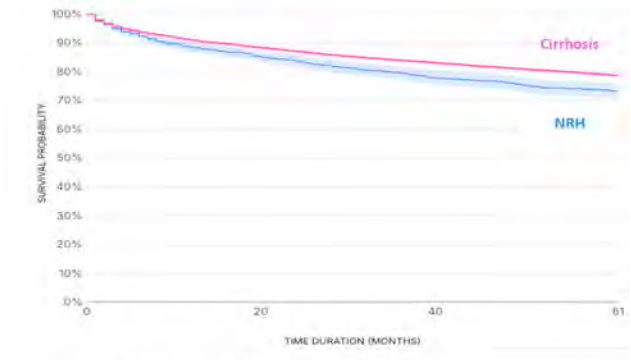
1491 | SURVIVAL OF PATIENTS WITH NODULAR REGENERATIVE HYPERPLASIA: A MAYO CLINIC PLATFORM USE CASE

Bridgette McNally[1] W. Ray Kim[1], [1]Mayo Clinic Arizona



Background: The Mayo Clinic Platform (MCP) is Mayo Clinic's enterprise-level data and analytics infrastructure designed to enable healthcare innovation using large-scale clinical data. It provides aggregated de-identified patient data and enables tools for analytics, artificial intelligence, and research, allowing collaborations between Mayo and external partners. In this work, we demonstrate its use for investigation of rare conditions such as nodular regenerative hyperplasia (NRH) of the liver. **Methods:** Using the MCP, a

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

search for patients with biopsy confirmed NRH with or without cirrhosis was conducted. For comparison, an equivalent search for biopsy confirmed, non-NRH cirrhosis was performed. Comparison between these two cohorts was conducted using MCP analytic tools. **Results:** Out of 8,171,580 unique patients included in MCP, 1,294 patients were identified in the NRH cohort and 14,907 patients in the non-NRH cirrhosis cohort. The average age and sex demographics were similar between the two groups. Total bilirubin, INR, ALT and AST were higher and platelet count was lower in the non-NRH cirrhosis group. Albumin was similar between the two groups. Most notably, survival probability at 61 months in the NRH cohort was near 82% compared to near 89% in the non-NRH cirrhosis group. **Conclusion:** MCP is an innovative and user-friendly tool, which harnesses the power of artificial intelligence and data networks; it can be utilized to study rare diseases such as NRH. As demonstrated in our current study, liver synthetic function was better preserved in the NRH cohort; however, survival probability was markedly lower in the NRH cohort. This emphasizes the importance of timely evaluation to determine the underlying etiology of NRH, which would allow for disease directed monitoring and therapy that may lead to improved survivability in this group.

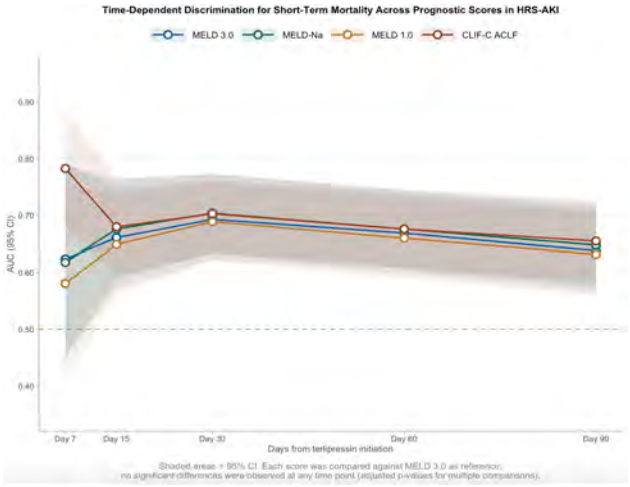
1492 | PROGNOSTIC PERFORMANCE OF MELD-BASED SCORES AND CLIF-C ACLF FOR 90-DAY MORTALITY IN HRS-AKI AT TERLIPRESSIN INITIATION: RESULTS FROM THE HRS-HARMONY CONSORTIUM



Xing Li[1] Tianqi Ouyang[1] R. Todd Frederick[2] Nneka Ufere[1] Douglas Simonetto[3] Constantine Karvellas[4] Hugo Vargas[5] Raymond Chung[1] Pratima Sharma[6] Clara Tow[7] J. Pedro Teixeira[8] Zachary Fricker[9] Stevan Gonzalez[10] Javier Neyra[11] Jevon Robinson[1] Sydney Whittaker[1] Kavish Patidar[12] Andrew Allegretti[1], [1]Massachusetts General Hospital, [2]California Pacific Medical Center, [3]Mayo Clinic Rochester, [4]University of Alberta, [5]Mayo Clinic Arizona, [6]University of Michigan Medical Center, [7]Albert Einstein College of Medicine, [8]University of New Mexico, [9]Beth Israel Deaconess Medical Center, [10]Baylor Scott and White All Saints Medical Center Fort Worth, [11]University of Alabama at Birmingham, [12]Houston Methodist Hospital

Background: HRS-AKI carries high short-term mortality, yet the prognostic performance of existing risk scores remains uncertain. MELD-based scores were developed to estimate transplant waitlist mortality and may not capture the distinct risk profile in HRS-AKI, especially in those treated with terlipressin. We sought to evaluate the discrimination of MELD-based scores and CLIF-C ACLF for short-term outcomes in HRS-AKI patients treated with terlipressin. **Methods:** We analyzed a multicenter retrospective cohort of 243 adults with HRS-AKI treated with terlipressin across 16 U.S. academic centers. MELD 1.0, MELD-Na, MELD 3.0, and CLIF-C ACLF scores were calculated at terlipressin initiation. The primary outcome was 90-day mortality, with liver transplantation (LT) not modeled as a competing risk in the primary analysis. Time-dependent ROC analysis using inverse probability of censoring weighting was used to assess discrimination at 7, 15, 30, 60, and 90 days. Secondary outcomes included terlipressin response, in-hospital renal replacement therapy (RRT). Reclassification analyses for 90-day mortality compared MELD 3.0 and MELD-Na using categorical and continuous Net Reclassification Improvement (NRI). **Results:** Among 243 patients, median MELD 3.0 was 35, and 90-day mortality was 42%. 28% underwent LT by 90 days. Non-survivors had significantly higher scores at terlipressin initiation (all $p < 0.001$). Discrimination for 90-day mortality was modest across all scores (AUCs: MELD 1.0 0.632, MELD-Na 0.648, MELD 3.0 0.638, CLIF-C ACLF 0.655), with no significant differences between scores (Figure). CLIF-C ACLF showed numerically higher discrimination at 7 days (AUC 0.783), though this was not statistically significant or sustained over time. Discrimination for terlipressin response and in-hospital RRT was similarly modest (AUCs 0.566–0.655). Categorical reclassification using pre-specified strata of clinical severity showed no meaningful improvement of MELD 3.0 over MELD-Na (NRI 0.03, $p = 0.63$), as MELD 3.0 shifted both survivors and non-survivors into higher risk strata, gaining sensitivity at the expense of specificity. Continuous NRI suggested modest improvement in risk ranking (NRI 0.19, $p = 0.007$) that did not translate into clinically meaningful reclassification. **Conclusion:** In HRS-AKI patients treated with terlipressin, MELD-based scores and CLIF-C ACLF

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

demonstrated only modest discrimination for short-term mortality, with no score outperforming others and MELD 3.0 offering no meaningful advantage over prior iterations. These findings highlight the limitations of current scores in a high-risk population and underscore the unmet need for dynamic, disease-specific prognostic models in HRS-AKI.

1493 | EFFECT OF COMBINED VILDAGLIPTIN AND SACUBITRIL/VALSARTAN THERAPY ON PORTAL HYPERTENSION IN CIRRHOTIC RATS

Masafumi Oyama[1] Kosuke Kaji[1] Hitoshi Yoshiji[2], [1]Nara Medical University Department of Gastroenterology, [2]Nara Medical University

Background: Portal hypertension (PH) is a major complication of cirrhosis, and conventional therapy with β-blockers is often limited by adverse effects such as hypotension, highlighting the need for novel pharmacological approaches. Recent studies have implicated increased activity of soluble epoxide hydrolase (sEH) and reduced levels of epoxyeicosatrienoic acids (EETs) in the pathogenesis of PH. Dipeptidyl peptidase-4 inhibitors (DPP-i) and angiotensin receptor–neprilysin inhibitors (ARNI) have been suggested to preserve EET bioactivity via suppression of sEH; however, their combined effects remain unclear. Therefore, we investigated the effects of these agents on portal pressure and liver fibrosis. **Methods:** Two rat cirrhosis models were used: a dietary model induced by a choline-deficient, L-amino acid-defined high-fat diet (CDAHFD) and a surgical model induced by bile duct ligation (BDL). Rats received vildagliptin (DPP-i; 10 mg/kg), sacubitril/valsartan (ARNI; 30 mg/kg), DPP-i + ARNI, or carvedilol (NSBB; 10 mg/kg). Portal pressure, hemodynamics, sEH activity, EET levels, endothelial function, vascular remodeling, and fibrosis were assessed by ELISA, qPCR, Western blotting, and

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

immunohistochemistry. **Results:** In CDAHFD rats, portal pressure elevation was significantly attenuated by DPP-i or ARNI, and combination therapy showed a reduction comparable to NSBB. Unlike NSBB, DPP-i and ARNI did not alter mean arterial pressure, heart rate, or cardiac output. Both drugs increased vasodilatory markers (Gch, Ddah1), enhanced eNOS phosphorylation, and reduced moesin phosphorylation. Sinusoidal capillarization (CD34), pathological angiogenesis (Vegfa, Ptgs2, Pigf, Vwf), Hedgehog pathway activation, and profibrotic gene expression (Acta2, Col1a1, Tgfb1, Ctgf) were suppressed. sEH expression and activity were elevated in CDAHFD rats and were reduced by both agents, with concomitant increases in hepatic EETs. Similar therapeutic effects were observed in BDL rats, confirming efficacy across two distinct PH models. **Conclusion:** DPP-i and ARNI improved portal hypertension and liver fibrosis and demonstrated additive benefits when combined. This therapeutic strategy may represent a novel treatment option for cirrhosis-associated portal hypertension.

1494 | PRESS-DERIVED ESTIMATED HVPG PREDICTS THE FULL CLINICAL COURSE OF CIRRHOSIS: FROM ACUTE DECOMPENSATION TO ACLF AND MORTALITY (PRESS : PORTAL PRESSURE REGRESSION AND ESTIMATION USING SIMPLE SERUM MARKERS)

Seul Ki Han[1] Hyung Tark Lee[1] Euiyoung Oh[1] Sang Gyune Kim[2] Soon Koo Baik[3] Hyun Jung Chung[1] Moon Young Kim[1], [1]Yonsei University Wonju College of Medicine, [2]Soonchunhyang University Bucheon Hospital, [3]Yonsei University Wonju College of Medicine, Wonju

Background: Hepatic venous pressure gradient (HVPG) is the gold standard for quantifying portal hypertension, but its invasiveness limits routine use. Non invasive test was widely used to cover up these limitations. **Methods:** We identified 670 patients with cirrhosis who underwent HVPG measurement and followed them longitudinally. External validation was performed in an independent cohort of 151 patients from a separate institution. We developed PRESS framework (Portal pressure Regression and Estimation using Simple Serum markers) model, a clinically interpretable regression-based model to (i) estimate continuous HVPG and (ii) classify clinically significant portal hypertension (CSPH; HVPG $\geq$10 mmHg) using routinely available variables. **Results:** After feature selection using repeated cross-validation, final models were comprised of five laboratory variables (INR, albumin, platelet count, total bilirubin, sodium). Regression analysis was applied to establish PRESS framework. Estimated HVPG (eHVPG) correlated with measured HVPG (Pearson r = 0.53). For CSPH classification, the model demonstrated an AUROC of 0.83 in the internal cohort and 0.73 in the external validation cohort. For acute decompensation, PRESS model stratified 1-year AD risk more sharply than measured HVPG (log-rank $p = 3.61\times10^{-10}$ vs 6.28×10^{-6}). This superiority was sustained over long-term follow-up for further AD ($p = 1.38\times10^{-17}$ vs 6.52×10^{-16}), ACLF ($p = 3.77\times10^{-16}$ vs 1.1×10^{-6}) and ACLF-related mortality ($p = 3.64\times10^{-14}$ vs 1.2×10^{-6}), with steeper Cox hazard gradients for both outcomes (further AD: HR = __vs ,ACLF: HR = 1.181 vs 1.084; ARM: HR = 1.178 vs 1.088; all $p < 0.001$). In a transient elastography included subset (n = 306), addition of liver stiffness measurement to PRESS model further improved CSPH prediction (AUROC 0.827 > 0.883). **Conclusion:** Using only routinely available variables, the PRESS model provides an interpretable, non-invasive estimate of portal pressure and predicts CSPH with external validation. It further enables clinically meaningful risk stratification for 1-year acute decompensation, subsequent decompensation, ACLF, and ACLF-related mortality.

Table 1. Multivariable Cox regression analyses for clinical outcomes according to measured HVPG and PRESS model.

Model	Outcome	Variable	HR (95% CI)	P
Age, Sex, MELD adjusted	1-year AD	HVPG	1.05 (1.02-1.09)	<0.001

1495 | THERAPY ESCALATION AND READMISSION PATTERNS IN HOSPITALIZED PATIENTS WITH HEPATIC ENCEPHALOPATHY

Joshua Pagán-Busigó[1] Elizabeth Peck[1] Yash Shah[1] Zachary Israeli[1] Lucie Pham[1] Rohan Karkra[1] Paul Gaglio[2], [1]Rutgers New Jersey Medical School, [2]Rutgers NJ Medical School

Background: Hepatic encephalopathy (HE) is associated with frequent recurrent hospitalizations, yet real-world therapy escalation patterns and their relationship to readmission risk remain incompletely characterized. We evaluated whether adjunctive therapy use identifies patients with more severe or recurrent HE at higher risk for readmission, while also assessing clinical and laboratory predictors of 90-day readmission. **Methods:** We performed a retrospective cohort study of patients admitted with HE at a tertiary academic center from January 2024 to January 2026. Admission-level data were collected across index and recurrent HE hospitalizations. Discharge therapy was classified as standard therapy (lactulose ± rifaximin), triple therapy (lactulose/rifaximin/zinc), or quadruple therapy (lactulose/rifaximin/zinc/levocarnitine). Primary outcomes were 30-day and 90-day HE readmission. Readmission rates were compared across therapy groups, and multivariable logistic regression was used to evaluate therapy strategy and non-therapy predictors of 90-day readmission, with standard errors clustered by patient. **Results:** A total of 102 patients contributed 347 HE admissions. Patient-level demographics and overall comorbidity burden were not independently associated with readmission. Readmission rates were highest among patients discharged on quadruple therapy. Thirty-day HE readmission was 28.4%, 32.3%, and 60.0% for standard, triple, and quadruple therapy, respectively. Ninety-day HE readmission was 54.7%, 57.1%, and 79.5%, respectively. Therapy strategy was not independently associated with readmission after adjustment. In adjusted non-therapy models, ascites was associated with 90-day readmission (OR 2.12, 95% CI 1.01–4.42, p = 0.046), as was admission lactate level (OR 2.92 per 1-unit increase, 95% CI 1.07–7.94, p = 0.036). In a separate model evaluating advanced therapy use, each additional HE admission increased the odds of discharge on triple or quadruple therapy (OR 1.42, 95% CI 1.17–1.73, p < 0.001). **Conclusion:** In this real-world HE cohort, triple and quadruple therapy were associated with higher unadjusted readmission rates but were not independently associated with readmission after adjustment. Ascites and admission lactate level emerged as potential markers of 90-day readmission risk. Advanced therapy use was more common during later HE admissions, suggesting that therapy escalation likely reflects recurrent HE burden and illness severity rather than a causal effect of therapy itself. These findings support further evaluation of whether earlier risk stratification and timely consideration of adjunctive therapy could reduce recurrent HE admissions.

1496 | TNF-α-ASTROCYTE-VEGF-C AXIS-DRIVEN MENINGEAL AND NASOPHARYNGEAL COMPENSATORY LYMPHANGIOGENESIS PROTECTS AGAINST HEPATIC ENCEPHALOPATHY IN LIVER CIRRHOSIS

Shao-Jung Hsu[1] Yu-Tang Chang[2] Ming-Chih Hou[1] Yasuko Iwakiri[3] Fa-Yauh Lee[4], [1]Taipei Veterans General Hospital, [2]University of California, Berkeley, [3]Yale University, [4]National Yang-Ming University

Background: Neuroinflammation and hyperammonemia drive hepatic encephalopathy (HE), a critical complication of liver cirrhosis. The clearance of cerebrospinal fluid (CSF) relies heavily on both the meningeal lymphatic network and the nasopharyngeal lymphatic plexus. While previous research established that increased meningeal lymphangiogenesis mitigates HE and neuroinflammation during early cirrhosis, this current investigation evaluates these broader CSF clearance mechanisms in advanced cirrhosis models and explicitly validates these pathways in human clinical cohorts. **Methods:** Advanced cirrhosis was induced in male Sprague-Dawley rats via common bile duct ligation. Clinically, MRI assessed nasopharyngeal drainage and meningeal lymphatic

flow in cirrhotic patients, comparing cohorts with and without HE. Additionally, *in vitro* studies utilized human primary astrocytes and an astrocyte cell line to assess underlying mechanisms. **Results:** Compared to early-stage counterparts, rats exhibiting advanced cirrhosis demonstrated upregulated nasopharyngeal and meningeal lymphangiogenesis. Notably, the severity of HE and neuroinflammation remained comparable between the two groups, despite exacerbated hyperammonemia and portal hypertension in advanced cirrhosis. Disruption of this compensatory lymphatic drainage—achieved surgically via deep cervical lymph node ligation or pharmacologically using lenvatinib—aggravated HE and neuroinflammation in the cirrhotic rat models. Strikingly, in the human clinical cohort (n = 42), cirrhotic patients suffering from HE demonstrated significantly diminished nasopharyngeal drainage alongside restricted flow in meningeal lymphatic channels compared to patients without HE. Mechanistically, *in vitro* analyses revealed that TNF-α upregulates VEGF-C (lymphangiogenic factor) protein expression within astrocytes. *In vivo*, acute lipopolysaccharide (LPS) administration significantly boosted blood TNF-α and cerebral VEGF-C levels in cirrhotic rats, whereas prolonged TNF-α blockade successfully inhibited both brain VEGF-C expression and subsequent meningeal lymphangiogenesis. **Conclusion:** Advanced liver cirrhosis induces compensatory nasopharyngeal and meningeal lymphangiogenesis through a TNF-α–astrocyte–VEGF-C signaling pathway, enhancing CSF drainage and limiting neuroinflammation and hepatic encephalopathy despite worsening hyperammonemia and portal hypertension. Disruption of these lymphatic networks aggravates neuroinflammation and HE in cirrhotic rats. Crucially, direct imaging of human patients confirms this functional relationship, demonstrating impaired meningeal and nasopharyngeal lymphatic drainage in cirrhotic patients with HE. Together, these translational findings identify compensatory lymphatic remodeling as an important protective mechanism against HE in advanced cirrhosis.

1497 | LIVERRISK SCORE CORRELATED WITH HEPATIC VEIN PRESSURE GRADIENT IN LIVER CIRRHOSIS

Hsin-Hua Lai[1] Pei-Shan Wu[2] Yun-Cheng Hsieh[3] Han-Chieh Lin[1] Ming-Chih Hou[1] Kuei-Chuan Lee[3], [1]Taipei Veterans General Hospital, [2]Taipei Veterans General Hospital, Taipei, Taiwan, [3]Taipei Veterans General Hospital, Taipei, Taiwan.

Background: Portal hypertension is a major complication of liver cirrhosis and is associated with adverse clinical outcomes. Although hepatic venous pressure gradient (HVPG) remains the gold standard for assessing portal hypertension, it requires invasive procedure. The LiverRisk Score (LRS) is a recently proposed scoring system that correlated with liver stiffness and predicted liver-related complications. Evaluating the association between LRS and HVPG may provide insight into its potential utility for identifying patients at high risk of portal hypertension. **Methods:** Patients with cirrhosis were retrospectively enrolled between March 2011 and November 2024. HVPG measurements and clinical parameters for calculating LRS, MELD, Child–Pugh, ALBI, APRI, and FIB-4 were collected. Spearman's correlation and linear regression analyses were performed to evaluate associations between HVPG and clinical parameters. ROC analysis was used to assess the predictive performance of each parameter for different HVPG level. Cox proportional hazards regression analysis was performed to identify predictors of clinical outcomes. **Results:** A total of 74 patients were analyzed (mean age 61.84 ± 11.72 years; 79.7% male), with hepatitis B being the most common etiology (41.9%). The mean LRS was 8.75 ± 2.34, and the mean HVPG was 17.19 ± 4.82 mmHg.LRS was significantly correlated with HVPG in Spearman's analysis ($r_s = 0.258$, $p = 0.027$). In univariate linear regression, LRS was positively associated with HVPG ($\beta = 0.308$, $R^2 = 0.095$, $p = 0.008$) and remained the only significant parameter in multivariable analysis ($\beta = 0.327$, $p = 0.008$). In patients with HVPG ≥ 16 mmHg, LRS demonstrated the only significant predictive performance (area under the ROC curve 0.711, $p = 0.001$), with an optimal cutoff value of 7.33.Regarding clinical outcomes, LRS was independently associated with new-onset hepatic encephalopathy (Hazard ratio = 1.244, $p = 0.027$) and acute kidney injury (Hazard ratio = 1.220, $p = 0.029$) during one-year follow-up in Cox multivariable regression. **Conclusion:** LRS is independently correlated with HVPG and demonstrates significantly predictive ability for patients with HVPG ≥ 16 mmHg. Additionally, LRS independently predicts new-onset hepatic encephalopathy and acute kidney injury, supporting its potential role as a non-invasive risk stratification tool in liver cirrhosis.

1498 | FRAILTY AS A PREDICTOR OF POST-TIPS HEPATIC ENCEPHALOPATHY, ACUTE KIDNEY INJURY, AND REHOSPITALIZATION

Abhinav Birda[1] Sahak Hovsepian[1] Nakul Ganju[2] Gevork Davtian[3], [1]Kaiser Permanente Los Angeles Medical Center, [2]Howard University Hospital, [3]Ross University School of Medicine

Background: Transjugular Intrahepatic Portosystemic Shunt (TIPS) placement is complicated by hepatic encephalopathy (HE) in up to 40% of patients, yet pre-procedural risk stratification remains imprecise. Frailty, a state of reduced physiologic reserve is highly prevalent in cirrhosis and predicts adverse outcomes including waitlist mortality, independent of ascites and HE. Whether frailty independently predicts post-TIPS HE, acute kidney injury (AKI), and rehospitalization has not been studied in a large real-world cohort. **Methods:** We conducted a retrospective cohort study using the TriNetX federated network (111 health systems). Adults undergoing TIPS (CPT 37182) were stratified by frailty using a modified frailty index (mFI): frail (≥ 2 of: diabetes, hypertension, heart failure, COPD, CKD, dementia) vs. non-frail (< 2). Cohorts were matched 1:1 on age, sex, race, and ethnicity. Primary outcome was 1-year incident HE (K76.82). Secondary outcomes included 1-year AKI (N17), rehospitalization, and mortality. Kaplan-Meier and Cox regression adjusting for age, sex, alcoholic cirrhosis, ascites, and esophageal varices were performed. **Results:** Of 12,284 TIPS patients, 8,667 (70.6%) met frailty criteria. After 1:1 matching (n = 1,239 per group), frail patients had higher 1-year HE (25.8% vs. 15.2%; HR 1.708, 95% CI 1.364–2.140, $p < 0.0001$), AKI (45.1% vs. 25.5%; HR 1.724, 95% CI 1.494–1.989, $p < 0.0001$), and rehospitalization (HR 1.115, 95% CI 1.016–1.224, $p < 0.0001$). Frailty remained an independent predictor of HE on multivariable Cox regression (aHR 1.889, 95% CI 1.638–2.178, $p < 0.0001$), alongside ascites (aHR 1.490) and esophageal varices (aHR 1.486). Frail patients paradoxically demonstrated lower 1-year mortality (21.9% vs. 28.2%; aHR 0.632, $p < 0.0001$), potentially reflecting indication bias from emergent TIPS in non-frail patients. **Conclusion:** Frailty was present in over 70% of TIPS recipients and independently predicted 1-year HE and AKI after adjustment for liver disease severity. These findings suggest that pre-procedural frailty assessment may identify patients warranting intensified post-TIPS surveillance, prophylactic lactulose, or enhanced shared decision-making. Additionally, prehabilitation with physical therapy and nutrition counseling may help ameliorate frailty and thus improve post-TIPS outcomes in this vulnerable population. The paradoxical mortality finding likely reflects differential TIPS indications by frailty status. Frailty screening should be incorporated into pre-TIPS risk stratification.

Table 1. Kaplan-Meier Outcomes: Frail vs. Non-Frail TIPS Patients (Matched Cohorts, n=1,239 each)

Outcome	Frail: n/N (%)	Non-frail: n/N (%)	HR (95% CI)	p-value
90-Day Outcomes				
Hepatic encephalopathy	155/938 (17.6%)	91/1,010 (9.9%)	1.681 (1.298–2.178)	< 0.0001
Acute kidney injury	405/1,239 (33.4%)	273/1,239 (23.0%)	1.439 (1.234–1.678)	< 0.0001
Rehospitalization†	883/1,239 (71.3%)	819/1,239 (66.1%)	1.078 (0.981–1.186)	0.065
1-Year Outcomes				
Hepatic encephalopathy	214/938 (25.8%)	118/1,010 (15.2%)	1.708 (1.364–2.140)	< 0.0001
Acute kidney injury	525/1,239 (45.1%)	291/1,239 (25.5%)	1.724 (1.494–1.989)	< 0.0001
Rehospitalization	944/1,239 (76.2%)	842/1,239 (68.0%)	1.115 (1.016–1.224)	< 0.0001
Overall mortality	271/1,239 (21.9%)	350/1,239 (28.2%)	0.609 (0.520–0.714)	0.0002

HR = hazard ratio from Kaplan-Meier log-rank analysis. All outcomes measured after index TIPS date. HE analysis excludes patients with prior HE. † Log-rank p=0.065; HR p<0.0001.

1499 | EMERGING SAFETY, PHARMACOKINETIC, AND PHARMACODYNAMIC RESULTS OF THE FIRST MULTIPLE-ASCENDING DOSE COHORT FROM THE PHASE 1 PHIN-001 STUDY OF PHIN-214 IN ADULTS WITH DECOMPENSATED CIRRHOSIS

Eric Lawitz[1] Tarek Hassanein[2] Jacqueline O'Leary[3] Anita Kohli[4] Mangesh Pagadala[5] Ethan Weinberg[6] Christina Lindenmeyer[7] Gary Reiss[8] Douglas Simonetto[9], [1]Texas Liver Institute, University of Texas Health San Antonio, [2]Southern California Research Center, [3]Dallas VAMC, [4]Arizona Liver Health, [5]The Liver Institute at Methodist Dallas, [6]University of Pennsylvania, [7]Cleveland Clinic, [8]Tandem Clinical Research, [9]Mayo Clinic Rochester

Background: Portal hypertension drives decompensation in cirrhosis, but outpatient treatment options are limited. PHIN-214 is a novel vasopressin analogue with partial V1a receptor agonism and reduced V2 activity, designed to induce splanchnic vasoconstriction and increase effective arterial volume. PHIN-214 is being developed for once-daily, subcutaneous, self-administration for outpatient management of portal hypertension and its associated complications. **Methods:** PHIN-001 (NCT05490888) is an ongoing Phase 1 dose-optimization study evaluating single ascending dose (SAD, completed) and multiple ascending doses (MAD, enrolling) of PHIN-214 in adults with cirrhosis. The primary objectives included safety, tolerability, pharmacokinetic, and pharmacodynamic assessments. **Results:** The first MAD cohort comprised of 6 diuretic-dependent participants with Child-Pugh Class B cirrhosis, who were treated over a 28-day dosing period. The first subject developed grade 4 hyponatremia after 4 consecutive daily doses. For the 5 subsequent subjects, an every-other-day lead-in dosing was administered to allow serum sodium to stabilize, followed by daily dosing through day 28. All 5 subjects discontinued diuretics prior to PHIN-214 dosing and remained off diuretics, completing the 28-days of dosing without worsening ascites or statistically significant increases in weight. Apart from the first subject, all adverse events considered at least possibly related to PHIN-214 were grade 1-2, generally transient (resolving within the first week), and included hyponatremia, abdominal discomfort, diarrhea, transient left leg swelling in one participant and injection-site blanching in one participant. To date, baseline demographics across SAD and MAD include 22 subjects ranging from 24–72 years of age [mean: 54], including 10 females and 12 males, with 11 Child-Pugh A and 11 Child-Pugh B patients. PHIN-214 produced on-target physiologic effects with mean eGFR [CKD-EPI cystatin C] improving by 31% (SD 22%, $p = 0.0019$) within 12 hours of dosing, with the magnitude of improvement correlated with PHIN-156 (active metabolite) exposure. Intra subject PK was stable across 28 days with no PHIN-214 or PHIN-156 accumulation. **Conclusion:** In decompensated cirrhotic subjects, 28 days of subcutaneous PHIN-214 with an every-other-day lead-in was well tolerated and produced rapid, exposure dependent improvements in eGFR consistent with selective V1a engagement. These data support continued MAD dose escalation and evaluation of PHIN-214 as an outpatient therapy for portal hypertension. Data from additional MAD cohorts will be presented.

1500 | CIRRHOSIS RECOMPENSATION: A SYSTEMATIC REVIEW WITH AGGREGATE META-ANALYSIS BY ETIOLOGY OF CIRRHOSIS

Guadalupe Garcia-Tsao[1] Gennaro D'Amico[2] Giovanni Perricone[3] Andrea Affronti[4] Carlo Alessandria[5] Eleonora Bellini[5] Fabrizio Bronte[6] Roberta D'Ambrosio[7] Antonio Galante[8] Fabrizio Gambino[6] Federica Latteri[6] Silvia Martini[9] Maria Cristina Morelli[10] Massimo Pinzani[11] Margherita Saracco[12] Caterina Stornello[13] Laura Turco[14] Emma Aragona[6], [1]Yale University, [2]ISMETT, Palermo - Clinica La Maddalena, Palermo, [3]ASST Grande Ospedale Metropolitano Niguarda - Milano, [4]Ospedale Riuniti Villa Sofia Cervello, Palermo, [5]UOC Gastroenterologia Molinette, [6]Ospedali Riuniti Villa Sofia Cervello, Palermo, [7]Gastroenterology and Hepatology, Ospedale Maggiore Policlinico, Milano, [8]ISMETT, Palermo, [9]Ospedale Molinette, Torini, [10]Azienda Ospedaliero-Universitaria di Bologna, Bologna, [11]ISMETT, [12]Ospidale Molinette, Torino, [13]Azienda Ospedaliera Policlinico, Palermo, [14]IRCCS Azienda Ospedaliero-Universitaria di Bologna

Background: Recompensation is a recent stage of cirrhosis in which a patient with decompensated cirrhosis (ascites, variceal hemorrhage and/or encephalopathy) regresses to a compensated stage following elimination/suppression of etiological agent. Since its first definition at Baveno VII, an increasing number of studies have emerged describing a large variability in the rate of recompensation (10-65%). **Methods:** We performed a systematic review with aggregate data meta-analysis of studies on recompensation stratified by etiology of cirrhosis. The study protocol is registered in PROSPERO CRD420251091140 and complies with PRISMA recommendations. We included RCTs or observational studies reporting recompensation published between January 2014 and March 2026 using PubMed, Embase and Cochrane databases; studies including patients with metabolic-associated liver disease were excluded. Pooled estimates were computed by random effects and heterogeneity by I^2 statistics. **Results:** We identified 39 studies (28 full reports, 11 abstracts) totaling 27,047 patients with decompensated cirrhosis. Etiology was HBV in 13 studies, HCV in 9, alcohol in 7, autoimmune in 2, biliary in 4, mixed in 5. Recompensation was defined according to Baveno VII criteria in 27 studies. The pooled recompensation rate was 35% (CI 29-42; I^2 = 98%): HBV 50% (42-59; I^2 = 95%), HCV 46% (33-59; I^2 = 95%), alcohol 24% (15-37; I^2 = 95%), autoimmune 35% (6-83; I^2 = 66%), biliary 27% (16-41; I^2 = 74%) mixed etiologies 15% (7-31; I^2 = 99%). There was significant heterogeneity both between and within etiologies, in part explained by the severity of liver dysfunction, with patients with greater severity being less likely to recompensate. The pooled recompensation rate was not significantly different according to the definition of recompensation, type of publication, or risk of bias. Recompensation was associated with a 70% lower risk of death (95% CI: 57%–79%) overall and by etiology. **Conclusion:** In the largest published cohort of patients with decompensated cirrhosis to date, recompensation occurred in 35% of patients following elimination or sustained suppression of the underlying etiology, with rates highest in HBV-related cirrhosis, followed by HCV-, alcohol-, and other etiologies. Recompensation was associated with significantly reduced mortality.

Meta-analysis of recompensation according to etiology

Background: Despite potential contamination risk and inadequate supply, human plasma has remained the only source for human serum albumin (pHSA) intravenous administration (IV) since the 1940s. Here we report a pivotal trial of OsrHSA, a recombinant HSA purified from bioengineered Oryza sativa (rice) endosperm (seeds). **Methods:** We conducted a randomized, positive-controlled, double-blind, and non-inferiority phase 3 trial with patients with liver cirrhosis and serum albumin $\leq$30 g/L. 328 patients with liver cirrhosis were randomly assigned (1:1) to once-daily 20g IV of OsrHSA or pHSA for up to 2 weeks. The primary outcome was the proportion of patients to reach a serum albumin level of 35g/L (non-inferiority margin $<$-0.16). Key secondary outcomes included colloid osmotic pressure, time-to-event (reaching a serum albumin level of 35 g/L), ascites severity and serum albumin. **Results:** 328 patients were randomly assigned: 165 patients were assigned to OsrHSA, and 163 to pHSA. OsrHSA was non-inferior to pHSA in primary outcome in the intent-to-treat (difference = -5.39%; lower limit of 97.5% CI = -0.1147), as-treated (difference = -6.98%; lower limit of 97.5% CI = -0.1252) and per-protocol (difference = -6.08%; lower limit of 97.5% CI = -0.1201) sets. There was no significant difference between OsrHSA and pHSA in all secondary outcomes. There were no clinically significant anti-drug or anti-host-cell-protein antibodies. Adverse events (OsrHSA, 87.8%; pHSA, 86.4%) or serious adverse events (OsrHSA, 12.2%; pHSA, 10.5%) were comparable. There were no treatment-related serious adverse events or deaths. **Conclusion:** Rice-derived HSA is non-inferior to plasma-derived HSA in efficacy and safety.

Figure : Outcomes. (**A**) Non-inferiority analysis of primary outcome in ITT, AT and per-protocol (PP) sets. PP included patients included all participants in the AT who did not have a major protocol deviation. The difference and lower 97.5% confidence level (CL) were calculated using Newcombe confidence interval. The non-inferiority margin was -16%. Hypothetical strategy MI imputation and stratified analysis was used for AT, ITT and PP. (**B**) Kaplan-Meier analysis of time to reach primary outcome (AT). P-value was analyzed using Logrank test and Cox regression models. (**C**) Serum albumin from predose to end of follow-up (albumin population, defined by patients in the AT who did not use other albumin products by EOT+30. OsrHSA, n=152; pHSA, n=154). Changes at EOT was calculated as adjusted least square means (SE). P-value was analyzed using an analysis of Covariance (ANCOVA). (**D**) Colloid osmatic pressure (albumin population, defined by patients in the AT who did not use other albumin products by EOT+30, OsrHSA, n=152; pHSA, n=154), ascites depth, abdominal circumference and body weight (ascites population, defined as patients who was diagnosed with ascites at baseline, OsrHSA, n=111, pHSA, n=119) were measured at baseline, EOT, EOT+7, EOT+14 and EOT+30. Changes at EOT was calculated as adjusted least square means (SE). P-value was analyzed using an analysis of Covariance (ANCOVA). (**E**) Serum creatinine, bilirubin, INR and MELD 3.0 scores were measured from baseline to end of follow-up (laboratory population, defined by patients in the AT who had at least one serum laboratory value after treatment). Datapoints are mean and error bars are standard deviation.

1502 | COMPARATIVE EFFECTIVENESS OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION VERSUS LACTULOSE FOR TREATMENT OF HEPATIC ENCEPHALOPATHY: A SINGLE BLIND, RANDOMISED CONTROL TRIAL

Sunil Dadhich[1] Arihant Seth[1] Saurabh Jain[1], [1]Dr. Sampurnanand Medical College, Jodhpur

Background: Hepatic encephalopathy (HE) is a common and serious complication of cirrhosis. Lactulose is the standard therapy, but its use is limited by gastrointestinal side effects and poor compliance. Polyethylene glycol (PEG) has emerged as a potential alternative with a faster onset of action. This study compared the efficacy and safety of PEG versus lactulose in overt HE. **Methods:** In this prospective, randomized, single-blind study, 100 patients with overt HE presenting with acute decompensation were included, of whom 37 had acute-on-chronic liver failure and 63 had acute decompensation without ACLF. Patients were randomized to receive lactulose (n = 50) or PEG (n = 50). The primary outcome was change in mean HESA score at 24, 48, and 72 hours. Secondary outcomes included time to resolution of HE, duration of hospital stay, changes in serum ammonia, and adverse events. **Results:** Baseline characteristics were comparable. The PEG group showed greater reduction in mean HESA scores at 24 hours (−0.44; 95% CI −0.80 to −0.08; p = 0.017), 48 hours (−0.54; 95% CI −0.92 to −0.16; p = 0.007), and 72 hours (−0.44; 95% CI −0.76 to −0.12; p = 0.008). Time to resolution and hospital stay were shorter with PEG but not statistically significant. Ammonia reduction was comparable. Adverse events were more frequent with lactulose (26% vs 10%, p = 0.038). Subgroup analysis suggested a trend toward greater benefit of PEG in patients with more severe disease (ACLF). **Conclusion:** PEG results in

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

faster clinical improvement and better tolerability than lactulose in overt HE and may be an effective alternative, particularly in hospitalized patients.

★ 1503 | RISK FACTORS ASSOCIATED WITH FALLS IN PATIENTS WITH LIVER CIRRHOSIS

Ester Palacio[1] Carlos Cespedes[1] Monica Pons[1] Sergi Quiroga[1] Nuria Roson[1] Elena Vargas-Accarino[1] Cristina Dopazo[1] Guillermo Cardenas[1] Victor Vargas[1] Macarena Simon-Talero[1] Lluis Castells[1] Isabel Campos-Varela[1], [1]Liver Unit. Hospital Vall d'Hebron

Background: Falls in patients with cirrhosis have been associated with worse quality of life, functional impairment, and death. There is evidence of a correlation between frailty, sarcopenia, and falls in the elderly population. We aimed at evaluating the role of muscle and frailty on falls in patients with cirrhosis. **Methods:** Single-center cross-sectional study. Patients with cirrhosis who underwent an abdominal computed tomography (CT) for any reason (June/2020- April/2024) were included. Sarcopenia was defined by the CT-based skeletal muscle index (SMI) at L3: <39 cm²/m² in women and <50 cm²/m² in men. Myosteatosis was assessed by measuring muscle attenuation on abdominal CT: <41 HU for BMI <25 kg/m² and <33 HU for BMI ≥ 25 kg/m². Frailty was defined by the Liver Frailty Index: frail >4.5. Sarcopenia was also evaluated by means of anthropometry, bioimpedance and ultrasonography of thigh and psoas muscle. Thigh muscle thickness index (TMTI) and psoas muscle thickness index (PMTI) were measured. Thigh elastography was also measured. Clinical, anthropometric, and quality-of-life data were also collected. **Results:** 248 patients with cirrhosis were included (26% women), median age of 62 years (IQR 56–68). The most common causes of cirrhosis were alcohol-related liver disease (42%), metabolic liver disease (22%), and hepatitis C virus infection (20%). Sarcopenia was present in 94 participants (38%), frailty in 92 (37%), and both were present in 37 patients (14.9%). Myosteatosis was present in 113 (46%) patients. Seventy-four subjects experienced falls, of whom 36% were women.In the univariate analysis, factors associated with a higher risk of falls were female sex (OR = 2.12; 95% CI 1.17–3.86; p = 0.01), diabetes (OR = 1.99; 95% CI 1.14–3.48; p = 0.01), hepatic encephalopathy (HE) (OR = 2.88; 95% CI 1.28–6.50; p = 0.01), myosteatosis (OR = 2.23; 95% CI 1.28–3.88; p = 0.005), and frailty (OR = 1.84; 95% CI 1.05–3.21; p = 0.03). Hospitalization was also associated with a higher risk of falls (OR = 1.77; 95% CI 1.02–3.08; p = 0.04). Neither sarcopenia, liver dysfunction, nor disease stage was associated with an increased risk of falls.In the multivariable model, the associations remained similar in magnitude and direction. Female sex (OR = 2.05; 95% CI 1.10–3.84; p = 0.02), diabetes (OR = 1.85; 95% CI 1.03–3.31; p = 0.04), myosteatosis (OR = 1.82; 95% CI 1.02–3.27; p = 0.04), and encephalopathy (OR = 2.42; 95% CI 1.00–5.85; p = 0.049) were significantly associated with an increased risk of falls, independently of disease severity, MELD-Na (OR = 0.99; 95% CI 0.95–1.04; p = 0.95). **Conclusion:** In patients with cirrhosis, female sex, diabetes, hepatic encephalopathy, and poor muscle quality (myosteatosis) were associated with an increased risk of falls, independently of disease stage. In our cohort, neither sarcopenia nor frailty were independently associated with an increased risk of falls.

Background: Accurate prediction of first hepatic decompensation in compensated advanced chronic liver disease (cACLD) remains an important unmet clinical need. We aimed to evaluate and compare the prognostic performance of commonly used non-invasive tests (NITs) for predicting first hepatic decompensation in cACLD. **Methods:** We performed a retrospective multicentre longitudinal cohort study using data from the Cirrhosis Outcomes and Research Endeavour (CORE) consortium, comprising 19 tertiary centres across nine countries. Adults with cACLD, defined as liver stiffness measurement (LSM) $\geq$10 kPa by vibration-controlled transient elastography and no prior hepatic decompensation, were included. Evaluated NITs were Fibrosis-4 index (FIB-4), NAFLD Fibrosis Score (NFS), AST-to-platelet ratio index (APRI), Model for End-Stage Liver Disease (MELD) 3.0, LSM, AGILE 3+, and AGILE 4. Prognostic performance for first hepatic decompensation was assessed using discrimination and calibration metrics. **Results:** A total of 2,895 patients were included; median age was 58.0 years, median BMI was 28.0 kg/m², and 46% were male. 435 patients (15.0%) developed first hepatic decompensation after a median of 32.1 months. AGILE 4 demonstrated the best discrimination (Harrell's C-statistic 0.759), followed by AGILE 3+ (0.744), NFS (0.720), FIB-4 (0.706), MELD 3.0 (0.685), LSM (0.680), and APRI (0.664). AGILE 4 also showed the best calibration, with a Brier score of 0.069. However, all models exhibited only moderate prognostic performance overall and showed calibration drift over time. **Conclusion:** AGILE 4 showed the best performance among the evaluated NITs, although its predictive accuracy was moderate. More robust prognostic models, incorporating disease-specific and dynamic longitudinal factors, are needed.

1505 | ANIMAL NAMING TEST CAN IDENTIFY COVERT HEPATIC ENCEPHALOPATHY IN PATIENTS WITH CIRRHOSIS WITH LIMITED INFLUENCE FROM AGE OR EDUCATIONAL LEVE

Takao Miwa[1] Shinji Unome[1] Masashi Aiba[1] Sachiyo Hirata[2] Satomi Nakashima[2] Kayoko Nishimura[2] Yoshiyuki Miwa[3] Teruo Maeda[4] Masahito Shimizu[1], [1]Gifu University, [2]Gifu University Hospital, [3]Miwa Clinic, [4]Nishimino Kosei Hospital

Background: The usefulness of the animal naming test (ANT) in identifying covert hepatic encephalopathy (CHE) is limited because adjustments for age and educational level are necessary. This study aimed to validate the ANT in Japanese patients with cirrhosis and to clarify whether such adjustments affect diagnostic performance. **Methods:** This multicenter cross-sectional study included Japanese patients with cirrhosis and healthy controls. Independent CHE factors were assessed using a logistic regression model, and the discriminative ability of the ANT alone versus an adjusted model was compared using the area under the receiver-operating characteristic curve (AUC). To demonstrate the association between the performance of ANT and the odds ratio (OR) of CHE, an adjusted restricted cubic spline (RCS) model with three knots was applied. **Results:** Among the 152 patients with cirrhosis and 56 controls, propensity score matching identified 43 individuals in each group. Patients with CHE had the lowest ANT scores, followed by those without CHE and healthy controls (14 vs. 17 vs. 19). A multivariable analysis showed that the ANT was an independent factor for identifying CHE (OR, 0.88; 95% confidence interval, 0.80-0.97; p = 0.009), whereas age and educational level were not. The RCS model revealed a rapid increase in the ORs of CHE with a decline in ANT performance **(Figure 1A)** . The AUC for the ANT alone in CHE diagnosis was comparable to that for the adjusted model using age and educational level (0.68 vs. 0.71; p = 0.350; **Figure 1B**). ANT performance was not influenced by age or educational level among those with CHE. The ANT's optimal, rule-out (90% sensitivity), and rule-in (90% specificity) cut-off values for identifying CHE were 15, 20, and 11, respectively. **Conclusion:** The ANT can identify CHE in Japanese patients with cirrhosis, and adjustment for age and educational level has a limited influence on its diagnostic performance.

1506 | EFFECT OF PROBIOTIC THERAPY ON FRAILTY IN PATIENTS WITH DECOMPENSATED CIRRHOSIS: A RANDOMIZED CONTROLLED TRIAL

Sunil Taneja[1] Savneet Singh[2] Harish Bhujade[3] Yaswant Kumar[2] Amol Patil[2] Kannupriya .[2] Arka De[2] Nipun Verma[2] Madhumita Premkumar[1] Ajay Duseja[1], [1]Postgraduate Institute of Medical Education & Research, [2]Postgraduate Institute of Medical education & Research, Chandigarh, India, [3]Postgraduate Institute of Medical Education & Research, Chandigarh, India

Background: Frailty is increasingly recognised as a major determinant of adverse outcomes in patients with decompensated cirrhosis. Microbiome-directed therapies, such as probiotics, may improve frailty by modulating systemic inflammation and ammonia metabolism. This study aimed to evaluate the impact of six months of probiotic therapy on frailty in patients with decompensated cirrhosis. **Methods:** This single-centre, prospective, open-label, randomized controlled trial included adults aged 18–75 years with decompensated cirrhosis and frailty. Frailty was assessed using the Liver Frailty Index(LFI). A total of 104 patients were randomized in a 1:1 ratio to receive either probiotics (VSL3 dose) plus standard medical treatment (pSMT; n = 52) or standard medical treatment alone (SMT; n = 52). The primary endpoint was the change in LFI at 6 months. Secondary endpoints included changes in MELD and MELD-Na scores, inflammatory markers (IL-6, CRP, ESR), serum ammonia, sarcopenia assessed by CT-derived skeletal muscle index (SMI), hospitalisation rates, survival, and adverse events. **Results:** The mean age was 51.9 ± 9.6 years, and 75% (n = 78) were males. Alcohol-associated liver disease was the most common aetiology (41.3%, n = 45), followed by MASLD (24.0%, n = 25). Mean MELD score was 13.46 ± 2.82, and median baseline LFI was 4.74(4.5-5.1) in pSMT group and 4.72(4.6-4.8) in SMT group)(p:0.81). Baseline inflammatory markers, ammonia levels and SMI were comparable between groups (p = > 0.05). At 6 months, patients receiving probiotics demonstrated significant improvement in frailty, with median LFI improving from 4.74 (4.5–5.1) at baseline to 4.28 (4.09–4.5) (p < 0.001) versus 4.72(4.6–4.8) to 4.73 (4.44–5.27) (p = 0.56) in SMT group. On multivariable analysis, inclusion in the probiotic arm (OR 0.12, 95% CI 0.04–0.36; p < 0.001), higher baseline SMI (OR 0.99, 95% CI 0.98–0.99; p = 0.001), and lower IL-6 levels (OR 0.12, 95% CI 0.04–0.36; p = 0.045) independently predicted improvement in frailty. There was significant improvement MELD Na score 16(13-18) to 14(11-16) (p = 0.001) in probiotic group as compared to 17.5(15.8-19.2) to 16.5(14-19)(p = 0.09) in SMT group. Median IL-6 levels declined from 17 pg/mL to 4 pg/mL (p < 0.001) and CRP decreased from 12.6 mg/L to 4 mg/L (p < 0.001) in the probiotic group. Serum ammonia levels also improved significantly from 128 mg/dL to 78 mg/dL (p < 0.001). Ten patients (19.2%) in the probiotic arm required hospitalisation versus twenty patients (38.5%) in the SMT group (p = 0.029), corresponding to an absolute risk reduction of approximately 19% and a number needed to treat of five. No significant difference in overall survival was observed between the two groups. (p = 0.10). **Conclusion:** Probiotic therapy in patients with decompensated cirrhosis significantly improves frailty, inflammatory markers, and serum ammonia levels while reducing hospitalization rates with no significant difference in survival rates.

1507 | HEPATIC ENCEPHALOPATHY SEVERITY AND RECURRENT EPISODES IMPROVE MORTALITY PREDICTION BEYOND MELD-NA: DEVELOPMENT OF THE HAMER SCORE

Ashok Kumar Choudhury[1] Divya Jaiswal[2] Radhika Sharma[2] Jitendra Singh[2] Roshan Koul[1] Manoj Sharma[1] Anoop Saraya[1] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences, [2]Institute of Liver and Billiary Sciences

Background: Hepatic encephalopathy (HE) is associated with poor survival in cirrhosis; however, not incorporated into the current MELD-Na–based liver allocation for transplant or prognostication. We evaluated the impact of severity and recurrence of HE on short-term mortality in hospitalized patients with cirrhosis. **Methods:** In this retrospective electronic medical record–based study, hospitalized patients with cirrhosis and HE were evaluated for 90-day mortality. Independent predictors identified on multivariate analysis were used to develop a simplified prognostic scoring system. **Results:** A total of 2,458 patients with HE were included, with a mean age of 44.3 ± 10.8 years, with predominant etiology being alcohol (72.8%) and MASLD (16.7%) with a 90-day mortality of 16.8%(414/2458). Grade 2, 3 or 4 HE at presentation was seen in 46.3%, 17.2% and 13.4% patients respectively. Recurrent HE was present in 10.1% patients and was associated with higher mortality compared to index HE episode (16.4% vs. 8.8%; $p < 0.001$). Prior TIPS placement was noted in 113 (4.6%) patients and was not associated with mortality. Spontaneous portosystemic shunt related HE in 44 (1.8%) and was associated with higher serum albumin, lower bilirubin, lower MELD-Na scores (22.6 ± 6.8 vs. 27.6 ± 8.9; $p = 0.008$), and lower mortality (4.5% vs. 17.1%; $p = 0.04$).On multivariate logistic regression, admission HE grade (OR 1.56, 95% CI 1.39–1.76; $p < 0.001$), recurrent HE (OR 1.88, 95% CI 1.34–2.65; $p < 0.001$), serum albumin (OR 0.61, 95% CI 0.49–0.77; $p < 0.001$), and MELD-Na (OR 1.13, 95% CI 1.11–1.15; $p < 0.001$) independently predicted mortality. Based on these variables, a simplified cutoff-based prognostic model, the HAMER score (HE grade–Albumin–MELD-Na–Recurrent HE), was developed. Scores were assigned as: HE grade 0–1 (0 points), grade 2 (1 point), and grade 3–4 (2 points); recurrent HE (≥2 episodes/year) was 2 points; serum albumin >3.5 g/dL (0 points), 2.8–3.5 g/dL (1 point), and <2.8 g/dL (2 points); and MELD-Na <15 (0 points), 15–25 (1 point), and ≥25 (2 points). The HAMER score ranged from 0–8 and stratified patients into low-risk (0–2), intermediate-risk (3–5), and high-risk (6–8) categories with corresponding 90-day mortality rates of <10%, 11%–35%, and > 50% respectively.The HAMER score reliably predicted mortality, higher score correlated with greater mortality (figure) The model showed a 25% relative improvement in predictive discrimination over HE grade alone and a 7.6% improvement over MELD-Na alone. **Conclusion:** HE severity and recurrent HE are independently associated with increased short-term mortality in cirrhosis. Incorporation of these along with serum albumin significantly improved prognostic discrimination beyond MELD-Na. The HAMER score is a simple bedside tool that may aid prognostication, escalation of care, ICU triage, and early liver transplant evaluation in patients hospitalized with HE, pending more future studies.

1508 | POST-TIPS HEPATIC ENCEPHALOPATHY IS MORE FREQUENT AND EARLIER IN MASH THAN IN ALCOHOL-ASSOCIATED CIRRHOSIS DESPITE COMPARABLE MORTALITY

Mohamed Nadeem[1] Qijun Yang[2] Amrit Khooblall[2] Jamile Wakim-Fleming[2] Sameer Gadani[2] Shilpa Junna[2], [1]Cleveland Clinic Foundation, [2]Cleveland Clinic

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is an established therapy for complications of portal hypertension. The role of cirrhosis etiology in the development of post-TIPS HE, waitlist mortality, and overall mortality has not been well studied in a large study cohort. To compare post-TIPS clinical outcomes between patients with metabolic dysfunction-associated steatohepatitis (MASH) and alcohol-associated liver disease (ALD). **Methods:** Single-center retrospective cohort study of adults undergoing TIPS, identified from an institutional

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

registry of 1,507 procedures. MASH-associated liver disease also included cases of cryptogenic cirrhosis; ALD included alcohol alone or in combination with chronic viral hepatitis. Outcomes were ascertained at 30 days, 90 days, and 1 year. Continuous variables were compared by Wilcoxon rank-sum test and categorical variables by chi-square or Fisher's exact test. Survival was estimated by Kaplan–Meier methods and compared by log-rank test. **Results:** Of 1,507 procedures, 958 patients met the inclusion criteria (MASH n = 458; ALD n = 500). MASH patients were older (median 63 vs 53 years, p < 0.001) and more often female (57% vs 29%, p < 0.001); ALD patients had higher rates of pre-TIPS hepatic encephalopathy (HE) (49% vs 31%, p = 0.004) and emergent TIPS (26% vs 20%, p = 0.025). Post-TIPS HE occurred more often in MASH (33.4% vs 21.8%, p < 0.001) and at every landmark: 30 days 18.6% vs 9.4%, 90 days 25.1% vs 13.2%, and 1 year 31.0% vs 17.2% (all p < 0.001). Time to HE was shorter in MASH (median 25 vs 45 days, p = 0.025). Post-TIPS liver failure (2.8% vs 3.8%, p = 0.52), transplant waitlist mortality (37.1% vs 39.7%, p = 0.46), and overall mortality (38.2% vs 40.3%, p = 0.56) did not differ; Kaplan–Meier curves showed no separation at any landmark. **Conclusion:** Despite comparable post-TIPS mortality, MASH-related cirrhosis is associated with more frequent and earlier post-TIPS hepatic encephalopathy than ALD-related cirrhosis. These findings support etiology-tailored counseling and intensified HE surveillance in the MASH population after TIPS.

Table 1. Patient characteristics by liver disease etiology group

1509 | LACTULOSE PLUS POLYETHYLENE GLYCOL VS. LACTULOSE MONOTHERAPY AFTER A FIRST HEPATIC ENCEPHALOPATHY EPISODE IN CIRRHOSIS: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Mahmoud Al-Bataineh[1] Jashnaveer Johal[1] Archana Salek[1] Bianca Patel[1] Brandon Cunha[1] Abdallah Hussein[1] Jason Hyman[2] Simona Rossi[1] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Lactulose is the cornerstone of both treatment and secondary prophylaxis of hepatic encephalopathy (HE) in cirrhosis, but recurrence rates remain high. Polyethylene glycol 3350 (PEG) has emerged as an effective acute HE treatment, yet its role as an adjunct to lactulose for secondary prevention after a first HE episode is unknown. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised cirrhotic patients (K74.6) with a first documented HE episode (K76.82) who were prescribed both lactulose and PEG 3350 within 6 months of their index event. Cohort 2 comprised cirrhotic patients with a first HE episode prescribed lactulose alone, with explicit exclusion of any PEG use. Both cohorts excluded prior hepatocellular carcinoma, liver transplant status, and prior TIPS procedure. Cohorts were balanced via 1:1 PSM yielding 1,565 patients per arm over a 6–12 month follow-up window. Pre-specified outcomes included repeat HE episodes, hepatic failure, need for intubation, ICU admission, hypotension, and all-cause mortality. **Results:** Post-PSM cohorts were well-balanced across matched covariates. Repeat HE episodes were paradoxically more frequent in the combination arm on MOA analysis (50.9% vs. 44.7%; RR 1.14, OR 1.28; p = 0.0006), though time-to-event analysis did not reach significance (HR 1.10, 95% CI 0.99–1.21; p = 0.072), with median time to recurrence of 135 vs. 233 days respectively. Hepatic failure rates did not differ significantly between arms (26.3% vs. 23.1%; HR 1.15, 95% CI 0.85–1.55; p = 0.37). Need for intubation was similar across both arms (9.3% vs. 8.0%; HR 1.11, 95% CI 0.88–1.41; p = 0.38). ICU admissions yielded zero events in either arm. Hypotension occurred significantly less frequently in the combination arm (76.5% vs. 80.8%; RR 0.95, OR 0.77; HR 0.82, 95% CI 0.76–0.89; p < 0.001), with a notably shorter median time to hypotension in the

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

lactulose-only arm (4 vs. 11 days). All-cause mortality was significantly lower in the combination arm (34.2% vs. 39.7%; RR 0.86, OR 0.79; HR 0.81, 95% CI 0.72–0.91; p = 0.0003). **Conclusion:** In this propensity-matched real-world cohort of cirrhotic patients following a first HE episode, lactulose plus PEG combination therapy was associated with significantly lower all-cause mortality and reduced hypotension compared to lactulose monotherapy, despite a higher observed rate of repeat HE documentation. These findings likely reflect a detection and engagement bias rather than therapeutic failure, and support prospective evaluation of PEG as a lactulose adjunct for secondary HE prophylaxis in cirrhosis.

1510 | POLYPHARMACY AND POTENTIALLY INAPPROPRIATE MEDICATION USE AS INDEPENDENT PREDICTORS OF HEPATIC DECOMPENSATION AND MORTALITY IN COMPENSATED CIRRHOSIS: A NATIONWIDE MULTI-INSTITUTIONAL COHORT STUDY

Noor Albusta[1] Mohamed Abdulla[2], [1]Lahey Hospital and Medical Center, [2]Royal College of Surgeons in Ireland

Background: Patients with cirrhosis frequently experience polypharmacy and are often exposed to potentially inappropriate medications (PIMs), including PPIs, opioids, benzodiazepines, and NSAIDs, each linked to adverse hepatic outcomes. However, whether cumulative medication burden, concurrent exposure to multiple PIMs, and underuse of indicated therapies independently predict decompensation and mortality remains unclear. We aimed to evaluate the dose-response relationship between polypharmacy, PIM burden, and outcomes in compensated cirrhosis. **Methods:** Using TriNetX, we studied adults (≥ 18 y) with compensated cirrhosis (no decompensation within 6 months of diagnosis) from Jan 2017–Dec 2024 with ≥ 12-month follow-up. Medication exposure was assessed during a 6-month landmark period. Polypharmacy: none (0–4 medications), moderate (5–9), severe (≥ 10). PIMs included opioids, benzodiazepines, systemic NSAIDs, and PPIs without indication; a PIM burden score (0–4) was calculated. Adherence to indicated medications (NSBB, lactulose/rifaximin, SBP prophylaxis) was assessed concurrently; a "dual medication gap" was defined as ≥ 1 PIM plus underfilling of ≥ 1 indicated medication. Primary outcome: time to first decompensation (ascites, HE, variceal hemorrhage, SBP, hepatorenal syndrome). Secondary outcomes: ACLF, 1-year mortality, 30-day readmission, AKI. Propensity score matching (1:1) on 32 covariates; Cox models estimated adjusted HRs. Subgroup analyses by etiology, age, and PIM class. **Results:** Among 64,218 adults (mean age 58.4 ± 11.2 y, 46.2% female; MASLD 36.8%, ALD 32.4%, viral 19.6%), median concurrent medications were 7 (IQR 4–12). At least one PIM was prescribed in 65.2%, and 28.6% had a dual medication gap. Over median 2.8-year follow-up, 28.7% decompensated. After matching, polypharmacy and PIM burden showed graded dose-response associations with decompensation (Table 1). Each PIM class drove decompensation through distinct mechanisms: PPIs via infection/HE, opioids/benzodiazepines via HE, NSAIDs via AKI/ascites. The dual medication gap conferred the highest risk (HR 1.72, 95% CI 1.58–1.87). Severe polypharmacy was associated with increased 1-year mortality (HR 1.36), ACLF (HR 1.54), and readmission (HR 1.42; all p < 0.001). Associations were strongest in ALD and age ≥ 65 (Table 2). **Conclusion:** Polypharmacy and PIM use independently accelerate decompensation in compensated cirrhosis in a dose-response manner, with exposure to all four PIM classes conferring a 2.4-fold increased hazard. Nearly one-third exhibited simultaneous overprescribing of harmful medications and underprescribing of indicated therapies — the highest-risk combination. These findings support cirrhosis-specific medication reconciliation and pharmacist-led deprescribing while optimizing guideline-indicated therapy.

Table 1. Dose-Response Association of Polypharmacy and PIM Burden with Hepatic Decompensation

Exposure	Decompensation HR (95% CI)	HE HR (95% CI)	AKI HR (95% CI)	1-Year Mortality HR (95% CI)

1511 | ENDOSCOPIC ESOPHAGEAL VARICES COMMONLY REPRESENT VENOVENOUS COLLATERALS IN PATIENTS WITH FONTAN CIRCULATION

Jordan Sack[1] Ayaz Aghayev[1] Marvin Ryou[1] Fred Wu[2] Stephen Zucker[1], [1]Brigham and Women's Hospital, [2]Boston Chilcren's Hospital

Background: The presence of esophageal varices has been considered a determining factor as to whether individuals with Fontan circulation should undergo combined heart-liver transplantation. However, these patients commonly develop venovenous collaterals, some of which course through the esophagus. We aimed to determine the prevalence and location of esophageal collaterals in patients with Fontan circulation who have endoscopic evidence of esophageal varices. **Methods:** This is a retrospective case series of 17 patients with Fontan circulation and endoscopic findings of esophageal varices. Cross-sectional abdominal imaging (cardiac MR, CT) was reviewed to determine the origin, course, and termination of submucosal esophageal veins. Findings were correlated with lab tests, imaging features, and hepatic and portal vein pressures measured using an endoscopic ultrasound-guided transgastric approach and/or during cardiac catheterization. **Results:** In 14 of 17 patients (82%), esophageal varices solely reflected venovenous collaterals arising from the central venous system and terminating in the pulmonary veins. Two patients (12%) with “classic” distal esophageal varices arising from the left gastric vein also manifested venovenous collaterals in the upper esophagus. In one patient, esophageal vessels arose directly from the aorta. The presence and grade of varices in the distal esophagus was associated with higher central venous pressures. There were no demographic, laboratory, imaging, or pressure correlates of “classic” esophageal varices, and no patient had a hepatic vein to portal pressure gradient above 4 mmHg. **Conclusion:** In patients with Fontan circulation, esophageal varices most commonly represent venovenous collaterals and are not indicative of portal hypertension. The endoscopic presence of esophageal varices generally reflects the patient’s cardiac status and is not a reliable indicator of the severity of underlying liver disease. That esophageal vessels may have an arterial origin in some patients suggests caution when contemplating endoscopic intervention.

Correlation between venovenous collaterals, endoscopy findings and vascular pressure measurements

grade 1 varices
grade 2 varices
grade 3 varices

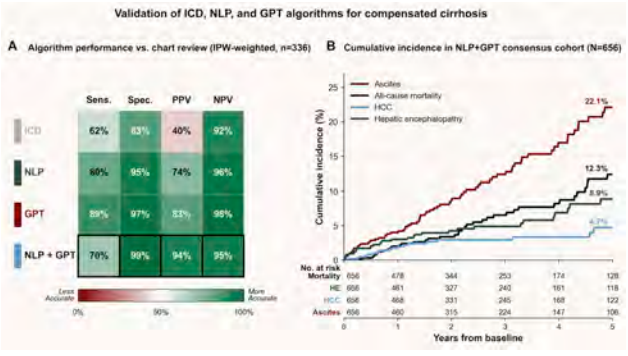
1512 | NATURAL LANGUAGE PROCESSING (NLP) AND LARGE LANGUAGE MODEL (LLM) ALGORITHMS OUTPERFORM ICD CODES FOR IDENTIFYING COMPENSATED CIRRHOSIS (CC) AND REVEAL HIGH RATES OF DECOMPENSATION AND MORTALITY IN A LARGE URBAN ACADEMIC COHORT



Giuseppe Cullaro Chip Bowman[1] Elina Stoffel[1] Eytan Palte[1] Elizabeth Verna[2], [1]Columbia University, [2]Columbia University Medical Center

Background: ICD-based algorithms are increasingly used to identify compensated cirrhosis (CC) in electronic health record and claims databases, but their accuracy for this phenotype is unknown. We compared ICD, rule-based natural language processing (NLP), and GPT-5.2 head-to-head, then quantified decompensation outcomes in the cohort from the most precise model. **Methods:** Adults ≥ 18 with any chronic liver disease ICD-10 code at Columbia University Irving Medical Center (2015–2025) and abdominal imaging within ± 365 days of baseline ($n = 6,843$) were classified by (1) ICD cirrhosis codes excluding decompensation codes, (2) NLP applied to imaging and notes, and (3) GPT-5.2 integrating notes, imaging, and labs. A stratified chart-review sample ($n = 336$, 8 algorithm-agreement strata) with CC defined per national definitions served as the gold standard; inverse probability weighting recovered population-level performance with bootstrap 95%

CIs.In the cohort of 656 patients meeting CC criteria by NLP + GPT-5.2 algorithms, we computed 1-, 3-, and 5-year Kaplan–Meier cumulative incidence of ascites (defined by imaging and/or medications), hepatic encephalopathy (HE) (medications), hepatocellular carcinoma (HCC) (imaging), and all-cause mortality. **Results:** Among the 6,843 screened patients, ICD codes identified the most as CC (24%), then GPT-5.2 (16%), then rule-based NLP (14%). On chart-review validation, ICD was the weakest classifier (Sens 62%, Spec 83%, PPV 40%, NPV 92%). NLP beat ICD on every metric (Sens 80%, Spec 95%, PPV 74%, NPV 96%; PPV vs ICD $p = 0.006$). GPT-5.2 was the best single algorithm (Sens 89%, Spec 97%, PPV 83%, NPV 98%; PPV vs NLP $p < 0.001$). Requiring NLP+GPT agreement maximized precision (Sens 70%, Spec 99%, PPV 94%, NPV 95%; PPV vs GPT $p < 0.001$).The NLP+GPT consensus cohort comprised 656 patients with a median age of 60 years; 54% were male, 38% were Hispanic, and 11% were non-Hispanic Black. MASLD was the leading etiology (27%), followed by viral hepatitis (18%), alcohol-related liver disease (15%), and autoimmune-related liver disease (12%). Baseline laboratory values: median platelet count 187 $\times 10^9$/L (IQR 123–242), total bilirubin 0.6 mg/dL (IQR 0.4–1.0), albumin 4.3 g/dL (IQR 3.9–4.6), and INR 1.1 (IQR 1.0–1.2). Median follow-up was 2.0 years (IQR 0.9–4.1).Cumulative incidence of incident outcomes at 1, 3, and 5 years was: ascites 4/13/22%, HE 3/5/9%, HCC 2/3/5%, and any decompensation 11/21/33%. All-cause mortality at the same timepoints was 2/7/13%. **Conclusion:** Accurately modeling CC in EHR- or claims-based datasets requires NLP and/or LLM-based analysis of unstructured fields — structured diagnosis codes alone are insufficient, misclassifying the majority of patients, and thereby limiting the interpretability and generalizability of these findings.

1513 | CRP AND IL-6 IDENTIFY PATIENTS WITH DACLD AT HIGH RISK OF FURTHER DECOMPENSATING EVENTS

Christian Sebesta[1] Benedikt Simbrunner[1] Georg Kramer[1] Paul Thöne[1] Marlene Hintersteininger[1] Jan Embacher[1] Lucie Simonis[1] Lorenz Balcar[1] Benedikt Hofer[1] Lukas Hartl[1] Mathias Jachs[1] Georg Semmler[1] Philipp Schwabl[1] Bernhard Scheiner[1] Dalila Costa[2] Albert Stättermayer[3] Michael Trauner[1] Mattias Mandorfer[1] Thomas Reiberger[1], [1]Medical University of Vienna, [2]University of Minho, Braga, Portugal, [3]AKH Vienna

Background: In decompensated advanced chronic liver disease (dACLD), hepatic dysfunction, portal hypertension (PH), and systemic inflammation (SI) may contribute differentially to the risk of further decompensation (FD) and liver-related death (LRD). We aimed to investigate previously proposed SI biomarker thresholds, C-reactive protein (CRP) ≥ 0.5 mg/dL and Interleukin-6 (IL-6) ≥ 14 pg/mL, in a temporal validation cohort, specifically in regards to their incremental predictive value for FD and LRD beyond MELD and hepatic venous pressure gradient (HVPG). **Methods:** Patients with dACLD underwent assessment of SI biomarkers (CRP, IL-6), MELD, and HVPG, and were prospectively followed. Multivariable regression models incorporated MELD, HVPG, and SI biomarkers for FD and LRD at short term (90 days, D90) and one year (Y1) were computed. Additional subgroup analyses were performed using thresholds for MELD ≥ 15 (i.e., transplant-relevant liver disease severity), and HVPG ≥ 16 mmHg (i.e., severe PH). **Results:** A total of 278 patients with dACLD (64% male; median age: 56 years; 66% alcohol-related liver disease) were included. At baseline, decompensation was evident by ascites in 92%, hepatic encephalopathy in 29%, and previous variceal bleeding in 8%. Median MELD was 13 and median HVPG was 19 mmHg. At Y1, the cumulative incidence of FD and LRD was 27.7% and 13.7%, respectively, while 6.5% of patients underwent liver transplantation.In multivariable Cox regression models adjusted for MELD and HVPG, both SI biomarkers were independently associated with FD: Specifically, higher CRP was linked to increased risk of D90 (adjusted hazard ratio [aHR] for logCRP: 2.48; $p < 0.001$) and Y1 (aHR: 2.30; $p < 0.001$) risk of FD. Similarly, higher IL-6 predicted D90 (aHR: 1.48 for logIL-6; $p = 0.004$) and Y1 (aHR: 1.37; $p = 0.007$) risk of FD.In models assessing LRD, additionally adjusted for age, CRP remained significantly associated with D90 LRD (aHR: 2.50; $p = 0.035$), whereas IL-6 showed only borderline association for D90 LRD (aHR: 1.63; $p = 0.054$). Neither SI biomarker was independently associated

with LRD at Y1.Competing-risk analyses accounting for liver transplantation and non–liver-related death as competing events showed that patients with CRP $\geq$0.5 mg/dL or IL-6 $\geq$14 pg/mL had a significantly higher cumulative incidence of FD (both $p < 0.05$). Importantly, stratification by these SI biomarker cut-offs consistently identified patients at particularly high risk of FD across MELD ($\geq$15 vs. <15) and HVPG strata ($\geq$16 vs. <16 mmHg). **Conclusion:** In patients with dACLD, CRP and IL-6 independently predict FD beyond MELD and HVPG. These findings support the use of SI biomarkers for refined clinical risk stratification and enrichment of trials with patients at particularly high short-term risk of FD events.

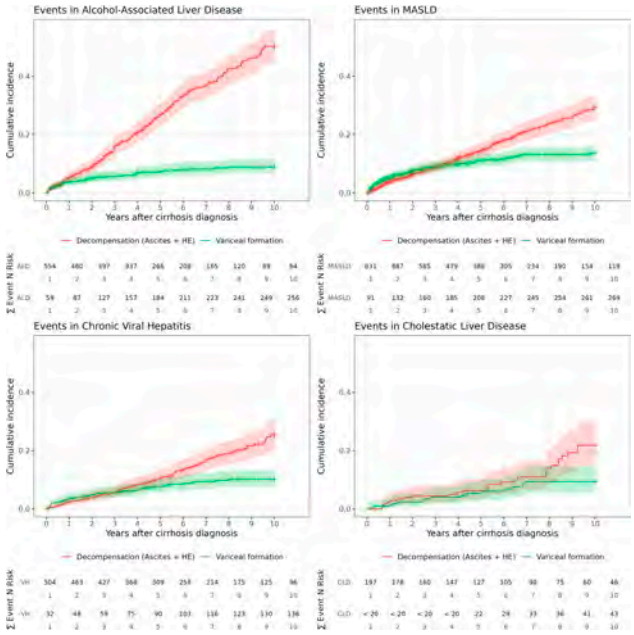
1514 | CIRRHOSIS ETIOLOGY AFFECTS PORTAL HYPERTENSION PROGRESSION



Nikhilesh Mazumder[1] Emma Ulrich[2] Chinmay Raut[2] Antonino Oliveri[2] Lishi Yin[2] Yanhua Chen[2] Elizabeth Speliotes[3], [1]University of Michigan Hospitals and Health Centers, [2]University of Michigan, [3]University of Michigan Medical Center

Background: Models of portal hypertensive (PH) progression developed in historical viral hepatitis (VH) cohorts propose that patients develop non-bleeding varices before decompensating. However the rising rate of steatotic (alcohol-associated [ALD], metabolic-associated [MASLD]) liver diseases relative to viral etiologies raise questions as to if this schema still holds given known differences in disease trajectory. We examine how patients with compensated cirrhosis experience PH events differently based on cause of liver disease. **Methods:** Adult patients included in the NIH *All of Us* Research Program were included at their first diagnosis of compensated cirrhosis. We used ICD codes to determine liver disease etiology (ALD, MASLD, VH, cholestatic [CLD]) as well as first decompensation (Ascites or HE) and included only individuals with liver disease from a single etiology. Patients were excluded if they had a decompensating event at time zero or within 30 days of inclusion, or if labs in the one year leading up to inclusion suggested undiagnosed liver disease. We determined each patient's first PH event via ICD codes, CPT procedural codes, and medications. We generated cumulative incidence estimates stratified by liver disease etiology. To quantify differences in disease trajectory, we ascertained the time in the first ten years during which the incidence of decompensation (ascites or HE) was greater than the incidence of non-bleeding variceal formation using bootstrapping. **Results:** Our cohort included 2,476 patients with compensated cirrhosis followed for a median of 4.4 years. Cause of liver disease was 27% ALD, 42% MASLD, 22% VH, and 9% CLD. The first diagnosed PH event in the cohort is 12% ascites, 7% HE, and 9% variceal formation, with 72% experiencing no event during follow-up. The 10-year cumulative incidence of any event was highest in ALD (59%), followed by MASLD (43%), VH (36%), and CLD (31%). Furthermore, we find that the trajectory of disease as measured by the divergence of the decompensation and variceal formation curves is highest in ALD at 18 months of follow-up, 6 years in MASLD and VH, and 9 years in CLD. **Conclusion:** We find that patients with ALD have the most rapidly progression of portal hypertensive complications, followed by MASLD and viral causes and trailed by CLD. This suggests that progression through disease stages is not monotonic and is dependent on etiology of liver disease. This

result emphasizes the importance of considering etiology when advising patients on their risk of future decompensation and informs changing patterns of complications as steatotic causes of liver disease increase in prevalence.

1515 | IMPACT OF SGLT2 INHIBITORS AND/OR GLP-1 RECEPTOR AGONISTS ON LIVER OUTCOMES AND MORTALITY IN PATIENTS WITH CIRRHOSIS OF DIVERSE ETIOLOGIES

Bowu Chen[1] Rui Huang[2] Taotao Yan[3] Xianhua Mao[4] Danfeng Ren[3] Sicheng Gao[5] Jie Wang[6] Yu Shi[6] Mingjuan Jin[7] Changqing Zhao[1] Ramsey Cheung[4] Mindie Nguyen[4], [1]Shuguang Hospital Affiliated to Shanghai University of Traditional Chinese Medicine, [2]Nanjing Drum Tower Hospital, [3]The First Affiliated Hospital of Xi'an Jiaotong University, [4]Stanford University Medical Center, [5]Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of TCM, [6]The First Affiliated Hospital, School of Medicine, Zhejiang University, [7]Department of Public Health, Second Affiliated Hospital, Zhejiang University School of Medicine

Background: The prevalence of both cirrhosis and metabolic dysfunction is increasing. Sodium-glucose cotransporter-2 inhibitors (SGLT2-I) and glucagon-like peptide-1 receptor agonists (GLP-1RA) have broad benefits in diabetes and MASLD, but their effects on cirrhosis of diverse etiologies remain limited. This study evaluated the impact of SGLT2-I and/or GLP-1RA on mortality and clinical outcomes in this high-risk population. **Methods:** We conducted a retrospective cohort study of SGLT2-I and/or GLP-1RA users and nonusers with cirrhosis at a large U.S. university medical center from January 2010 to June 2025. We evaluated all-cause, liver-related and nonliver-related mortality, obtained by individual medical record review and supplemented by National Death Index search. We also evaluated major adverse liver outcomes (MALO): HCC, liver decompensation and transplantation (LT). Baseline characteristics were balanced via 1:4 propensity score matching (PSM, caliper 0.1). Associations with outcomes were evaluated using Fine-Gray competing risk models (competing events: LT, death or alternate cause of death where applicable). Robustness was assessed with demographic and clinical subgroup analyses including user groups (SGLT2-I alone, GLP-1RA alone and combination), 12- and 24-month landmark analyses and sensitivity analyses including time-varying Cox regression, stricter-caliper PSM (0.01) and inverse probability of treatment weighting (IPTW) as alternative matching method. **Results:** Our study included 14,687 adult patients with cirrhosis (1,150 users and 13,537 nonusers) after excluding HIV infection, LT before index, or study medication use before cirrhosis. PSM yielded a cohort of 1,007 users and 2,696 nonusers with balanced characteristics (standardized mean difference [SMD] $\leq$ 0.1). All-cause, liver-related and nonliver-related mortality were lower in users than nonusers (64.45 vs. 122.97, 26.51 vs. 55.88, and 33.27 vs. 55.70 per 1,000 person-years, respectively), as well as incidence rates of MALO, HCC and liver decompensation (122.93 vs. 188.60, 10.26 vs. 25.74, and 121.15 vs. 170.47 per 1,000 person-years, respectively) (all $P < 0.001$) (Figure 1). On multivariable regression analyses, compared with nonusers, users had lower risks of all-cause (sHR 0.52, 95% CI 0.43–0.63), liver-related (sHR 0.48, 95%CI 0.36–0.64), and nonliver-related mortality (sHR 0.63, 95%CI 0.48–0.83), as well as lower risks of MALO (sHR 0.55, 95%CI 0.46–0.66), HCC (sHR 0.39, 95%CI 0.24–0.64), and liver decompensation (sHR 0.61, 95% CI 0.49–0.74). Findings were consistent across subgroup, landmark, and sensitivity analyses. **Conclusion:** SGLT2-I and/or GLP-1RA use was associated with lower risks of adverse liver events and improved survival both from liver and nonliver causes in patients with cirrhosis and should be further studied in this population.

1516 | IMPACT OF PRE-EXISTING CKD SEVERITY ON CLINICAL OUTCOMES IN CIRRHOSIS: A PROPENSITY SCORE-MATCHED COHORT ANALYSIS

Bianca Patel[1] Jashanveer Johal[1] Archana Salek[1] Mahmoud Al-Bataineh[1] Brandon Cunha[1] Abdallah Hussein[1] Jason Hyman[2] Yecheskel Schneider[1], [1]Virtua Health, [2]Einstein Medical Center

Background: Chronic kidney disease (CKD) is a well-recognized comorbidity in cirrhosis, but the degree to which baseline CKD severity independently predicts hepatic decompensation, infection, bleeding, and mortality in this population has not been well characterized in large real-world cohorts. **Methods:** Using the TriNetX Global Collaborative Network, we performed a propensity score–matched retrospective cohort study of adults with cirrhosis and pre-existing CKD stage 1–3 versus CKD stage 4–5. Patients with ESRD, HCC, liver transplant, HIV, chronic viral hepatitis, or SLE were excluded. One-to-one matching yielded 3,165 patients per cohort. Outcomes included ascites, hepatic encephalopathy (HE), hospitalization/ED visits, bleeding, infection, mortality, and renal failure/hemodialysis. **Results:** Post-PSM cohorts were well-balanced across matched covariates. All-cause mortality was markedly higher in the CKD 4-5 cohort (31.3% vs. 20.0%; HR 0.53, 95% CI 0.48–0.59; log-rank $p < 0.001$), representing the dominant finding across the study. New ascites did not differ significantly between CKD stages on time-to-event analysis (HR 0.91, 95% CI 0.73–1.13; $p = 0.39$). HE was modestly more frequent in the CKD 1-3 arm on cumulative risk analysis (3.6% vs. 2.6%; RR 1.40; $p = 0.024$) but did not reach significance on KM analysis (HR 1.18, 95% CI 0.87–1.59; $p = 0.29$). ED visits and inpatient admissions were slightly higher in the CKD 1-3 arm by fixed-time risk (53.1% vs. 48.9%; $p = 0.0009$) with nearly identical time-to-event rates (HR 0.97; $p = 0.39$) and median time to first encounter of 160 vs. 156 days. Clinical bleeding trended higher in the CKD 1-3 arm on cumulative risk (9.5% vs. 7.1%; $p = 0.0006$) but did not reach significance on KM analysis (HR 1.17, 95% CI 0.99–1.39; $p = 0.072$). Infection rates did not differ significantly on time-to-event analysis (HR 0.96, 95% CI 0.87–1.06; $p = 0.46$). Renal failure or need for hemodialysis was significantly more frequent in the CKD 4-5 arm on KM analysis (HR 0.76, 95% CI 0.63–0.93; $p = 0.007$) despite a non-significant MOA result, reflecting higher event clustering over time in the advanced CKD group. **Conclusion:** In this propensity-matched cohort, CKD stage 4–5 in cirrhosis was associated with higher all-cause mortality and renal failure than CKD stage 1–3, with no significant differences in ascites, hepatic encephalopathy, or infection on time-to-event analysis. These findings identify advanced CKD as a key prognostic marker and support early nephrology co-management. Higher rates of HE, hospitalization, bleeding, and infection observed in the CKD 1–3 group likely reflect competing mortality in the CKD 4–5 cohort, resulting in less time at risk for nonfatal outcomes.

1517 | SPIRONOLACTONE IS ASSOCIATED WITH IMPROVED SURVIVAL AND RENAL OUTCOMES COMPARED WITH FUROSEMIDE IN CIRRHOSIS-RELATED ASCITES: A PROPENSITY-MATCHED COHORT STUDY

Delano Carty[1] Dilcia Maldonado[1] FNU Deepali[1] Cameron Gill[1] Damion Persad[1] Ghideon Ezaz[1], [1]Jefferson Einstein Philadelphia

Background: Diuretics are central to the management of ascites in cirrhosis, with current guidelines favoring mineralocorticoid receptor antagonists (MRAs) as first-line therapy. However, real-world comparative

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

outcomes between MRAs and loop diuretics remain incompletely defined **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network (2010–2026). Adult patients with cirrhosis and ascites were stratified by exposure to spironolactone (MRA group) or furosemide (loop diuretic group). Patients with end-stage renal disease, malignancy, liver transplantation, or overlapping diuretic exposure were excluded. Propensity score matching (1:1) was performed to balance demographics, liver disease severity, renal function, and comorbidities, yielding 38,271 patients per cohort. Outcomes included all-cause mortality, acute kidney injury (AKI), hepatorenal syndrome (HRS), spontaneous bacterial peritonitis (SBP), hospitalization, paracentesis, esophageal varices, and hepatic encephalopathy over a 5-year follow-up period. **Results:** After matching, furosemide use was associated with higher mortality compared with spironolactone (32.7% vs 29.5%; HR 1.14, 95% CI 1.11–1.17; $p < 0.001$). The furosemide group also demonstrated increased risk of AKI (23.2% vs 19.1%; RR 1.21), HRS (4.4% vs 3.8%; RR 1.14), hospitalization (39.2% vs 34.9%; RR 1.12), and paracentesis (13.3% vs 12.7%; RR 1.06) (all $p < 0.01$). There was no significant difference in SBP incidence between groups. Spironolactone use was associated with slightly higher rates of esophageal varices (20.3% vs 18.8%) and hepatic encephalopathy (12.8% vs 12.0%), though effect sizes were modest. **Conclusion:** In this large propensity-matched cohort of patients with cirrhosis and ascites, spironolactone use was associated with improved survival and lower risk of renal complications compared with furosemide. These findings support guideline-recommended use of MRAs as first-line therapy and highlight potential risks associated with loop diuretic–dominant strategies in cirrhosis.

1518 | IMPACT OF TIMING AND INTENSITY OF LACTULOSE AND RIFAXIMIN ADMINISTRATION ON OUTCOMES IN HOSPITALIZED PATIENTS WITH HEPATIC ENCEPHALOPATHY

Sandeep Sikerwar[1] Elizabeth Verna[1] Arun Jesudian[2] Giuseppe Cullaro[1], [1]Columbia University Medical Center, [2]Weill Cornell Medicine

Background: Hepatic encephalopathy (HE) is a leading cause of preventable readmission in cirrhosis, yet no prior study has systematically evaluated whether timing and intensity of inpatient lactulose and rifaximin administration affect outcomes. We assessed whether early lactulose (≤ 12 hours), aggressive initial lactulose dosing (> 3 doses/24 hours), and early rifaximin (≤ 24 hours) were associated with improved outcomes in hospitalized patients with HE. **Methods:** We conducted a retrospective cohort study of hospitalized patients with cirrhosis who received either lactulose or rifaximin at Columbia University Irving Medical Center from November 2019–December 2025. Admissions were classified as overt HE or non-overt HE using a large language model (LLM; GPT 5.5) with hepatologist validation. Length of stay (LOS; negative binomial regression, measured from first dose to discharge to address guarantee-time bias), 30-day readmission, and 30-day mortality were analyzed using multivariable models. **Results:** A total of 4,520 HE hospitalizations were identified (1,361 overt, 3,159 non-overt). Mean LOS was 7.4 days in overt and 8.3 days in non-overt HE, 30-day readmission was 31% in both groups, and 30-day mortality was 17% in overt and 9% in non-overt HE. In a sample of 160 notes stratified by West Haven (WH) grade and LLM confidence level, exact agreement between the LLM and physician reviewer was 87.4% (140/160; $\kappa = 0.81$). After adjusting for age, sex, race/ethnicity, admission MELD 3.0, ICD-coded ascites, AKI, spontaneous bacterial peritonitis, variceal bleeding, and systemic antibiotic use, early lactulose was associated with a 19% shorter LOS in both overt HE (IRR 0.81, 95% CI 0.74–0.90) and non-overt HE (IRR 0.81; 95% CI 0.73–0.89). Aggressive lactulose was associated with a 16% shorter LOS in overt HE (IRR 0.84; 95% CI 0.75–0.94), and early rifaximin was associated with a 25% shorter LOS in non-overt HE (IRR 0.75; 95% CI 0.68–0.83). After the same adjustment, aggressive lactulose was associated with increased 30-day readmission in overt HE (OR 1.42, 95% CI 1.05–1.92), attenuated in patients without AKI (OR 0.85, 95% CI 0.46–1.53). Early lactulose was associated with 40% lower odds of 30-day mortality in overt HE (OR 0.60, 95% CI 0.42–0.85), and early rifaximin with 47% lower odds of 30-day mortality in non-overt HE (OR 0.53, 95% CI 0.37–0.75), preserved among rifaximin-naïve patients (OR 0.41, 95% CI 0.24–0.66). **Conclusion:** Earlier inpatient lactulose administration is associated with shorter LOS and decreased mortality in patients with both overt and non-overt HE. Early rifaximin is associated with shorter LOS and decreased mortality in non-overt HE. Aggressive lactulose is associated with decreased LOS in overt HE but increased readmission risk that may be driven by concurrent AKI. These findings support treating HE as a time-sensitive condition and motivate prospective evaluation of timing-based treatment protocols.

1519 | DO PROBIOTICS IMPROVE OUTCOMES IN SPONTANEOUS BACTERIAL PERITONITIS? A REAL-WORLD MULTICENTER COHORT STUDY

Adham Obeidat[1] Ahmad Alqam[2] Scott Kuwada[3], [1]Presbyterian Medical Group, [2]University of New Mexico, [3]University of Hawaii

Background: Spontaneous bacterial peritonitis (SBP) remains a severe complication of decompensated cirrhosis, with high recurrence and mortality. Antibiotic treatment for SBP can disrupt the gut microbiota and increase the risk of Clostridioides difficile infection (CDI) and antibiotic-associated diarrhea. Probiotic supplementation has been proposed as a strategy to restore colonization resistance and reduce these complications; however, its role in patients undergoing treatment for SBP remains uncertain. **Methods:** We performed a retrospective cohort study using the TriNetX network including adults with SBP treated with systemic antibiotics. Patients were stratified by probiotic exposure versus no probiotic use. Propensity score matching was used to balance baseline characteristics and comorbidities between cohorts. The primary outcome was CDI. Secondary outcomes included antibiotic-associated diarrhea, mortality, hyponatremia, sepsis, hepatic encephalopathy, and hepatorenal syndrome (HRS). Odds ratios (ORs) and 95% confidence intervals (CIs) were calculated for all outcomes. **Results:** After propensity score matching, baseline characteristics were well balanced between cohorts. Probiotic use was associated with a higher chance of CDI but lower mortality compared with controls. Rates of antibiotic-associated diarrhea, hyponatremia, sepsis, and hepatic encephalopathy were comparable between groups, whereas HRS was less frequent among patients receiving probiotics (Table 1). **Conclusion:** In this multicenter cohort of patients with SBP receiving systemic antibiotics, probiotic use was not associated with reduced CDI, antibiotic-associated diarrhea, sepsis, hyponatremia, or hepatic encephalopathy. However, probiotics were associated with lower in-hospital mortality and reduced hepatorenal syndrome. To our knowledge, this is among the first large multicenter studies evaluating probiotics in antibiotic-treated SBP patients. These findings are hypothesis-generating and warrant prospective randomized studies to better define the role of probiotics in this high-risk population.

Table 1. Clinical Outcomes Among Patients With Spontaneous Bacterial Peritonitis Receiving Antibiotics With Versus Without Probiotic Therapy

Outcome	Probiotics n/N (%)	No Probiotics n/N (%)	Risk Difference (95% CI)	Odds Ratio (95% CI)	P Value
C. difficile colitis	115/523 (22.0%)	96/655 (14.7%)	0.073 (0.029 to 0.118)	1.641 (1.216–2.214)	0.001
Mortality	174/782 (22.3%)	238/778 (30.6%)	−0.083 (−0.127 to −0.040)	0.649 (0.517–0.815)	<0.001
Antibiotic-associated diarrhea	44/793 (5.5%)	29/793 (3.7%)	0.019 (−0.002 to 0.040)	1.548 (0.958–2.500)	0.072
Hyponatremia	296/793 (37.3%)	328/793 (41.4%)	−0.040 (−0.088 to 0.008)	0.844 (0.690–1.033)	0.100
Sepsis	346/793 (43.6%)	332/793 (41.9%)	0.018 (−0.031 to 0.066)	1.075 (0.881–1.311)	0.477
Hepatic encephalopathy	187/793 (23.6%)	191/793 (24.1%)	−0.005 (−0.047 to 0.037)	0.973 (0.772–1.225)	0.814
Hepatorenal syndrome	102/793 (12.9%)	141/793 (17.8%)	−0.049 (−0.085 to −0.014)	0.683 (0.518–0.900)	0.007

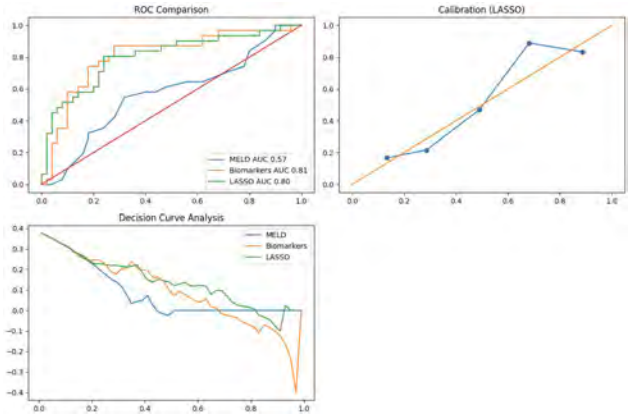
★ 1520 | BEYOND MELD-NA: A LASSO-INTEGRATED URINARY BIOMARKER MODEL REWRITES 3-MONTH MORTALITY PREDICTION IN PATIENTS WITH CIRRHOSIS AND ACUTE KIDNEY INJURY



Deep Patel[1] Ajay Kumar[1] Ujjwal Sonika[1] Aman Agrawal[1] Ashok Dalal[1] Siddharth Srivastava[1] Sanjeev Sachdeva[1], [1]G.B.Pant Hospital (GIPMER, New Delhi)

Background: Acute kidney injury (AKI) in cirrhosis is a major determinant of short-term mortality, yet current prognostic tools remain suboptimal. MELD-Na relies on serum creatinine, which poorly reflects renal structural injury in cirrhosis due to altered physiology. Urinary biomarkers such as NGAL and IL-18 capture tubular

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

injury and may enhance risk prediction beyond conventional models. This study compares the predictive performance of MELD Na, urinary Neutrophil gelatin-associated lipocalcin (uNGAL), urinary Interleukin-18 (uIL-18) and a LASSO-derived multivariate model for 3-month mortality in cirrhotic patients with AKI. **Methods:** Patients with decompensated cirrhosis with AKI admitted in tertiary care centre from January 2023 to December 2025 screened and enrolled after excluding patients with Chronic kidney disease, Hepatocellular Carcinoma, respiratory or circulatory failure and recent coronary intervention. Baseline demographic, clinical and laboratory parameters including day 3 uNGAL and uIL-18 recorded. Patients were followed up for 3 months. Primary outcome was 3-month all-cause mortality and predictor discrimination assessed using AUROC and Delong's test. LASSO regression model analysed with Discrimination curve and Net Reclassification Improvement (NRI) analysis. **Results:** Total of 81 patients were enrolled. The 3-month all-cause mortality was 38.27% (31 patients) with 29 liver-related events. MELD-Na AUROC 0.57 (95% CI 0.44-0.70), Biomarker-based model AUROC 0.81 (95% CI 0.70-0.89) and the LASSO model (combining MELD Na with biomarkers) AUROC 0.80 (95% CI 0.69-0.87, bootstrap-corrected 0.77). Both biomarker and LASSO models significantly outperformed MELD-Na ($p < 0.001$). The LASSO model showed substantial risk reclassification improvement (NRI 96% vs MELD, 63% vs Biomarker model) and superior clinical utility on decision curve analysis. **Conclusion:** Urine NGAL and IL-18 improve prediction of 3-month mortality beyond MELD Na in Cirrhotic AKI. A LASSO-integrated model provides superior discrimination, calibration and reclassification, supporting its role in advancing precision prognostication in cirrhosis.

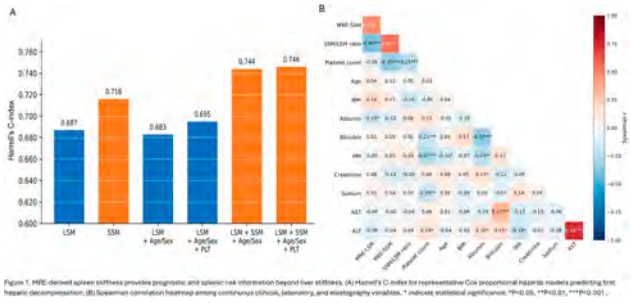
1521 | COMPLEMENTARY PROGNOSTIC VALUE OF MAGNETIC RESONANCE ELASTOGRAPHY–BASED SPLEEN AND LIVER STIFFNESS IN ADVANCED CHRONIC LIVER DISEASE



Caixin Qiu[1] Maysa Eslami[1] Jiahui Li[1] Hao Wu[1] Kevin Glaser[1] Sudhakar Venkatesh[2] Fang-Shu Ou[1] Alina Allen[2] Vijay Shah[2] Richard Ehman[2] Meng Yin[1], [1]Mayo Clinic, [2]Mayo Clinic Rochester

Background: Portal hypertension drives hepatic decompensation in compensated advanced chronic liver disease (cACLD), and spleen stiffness measurement (SSM) is an emerging noninvasive marker of portal hypertension–related risk. Current SSM largely relies on ultrasound-based elastography, which may be limited by technical challenges and separate liver-spleen acquisitions. Magnetic resonance elastography (MRE) enables standardized, concurrent assessment of liver and spleen stiffness. We evaluated whether MRE-derived SSM provides independent prognostic information for decompensation beyond liver stiffness measurement (LSM) alone. **Methods:** Patients with cACLD who underwent index MRE between March 2022 and September 2024 were included if they had elevated MRE-LSM (>3.6 kPa) or liver biopsy stage $\geq$F3, without ascites, hepatic encephalopathy, or variceal bleeding before or at the time of index MRE. The primary outcome is time to first hepatic decompensation, defined as the time from index MRE date to first hepatic decompensation, with patients who did not experience decompensation censored at their last documented follow-up. Cox proportional hazards regression was used to assess associations of LSM and SSM with the development of decompensation. Multivariable models sequentially adjusted for age, sex, LSM, platelet count, and splenomegaly. Harrell's C-index was used to assess model discrimination. Spearman correlation was used to evaluate associations among continuous clinical, laboratory, and elastography variables. $P<0.05$ was considered significant. **Results:** This study includes 283 patients (mean age, 56.3 ± 13.4 years; 48.1% women) with cACLD; 69 (24.4%) patients developed hepatic decompensation during a median follow-up of 961 days. LSM was associated with decompensation in univariable Cox analysis, HR 1.39 per 1 kPa, 95% CI 1.25–1.55, $P<0.001$, C-index 0.687 (Figure 1A). After adjustment for age, sex and platelet, LSM remained significant (HR 1.36, 95% CI 1.22–1.52, $P<0.001$). SSM showed higher discrimination in univariable analysis (HR 1.42 per 1 kPa, 95% CI 1.29–1.57, $P<0.001$, C-index 0.716). After adjustment for age, sex, and LSM, SSM remained independently associated with decompensation (HR 1.40, 95% CI 1.24–1.57, $P<0.001$, C-index 0.746). This association persisted after additional adjustment for platelet and splenomegaly (HR 1.28, 95% CI 1.10–1.50, $P=0.001$). SSM was inversely correlated with platelet

count, Spearman r = -0.354, P < 0.001, whereas LSM was not, r = -0.093, P = 0.118 (Figure 1B). **Conclusion:** MRE-derived spleen stiffness is independently associated with first hepatic decompensation beyond liver stiffness. Spleen stiffness may capture complementary splenic and portal hypertension–related risk not fully reflected by liver stiffness alone.

1522 | ACUTE MORTALITY ASSOCIATED WITH CHEST TUBE PLACEMENT IN HEPATIC HYDROTHORAX

Butros Fakhoury[1] Ali Khan[1] Omar Albhaisi[1] Shaurya Prakash[1] Amon Asgharpour[1] Juan Pablo Arab[1],
[1]Virginia Commonwealth University

Background: Hepatic hydrothorax is a serious complication of advanced cirrhosis occurring in 4-12% of patients with portal hypertension. Chest tube placement is generally discouraged due to concerns about continuous pleural fluid drainage worsening circulatory dysfunction and precipitating renal failure, infection, and electrolyte disturbances. Nevertheless, chest tube use continues in clinical practice with increasing trends reported over time. We compared risks of acute kidney injury, shock, and mortality following chest tube placement versus therapeutic thoracentesis in patients with cirrhosis and hepatic hydrothorax. **Methods:** This retrospective cohort study used the TriNetX U.S. Collaborative Network, which aggregates de-identified electronic health records from over 60 U.S. health care organizations. We identified adults with cirrhosis, ascites, pleural effusion, and diuretic use (spironolactone or furosemide) between January 2012 and January 2025. The index date was the first instance of chest tube placement or therapeutic thoracentesis. Patients were excluded if they had an alternative cause of pleural effusion before or up to 2 days from index date, prior liver transplantation, missing laboratory values within 90 days, or acute kidney injury or shock within 7 days before the index procedure. Propensity score matching (1:1) was performed using demographics, MELD-Na components, markers of hepatic decompensation, and critical illness indicators. Primary outcomes were 30-day acute kidney injury, shock, and all-cause mortality. Time-to-event analyses used Kaplan-Meier estimates and Cox proportional hazards models. **Results:** After propensity score matching, 463 patients in each group had balanced baseline characteristics (mean age 58 years, 62% male, mean bilirubin 3.9 mg/dL, albumin 2.7 g/dL, INR 1.6). Within 30 days, chest tube placement was associated with significantly higher risks of acute kidney injury (14.7% vs 10.6%; HR, 1.45; 95% CI, 1.00-2.09; P = 0.02), shock (8.0% vs 4.5%; HR, 1.81; 95% CI, 1.06-3.09; P = 0.03), and death (9.9% vs 5.6%; HR, 1.79; 95% CI, 1.11-2.90; P = 0.02) compared with thoracentesis. Liver transplantation rates did not differ significantly (3.5% vs 2.2%; HR, 1.62; 95% CI, 0.73-3.56; P = 0.23). **Conclusion:** In this propensity-matched cohort, chest tube placement in hepatic hydrothorax was associated with higher 30-day risks of acute kidney injury, shock, and mortality compared with therapeutic thoracentesis. These findings support current guideline recommendations to avoid chest tube placement when safer alternatives exist, favoring thoracentesis with early evaluation for definitive therapies like TIPS or liver transplantation.

1523 | TWO INDEPENDENT CARDIAC RISK FACTORS FOR HEPATIC DECOMPENSATION IN CIRRHOSIS: QTC PROLONGATION AND CIRRHOTIC CARDIOMYOPATHY

Takashi Kitagataya[1] Goki Suda[1] Kiko Toda[1] Daisuke Yokoyama[1] Takatsugu Tanaka[1] Akimitsu Meno[1] Masatsugu Ohara[1] Masato Nakai[1] Takuya Sho[1] Naoya Sakamoto[1], [1]Hokkaido University

Background: Cardiac complications, including cirrhotic cardiomyopathy (CCM) and QTc prolongation, are common in liver cirrhosis and are associated with disease progression. CCM, diagnosed by the 2019 Cirrhotic Cardiomyopathy Consortium criteria, encompasses structural and functional myocardial abnormalities, while QTc prolongation reflects electrophysiological derangements. Notably, QTc prolongation was removed from the 2019 CCM diagnostic criteria due to concerns about specificity and unclear mechanistic links to cardiac dysfunction. Whether these two cardiac abnormalities independently predict hepatic decompensation and whether they identify distinct patient populations remains to be established. **Methods:** This retrospective cohort study enrolled 78 patients with liver cirrhosis confirmed by transient elastography (liver stiffness $\geq$12.5 kPa) who underwent both echocardiographic assessment for CCM and electrocardiographic evaluation for QTc measurement at Hokkaido University Hospital (January 2014–April 2024). QTc prolongation was defined using sex-specific thresholds (>450 ms in males, >470 ms in females) with the Fridericia correction. CCM was diagnosed according to the 2019 Cirrhotic Cardiomyopathy Consortium criteria. The primary endpoint was hepatic decompensation (ascites, variceal bleeding, or overt hepatic encephalopathy). Time-to-event analyses used the Kaplan–Meier method and Cox proportional hazards regression. **Results:** CCM was present in 50.0% (39/78) and QTc prolongation in 15.4% (12/78), with co-occurrence in only 9.0% (7/78). Hepatic decompensation incidence was significantly higher in both the CCM-positive group (HR 3.23, 95% CI 1.34–7.77; p = 0.009) and the QTc-prolonged group (HR 2.68, 95% CI 1.12–6.42; p = 0.023). No differences were observed in overall survival or cardiovascular events. Multivariate Cox regression identified QTc prolongation (HR 2.52, 95% CI 1.04–6.12, p = 0.042) and CCM (HR 2.64, 95% CI 1.07–6.49, p = 0.035) as independent predictors, alongside Child-Pugh grade B/C (HR 3.57, p = 0.002) and HCC beyond Milan criteria (HR 3.94, p = 0.004). QTc prolongation was more strongly associated with decompensation in Child-Pugh grade A patients (HR 3.81, 95% CI 1.17–12.45, p = 0.017) than in grade B/C patients (p = 0.578). **Conclusion:** QTc prolongation and CCM are independent predictors of hepatic decompensation with limited phenotypic overlap (9.0%), suggesting they represent distinct cardiac manifestations in cirrhosis. Comprehensive cardiac assessment incorporating both electrocardiographic and echocardiographic evaluation may improve risk stratification, particularly in compensated cirrhosis.

1524 | INDETERMINATE PERITONITIS IN CIRRHOSIS: A DISTINCT HIGH-RISK PHENOTYPE BETWEEN SECONDARY AND SPONTANEOUS BACTERIAL PERITONITIS

Kahler Doyle[1] Brayden Doyle[2] Viraj Gandhi[1] Mohammad Ashfaq[3], [1]TCU Anne Burnett School of Medicine, [2]TCU College of Science and Engineering, [3]Baylor Scott & White Liver Consultants of Texas

Background: Distinguishing secondary peritonitis (SecP) from spontaneous bacterial peritonitis (SBP) in cirrhotic patients is critical, as SecP often requires procedural intervention. However, a subset of patients present with features overlapping both, including elevated polymorphonuclear cells (PMNs), polymicrobial or fungal cultures, or biochemical abnormalities consistent with Runyon's criteria. These "indeterminate peritonitis" (IP) cases are frequently managed variably in clinical practice. We aimed to compare clinical characteristics, peritoneal fluid profiles, management patterns, and outcomes across SecP, IP, and SBP. **Methods:** We performed a retrospective cohort study of cirrhotic patients admitted with peritonitis (n = 401), classified as SecP (n = 72), IP (n = 61), or SBP (n = 268) based on clinical, microbiologic, and biochemical criteria. Baseline characteristics, peritoneal fluid analyses, microbiology, antibiotic utilization, procedural interventions, and clinical outcomes were compared across groups using appropriate statistical tests. **Results:** There were no significant differences in age, sex, race, comorbidities, cirrhosis etiology, hepatic encephalopathy, or varices. SecP had a lower median admission MELD 3.0 (21.5 [16–28.2]) compared to IP (25 [21–32]) and SBP (24 [19–30]; $p = 0.018$). Early and late peritoneal fluid analyses demonstrated lower glucose and higher LDH in SecP and IP versus SBP, with no differences in PMNs, albumin, or protein. Peritoneal fluid cultures were more frequently positive in SecP (86.1%) and IP (50.8%) versus SBP (25%; $p < 0.001$), with higher rates of fungal (31.9% vs 9.8%) and polymicrobial infections (44.4% vs 16.4%) in SecP versus IP (both $p < 0.001$). Multidrug-resistant organisms were more common in SecP (27.8%) than IP (6.6%) or SBP (6.3%; $p < 0.001$). SecP patients received more inpatient antibiotics (5 [3-8]) than IP (3 [2-5]) and SBP (0 [0-1]) and underwent more abdominal procedures (43.1% vs 4.9% vs 7.5%) (both $p < 0.001$). ICU admission, vasopressor use, and mechanical ventilation were highest in SecP and IP (all $p \leq 0.005$). Median length of stay was longest in SecP (14.5 days) versus IP (9) and SBP (7.5; $p < 0.001$). SBP patients were more often discharged home (48.5% vs 22.2% vs 29.5%; $p < 0.001$) and more frequently received prophylactic antibiotics. Median time to readmission was shortest in SecP (23 days), 28 in IP and longest in SBP (47.5; $p = 0.011$). Mortality at 30, 60, and 90 days was highest in IP, followed by SecP, and lowest in SBP (all $p < 0.001$). **Conclusion:** Indeterminate peritonitis represents a clinically distinct and high-risk group with outcomes comparable to SecP, despite overlapping features with SBP. Biochemical and microbiologic profiles suggest closer alignment with SecP, while management patterns remain heterogeneous. Improved classification frameworks may improve risk stratification and guide more consistent treatment strategies in this population.

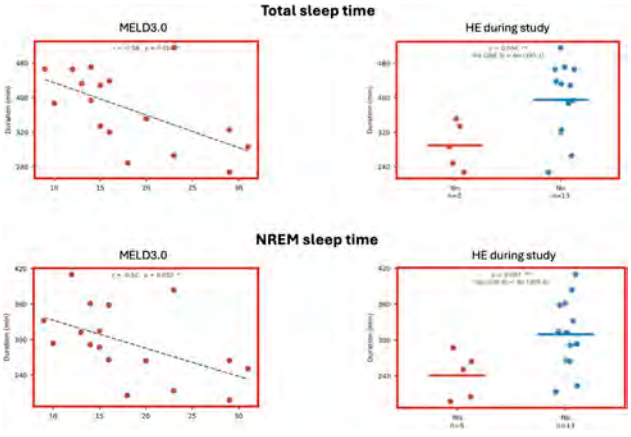
1525 | AMBIENT SLEEP MONITORING IDENTIFIES SLEEP ALTERATIONS ASSOCIATED WITH DISEASE SEVERITY IN DECOMPENSATED CIRRHOSIS



Alberto Calleri[1] Ali Mirzazadeh[2] Camille Kezer[1] Diego Drumond Westgeest e Sousa[1] Yigit Yazarkan[1] Kamalpreet Hara[1] Katherine Williams[1] Daniel Penrice[3] Patrick Kamath[1] Vijay Shah[1] Dina Katabi[4] Douglas Simonetto[1], [1]Mayo Clinic Rochester, [2]Massachusetts Institute of Technology, Cambridge, MA, USA, [3]Mayo Clinic Health System - Eau Claire, [4]Massachusetts Institute of Technology; Emerald Innovations Inc., Cambridge, MA, USA

Background: Sleep disturbances are common in patients with cirrhosis and hepatic encephalopathy (HE). However, longitudinal characterization of sleep patterns in real-world home settings remains limited. EMERALD is an ambient wireless sensor capable of passively monitoring sleep characteristics. We evaluated the feasibility and clinical correlates of wireless sensor-derived sleep metrics in patients with decompensated cirrhosis. **Methods:** Patients with decompensated cirrhosis were prospectively enrolled in a 3-month cirrhosis-specific remote patient monitoring (CiRPM) program integrating EMERALD sensors. Devices were installed in patient bedrooms and continuously captured sleep metrics including total sleep duration, non-rapid eye movement (NREM) sleep, deep sleep (N3), longest uninterrupted sleep period, and number of sleep periods per night. Sleep parameters were analyzed according to baseline demographics, liver disease severity (MELD 3.0), Liver Frailty Index (LFI), Animal Naming Test (ANT), history of HE and HE-related index hospitalization. **Results:** Among 18 patients included in the analyses, median age was 55 years (IQR 53-67), 50% were female, median BMI was 28.0 kg/m² (IQR 24-32), and median MELD 3.0

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

was 16 (IQR 14-23). Fourteen patients (77.8%) had a prior history of HE, while 5 (27.8%) were hospitalized for HE during the study period. During follow-up, EMERALD successfully captured 982 nights of home sleep data. More advanced liver disease was consistently associated with worse sleep domains: MELD 3.0 inversely correlated with total sleep duration ($r = -0.58$, $p = 0.014$), NREM sleep ($r = -0.52$, $p = 0.032$), N3 sleep ($r = -0.49$, $p = 0.046$), and longest sleep period ($r = -0.56$, $p = 0.019$), while showing increased sleep fragmentation ($r = 0.61$, $p = 0.009$). Patients with MELD 3.0 ≥ 15 had significantly shorter total sleep time compared with those with MELD < 15 (5.7 vs 7.3 hours/night, $p = 0.004$). Presence of HE was similarly associated with impaired sleep characteristics: patients admitted for HE had shorter total sleep (4.8 vs. 6.6 hours/night, $p = 0.004$) and NREM sleep (4.0 vs. 5.2 hours/night, $p = 0.007$) compared with those admitted for non-HE etiologies; patients with prior HE history had lower total sleep (5.8 vs. 7.1 hours/night, $p = 0.017$) and N3 sleep (28.7 vs. 44.6 min, $p = 0.048$) compared with those without. No consistent significant associations between sleep metrics and LFI or ANT assessed at baseline were identified. **Conclusion:** Passive, continuous ambient sleep monitoring is feasible in patients with decompensated cirrhosis and identifies sleep alterations associated with disease severity and history of HE, supporting its potential as a digital biomarker for longitudinal home monitoring in advanced liver disease.

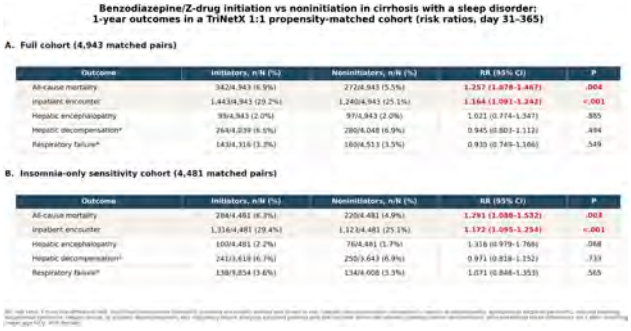
1526 | BENZODIAZEPINE/Z-DRUG INITIATION IN CIRRHOSIS: HIGHER MORTALITY WITHOUT EXCESS HEPATIC ENCEPHALOPATHY IN A PROPENSITY-MATCHED REAL-WORLD COHORT



Akram Alnounou[1] Mohammad Alabbas[2] Ezzeldien Ibrahim[3] Ahmad Alhusen[4] Riddhi Machchhar[5] Eric Sieloff[6] Syed-Mohammed Jafri[7], [1]Western Michigan University Homer Stryker M.D. School of Medicine, Kalamazoo, MI, [2]Cleveland Clinic Foundation, Cleveland, OH, [3]University of Missouri-Columbia, Columbia, MO, [4]Advocate Illinois Masonic Medical Center, Chicago, IL, [5]Hackensack Meridian Ocean University Medical Center, [6]Western Michigan University Homer Stryker M.D. School of Medicine, [7]Henry Ford Health System

Background: Benzodiazepines and non-benzodiazepine ("Z-drug") hypnotics are commonly prescribed for sleep disturbance in cirrhosis despite concern that sedation may precipitate hepatic encephalopathy (HE). Whether initiating these agents after a sleep-disorder diagnosis is safe in cirrhosis is uncertain. We compared initiation with noninitiation for incident HE, mortality, and inpatient encounters. **Methods:** Adults aged ≥ 18 years with cirrhosis and a sleep-disorder diagnosis at least 1 month after cirrhosis were identified in the TriNetX Research Network (111 health care organizations). After a 1-year washout, initiators had a benzodiazepine/Z-drug medication record within 1 month after sleep diagnosis; noninitiators had none in that window. Patients with prior HE, liver transplant, palliative-care encounter, or decompensation or death during the first month after sleep diagnosis were excluded. Cohorts were 1:1 propensity-score matched on demographics, liver-related diagnoses, comorbidities, respiratory failure/sleep apnea, opioids, CNS-active medications, and cirrhosis medications. Outcomes were assessed from day 31 through day 365 and reported as risk ratios (RRs) with 95% CIs. **Results:** After matching, 4,943 initiators and 4,943 noninitiators were analyzed. Initiation was not associated with incident HE (99/4,943 [2.0%] vs 97/4,943 [2.0%]; RR 1.021, 95% CI

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

0.774–1.347; P = .885). Initiation was associated with higher mortality (342/4,943 [6.9%] vs 272/4,943 [5.5%]; RR 1.257, 95% CI 1.078–1.467; P = .004) and inpatient encounters (1,443/4,943 [29.2%] vs 1,240/4,943 [25.1%]; RR 1.164, 95% CI 1.091–1.242; P < .001), whereas a hepatic decompensation composite (RR 0.945, 95% CI 0.803–1.112) and respiratory failure (RR 0.935, 95% CI 0.749–1.166) did not differ. In an insomnia-only cohort, mortality (6.3% vs 4.9%; RR 1.291, 95% CI 1.088–1.532; P = .003) and inpatient encounters (29.4% vs 25.1%; RR 1.172, 95% CI 1.095–1.254; P < .001) remained higher, while HE remained non-significant (2.2% vs 1.7%; RR 1.316, 95% CI 0.979–1.768; P = .068). **Conclusion:** In this matched EHR cohort, benzodiazepine/Z-drug initiation after a sleep-disorder diagnosis in cirrhosis was not associated with incident HE but was associated with higher 1-year mortality and inpatient encounters. Prospective studies should test cirrhosis-specific sleep-treatment strategies with direct measures of medication use, liver disease severity, and cause of death.

Benzodiazepine/Z-drug initiation vs noninitiation in cirrhosis with a sleep disorder: 1-year outcomes in a TriNetX 1:1 propensity-matched cohort (risk ratios, day 31-365)

A. Full cohort (4,943 matched pairs)

Outcome	Initiators, n/N (%)	Noninitiators, n/N (%)	RR (95% CI)	P
All-cause mortality	342/4,943 (6.9%)	272/4,943 (5.5%)	1.257 (1.078-1.467)	.004
Inpatient encounter	1,443/4,943 (29.2%)	1,240/4,943 (25.1%)	1.164 (1.091-1.242)	<.001
Hepatic encephalopathy	99/4,943 (2.0%)	97/4,943 (2.0%)	1.021 (0.774-1.347)	.885
Hepatic decompensation*	264/4,039 (6.5%)	280/4,048 (6.9%)	0.945 (0.803-1.112)	.494
Respiratory failure*	143/4,316 (3.3%)	160/4,513 (3.5%)	0.935 (0.749-1.166)	.549

B. Insomnia-only sensitivity cohort (4,481 matched pairs)

Outcome	Initiators, n/N (%)	Noninitiators, n/N (%)	RR (95% CI)	P
All-cause mortality	284/4,481 (6.3%)	220/4,481 (4.9%)	1.291 (1.086-1.532)	.003
Inpatient encounter	1,316/4,481 (29.4%)	1,123/4,481 (25.1%)	1.172 (1.095-1.254)	<.001
Hepatic encephalopathy	100/4,481 (2.2%)	76/4,481 (1.7%)	1.316 (0.979-1.768)	.068
Hepatic decompensation*	241/3,618 (6.7%)	250/3,643 (6.9%)	0.971 (0.818-1.152)	.733
Respiratory failure*	138/3,854 (3.6%)	134/4,008 (3.3%)	1.071 (0.846-1.353)	.565

1527 | ASCITES CHARACTERISTICS IN ADULTS WITH FONTAN CIRCULATION

Wesley Dixon[1] Sean Sanker[2] Michael Rosamilia[1] Stephen Zucker[1] Fred Wu[3] Jordan Sack[1], [1]Mass General Brigham, [2]Boston Children's Hospital, [3]Boston Children's Hospital

Background: Ascites is a late complication of the Fontan operation arising from a multifactorial pathophysiology that includes elevated central venous pressure, lymphatic congestion, and hepatic fibrosis. Characteristics of Fontan-related ascites and their clinical implications have not been systematically described. **Methods:** We retrospectively analyzed adults across two centers who underwent ≥1 paracentesis ≥5 years after Fontan. Demographic and clinical characteristics were from the time of initial paracentesis. Hemodynamics and hepatic pressures were obtained within 6 and 18 months of initial paracentesis, respectively. When available, liver histology and stiffness were recorded. Outcomes included varices, hepatic encephalopathy, hepatocellular carcinoma, transplant, and death. Serum-ascites albumin gradient (SAAG), total protein (TP), and neutrophil count were collected from each paracentesis. High SAAG and high TP were defined as ≥1.1 g/dL and ≥2.5 g/dL, respectively. First and last paracenteses were compared using linear mixed-effect modeling. **Results:** Among 41 adults with Fontan circulation (49% male; 39% atriopulmonary, 32% extracardiac, 24% lateral tunnel, 5% Kawashima), index paracentesis occurred at median 32.9 (IQR 30.0-41.9) years, or 27.7 (21.4-30.6) years after Fontan (**Figure 1A**). No patient had malignant or nephrotic ascites. Patients with high SAAG (44%) more commonly had hepatitis C infection or protein-losing enteropathy, and had a higher risk of death or transplant (**Figure 1B**). Presence of bridging fibrosis on liver biopsy was similar between groups. However, high SAAG was not associated with time to death or transplant by Cox proportional hazards analysis (HR 1.82, 95% CI 0.79-4.22). Compared to low TP, patients with high TP (88%) had less protein-losing enteropathy (8.3% vs. 60%; p = 0.017), less hepatocellular carcinoma (2.8% vs. 40%; p = 0.035), and similar rates of death or transplant (53% vs. 80%; p = 0.40). Among 30 patients with serial paracenteses, only 20% changed SAAG/TP category, with transition from low to high SAAG being most common [4 (13%)]. SAAG remained stable over time ($\beta = 0.0071$ g/dL/year, p = 0.57), whereas ascitic total protein tended to decrease ($\beta = -0.082$ g/dL/year, p = 0.0060). Median index ascitic neutrophil count was 63.5 (26.0-578.4) cells/mL; 19 (46%) ever had neutrophil count ≥250 cells/mL and 4 (9.8%) had ≥250 cells/mL on paracenteses >1 month apart, but these had no association with death or transplant (p = 0.90 for both). **Conclusion:** Approximately half of Fontan patients with ascites have low SAAG, an unexpected finding that may challenge the assumption that Fontan ascites behaves like typical portal hypertensive ascites. Ascites characteristics were generally stable within patients, though TP did demonstrate a modest decrease over time. Higher SAAG trended towards worse survival.

1528 | EARLY OUTCOMES AFTER EMERGENT VS NON-EMERGENT TIPS: 90-DAY MORTALITY, HEPATIC ENCEPHALOPATHY, AND MELD 3.0 TRAJECTORY

Ashley Lamba[1] Eusha Hasan[2] Ian Rumball[3] Ethan Davoudzadeh[4] Nayan Tiwary[5] Anwesha Satapathy[2] Craig Greben[2] Jonathan Weinstein[2] Sanjaya Satapathy[2], [1]UCLA, [2]Northwell Health, [3]Medical College of Wisconsin, [4]Memorial Sloan Kettering, [5]Morristown Medical Center

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is an established therapy for complications of portal hypertension, including refractory ascites and uncontrolled variceal hemorrhage. Hepatic encephalopathy (HE) remains one of the most frequent and clinically impactful complications after TIPS, contributing to readmissions and early morbidity. Outcomes following TIPS may vary by procedural urgency, particularly regarding short-term mortality and HE. This study evaluated 90-day outcomes and MELD 3.0 trajectories after emergent versus non-emergent TIPS in a sensitivity cohort excluding patients with baseline HE. **Methods:** In this HE-excluded cohort, 90-day survival was compared using Kaplan–Meier analysis with log-rank testing. Incident HE within 90 days was assessed using Fine–Gray competing-risks regression (event = HE; competing event = death), adjusted for age and baseline MELD 3.0. MELD 3.0 trajectories at baseline, 1 week, and 1 month were analyzed using a linear mixed-effects model with repeated measures and unstructured covariance. **Results:** A total of 128 patients underwent TIPS placement, including 42 emergent and 86 non-emergent procedures. Emergent TIPS patients had significantly lower albumin (2.62 vs 3.26 g/dL, p < 0.0001) and higher INR (1.58 vs 1.36, p = 0.0053) at baseline, consistent with greater clinical acuity. Variceal hemorrhage accounted for 90.5% of emergent TIPS indications, whereas refractory ascites accounted for 53.5% of non-emergent cases (p < 0.001). Baseline MELD 3.0 was the strongest independent predictor of mortality (HR 1.14 per point; p = 0.0035).In the sensitivity cohort excluding patients with baseline HE (n = 116; 37 emergent, 79 non-emergent), 90-day mortality was higher after emergent TIPS (21.6% vs 7.6%), with significantly worse survival (log-rank p = 0.0251). Emergent TIPS was associated with an increased risk of 90-day HE (adjusted subdistribution hazard ratio [sHR] 2.14; 95% CI, 1.12–4.08; p = 0.0206). MELD 3.0 scores increased significantly over time (p < 0.0001), but neither TIPS urgency (p = 0.3475) nor the urgency-by-time interaction (p = 0.6724) was significant. **Conclusion:** In patients without baseline HE, emergent TIPS was associated with higher 90-day mortality and a greater risk of incident HE compared with non-emergent TIPS. Despite these differences in clinical outcomes, MELD 3.0 trajectories over early follow-up were similar between groups, suggesting that excess early mortality after emergent TIPS may reflect pre-procedural clinical acuity rather than accelerated hepatic deterioration after shunt placement. These findings highlight the need for intensified monitoring in the early post-procedural period for emergent TIPS recipients.

1529 | VALIDATION OF LIVER CIRRHOSIS NETWORK CRITERIA FOR CIRRHOSIS DIAGNOSIS USING NATURAL LANGUAGE PROCESSING FOR PREDICTING DECOMPENSATION USING A MULTI-CENTER STUDY

Scott Silvey[1] Nilang Patel[2] Jacqueline O'Leary[3] Jasmohan Bajaj[1], [1]Virginia Commonwealth University, [2]Richmond VA Medical Center, [3]Dallas VAMC

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: The NIH-sponsored liver cirrhosis network (LCN) provided a consensus clinical definition for cirrhosis diagnosis, which includes a liver biopsy, blood-based, elastography, or imaging-based biomarkers. However, these need validation. **Aim:** Validate LCN criteria for cirrhosis for predicting decompensation. **Methods:** LCN criteria : (liver bx w cirrhosis < 5 yrs or 2 of the following: cirrhosis liver bx > 5 yrs, varices (< 3 yrs), imaging (nodularity +splenomegaly/collaterals < 1 yr), blood-based (FIB-4 > 2.67 or Platelets < 150/mL < 6 mths) or elastography (VCTE > 12.5 Kpa/MRE > 5Kpa < 1 yr).Cohort : We used the Veterans Affairs Corporate Data Warehouse (VA-CDW) charts from Richmond and Dallas VAs to create a cohort with initial cirrhosis diagnosis between 2009-2023 through ICD-9/10 codes. Using a combination of natural language processing (NLP) through record review, we determined LCN criteria & excluded pts with decompensation/events occurring within 30 days. Cohort details between LCN criteria yes/no were compared. We performed time-to-event analysis using competing risks regression for new decompensation (ascites, SBP, HCC, HE, or variceal bleed) between groups till Jan 1 2024, at which point those without new decompensation were censored. Multivariable models for decompensation were created. Then each LCN component's relative importance was measured using model coefficient comparison & decline in C-Index after removal. **Results:** We included 5465 compensated cirrhosis pts (Fig 1, 64 yrs, 96.3% men, 25.9% alcohol). 2333 (42.7%) met the LCN criteria [7.5%) liver Bx w/in 5 yrs, 93.7% blood-based, 37.0% varices, 89.5% imaging & 1.3% liver bx > 5 yrs]. MRE/VCTE was not widely done. Those who met LCN criteria were more likely to be White, less likely to have an alcohol etiology, were more likely to be on propranolol/PPI, higher CCI/MELD-Na, with lower albumin and WBC counts (Table 1).27.1% had a decompensating event & 59.0% died. Median time-to-first decompensation was 3.96 yrs, & median follow-up time/pt was 7.38 years. On time-to-event analysis with competing risk of death, LCN criteria pts had a higher risk of new decompensation (sub-distribution HR (sHR) 2.04 [1.83-2.28], $p < 0.001$), which persisted on multivariable analysis (Table 2, adj. sHR: 1.73 [1.51-1.97], $p < 0.001$). Others were lower CCI, propranolol, lower albumin, & lower WBC.Components : Blood-based (FIB-4/Platelet) features had the greatest relative importance & led to the greatest drop in C-index when removed (Table 3). Having more LCN components also raised decompensation risk (adj. sHR: 1.45 [1.35-1.55] X risk for each extra component, $p < 0.001$). **Conclusion:** Fulfilling the LCN criteria detected through NLP for cirrhosis diagnosis was associated with a significantly higher rate of decompensation versus conventional clinical criteria across two large VA sites. Blood-based biomarkers had the highest impact on LCN criteria's impact on decompensation.

1530 | SHORT- AND LONG-TERM OUTCOMES OF TERLIPRESSIN + ALBUMIN VS TRIPLE THERAPY IN HEPATORENAL SYNDROME: A U.S. REAL-WORLD COHORT STUDY

Islam Rajab[1] Ahmed Emara[2] Ameer Awashra[3] Mohamed Saad Rakab[4] Mohammad Kathem Salah[3] Zaid Sawaftah[3] Ahmed Sawafta[5] Ali Bani Odeh[3] Osama Nizar Jaber[3] Dhruv Patel[6] Mina Alkomos[7] Mohamed Elnaggar[8] Walid Baddoura[7] Nikolaos Pyrsopoulos[9], [1]Department of Internal Medicine, St. Joseph University Medical Center, Paterson, NJ, USA, [2]Faculty of Medicine, Al-Azhar University, Cairo, Egypt, [3]Department of Medicine, An-Najah National University, Nablus, West Bank, Palestine, [4]Faculty of Medicine, Mansoura University, Mansoura, Egypt, [5]. University Medical Center, Paterson, NJ, U, [7]Department of Gastroenterology and Hepatology, St. Joseph University Medical Center, Paterson, NJ,US, [8]Hospital Medicine department, Hartford healthcare, Hartford, CT. USA, [9]Liver Disease in New Jersey, NYU Grossman School of Medicine,NYU Langone Transplant Institute, NJ.US

Background: Terlipressin plus albumin is now the preferred therapy for hepatorenal syndrome–acute kidney injury (HRS-AKI), yet real-world comparative data against midodrine–octreotide–albumin (MOA) in the United States remain limited. We evaluated short- and long-term outcomes of both regimens using a large, multi-center electronic health-record network. **Methods:** Adults with HRS were identified in the TriNetX U.S. Collaborative Network (data cutoff July 2025). Cohorts included patients receiving terlipressin + albumin versus MOA. After applying prespecified exclusions, 8,692 patients were eligible. Propensity-score matching (1:1; caliper 0.1) balanced demographics, comorbidities, and laboratory values, yielding 196 patients per group. Outcomes included ICU admission (primary) and mortality, hyponatremia, arrhythmia, pulmonary edema, ischemic heart disease (IHD), fluid overload, and HRS recovery (secondary). Kaplan–Meier estimates and hazard ratios (HRs) were computed at 1 month, 3 months, and 1 year. **Results:** Among 392 matched patients (mean age 60.8 years; 68.6% male), terlipressin was associated with significantly fewer ICU admissions at 1 month (HR 0.30; 95% CI 0.095–0.97), 3 months (HR 0.21; 95% CI 0.07–0.63), and 1 year (HR 0.23; 95% CI 0.085–0.62). One-year ICU admission occurred in 5.6% with terlipressin vs 13.4% with MOA (risk difference –7.8%, p = 0.017). Mortality did not differ at any interval: 1-month HR 0.97 (p = 0.85); 3-month HR 1.08 (p = 0.58); 1-year HR 1.09 (p = 0.52). Terlipressin was associated with higher risk of fluid overload at 3 months and 1 year (HR 2.73; 95% CI 1.10–6.76). No significant between-group differences were observed in arrhythmia, pulmonary edema, hyponatremia, or renal replacement therapy. HRS recovery at 1 year was similar (26.5% vs 24.1%). IHD showed a temporal pattern: lower early events with terlipressin but convergence by 1 year. **Conclusion:** In this large U.S. real-world analysis, terlipressin + albumin significantly reduced ICU admissions compared with MOA across all time-points, with no mortality advantage and a higher rate of fluid overload over long-term follow-up. These findings support current guidance favoring terlipressin for HRS-AKI while underscoring the need for careful volume and respiratory monitoring. Further prospective studies are warranted to optimize patient selection and mitigate adverse-event risk.

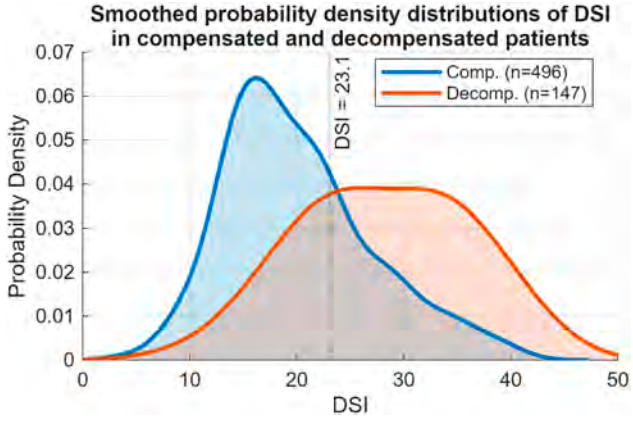
1531 | THE ORAL CHOLATE CHALLENGE TEST (HEPQUANT DUO®) DISCRIMINATES DECOMPENSATION IN ADVANCED CHRONIC LIVER DISEASE



Michael McRae[1] Joanne Imperial[2] Gregory Everson[3], [1]Custom DX Solutions LLC, [2]HepQuant LLC, [3]HepQuant

Background: Identifying patients with compensated advanced chronic liver disease (CLD) who are at risk for decompensation (DC) remains a central clinical goal. The Disease Severity Index (DSI), derived from the oral cholate challenge test (OCCT), is a quantitative measure of global liver disease severity ranging from 0 (healthy) to 50 (severe dysfunction). This analysis evaluated whether DSI identifies patients with advanced CLD who had DC or subsequently experience liver-related clinical progression. **Methods:** Data from 6 clinical studies were analyzed, representing a total of 643 subjects. Baseline DSI was evaluated for discrimination of Child-Pugh (CP) B at baseline or subsequent liver-related clinical progression during follow-up (liver-related death, CP progression, variceal hemorrhage, ascites, and/or encephalopathy). The OCCT involved oral administration of deuterium-labelled (d4-) cholate, blood

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

sampling at 20 and 60 minutes, and quantification of the d4-cholate by LC-MS/MS. Test parameters, including DSI, were calculated for each subject. Optimal thresholds for discriminating compensated versus decompensated were selected using Youden's index, 90% sensitivity (rule-out), and 90% specificity (rule-in). Distributional separation was visualized using kernel density estimates. Discrimination was assessed by AUROC, sensitivity, and specificity. Multivariable logistic regression (LR) evaluated the association of DC status with DSI adjusted for disease etiology. **Results:** The cohort had mean age 56 ± 11 years, BMI 31 ± 6 kg/m^2, and 57% were male. Liver disease etiologies included chronic hepatitis C (51%), MASH (18%), PSC (8%), alcohol-associated liver disease (7%), and other (16%). A total of 147 subjects (23%) had CP B cirrhosis or experienced a clinical progression event during follow-up. Higher DSI values were associated with greater odds of DC, and DSI discriminated decompensated/progressed from compensated subjects with an AUROC of 0.78 (95% CI 0.73–0.82). The Youden index threshold was DSI >23.1 with sensitivity 0.71 (0.61–0.85) and specificity 0.72 (0.58–0.82). Rule-out and rule-in thresholds were DSI ≤17.8 and >30.1, respectively. In multivariable LR adjusted for disease etiology, DSI remained independently associated with decompensated liver disease, with an adjusted odds ratio of 1.17 per unit increase (95% CI 1.13–1.20, p < 0.0001). Compared with hepatitis C, MASH was associated with lower adjusted odds of DC, whereas PSC was associated with higher adjusted odds. **Conclusion:** The OCCT-derived DSI identified patients with prior or subsequent liver-related DC and remained independently associated with DC after adjustment for etiology. DSI thresholds selected herein may support future external validation of clinically useful risk strata for patients with advanced CLD. Further prospective validation is warranted to define its role in DC risk assessment and clinical decision-making.

1532 | METHYLGLYOXAL DETOXIFICATION MITIGATES ENDOTOXIN-INDUCED PORTAL HYPERTENSION AGGRAVATION VIA RESTORATION OF LIVER SINUSOIDAL ENDOTHELIAL CELL MITOCHONDRIAL FUNCTION AND VASCULAR INTEGRITY

Dinesh Mani Tripathi[1] Vaibhav Tiwari[1] Rajni Yadav[1] Manisha .[1] Bitan Guchhait[1] Himanshi .[1] Aishwarya Bhatnagar[1] Savneet kaur[1] anupam kumar[1] Shiv Kumar Sarin[1], [1]Institute of Liver and Biliary Sciences

Background: Endotoxemia contributes to portal hypertension (PHT) in both cirrhotic and non-cirrhotic patients, mainly due to impaired liver sinusoidal endothelial cell (LSEC) function. We hypothesised that endotoxemia-driven glycolytic rewiring in LSECs promotes the pathological accumulation of methylglyoxal (MGO), thereby impairing mitochondrial bioenergetics and contributing to the development of PHT. We investigated the roles of MGO accumulation and its detoxification in restoring LSEC mitochondrial function and vascular homeostasis **Methods:** Endotoxemia was induced via 50% caecal ligation and puncture (CLP) in non-cirrhotics and via lipopolysaccharide (1mg/kg b.wt intraperitonially) in CCl_4-cirrhotic rats. MGO detoxification was achieved by activating Glo-1 with hesperetin (40 mg/kg b.wt, orally, 7 days). Systemic and hepatic Hemodynamic parameters, LSEC functionality and sinusoidal remodelling were assessed. Intracellular MGO levels, Glo-1 enzymatic activity, and D-lactate production were quantified. Metabolomic profiling and mitochondrial bioenergetics of LSECs were analysed. Endothelial integrity using trans-endothelial electrical resistance (TEER), vascular permeability assays (Lucifer yellow, Dextran 40 kDa), tube formation, and leukocyte adhesion assays was assessed. Molecular profiling of Glo-1, MCP1, HMGB1, junctional markers (VE-cadherin and Claudin-5) and survival analysis was performed. **Results:** Hesperetin-mediated Glo-1 activation significantly attenuated portal pressure and hyperdynamic circulation in both cirrhotic (CCl_4+LPS) (-20%) and non-cirrhotic (CLP) (-33%) models. MGO detoxification was validated by a significant reduction in intracellular MGO levels and an increase in D-lactate production (p < 0.001). LCMS-based LSECs Metabolomic profiling revealed that Go-1 activation (Hesperetin) reversed mitochondrial impairment, evidenced by restored mitochondrial respiration (OCR) (p < 0.01) and reduced glycolytic stress (ECAR) (p < 0.001). Structurally, LSECs fenestrae restoration, mitochondrial biomass, and mitochondrial potential, and a reduction in mitochondrial ROS was observed upon Glo-1 activation. TEER and vascular permeability, increased levels of the endothelial junctional proteins VE-cadherin and Claudin-5 confirmed the restored endothelial barrier integrity (p < 0.01).

Improved Tube-formation capacity, and leukocyte adhesion was significantly reduced upon treatment. Pro-inflammatory mediators were downregulated in both LSECs and hepatic tissue following hesperetin treatment ($p < 0.02$). Consequently, survival increased by 28% in cirrhotics (N = 8 each group) **Conclusion:** Pharmacological detoxification of methylglyoxal mitigates LSEC mitochondrial impairment, thereby improving mitochondrial function and integrity, attenuating portal hypertension, and improving survival during sepsis in cirrhosis

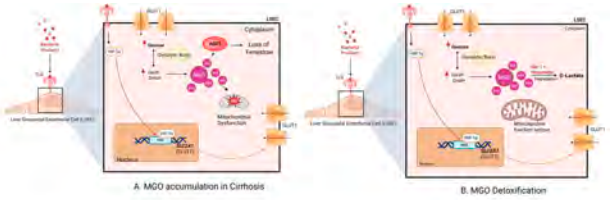

Figure. Schematic of the molecular mechanism by which methylglyoxal detoxification restores liver sinusoidal endothelial cell (LSEC) function and mitigates the aggravation of endotoxin-induced portal hypertension.

1533 | JUST-IN-TIME, SIMULATION-BASED PARACENTESIS TRAINING FOR HOSPITAL MEDICINE TEAMS: A PILOT STUDY

Bryan Kim[1] Jeemin Kwon[2] Jonathan Helali[3] Sean McCarthy[3] Marco Castelo[3] Christopher Moriates[3] Alexander Monto[1] Satya Patel[3] Arpan Patel[1], [1]Division of Gastroenterology, Hepatology, and Nutrition, VA Greater Los Angeles Healthcare System, [2]David Geffen School of Medicine at UCLA, [3]VA Greater Los Angeles Healthcare System

Background: Despite guideline recommendations for timely bedside paracentesis in hospitalized patients with ascites, hospital medicine teams are performing fewer procedures, underscoring the need for scalable approaches to procedural training. To address this gap, we developed and pilot tested a just-in-time, simulation-based paracentesis training curriculum at a Veterans Affairs (VA) medical center. **Methods:** The curriculum was designed using principles of adult learning theory and human-centered design to align procedural education with hospitalist workflow, learner needs, and bedside practice. Training included hands-on ultrasound-guided procedural simulation and real-time feedback from experienced procedural instructors. Hospitalists completed anonymous pre- and post-training surveys assessing comfort with ultrasound-guided paracentesis tasks and supervision, as well as acceptability, feasibility, and simulation fidelity. All items used 5-point Likert scales (1 = strongly disagree; 5 = strongly agree). Pre-post differences were analyzed using Wilcoxon signed-rank tests. **Results:** Nineteen hospitalists completed matched surveys. Comfort improved significantly across all procedural domains, including identifying a safe pocket (median 3 [interquartile range (IQR) 2–4] vs. 5 [4–5], $p < 0.01$), performing paracentesis (3 [2–4] vs. 4 [4–5], $p < 0.01$), and supervising a trainee (2 [2–4] vs. 4 [4–5], $p < 0.01$) (**Figure 1**). Acceptability (n = 19) was uniformly high, with a median rating of 5 [5–5] on six of eight items. All respondents (100%) agreed or strongly agreed that the module met their approval as a learner, that the time required was appropriate, that they would welcome future use, and that it was preferable to other methods of procedural skills education. Simulation fidelity received slightly lower ratings, specifically tactile feel (median 4, IQR 4–5) and overall accuracy of the experience (median 4, IQR 4–5), although at least 95% still rated each above or equal to 4. The majority of respondents who provided optional qualitative comments expressed interest in using this 'just-in-time' model to teach residents. **Conclusion:** A brief, just-in-time, simulation-based paracentesis curriculum was highly acceptable and feasible to hospitalists. Despite lower ratings of simulator fidelity, confidence in all domains improved, suggesting that high tactile realism may not be required. These findings support scalable, workflow-aligned approaches to strengthening bedside procedural competency among hospital medicine teams. Future work includes spreading training to internal medicine residents and examining whether training improves timely bedside paracenteses rates and reduces referral rates to interventional radiology.

Figure 1: Changes in Comfort Levels with Just-in-Time, Simulation-Based Paracentesis Simulation Training

Change in hospitalist comfort with diagnostic paracentesis before and after a simulator-based training module. Each thin gray line represents one of 17 hospitalists who completed both surveys, connecting their pre-training score to their post-training score on a 5-point Likert scale (1 = not at all comfortable; 2 = somewhat comfortable, 3 = neutral, 4 = somewhat comfortable, 5 = very comfortable). The red line indicates the group mean at each timepoint. Comfort improved significantly on all three domains: identifying a safe fluid pocket on ultrasound (median 3 → 5, Wilcoxon signed-rank $p < .001$), performing a diagnostic paracentesis (median 3 → 4, $p < .001$), and supervising a trainee performing the procedure (median 2 → 4, $p < .001$).

1534 | REAL-WORLD TERLIPRESSIN TREATMENT PATTERNS AND OUTCOMES IN HEPATORENAL SYNDROME-ACUTE KIDNEY INJURY (HRS-AKI): PRELIMINARY DATA FROM NINE US HOSPITALS

Stevan Gonzalez[1] Aanchal Kapoor[2] A. Sidney Barritt[3] Todd Frederick[4] Brian Wentworth[5] Justin Belcher[6] Mary Thomson[7] Sajid Jalil[8] Elsa Solà[8] Xingyue Huang[9] Sneha Kelkar[10] Rishi Verma[10] Kyle Roney[10] Mary Panaccio[9] Christopher White[9], [1]Baylor Scott and White All Saints Medical Center Fort Worth, [2]Cleveland Clinic, Cleveland, OH, [3]University of North Carolina, Chapel Hill, NC, [4]California Pacific Medical Center, San Francisco, CA, [5]University of Virginia Medical Center, Charlottesville, VA, [6]Yale School of Medicine, New Haven, CT, [7]University of Minnesota, Minneapolis, MN, [8]Stanford University, Palo Alto, CA, [9]Keenova Pharmaceuticals, Bridgewater, NJ, [10]OPEN Health, New York, NY

Background: Despite being the only FDA approved pharmacological therapy indicated to improve kidney function in adults with hepatorenal syndrome-acute kidney injury (HRS-AKI) and recommended by multiple clinical guidelines, terlipressin use in real-world US settings remains limited. This study evaluates characteristics, treatment patterns, and clinical outcomes of HRS-AKI treated with terlipressin in real-world US clinical settings. **Methods:** A multi-center, retrospective chart review study was conducted among adults hospitalized between 2023-2026 with cirrhosis and HRS-AKI. Terlipressin was administered as part of clinical care in a real-world setting according to current FDA labelling guidance (ACLF < 3, SCr < 5). Response to terlipressin was evaluated based on SCr at end of treatment or day-14 relative to baseline defined as complete response (CR; SCr < 0.3 mg/dL above baseline value), partial response (PR; SCr ≥ 0.3 mg/dL above baseline value and regression of AKI stage) or no response (no regression of AKI stage). Verified HRS reversal was evaluated among patients with ≥ 3 days terlipressin use and was defined as two consecutive SCr values ≤ 1.5 mg/dL measured on separate days and alive without renal replacement therapy (RRT) at day 10. **Results:** Nine hospitals provided data for 98 patients (average age 57.5 years (standard deviation ± 11.6); 78% White; 61% male). Terlipressin was first-line vasoconstrictor (mono- or combination therapy) in 34% of patients. Other first-line therapies included midodrine and/or octreotide (60%) and norepinephrine (5%). Average duration of terlipressin use was 6.5 days, with administration in the general ward (55%), intensive care unit (24%), step-down unit (17%), or a combination (3%). Average SCr at initiation was 2.9 (0.9). CR to terlipressin was observed in 38% of patients, PR in 28%, and no response in 34%. Verified HRS reversal was achieved in 31% of patients. Complete response and HRS reversal rates were higher among patients with lower SCr at terlipressin initiation (Table 1). Terlipressin-related adverse events were reported in 30% (29/98) of patients, most commonly respiratory failure (6/98, 6%). After terlipressin initiation, 22% of patients required RRT and 18% underwent liver transplant. In-hospital mortality was 17%, with 81% alive 30 days after discharge. Among 81 patients alive at discharge, most were discharged home to self-care (50%) or home health care (5%), 10% to hospice, 8% to rehabilitation facility, and 9% to other facilities. **Conclusion:** Two-thirds of HRS-AKI patients experienced CR or PR to terlipressin and almost one-third achieved verified HRS reversal, providing real-world validation to the findings from the pivotal Phase III CONFIRM trial. Patients initiating terlipressin treatment with lower SCr had higher rates of CR and verified HRS reversal, suggesting benefit to earlier initiation in clinical practice.

Table 1. Response and verified HRS reversal by SCr at terlipressin initiation

Variable	Statistic or Category	Overall patients	SCr <2 mg/dL at terlipressin initiation	SCr 2 to <3 mg/dL at terlipressin initiation	SCr: 3 to <5 mg/dL at terlipressin initiation
		(N = 98)	(N = 17)	(N = 41)	(N = 40)
HRS-AKI response*, N (%)	Complete Response	34 (37.8)	7 (46.7)	16 (41.0)	11 (30.6)
	Partial Response	25 (27.8)	4 (26.7)	12 (30.8)	9 (25.0)
	No Response	31 (34.4)	4 (26.7)	11 (28.2)	16 (44.4)
		(N = 80)	(N = 15)	(N = 34)	(N = 31)
Verified HRS Reversal, N (%)	Yes	25 (31.3)	8 (53.3)	13 (38.2)	4 (12.9)
	No	55 (68.8)	7 (46.7)	21 (61.8)	27 (87.1)

*Percents may not add up to 100% due to rounding

SCr: serum creatinine; HRS-AKI: hepatorenal syndrome-acute kidney injury

1535 | VITRO SCORE PREDICTS ACUTE KIDNEY INJURY, HEPATIC ENCEPHALOPATHY, AND SPONTANEOUS BACTERIAL PERITONITIS IN PATIENTS WITH CIRRHOSIS

Yun-Cheng Hsieh[1] Pei-Chang Lee[1] Kuei-Chuan Lee[1] Pei-Shan Wu[1] Yu-Jen Chen[1] Han-Chieh Lin[1] Ming-Chih Hou[1], [1]Taipei Veterans General Hospital

Background: Von Willebrand factor (vWF), a marker of endothelial dysfunction, reflects portal hypertension in cirrhosis. The vWF-to-thrombocyte ratio (VITRO) score has been reported as a noninvasive biomarker for predicting hepatic decompensation and mortality. However, its direct correlation with hepatic venous pressure gradient (HVPG) and its specific predictive value for distinct decompensating events remain to be fully elucidated. We investigated the clinical significance and prognostic utility of the VITRO score in patients with cirrhosis. **Methods:** Between 2000 and 2020, 183 patients with cirrhosis were prospectively enrolled at Taipei Veterans General Hospital. Among them, 77 patients underwent HVPG measurement. Plasma vWF levels were measured by ELISA, and the VITRO score was calculated by dividing vWF levels (mIU/mL) by platelet counts (10^9 /L). **Results:** Among the 183 patients, 141 were male (77%); 67 (37%) and 28 (15%) had Child-Pugh class B and C cirrhosis, respectively. The VITRO score increased with Child-Pugh class (A: 19.00 ± 13.99; B: 35.12 ± 33.48; C: 39.36 ± 28.82; $p < 0.001$) and correlated with MELD score ($r = 0.449$, $p < 0.001$). Notably, the VITRO score significantly correlated with HVPG ($r = 0.252$, $p = 0.027$), and patients with high-risk esophageal varices had higher VITRO scores (31.53 ± 23.20 vs. 27.02 ± 27.03, $p = 0.042$). During a median follow-up of 25.6 months (IQR, 10.2–35.9), 40 patients died. In multivariable analysis, a higher VITRO score (≥ 20) independently predicted acute kidney injury (HR, 2.14; 95% CI, 1.20–3.82), hepatic encephalopathy (HR, 2.29; 95% CI, 1.09–4.80), and spontaneous bacterial peritonitis (HR, 2.51; 95% CI, 1.03–6.12). However, VITRO score was not associated with variceal bleeding, new ascites formation, or survival. **Conclusion:** The VITRO score reflects portal hypertension and hepatic dysfunction. Furthermore, it independently predicts the occurrence of acute kidney injury, hepatic encephalopathy, and spontaneous bacterial peritonitis, supporting its potential role as a noninvasive risk stratification marker in patients with cirrhosis.

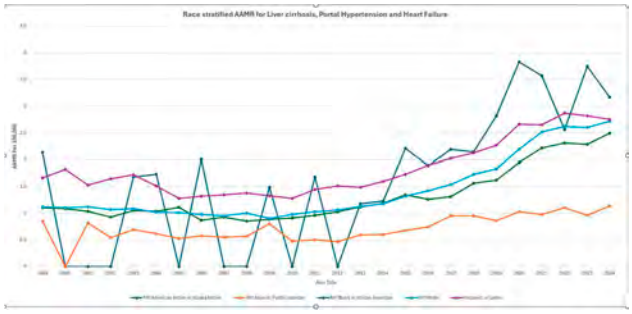
1536 | NATIONAL MORTALITY TRENDS IN CIRRHOSIS WITH CONCURRENT HEART FAILURE AND PORTAL HYPERTENSION IN THE UNITED STATES: A CDC WONDER ANALYSIS, 1999–2024



Neha Singh[1] Manish Kc[1], [1]North Alabama Medical Center

Background: Cirrhosis, portal hypertension, and heart failure frequently coexist constituting a complex clinical entity recognised as cirrhotic cardiomyopathy and cardiorenal syndrome. These disorders share the same pathophysiology such as neurohormonal activation leading to major challenges in clinical management. Despite the growing burden of these comorbid conditions, national long term mortality trends remain poorly studied. This study aims to analyse the mortality trends and demographic disparities related to concurrent cirrhosis, portal hypertension, and heart failure in the United States from 1999 to 2024. **Methods:** We performed a national level mortality analysis with the help of CDC WONDER Database from 1999-2024 among patients for Heart Failure (ICD-10 codes: I50), Portal hypertension (ICD code: K76.6 and Fibrosis and cirrhosis of Liver (ICD-10 codes:K74). Data were stratified by Race (American Indian or Alaska Native, Asian or Pacific Islander, Black or African American, White, Hispanic or Latino), sex and age groups (25-85+). We calculated age-adjusted mortality rates per 100,000 population based on the 2000 US standard population. Temporal trends were analyzed using Joinpoint regression to calculate annual percent change (APC), with statistical significance defined by $p < 0.05$. **Results:** Mortality rates for cirrhosis associated with heart failure and concurrent portal hypertension were consistently rising throughout the study period in all demographic populations, with a more significant trend noticed after 2010. Females demonstrated a statistically significant upward trend (2010-2018, APC = 7.43%, $p < 0.05$) from 2010 to 2021, with more rapid increase seen after 2018 (2018-2021, APC = 15.54%, $p < 0.05$). The trend stabilized after 2021 (APC = 2.10%, p =

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

0.28) and maintained it until the end of the study period. Males exhibited similar upward trend (2010-2018, APC = 7.58%, p < 0.05) along with rise observed after 2018 (2018-2021, APC = 12.96%, p < 0.05), but they maintained increasing pattern even after 2021 (APC = 3.14%, p < 0.05). While White subgroup displayed a significant rise between 2018 and 2021 (APC = 14.09%, p < 0.05), a statistically significant rise in AAMRs was observed during 2010-2024 (APC = 7.90%, p < 0.05) among Black/African American populations. The longest duration of upward trend in AAMRs from 2009 to 2024 (APC = 6.07%, p < 0.05) was identified among Hispanic/Latino populations. Among American Indian/Alaska Native populations, the highest mortality rates with sustained growth were observed. **Conclusion:** This analysis shows a marked and continuous increase in death rates among patients with cirrhosis, portal hypertension, and heart failure over the past 20 years. Mortality began rising more rapidly between 2010 and 2018 and worsened further during 2018–2021, suggesting that current treatment approaches may not be adequately addressing the combined impact of these serious conditions.

1537 | CYSTATIN C VERSUS CREATININE FOR MORTALITY PREDICTION IN PATIENTS WITH CIRRHOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Eliabe Abreu[1] Bernardo Moraes[2] Gabriel Prusch Fernandes[3] Diego Sousa[1] Luisa Visentini[4] Yigit Yazarkan[1] Yohanna Idsabella Rossi[5] Ana Francesca Leite[6] Sriharsha Koduru[7] Manal Abdelmalek[1] Patrick Kamath[1] Guilherme Cancado[8], [1]Mayo Clinic Rochester, [2]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, [3]Montefiore Medical Center, New York, USA, [4]Universidade do Oeste Paulista, Presidente Prudente, Brazil., [5]Universidade Federal de Ciências da Saúde de Porto Alegre, Porto Alegre, Brazil, [6]Universidade do Estado de Minas Gerais, Passos, Brazil, [7]Jawaharlal Institute of Postgraduate Medical Education and Research, Pondicherry, India, [8]Universidade Federal de Minas Gerais; Hospital da Polícia Militar de Minas Gerais, Brazil.

Background: Accurate short-term mortality prediction is central to risk stratification and transplant prioritization in patients with cirrhosis. MELD models are creatinine-based and remain the cornerstone of prognostication. Cystatin C (CysC) has emerged as an alternative marker to creatinine for renal function assessment. We conducted a systematic review and meta-analysis to compare the prognostic performance of CysC and creatinine for mortality prediction in patients with cirrhosis. **Methods:** PubMed, EMBASE, and Web of Science were systematically searched for studies comparing CysC with creatinine for mortality prediction in adults with cirrhosis. Studies enrolling patients with ACLF or evaluating post-LT or post-TIPS outcomes were excluded. Random-effects meta-analyses were performed using the ratio of hazard ratios (RHRs), ratio of adjusted hazard ratios (RaHRs), and pooled areas under the receiver operating characteristic curve (AUCs), when available. Prespecified subgroup analyses were performed to evaluate the prognostic performance according to the baseline acute kidney injury status and clinical setting. **Results:** Ten studies, including 2,149 patients, met the inclusion criteria. Overall, 66.0% (n = 1,419) were male, but no data were available on sarcopenia. The leading etiologies of cirrhosis were viral hepatitis (n = 656, 30.5%) and alcohol-related disease (n = 641, 29.8%). In the overall analysis, CysC was not significantly superior to creatinine for mortality prediction (RHR 1.19, 95% CI 0.99–1.42; $I^2 = 59.5\%$; 1,530 patients). However, subgroup analyses suggested improved prognostic performance of CysC among patients without acute kidney injury at baseline (RHR 1.17, 95% CI 1.05–1.30; $I^2 = 0\%$; 1,092 patients) and in non-hospitalized cohorts (RHR 1.18, 95% CI 1.04–1.33; 877 patients). No statistically significant difference was found when stratifying according to compensation status (p = 0.716). For 90-day mortality prediction, the pooled AUCs were 0.805 for CysC and 0.713 for creatinine (p = 0.5). **Conclusion:** In this meta-analysis, CysC outperformed creatinine in predicting mortality in patients with cirrhosis without AKI at baseline and in an outpatient setting. Although CysC may be superior to creatinine in predicting outcomes in some patients with cirrhosis, the implementation of CysC-based models is constrained by limited availability and higher costs. Prospective studies with better patient stratification according to age, gender, muscle mass, hospital setting, compensation status, and measured GFR are needed to understand whether the prognostic power of CysC outweighs its restricted availability and increased expense compared to creatinine.

1538 | BETA-BLOCKER PRESCRIBING TRENDS IN CIRRHOSIS FROM 2013–2025: INCREASING CARVEDILOL USE AND RESIDUAL METOPROLOL EXPOSURE IN PATIENTS WITH POTENTIAL CSPH

Ashley Zhang[1] Farinaz Ghodrati[1] Marina Serper[1] David Kaplan[1] Nadim Mahmud[1], [1]Hospital of the University of Pennsylvania

Background: In patients with compensated cirrhosis, clinically significant portal hypertension (CSPH) is a key driver of decompensation. Recent years have seen a paradigm shift towards earlier use of non-selective beta-blockers (NSBBs), namely carvedilol, to reduce portal pressure and prevent first decompensation. However, real-world beta-blocker prescribing patterns in cirrhosis remain poorly characterized, including the extent to which patients with potential CSPH continue to receive cardioselective rather than portal hypertension-directed beta-blockers. We aimed to evaluate temporal trends in beta-blocker prescribing among patients with cirrhosis and characterize noninvasive evidence of CSPH among metoprolol-treated patients without NSBB exposure. **Methods:** This was a retrospective cohort study using a single-institution patient registry (CDOTS). Adult patients with cirrhosis from 2013 to 2025 were identified. Demographic data included age, sex, and race. Beta-blockers were classified into NSBBs and cardioselective. Linear regression was used to evaluate temporal trends in overall beta-blocker prescribing amongst cirrhosis patients, which was further stratified by specific beta-blocker. Among patients receiving metoprolol without evidence of portal hypertension-directed NSBB therapy, we also evaluated transient elastography and platelet data (within 180 days) to assess noninvasive evidence of CSPH, classified according to Baveno VII-aligned criteria. **Results:** A total of 18,226 patients with cirrhosis from 2013 to 2025 were included; with a median age of 59 years, 62.1% were male, and 64.1% self-identified as White. Over time, the use of beta-blockers, regardless of selectivity, has remained stable (beta 0.01, 95% CI -0.35 to 0.37, $p = 0.94$; **Figure panel A**). When focusing on specific agents, the use of carvedilol has increased significantly over time (beta 2.05, 95% CI 1.68 to 2.42, $P < 0.001$), while nadolol and propranolol have declined (e.g., -2.00 for nadolol, 95% CI -2.31 to -1.70, $p < 0.001$; **Figure panel B**). The use of metoprolol remained stable ($p > 0.05$) though was overtaken by carvedilol as the most commonly prescribed beta blocker in 2025. Among 3,330 cirrhosis patients treated with metoprolol without prior NSBB therapy, only 277 (8.3%) had paired elastography and platelet measurements. Among these, 39 (14.1%) met at least one noninvasive criterion for CSPH, including 32 with liver stiffness ≥ 25 kPa consistent with ruled-in CSPH. **Conclusion:** Carvedilol use increased significantly over time and became the most commonly prescribed beta blocker by 2025 in cirrhosis patients. Among metoprolol-treated patients without portal hypertension-directed NSBB therapy, noninvasive portal hypertension assessment was infrequently performed, yet 14.1% of phenotyped patients met CSPH criteria, suggesting a potentially underrecognized population who may benefit from evaluation for NSBB therapy.

1539 | HELICOBACTER PYLORI INFECTION AND PEPTIC ULCER RECURRENCE IN CIRRHOTIC PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Yusuf Kagzi[1] Harjot Bath[2] Sonu Dhillon[3], [1]University of Illinois College of Medicine Peoria, [2]Fellow, [3]Program Director

Background: Peptic ulcer disease (PUD) is associated with higher mortality in cirrhotic patients in comparison to the general population. Helicobacter pylori (H. pylori) is one of the leading causes of PUD globally. The goal of eradication therapy is to promote healing and reduce recurrence in the general population however its efficiency in cirrhotic patients remains unclear. This meta-analysis evaluates recurrence, eradication outcomes, and ulcer healing in PUD secondary to H. pylori infection in cirrhotic patients. **Methods:** A systematic search of electronic databases was performed from inception through May 2026 to identify studies evaluating recurrent PUD and H. pylori in patients with cirrhosis. The primary outcome was ulcer recurrence following H. pylori therapy. The secondary outcomes were H. pylori prevalence, eradication rate, ulcer healing, and other clinical characteristics. Studies lacking extractable data or including non-cirrhotic populations were excluded. Pooled proportions were calculated using a random-effects model. Arcsine square root transformation was applied to stabilize variances prior to pooling. Statistical heterogeneity was assessed using Cochran's Q test and the I^2 statistic. All analyses were performed using the metafor package (version 4.8-0) in R version 4.5.1. **Results:** Eight studies including 719 patients with cirrhosis-associated PUD were included, 74% were male. Alcoholic cirrhosis accounted for 30.46% (95% CI 26.34-33.53), while 69.54% (95% CI 67.47-74.53) had non-alcoholic cirrhosis. The pooled study population included 51.66% (95% CI 51.61-51.71) Child-Pugh A patients and 48.34% (95% CI 48.29-48.39) Child-Pugh B/C. The pooled prevalence of esophageal varices was 60.36% (95% CI 60.30-60.41). The mean treatment duration across studies was 3.25 ± 1.03 weeks.The pooled prevalence of cirrhotic patients with H. Pylori induced PUD was 87.10% (95% CI 64.30-99.10) (Figure 1). Following treatment, the pooled H. pylori eradication rate was 80.11% (95% CI 63.44-93.78). Endoscopic ulcer healing following H. pylori eradication was observed in 86.28% (95% CI 73.95-95.02).Following H. pylori eradication, the pooled ulcer recurrence rate was 87.21% (95% CI 58.30-100.00), with H. pylori positivity observed in 84.40% (95% CI 80.60-88.20) of recurrent ulcers. In the recurrent ulcer subgroup, 40.43% (95% CI 40.37-40.49) were Child–Pugh A and 59.57% (95% CI 59.51-59.63) were Child–Pugh B/C. The prevalence of portal hypertensive gastropathy was 60.22% (95% CI 60.13-60.32). **Conclusion:** Cirrhotic patients demonstrated significant H. pylori prevalence with favorable eradication and healing outcomes; however, ulcer recurrence remained common. Further studies are necessary to identify the risk factors involved in recurrence in cirrhotic patients.

H. pylori prevalence among cirrhotic patients with PUD

Hintersteininger[2] Emilia Korn[2] Mathias Jachs[2] Lukas Hartl[2] Benedikt Simbrunner[1] Georg Semmler[2] Michael Trauner[2] Albert Stättermayer[2] Mattias Mandorfer[1] Thomas Reiberger[1] David Bauer[2], [1]Medical University of Vienna, [2]Division of Gastroenterology and Hepatology, Department of Medicine III,Medical University of Vienna

Background: Prediction of hepatic decompensation in compensated advanced chronic liver disease (cACLD) remains challenging. We assessed whether liver and spleen stiffness measurements obtained using Supersonic Imagine 2D-shear wave elastography (SSI-LSM and SSI-SSM), alone or incorporated into composite scores, improve risk stratification for hepatic decompensation. **Methods:** We performed a prospective study including patients with cACLD, who underwent hepatic venous pressure gradient (HVPG) assessment with same-day SSI-LSM and SSI-SSM. Patients with unreliable SSI-LSM, defined as an IQR/median >30% (n = 55), were excluded. The associations between SSI-LSM, SSI-SSM, and combined elastography-based prediction models with hepatic decompensation were evaluated using Fine–Gray competing-risk regression, considering liver transplantation and death as competing events. Predictive discrimination was quantified using time-dependent C-statistics adapted for competing risks at 1 year (Y1), and clinical utility was explored by decision-curve analysis (DCA). SSI-LSPS (LSM-Spleen size-to-platelet ratio), SSI-ANTICIPATE (LSM, PLT) and SSI-LPS (LSM-platelet-SSM) were calculated according to their original publications. **Results:** The cohort comprised 142 patients. Median age was 56 years, 76% were male, median HVPG was 11 mmHg, 57.7% had CSPH, and the Y1 cumulative incidence of hepatic decompensation was 9.2%. Median SSI-LSM was 24.6 kPa (IQR 13.3–50.0), while median SSI-SSM was 50.4 kPa (IQR 30.9–66.0). 52% of patients had SSI-LSM values >21 kPa and 65% had SSI-SSM values >40 kPa.In Fine–Gray competing-risk models, higher SSI-LSM was associated with an increased risk of Y1 hepatic decompensation, with an sHR of 1.02 per 1-kPa increase (95% CI 1.01–1.03). Similarly, per IQR increase, SSI-LSPS, SSI-LPS, and SSI-ANTICIPATE were all associated with subsequent decompensation, with sHRs of 2.53 (95% CI 1.69–3.79), 3.14 (95% CI 1.79–5.52), and 3.15 (95% CI 1.78–5.58), respectively; all p values were <0.001. At Y1, time-dependent AUROCs were 0.73 for SSI-LSM, 0.67 for SSI-SSM, and 0.83 for HVPG. Compared with SSI-LSM alone, discrimination improved significantly with SSI-LPS and SSI-ANTICIPATE, both achieving an AUROC of 0.77, with p values of 0.031 and 0.016, respectively. SSI-LSPS showed the highest numerical AUROC among the elastography-based composite models at 0.81, although this did not reach statistical significance compared with SSI-LSM alone (p = 0.053). In DCA, SSI-LSPS provided the most consistent net benefit across clinically relevant thresholds, whereas SSI-ANTICIPATE showed the greatest utility at intermediate risk thresholds. **Conclusion:** SSI-2D-SWE–derived models may improve prediction of hepatic decompensation in patients with cACLD compared with SSI-LSM alone. These findings support the use of SSI-models for risk stratification, while the added value of SSI-SSM needs further investigation.

1541 | WEEKEND AND HOLIDAY ADMISSIONS ARE ASSOCIATED WITH DELAYED DIAGNOSTIC PARACENTESIS AND HIGHER IN-HOSPITAL MORTALITY AMONG PATIENTS WITH CIRRHOSIS AND ASCITES

Alexander Zhu[1] Mahdi Al Sayed Ahmad[1] Meghan Cloutier[1] Ikjot Singh[1] Eliane Atallah[1] Edward Tamale[1] Inioluwa Dada[1] Michael Toledano[1] Mousaali Nabi[1] Shadi Abuhashem[1] Andrew Georgi[1] Anthony Martinez[1], [1]University at Buffalo

Background: Timely diagnostic paracentesis is critical for hospitalized patients with cirrhosis and ascites to rule out spontaneous bacterial peritonitis. While early paracentesis is associated with reduced mortality, prior literature specifically examining the weekend effect on diagnostic paracentesis is limited primarily to administrative database analyses lacking granular clinical detail. We examined whether weekend or holiday admission was associated with delays in diagnostic paracentesis and adverse in-hospital outcomes among patients with cirrhosis and ascites. **Methods:** We conducted a retrospective cohort study of adults with cirrhosis and ascites hospitalized at a tertiary care safety-net hospital between 2023 and 2024 who underwent diagnostic paracentesis performed by interventional radiology. Weekend or holiday admission was defined as admission occurring on Friday after 2:00 PM, Saturday, Sunday, or a United States national holiday. Primary outcomes were time from first physician contact to diagnostic paracentesis and in-hospital mortality. Secondary outcomes included length of stay, acute kidney injury, and 30-day readmission. Associations with in-hospital mortality were evaluated using multivariable regression adjusting for age and MELD-Na. **Results:** Among 141 patients, 44 (31%) were admitted on a weekend or holiday and 97 (69%) on a weekday. Median time to diagnostic paracentesis was significantly longer among weekend or holiday admissions than among weekday admissions (61.5 vs 27.0 hours; p = 0.018). In-hospital mortality was higher among weekend or holiday admissions (29.5% vs 12.4%; p = 0.013). After adjustment for age and MELD-Na, weekend or holiday admission remained independently associated with higher in-hospital mortality (adjusted OR 3.91, 95% CI 1.46–10.49, p = 0.007). Length of stay, acute kidney injury, and 30-day readmission did not differ significantly between groups. **Conclusion:** Weekend or holiday admission is associated with delayed diagnostic paracentesis and higher in-hospital mortality among patients with cirrhosis and ascites, independent of liver disease severity. These findings highlight a systems-level gap in access to time-sensitive diagnostic procedures on weekends and holidays and identify an important target for quality improvement interventions.

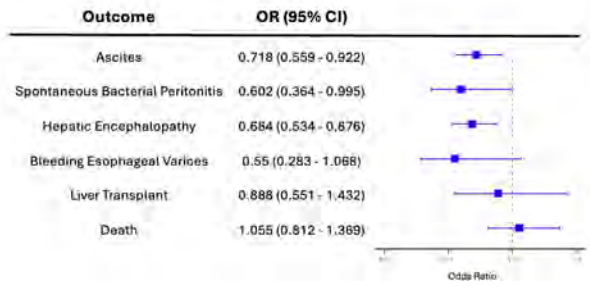
1542 | COMPARISON OF CIRRHOSIS DECOMPENSATION OUTCOMES BETWEEN TYPE 1 AND TYPE 2 DIABETES IN A PROPENSITY-MATCHED COHORT

Darya Herscovici[1] Ami Patel[1] Emilee Herringshaw[1] Chimsom Agbim[1] Deepika Devuni[1], [1]University of Massachusetts Chan Medical School



Background: Diabetes is a known risk factor for cirrhosis and has been associated with increased risk for hepatic encephalopathy (HE) in prior studies. Although Type 2 diabetes mellitus (T2DM) has been shown to be an independent risk factor for poor prognosis in patients with cirrhosis, it remains unclear whether outcomes differ between Type 1 diabetes mellitus (T1DM) and T2DM given their distinct disease pathophysiology. This study aimed to assess whether decompensation outcomes of cirrhosis differ between patients with T1DM and T2DM. **Methods:** Data was collected using a TriNetX query of the United States Collaborative Network – an electronic network of 66 healthcare organizations. Adults with a history of either T1DM or T2DM prior to cirrhosis diagnosis between 1/1/2015-1/1/2025 were identified by ICD-10 codes, excluding those with hepatocellular carcinoma and cholangiocarcinoma. Propensity score matching (PSM) was used to balance cohorts 1:1 by age, sex, race, ethnicity, cardiometabolic risk factors, complications of diabetes, A1c, BMI, insulin use, and GLP-1 use. Outcomes included ascites, spontaneous bacterial peritonitis (SBP), HE, bleeding esophageal varices (BEV), liver transplantation (LT), and death up to 10 years post diagnosis. Data were analyzed using univariate and multi-variate analyses and reported using odds ratio (OR) with 95% confidence intervals.

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Results: Before PSM, patients with T2DM and cirrhosis (n = 124,412) were more likely to be older (57.9 vs 49.5, p < 0.01), be of Hispanic or Latino ethnicity (12.9% vs 7.9%, p < 0.01), male (56.3% vs 48.9%, p < 0.01) and more likely to have comorbid hypertension (54.0% vs 34.4%, p < 0.01), hyperlipidemia (29.3% vs 14.9%, p < 0.01), coronary artery disease (16.3% vs 7.9%, < 0.01), and heart failure (16.7% vs 10.0%, p < 0.01) compared to patients with T1DM and cirrhosis (n = 610). After PSM, cirrhosis and T1DM (n = 605) was associated with a lower risk of ascites (OR 0.72, 95% CI 0.56-0.92), SBP (OR 0.60, 95% CI 0.36-0.99), HE (OR 0.68, 95% CI 0.53-0.88) and a trend toward lower incidence of BEV (OR 0.55, 95% CI 0.28-1.07) as compared to T2DM. There were no significant differences in LT (5.6% vs 6.3%, p = 0.63) and death (25.3% vs 24.3%, p = 0.69) between cohorts. **Conclusion:** Among patients with cirrhosis and diabetes, T1DM was significantly associated with decreased risk of ascites, SBP, and HE compared to T2DM. In contrast, need for LT and mortality were similar between cohorts. These findings suggest that insulin resistance, suggestive of a pro-inflammatory state, may exacerbate metabolic and inflammatory pathways involved in cirrhosis decompensation for patients with T2DM. Further studies are needed to better characterize the mechanistic differences between T1DM and T2DM in cirrhosis.

1543 | BEYOND DIURESIS: SGLT2 INHIBITORS AS A NOVEL STRATEGY FOR HYPONATREMIA AND HEPATIC COMPLICATIONS IN CIRRHOSIS

Shreya Sanghvi[1] FNU Deepali[1] Ghideon Ezaz[2], [1]Jefferson Einstein Philadelphia, [2]Jefferson Einstein Philadelpia

Background: Hyponatremia affects nearly half of cirrhotic patients with ascites and independently predicts major complications including hepatic encephalopathy, hepatorenal syndrome, and spontaneous bacterial peritonitis. Current treatments are inadequate: fluid restriction fails most patients, tolvaptan is limited by hepatotoxicity and restricted to short-term use. SGLT2 inhibitors promote electrolyte-free water clearance through osmotic diuresis We hypothesized that SGLT2i, added to standard diuretic therapy, would enhance sodium correction in cirrhotic patients with hyponatremia and ascites. **Methods:** Using the TriNetX US Collaborative Network (66 healthcare organizations), we conducted a 1:1 propensity score–matched retrospective cohort study of adults with cirrhosis, ascites, and hyponatremia (serum sodium $\leq$130 mEq/L). Patients receiving SGLT2 inhibitors plus standard diuretics were compared to those on standard diuretics alone. Those with malignant ascites, liver or kidney transplant history, type 1 diabetes, or end-stage renal disease were excluded. The primary outcome was sodium correction to $\geq$135 mEq/L within 180 days. Secondary outcomes included hepatic encephalopathy, hepatorenal syndrome, and spontaneous bacterial peritonitis. Safety outcomes included AKI, UTI, and diabetic ketoacidosis. **Results:** After propensity score matching, 800 patients were retained per cohort with well-balanced baseline characteristics. The primary outcome of sodium correction to $\geq$135 mEq/L was achieved in 67.3% of SGLT2i patients versus 63.8% of diuretic-only patients, a difference that did not reach statistical significance (RR 1.055, 95% CI 0.982–1.133; p = 0.141). However, SGLT2i use was associated with a significantly lower likelihood of persistent hyponatremia at 180 days (68.4% vs. 73.1%; HR 0.792; p < 0.001) and a reduced incidence of hepatic encephalopathy (13.0% vs. 16.8%; HR 0.691; p = 0.004). Safety outcomes also favored the SGLT2i group, with lower rates of AKI (36.0% vs. 38.4%; HR 0.843; p = 0.037) and urinary tract infection (8.8% vs. 11.0%; HR 0.706; p = 0.029), while rates of spontaneous bacterial peritonitis, hepatorenal syndrome, and diabetic ketoacidosis did not differ significantly between groups. **Conclusion:** In this propensity score–matched real-world study of cirrhotic patients with ascites and hyponatremia, SGLT2i added to standard diuretic therapy did not significantly improve sodium correction to $\geq$135 mEq/L compared to diuretics alone. However, SGLT2i use was associated with a significantly lower risk of HE and reduced likelihood of persistent hyponatremia, without a significant increase in AKI, UTI, or DKA. These exploratory findings suggest a potential hepatoprotective benefit of SGLT2i in this population and support the need for prospective trials to evaluate their role in managing hyponatremia and cirrhosis-related complications.

1544 | PROFILE OF ACUTE KIDNEY INJURY IN DECOMPENSATED CHRONIC LIVER DISEASE AND CORRELATION OF VARIOUS GRADES OF AKI WITH OUTCOME: A PROSPECTIVE OBSERVATIONAL STUDY

Ajay Jain[1] Nishant Shrivastava[2] Suchita Jain[3] Shohini Sikdar[4] Sudhanshu Yadav[4], [1]Shalby Hospital, [2]All India Institute of Medical Sciences Bhopal, [3]Sri Aurobindo Institute of Medical Sciences, [4]Shalby Institute of Gastroenterology

Background: Acute kidney injury (AKI) is a serious and frequent complication occuring in up to 20–50% of hospitalized cirrhotics and contributing to in-hospital morbidity and mortality. Traditional diagnostic thresholds based on absolute serum creatinine values underestimate renal impairment in cirrhotic patients due to reduced muscle mass, altered creatinine metabolism, and volume distribution. The revised International Club of Ascites (ICA) AKI criteria — based on dynamic changes in creatinine ($\geq$0.3 mg/dL within 48 hours or $\geq$50% increase within 7 days) — offer a more sensitive and clinically actionable classification. Hence, we aimed **to study the clinical, biochemical, and microbiological profile of AKI in hospitalized cirrhotic patients using ICA-AKI criteria, and to evaluate the correlation of AKI severity grade with in-hospital outcomes, including metabolic complications, requirement for renal replacement therapy, and mortality. Methods:** This was a prospective observational study conducted over 13 months. All cirrhotic patients admitted during the study period, those who developed AKI as defined by ICA-AKI criteria, were enrolled. Patients with pre-existing chronic kidney disease, renal calculi, or prior renal/liver transplantation were excluded. AKI was staged into Grades 1, 2, and 3 as per ICA criteria. Clinical features, etiology, comorbidities, liver severity scores (Child-Turcotte-Pugh [CTP], MELD, MELD-Na), biochemical parameters, microbiological culture results, and in-hospital outcomes (acidosis, hyperkalaemia, haemodialysis, discharge, death) were systematically recorded. **Results:** Of 314 admitted cirrhotic patients, 93 (29.6%) developed AKI. The median age was 48 years (IQR: 42.0–64.5); 87.1% were male. Of these 93; 36 patients (38.7%) had grade I; 30 (32.3%) had grade II; 27 (29.0%) had grade III AKI. The dominant etiology was alcohol (62.4%), followed by MASLD (15.1%), Hepatitis B (11.8%), Hepatitis C (5.4%), and autoimmune hepatitis (5.4%). The majority (73.1%) were CTP class C. Serum creatinine, SGOT, GGT, and albumin differed significantly across AKI grades ($p < 0.05$), with higher grades showing greater enzyme elevation and lower albumin. Ascites was significantly more prevalent in higher AKI grades ($p = 0.028$). Urine culture was positive in 50.5%; blood culture in 18.3%, ascitic fluid culture in 6.5%, sputum in 2.2%, and bile in 1.1% of patients. Overall in-hospital mortality was 8.3% in Grade 1 to 59.3% in Grade 3 ($p < 0.001$). **Conclusion:** AKI affects nearly one-third of patients hospitalized with cirrhosis and is multifactorial in origin. Infections, particularly urinary are the most common precipitating factor.The ICA-AKI staging system correlates robustly with liver disease severity. Higher AKI grades are independently associated with greater rates of metabolic acidosis, hyperkalaemia, requirement for renal replacement therapy, and markedly increased in-hospital mortality.

Key parameters by AKI grade:

Parameter	Grade 1 (n=38)	Grade 2 (n=30)	Grade 3 (n=27)
MELD Score (mean)	21.69	25.26	31.29
MELD-Na Score (mean)	24.1	27.8	32.4
Metabolic Acidosis	5.6%	26.7%	59.3%
Hyperkalaemia	8.3%	26.7%	40.7%
Haemodialysis Required	2.8%	20.0%	40.7%
In-Hospital Mortality	8.3%	33.3%	59.3%
Discharged (Survivors)	91.7%	66.7%	40.7%

All inter-grade differences for MELD/MELD-Na, acidosis, hyperkalaemia, haemodialysis, and mortality were statistically significant ($p<0.05$ to $p<0.001$).

1545 | GLUCAGON-LIKE PEPTIDE-1 RECEPTOR AGONISTS AND OUTCOMES IN PATIENTS WITH CIRRHOSIS AND PORTAL HYPERTENSION: A SYSTEMATIC REVIEW AND META-ANALYSIS

Rayan Alataa[1] Mohamed Farag[1] Abeer Qasim[1] Harish Patel[1], [1]Bronxcare Hospital

Background: Glucagon-like peptide-1 receptor agonists (GLP-1 RAs) have demonstrated profound metabolic and histologic benefits in metabolic dysfunction-associated steatohepatitis (MASH). However, their efficacy and safety in patients with established cirrhosis and portal hypertension remain incompletely characterized. Recent updates to practice guidelines highlight the urgent need to synthesize data on liver-specific outcomes in this high-risk population. This systematic review and meta-analysis evaluates the impact of GLP-1 RAs on hepatic decompensation, portal hypertension

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

events, hepatocellular carcinoma (HCC), and liver-related mortality in patients with cirrhosis. **Methods:** A comprehensive literature search of PubMed/MEDLINE, EMBASE, Cochrane Library, and Web of Science was conducted from inception to May 2026. We included cohort studies, target trial emulations, and randomized controlled trials comparing GLP-1 RA users to non-users or users of other glucose-lowering medications in patients with compensated or decompensated cirrhosis. The primary outcome was the incidence of hepatic decompensation. Secondary outcomes included portal hypertension events (ascites, variceal bleeding, hepatic encephalopathy), incident HCC, and liver-related mortality. Pooled hazard ratios (HR) with 95% confidence intervals (CI) were calculated using a DerSimonian-Laird random-effects model. Heterogeneity was assessed via the I^2 statistic. **Results:** Eighteen studies comprising approximately 2.4 million patients were included. GLP-1 RA use was associated with a significant 42% reduction in the risk of hepatic decompensation compared to control therapies (pooled HR 0.58, 95% CI 0.47–0.72, $P < 0.001$; $I^2 = 52\%$). Furthermore, GLP-1 RAs significantly reduced the incidence of specific portal hypertension events, including ascites and variceal bleeding (HR 0.55, 95% CI 0.41–0.74, $P < 0.001$). The risk of incident HCC was also significantly lower in the GLP-1 RA cohort (HR 0.61, 95% CI 0.48–0.77, $P < 0.001$). Crucially, GLP-1 RA therapy was associated with a 36% reduction in liver-related mortality (HR 0.64, 95% CI 0.51–0.80, $P < 0.001$). **Conclusion:** In patients with cirrhosis, GLP-1 RA therapy is associated with substantial reductions in hepatic decompensation, portal hypertension events, HCC, and liver-related mortality. These findings support the expanding role of GLP-1 RAs beyond metabolic control, positioning them as a potentially disease-modifying therapy for advanced chronic liver disease. Prospective trials specifically powered for portal hypertension outcomes are warranted to confirm these observational findings.

1546 | LOW-DOSE MIDODRINE ACHIEVES COMPARABLE HEMODYNAMIC BENEFIT WITH FEWER ADVERSE EVENTS COMPARED WITH STANDARD-DOSE THERAPY IN ELDERLY CIRRHOTIC PATIENTS

Vinod Arora[1] Shiv Kumar Sarin[2] Rajan Vijayaraghavan[1] Imran Khan[2], [1]Institute of Liver and Biliary Sciences, [2]ILBS

Background: Midodrine is commonly used in cirrhosis patients with hypotension and concurrent use of non-selective beta-blockers (NSBB) and in management of refractory ascites;. Administration of higher doses in advanced cirrhosis is frequently limited by supine hypertension, reflex bradycardia, and urinary retention, particularly in elderly patients. Whether lower-dose midodrine can maintain clinical efficacy with improved tolerability has is not known. We evaluated the efficacy and safety of low-dose (< 15 mg/day) versus standard-dose (15–30 mg/day) midodrine in elderly cirrhotic males. **Methods:** In this retrospective cohort analysis conducted at ILBS, New Delhi between December 2024-March 2026 we evaluated 62 cirrhotic patients age > 65 years receiving midodrine for refractory ascites were analysed; low-dose group (median dose 10 mg/day, n = 32) and standard-dose group (median dose 22.5 mg/day, n = 30). Primary endpoint was improvement in mean arterial pressure (MAP) at 30 days. Secondary endpoints included change in serum creatinine, ascites control, reduction in paracentesis requirement, incidence of adverse events (urinary retention, bradycardia, supine hypertension), treatment discontinuation, and subgroup safety analysis in elderly males aged > 65 years. **Results:** Baseline characteristics were comparable between the low-dose and standard-dose groups, including mean age was comparable (69.2 ± 3.4 vs 68.8 ± 3.7 years; p = 0.65); MELD score (18 ± 4.2 vs 19 ± 4.5; p = 0.48); MAP (62 ± 5.5 vs 63 ± 6.1 mmHg; p = 0.61), and serum creatinine (1.3 ± 0.4 vs 1.4 ± 0.5 mg/dL; p = 0.44). Most frequent etiologies of cirrhosis were MASLD (13 [41%] vs 12 [40%]) and alcohol (10 [31%] vs 9 [30%]), which were comparable (p = 0.85). Primary indications for midodrine included refractory ascites (n = 43, 69%) and HRS-AKI (n = 19, 31%). Concomitant use of non-selective beta-blockers was present in 31% (n = 10) of the low-dose cohort and 30% (n = 9) of the standard-dose cohort (p = 0.92).At end of the 30 days, improvement in MAP was similar between low-dose and standard-dose groups (+8.2 vs +9.1 mmHg; p = 0.29), as was improvement in serum creatinine (-0.18 vs -0.21 mg/dL; p = 0.52). Ascites control rates were comparable between low-dose and standard-dose groups (58% vs 61%; p = 0.74), with similar reduction in median paracentesis requirement (-2 [IQR -4 to 0] vs -3 [IQR -5 to -1] sessions/month; p = 0.18).Adverse events were significantly lower with low-dose therapy, including urinary retention (4/62 [6.5%] vs 13/62 [21.0%]; p = 0.02), supine hypertension (2/62 [3.2%] vs 8/62 [12.9%]; p = 0.04), and treatment discontinuation due to intolerance (5/62 [8.1%] vs 15/62 [24.2%]; p = 0.01). **Conclusion:** Low-dose midodrine achieved comparable hemodynamic and renal benefit with substantially fewer adverse events compared with standard-dose therapy, particularly in elderly cirrhotic males.

1547 | ENDOSCOPIC ULTRASOUND-GUIDED PORTAL PRESSURE GRADIENT MEASUREMENT (EUS-PPG) IN PATIENTS WITH NON-CIRRHOTIC PORTAL FIBROSIS (NCPF): SAFETY, FEASIBILITY, AND CORRELATION WITH HISTOLOGICAL SUBTYPE — THE EU-PORTAL STUDY

Harsh Tevethia[1] Sanda Kavitha[2] Vinod Arora[2] Chhagan Bihari[2] Guresh Kumar[2] Shiv Kumar Sarin[2], [1]Institute of Liver and Biliary Sciences(ILBS),New Delhi, [2]ILBS

Background: Portal Venous Pressure (PVP) truly reflects the pre-and peri-sinusoidal resistance to flow of blood in patients with Non-cirrhotic portal fibrosis (NCPF). Hepatic venous pressure gradient (HVPG) is classically lower in NCPF patients and does not reflect the true PVP. Splenic stiffness measurement (SSM) remains the only indirect method to assess PVP. EUS -guided PVP is reliable and using the hepatic vein pressure measurement gives PVP gradient (EUS-PPG). Although data in cirrhotic patients has been encouraging, whether EUS-PPG is safe in NCPF patients who have disproportionately large spleen and collaterals, and whether it correlates with histological subtypes that define this condition has not been studied. We designed this study to evaluate the safety, technical feasibility, and clinical utility of EUS-PPG in patients with NCPF. **Methods:** Twenty-one consecutive patients with NCPF underwent EUS-PPG measurement between January 2025 and March 2026. Each patient had baseline clinical, biochemical data recorded alongside HVPG measurement, liver biopsy with histopathological subtyping, and a detailed assessment of technical success and procedural safety. PPG was measured with a 25G EUS FNA needle, transducer and patient monitor with pressure module. The intrahepatic left portal vein as well as left/middle hepatic vein was punctured and a total of 3 readings were taken. The objectives included correlation with HVPG, variceal bleed,Portal vein pressure(PVP) with SSM, safety, and histological subtypes in NCPF. **Results:** The study population had predominant males (71.4%), mean age 32.01 ± 4.2 years, mean HVPG 7.02 ± 2.2 mmHg, liver stiffness measurement (LSM) 10.06 ± 1.78kPa and Splenic stiffness measurement (SSM) 77.71 ± 14.2kPa. Mean portal vein diameter was 13.70 ± 2.06, EUS guided direct PVP was 37.33 ± 9.28 mmHg and PPG was 16.02 ± 2.70 mmHg. Clinically significant portal hypertension (HVPG > 10 mmHg) did not corelate with PPG (r = 0.083). Patients with a history of variceal bleeding (n = 9, 42.9%) had significantly higher PVP (42.89 vs 34.92 mmHg, p < 0.001) and PPG (18.49 vs 14.18 mmHg, p < 0.001) compared to non-bleeders. PVP corelated with SSM (r = 0.87). SSM values were significantly higher in bleeders as compared to the non bleeders(93.4 ± 5.8 vs 64.9 ± 8.0 kpa p = 0.00) clearly reflecting higher PVP as a predictor. On liver biopsy, incomplete septal cirrhosis was associated with the higher PPG values than obliterative porto-venopathy and nodular regenerative hyperplasia subtypes (18.51 vs 13.87 mmHg, p < 0.001), suggesting that EUS-PPG can detect haemodynamic differences across histological subtypes.Technical success was 100% with no major post-procedure complication. **Conclusion:** EUS-PPG is safe and helpful in segregating NCPF patients with high risk of bleeding. While HVPG has little clinical relevance , PVP corelates strongly with SSM, portal hypertensive complications and histopathological subtype

1548 | A DIVERSE BILE ACID POOL PREDICTS 90-DAY KIDNEY RECOVERY IN HOSPITALIZED PATIENTS WITH DECOMPENSATED CIRRHOSIS AND ACUTE KIDNEY INJURY

Giuseppe Cullaro Brendan Blackburn[1] Elizabeth Verna[2], [1]Columbia University, [2]Columbia University Medical Center

Background: Acute kidney injury (AKI) is common in hospitalized patients with cirrhosis and recovery is heterogeneous. AKI and its recovery in cirrhosis are the cumulative result of multiple insults, of which the circulating bile acid (BA) pool is one. We profiled the BA pool by both its size and its composition and tested the association of each with 90-day AKI recovery. **Methods:** We performed targeted LC-MS quantification of 23 BAs (e.g., conjugated, unconjugated, sulfated) in paired protein-bound and protein-depleted serum fractions from the first specimen per hospitalization in a two center prospective cohort of patients with decompensated cirrhosis. AKI stage was assigned by KDIGO using outpatient baseline creatinine (bCr) and serum creatinine (sCr) at time of specimen collection. The primary outcome was 90-day AKI recovery (AKI-R), defined as a reduction sCr to within 150% of bCr. A *diversification score* was the mean of z-scored proportions of secondary BAs, UDCA-pathway species, and sulfated metabolites in the combined bound + unbound pool. Logistic regression for recovery was adjusted for total bilirubin (TB) and AKI stage at specimen collection. A 2×2 model partitioned the AKI cohort at the medians of TB and diversification, with the worst-prognosis cell (high-TB / low-div) as the reference. **Results:** Among 142 patients with 152 unique hospitalizations, 7 had no AKI, 66 had Stage 1, and 79 had ≥ Stage 2 AKI. Median age was 55; 43% female, 22% MASH, 41% ALD. albumin was 3.3 g/dL, INR 2.1, bCr 0.9 mg/dL, sCr at draw 1.7.Median total Bilirubin (TB) was 6.0 mg/dL. The total serum BA pool (bound + unbound) correlated with TB ($\rho = 0.37$, $p < 0.001$). Median pool size was 140,100 / 167,000 / 136,100 nM and median diversification was −0.32 / −0.24 / −0.14 in no AKI / Stage 1 / ≥ Stage 2.After adjusting for TB and AKI stage, diversification was associated with AKI recovery (adjusted OR 2.17 per unit, 95% CI 1.20–4.08). Driving species included the microbial-derived secondary BAs HDCA (aOR 1.22, $p = 0.04$) and TLCA (aOR 1.25, $p = 0.05$); non-diverse G-CDCA (primary) trended inversely (aOR 0.90, $p = 0.09$). In the 2×2 model (TB cut-point 6.0 mg/dL, diversification cut-point −0.18, adjusted for AKI stage), high-TB / low-diversification carried the lowest recovery (12%); relative to this reference, recovery rose to 26% in low-TB / low-div (aOR 3.23, 0.87–15.76), 24% in low-TB / high-div (aOR 2.64, 0.60–14.15), and 30% in high-TB / high-div (aOR 4.41, 1.19–21.75; $p = 0.040$) — high diversification rescued recovery even among bilirubin-high patients. **Conclusion:** A diverse circulating BA pool predicts 90-day kidney recovery in hospitalized patients with decompensated cirrhosis and AKI, independent of TB level and AKI severity — even among the most cholestatic patients. These data support the serum BA pool not only as a targetable entity to promote AKI recovery, but also as a measurable index of disease severity in hospitalized decompensated cirrhosis.

1549 | ASSESSMENT OF DISCORDANCE OF GLYCEMIC INDICATORS IN CIRRHOSIS

Norah Liang[1] Celeste Thomas[1] Mary Rinella[1] Raghavendra Mirmira[1] Alan Hutchison[1], [1]The University of Chicago

Background: Background: and Aims: Cirrhosis contributes to disruptions in glucose metabolism. As a result, traditional approaches to diagnosing and managing diabetes are often discordant and not reflective of dysglycemia. This complicates screening and surveillance of diabetes, leading to under diagnosis and missed treatment opportunities. We aimed to identify factors predictive of diabetes biomarker concordance in individuals with cirrhosis. **Methods: Methods::** We identified subjects in the National Health And Nutrition Examination Survey (NHANES) database cohort from

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

2017-2020 with liver elastography measurements. Additionally, we enrolled individuals with cirrhosis without diabetes under evaluation for liver transplantation. We continuously collected subject laboratory evaluations across both inpatient hospitalizations and outpatient encounters. We developed multivariable equations using fasting plasma glucose (FPG), hemoglobin A1c (HbA1c), serum albumin, creatinine, total bilirubin, hemoglobin, sodium, and in the prospective data only, mean cellular volume, INR, fructosamine, and 1,5-anhydroglucitol. **Results: Results::** In the NHANES database, multivariable linear regression confirmed fasting plasma glucose significantly predicted hemoglobin A1c (HbA1c) globally (β = 0.025, $p < 0.001$) and in advanced liver tissue stiffness subsets (kPa $\geq$ 15: β = 0.021, $p < 0.001$). However, covariance profiles shifted when stratified by distinct elastography bands (5-10 kPa: R^2 = 0.75 vs. 15-20 kPa: R^2 = 0.45; Figures A, B). In the institutional validation cohort (N = 66 observations), multi-imputation covariance maps were generated across 10 iterations (Figure C). Clinical setting time interval matching demonstrates an environmental decoupling in biomarker tracking (Figure D). Inpatient encounters (n = 10) preserved a positive trending profile between FPG and HbA1c (R^2 = 0.38, p = 0.056), whereas outpatient encounters (n = 56) had a negative correlation (R^2 = 0.13, p = 0.0064). In multivariable Multiple Imputation by Chained Equations regression to account for missing data, fasting plasma glucose lost all independent predictive value for HbA1c (β = 0.002, p = 0.297), while fructosamine emerged as a significant but weak metabolic predictor (β = 0.004, p = 0.005). **Conclusion: Conclusion::** The NHANES data stratifying by liver stiffness kPa showed greater concordance of HbA1c and FPG than the prospective cohort of individuals with cirrhosis without diabetes undergoing liver transplant evaluation. This suggests that Hba1c-FPG discordance may be worse in decompensated cirrhosis that is not captured by liver stiffness measurements. Future work will need to better risk-stratify individuals with cirrhosis who may have discordance between their HbA1c and FPG measurements.

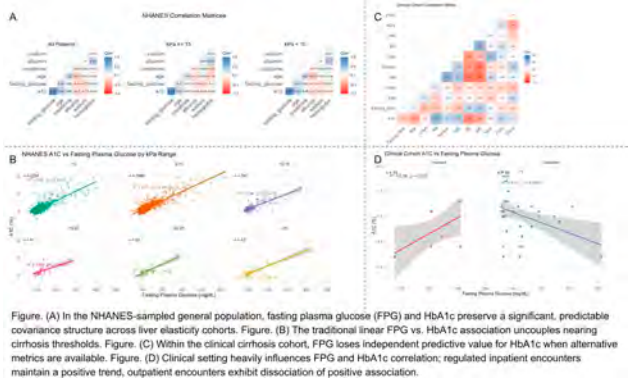

Figure. (A) In the NHANES-sampled general population, fasting plasma glucose (FPG) and HbA1c preserve a significant, predictable covariance structure across liver elasticity cohorts. Figure. (B) The traditional linear FPG vs. HbA1c association uncouples nearing cirrhosis thresholds. Figure. (C) Within the clinical cirrhosis cohort, FPG loses independent predictive value for HbA1c when alternative metrics are available. Figure. (D) Clinical setting heavily influences FPG and HbA1c correlation; regulated inpatient encounters maintain a positive trend, outpatient encounters exhibit dissociation of positive association.

1550 | EARLY TIPS VS EXTENDED-INTERVAL PREEMPTIVE TIPS FOR ESOPHAGEAL VARICEAL BLEEDING: A MULTI-INSTITUTIONAL PROPENSITY-MATCHED ANALYSIS FROM THE TRINETX RESEARCH NETWORK

Avleen Kaur[1] Savio John[2], [1]Upstate Medical University, [2]Suny Upstate Medical University

Background: Preemptive TIPS (pTIPS) within 72 hours of variceal bleeding improves survival in high-risk cirrhosis, yet fewer than 10% of eligible patients receive pTIPS within this window due to logistical barriers. This multi-institutional study analyzes outcomes and mortality after extending the pTIPS window beyond 72 hours. **Methods:** Retrospective cohort study using TriNetX (44 HCOs). Adults with cirrhosis undergoing TIPS within

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

28 days of variceal bleeding were stratified into early (≤72h) and extended-interval (days 4–28) cohorts. 1:1 propensity score matching adjusted for age, MELD variables, dialysis, hepatic encephalopathy, ascites, diabetes, CKD, vasopressors, critical care needs, and pleural effusion. Primary outcome: 1-year all-cause mortality. Secondary outcomes included decompensation events. **Results:** A total of 547 patients were included: 295 in the early TIPS group and 252 in the extended-interval TIPS group, with follow-up of 175.8 and 172.6 person-years, respectively. The mean age was 53.5 years across both cohorts; 77% were White and 69% were male. Beta-blocker utilization was lower among early TIPS recipients (49% vs. 78%). Median MELD-Na scores were similar between groups (16 [11–21] vs. 16 [12–20]). Vasopressor use and critical care utilization were comparable. Prior to matching, the extended-interval TIPS cohort demonstrated higher prevalence of ascites (76.19% vs. 47.46%, p = 0.01), hepatic failure (61.11% vs. 45.76%, p = 0.01), CKD (20.24% vs. 8.81%, p = 0.01), and carvedilol use (28.18% vs. 14.24%, p = 0.01).Following 1:1 propensity score matching, 187 pairs were evaluated with balanced baseline characteristics (SMD < 0.2). One-year mortality trended higher in the early TIPS cohort (30.48% vs. 23.52%; OR 1.43, 95% CI 0.83–2.07; p = 0.13), similarly for 2-year mortality (33.71% vs. 25.71%; OR 1.47, 95% CI 0.93–2.33; p = 0.10); however, neither achieved statistical significance. Hepatic encephalopathy was similar between groups (21.25% vs. 28.09%; OR 0.69, 95% CI 0.34–1.40; p = 0.30). No episodes of recurrent variceal bleeding were recorded in either cohort following matching Table 1. **Conclusion:** In this extended-interval preemptive TIPS analysis, delayed TIPS placement demonstrated comparable one-year mortality relative to early TIPS, aligning with findings reported by Dunne et al. (2023)[1] and Dong et al. (2024)[2]. Study limitations include reliance on administrative coding and the lack of detailed clinical variables such as Child-Pugh score. Prospective studies are needed for confirmation. Dunne et al. Effect of time to pre-emptive transjugular intrahepatic portosystemic shunt on patient outcome, a UK multicentre cohort study. *Aliment Pharmacol Ther.* 2023. Dong et al.The time window for pre-emptive transjugular intrahepatic portosystemic shunt could be extended to 5 days. *Heliyon.* 2024 Feb 15.

Clinical Outcomes After Propensity Matching

Outcome	TIPS in 3 Days	TIPS in 28 Days	Odds Ratio (95% CI)	p-value
One-Year Mortality (n=187 vs 187)	30.48%	23.52%	1.43 (0.83, 2.07)	0.13
2-Year Mortality (n=175 vs 175)	33.71%	25.71%	1.47 (0.93, 2.33)	0.10
Variceal Bleeding (n=186 vs 186)	0%	0%	—	—

1551 | ASSOCIATIONS BETWEEN CT-DERIVED ORGAN AND MUSCLE MORPHOLOGY AND CONTINUOUS GLYCEMIC PATTERNS IN CIRRHOSIS WITHOUT DIABETES

Yousef Husein[1] Alan Hutchison[1] Mary Rinella[1] Raghavendra Mirmira[1] Celeste Thomas[1], [1]The University of Chicago

Background: Cirrhosis is associated with changes in insulin resistance, altered body composition, and an increased risk of hypoglycemia and hyperglycemia. Although glucose dysregulation and body composition changes in cirrhosis have been studied, the relationship between quantitative CT-derived organ and muscle morphology and continuous glycemic patterns in cirrhosis remains poorly understood. **Methods:** Continuous glucose monitoring (CGM; Abbott Libre Pro) and CT scans from forty-six individuals with cirrhosis without diabetes were collected. TotalSegmentator, a deep learning-based tool, was used to segment organs and muscles from CT scans and to compute volume (mm3) and intensity (Hounsfield units) values for each scan. Percentages were calculated to quantify the proportion of time each patient spent in hypoglycemia (< 70 mg/dL), normoglycemia (70–139 mg/dL), mild hyperglycemia (140–179 mg/dL), and hyperglycemia (≥ 180 mg/dL). CT-derived volumes and attenuation measurements, along with CGM-derived glycemic metrics relationships, were analyzed. **Results:** Greater liver volume (normalized by height) was associated with less time in normoglycemia (< 70 mg/dL or > 179 mg/dL; Pearson's r = -0.51, p = 0.02), and more time in time in hypoglycemia (< 70 mg/dL; r = 0.52, p = 0.02) . Greater gluteus maximus volume (normalized by height) was associated with greater time in normoglycemia (> 70 mg/dL and < 180 mg/dL; r = 0.92, p = 0.001). A decrease in pancreatic attenuation (corresponding to higher pancreatic fat content) was associated with more time in mild hyperglycemia (≥ 140 mg/dL, < 180 mg/dL; r = -0.58, p = 0.02) and hyperglycemia (≥ 180; r = -0.49, p = 0.05). **Conclusion:** In individuals with cirrhosis without diabetes, CT-derived liver and gluteus maximus muscle volumes showed an association with glucose levels. In metabolic dysfunction-associated liver disease hepatomegaly is associated with insulin resistance - we show this here in cirrhosis as well. Additionally, pancreatic fat content shows a significant relationship with hyperglycemia, confirming known pathophysiology previously less described in cirrhosis. These results suggest that conducting a CT scan body morphology analysis can help identify those at risk of glycemic dysregulation.

1552 | COMPARATIVE EFFECTIVENESS OF SPLENIC-PROBE VERSUS STANDARD LIVER-PROBE TRANSIENT ELASTOGRAPHY FOR THE PREDICTION OF CLINICAL DECOMPENSATION IN PATIENTS WITH CIRRHOSIS

Sanda Kavitha[1] Sudhir Verma[2] Ishank Johri[3] Srajit Singh[3] Vinod Arora[3] Rajan Vijayaraghavan[3] Satender Pal Singh[3] Sarthak Chanana[3] Ananthu Naryanan[3] Shiv Kumar Sarin[3], [1]Institute Liver and Biliary Sciences, [2]King George Medical University, [3]Institute of Liver and Biliary Sciences

Background: Non-Invasive assessment of portal hypertension is evolving. Utility of Standard liver-probe (75MHz) liver stiffness measurement (LSM) plateaus in advanced cirrhosis due to an artificial ceiling effect failing to reflect portal hypertension dynamics. As clinical decompensation is primarily driven by rapid rise in portal pressure, there is need for a higher stiffness measurement tool. We evaluated the performance of splenic-probe LSM against standard liver-probe LSM and traditional biomarkers for predicting clinical decompensation **Methods:** We conducted a retrospective cohort analysis of 181 patients with cirrhosis. Primary composite decompensation was defined as the presence of ascites , Hepatic encephalopathy (HE), clinical jaundice (Bilirubin > 2mg/dl), or Upper gastrointestinal bleeding (UGIB). Diagnostic performance was evaluated using Receiver Operating Characteristic (ROC) curve analysis, and Area Under the Curve (AUC) values were compared using DeLong's test. Optimal cutoffs were derived via the Youden Index **Results:** The analysed cohort consisted of 181 patients with a mean age of 53.4 + 8.2 years, with a male predominance (72%), with most common etiology associated with Alcohol-Associated Liver Disease (AALD -54%) and Metabolic Dysfunction-Associated Steatohepatitis (MASH- 36%). When evaluated for its global ability to predict the primary composite endpoint Splenic-Probe LSM demonstrated superior with AUC of 0.89 (95% CI: 0.84-0.93), outperforming total bilirubin (AUC 0.79), standard liver-probe LSM (AUC 0.74), and platelet Count (AUC 0.71).The optimal LSM cutoff was in with splenic probe 81.5 kPa (sensitivity -88.2% , specificity-82.4%), whereas the liver probe exhibited low specificity (58.1%) due to capped values. For isolated secondary endpoints, the splenic probe performed better particularly for development of moderate-severe ascites (0.91vs. 0.72) and UGIB (0.87 vs. 0.70). **Conclusion:** In cirrhosis, a higher frequency splenic-probe elastography was found superior compared to conventional liver probe in assessment of risk of acute decompensation . As the splenic probe elastography provides more accurate data for prediction of portal hypertension driven complications , it is recommended in patients with LSM 70 or above in cirrhosis.

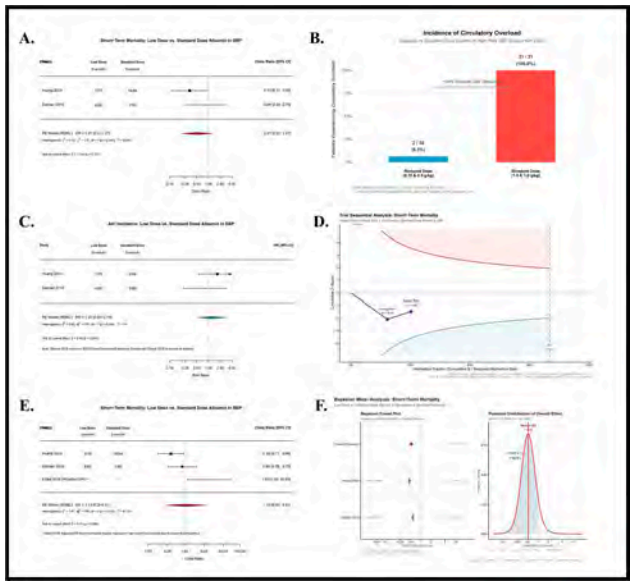
1553 | RESTRICTED VERSUS STANDARD ALBUMIN DOSING FOR SPONTANEOUS BACTERIAL PERITONITIS: A SYSTEMATIC REVIEW, META-ANALYSIS, TRIAL SEQUENTIAL ANALYSIS, AND BAYESIAN SYNTHESIS



Sri Ram Charan Gundapaneni[1] Sampurna Sengupta[2] Sunanda Chagam Reddy[3] Muhammad Zuhaz Azeem[4] Reshma Agarwal[5] Ashwin Rumalla[1] Sameer Kumar

Majety[6], [1]UCF/HCA Florida Ocala, [2]Kamineni Academy of Medical Sciences and Research Centre, [3]Mediciti Institute of Medical Sciences, [4]National University of Sciences and Technology, [5]ChinaMedical University, [6]Xiamen University School of Medicine

Background: Albumin is the standard of care in spontaneous bacterial peritonitis (SBP) to prevent renal dysfunction and reduce mortality, but standard weight-based dosing may increase volume-related complications. Evidence supporting lower or restricted dosing remains limited. **Methods:** PubMed, Ovid, and Embase were searched for studies evaluating restricted or reduced albumin dosing compared with standard albumin dosing in adults with SBP. Pooling was performed when at least two studies reported comparable outcomes. Random-effects meta-analyses were used for acute kidney injury (AKI), short-term mortality, and circulatory overload. Trial sequential analysis (TSA) and Bayesian meta-analysis were performed for mortality. **Results:** Seven studies were included. Four studies contributed to quantitative or sensitivity analyses, while three were retained for narrative synthesis because they were not suitable for pooling. Among the narrative studies, one non-comparative cohort lacked a dose comparator, one mechanistic study primarily reported inflammatory, hemodynamic, and renal Doppler outcomes rather than clinical endpoints, and one large real-world utilization study highlighted gaps in albumin adherence, access, and institutional delivery. Together, they highlight heterogeneity in albumin protocols, outcome definitions, adherence, and access. In pooled prospective cohorts, restricted dosing was not associated with a significant difference in AKI compared with standard dosing (RR 1.22, 95% CI 0.53-2.78; $p = 0.644$; $I^2 = 0\%$), although AKI definitions differed. Short-term mortality favored restricted dosing but did not reach statistical significance (OR 0.51, 95% CI 0.20-1.27; $p = 0.147$; $I^2 = 26.8\%$). TSA estimated a required information size of 840 patients; available prospective-cohort data represented less than 30% of this threshold, with the final cumulative Z score remaining within monitoring boundaries, indicating insufficient evidence for a definitive frequentist conclusion. Bayesian synthesis supported the same direction of effect, with a posterior median OR of 0.53 and a 90.5% posterior probability that restricted dosing reduced short-term mortality. For safety, one standalone study reported markedly lower circulatory overload with reduced dosing compared with standard weight-based albumin (2/32 [6.2%] vs 31/31 [100%]; RR 0.077, 95% CI 0.023-0.254; $p < 0.0001$), suggesting a strong but preliminary safety signal. **Conclusion:** Across seven studies, restricted albumin dosing in SBP showed no clear increase in AKI, a consistent but inconclusive signal toward lower short-term mortality, and lower circulatory overload in standalone safety data. The evidence remains small, heterogeneous, and underpowered. Adequately powered randomized trials are needed to define an albumin strategy that balances renal protection, survival, and volume-related safety.

1554 | DISCORDANCE BETWEEN ICD CODES, LACTULOSE/RIFAXIMIN EXPOSURE, AND NOTE-DERIVED DOCUMENTATION FOR HEPATIC ENCEPHALOPATHY: A MIMIC-IV STUDY

Thanathip Suenghataiphorn[1] Narathorn Kulthamrongsri[2] Pojsakorn Danpanichkul[3], [1]Yale/Griffin Hospital, [2]University of Hawaii, [3]Texas Tech University Health Sciences Center

Background: Hepatic encephalopathy is commonly identified in observational studies using administrative diagnosis codes, but coding may incompletely capture clinically documented disease. Medication-based definitions using lactulose or rifaximin may improve sensitivity but can capture non-HE indications or treatment exposure without explicit diagnostic attribution. We evaluated overlap and discordance among ICD codes, medication exposure, and discharge-summary-derived documentation for hepatic encephalopathy in MIMIC-IV. **Methods:** We performed a retrospective cohort study of adult MIMIC-IV hospitalizations with cirrhosis or

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

suspected chronic liver disease and available clinical data. Hepatic encephalopathy was identified using three approaches: ICD diagnosis codes for hepatic encephalopathy or hepatic coma; medication exposure defined by lactulose and/or rifaximin use during hospitalization or at discharge; and note-derived NLP identifying discharge-summary documentation of hepatic encephalopathy, liver-attributed altered mental status, hyperammonemia-related encephalopathy, asterixis, or lactulose/rifaximin use specifically attributed to hepatic encephalopathy. We quantified overlap across definitions and compared ICU admission, mechanical ventilation, hospital length of stay, in-hospital mortality, discharge disposition, and 30-day readmission across discordant groups. **Results:** Among 49,460 eligible hospitalizations, 34,122 (69.0%) met at least one hepatic encephalopathy definition. ICD codes identified 25,929 admissions (52.4%), medication exposure identified 15,415 (31.2%), and note-derived extraction identified 12,083 (24.4%). Only 5,404 admissions, representing 15.8% of HE-positive admissions, were positive by all three methods. Among note-derived HE admissions, 4,869 (40.3%) lacked an HE ICD code. ICD-negative/note-positive admissions included 2,658 medication-positive and 2,211 medication-negative admissions. Patients who were ICD-negative, medication-positive, and note-positive had median MELD-Na proxy 22.8, ICU admission rate 23.8%, mechanical ventilation rate 8.9%, median length of stay 5 days, in-hospital mortality 6.3%, and 30-day readmission 33.5%. **Conclusion:** ICD codes, lactulose/rifaximin exposure, and discharge-summary-derived documentation identified substantially overlapping but discordant hepatic encephalopathy populations. ICD-only definitions may miss clinically documented HE, while medication-only definitions may capture treatment exposure without explicit HE attribution. Multimodal phenotyping may improve cohort construction for hepatic encephalopathy research using electronic health record data.

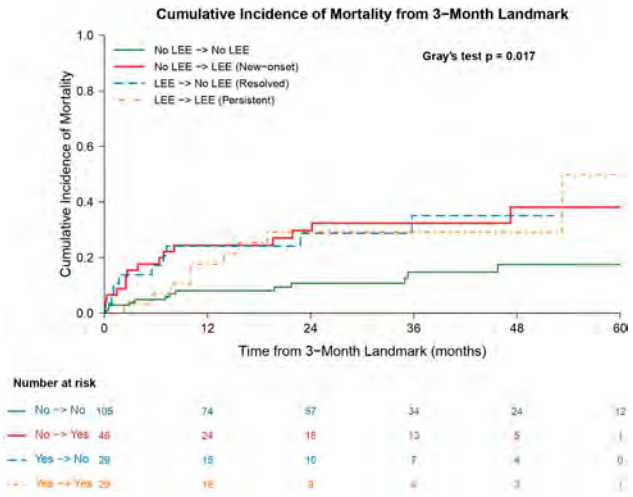
1555 | PREVALENCE, RISK FACTORS, AND CLINICAL IMPACT OF LOWER EXTREMITY EDEMA AFTER TIPS: AN ALTA GROUP STUDY



Tsung-Chieh Yang[1] K. Pallav Kolli[1] Justin Boike[2] Mike Fallon[3] Bartley Thornburg[2] Lisa VanWagner[4] Elizabeth Verna[5] Jennifer Lai[1], [1]University of California-San Francisco, San Francisco, California, USA, [2]Northwestern University Feinberg School of Medicine, Chicago, Illinois, USA, [3]University of Arizona College of Medicine-Phoenix, Phoenix, Arizona, USA, [4]University of Texas Southwestern Medical Center, Dallas, Texas, USA, [5]Columbia University Irving Medical Center, New York, New York, USA

Background: Lower extremity edema (LEE) is a common yet underrecognized complication following transjugular intrahepatic portosystemic shunt (TIPS) placement. We aimed to characterize the prevalence, risk factors, and prognostic significance of post-TIPS LEE trajectories, including new-onset, persistent, and resolved LEE. **Methods:** Adults with portal hypertension undergoing TIPS placement between July 2019 and January 2025 were prospectively enrolled at 13 U.S. centers in the Advancing Liver Therapeutic Approaches (ALTA) Study Group. Among 852 patients, 489 with documented baseline LEE status were included after excluding TIPS failure, undeployed TIPS, poor data quality, and 302 patients without baseline physical examination documentation of LEE status. LEE status was recorded as present or absent at baseline and protocolized 1-, 3-, 6-, and 12-month follow-up visits. Patients surviving with evaluable 3-month LEE data constituted the M3 landmark cohort for mortality analyses. Primary outcomes were LEE development and resolution; the secondary outcome was all-cause mortality from M3 by LEE trajectory. Outcomes were analyzed using competing risk regression, with death, liver transplantation (LT), and TIPS occlusion as competing events for LEE outcomes, and LT and TIPS occlusion for mortality. **Results:** Among 489 patients, median age was 58 years, 59.3% were male, median MELD-Na was 15, and 45.2% underwent TIPS for ascites. At baseline, 119 (24.3%) had LEE. By 12 months, new-onset LEE developed in 29.2% without baseline LEE, while LEE resolved in 50.7% with baseline LEE. In multivariable analyses, higher pre-TIPS right atrial pressure (RAP) (OR 1.12, 95% CI 1.02–1.22; p = 0.016), higher MELD-Na score (OR 1.09, 95% CI 1.01–1.19; p = 0.030), and TIPS for ascites (OR 2.39, 95% CI 1.13–5.12; p = 0.024) were independently associated with new-onset LEE, whereas lower MELD-Na score predicted LEE resolution (OR 0.91, 95% CI 0.83–0.99; p = 0.043). Mortality differed across the four LEE trajectory groups (Gray's test, p = 0.017; Figure 1). Compared with patients who never developed LEE, those with new-onset LEE had higher mortality from 12 months (24.3% vs. 8.1%; p = 0.021) through 60 months (38.1% vs. 17.5%; p = 0.042). In multivariable competing risk models, new-onset LEE (sHR 2.23, 95% CI 1.05–4.74; p = 0.036), age, and MELD-Na score were independently associated with mortality. **Conclusion:** New-onset LEE is common and independently associated with increased post-TIPS mortality. Higher pre-TIPS RAP, MELD-Na score, and ascites indication identify patients at greatest risk for LEE development, while lower MELD-Na score predicts LEE resolution. These findings support more rigorous pre-procedural cardiovascular assessment, including echocardiography with strain imaging, and cardiology

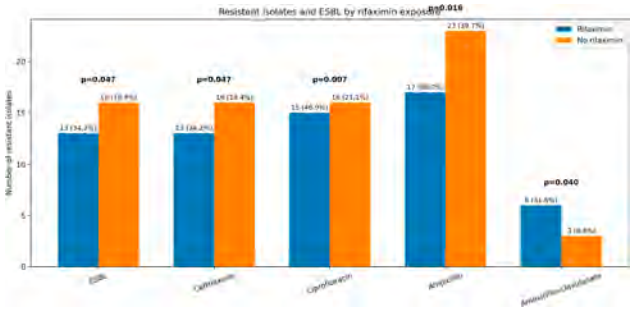
1556 | SHORT-COURSE TERLIPRESSIN IS AS EFFECTIVE AND SAFE AS STANDARD THERAPY FOR ACUTE VARICEAL BLEEDING: A META-ANALYSIS OF RANDOMIZED TRIAL

Erick Brandon[1] Jasper Polloso[2], [1]St. Luke's Medical Center Quezon City, [2]St. Luke's Medical Center

Background: Terlipressin is a key component of acute variceal bleeding (AVB) management, traditionally continued for 2–5 days after achieving endoscopic hemostasis. However, the optimal duration of therapy remains uncertain. Earlier randomized trials suggested that shorter courses may be sufficient, but previous meta-analyses did not include newer high-quality trials and lacked detailed safety assessment. This updated meta-analysis evaluates the efficacy and safety of short-course (<48 hours) versus standard-course (>72 hours) terlipressin therapy following endoscopic variceal ligation. **Methods:** A systematic search identified randomized controlled trials comparing short- and standard-course terlipressin in adults with cirrhosis and AVB. Five RCTs (n = 569) met inclusion criteria. Pooled risk ratios (RRs) were calculated using a random-effects model. Primary outcomes were 5-day rebleeding and mortality; secondary outcomes included overall and category-specific adverse events. **Results:** Short-course terlipressin demonstrated no significant difference in 5-day rebleeding compared with standard therapy (RR 1.03; 95% CI 0.59–1.80; p = 0.90). Long-term mortality and rebleeding at 30–42 days were also similar between groups. Overall adverse events were significantly lower in the short-course arm (RR 0.71; 95% CI 0.60–0.83; p = 0.01), though subgroup analyses of cardiovascular, gastrointestinal, and infection-related events did not reach significance due to low event counts. **Conclusion:** Short-course terlipressin (?48 hours) is as effective as standard-course therapy (48–120 hours) for preventing rebleeding and mortality in acute variceal bleeding and is associated with a lower overall risk of adverse events. These findings support shorter terlipressin regimens as a safe and potentially more cost-effective approach. Larger, multicenter, double-blind trials are warranted to confirm non-inferiority and clarify safety outcomes.

Disclosures: Erick Brandon:Nothing to Disclose, Jasper Polloso:Nothing to Disclose.

1557 | LONG-TERM RIFAXIMIN USE IS ASSOCIATED WITH INCREASED ANTIMICROBIAL RESISTANCE AND ESBL-PRODUCING ORGANISMS IN DECOMPENSATED CIRRHOSIS PATIENTS WITH FIRST-EPISODE SPONTANEOUS BACTERIAL PERITONITIS



Issac Vargas Olmos[1] Graciela Castro-Narro[2], [1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador,

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

[2]Hospital Médica Sur, Ciudad de México. Instituto Nacional de Ciencias Médicas y Nutrición

Background: Bacterial infections are a leading cause of mortality in patients with cirrhosis, with spontaneous bacterial peritonitis (SBP) representing one of the most severe complications. Rifaximin is widely used for hepatic encephalopathy; however, its potential impact on antimicrobial resistance remains uncertain. We aimed to evaluate the association between long-term rifaximin use and antimicrobial resistance, including extended-spectrum beta-lactamase (ESBL)-producing organisms, in patients with decompensated cirrhosis and a first episode of SBP. **Methods:** We conducted a retrospective study including cirrhotic patients with a first episode of SBP between 2016 and 2022. Inclusion criteria were diagnostic paracentesis within 24 hours of admission and no antibiotic exposure within the previous 90 days. Patients were stratified in two groups according to long-term rifaximin use ($\geq$30 days). Descriptive statistics were summarized using measures of central tendency and proportions. Group comparisons were performed using cross-tabulations with chi-square or Fisher's exact tests, as appropriate. Subgroup analyses were conducted according to cirrhosis etiology. **Results:** A total of 140 patients were included, of whom 39 (27.9%) had long-term rifaximin exposure and 101 (72.1%) did not. Baseline clinical characteristics were comparable between groups. The distribution of causative organisms was similar. Escherichia coli was the most frequent isolate in both groups (51.3% vs 52.5%), followed by Streptococcus spp. (23.1% vs 21.8%), Klebsiella spp. (10.3% vs 7.9%), Enterococcus spp. (2.6% vs 2.0%), other Gram- positive organisms (5.1% vs 4.0%), and other Gram-negative organisms (7.7% vs 11.9%). In contrast, antimicrobial resistance was higher among patients receiving rifaximin. ESBL-producing organisms were more frequent (34.2% vs 18.4%, p = 0.047), as was resistance to ceftriaxone (34.2% vs 18.4%, p = 0.047). Increased resistance was also observed for ciprofloxacin (46.9% vs 21.1%, p = 0.007), ampicillin (68.0% vs 39.7%, p = 0.016), and amoxicillin-clavulanate (31.6% vs 8.6%, p = 0.040). Subgroup analysis by cirrhosis etiology showed that this association was most pronounced in patients with cryptogenic cirrhosis (p = 0.048). **Conclusion:** Long-term rifaximin use is associated with increased antimicrobial resistance and ESBL-producing organisms in patients with decompensated cirrhosis and first-episode SBP, without changes in pathogen distribution. These findings support a more selective use of rifaximin and highlight the importance of balancing its clinical benefits against the potential risk of promoting antimicrobial resistance

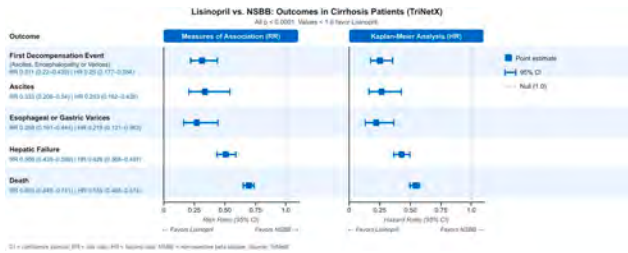
1558 | COMPARATIVE EFFECTIVENESS OF CIPROFLOXACIN VS TRIMETHOPRIM-SULFAMETHOXAZOLE FOR SECONDARY SBP PROPHYLAXIS IN CIRRHOSIS WITH ASCITES: A PROPENSITY-MATCHED NATIONAL COHORT STUDY

Delano Carty[1] Dilcia Maldonado[1] FNU Deepali[1] Cameron Gill[1] Ghideon Ezaz[1], [1]Jefferson Einstein Philadelphia

Background: Secondary prophylaxis for spontaneous bacterial peritonitis (SBP) is standard of care in cirrhosis; however, the optimal antibiotic regimen remains uncertain. Fluoroquinolones are widely used but concerns regarding antimicrobial resistance and adverse outcomes persist and comparative effectiveness data with alternative regimens are limited. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network (2010–2026). Adult patients ($\geq$18 years) with cirrhosis, ascites and prior SBP were identified.Patients were stratified by exposure to ciprofloxacin or trimethoprim-sulfamethoxazole, with the index date defined as first prescription. Patients were required to have no prior exposure to the comparator antibiotic before index or any recent antibiotic exposure, secondary peritonitis, ESRD/CKD.Propensity score matching (1:1) using a nearest-neighbor algorithm with a caliper of 0.1 was performed to adjust for demographics, markers of liver disease severity(MELD score), hepatic encephalopathy, varices, comorbidities (diabetes melitus, chronic kidney disease and or ESRD), prior infections, prior antibiotic exposure, medication use (rifaximin, proton pump inhibitors), and healthcare utilization. Covariate balance was confirmed using standardized mean differences $<$0.1. Matched cohorts included 21,532 patients per group.Outcomes over 3 years included all-

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



cause mortality, hepatorenal syndrome, acute kidney injury, sepsis, recurrent SBP, multidrug-resistant organism infection (ESBL E. Coli, Klebsiella), and *Clostridioides difficile* infection. Time-to-event analyses were performed using Kaplan-Meier methods and Cox proportional hazards models. **Results:** Over 3 years, ciprofloxacin use was associated with significantly higher **all-cause mortality** compared with TMP-SMX (38.8% vs 29.1%; **HR 1.58, 95% CI 1.53–1.63; p < 0.001**).Ciprofloxacin was also associated with increased risk of: **Hepatorenal syndrome** (6.0% vs 1.9%; RR 3.12) **Acute kidney injury** (33.0% vs 28.1%; RR 1.18) **Sepsis** (15.3% vs 14.5%; RR 1.05) (all $p < 0.05$) Recurrent SBP was infrequent but more common in the ciprofloxacin group (0.1% vs 0.05%; **HR 2.86; p = 0.002**).There were **no significant differences** in multidrug-resistant organism infection or *Clostridioides difficile* infection between groups. **Conclusion:** In this large propensity-matched cohort of patients with cirrhosis, ascites and prior SBP, ciprofloxacin prophylaxis was associated with **higher mortality, increased risk of renal complications, Sepsis, recurrent SBP** compared with TMP-SMX, without evidence of reduced multidrug-resistant infections. These findings suggest that fluoroquinolone-based prophylaxis **may be associated with worse clinical outcomes** and support the need for prospective studies to re-evaluate optimal strategies for secondary SBP prophylaxis.

1560 | LISINOPRIL VERSUS NON-SELECTIVE BETA BLOCKER FOR PREVENTION OF DECOMPENSATION IN COMPENSATED LIVER CIRRHOSIS: A RETROSPECTIVE COHORT STUDY

Balkrishna Sapariya[1] Prince Gosai[2] Ciandra D'Souza[1], [1]Wright State University | Miami Valley Hospital | Dayton OH, [2]Case Western Reserve University | University Hospitals Cleveland Medical Center | Cleveland OH

Background: Liver cirrhosis is a major healthcare burden, and median survival varies from compensated phase (>12 years) to decompensated phase (~2 years). Conversion to decompensation occurs at 5-7% annually, with roughly 58% within 10 years. Progressive portal hypertension (driven by nitric oxide release, renin-aldosterone angiotensin system-RAAS) is the main factor for decompensation, leading to mainly ascites, varices, and encephalopathy. Only non-selective beta blockers (NSBBs- especially carvedilol) are recommended by AASLD, but no other agent is recommended for prevention. Liver injury stimulates expressions of RAAS components (ACE and angiotensin receptor 1), driving inflammation and fibrogenesis. ACE inhibitors therefore have theoretical benefits in cirrhosis. From the same class, Lisinopril does not require hepatic activation, making it suitable for study in liver cirrhosis. **Methods:** A retrospective cohort study was conducted using the TriNetX database (2001 to 2025). Cohorts were defined as adults (18-90 years) with 'Fibrosis and Cirrhosis of Liver' (ICD-10 K74) who were prescribed lisinopril or NSBBs (Carvedilol, Propranolol, or Nadolol), while excluding any decompensation, hepatocellular carcinoma, and pregnancy before starting any medication. Propensity score matching was applied to balance characteristics. The first decompensation event, individual event, hepatic failure, and all-cause mortality in 10 years were studied as outcomes using relative risk (RR-cumulative) and hazard ratio (HR-time dependent) calculation by an in-built statistical tool. Forest plot images were created with assistance from Claude AI. **Results:** After matching, each cohort included 10,437 patients (mean age ~58 years, SD < 0.1). Patients receiving lisinopril had a lower risk of developing any first decompensation event (RR 0.311, 95% CI 0.220-0.439; HR 0.25, 0.177-0.354) as compared to NSBB in 10 years. It also had a lower risk of ascites and varices. Analysis also showed reduced hepatic failure (RR 0.506, 0.435-0.589; HR 0.426, 0.365-0.497) and all-cause mortality (RR 0.693, 0.649-0.741; HR 0.535, 0.498-0.574) in the lisinopril cohort. P-values were < 0.0001 for all outcomes. **Conclusion:** In this study, lisinopril demonstrated superior efficacy compared to NSBB (standard of care) in preventing hepatic decompensation. It is likely due to its effects on hemodynamics (reduction of portal pressure) as well as liver inflammation and fibrogenesis by blocking RAAS. Hepatic failure was selected as a surrogate for liver-related mortality (no liver-related death in TriNetX). Reduced 10-year all-cause mortality can be confounded due to cardiovascular benefits. Lisinopril or ACE inhibitor as a group is commonly prescribed and are affordable (one third of all antihypertensives). This study demonstrated the potential benefits of lisinopril in cirrhosis, but prospective studies are warranted to confirm these findings.

1561 | LOW SYSTOLIC BLOOD PRESSURE IDENTIFIES INCREASED RISK OF AKI HOSPITALIZATION AMONG PATIENTS ON NONSELECTIVE BETA-BLOCKERS UNDERGOING OUTPATIENT PARACENTESIS

Kai Fu[1] Marina Serper[1] Siqi Zhang[1] Nadim Mahmud[1], [1]Hospital of University of Pennsylvania

Background: Nonselective beta-blockers (NSBBs) can reduce portal hypertension and prevent variceal bleeding in patients with cirrhosis. However, their safety in advanced cirrhosis remains debated, as NSBBs may also exacerbate renal hypoperfusion and cause acute kidney injury (AKI), particularly in patients with hypotension, infection, and refractory ascites. We evaluated whether pre-paracentesis systolic blood pressure modifies the association between NSBB use and risk of AKI hospitalization after outpatient paracentesis. We also aimed to identify ranges of systolic blood pressure below which NSBBs may be associated with increased AKI hospitalization. **Methods:** We conducted a national retrospective cohort study of 9,245 Veterans with cirrhosis undergoing 55,525 outpatient paracenteses. The primary exposure was an active NSBB prescription at the time of paracentesis. The primary outcome was hospitalization with AKI within 7 days. Relevant demographic, clinical, laboratory, medication, and procedural variables were obtained. Pre-paracentesis systolic blood pressure was transformed using restricted cubic splines to account for non-linearity. Adjusted mixed-effects logistic regression was used to evaluate the association between NSBB use, systolic blood pressure, and AKI hospitalization, including an interaction between NSBB use and systolic blood pressure, with random effects for patient and center. **Results:** Among 55,525 outpatient paracenteses, 14,231 (25.6%) occurred in patients receiving NSBBs, and 1,003 (1.8%) led to hospitalizations with AKI within 7 days. Compared with non-users, patients on NSBBs had similar MELD-Na scores and systolic blood pressure, but higher rates of diabetes mellitus, coronary artery disease, diuretic use, and hepatic encephalopathy medication use (each $p < 0.001$). Systolic blood pressure significantly modified the association between NSBB use and AKI hospitalization ($p = 0.029$). Albumin administration was associated with lower odds of hospitalization with AKI (OR 0.62, 95% CI 0.50-0.76), whereas lower sodium, higher bilirubin, lower eGFR, diabetes mellitus, and prior antibiotic use were associated with higher odds. Adjusted predicted risk curves demonstrated a higher predicted risk of AKI hospitalization among patients on NSBBs at lower systolic blood pressure levels, particularly below 100 mmHg, with attenuation of this difference at higher levels (Figure 1). **Conclusion:** In this national cohort of Veterans undergoing outpatient paracentesis, lower pre-paracentesis systolic blood pressure modified the association between NSBB use and AKI hospitalization risk. At systolic blood pressure levels below approximately 100 mmHg, patients receiving NSBBs had significantly higher predicted risk of AKI hospitalization, suggesting that pre-paracentesis blood pressure may help identify patients who warrant closer monitoring or individualized NSBB management.

1562 | BRTO FACILITATES RECOMPENSATION IN DECOMPENSATED CIRRHOSIS WITH PORTOSYSTEMIC SHUNT SYNDROME

Aika Kirihara[1] Tsuyoshi Ishikawa[1] Natsuko Nishiyama[1] Maho Egusa[1] Ryo Sasaki[1] Tatsuro Nishimura[1] Taro Takami[1], [1]Yamaguchi University Graduate School of Medicine

Background: Portosystemic shunt (PSS) syndrome is increasingly recognized as a contributor to hepatic encephalopathy and liver dysfunction in decompensated cirrhosis. Meanwhile, recompensation and expanded recompensation have emerged as important therapeutic goals in cirrhosis management. However, the impact of PSS occlusion on these outcomes remains unclear. We evaluated recompensation outcomes after balloon-occluded retrograde transvenous obliteration (BRTO) for PSS syndrome. **Methods:** We retrospectively analyzed 32 patients with decompensated cirrhosis who underwent BRTO for PSS syndrome and were followed for ≥ 12 months. Eligible patients had Child-Pugh class B/C cirrhosis and/or prior

decompensating events, including variceal bleeding, hepatic encephalopathy, or ascites. Recompensation was defined as sustained resolution of decompensating events without ongoing therapy together with improved liver function at 12 months. Expanded recompensation was assessed using modified criteria allowing stable low-dose maintenance therapy reflective of real-world clinical practice. Predictors associated with recompensation outcomes were analyzed. **Results:** The rates of recompensation and expanded recompensation after BRTO were 28.1% and 62.5%, respectively. Lower baseline serum creatinine was significantly associated with recompensation, whereas lower liver stiffness by transient elastography was significantly associated with expanded recompensation. Receiver operating characteristic analysis identified optimal cutoff values of creatinine $\leq$0.63 mg/dL (AUROC 0.81) for recompensation and liver stiffness $\leq$26.3 kPa (AUROC 0.77) for expanded recompensation. Kaplan–Meier analysis demonstrated significant differences in cumulative overall survival among patients who achieved recompensation (n = 9), those who achieved only expanded recompensation (n = 11), and those who achieved neither criterion (n = 12) (log-rank p = 0.0028). **Conclusion:** PSS occlusion with BRTO may facilitate recompensation in patients with decompensated cirrhosis and PSS syndrome. Baseline renal function and liver stiffness may help identify patients most likely to benefit from shunt occlusion. These findings suggest that PSS syndrome may represent a potentially reversible driver of decompensation in cirrhosis.

1563 | MICROBIAL SPECTRUM AND ANTIMICROBIAL RESISTANCE IN SPONTANEOUS BACTERIAL PERITONITIS: A MULTICENTER STUDY FROM FOUR TERTIARY CENTERS IN INDIA

Harshad Devarbhavi[1] Yashwanth M[2] Vishwas Shetty[3] Venkatakrishnan Leelakrishnan[3] Shiran Shetty[4] Shine Sadasivan[5] Rohit Duddagi[2] Sangam HB[2] Chiranth Basavaraj[2] Sandesh Modi[2] Durga Prasad Muddala[2] Mallikarjun Patil[2], [1]St. John's Medical College Hospital, Bangalore, India, [2]St. John's Medical College Hospital, Bangalore, [3]PSG Institue of Medical Sciences and Research, Coimbatore, [4]Kasturba Medical College, Manipal, [5]Amrita Institute of Medical Sciences, Kochi

Background: Spontaneous bacterial peritonitis (SBP) is a life-threatening complication of cirrhosis. The antimicrobial landscape is rapidly evolving, driven by rising rates of multidrug-resistant (MDR), extensively drug-resistant (XDR), and pandrug-resistant (PDR) organisms, alongside a shift in the microbiological profile of causative pathogens, threatening the adequacy of empirical therapy. We aimed to study culture positivity rates, causative organisms, and antimicrobial resistance patterns in patients with cirrhosis and SBP. **Methods:** We conducted a multicenter study across four university hospitals in southern India. Patients with cirrhosis and ascitic culture-positive SBP (ascitic fluid PMN $\geq$ 250/mm³) were enrolled, and antibiotic susceptibility patterns were analyzed. Resistance profiles were classified per standard definitions; MDR: non-susceptible to $\geq$1 agent in $\geq$3 antibiotic categories; XDR: non-susceptible to all but $\leq$2 antibiotic categories; PDR: non-susceptible to all categories tested (Clin Microbiol Infect 2012;18:268–281) **Results:** A total of 118 culture-positive SBP episodes were analyzed (mean age 51 years; bilirubin 7.4 mg/dL; albumin 2.3 g/dL; INR 2.11; creatinine 1.61 mg/dL; sodium 130 mEq/L). Gram-negative organisms predominated (79.7%; n = 94), with *E. coli* (30.5%), *Klebsiella pneumoniae* (24.6%), and *Acinetobacter baumannii* (5.9%) being the most common. Gram-positive organisms accounted for 20.3% (n = 24), including *Staphylococcus haemolyticus*, *Enterococcus faecium*, and *Enterococcus faecalis*. Notably, several rare and previously unreported isolates were identified in SBP such as *Stenotrophomonas maltophilia*, *Serratia marcescens*, *Sphingomonas paucimobilis*, *Providencia rettgeri*, *Roseomonas gilardii*, *Chryseobacterium indologenes*, and *Bordetella bronchiseptica*.Resistance profiles were alarmingly high: MDR organisms accounted for 49.2% (n = 58), XDR for 34.7% (n = 41), and PDR for 3.4% (n = 4) with a combined difficult-to-treat burden of over 50%, seriously undermining the adequacy of empirical antibiotic regimens in SBP. **Conclusion:** SBP microbiology has undergone a paradigm shift. Rising MDR/XDR/PDR rates render cephalosporins and fluoroquinolones increasingly inadequate as empirical therapy, while carbapenem utility is also declining (~39% resistance). The isolation of rare and unprecedented environmental pathogens (*Roseomonas*, *Chryseobacterium*, *Sphingomonas*, *Bordetella bronchiseptica*) likely reflects profound immunosuppression in these patients and antibiotic selection pressure. Center-specific antibiograms, culture-directed therapy, and antimicrobial stewardship are now essential. International society guidelines must acknowledge the heterogeneity of antimicrobial resistance patterns across regions and move toward greater individualization of empiric therapy, incorporating local microbiologic data and stewardship principles.

1564 | EARLY VS DELAYED INITIATION OF NONSELECTIVE BETA-BLOCKERS AFTER SPONTANEOUS BACTERIAL PERITONITIS: IMPLICATIONS FOR OUTCOMES IN CIRRHOSIS

Lan Nguyen[1] Sandra Chehayeb[1] Mahinaz Mohsen[2] Anthony Martinez[1], [1]University at Buffalo, [2]Rutgers New Jersey Medical School

Background: Nonselective beta-blockers (NSBB) are frequently withheld during acute spontaneous bacterial peritonitis (SBP) due to concerns for hemodynamic dysfunction. Although reinitiation of NSBB after clinical stabilization is recommended, the optimal timing remains unclear. We therefore conducted a retrospective study to compare outcomes associated with early versus delayed NSBB reinitiation following SBP, aiming to identify a clinically relevant therapeutic window. **Methods:** A retrospective cohort study was performed using the TriNetX network, including adults with cirrhosis and SBP between 1/1/2010 and 1/1/2026. Patients were stratified by timing of NSBB exposure (carvedilol, nadolol, or propranolol): within 1 month or between 1 and 2 months after SBP. Propensity score matching balanced baseline demographics, comorbidities, and medications. Outcomes included hepatorenal syndrome (HRS), ascites, variceal bleeding, hypotension, undifferentiated shock, liver transplantation, and all-cause mortality at 3 months, 6 months, 1 year, and 2 years. Hazard ratios (HRs) with 95% confidence intervals (CIs) were estimated using Kaplan-Meier analysis. **Results:** Compared with NSBB use between 1 to 2 months, exposure within 1 month after SBP was associated with a higher risk of HRS at 3 months (HR 1.41; CI 1.11-1.79), 6 months (HR 1.33; CI 1.11-1.59), 1 year (HR 1.34; CI 1.15-1.56), and 2 years (HR 1.30; CI 1.13-1.49). Early reinitiation also carried an increased risk of undifferentiated shock from 3 months (HR 1.32; CI 1.08-1.61) to 2 years (HR 1.15; CI 1.02-1.30). All-cause mortality was similarly greater in the early reinitiation cohort from 3 months (HR 1.41; CI 1.25-1.58) to 2 years (HR 1.29; CI 1.20-1.40). No significant differences were observed in ascites, hypotension, variceal bleeding, or liver transplantation across all time points. **Conclusion:** NSBB reinitiation within 1 month after SBP was linked to higher risks of HRS, undifferentiated shock, and all-cause mortality compared with that between 1 to 2 months. These findings suggest that the first month after SBP may represent a more vulnerable period for NSBB therapy. However, delaying reinitiation beyond the first month may allow recovery of effective arterial blood volume and renal perfusion, improving clinical outcomes. Incorporating a more standardized timeline for NSBB therapy into post-discharge care may help reduce adverse outcomes in patients with cirrhosis. Future studies should prioritize confirming these findings and further refining the optimal timing for NSBB reinitiation following SBP.

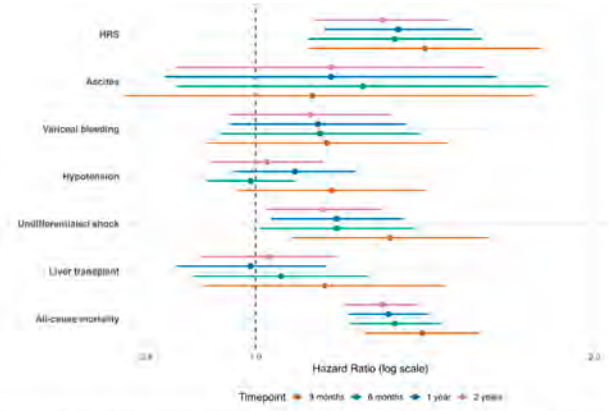

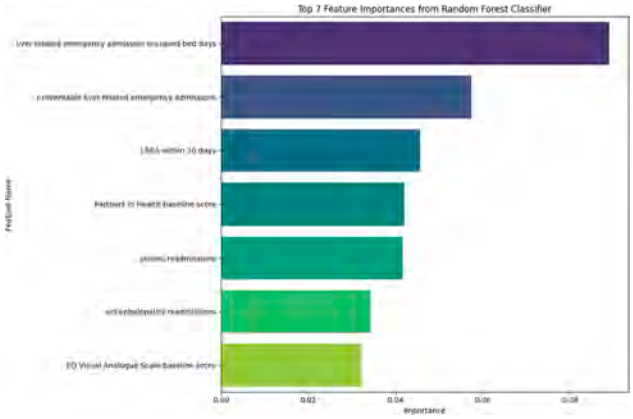

Figure 1. Forest plot demonstrating hazard ratios with 95% confidence intervals for clinical outcomes following NSBB initiation within 1 month versus 1-2 months after SBP in patients with cirrhosis. Outcomes were evaluated at 3 months, 6 months, 1 year, and 2 years. The vertical dashed line represents a HR of 1.0 (no difference between cohorts). HRs greater than 1 indicate increased risk associated with NSBB initiation within 1 month after SBP.

1565 | CONSTRUCTION OF A MACHINE LEARNING MODEL FOR PREDICTING READMISSIONS IN CIRRHOSIS: A MULTI-CENTER STUDY

Peter Rose[1] Richard Woodman[2] Sumudu Narayana[1] Alan Wigg[3] ALFIE Investigator Group[4], [1]South Australia Liver Transplant Unit, [2]Flinders University, [3]South Australian Liver Transplant Unit, [4]ALFIE Investigator Group

Background: Patients hospitalized with cirrhosis have high rates of early, unplanned readmissions. These are expensive and associated with worse outcomes. Identifying patients at high risk of readmission will allow appropriate distribution of resources to these patients to prevent readmissions and improve outcomes. Current prediction models demonstrate suboptimal performance, limiting their clinical utility. Our aim was to construct a machine learning model (MLM) predicting liver related emergency admissions (LREA) from a multicenter patient cohort. **Methods:** LREA data was analyzed from the multicenter Australian Liver Failure (ALFIE) trial database of 146 patients. Patients were enrolled following an inpatient admission with a complication of cirrhosis. Over 80 variables were analyzed and pre-processed. The cohort was split into a training and test cohort for internal validation. A random forest classifier model was constructed. Coding for the construction of the MLM was performed in Google Colab. Model performance was evaluated for accuracy and area under receiver operating curve (AUROC). Feature importance was analysed. **Results:** A total of 384 LREA occurred over a median follow-up of 2.0 years, with 116 patients (79%) having at least one LREA. The accuracy of the MLM was 0.628 and the AUROC was 0.904. Variables with highest feature importance included those with previous readmissions for ascites or encephalopathy, baseline Partners in Health score and baseline EQ Visual Analogue Scale score (Figure 1). **Conclusion:** We internally validated a MLM predicting LREA in a real-world multicenter cohort with fair accuracy and excellent AUROC. Variables with highest feature importance included self-reported patient knowledge and health-related quality of life measures which are rarely incorporated in current prediction models.

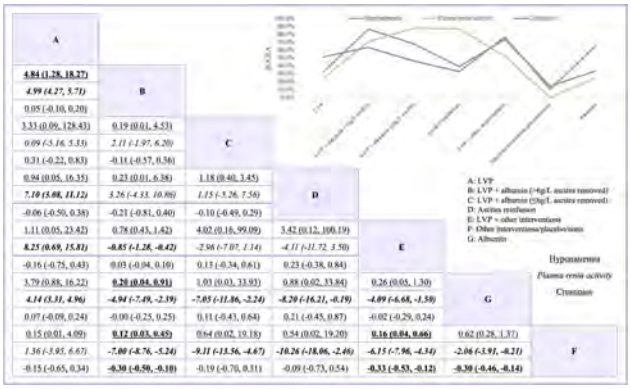
1566 | COMPARATIVE EFFICACY OF ALBUMIN-BASED AND OTHER INTERVENTIONS FOR HYPONATREMIA, PLASMA RENIN ACTIVITY, AND CREATININE IN DECOMPENSATED CIRRHOSIS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS



Wen Xie[1] Wanting Yang[1] Ligai Liu[1] Ruizhi Zheng[2] Hong Zhao[1] Yanbin Wang[1] Ying Cao[1], [1]Beijing Ditan Hospital, Capital Medical University, [2]Ruijin Hospital, Shanghai Jiao Tong University School of Medicine

Background: Human albumin infusion is widely used in the treatment of decompensated cirrhosis, yet evidence from randomized controlled trials (RCTs) remains inconsistent regarding its effects on neurohumoral

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

activation and renal function. We conducted a systematic review and network meta-analysis (NMA) to evaluate the comparative efficacy of human albumin-based and other interventions on hyponatremia incidence, plasma renin activity (PRA), and serum creatinine. **Methods:** We searched Web of Science, PubMed, and Embase from inception to February 2025 for RCTs evaluating human albumin in patients with decompensated cirrhosis. Seven intervention strategies (A-G, see figure legend for details) were compared. Outcomes were post-treatment hyponatremia, changes in PRA and creatinine. A frequentist random-effects NMA was performed, and treatment rankings were estimated using surface under the cumulative ranking curve (SUCRA). Systematic Review Registration: PROSPERO CRD420261374214. **Results:** A total of 44r RCTs involving 4,771 participants were included. For hyponatremia (17 trials, n = 1,582), large volume paracentesis (LVP) combined with high-dosage albumin (> 6 g/L ascites removed) was associated with the greatest reduction compared with control strategies (odds ratio [OR] 0.12, 95% CI 0.03–0.45) and had the highest ranking probability (SUCRA 87.2%). For PRA (18 trials, n = 1,207), most active interventions, except LVP alone, inhibited PRA elevation, with LVP combined with low-dosage albumin showing the highest ranking (SUCRA 88.3%). For serum creatinine (28 trials, n = 2,134), LVP combined with other colloids/vasoactive agents, albumin alone, and LVP combined with high-dosage albumin all demonstrated modest reductions versus control, with no significant differences among them. Sensitivity analyses supported the robustness of findings. **Conclusion:** In patients with decompensated cirrhosis, LVP combined with high-dosage albumin is the most effective treatment for reducing hyponatremia risk. Multiple albumin-based regimens similarly suppress renin-angiotensin-aldosterone system activation and stabilize PRA and creatinine.

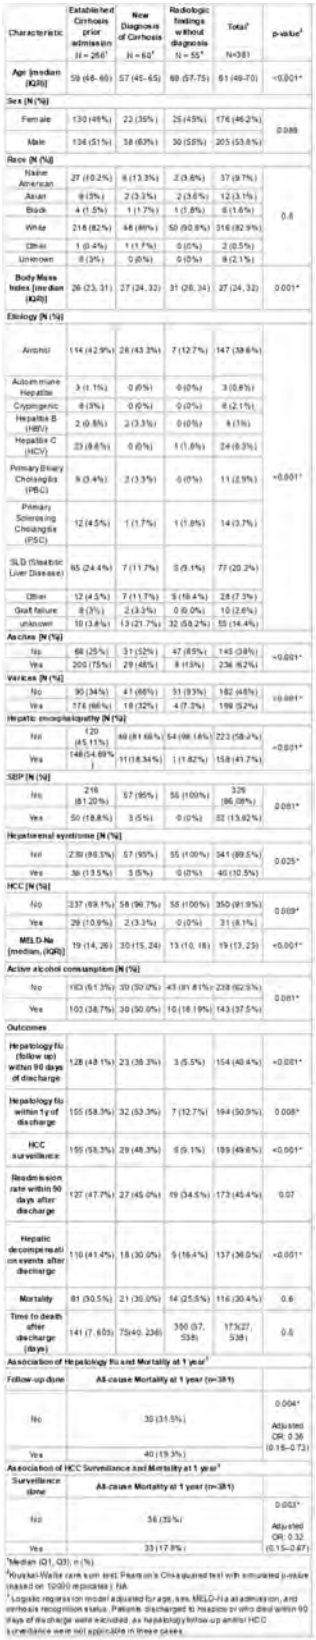
1567 | TRANSITIONS OF CARE AMONG PATIENTS HOSPITALIZED WITH RADIOGRAPHIC FINDINGS SUGGESTIVE OF CIRRHOSIS



Hugo Vargas[1] Sharon Lechtig-Wasserman[1] Fatmaelzahraa Abdelfattah[1] Stacey Rolak[1] Fares Jamal[1] Abdullah Hamad[1], [1]Mayo Clinic Arizona

Background: Cirrhosis is associated with high readmission rates and adverse outcomes but is often unrecognized during acute care encounters. We evaluated rates of recognition and follow-up among patients with radiographic findings suggestive of cirrhosis. **Methods:** Retrospective single-center cohort study of patients presenting to the ED or hospitalized between 1/2022–1/2023. Abdominal US, CT, and MR reports were screened for findings suggestive of cirrhosis, including “nodular liver,” “portal hypertension,” and “cirrhosis.” Patients were stratified by the presence of a prior cirrhosis diagnosis using ICD-10 codes. Cases without a prior diagnosis were further evaluated using Liver Cirrhosis Network (LCN) criteria. Transitions of care after discharge were assessed including hepatology follow-up, hepatocellular carcinoma (HCC) surveillance (defined as imaging semiannually and/or Alpha-fetoprotein), liver transplant evaluation, and outpatient diagnostic work-up. The primary outcome was all-cause mortality according to recognition status and completion of liver-related follow-up. Secondary outcomes included decompensation events and hospital readmission. **Results:** 381 patients with radiologic findings suggesting cirrhosis were identified. Of these, 266 (69.8%) had an established diagnosis of cirrhosis (group A); 60 (15.7%) were diagnosed during admission (group B), and 55 (14.4%) remained undiagnosed despite suggestive imaging findings (group C). During hospitalization, 91.4% of patients in group A met LCN criteria for cirrhosis, compared with 66.7% and 47.3% in groups B and C, respectively ($p < 0.001$). Appropriate hepatology follow-up within 90 days occurred in 48.1%, 38.3%, and 5.5% of patients in groups A, B, and C, respectively ($p < 0.001$). HCC surveillance occurred in 58.3%, 48.3%, and 9.1% of patients, respectively ($p < 0.001$). Hospital readmission within 90 days, 1-year mortality, and time to death from discharge did not differ between groups (Table 1). Proper HCC surveillance and hepatology follow-up were independently associated with lower 1-year mortality in the overall cohort [OR 0.32 (95% CI 0.15–0.67), p = 0.003 and OR 0.36 (95% CI 0.18–0.73), p = 0.004, respectively]. **Conclusion:** Patients with unrecognized cirrhosis demonstrated substantial gaps in transitions of care, with markedly lower rates of hepatology follow-up and HCC surveillance. Despite these differences, mortality and readmission rates were similar across groups, suggesting that even patients with subtle radiologic findings remain at significant risk for adverse outcomes. Notably, both hepatology follow-up and appropriate HCC surveillance were independently associated with significantly

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

lower 1-year mortality in the overall cohort. Improving recognition of liver disease and timely linkage to hepatology care may improve long-term outcomes.

1568 | RICE RECOMBINANT HUMAN ALBUMIN IS NOT FULLY EQUIVALENT TO PLASMA-DERIVED HUMAN ALBUMIN IN TERMS OF POST-TRANSLATIONAL MODIFICATIONS AND IMMUNOGENICITY PROFILE

Anna Mestre[1] Raquel Horrillo[1] Jordi Vidal[1] Isabel Bravo[1] Montse Costa[1], [1]Grifols

Background: Recombinant human albumin (rHA) is emerging as a therapeutic alternative to plasma-derived human albumin (pdHA), with several programs in clinical development. Recently, for the first time a rHA (from Healthgen Biotechnology) has received regulatory approval in China for the treatment of hypoalbuminemia in patients with liver cirrhosis. Despite these advances, safety and immunogenicity of rHA remain as key concerns considering the final aim of treating human patients with a recombinant protein in gram's doses. In this context, understanding how rice rHA compares with pdHA is of critical importance. Therefore, this study presents the comparative assessment of albumin post-translational modifications (PTMs) profile and ex vivo immunogenicity in human cells for rice-derived rHA vs pdHA. **Methods:** PTMs of pdHA and rice rHA were assessed on the intact protein mass (top-down) using ultra high-performance liquid chromatography coupled to electrospray ionization quadrupole time-of-flight mass spectrometry (LC-ESI-qTOF-MS). PTMs were tentatively assigned by exact mass comparison with reported modifications and expressed as percentage of relative intensity. Immunogenicity risk within the adaptive immunity was assessed using a dendritic cell-T cell (DC-T) proliferation assay, employing human leukocyte antigen-typed peripheral blood mononuclear cells from 40 healthy donors. Monocyte-derived DCs were loaded with either albumin (15 µM) and co-cultured with autologous T cells labeled with carboxyfluorescein succinimidyl ester. CD4+ T cell proliferation was measured by flow cytometry at day 7. The response index (RI) was calculated considering the strength of the response as well as the frequency of that

response. Both assessments were performed by two independent CROs under blind conditions. **Results:** Remarkable differences in albumin PTMs were observed between rice-derived rHA and pdHA. rHA showed an increased N-terminal truncation (HSA-DA 18.5% vs 4.08% for pdHA), which is associated with reduced metal-binding and antioxidant capacity, and increased glycated isoforms (sum of glycated forms: 22.5% vs 12.8%), consistent with protein expression in rice. In the DC-T assay, rHA induced CD4+ T cell responses in 57.5% of donors (23/40; 20 of them with ANOVA $p \leq 0.05$) with a strength of response of 2.39, resulting in a RI of 1.376. The RI for rHA exceeded the threshold of 1, indicative of elevated antigenicity risk for biotherapeutics and consistent with its higher PTM burden, whereas pdHA remained well below this threshold (RI: 0.273), supporting a lower antigenicity risk profile. **Conclusion:** Compared with pdHA, rHA displays a distinct PTM profile characterized by increased truncation and glycation, together with substantially higher antigenicity in adaptive immunity. While not a predictor of clinical outcomes, these results provide early immunogenicity risk evidence supporting non-equivalence between rHA and pdHA.

1569 | NATURAL HISTORY FOLLOWING FIRST EPISODE OF DECOMPENSATION IN LIVER CIRRHOSIS: A RETROSPECTIVE COHORT STUDY WITH MORTALITY LINKAGE IN A METROPOLITAN AUSTRALIAN HEALTH NETWORK

Edward Meehan[1] Nicholas Mulkearns[1] Chuanxin (Tony) Jia[1] Cindy Truong[1] Marjorie Zhang[2] Liam Brennan-Xie[1] Ella Yang[1] Manal Ajmal[1] Niranjan Arachchi[1] Zina Valaydon[1], [1]Western Health, [2]Wesetern Health

Background: Life expectancy following presentation with first episode decompensation of cirrhosis has been minimally described in a contemporary Australian context. We aimed to describe patient characteristics, estimate life expectancy, and assess associations between 90-day survival and MELD score, in a metropolitan health network (Western Health) in Victoria, Australia. **Methods:** We retrospectively enrolled all adults with liver cirrhosis hospitalised at Western Health from 01/01/2019 to 30/04/2023 primarily for a first decompensation episode, defined by presence of ascites, variceal bleeding, hepatic encephalopathy, or jaundice (HREC/23/WH/101106). We excluded patients whose first decompensation occurred prior to 2019 or outside our network, or who had hepatocellular carcinoma (HCC) at index presentation. Patients who subsequently developed HCC were censored from survival analysis at the time of HCC diagnosis. The primary outcome was death, and we performed data linkage with the Births, Deaths, and Marriages Registry up to 02/02/2026. We performed survival analysis with Kaplan-Meier curves and log-rank testing for MELD-score category. **Results:** 162 patients were hospitalised for a first episode decompensation of cirrhosis during the study period. 61.1% were male, and median age was 56.5 years (IQR 46 - 67). The median follow-up period was 1037.5 days (IQR 262 - 1855.3). The aetiology involved alcohol in 82.1% of patients, 72.9% of whom were still drinking, viral hepatitis in 16.7%, metabolic dysfunction in 14.8%, and autoimmune disease in 1.9%. The median Elixhauser comorbidity index score was 3 (IQR 1 - 4), and the median MELD score was 18 (IQR 13 – 22). The median INR was 1.5 (IQR 1.3 - 1.9), bilirubin was 66 (IQR 29 – 143), and albumin 26 (IQR 22 – 29). 117 patients (72.2%) had ascites, 37 (22.8%) had hepatic encephalopathy, and 35 (21.6%) had variceal bleeding. 14 (8.6%) were admitted to intensive care, and 8 (4.9%) discharged against medical advice. 5 (3.1%) developed HCC during follow up. 89 patients (54.9%) died, and median survival time was 1687 days (95% CI 896 – NA). 11 (6.8%) died during their initial presentation, and 30 (18.5%) died within 90 days of it, including 75% with a MELD score of 40 or more ($p = 0.0094$) (Figure 1). **Conclusion:** We found high rates of 90-day and overall mortality and significant associations with MELD score in this contemporary Australian cohort. Overall mortality across follow-up was similar to that seen among patients with cirrhosis and decompensation in a cohort in Queensland, Australia, while 90-day mortality was slightly higher than rates seen in the original prospective validation study of the MELD score. Limitations included the retrospective design, and the absence of a cancer registry to confirm HCC incidence. First episode decompensation continues to portend a poor prognosis, and the MELD score remains a useful tool in contemporary Australian patients.

1570 | ASSOCIATION BETWEEN ANTIBIOTIC INDICATION ON LENGTH OF HOSPITAL STAY IN HOSPITALIZED PATIENTS WITH CIRRHOSIS

Ruwani Alwis[1] Shahid Habib[1] Meghana Vukkhadkar[1], [1]Liver Institute PLLC

Background: Bacterial infections are a major cause of morbidity and mortality in patients with cirrhosis, contributing to prolonged hospitalizations and increased healthcare costs.This study aimed to evaluate the association between antibiotic indication (prophylaxis, preemptive therapy, or treatment of acute infection) and hospital length of stay (LOS) in hospitalized patients with cirrhosis. **Methods:** This IRB-approved retrospective single-center study included 353 hospitalized patients with cirrhosis of any etiology who received systemic antibiotics during inpatient admission. Patients were categorized into three groups based on antibiotic indication: prophylaxis, preemptive therapy, or treatment of acute infection. Outcomes included age, sex, mean highest Model for End-Stage Liver Disease (MELD) score, and LOS. Between-group comparisons of LOS were performed using one-way analysis of variance (ANOVA) with post hoc pairwise t-tests. **Results:** Among the 353 patients included, 121 received prophylactic antibiotics, 64 received preemptive therapy, and 168 were treated for acute infection.The prophylaxis group included 85 male and 36 female patients, with a mean age of 54 years, mean MELD score of 16.86, and mean LOS of 7.24 days.The preemptive therapy group included 39 male and 25 female patients, with a mean age of 56.5 years, mean MELD score of 22.48, and mean LOS of 7.75 days.The acute infection group included 93 male and 75 female patients, with a mean age of 56.36 years, mean MELD score of 19.49, and mean LOS of 10.69 days.Overall differences in LOS among the three groups were statistically significant (one-way ANOVA, p = 0.003). Post hoc pairwise t-tests demonstrated longer LOS in the acute infection group compared with both the prophylaxis group (p = 0.001) and the preemptive therapy group (p = 0.02). No significant difference in LOS was observed between the prophylaxis and preemptive therapy groups (p = 0.66). **Conclusion:** Among hospitalized patients with cirrhosis receiving antibiotics, treatment for acute infection was associated with significantly longer hospital LOS compared with prophylactic or preemptive antibiotic use. These findings suggest that acute infection may contribute substantially to hospitalization burden in patients with cirrhosis.

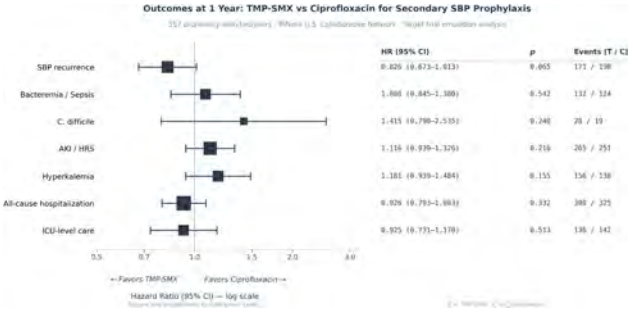
1571 | TRIMETHOPRIM-SULFAMETHOXAZOLE VERSUS CIPROFLOXACIN FOR SECONDARY PROPHYLAXIS OF SPONTANEOUS BACTERIAL PERITONITIS: A TARGET TRIAL EMULATION ANALYSIS IN A U.S. MULTICENTER COHORT



Ali Emre Bardak[1] Nazli Begum Ozturk[2] Hind El Naamani[1] Ahmet Gurakar[3], [1]Boston Medical Center - Brighton, Boston, MA, USA, [2]Saint Louis University School of Medicine, St. Louis, MO, USA, [3]Johns Hopkins University School of Medicine, Baltimore, MD, USA

Background: After first-episode spontaneous bacterial peritonitis (SBP), secondary antibiotic prophylaxis is standard of care. With norfloxacin unavailable in the U.S., trimethoprim-sulfamethoxazole (TMP-SMX) and ciprofloxacin are the practical alternatives despite no head-to-head randomized trials, and major guidelines treat them as equivalent. **Methods:** Using a target trial emulation analysis framework, we compared TMP-SMX versus ciprofloxacin for secondary SBP prophylaxis in the TriNetX U.S. Collaborative Network. Eligible

patients were adults with cirrhosis (K70.3, K74.6) and a first SBP episode (K65.2) between 2015 and 2025 who received TMP-SMX or ciprofloxacin 7-14 days post-SBP. To isolate prophylactic from therapeutic intent, patients with any study antibiotic within 6 days of SBP or any concurrent extra-peritoneal infection (urinary, respiratory, skin, intra-abdominal, ENT) within 14 days of SBP were excluded. 1:1 propensity score matching was used to balance covariates, including demographics, cirrhosis etiology, decompensation burden, cardiometabolic comorbidities, CKD stage, beta-blockers, diuretics, MELD-component labs, hemoglobin, and platelet count. Outcomes were assessed from day 7 through day 365 by Kaplan-Meier analysis. Primary outcome was SBP recurrence; secondary outcomes were bacteremia/sepsis, C. difficile, AKI/HRS, hyperkalemia, all-cause hospitalization, and ICU-level care. **Results:** Before matching, 565 TMP-SMX and 1,797 ciprofloxacin recipients met criteria; 557 patients were matched in each group. After matching, 1-year SBP cumulative incidence was 35.4% with TMP-SMX vs 42.6% with ciprofloxacin (171 vs 198 events; HR 0.826, 95% CI 0.673–1.013; p = 0.065). No significant differences were observed for bacteremia/sepsis (HR 1.080, 95% CI 0.845–1.380; p = 0.542), C difficile infection (HR 1.415, 95% CI 0.790–2.535; p = 0.240), AKI/HRS (HR 1.116, 95% CI 0.939–1.326; p = 0.216), hyperkalemia (HR 1.181, 95% CI 0.939–1.484; p = 0.155), all-cause hospitalization (HR 0.926, 95% CI 0.793–1.083; p = 0.332), or ICU-level care (HR 0.925, 95% CI 0.731–1.170; p = 0.513). **Conclusion:** In a U.S. real-world cohort emulating a head-to-head trial of TMP-SMX versus ciprofloxacin for secondary SBP prophylaxis, no statistically significant differences were observed in infectious, renal, healthcare utilization, or hyperkalemia outcomes at 1 year, supporting current guideline equipoise. A directional 7-percentage-point absolute reduction in 1-year SBP recurrence with TMP-SMX did not reach statistical significance but warrants prospective evaluation.

1572 | IMMUNOMETABOLISM OF T CELLS FROM ASCITES IN PATIENTS WITH ADVANCED CHRONIC LIVER DISEASE

Hannah Schwarz[1] Ingrid Wei Zhang[1] Pavitra Kumar[1] Hasan Tarik Cosgun[1] Charalampos Pavlidis[1] Juan Wang[1] Frank Tacke[1] Linda Hammerich[1] Cornelius Engelmann[1], [1]Department of Hepatology & Gastroenterology, Charité – Universitätsmedizin Berlin

Background: Patients with advanced liver cirrhosis develop ascites as one of the first signs of decompensation. This is associated with an increased risk of infections such as spontaneous bacterial peritonitis (SBP), in which cirrhosis-associated immune dysfunction plays a pathogenic role. While immune dysfunction and metabolic perturbations in circulating immune cells are well described, their role in the peritoneal compartment has remained unclear. We therefore aim to characterize the metabolic and functional properties of ascites T lymphocytes, as the predominant population in ascites. **Methods:** Peripheral blood and ascites samples were obtained from patients with acutely decompensated cirrhosis without SBP. $CD3^+$ T cells were isolated by magnetic cell separation and subjected to phenotypic and metabolic analyses using the Seahorse XF Analyzer and Spectral Flow Cytometry. **Results:** A total of 30 patients were included (63.3% male, 36.7% female), with alcohol-related liver disease as the predominant etiology (66.7%) and a median MELD score of 16.6. Ascites T cells show a more antigen-experienced phenotype with increased memory $CD4^+$ T cells ($CD45RO^+$) (61.05% vs. 36.31%, adjusted $p < 0.0001$), elevated TIGIT expression and significantly higher frequency of $PD\text{-}1^+$ $CD4^+$ T cells (33.09% vs. 14.17% adjusted $p < 0.001$). Regulatory T cells were more abundant in peripheral blood (6.74% vs. 9.36%, adjusted $p < 0.005$). Along with these phenotypic changes, ascites T cells show comparable basal respiration (ascites: 4.028, n = 24 vs. blood: 3.594, n = 21 pmol O_2/min/µg protein), but significantly higher maximal respiration (21.52, n = 24 vs. 13.29, n = 21 pmol O_2/min/µg protein, $p < 0.001$) and spare respiratory capacity (504.2%, n = 24 vs. 327.1%, n = 21, p = 0.0003). Elevated proton leak (0.40, n = 24 vs. 0.28, n = 15 pmol O_2/min/µg protein, p = 0.0204) and reduced coupling efficiency (88.71% n = 24 vs. 92.55% n = 21, p = 0.1071) indicated impaired mitochondrial energy production despite unchanged ATP-linked respiration (3.67 n = 24 vs 3.52 n = 21 pmol O_2/min/µg protein , p = 0.5024). Additionally, T cells from ascites showed higher glycolytic capacity compared to blood T cells (p = 0.0232). Given the mitochondrial dysfunction in ascites T cells, we investigated whether Elamipretide, a cardiolipin-stabilizing tetrapeptide targeting the electron transport chain, could restore mitochondrial health. Indeed,

Elamipretide treatment led to a partial recovery of mitochondrial function in ascites T cells. **Conclusion:** T cells from ascites display enhanced mitochondrial respiratory capacity but reduced energetic efficiency. Spectral Flow Cytometry analysis further reveals an enrichment of PD-1^{+} T cells. These findings suggest a functionally impaired T cell state, potentially driven by extrinsic factors within the ascites environment, which may increase the risk of infectious complications.

1573 | SAFETY AND EFFICACY OF LOW-DOSE ALBUMIN IN PATIENTS WITH SPONTANEOUS BACTERIAL PERITONITIS: A PROPENSITY SCORE-MATCHED ANALYSIS

Sayan Malakar[1] Virendra Singh[1] Sumit Rungta[2] Rahul Jangra[2] Amandeep Singh[1] Jahnvi Dhar[1] Upasna Rajput[1] Anmol Anmol[1], [1]Punjab Institute of Liver and Biliary Sciences, [2]KGMU

Background: Intravenous antibiotics and standard dose of albumin (1.5g/kg/day on day 1 and 1 g/kg/day on day 3) remain the mainstay of therapy in patients with spontaneous bacterial peritonitis (SBP). We aimed to evaluate the safety and efficacy of low-dose albumin (20 grams/ day on days 1 and 3) in patients with SBP. **Methods:** In this exploratory retrospective cohort study, 161 patients with SBP were included. Of 161 patients, 58 received low-dose albumin, and 103 received standard-dose albumin. After propensity-score matching (PSM), 52 patients were included in each group. Primary outcomes inclde resolution of SBP, reversal of acute kidney injury (AKI) and 90-day mortality . Secondary outcome measures were length of hospital stays and adverse events. Primary and secondary outcomes were estimated and compared between two groups. **Results:** In the unmatched cohort, the age at presentation was 45.4 ± 10.58 years (males: 84.5%). Following PS matching (1:1), there were no significant differences between their demographics, laboratory and severity (Table 1). In the PSM cohort, concomitant AKI was present in 54 patients [26 (50%) in the standard albumin group vs 28 (53.8%) in the low-dose albumin group; p = 0.85]. After 48 hours, SBP resolution was noted in 40 patients (76.9%) in the standard albumin group and 42 (80.8%) in the low-dose albumin group (p = 0.81). There was no significant differences in day-3, day-7 AKI resolution [10 (19.2%) vs 14 (27%); p = 0.12 and 16 (38.7%) vs 13 (34%); p = 0.14, respectively], hospital stay [12.52 ± 3.79 days vs 12.71 ± 3.90 days; p = 0.79] and 90-day mortality [8 (15.3%) vs 11 (21.1%); p = 0.30] between the two groups. Adverse events were higher in the standard dose albumin group [9 (17.3%) vs 2 (3.8%); p = 0.01] **.** In the Kaplan-Meier analysis in the PSM cohort, there was no difference in mortality between the standard- and low-dose albumin groups when adjusted for Child-Turcot-Pugh and Model for End Stage Liver Disease-Sodium (MELD-Na) score [ajusted hazard ratio: 1.01 (95% confidence interval : 0.48-2.12), p = 0.94]. **Conclusion:** Low-dose albumin is safe and effective in managing SBP.

Table: 1

Demographic, clinical, biochemical parameters and outcome after propensity-score matched cohorts of standard dose and low dose albumin group

Variable	Overall (n=104)	Standard dose albumin (n=52)	Low Dose albumin (n=52)	p-value

Background: Hepatorenal syndrome (HRS) is a form of kidney dysfunction that occurs in patients with liver cirrhosis. It recognizes HRS-AKI, characterized by an abrupt impairment of kidney function and HRS-CKD with eGFR of < 60ml/min/1.73m > 90 days. In hospital mortality associated with HRS has decreased from 44% to 24% between 2005 and 2014 data from the National Inpatient Sample (NIS) database, showing a decline attributed to increased rates of liver transplantation and expanded use of renal replacement therapy. **Methods:** This is a retrospective study. Data were obtained from a non-liver transplant medical center in South Texas covering the period 2020–2023. We assessed factors associated with overall mortality in patients with HRS. Statistical analyses included descriptive statistics, independent samples t-tests, chi-square analysis, and binary logistic regression to identify independent predictors of overall mortality. **Results:** In this retrospective cohort of patients with hepatorenal syndrome (HRS) from a non-transplant center serving a predominantly Hispanic population in South Texas, overall mortality was 23%, reflecting the persistently poor prognosis of HRS in community-based settings. HRS-AKI was the predominant phenotype (75%), with alcohol-related liver disease (43%) and MASH (39%) representing the leading etiologies of underlying cirrhosis. MELD score emerged as the sole independent predictor of overall mortality, with each one-point increase conferring 11% higher odds of death (OR 1.11, 95% CI 1.003–1.228, p = 0.044). Among patients requiring ICU-level care, both age and MELD score were significant predictors of ICU mortality each additional year of age increased the odds by 4.6% **(** OR 1.046, p = 0.002), while each one-point rise in MELD increased the odds by 35% **(** OR 1.35, p = 0.04). Among clinical precipitants, acute hepatic encephalopathy was the most frequent, occurring in 28% of patients. Treatment utilization reflected the real world, resource limited context of this cohort: Midodrine/octreotide: 45.8% , albumin challenge: 27.9, and vasopressors 14.7% **Conclusion:** This study provides important real-world data from a predominantly Hispanic population in South Texas and highlights the urgent need for earlier recognition, risk stratification, and improved access to advanced liver care for patients with HRS managed outside transplant referral centers which remain challenge. It is important to note that terlipressin was approved at our institution in late 2023. Therefore, most patients in this cohort (2020–2023) were managed according to prior guidelines.

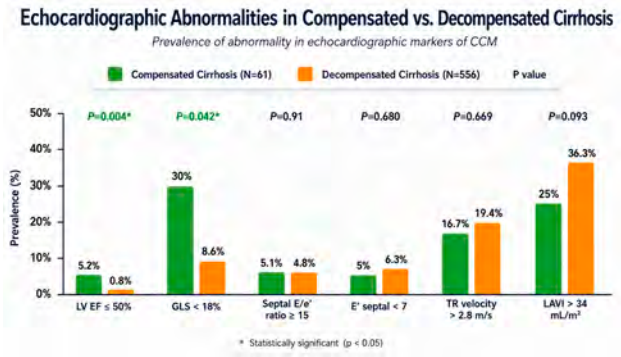
1575 | EFFICACY AND SAFETY OF PERCUTANEOUS ASPIRATION SCLEROTHERAPY WITH MINOCYCLINE FOR SYMPTOMATIC HEPATIC CYSTS

Tomohiro Oikawa[1] Takayuki Kogure[1] Mari Satoh[1] Kennichi Satoh[1], [1]Tohoku Medical and Pharmaceutical University

Background: Laparoscopic deroofing surgery is the standard treatment for patients with symptomatic hepatic cysts. Alternatively, aspiration sclerotherapy is a minimally invasive treatment considered for patients unable to tolerate surgery. While most reports describe the use of ethanol as a sclerosing agent, fewer studies have cited polidocanol, tetracycline, or minocycline. The efficacy of aspiration sclerotherapy remains limited compared with surgical intervention due to inadequate destruction of the inner cystic epithelium. Minocycline, a broad-spectrum antibiotic, is highly acidic and induces inflammation and tissue damage in the cyst epithelium. However, detailed reports on its therapeutic efficacy and safety are limited. Here, we evaluate a modified method of minocycline aspiration sclerotherapy (MINO sclerotherapy) for symptomatic hepatic cysts, which achieved a low recurrence rate. **Methods:** This study was approved by the ethics committee of our institution. Between 2020 and 2026, 10 patients

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.



underwent MINO sclerotherapy at our institution. Ultrasound-guided cyst aspiration was performed using a pigtail catheter system. Following complete fluid drainage, the cyst was washed with saline through the catheter. The catheter was left open until the following morning. Thereafter, a minocycline solution (200 mg in 10 mL of saline) was injected into the cyst, and the catheter was clamped for at least 8 hours. This minocycline administration was repeated daily for 3 to 4 days. **Results:** The indications for cyst aspiration included liver function abnormalities and cholangitis due to bile duct stenosis (n = 3), bacterial infection of the cyst fluid (n = 6), and intracystic hemorrhage (n = 1). Pre-treatment cyst diameters ranged from 5 to 15 cm (median: 11.6 cm, mean: 10.2 cm). The treatment achieved a reduction in cyst size ranging from 71.2% to 86.7% (median: 76.7%, mean: 77.2%). Following drainage, all symptoms and clinical findings resolved. During a follow-up period of 6 months or longer, no patients exhibited cyst regrowth or recurrence of symptoms. Regarding treatment-related complications, mild pain at the catheter insertion site occurred in all cases, with 6 patients requiring acetaminophen. One patient developed a transient fever during minocycline infusion; however, no other adverse events were observed. **Conclusion:** Percutaneous aspiration sclerotherapy with minocycline is an effective and safe procedure for symptomatic hepatic cysts. This treatment represents a viable option for patients who are not candidates for deroofing surgery or those requiring urgent drainage due to severe cyst fluid infection.

1576 | THE PRESENCE OF CIRRHOTIC CARDIOMYOPATHY IS NOT EXCLUSIVE TO DECOMPENSATED CIRRHOSIS: A RETROSPECTIVE COHORT STUDY

Rawia Aburumman[1] Andre Hall[2] Murray Coetzee[1] James Slaughter[3] Ashley Spann[1] Deepak Gupta[1] Anthony Dreher[4] Manhal Izzy[1], [1]Vanderbilt University Medical Center, Department of Medicine, [2]Vanderbilt University School of Medicine, [3]Vanderbilt University Medical Center, Department of Biostatistics, [4]Vanderbilt Center for Transplant Science

Background: Cirrhotic cardiomyopathy (CCM) is an underrecognized complication of advanced liver disease characterized by impaired cardiac function in the absence of underlying primary heart disease. While prior studies showed that CCM affects a large proportion of patients with decompensated cirrhosis, the existence of CCM in the setting of compensated disease is yet to be explored. In this study, we aim to compare the prevalence of CCM between compensated and decompensated cirrhosis and evaluate associated echocardiographic characteristics. **Methods:** We performed a retrospective analysis of adult patients with cirrhosis who were wait-listed for liver transplantation at a large academic center in North America between 11/2020 and 4/2025. Patients with primary cardiac pathology prior transplant were excluded. Patients were stratified into compensated versus decompensated cirrhosis based on having > 1 decompensating event (i.e., ascites, hepatic encephalopathy, bleeding varices). CCM prevalence and echocardiographic parameters were compared between groups. **Results:** The study included 617 patients of whom 61 (9.9%) had compensated cirrhosis and 556 (90.1%) had decompensated cirrhosis. When comparing compensated vs. decompensated groups, median age (61 vs. 60, $p = 0.86$) and body mass index (29.5 vs. 29.6, $p = 0.39$) were comparable between groups and the majority were non-Hispanic white (82% vs. 92%, $p = 0.004$). MASLD was present in 37.4% of the decompensated group and 29.5% of the compensated group. The prevalence of CCM didn't differ significantly between compensated and decompensated patients (16.7% vs. 15.8%, $p = 0.87$). However, compensated patients had higher prevalence of abnormal left ventricular ejection fraction (EF) $\leq 50\%$ (5.2% vs. 0.8%, $p = 0.004$), and global longitudinal strain (GLS) $< 18\%$ (30.0% vs. 8.6%, $p = 0.042$). Both groups have had comparable rates of abnormalities in the diastology variables of CCM. **Conclusion:** This exploratory analysis is the first to demonstrate that CCM exists in patients with compensated cirrhosis and is not exclusive to decompensated disease. These findings highlight the complexity of cardiac dysfunction in cirrhosis and pave the path for investigation of CCM impact on compensated disease.

1577 | RIFAXIMIN MEDS TO BEDS: A RETROSPECTIVE ANALYSIS OF RIFAXIMIN FILLING TIME AND THE IMPACT ON 30-DAY READMISSION FOR HEPATIC ENCEPHALOPATHY

Daniel Cain[1] Kailey Nguyen[2] Mufaddal Jafferjee[1] Sidart Pradeep[3] Nina Kanase[1] Simran Demla[1] Bilal Khoncarly[1] Samar Taqvi[1] Sabine Itani[1] Indudeep Bedi[1] Jordan Santos[1] Caroline Gregory[1] Sanjay Shori[4] Apurva Modi[5] Shovendra Gautam[1], [1]Baylor Scott & White- All Saints Medical Center, [2]Baylor Scott & White- All Saints Medical Center I, [3]Transplant Hepatology at UT Health San Antonio, [4]Texas Christian University Burnett School of Medicine, [5]Baylor Health, Liver Consultants of Texas

Background: Hepatic encephalopathy (HE) is a well-known complication of chronic liver disease (CLD), and the non-systemic antibiotic rifaximin has been well documented in reducing this complication. The purpose of this study is to determine if the timing of rifaximin access after hospital discharge for HE impacted the 30-day readmission rates for HE. **Methods:** This is a two-center retrospective analysis within the same metroplex, using two liver transplant centers. The primary objective was to evaluate the impact of the timing for medication access to rifaximin on 30-day readmissions for hepatic encephalopathy (HE). The time intervals evaluated were: day of discharge, within 7-days of discharge, within 30-days of discharge, and never filled. Patients were selected from January 2021 to March 2024 who had HE as a primary diagnosis with their charts then manually reviewed. Exclusion criteria were applied to create study populations from each hospital (Baylor Scott & White- All Saints Medical Center in Fort Worth, TX (BAS) and Baylor Scott & White- Baylor University Medical Center in Dallas, TX (BUMC)). 192 patients from BAS and 240 patients from BUMC met inclusion criteria. Statistical analysis of the entire study cohort, BAS and BUMC Cohorts individually, and BAS vs BUMC was then done. **Results:** Rifaximin refill timing did not show statistical significance in 30-day HE related readmissions at any time point or when evaluating the study cohort as a whole or by individual site (See Table). Filling rifaximin at discharge was not associated with reduced readmission at BAS (OR 0.89, 95% CI 0.19–4.24, p = 0.70) or BUMC (OR 0.62, CI 0.24-1.59, p = 0.32). Filling rifaximin within 7 days of discharge was not associated with lower readmission (BAS: OR 1.30, CI 0.03-54.76, p = 0.81; BUMC: OR 2.23, CI 0.21-23.54, p = 0.51), although subgroup sizes were small. Likewise, filling within 30 days of discharge did not show significant impact at BAS (OR 3.44, CI 0.30-39.37, p = 0.44) or BUMC (OR 0.93, CI 0.10-8.46, p = 0.95). **Conclusion:** This study was unable to find a significant impact in the timing of rifaximin prescription access after hospital discharge on 30-day readmissions for HE across all time intervals (0-days, 7-days, 30-days, and never filled). The impact of using only transplant centers, which have additional resources, and the low power of some subgroups likely led to these results. The authors believe further evaluation incorporating non-liver transplant institutions would provide additional insight into the timing of rifaximin access and 30-day hospital readmissions. The benefits of rifaximin for HE have been well documented and a study with increased power in the above-mentioned sub-groups may provide additional insight on how timing of access plays a key role in ensuring this population has the best management and outcomes.

1578 | RESPONSE TO LOW FIXED DOSE ALBUMIN FOR THE TREATMENT OF SPONTANEOUS BACTERIAL PERITONITIS: A RETROSPECTIVE ANALYSIS

Dylan Nunn[1] Arun Chacko[2] Shaik Riyaz[2] Jamil Abdo[1] Uday Zachariah[2] CE Eapen[2] Ashish Goel[2] Santosh Kumar[2] Ashwani Singal[1], [1]University of Louisville School of Medicine, [2]Christian Medical College Vellore

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Spontaneous bacterial peritonitis (SBP) is a life-threatening condition associated with an increased risk of acute kidney injury (AKI). Current AASLD guidelines recommend high-dose albumin administration on day 1 and day 3 following SBP detection to reduce the risk of AKI; however, fluid overload may limit tolerability. At a quaternary hospital in South India, patients are treated with low-dose daily albumin due to a perceived higher occurrence of fluid overload with standard dosing, but the optimal duration of this lower dose remains unclear. This study aimed to analyze the incidence of new-onset AKI among patients with SBP treated with low-dose daily albumin for $\leq$ 3 days vs > 3 days. **Methods:** Using a retrospective cohort from 2024-2025, we identified adults admitted with SBP treated with fixed low-dose albumin (0.3 g/kg/day). Patients were grouped based on albumin duration ($\leq$3 days vs >3 days). Patients with chronic kidney disease, obstructive causes of AKI, and urinary tract infections were excluded. New onset AKI on day 5 was assessed using the KDIGO criteria. **Results:** A total of 123 patients with SBP treated with low-dose daily albumin were included in the analysis. Of these patients, 45 received low-dose albumin for $\leq$3 days and 78 received it for >3 days. Patients who received albumin for >3 days had more severe liver disease at baseline, indicated by higher rates of tense ascites (96.2% vs 80.0%, p=0.008), higher total bilirubin (6.70 vs. 3.50, p=0.006), higher INR (2.30 vs 1.87, p=0.049), and higher MELD (22.69 vs 19.51, p=0.018) and MELD-Na scores (26.49 vs. 22.38, p=0.003).New-onset AKI occurred in 4 patients in the $\leq$3 days group and 2 patients in the >3 days group (8.9% vs. 2.6%, p=0.19). SBP resolution rates (84.4% vs 74.4%, p=0.259), reported symptoms of fluid overload (4.4% vs 3.8%, p=1.000), and survival at discharge (91.9% vs. 92.3%, p= 1.000) were similar. Patients treated for >3 days had significantly longer hospital stays (6 vs 4 days, p<0.001).Lower sodium and higher baseline total bilirubin were associated with AKI at day 5 on univariate analysis. Lower sodium independently predicted mortality on multivariate analysis (OR 0.812, 95% CI 0.812-0.997, p=0.044). **Conclusion:** Patients treated with low-dose daily albumin for > 3 days and for $\leq$ 3 days had a similar rate of AKI at day 5. There was no difference in the rate of reported fluid overload symptoms. These findings suggest that prolonged courses of low-dose daily albumin in SBP patients may not provide short term clinical benefit. Prospective comparative studies are needed to evaluate the efficacy and safety of low-dose albumin administration compared to standard dosing.

Variable	Total (n=123)	Albumin ≤3 days (n=45)	Albumin >3 days (n=78)	P value
Total Bilirubin (mg/dL)	5.11 (2.33-9.66)	3.50 (1.90-5.60)	6.70 (2.91-10.61)	0.006
INR	2.25 (1.62-2.77)	1.87 (1.43-2.53)	2.30 (1.85-2.79)	0.049
Creatinine at admission (mg/dL)	0.90 ± 0.22	0.88 ± 0.20	0.90 ± 0.23	0.637
Creatinine at Day 3 (mg/dL)	0.78 (0.62-0.96)	0.78 (0.62-1.03)	0.79 (0.62-0.95)	0.885
Creatinine at Day 5 (mg/dL)	0.73 (0.61-0.91)	0.76 (0.62-0.93)	0.72 (0.60-0.91)	0.803
AKI at day 5	6 (4.9%)	4 (8.9%)	2 (2.6%)	0.190
SBP Response	96 (78.0%)	38 (84.4%)	58 (74.4%)	0.259
Ascitic fluid TC at 48 hours (/cumm)	320.00 (180.00-1100.00)	300.00 (165.00-600.00)	350.00 (200-1222.50)	0.186
Ascitic fluid neutrophils at 48 hours (%)	78.00 (50.00-89.00)	72.00 (39.50-89.50)	80.00 (55.75-87.75)	0.377
Complications of albumin	5 (4.1%)	2 (4.4%)	3 (3.8%)	1.000
Hospital stay among survivors (days)	5.00 (4.00-7.00)	4.00 (3.00-5.00)	6.00 (5.00-8.25)	<0.001
Alive at discharge	113 (91.9%)	41 (91.1%)	72 (92.3%)	1.000

Lai[1], [1]University of California-San Francisco, San Francisco, California, USA, [2]Northwestern University Feinberg School of Medicine, Chicago, Illinois, USA, [3]University of Arizona College of Medicine-Phoenix, Phoenix, Arizona, USA, [4]University of Texas Southwestern Medical Center, Dallas, Texas, USA, [5]Columbia University Irving Medical Center, New York, New York, USA, [6]University of Florida, Gainesville, Florida, USA, [7]University of Wisconsin School of Medicine and Public Health, Madison, Wisconsin, USA

Background: The impact of computed tomography (CT)-derived body composition on outcomes after transjugular intrahepatic portosystemic shunt (TIPS) placement remains unclear, particularly in non-cirrhotic portal hypertension (PH). This study evaluated associations between CT-derived body composition and post-TIPS outcomes. **Methods:** Adults with PH undergoing TIPS placement between July 2019 and January 2025 were prospectively enrolled at 13 U.S. centers in the Advancing Liver Therapeutic Approaches (ALTA) Study Group. This sub-study included patients from five ALTA centers with baseline CT images. CT measures at L3 included skeletal muscle index (SMI), muscle attenuation, visceral adipose tissue index (VATI), subcutaneous adipose tissue index (SATI), total adipose tissue index, VATI/SATI ratio, sarcopenia, and myosteatosis. Sarcopenia was defined as SMI <50 cm²/m² in men and <39 cm²/m² in women; myosteatosis as muscle attenuation <41 HU for body mass index <25 kg/m² and <33 HU for ≥ 25 kg/m². CT images were analyzed by trained personnel blinded to outcomes. The primary endpoint was all-cause mortality, with subgroup analyses by PH etiology, TIPS indication, and sex. Secondary endpoints included any/overt hepatic encephalopathy (HE) hospitalization, post-TIPS hospitalization rates, and MELD-Na increase ≥ 5. Competing risk regression considered liver transplantation (LT)/TIPS occlusion for mortality and death/LT/TIPS occlusion for secondary time-to-event endpoints. Models adjusted for age, sex, PH etiology, history of ascites, history of HE, and baseline MELD-Na. **Results:** Among 255 patients (201 cirrhosis; 54 non-cirrhotic PH), median age was 57 years, 62.7% were male, median MELD-Na was 13, and sarcopenia prevalence was 45.9%. During a median follow-up of 25.8 months, 65 (25.5%) deaths occurred. In multivariable analysis, sarcopenia (sHR 2.04, 95% CI 1.22–3.42; $p = 0.007$) and age (sHR 1.07 per year; $p < 0.001$) independently predicted mortality, whereas myosteatosis and adipose tissue indices did not. The association between sarcopenia and mortality was consistent across PH etiologies (cirrhosis, $p = 0.007$; non-cirrhotic PH, $p = 0.010$; Figure 1), sex subgroups (male, $p = 0.004$; female, $p = 0.029$), and TIPS indications for gastrointestinal bleeding ($p = 0.031$) or portal vein thrombosis ($p = 0.002$), but not ascites ($p = 0.570$). No CT-derived body composition measure was associated with any/overt HE hospitalization, post-TIPS hospitalization rates, or MELD-Na worsening. **Conclusion:** Among CT-derived body composition measures, sarcopenia independently predicted post-TIPS mortality in both cirrhosis and non-cirrhotic PH, whereas myosteatosis and adipose tissue indices were not associated with mortality or other outcomes. Routinely acquired pre-TIPS CT may support risk stratification and identify sarcopenia as a potentially modifiable target to improve survival.

1580 | DISEASE PROGRESSION AND OUTCOMES OF ACUTE KIDNEY INJURY IN ALCOHOL-RELATED VERSUS MASH CIRRHOSIS

Karim Besir[1] Don Rockey[1], [1]Medical University of South Carolina (MUSC)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Acute kidney injury (AKI) is a common complication in patients with cirrhosis and is associated with significant morbidity and mortality. Although both alcohol-related (ETOH) and metabolic dysfunction-associated steatohepatitis (MASH) cirrhosis represent leading causes of end-stage liver disease, data comparing AKI severity, progression, and hospitalization outcomes between these etiologies remain limited. Here, we hypothesized that renal disease progression and clinical outcomes differ among patients with ETOH and MASH cirrhosis hospitalized with AKI. **Methods:** We retrospectively examined electronic health records of hospitalized patients with cirrhosis admitted to the Medical University of South Carolina (MUSC) between 2012 and 2023 with AKI defined by the Acute Kidney Injury Network (AKIN) criteria. Patients with ETOH and MASH cirrhosis were compared for baseline characteristics, renal disease progression, and hospitalization outcomes. A power calculation was performed assuming that patients with ETOH cirrhosis would have greater AKI severity reflected by at least a 0.5 mg/dL greater delta creatinine (peak creatinine minus baseline creatinine) compared to patients with MASH cirrhosis. This yielded a total requirement for 163 patients, including 112 and 51 patients with ETOH and MASH cirrhosis, respectively. Multivariable logistic regression analyses were performed using SPSS. **Results:** A total of 180 patients with cirrhosis admitted with AKI were included - 116 patients with ETOH cirrhosis, 52 patients with MASH cirrhosis, and 12 patients with other cirrhosis etiologies. Patients with MASH cirrhosis were older and more frequently had diabetes mellitus and CKD (**Table 1**). Patients with ETOH cirrhosis were more commonly male. Baseline creatinine was higher among patients with MASH cirrhosis (1.2 vs 1.0 mg/dL, $p = 0.026$), while patients with ETOH cirrhosis had higher admission creatinine (2.6 vs 2.1 mg/dL, $p = 0.200$) and peak creatinine (3.2 vs 2.5 mg/dL, $p = 0.046$). In addition, patients with ETOH cirrhosis had a significantly greater change in creatinine from baseline to peak levels compared with patients with MASH cirrhosis (2.2 vs 1.3 mg/dL, $p = 0.043$). Rates of intensive care unit admission (43% vs 26%, $p = 0.183$) and in-hospital mortality (28% vs 21%, $p = 0.657$) were higher among patients with ETOH cirrhosis following regression analysis, though these differences were not statistically significantly different. **Conclusion:** Among hospitalized patients with cirrhosis and AKI, patients with ETOH cirrhosis had significantly greater progression of renal dysfunction, reflected by a larger increase in creatinine from baseline to peak levels, than patients with MASLD. These findings may reflect the systemic and nephrotoxic effects of alcohol, including oxidative stress and hemodynamic dysregulation, which may contribute to a more severe AKI phenotype and worse clinical course in this population.

Table 1. Characteristics and Outcomes Among Patients with ETOH vs MASH Cirrhosis

Variable	ETOH (n=116)	MASH (n=52)	p-value
Age (years ± SD)	58 ± 11.0	67 ± 11	<0.001
BMI (kg/m² ± SD)	26 ± 5	28 ± 5	0.100
Females (%)	21 (19)	24 (46)	0.023
Diabetes mellitus (%)	23 (20)	33 (64)	<0.001
Chronic kidney disease (%)	12 (10)	13 (25)	0.032
Ascites (%)	74 (64)	30 (57)	0.680
Hepatic encephalopathy (%)	38 (33)	15 (29)	0.868
ICU admission (%)	50 (43)	13 (26)	0.183
Baseline creatinine (mg/dL ± SD)	1.0 ± 0.3	1.2 ± 0.3	0.026
Admission creatinine (mg/dL ± SD)	2.6 ± 2.1	2.1 ± 1.7	0.200
Peak creatinine (mg/dL ± SD)	3.2 ± 2.2	2.5 ± 1.7	0.046
Delta creatinine (mg/dL ± SD)	2.2 ± 2.2	1.3 ± 1.7	0.043
In-hospital mortality (%)	33 (28)	11 (21)	0.657

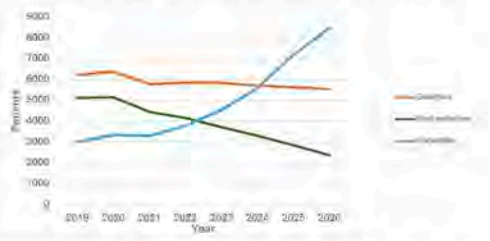
1581 | BETA-BLOCKER UTILIZATION IN U.S. VETERANS WITH CIRRHOSIS AND CLINICALLY SIGNIFICANT PORTAL HYPERTENSION

Claire Durkin[1] Vera Yakovchenko[2] Patrick Spoutz[3] Sumedha Chhatre[4] Shari Rogal[1], [1]University of Pittsburgh, [2]VA Pittsburgh Healthcare System, [3]U.S. Department of Veterans Affairs, [4]Philadelphia Corporal Michael J. Crescenz VA Medical Center



Background: Recent AASLD guidelines and Baveno VII criteria recommend carvedilol for clinically significant portal hypertension (CSPH) in cirrhosis due to greater portal pressure reduction, hepatic decompensation prevention, and potential survival benefit compared to traditional non-selective beta blockers (BBs). However, its adoption into routine clinical practice remains poorly characterized. **Methods:** This retrospective cohort study used Veterans Health Administration (VA) data to evaluate adults (≥ 18 years) with cirrhosis and CSPH from 2019–2025. Cirrhosis was identified using ≥ 1 inpatient or ≥ 2 outpatient ICD-10 codes. CSPH was defined by platelet count $< 150 \times 10^9$/L. Patients with prior liver transplant or transjugular intrahepatic portosystemic shunt were excluded. Clinical and demographic characteristics were compared by BB exposure group based on any prescription fill: carvedilol, non-selective BB (propranolol, nadolol, or labetalol), selective BB, or no BB. Multivariable logistic regression identified factors associated with carvedilol receipt, adjusting for age, sex, race/ethnicity, Charlson comorbidity index, cirrhosis etiology, Model for End-Stage Liver Disease (MELD) 3.0, ascites, encephalopathy, variceal hemorrhage, VA facility complexity level, gastroenterology (GI) visit within 1 year, and esophagogastroduodenoscopy (EGD) within 3 years. **Results:** From 2019-2025, Veterans with

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

cirrhosis and CSPH receiving carvedilol increased nearly 3-fold (2,998 to 8,487), while non-selective BB use declined by over half (5,128 to 2,359; **Figure**). In contrast, selective BB and no BB use remained stable, as did annual EGD rates (23.9-29.9%). Although MELD scores were similar (range 9-11), history of hepatic decompensation was more frequent among patients receiving non-selective BB (66%) versus carvedilol (44%), selective BB (36%), or no BB (40%), including ascites, encephalopathy, and variceal bleeding (all $p < 0.001$). Metabolic dysfunction-associated liver disease (MASLD) was more common among patients receiving carvedilol (20%) and selective BB (18%) compared to non-selective BB (13%; $p < 0.001$). Carvedilol and non-selective BB recipients were more likely to receive GI care and EGD screening (both $p < 0.001$). Factors associated with carvedilol receipt included older age, male sex, Black race, greater comorbidities, MASLD, higher MELD, variceal bleeding, higher VA facility complexity, and GI consultation, whereas encephalopathy and recent EGD were associated with lower odds of carvedilol receipt (all $p < 0.05$, **Figure**). **Conclusion:** Carvedilol use rapidly increased and surpassed non-selective BB use among Veterans with cirrhosis and CSPH over the past 5 years, suggesting early adoption of evidence-based practice. Variation in carvedilol use by clinical characteristics and healthcare utilization highlights opportunities to improve implementation of CSPH management across VA settings.

1582 | CAP-ASSISTED ENDOSCOPIC POLIDOCANOL SCLEROTHERAPY FOR BLEEDING INTERNAL HEMORRHOIDS IN CIRRHOSIS: LONG-TERM RESULTS OF A RANDOMIZED TRIAL OF LIQUID VERSUS FOAM

Srajit Singh[1] Vikram Bhatia[1] Ishank Johri[1], [1]Institute of Liver and Biliary Sciences, New Delhi

Background: Lower gastrointestinal bleeding in cirrhosis is frequently multifactorial, with internal hemorrhoids, rectal varices, and portal hypertensive colopathy often coexisting. Evidence for hemorrhoid-directed therapy in portal hypertension remains limited. We evaluated the safety, hemostatic efficacy, and long-term outcomes of cap-assisted endoscopic sclerotherapy using liquid versus foam polidocanol in cirrhotic patients with bleeding internal hemorrhoids. **Methods:** In this single-center prospective randomized trial, adults with cirrhosis/portal hypertension and anorectal bleeding were screened between November 2023 and July 2025. Patients with confirmed bleeding internal hemorrhoids were randomized 1:1 to cap-assisted endoscopic sclerotherapy with either 1.5% liquid polidocanol or Tessari-method foam polidocanol. Injections were delivered submucosally using a standardized left-posterior-right-anterior sequence under cap visualization. The primary endpoint was complete bleeding cessation by day 7. Secondary endpoints included 8-week bleeding control, post-procedure pain, rescue transfusion/therapy, adverse events, and long-term rebleeding during follow-up until May 2026. **Results:** Of 180 screened patients, internal hemorrhoids were identified in 103 patients, 57%. Twenty-five patients were randomized: foam $n = 12$ and liquid $n = 13$. Coexisting rectal varices were present in 8/25 patients, 32%, and portal hypertensive colopathy in 13/25, 52%, highlighting the diagnostic complexity of anorectal bleeding in cirrhosis. Day-7 bleeding cessation occurred in 22/25 patients, 88% overall: 10/12, 83.3%, with foam and 12/13, 92.3%, with liquid; $p = 0.42$. At 8 weeks, bleeding control remained high at 90% among evaluable patients, with no early rebleeding in the liquid arm. Immediate post-procedure pain was higher with foam; $p = 0.028$. Rescue transfusion was numerically more frequent with foam, OR 5.14; 95% CI 0.46–56.9. During extended follow-up censored in May 2026, median follow-up was

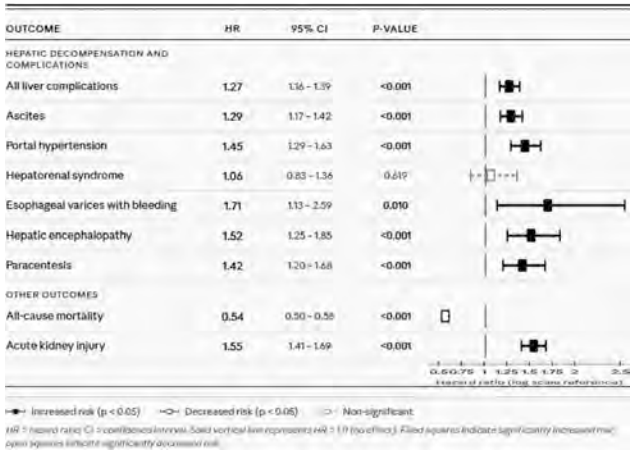
20 months. Long-term outcomes favored liquid polidocanol, with more durable bleeding control and fewer late rebleeding events compared with foam. No major procedure-related adverse event, ulcer-related bleeding, sepsis, or hepatic decompensation occurred. **Conclusion:** Cap-assisted endoscopic polidocanol sclerotherapy achieved rapid hemostasis and durable bleeding control in cirrhotic patients with diagnostically complex anorectal bleeding. Liquid polidocanol was associated with lower post-procedure pain and more favorable long-term bleeding outcomes than foam. These findings support liquid CAES as a standardized, minimally invasive treatment option for bleeding internal hemorrhoids in portal hypertension and justify validation in larger multicenter trials.

Table



Per protocol analysis	Total (N = 25)	Foam sclerotherapy group (N = 12)	Liquid sclerotherapy group (N = 13)	Odd's ratio (CI)
Complete bleeding cessation at 7 days	22 (88%)	10 (83.4%)	12 (92.3%)	0.42 (0.03-5.30)
Complete bleeding cessation till 4 weeks	19/24 (79.2%)	9/11 (82%)	10/13 (77%)	0.74 (0.10-5.5)
Complete bleeding cessation till 8 weeks	19/21 (90%)	9/11 (82%)	10/10 (100%)	0.18 (0.008-4.27)

1583 | GUIDELINE-DIRECTED MEDICAL THERAPY IN PATIENTS WITH CONCURRENT HFREF AND COMPENSATED CIRRHOSIS: REAL-WORLD OUTCOMES

Basil Jalamneh[1] Abdallah Hatem[2] Mohammed Alabbas[3] Mohamed Noor AbuHammor[1] Aravinthan Vignarajah[1] Omar Sims[1] Dian Chiang[1], [1]Cleveland Clinic Foundation, [2]Virtua Health, [3]Cleveland Clinid Foundation

Background: Patients with cirrhosis have been systematically excluded from landmark heart failure trials, leaving a critical evidence gap regarding the safety and hepatic consequences of guideline-directed medical therapy (GDMT) in this population. Despite concerns about renal dysfunction, hypotension, and portal hemodynamic perturbation, GDMT is increasingly prescribed in patients with compensated cirrhosis and heart failure with reduced ejection fraction (HFrEF). Real-world data on liver-related outcomes in this context are lacking. **Methods:** We conducted a retrospective comparative effectiveness study using the TriNetX US Collaborative Network (66 healthcare organizations) to evaluate adults with HFrEF and compensated cirrhosis without prior hepatic decompensation. Patients receiving full or near-complete GDMT ($\geq$3 of 4 pillars) were compared to those receiving incomplete or no GDMT ($\leq$2 pillars). Propensity score matching (1:1) balanced demographics, cardiovascular comorbidities, and hepatic and renal laboratory parameters. The observation period was 12 months. Primary outcomes included a composite of liver-related complications (ascites, hepatic encephalopathy [HE], hepatorenal syndrome [HRS], and variceal bleeding) and paracentesis. Secondary outcomes included acute kidney injury (AKI), hepatocellular carcinoma (HCC), and all-cause mortality. **Results:** The analysis yielded 5,052 matched patients in each cohort. Compared with incomplete or no GDMT, full or near-complete GDMT was associated with significantly higher rates of composite liver complications (HR 1.26; 95% CI 1.15–1.38; $p < 0.001$), ascites (HR 1.28; 95% CI 1.17–1.42), HE (HR 1.52; 95% CI 1.24–1.85), portal hypertension (HR 1.44; 95% CI 1.28–1.62), esophageal variceal bleeding (HR 1.71; 95% CI 1.13–2.58), AKI (HR 1.54; 95% CI 1.41–1.69), and need for paracentesis (HR 1.41; 95% CI 1.19–1.68). Risk of HRS did not differ significantly between groups (HR 1.06; 95% CI 0.83–1.35). Conversely, full or near-complete GDMT was associated with substantially lower all-cause mortality (HR 0.53; 95% CI 0.49–0.58; $p < 0.001$) and a lower incidence of HCC. Figure-1. **Conclusion:** In this large real-world cohort of patients with compensated cirrhosis and HFrEF, full or near-complete GDMT was associated with increased rates of hepatic decompensation events, portal hypertensive complications, and AKI, yet conferred a significant survival benefit. These findings reveal a clinically important trade-off between cardiac optimization and hepatic risk in this vulnerable population. They underscore the need for individualized, multidisciplinary management and prospective studies to define the optimal therapeutic approach for patients with concomitant HFrEF and cirrhosis. The survival benefit despite the hepatic risk observed could be related to improved cardiovascular outcomes, but more investigation is warranted.

1584 | EUS-GUIDED DIRECT PORTAL PRESSURE GRADIENT (EUS-PPG) CORRELATES WITH MEANINGFUL LONG-TERM CLINICAL OUTCOMES

Tyler Doty[1] Don Rockey[2] Lindi Newton[1] Kevin Pak[1] Jerome Edelson[1], [1]Brooke Army Medical Center, [2]Medical University of South Carolina

Background: The hepatic venous pressure gradient (HVPG) has long been used a prognostic indicator for predicting variceal hemorrhage (VH), decompensation, and other clinical outcomes. EUS-guided direct portal pressure gradient (EUS-PPG) allows for direct measurements of portal pressure. Data correlating the PPG to long-term clinical outcomes is lacking. We aimed to characterize the relationship between PPG and clinical outcomes. **Methods:** We retrospectively evaluated consecutive patients at our facility who underwent EUS-PPG measurement to evaluate the severity of liver disease from 2021-2025. Extensive clinical data were abstracted, including demographics, liver function tests, pressure measurements, additional interventions, and adverse events. Outcomes over a 4-year follow-up period, including liver decompensation events such as hepatic encephalopathy (HE), VH, and ascites, hospitalizations, and initiation or changes to non-selective beta blocker (NSBB) therapy were recorded. We also evaluated whether PPG measurements lead to initiation or changes in medical management as well as any directly visualized disease progression noted on endoscopy such as new or worsening esophageal or gastric varices. **Results:** A total of 57 patients underwent EUS-PPG during the study period. The mean age was 62, and women made up 49% of the cohort. 29 patients had cirrhosis, with 5 diagnosed post-procedure. The most common cause of liver disease was MASLD. At the time of PPG measurement, 24 of 29 with cirrhosis were compensated. 21 patients had endoscopic evidence of portal hypertension (pHTN), including 14 with portal hypertensive gastropathy, 7 with esophageal varices, and 1 with gastric varices. The mean PPG in patients with endoscopic evidence of pHTN was 8.4 compared to 4 in those without pHTN. 10 patients had varices at time of EUS-PPG, and the mean PPG was 9mmHg. 12 patients were initiated on NSBBs or changed dosage after EUS-PPG. There were 7 decompensations during the 4-year follow up period after PPG measurement, including 4 patients with worsening ascites, 2 with HE, and 3 patients with VH. Patients with higher PPG values were more likely to decompensate while those with lower values less likely to decompensate (**Figure**). Higher MELD-NA, APRI, and FIB-4 scores directly correlated with higher mean EUS-PPG ($p = 0.037$). A total of 5 cirrhotics (17%) died during the 4-year follow up period. The mortality did not correlate with PPG. **Conclusion:** In patients with underlying liver disease, EUS-PPG correlates with meaningful clinical features, including markers of fibrosis and MELD-Na. PPG values also correlated with clinical outcomes, including decompensation events.

1585 | EFFECTIVENESS OF TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT IN IMPROVING CLINICAL OUTCOMES OF PATIENTS WITH HEPATORENAL SYNDROME: A SYSTEMATIC REVIEW AND META-ANALYSIS

Yeonjung Ha[1] Young Chang[2] Do Seon Song[3], [1]CHA Bundang Medical Center, CHA University, [2]Soonchunhyang University, [3]Department of Internal Medicine St. Vincent's Hospital College of Medicine, The Catholic University

Background: Hepatorenal syndrome (HRS) is a life-threatening complication in patients with cirrhosis with limited treatment options. Although transjugular intrahepatic portosystemic shunt (TIPS) may serve as a salvage or alternative therapy for portal hypertension-

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

related complications, its role in HRS has not been clearly established. This study aimed to evaluate the effects of TIPS on renal function and survival in patients with HRS through a systematic review and meta-analysis. **Methods:** A comprehensive literature search was conducted in PubMed, Embase, the Cochrane Library, and KoreaMed from inception to July 14, 2025, to identify studies reporting outcomes of TIPS in patients with HRS. The primary outcome was changes in renal function, assessed by serum creatinine (sCr) and urine output. Secondary outcomes included in-hospital mortality and survival rates at 3, 6, and 12 months. Pooled estimates were calculated using random-effects models. **Results:** Sixteen studies were included, comprising 10 single-arm and 6 comparative studies. Following TIPS placement, renal function improved significantly, with a mean reduction inserum creatinine of 1.07 mg/dL (95% CI, −1.45 to −0.70) and a mean increase in urine output of 1,007.14 mL (95% CI, 620–1,395). TIPS was associated with a lower risk of in-hospitalmortality than non-TIPS management (OR 0.50; 95% CI, 0.33–0.77). The pooled survival rates at 3, 6, and 12 months were 85%, 77%, and 59%, respectively. Complications werevariably reported across studies, and hepatic encephalopathy was the most commonly reported adverse event. **Conclusion:** TIPS was associated with improved renal function and reduced in-hospital mortality in selected patients with HRS.

1586 | BASELINE OSTEOSARCOPENIA AND LONGITUDINAL MUSCULOSKELETAL DECLINE ARE ASSOCIATED WITH CLINICAL PROGRESSION IN CIRRHOSIS

Anaisa Carranza-Carrasco[1] Osvely Méndez-Guerrero[2] Yesica Meraz Arredondo[1] Rodrigo Guerrero-Guerrero[1] Claudia López-López[1] Fabiola M Del Razo-Olvera[1] Alma Estanes-Hernández[1] Graciela Castro-Narro[3] Nalu Navarro-Alvarez[4], [1]Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, [2]Instituto Nacional de Ciencias Medicas y Nutrición Salvador Zubiran, [3]Hospital Médica Sur, Ciudad de México. Instituto Nacional de Ciencias Médicas y Nutrición, [4]University of Colorado Anschutz Medical Campus/ Instituto Nacional de Ciencias Médicas y Nutrición

Background: Clinical progression in cirrhosis is often assessed by liver disease severity, but patients with similar hepatic function can follow very different clinical trajectories. Loss of bone and skeletal muscle may capture a broader state of systemic vulnerability that is not fully reflected by conventional liver scores. Osteosarcopenia, defined by the coexistence of osteoporosis and sarcopenia, may therefore identify patients at higher risk for decompensation and death. We evaluated whether baseline osteosarcopenia was associated with clinical progression in cirrhosis and whether patients who progressed had greater longitudinal loss of bone density (BMD) and skeletal muscle mass. **Methods:** We conducted a prospective cohort study of patients with cirrhosis followed for one year. Clinical progression was defined as first decompensation, further decompensation, or death; liver transplantation was treated as a censoring event. Baseline liver disease severity was assessed using Child-Pugh classification. Baseline osteosarcopenia and longitudinal musculoskeletal changes were evaluated by DXA. Clinical progression-free survival was evaluated using Kaplan-Meier curves and the log-rank test. Cox proportional hazards regression was used to assess the association between baseline osteosarcopenia and clinical progression, adjusted for age, sex, and Child-Pugh class. In the subgroup with follow-up DXA assessment, changes in femoral BMD, lumbar spine BMD, and appendicular skeletal muscle index (ASMI) were compared by progression status. **Results:** A total of 100 patients were included, of whom 53 developed clinical progression during follow-up. Baseline osteosarcopenia was associated with lower clinical progression-free survival (log-rank $p < 0.001$) and remained independently associated with clinical progression after adjustment for age, sex, and Child-Pugh class (HR 2.50, 95% CI 1.29-4.87; $p = 0.007$). Patients who progressed were older than those who did not (56 [50-62] vs. 53 [45.5-59.5] years; $p = 0.045$), while sex distribution was similar. Alcohol-related cirrhosis was more frequent among patients with progression (26.42% vs. 6.38%; $p = 0.013$). Patients who progressed also had more advanced liver disease at baseline, with fewer Child-Pugh A patients and more Child-Pugh B/C patients ($p < 0.001$). Among patients with follow-up DXA ($n = 75$), clinical progression was accompanied by greater declines in femoral BMD, lumbar spine BMD, and ASMI (Figure 1). **Conclusion:** Osteosarcopenia was independently associated with clinical progression and lower progression-free survival in patients with cirrhosis. Patients who progressed also had greater longitudinal loss of bone density and skeletal muscle mass. Bone and muscle assessment may add clinically useful information to progression risk assessment in cirrhosis.

1587 | REAL-WORLD EVALUATION OF A MULTIMODAL SYMPTOM-DIRECTED CARE STRATEGY FOR MUSCLE CRAMPS IN AMBULATORY PATIENTS WITH CIRRHOSIS

Manasa Alla[1] Anand Kulkarni[2] Mithun Sharma[1] Padaki Nagaraja Rao[1] Sowmya T R[1] Shantan Venishetty[1], [1]AIG hospitals, [2]Asian Institute of Gastroenterology

Background: Muscle cramps are common in cirrhosis and are frequently associated with impaired sleep, frailty, and reduced quality of life. Existing therapeutic data are limited and largely focused on isolated pharmacological interventions. We evaluated the effect of a structured multimodal symptom-directed intervention on muscle cramps and patient-centered outcomes in ambulatory cirrhosis patients. **Methods:** This retrospective study included adult ambulatory patients with clinically or radiologically diagnosed cirrhosis and clinically significant muscle cramps attending a tertiary care hepatology outpatient department between July 2025 and February 2026. Patients with overt hepatic encephalopathy grade ≥ 2, active infection, severe renal dysfunction, hepatocellular carcinoma, or severe neurological illness were excluded. Patients received a 12-week multimodal intervention comprising taurine 3 g/day, L-carnitine 1.2–1.8 g/day, dietary protein optimization, bedtime snack advice, and counselling for mild resistance exercises. Baseline demographic and clinical parameters, frailty assessment (SARC-F and chair-stand testing), and sleep quality using Pittsburgh Sleep Quality Index (PSQI) were recorded. Primary outcome was change in muscle cramp frequency and severity at 12 weeks. Secondary outcomes included changes in sleep quality, frailty parameters, falls, and patient-reported functional status **Results:** A total of 50 patients were included with a mean age of 52.6 ± 10.9 years; 70% were male. Alcohol-related liver disease (41%) and MASLD (29%) were the predominant etiologies. Ascites was present in 48% and refractory ascites in 31% of patients. Baseline poor sleep quality (PSQI >5) and frailty were present in 68% and 36% of patients, respectively. At 12 weeks, median weekly cramp frequency reduced from 5 (IQR 4–7) to 2 (IQR 1–4) episodes/week ($p<0.001$), while median cramp severity score improved from 7 (IQR 6–8) to 3 (IQR 2–5) ($p<0.001$). Overall, 72% of patients achieved $\geq 50\%$ reduction in cramp frequency. Mean PSQI scores improved significantly from 10.2 ± 3.1 to 6.1 ± 2.8 ($p<0.001$), with reduction in nocturnal cramp-related awakenings from 64% to 29% ($p<0.001$). Significant improvement was also observed in frailty measures, with mean SARC-F scores improving from 4.1 ± 1.2 to 2.9 ± 1.1 ($p=0.01$). Patients adherent to both supplementation and resistance exercise demonstrated greater symptomatic improvement compared to partially adherent patients (78% vs 46%, $p=0.02$).No major treatment-related adverse events were observed. Mild gastrointestinal intolerance occurred in 8% of patients and did not require discontinuation **Conclusion:** A multimodal symptom-directed intervention integrating taurine, L-carnitine, nutritional optimization, and resistance exercise was associated with significant improvement in muscle cramp burden, sleep quality, and functional status in ambulatory patients with cirrhosis.

1588 | ADVERSE EFFECTS OF ALBUMIN THERAPY IN CIRRHOSIS-ASSOCIATED ACUTE KIDNEY INJURY

Karim Besir[1] Don Rockey[1], [1]Medical University of South Carolina (MUSC)

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Background: Acute kidney injury (AKI) is a frequent and serious complication in cirrhosis, associated with high morbidity and mortality. Albumin is well established in the management of hepatorenal syndrome (HRS-AKI); however, its role in non-HRS AKI remains unclear, with prior studies showing conflicting results regarding renal recovery and survival. Given these inconsistencies and the lack of reliable data, we evaluated the association between albumin therapy and clinical outcomes among hospitalized cirrhotic patients with AKI. **Methods:** This retrospective cohort study used the TriNetX Global Collaborative Network, including adults ≥18 years with a diagnosis of cirrhosis who were hospitalized with AKI. Patients were identified and stratified into two cohorts: Cohort 1 (N = 42,568) did not receive albumin, and Cohort 2 (N = 23,506) received albumin. Propensity score matching was performed to balance demographics, comorbidities, concurrent medications, and relevant laboratory values between groups. The index event was defined as the onset of AKI, and patients with HRS-AKI and/or clinical outcomes prior to the index event were excluded. The primary outcome was mortality within 30 days of hospital admission, and secondary outcomes included the development of pulmonary edema, heart failure, a composite of liver-related complications (spontaneous bacterial peritonitis (SBP), hepatic encephalopathy (HE), ascites, esophageal variceal bleeding (EVB)) and incident infection within 30 days of hospital admission. **Results:** A total of 87,514 patients with cirrhosis hospitalized with acute kidney injury (AKI) were identified (mean age 66 ± 13 years). Among these, 25,836 patients received albumin, 46,031 did not receive albumin, and exposure data were not available on the remaining patients. After propensity score matching, two well-balanced cohorts were generated (N = 22,808 in each). Albumin use in patients hospitalized with AKI was associated with a significantly higher 30-day mortality compared to no albumin (31% vs 17%; OR 2.29; $p < 0.0001$), as well as higher rates of in-hospital pulmonary edema, heart failure, and infection (**Table 1**). Additionally, liver-related complications, including SBP, HE, ascites, and EVB were significantly higher in the albumin group (14% vs 5%; OR 3.1; $p < 0.0001$). In addition, 1-year mortality was 46% in the albumin group vs. 28% in the no-albumin group (OR 2.21; $p < 0.0001$). **Conclusion:** Our results show that patients who received albumin during hospitalization for AKI experienced higher 30-day mortality rates, pulmonary edema, heart failure, liver-related complications, and infections despite rigorous matching. These findings suggest that albumin should be used cautiously in patients with cirrhosis and AKI.

Table 1. Outcomes

	No Albumin* N (%)	Albumin N (%)	Odd's ratio (CI)	p-value
Pulmonary edema	400 / 21,661 (2)	996 / 20,722 (5)	2.68 (2.32–3.11)	<0.0001
Heart failure	316 / 18,316 (2)	474 / 18,024 (3)	1.54 (1.33–1.78)	<0.0001
Any liver complication	726 / 14,042 (5)	1398 / 9,674 (14)	3.10 (2.82–3.41)	<0.0001
Infection*	584 / 8,267 (7)	778 / 7,239 (11)	1.59 (1.43–1.77)	<0.0001
30-day mortality	3,589 / 21,566 (17)	6,971 / 22,195 (31)	2.29 (2.19–2.40)	<0.0001
1-year mortality	5,430 / 19,492 (28)	9,264 / 20,104 (46)	2.21 (2.12–2.31)	<0.0001

*Denominator totals vary because some patients had incomplete data or were lost to follow-up.
*Infections included SBP, pneumonia, UTI, skin/soft tissue, and bacteremia

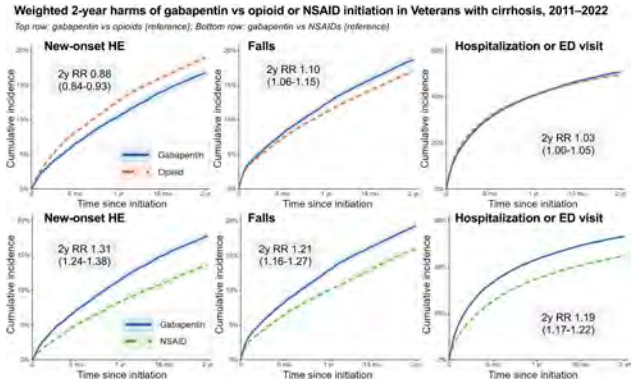
1589 | COMPARATIVE RISKS OF GABAPENTIN VERSUS OPIOIDS AND NSAIDS IN VETERANS WITH CIRRHOSIS: HARM TRADE-OFFS FROM A TARGET TRIAL EMULATION



Jessica Rubin[1] Rebecca Loeb[2] Catherine Lee[2] Hui Shen[3] Katherine Hoggatt[1] Salomeh Keyhani[1] Jennifer Lai[2], [1]Center for Data to Discovery and Delivery Innovation (3DI); University of California, San Francisco, [2]University of California, San Francisco, [3]San Francisco VA Health Care System; University of California, San Francisco

Background: Up to 80% of patients with cirrhosis suffer from chronic pain, but every analgesic class carries meaningful risk. Amid efforts to reduce opioid use, gabapentin prescribing has risen sharply, now reaching up to a quarter of patients with cirrhosis. Gabapentin's central nervous system (CNS) harms (e.g., falls, sedation) are increasingly recognized in high-risk groups such as older adults but remain understudied in cirrhosis, where renal impairment, polypharmacy, and impaired neurocognitive reserve may heighten susceptibility. Without cirrhosis-specific comparative data, it remains unclear whether rising gabapentin use reflects safer prescribing or a new source of harm. **Methods:** Using SOOTHE (Safety and Outcomes related to Opioids and other Therapeutics in End-stage liver disease), a national cohort of Veterans with cirrhosis, we emulated two target trials with a new-user, active-comparator design, comparing gabapentin initiation to opioids (primary) and NSAIDs (secondary). Eligible Veterans

were ≥18 years with cirrhosis and chronic pain. For each analysis, index date was the first qualifying fill after a 12-month washout of both drugs in that comparison; those initiating both within 14 days were excluded. Separate propensity models per comparison were used to estimate stabilized IPTW. By intention-to-treat, we estimated weighted 2-year cumulative incidence and relative risks (RR) for new hepatic encephalopathy (HE; among those without baseline HE), falls, and hospitalization or ED visit, treating death and transplant as competing events. **Results:** We identified 14,448 gabapentin and 31,312 opioid initiators, and 18,438 gabapentin and 20,563 NSAID initiators. In the primary comparison, median age was 64y, 96% were male, 43% had ascites, and 17% prior HE; median MELD 3.0 was 11. After weighting, all measured covariates were balanced (SMDs <0.1), despite large pre-weighting differences in disease severity and comorbidity. Versus opioid initiators, gabapentin initiators had a lower 2-year risk of new HE (16.8% vs 19.0%; RR 0.88, 0.84-0.93) but a higher fall risk (18.7% vs 16.9%; RR 1.10, 1.06-1.15); hospitalization was similar (RR 1.03, 1.00-1.05). Versus NSAID initiators, gabapentin initiators had a higher risk of falls, HE, and hospitalization (RRs 1.19-1.31) **(Fig)** . **Conclusion:** Despite its rising use, gabapentin was not a uniformly safer analgesic among Veterans with cirrhosis and chronic pain. Gabapentin initiation carried higher fall risk than both opioid and NSAID initiation, consistent with its known CNS harms; it conferred lower HE risk than opioids, which are recognized HE precipitants. Weighting balanced measured confounders but cannot fully account for unmeasured confounding (e.g., frailty, functional status, pain severity). Yet the consistent excess in falls across comparators supports genuine gabapentin-related harm and cautions against reflexive substitution of gabapentin for opioids.

1590 | PREDICTORS OF SEVERE FALLS IN A MULTICENTER NORTH AMERICAN COHORT OF OUTPATIENTS WITH CIRRHOSIS

Puneeta Tandon[1] Jacqueline O'Leary[2] Jennifer Lai[3] K Rajender Reddy[4] Florence Wong[5] Guadalupe Garcia-Tsao[6] Scott Biggins[7] Philip Vutien[8] Hugo Vargas[9] Patrick Kamath[10] Ana Teresa Limon-Miro[1] Brian Bush[11] Scott Silvey[11] Jasmohan Bajaj[11], [1]University of Alberta, [2]Dallas VA Medical Center, [3]University of California San Francisco, [4]University of Pennsylvania, [5]University of Toronto, [6]Yale University, [7]University of Pittsburgh, [8]University of Washington, [9]Mayo Clinic Arizona, [10]Mayo Clinic, Rochester, [11]Virginia Commonwealth University

Background: Falls are increasingly recognized as a major contributor to morbidity and mortality in patients with cirrhosis. Prior studies demonstrate strong associations between minimal hepatic encephalopathy, sarcopenia, frailty, cognitive impairment, and fall risk. The North American Consortium for the Study of End-Stage Liver Disease (NACSELD) is a prospective cohort of outpatients with compensated and decompensated cirrhosis recruited from 11 centers across North America. This cohort provides a unique opportunity to examine falls in a large, multicenter sample with prospectively collected, multidimensional data. **Methods:** Patients were assessed at baseline for a history of severe falls (those requiring hospitalization or resulting in a fracture) in the three months prior to enrollment. Baseline variables were summarized and compared between patients with and without a history of severe falls using the Wilcoxon rank-sum test or Pearson's chi-squared test as appropriate. Multivariable logistic regression models were fit to identify independent predictors of severe falls, including all variables that were statistically significant ($p < 0.05$) on univariable comparison. **Results:** 1007 outpatients with cirrhosis (median age 62 [IQR 55–68], 69% male, median Model for End-Stage Liver Disease [MELD] 3.0 score 11 [IQR 8–16], 39% compensated), all with controlled liver disease etiology, were prospectively enrolled. One hundred fourteen participants (11.3%) reported a severe fall in the three months prior to enrollment. On univariable analysis, patients who fell had higher MELD-3.0 scores, higher Charlson Comorbidity Index scores, greater opioid use, higher Clinical Frailty Scale (CFS) and Liver Frailty Index scores, longer EncephalApp Stroop times, and lower Duke Activity Status Index (DASI) scores (all p0.05). On multivariable logistic regression, current opioid use (adjusted odds ratio [aOR] 2.29, 95% CI: 1.30–3.92, $p = 0.003$), higher CFS score (aOR 1.39, 95% CI:

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

1.11–1.73, p = 0.004), and lower DASI score (aOR 0.97, 95% CI: 0.95–0.99, p < 0.001) were the only independent predictors of severe falls. **Conclusion:** In this contemporary, multicenter outpatient cohort of patients with etiology-controlled cirrhosis, opioid use, frailty, and reduced functional capacity were identified as independent predictors of severe falls and represent actionable targets for fall prevention.

1591 | URINARY L-FABP AND [TIMP-2]×[IGFBP7] DETECT EARLY RENAL HYPOPERFUSION IN PROPRANOLOL-TREATED CIRRHOTIC RATS

Hui-Chun Huang[1] Chiao-Lin Chuang[1] Shao-Jung Hsu[2] Ming-Chih Hou[1] Fa-Yauh Lee[2], [1]Taipei Veterans General Hospital, [2]National Yang-Ming University

Background: Non-selective beta-blockers (NSBBs) are the mainstay of treatment for variceal hemorrhage in cirrhotic patients. However, the safety of NSBBs in decompensated cirrhosis has been questioned due to concerns about triggering hemodynamic derangement, which could adversely affect renal function. The development of hypotension and renal hypoperfusion are clinical signs of circulatory dysfunction. Thus, we investigate the thorough hemodynamics of rats with common bile duct ligation (CBDL)-induced liver cirrhosis receiving propranolol treatment. Also, we studied the diagnostic utility of several urinary biomarkers respectively for early detection of renal hypoperfusion in propranolol-treated CBDL rats. **Methods:** Four weeks after CBDL, rats were randomized to receive oral distill water (DW) or propranolol (30 mg/kg/day) for 2 weeks then placed individually in the polycarbonate metabolic cages to collect 24-hour urine on the 15th day. The urinary NGAL, IL-18, KIM-1, L-FABP, TIMP-2, IGFBP7, and CHI3L1 levels were measured. On the 16th day post treatment, systemic and renal hemodynamics were evaluated, and blood was collected for the assessment of concentrations of albumin, alanine transaminase (ALT), aspartate aminotransferase (AST), total bilirubin, blood urea nitrogen (BUN), creatinine, tissue necrosis factor-α (TNF-α), interleukine-1β (IL-1β), and interleukine-6 (IL-6). **Results:** Propranolol treatment led to significant decreases in mean arterial pressure (MAP), heart rate, portal pressure (PP), and renal blood flow (RBF) in CBDL rats (p < 0.05). Both MAP and PP significantly correlated with RBF, while RBF inversely correlated with urinary liver-type fatty acid-binding protein (L-FABP) and the combination of tissue inhibitor of metalloproteinase-2 and insulin-like growth factor binding protein-7 ([TIMP-2]x[IGFBP7]) levels in propranolol-treated CBDL rats (p < 0.05). Propranolol-treated CBDL rats with severe hypotension (MAP < 65 mmHg) showed significantly higher IL-1β, but lower IL-6 levels than those with MAP ≥ 65 mmHg (p < 0.05). **Conclusion:** NSBBs treatment in cirrhosis may need to be individualized accompanied by careful monitoring of blood pressure and inflammatory condition. Urinary biomarkers, such as L-FABP and [TIMP-2]x[IGFBP7] serve as good candidates for detecting renal hypoperfusion following NSBBs treatment. The changes in MAP, serum IL-1β and IL-6 over time might allow the physicians to predict the possibility of NSBBs-induced AKI in cirrhotic patients.

Correlation between renal blood flow and urinary levels of NGAL (A), IL-18 (B), KIM-1 (C), L-FABP (D), [TIMP-2]x[IGFBP7] (E), and CHI3L1 (F) in propranolol-treated common bile duct ligated (CBDL) rats. CHI3L1, Chitinase-3-like protein 1; IGFBP7, insulin-like growth factor-binding protein 7; IL-18, interleukin-18; KIM-1, kidney injury molecule 1; L-FABP, liver-type fatty acid-binding protein; NGAL, neutrophil gelatinase-associated lipocalin; TIMP-2, tissue inhibitor of metalloproteinases-2. Urinary values of L-FABP (G) and [TIMP-2]x[IGFBP7] (H) increased in propranolol-treated CBDL rats with MAP < 65 mmHg. DW, distilled water.

1592 | CORRELATION OF BAVENO VII AND ANTICIPATE-NASH NONINVASIVE MODELS WITH HVPG IN PATIENTS WITH MASH CIRRHOSIS: FINDINGS FROM A PHASE 2B BELAPECTIN TRIAL

Naim Alkhouri[1] Naga Chalasani[2] Eric Lawitz[3] Raj Vuppalanchi[4] Edward Mena[5] Khurram Jamil[6] Mazen Noureddin[7], [1]Summit Clinical Research, [2]Indiana University Medical Center, [3]The Texas Liver Institute University of Texas Health San Antonio, [4]Indiana University School of Medicine, [5]California Liver Reasearch Instituite, [6]Galectin Therapeutics, [7]Houston Methodist Hospital. Summit Clinical Research

Background: Belapectin is a novel galectin-3 inhibitor was evaluated in the Phase 2b GT-026 trial in patients with MASH cirrhosis and portal hypertension. Belapectin 2 mg/kg previously demonstrated lower hepatic venous pressure gradient (HVPG) and reduced incidence of varices in subjects without baseline varices. In recent years, noninvasive tests (NITs) have increasingly been utilized to assess portal hypertension and clinically significant portal hypertension (CSPH). We evaluated the correlation of two NIT-based models, Baveno VII criteria and ANTICIPATE-NASH, with HVPG, the gold standard assessment for portal hypertension. **Methods:** Subjects with compensated MASH cirrhosis underwent HVPG assessment at baseline. Portal hypertension was defined as HVPG ≥ 6 to < 10 mmHg and CSPH as HVPG ≥ 10 mmHg. Baveno VII categories (CSPH, probable CSPH, low/no risk CSPH) were defined using liver stiffness measurement (LSM) and platelet count. The ANTICIPATE-NASH model incorporates LSM, platelet count, and body mass index to estimate CSPH probability. Probability categories included 0–25%, 25–50%, 50–75%, and $\geq 75\%$, with $\geq 75\%$ considered rule-in for CSPH and $\geq 50\%$ representing an enrichment population for clinical trials. Agreement between HVPG-defined CSPH and NIT-based models was assessed using kappa statistics. **Results:** Of 161 patients with HVPG data, 131 had lab data to calculate Baveno/ANTICIPATE-NASH criteria. At baseline, HVPG assessment identified CSPH in 67.1% (n = 108) of subjects, with the remaining 32.9% (n = 53) having portal hypertension without CSPH. By Baveno VII criteria, 51.1% (n = 67) met CSPH criteria, 23.7% (n = 31) were probable CSPH, and 25.2% (n = 33) were low/no risk. Agreement between HVPG-defined and Baveno VII CSPH classification yielded a kappa of 0.44 (95% CI 0.24–0.58; $p < 0.001$). By ANTICIPATE-NASH model, CSPH probability distribution was: 0–25% in 13.0% (n = 17), 25–50% in 22.1% (n = 29), 50–75% in 26.7% (n = 35), and $\geq 75\%$ in 38.2% (n = 50). Agreement between HVPG-defined CSPH and ANTICIPATE-NASH $\geq 75\%$ probability yielded a kappa of 0.41 (95% CI 0.28–0.61; $p < 0.001$).Among subjects with HVPG-defined CSPH, 62.6% met CSPH criteria by Baveno VII, 48.4% met the $\geq 75\%$ CSPH probability threshold using the ANTICIPATE-NASH model. **Conclusion:** In this Phase 2b cohort of compensated MASH cirrhosis, both Baveno VII and ANTICIPATE-NASH demonstrated moderate concordance vs HVPG-defined CSPH. The prevalence of CSPH by HVPG was higher than estimated by either noninvasive model, suggesting that both algorithms may underestimate the true burden of CSPH in this population. Baveno VII demonstrated slightly greater concordance and broader clinical stratification vs HVPG-defined CSPH than ANTICIPAT E NASH model, which may need revisiting to further refine CSPH in MASH cirrhosis. These findings support the role of noninvasive risk stratification tools in identifying patients with CSPH to enrich clinical trial populations in MASH cirrhosis.

1593 | CLINICAL SIGNIFICANCE OF EARLY RISES IN ASPARTATE- AND ALANINE AMINOTRANSFERASE ON HEPATIC ENCEPHALOPATHY POST-TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT

Stijn de Reus[1] Ellen Werner[1] Diederick van Doorn[2] Michelle Spaan[2] Diederik Bijdevaate[1] Kay Pieterman[1] Felix Piecha[3] Peter Hübener[3] Harry Janssen[1] Bettina Hansen[1] Adriaan Van der Meer[1] Robert Bart Takkenberg[2] Raoel Maan[1], [1]Erasmus University Medical Center, Rotterdam, the Netherlands, [2]Amsterdam University Medical Center, Amsterdam, the Netherlands, [3]University Medical Center Hamburg-Eppendorf, Hamburg, Germany

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is an established treatment for portal hypertensive complications. Aspartate- and alanine aminotransferase (AST, ALT) rises occur in up to 95% of patients post-TIPS, but their clinical significance remains unclear. We hypothesized that early AST/ALT elevations reflect shunt-related hepatic changes and are associated with increased ammonia exposure, increasing the risk of hepatic encephalopathy (HE). **Methods:** This retrospective study included consecutive cirrhotic patients undergoing TIPS between January 2007 and December 2023 at tertiary centers in the Netherlands and Germany. TIPS indications were set by treating hepatologists. AST/ALT was recorded at baseline, day one and seven post-TIPS, when available by using predefined windows. The primary endpoint was early HE (eHE), defined as any HE-grade within 30 days post-TIPS. **Results:** We included 547 patients; 368 male (67%), with a median age of 58 (IQR 52 – 65). The most common etiology of cirrhosis was alcohol-related in 296 (54%) patients, and refractory ascites was the main TIPS-indication (n = 285, 52%).Median baseline AST and ALT were 44 (IQR 33 – 78) and 26 U/L (IQR 19 – 45). On day one, AST and ALT increased in 257 (85%) and 234 (75%) patients. Median Δ AST and Δ ALT were 32 (IQR 8 – 75) and 12 U/L (IQR 1 – 33) on day one. Among patients with all available labs that had an AST increase on day one, 65% (106/164) had a subsequent decline on day seven, compared with 42% (72/170) for ALT.Within 30 days post-TIPS, 125 patients experienced eHE (23%). Each 50 U/L increase in Δ AST on day one was associated with a borderline increase in eHE risk (OR 1.01 , 95% CI 1.00 – 1.02, p = 0.06), but this was weakened when adjusting for MELD, age and prior HE (OR 1.01, 95% CI 0.99 – 1.02). Δ ALT on day one was not related to eHE (OR 1.03, 95% CI 0.99 – 1.07). Given the rise-fall pattern of AST post-TIPS, we evaluated patients who retained high AST (≥ 100 U/L) on day seven, despite a decline from peak level. Using Firth's penalization to account for small sample size (n = 164), this was associated with eHE (OR 3.69, 95% CI 1.45 - 10.09, p = 0.01). **Conclusion:** Early post-TIPS rises in AST and ALT are common, typically mild, and not independently associated with eHE. Persistent AST elevation on day seven, in contrast, could be linked to increased risk of eHE. Given that this observation is limited by small sample size, this finding must be confirmed. While early transaminase rises likely overlap with other risk factors for eHE, they may still signal an adverse clinical phenotype and support consideration of preventive HE strategies.

1594 | GUIDELINE ADOPTION AFTER BAVENO VII: TRENDS IN ENDOSCOPIC SURVEILLANCE AMONG COMPENSATED ADVANCED CHRONIC LIVER DISEASE PATIENTS ON NON-SELECTIVE BETA BLOCKER

Muhammad Ali Butt[1] Timothy Davie[2] Abdul Wasaay Khurram[3] Prowpanga Udompap[4], [1]Division of Gastroenterology, Hepatology and Nutrition, University of Minnesota, [2]Department of Medicine, University of Minnesota, [3]Department of Medicine, Henry Ford Jackson Hospital, [4]Minneapolis VA Medical Center

Background: Baveno VII guidelines (2022) recommend that patients with compensated advanced chronic liver disease (cACLD) on a non-selective beta blocker (NSBB) can forgo screening esophagogastroduodenoscopy (EGD). Whether this recommendation has been adopted in clinical practice remains unknown. We evaluated trends in EGD screening among cACLD patients on NSBBs before and after Baveno VII publication. **Methods:** Using the TriNetX US Collaborative Network (67 institutions), we identified two cohorts of cACLD patients initiated on an NSBB (carvedilol, propranolol, or nadolol): pre-Baveno VII (January 2019-April 2022) and post-Baveno VII (May 2022-May 2024). cACLD was defined by cirrhosis ICD-10 codes and absence of prior decompensation events (ascites, variceal bleeding, or hepatic encephalopathy) and hepatocellular carcinoma. Index date was the first NSBB prescription within the observation window. Patients were followed for 24 months. Propensity score matching (1:1) was performed on age, sex, race, ethnicity, cirrhosis etiology, MELD component laboratories, and comorbidities. The primary outcome was EGD within 24 months of NSBB initiation, excluding patients who underwent EGD within the 12 months preceding NSBB initiation. A pre-specified subgroup analysis was performed in patients with documented non-bleeding esophageal varices. A sensitivity analysis excluding carvedilol was performed to address potential indication bias. **Results:** After propensity matching, each cohort included 35,601 patients (pre- vs post-Baveno VII). All standardized mean differences were <0.1. EGD rates were 13.3% pre- vs 14.1% post-Baveno VII (OR 0.934, 95% CI 0.889 - 0.981, $p=0.006$), indicating no reduction in endoscopic surveillance following guideline publication. This finding was consistent after excluding carvedilol users (14.4% vs 15.9%; OR 0.891, 95% CI 0.822 - 0.965, $p=0.005$; $n=12,136$ matched pairs). In subgroup analysis among 13,675 matched pairs with known non-bleeding varices, EGD rates were 24.6% pre- vs 27.0% post-Baveno VII (OR 0.883, 95% CI 0.824–0.947, $p<0.001$), demonstrating persistently high and increasing surveillance rates. Carvedilol use increased significantly post-Baveno VII across all analyses (43.4% to 46.2% in the primary cohort; 31.9% to 36.7% in the variceal subgroup), while propranolol and nadolol use declined. **Conclusion:** Despite Baveno VII recommendations, EGD surveillance rates among cACLD patients on NSBBs have not declined in a large real-world US cohort, with rates remaining highest in patients with known non-bleeding varices. These findings suggest significant guideline-to-practice gaps and highlight the need for targeted educational interventions to promote appropriate de-escalation of endoscopic surveillance in this population.

Table 1. EGD rates within 24 months of NSBB initiation across primary, sensitivity, and subgroup analyses

Outcomes assessed after propensity score matching (1:1). Patients with EGD within 12 months prior to index NSBB prescription are excluded from primary outcome analysis.

Analysis	Matched pairs (n)	Pre-Baveno VII EGD rate	Post-Baveno VII EGD rate	Risk difference (95% CI)	Odds ratio (95% CI)	p-value
Primary analysis All NSBBs	35,601	13.3% (3,581 / 27,025)	14.1% (3,786 / 26,927)	−0.008 (−0.014, −0.002)	0.934 (0.889–0.981)	0.006
Sensitivity analysis Propranolol + nadolol only	12,136	14.4% (1,329 / 9,218)	15.9% (1,475 / 9,272)	−0.015 (−0.025, −0.005)	0.891 (0.822–0.965)	0.005
Subgroup analysis Known non-bleeding varices, all NSBBs	13,675	24.6% (2,039 / 8,292)	27.0% (2,206 / 8,181)	−0.024 (−0.037, −0.010)	0.883 (0.824–0.947)	<0.001

A negative risk difference indicates higher EGD rates in the post-Baveno VII cohort. EGD = esophagogastroduodenoscopy; NSBB = non-selective beta blocker; CI = confidence interval. cACLD defined by cirrhosis ICD-10 codes and absence of decompensation events. Index date = first NSBB prescription within the observation window.

1595 | ANTIBIOTIC EXPOSURE AND OUTCOMES IN SPONTANEOUS BACTERIAL PERITONITIS: MORTALITY, RESISTANCE, AND RECURRENCE

Samuel Levine[1] Nishanth Eluri[1] Halicki Barbara[1] Frank Lin[1] Daniel Guirguis[1] Ibrahim Ragab[1] Het Patel[1] Ashley Tran[2], [1]St. Luke's University Hospital, [2]St. Luke's University Health Network

Background: Prophylaxis against spontaneous bacterial peritonitis (SBP) is recommended for patients with decompensated cirrhosis at high risk for, or have a history of, SBP. Ciprofloxacin, and trimethoprim-sulfamethoxazole (TMP-SMX) have been traditionally used for these indications. However, emerging data

suggest SBP prophylaxis may be associated with adverse outcomes, including multidrug-resistant organisms, breakthrough infection, recurrence, and mortality, likely driven by rising antimicrobial resistance. This study evaluated the effects of recent antibiotic exposure on mortality and antimicrobial resistance in patients presenting with an index episode of SBP, as well as the association between secondary SBP prophylaxis and recurrence. **Methods:** This retrospective chart review included patients with cirrhosis admitted with an index episode of SBP between 2021 and 2024 across the St. Luke's University Health Network. Multivariable regression models were used to assess 30- and 90-day mortality, while unadjusted relative risks evaluated antimicrobial resistance and SBP recurrence within 180 days. **Results:** 120 patients with cirrhosis and index SBP were identified. 30- and 90-day mortality were 23.3% and 27.5% respectively. 64 patients (53.3%) had antibiotic exposure within 3 months prior to SBP presentation. Antibiotic exposure was not associated with 30-day (RR 0.87, 95% CI 0.45-1.68) or 90-day mortality (RR 0.80, 95% CI 0.45-1.44) after adjusting for age, sex, BMI, comorbidities, MELD 3.0, and recent hospitalizations. Of 25 ascitic fluid cultures with speciation, 7 (28.0%) demonstrated antibiotic resistance to fluoroquinolones, TMP-SMX, or both. Resistance was observed in 6 of 14 (42.9%) cultures from patients with prior antibiotic exposure compared to 1 of 11 (9.1%) without exposure, although this difference was not statistically significant ($p = 0.061$). 19 patients developed recurrence of SBP within 180 days, including 15 who received secondary prophylaxis. Patients receiving secondary prophylaxis had an increased risk of SBP recurrence (RR 4.83, 95% CI 1.71-13.69, $p < 0.001$). **Conclusion:** Recent studies have challenged the practice of SBP prophylaxis in patients with cirrhosis. In this analysis, prior antibiotic exposure was not associated with increased mortality, which may reflect the high burden of comorbidities in the study population. A substantially higher proportion of resistant ascitic fluid cultures was observed among patients with prior antibiotic exposure compared to those without; however, this relationship approached, but did not reach, statistical significance, likely due to limited sample size. Notably, secondary SBP prophylaxis was associated with an increased risk of recurrent SBP. These findings highlight the need to re-evaluate SBP prophylaxis strategies.

1596 | HYPER-ACUTE LIVER INJURY FOLLOWING TRANSJUGULAR INTRAHEPATIC PORTOSYSTEMIC SHUNT PLACEMENT: EARLY PREDICTORS OF 30-DAY MORTALITY

Anna Thiemann[1] Todd Frederick[1] Yohanna Khachiyan[1] Shruti Vaidya[1] Sylvia Sudat[1], [1]California Pacific Medical Center

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is a well-established intervention for portal hypertension and its complications. Hyperacute liver injury immediately following the procedure is rare and poorly characterized. In a retrospective cohort at a single tertiary care center in Northern California, we previously observed that marked abnormalities in AST, ALT, INR, and total bilirubin within 48 hours after TIPS placement were strongly associated with mortality after 30 days. In this study, we sought to determine whether the magnitude of post-procedural laboratory changes predicts 30-day mortality. **Methods:** We performed a retrospective review of all patients who underwent TIPS at our center between March 2015 and January 2024. The primary outcome was all-cause mortality at 30 days. Differences in laboratory deltas between survivors and non-survivors were assessed using the Mann-Whitney U test given non-normal data distributions. ROC analysis was performed to assess the discriminatory ability of individual markers. Youden index-optimal cutoffs were identified for each marker, and PPV, NPV, and OR were calculated via binary logistic regression. **Results:** 561 patients underwent TIPS during the study period. 9 were excluded due to signs of severe liver injury prior to TIPS (AST and/or ALT >10 ULN). 29 (5.3%) died within 30 days. Most common causes of death included hemorrhagic complications (32%), hepatic decompensation (24%), sepsis (9%), and respiratory failure (9%). Non-survivors demonstrated significantly higher post-procedural Δ AST compared to survivors (median 53 vs. 21 U/L, $p = 0.0002$), higher Δ ALT (median 18 vs. 9 U/L, $p = 0.007$), and higher Δ bilirubin (median 1.00 vs. 0.30 mg/dL, $p = 0.025$). Δ INR did not differ significantly between groups (median 0.20 vs. 0.10, $p = 0.234$). On ROC analysis, Δ AST demonstrated the highest discriminatory ability (AUC 0.707), followed by Δ ALT (AUC 0.649) and Δ bilirubin (AUC 0.623). Δ AST ≥ 50 U/L, yielded an OR of 3.50 (95% CI 1.64–7.47, $p = 0.001$).

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Δ bilirubin ≥1.0 mg/dL demonstrated an OR 4.14 (95% CI 1.94–8.85, p < 0.001). And Δ ALT ≥30 U/L produced an OR of 3.03 (95% CI 1.42–6.50, p = 0.004). Across all significant markers, NPV consistently exceeded 95%, while PPV remained < 20%. **Conclusion:** Post-procedural elevations in AST, ALT, and bilirubin were each significantly associated with 30-day mortality following TIPS. Specific laboratory thresholds (Δ AST ≥50, Δ ALT ≥30, and Δ bilirubin ≥1) identify patients at substantially elevated mortality odds, and may be useful in identifying low-risk patients after TIPS due to their high NPV. These findings support the hypothesis that hyper-acute liver injury following TIPS, potentially ischemic in etiology, portends poor short-term outcomes. Prospective validation is needed to determine whether early identification of these laboratory patterns can guide post-procedural monitoring or intervention strategies to improve survival.

Table 1

Post-procedural laboratory delta values by 30-day mortality status (n=552). Patients with AST or ALT >10x ULN excluded. Median (IQR); Mann-Whitney U test.

	Overall (n=552)	Survived (n=523)	Died at 30d (n=29)	p-value
COHORT				
30-day mortality	29 (5.3%)	–	–	–
LABORATORY DELTAS (POST − PRE), median (IQR)				
Δ AST (U/L)	24 (9–54)	21 (9–51)	53 (28–200)	0.0002
Δ ALT (U/L)	9 (3–25)	9 (2–24)	18 (6–80)	0.007
Δ Total bilirubin (mg/dL)	0.30 (0.00–0.80)	0.30 (0.00–0.80)	1.00 (0.10–1.50)	0.025
Δ INR	0.10 (0.00–0.20)	0.10 (0.00–0.20)	0.20 (0.00–0.30)	0.234
DISCRIMINATORY PERFORMANCE (AUC)				
Δ AST	0.707	Best individual predictor		
Δ ALT	0.649			
Δ Total bilirubin	0.623			
Δ INR	0.564

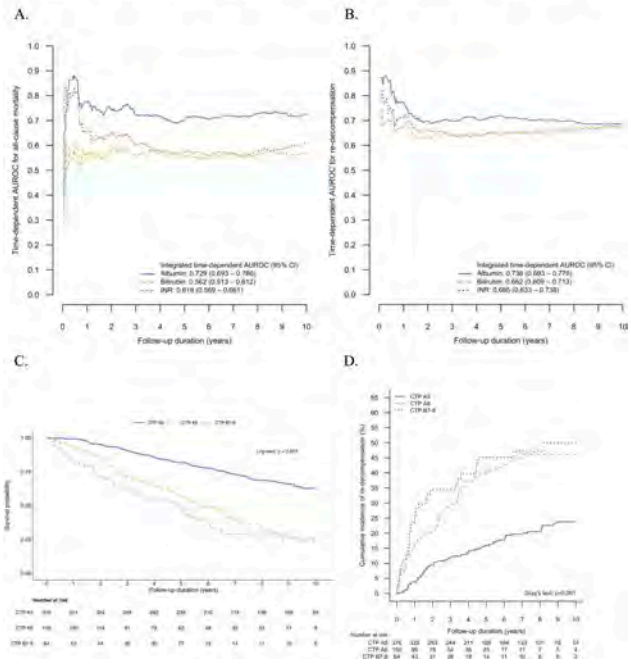
1597 | OPTIMAL BIOCHEMICAL CRITERIA FOR HEPATIC RECOMPENSATION IN HEPATITIS B VIRUS-RELATED CIRRHOSIS



Yangyue Zhang[1] Vincent Wong[1] Terry Cheuk-Fung Yip[1] Jimmy Che-To Lai[1] Xinrui Jin[1] Vicki Hui[1] Junlong DAI[1] Grace Wong[1], [1]The Chinese University of Hong Kong

Background: Under Baveno VII, hepatic recompensation requires stable biochemical improvement in liver function tests including albumin, international normalised ratio (INR), and bilirubin, but the prognostic implication of each parameter remain unclear. We aimed to evaluate the discriminatory and prognostic performance of these parameters and to validate the clinical utility of the Child-Pugh score in patients with hepatitis B virus (HBV)-related cirrhosis. **Methods:** This retrospective cohort study identified patients with HBV-related cirrhosis and prior hepatic decompensation from a territory-wide electronic healthcare database in Hong Kong. All had complete HBV DNA suppression and absence of decompensation events for at least 12 months. The primary outcome was all-cause mortality, and the secondary outcome was re-decompensation. Analyses were performed on both multiply imputed and complete-case datasets. **Results:** 871 patients were included (67.4 % male; median age 62.4 years). Over a median follow-up of 65.7 (IQR 30.7-109.6) months, 320 (36.7%) patients died and 274 (31.5%) developed re-decompensation. Albumin showed the highest discriminatory performance for mortality (integrated time-dependent area under the receiver operating characteristic curve 0.729 [95% CI 0.693-0.766]), followed by INR (0.618 [95% CI 0.569-0.661]) and bilirubin (0.562 [95% CI 0.513-0.612]). A similar pattern was observed for re-decompensation. All three parameters were significantly associated with mortality and re-decompensation after adjustment for age and sex in the restricted cubic spline analyses. In the multivariable model, however, albumin was the only independent predictor of mortality (adjusted hazard ratio 0.910 [95% CI 0.891-0.929]). In contrast, all three parameters independently predicted re-decompensation, with adjusted subdistribution hazard ratios (95% CI) of 0.917 (0.892-0.943) for albumin, 1.014 (1.001-1.026) for bilirubin, and 1.314 (1.148-1.504 per 0.1-unit increase) for INR. Similar results were observed in both the imputed and complete-case analyses. The 5-year survival probability decreased from 81.6%, 57.7%, to 48.6% in patients with Child-Pugh scores of A5, A6, and B7-8, respectively (log-rank test, p < 0.001). The stepwise increase was observed in the cumulative incidence of re-decompensation across the Child-Pugh score categories. **Conclusion:** Albumin is the strongest predictor of mortality and re-decompensation in patients with clinical recompensation. Patients with Child-Pugh A5 at clinical recompensation had the lowest risk of adverse outcomes.

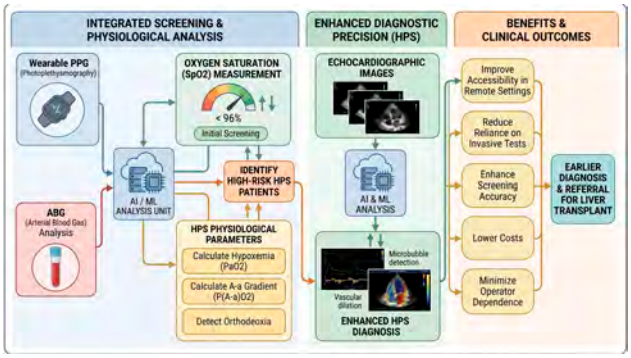
1598 | BRIDGING THE OXYGEN GAP: LEVERAGING ARTIFICIAL INTELLIGENCE TO UNMASK HEPATOPULMONARY SYNDROME



Joshika Agarwal[1] Jahnavi Mikkilineni[2] Avneet Kaur[3] Ridhi Malhotra[4] Shivaram Poigai Arunachalam[5], [1]Mercy Catholic Medical Center, Darby, PA, [2]John Hopkins University, [3]Medstar Georgetown University(Baltimore) program, [4]Manipal College of Medical Sciences, Pokhara, Nepal, [5]Mayo Clinic, Rochester, MN

Background: Most patients with hepatopulmonary syndrome (HPS) are asymptomatic, leading to delayed diagnosis and increased mortality, given that the only definitive treatment is liver transplant. The current gold standard diagnostic test includes contrast-enhanced echocardiography (CE) or a technetium-99m macroaggregated albumin (Tc-MAA) scan, accompanied by arterial-blood gas (ABG) analysis or pulmonary angiography. However, it is expensive, time-consuming, invasive, and not widely accessible. Noninvasive screening with pulse oximetry (SPO2) also lacks both sensitivity and specificity, resulting in underdiagnosis. These limitations highlight the need for advanced diagnostic methods through artificial intelligence (AI). **Methods:** A literature search including original studies was conducted using PubMed, NEJM, Lancet, and Google Scholar using broad terms related to HPS and AI. Outcomes assessed included AI performance in diagnosis, risk stratification, and prediction compared with standard diagnostic modalities. **Results:** HPS is quantitatively described by liver disease, hypoxemia (PaO_2 <80 mmHg), elevated alveolar–arterial gradient (≥ 15–20 mmHg), and intrapulmonary vascular dilatations (IPVD) causing right-to-left shunting. Orthodeoxia (≥ 3–5% rise in SpO2 in supine position) is specific. These non-invasive variables can be combined with AI-algorithms and machine learning (ML) methods for prompt screening. A study by Li YJ et al. showed a two-step ML model using ABG to predict IPVD in cirrhotic patients followed by targeted CE, attaining 87.2% accuracy. Wearable photoplethysmography (PPG) and ABG analysis integrated with AI may enable measurement of oxygen saturation of less than 96% as an initial screening tool to further calculate hypoxemia (PaO2), alveolar-arterial gradient and orthodeoxia, helping in detecting high-risk patients and enabling real-time exposure of subtle physiological changes. AI and ML can be applied to analyze echocardiographic images from CE to enhance diagnostic precision in HPS. Machine learning can improve accessibility of these screening tests in remote settings, reduce reliance on invasive tests, enhance screening accuracy, lower costs, and minimize operator dependence, facilitating earlier diagnosis of HPS and referral for liver transplant. **Conclusion:** AI-integrated methods for early, efficient

HPS diagnosis has significant potential and scope in upcoming future. However, these are theories, yet to be studied and applied in real-life scenarios. There is a growing need for the research with large sample size, data standardization, validation and generalizability. Overcoming challenges such as 'black box' nature of ML is important for widespread clinical adoption.

1599 | RATIONAL DESIGN OF A BIFUNCTIONAL VASOPRESSIN 1A RECEPTOR (V1AR) PARTIAL AGONIST FOR SUBCUTANEOUS OUTPATIENT DELIVERY: LESSONS FROM THE CLINICAL DEVELOPMENT OF OCE-205

Ed Cable[1] Kazimierz Wiśniewski[1] John Lucas[1] Glenn Croston[1], [1]Rallidae Therapeutics

Background: Decompensated cirrhosis remains associated with a broad range of severe consequences and high mortality. V1aR agonism is clinically validated by decades of experience with terlipressin, which partially corrects the vasodilatory circulatory dysfunction of advanced cirrhosis, reducing portal hypertension, increasing arterial pressure, enhancing renal perfusion and reducing hypoxia-driven renal injury. Additionally, continuous terlipressin infusion decreases ascites and sarcopenia. These clinical benefits occur in spite of terlipressin, a prodrug of lysine vasopressin, being a full agonist at both V1aR and V2R.OCE-205, the selective V1aR partial agonist, demonstrated clinical translation in healthy volunteers producing an increase of 10-15 mm Hg in mean arterial pressure with no evidence of excess vasoconstriction. Proteolytic degradation of OCE-205 following SC delivery produces an active, V1aR full agonist metabolite, changing the agonist-antagonist balance and increasing the E_{max} about 15%. Therefore, OCE-205 is now limited to IV delivery where little proteolysis is observed (Fig). Building upon the clinical findings of OCE-205, the putative protease substrate site (box) and candidate protease, matriptase, were identified. *In vitro* studies demonstrated matriptase-mediated metabolism of OCE-205 and analogs incorporating modifications within the substrate recognition site eliminated matriptase degradation *in vitro*, with several analogs retaining V1aR partial agonist activity and increased V1aR selectivity relative to OCE-205 (Table). **Methods:** The Expasy Peptide-Cutter was used to analyze OCE-205. Human V1aR and V2 receptor *in vitro* assays were performed with commercially available methods, using AVP and OCE-205 as controls. Proteolytic stability was tested *in vitro* with recombinant enzymes, and reaction products were analyzed by HPLC and UV/Vis or HPLC/MS. **Results:** Novel V1aR partial agonists have been identified, including analogs that are resistant to matriptase cleavage. These matriptase resistant analogs are also V1aR-selective partial agonists, with selectivity for human V1aR vs V2R even greater than that of OCE-205. **Conclusion:** The first-generation bifunctional, selective V1aR partial agonist, OCE-205, provided V1aR partial agonist clinical validation of safety and efficacy with IV delivery butcould not be developed for outpatient SC administration due to the formation of a full agonist metabolite catalyzed by a trypsin-like protease. The current work identifies novel V1aR partial agonists that are no longer matriptase substrates. Development of a bifunctional V1aR partial agonist that is no longer proteolytically degraded will provide important progress for decompensated cirrhosis patients, providing SC outpatient delivery to favorably reduce the hemodynamic imbalances responsible for the broad range of decompensation events and mortality.

1600 | RISING PREVALENCE OF HYPONATREMIA IN HEPATORENAL SYNDROME HOSPITALIZATIONS AND ITS ASSOCIATION WITH IN-HOSPITAL MORTALITY AND RESOURCE UTILIZATION

Nishanth Eluri[1] Brett Cohen[1] Daniel Guirguis[1] Renata Lerer[2], [1]St. Luke's University Hospital, [2]St. Luke's University Hospital Network

Background: Hepatorenal syndrome (HRS) is a life-threatening complication of advanced cirrhosis marked by severe circulatory dysfunction and high short-term mortality. Hyponatremia, reflecting impaired free water clearance, is common in decompensated cirrhosis and linked to poor outcomes. Contemporary data on its epidemiology and clinical significance in HRS remain limited. We evaluated temporal trends and the association of concurrent hyponatremia with mortality and healthcare utilization in US HRS hospitalizations. **Methods:** Using the National Inpatient Sample (2018–2022), HRS hospitalizations were identified and stratified by hyponatremia status. Survey-weighted logistic regression estimated crude and adjusted odds ratios for in-hospital mortality, adjusting for demographics, comorbidities, and hospital characteristics; survey-weighted linear regression assessed length of stay and total charges. **Results:** The weighted HRS subpopulation comprised approximately 262,895 hospitalizations (n = 52,579 unweighted). HRS incidence rose from 0.121% in 2018 to 0.180% in 2022, and the prevalence of concurrent hyponatremia rose from 45.7% to 54.0%.Crude in-hospital mortality was 25.5% (95% CI 24.9%–26.1%) with hyponatremia and 26.6% (95% CI 26.0%–27.1%) without. Unadjusted, hyponatremia was associated with modestly lower odds of death (OR 0.947, 95% CI 0.910–0.985, p = 0.006); this persisted after adjustment for demographic and hospital-level factors (aOR 0.944, 95% CI 0.905–0.984, p = 0.007).Hyponatremia was associated with longer LOS (mean 12.2 vs. 10.3 days; β = +1.83 days, 95% CI 1.58–2.09, p < 0.001) and higher total charges (mean $192,968 vs. $168,435; β = +$24,466, 95% CI $17,805–$31,127, p < 0.001).Patients with hyponatremia had higher rates of malnutrition (23.2% vs. 18.5%), while those without more frequently had DM2 (34.8% vs. 26.2%), hyperlipidemia (22.6% vs. 17.5%), CAD (14.5% vs. 9.9%), CKD3 (36.5% vs. 27.7%), and ESRD (13.2% vs. 11.0%). Shock (29.2% vs. 27.7%) and vasopressor use (10.3% vs. 9.7%) were more common with hyponatremia. **Conclusion:** Among US HRS hospitalizations, concurrent hyponatremia has become increasingly prevalent and associated with greater healthcare utilization despite lower adjusted in-hospital mortality. This likely reflects residual confounding from differences in comorbidity profiles, coding patterns, and treatment selection rather than a true protective effect. Hyponatremia in HRS identifies a complex, high-resource complication warranting further study to define its prognostic significance.

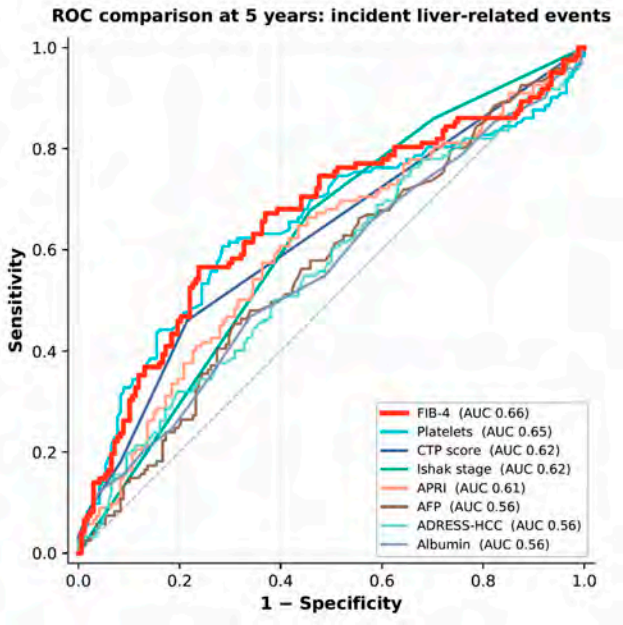
1601 | NON-INVASIVE FIBROSIS INDICES PREDICT LIVER-RELATED EVENTS ACROSS ETIOLOGIES IN A LONG-TERM COHORT OF COMPENSATED ADVANCED CHRONIC LIVER DISEASE



Wesam Aleyadeh[1] Jonathan Lim[1] Christopher Sollenberger[2] Christine Hsu[3], [1]National Institutes of Health, [2]Perelman School of Medicine, [3]National Institute of Diabetes, Digestive

Background: Non-invasive tests (NITs) have been validated for fibrosis staging but their performance in predicting LREs in patients with compensated advanced liver disease (cACLD) irrespective of etiology is less defined. We evaluated baseline NITs as predictors of incident LREs and hepatocellular carcinoma (HCC) in an etiologically diverse cACLD cohort. **Methods:** This is a retrospective study at a single tertiary center of patients with a diagnosis of cACLD (Ishak 4-6 or clinical diagnosis). Follow-up date started at the time of cACLD diagnosis. The primary outcome was a composite LRE (incident varices on imaging or endoscopy, ascites, spontaneous bacterial peritonitis, hepatic encephalopathy, HCC, or liver-related death). Baseline FIB-4, APRI, Child-Turcotte-Pugh (CTP) score, ADRESS-HCC, Ishak stage, and laboratory values were tested in Cox models adjusted for age and sex. In a sensitivity analysis, etiology on impact of LRE was evaluated. Discrimination was assessed by time-dependent AUC. **Results:** 429 had cACLD daignosis and 39 patients with history of LRE on or before index date were excluded, yielding 390 patients. 59% were male and the mean age 48 ± 13 years. 81% viral (HCV 57%, HBV 14%, HDV 11%) and 8.3% MASLD. 55% were Caucasian, 20% were black, and 17% Asian. At baseline, 56% of HCV and 91% of HBV patients were treated. Over a median 6.4 years (IQR 2.1-11.2), 199 patients (51%) had an LRE, 46 (12%) HCC, and 99 (25%) died. Adjusted for age and sex, FIB-4 > 2.67 was

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

associated with the composite LRE (aHR 2.27, 95% CI 1.66-3.11), as were APRI >1.0 (HR 1.76), CTP score (HR 1.45/point), Ishak score (HR 1.59/point), splenomegaly (HR 1.95), and lower albumin (HR 0.63 per g/dL). Five-year cumulative LRE incidence was 52% with FIB-4 >2.67 versus 25% <2.67 (log-rank P<0.001). At 5 years, FIB-4 and platelet count showed the highest discrimination for the composite LRE (AUC 0.66 and 0.65, respectively). For HCC, AFP and APRI >1 (HR 2.36) had the strongest associations, while discrimination was highest for ADRESS-HCC and FIB-4 (AUC 0.82 and 0.80 at 1-year; 0.69 and 0.70 at 5-years). **Conclusion:** In a long-term cACLD cohort, baseline FIB-4 independently predicted 2-fold higher risk of incident LREs with moderate discrimination. FIB-4 and ADRESS-HCC showed good discrimination for HCC. This validates FIB-4's ability to risk stratify but suggests it is better for group-level stratification alongside other prognostic scores.

1602 | DOES CIRRHOSIS ETIOLOGY MATTER? OUTCOMES IN PERITONITIS BY UNDERLYING LIVER DISEASE

Kahler Doyle[1] Brayden Doyle[2] Viraj Gandhi[1] Nibras Saya[3] Mohammad Ashfaq[4], [1]TCU Anne Burnett School of Medicine, [2]TCU College of Science and Engineering, [3]UT Dallas, [4]Baylor Scott & White Liver Consultants of Texas

Background: Cirrhosis etiology influences disease progression, comorbidity burden, care needs, and outcomes. However, differences in readmission and survival among patients with alcohol-associated liver disease (EtOH), hepatitis C virus (HCV), and metabolic dysfunction–associated steatohepatitis (MASH)-related cirrhosis presenting with peritonitis remain incompletely characterized. **Methods:** We performed a retrospective cohort study of cirrhotic patients admitted with peritonitis, stratified by etiology: EtOH, HCV, or MASH-related cirrhosis. Demographics, comorbidities, microbiologic findings, management patterns, follow-up, readmission, and mortality were compared using univariate analyses. Competing-risk regression evaluated readmission, and Kaplan–Meier analysis assessed overall survival. Artificial intelligence (AI)–assisted tools were used to improve readability and language clarity. **Results:** A total of 286 patients were included: EtOH n = 163, HCV n = 53, and MASH n = 70. Patients with MASH-related cirrhosis were older than those with EtOH-related cirrhosis (66.0 vs 56.0 years, p < 0.001) and had a higher burden of metabolic comorbidities, including diabetes (62.9%, OR 7.82 vs EtOH), obesity (41.4%, OR 4.10), hyperlipidemia (38.6%, OR 3.47), and hypothyroidism (27.1%, OR 6.37) (all p < 0.001).MASH-related cirrhosis demonstrated higher cumulative readmission than EtOH (Gray's p = 0.006), with increased 90-day (50.0% vs 32.5%, OR 2.08), 180-day (54.3% vs 37.4%, OR 1.99), and 1-year readmission (61.4% vs 40.5%, OR 2.34). They were more likely to receive outpatient gastroenterology (45.7% vs 16.0%, OR 4.44) and hepatology follow-up (44.3% vs 19.6%, OR 3.25), suggesting greater specialty-care utilization after hospitalization. Despite these differences, overall survival did not differ significantly by Kaplan–Meier analysis (log-rank p = 0.420), although patients with MASH-related cirrhosis exhibited higher long term mortality compared with EtOH patients on univariate analysis (5-year mortality 84.3% vs 68.7%, OR 2.44, p = 0.016). HCV patients had higher rates of malignancy-related findings, including positive cytology (OR 11.06) and hepatocellular carcinoma (OR 2.48). **Conclusion:** Among cirrhotic patients admitted with peritonitis, etiology was associated with distinct comorbidity profiles, care patterns, readmission risk, and malignancy findings. MASH-related cirrhosis was characterized by older age, substantial metabolic comorbidity burden, increased specialty follow-up, and higher readmission rates, while HCV-related cirrhosis was associated with greater malignancy-related findings. Although overall survival did not differ significantly across etiologies, these findings suggest that etiology-specific risk profiles may inform post-discharge planning, outpatient surveillance, and interventions to reduce recurrent hospitalization in this complex population.

1603 | CULTURE-POSITIVE VS CULTURE-NEGATIVE CIRRHOTIC PERITONITIS: CLINICAL DIFFERENCES AND OUTCOMES

Kahler Doyle[1] Brayden Doyle[2] Viraj Gandhi[1] Mohammad Ashfaq[3], [1]TCU Anne Burnett School of Medicine, [2]TCU College of Science and Engineering, [3]Baylor Scott & White Liver Consultants of Texas

Background: Peritoneal fluid culture (PFC) positivity may identify a distinct subset of cirrhotic patients with peritonitis, though its impact on management and outcomes remains incompletely defined. We compared clinical characteristics, treatment patterns, and longitudinal outcomes between culture-positive and culture-negative peritonitis. **Methods:** We conducted a retrospective cohort study of cirrhotic patients admitted with peritonitis, stratified by PFC status. Clinical variables, microbiology, treatment patterns, procedures, and outcomes were compared using univariate analyses with odds ratios (OR) and 95% confidence intervals (CI). Time-to-event outcomes were assessed using Kaplan–Meier survival analysis and competing-risk regression for readmission, with log-rank and Gray's tests. Artificial intelligence (AI)–assisted tools were used to enhance clarity and readability. **Results:** A total of 386 patients were included (culture-negative n = 225; culture-positive n = 161). Culture-positive peritonitis was associated with longer length of stay (7.0 [5.0–14.0] vs 10.0 [5.0–18.0], p = 0.010) and greater inflammatory burden, including higher early PFA PMNs and lower glucose. Blood culture positivity was more frequent (OR 1.73, 95% CI 1.06–2.80).Culture-positive patients demonstrated greater illness severity and resource utilization, including higher rates of ICU consultation (OR 2.67, 1.75–4.08), ICU admission (OR 2.44, 1.39–4.26), mechanical ventilation (OR 3.88, 1.99–7.56), vasopressor use (OR 2.46, 1.32–4.58), and central venous access (OR 1.76, 1.17–2.66). Procedural burden was also increased, including exploratory laparotomy (OR 6.10, 2.00–18.60), abscess drainage (OR 3.48, 1.31–9.25), and non-paracentesis abdominal procedures (OR 2.54, 1.39–4.64).Microbiologic complexity and treatment intensity were greater among culture-positive patients, with increased infectious disease consultation (OR 1.89, 1.26–2.85), broader antimicrobial use including MRSA (OR 3.23), antifungal (OR 3.28), anaerobic (OR 2.92), and broad-spectrum therapy (OR 1.98), and higher rates of multidrug-resistant and polymicrobial infections.Outcomes were worse among culture-positive patients, including higher 30-day (OR 1.59), 90-day (OR 1.76), 180-day (OR 1.79), 3-year (OR 1.59), 4-year (OR 1.33), and 5-year mortality (OR 1.64). They were less likely to be discharged home (OR 0.41, 0.27–0.62) and more likely to require skilled nursing facility placement (OR 2.30, 1.05–5.05). Cumulative incidence of readmission did not differ significantly (Gray's p = 0.268). **Conclusion:** Culture-positive peritonitis in cirrhosis is associated with greater infection severity, increased procedural and critical care utilization, and worse short- and long-term survival. PFC positivity appears to be a meaningful prognostic marker and may identify patients requiring more aggressive management and closer follow-up.

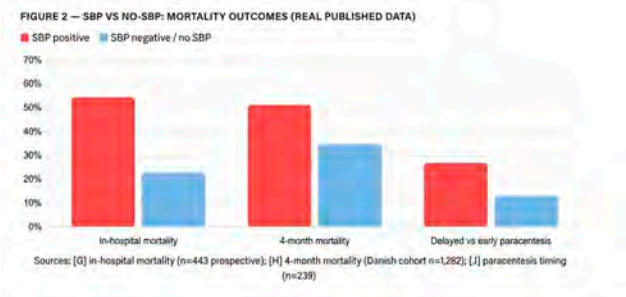
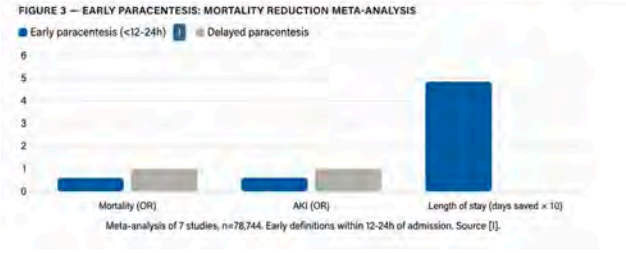
1604 | TIME-TO-TAP MATTERS: MORTALITY AND KIDNEY OUTCOMES WITH EARLY VS DELAYED PARACENTESIS IN SBP-ASSOCIATED HE



Azfar Hameed[1] Zakia Hameed[2] Diana Chavez Velasquez[3] Jorge Chavez Velasquez[3], [1]Hendrick Medical Center, [2]CMH Institute of Medical Sciences, Bahawalpur, Pakistan, [3]Universidad Privada Antenor Orrego



Background: Spontaneous bacterial peritonitis (SBP) is a high-impact, often clinically silent precipitant of hepatic encephalopathy (HE) in cirrhosis, with up to 50% lacking fever, leukocytosis, or abdominal tenderness. Although guidelines recommend diagnostic paracentesis for all hospitalized cirrhotics with ascites, real-world adherence remains inconsistent. We synthesized contemporary evidence to estimate SBP prevalence in this setting, quantify associated mortality, and evaluate whether early diagnostic paracentesis improves outcomes. **Methods:** Multi-source evidence synthesis included: a worldwide epidemiologic meta-analysis (99 studies; n = 5,861,142); a prospective ascites cohort (n = 443); a Danish national cohort (n = 1,282); two meta-analyses comparing early vs delayed paracentesis (n = 78,744 and n = 116,174); an SBP cohort study (n = 239); a national inpatient sample (n = 17,711); and ICU cohorts from MIMIC-III (n = 620) and MIMIC-IV (n = 601). SBP was defined as ascitic PMN $\geq$ 250 cells/mm³. Outcomes were in-hospital and 4-month mortality, acute kidney injury (AKI), and length of stay. **Results:** Across datasets, SBP occurred in 10%–30% of hospitalized cirrhotics with ascites and was associated with markedly higher mortality than sterile ascites (in-hospital 54.5% vs 22.8%; p < 0.001).

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

Four-month mortality was 51.2% vs 34.7% without SBP (adjusted HR 1.54; 95% CI 1.18–2.00). In ICU HE cohorts, 28-day mortality was 18.64%. Despite risk, only 55.5% of hospitalized patients with HE and/or ascites underwent paracentesis. Early paracentesis ($\leq$12–24 hours) was associated with lower in-hospital mortality (OR 0.61; 95% CI 0.46–0.82; p = 0.001), reduced AKI (OR 0.62), and shorter hospitalization (−4.85 days; p < 0.001). In an SBP cohort, delayed paracentesis was associated with higher mortality (27% vs 13%; p = 0.007). **Conclusion:** SBP is a frequent and lethal, yet modifiable, contributor to adverse outcomes in cirrhotic HE. Evidence across large independent sources supports early diagnostic paracentesis as a scalable, quality-improvement target. Coagulopathy alone should not delay the procedure, given published safety data at INR up to 8 and platelets as low as 19,000/µL without prophylactic transfusion. Establishing universal early paracentesis for HE admissions with ascites may reduce preventable inpatient deaths.

1605 | IMPACT OF PALLIATIVE CARE ON RESOURCE UTILIZATION AMONG HOSPITALIZATIONS WITH HEPATORENAL SYNDROME: A US NATIONAL STUDY (2016 TO 2022)

Abhin Sapkota[1] Anas Almoghrabi[2] Kriti Katuwal[3], [1]John H. Stroger Jr. Hospital of Cook County, [2]John H. Stroger, Jr. Hospital of Cook County, [3]Lumbini Medical College, Palpa, Nepal

Background: Hepatorenal syndrome (HRS) is associated with high morbidity, mortality, and healthcare utilization. Palliative care consultation (PCC) may promote goal-concordant care and optimize resource use, yet trends and disparities in PCC among HRS hospitalizations as well the impact on resource utilization remain unclear. We evaluated temporal trends, sociodemographic disparities, and the association of PCC with resource utilization in HRS hospitalizations across the United States. **Methods:** We performed a retrospective cohort study using the National Inpatient Sample from 2016 to 2022. Adult hospitalizations with a primary or secondary diagnosis of HRS were identified using ICD-10-CM code K76.7. PCC was identified using the validated ICD-10-CM code. Survey weights were applied to generate national estimates. Multivariable survey logistic regression identified predictors of PCC, adjusting for demographic factors, comorbidities and hospital characteristics. Resource utilization outcomes included total hospital charges, length of stay, vasopressor use, mechanical ventilation, blood transfusion, dialysis, and paracentesis. Temporal trends in PCC utilization were assessed across study years. **Results:** An estimated 343,175 hospitalizations with HRS were identified during the study period, of which 95,555 (27.8%) received PCC. In adjusted analysis, Hispanic patients had lower odds of receiving PCC compared with White patients, adjusted (aOR 0.77, p < 0.001) . Females also had lower odds compared with males (aOR 0.93, p < 0.001). PCC was more likely in metropolitan teaching hospitals, (aOR 1.59, p < 0.001) compared to rural hospitals, and among Medicaid (aOR 1.19, p < 0.001) and self-pay patients (aOR 1.59, p < 0.001) compared with Medicare beneficiaries. Mean total hospital charges were significantly lower in the PCC group (153,068 dollars vs 182,579 dollars, p < 0.001). Length of stay was shorter among patients receiving PCC, (10.44 vs 11.51 days, p < 0.001). Mortality was higher in the PCC group, approximately 50% versus 17%. Vasopressor use (aOR 1.65, p < 0.001) and ventilator use (aOR 1.47, p < 0.001) were more likely among PCC group, likely reflecting greater illness severity at the time of consultation. Blood transfusion (aOR 0.90, p < 0.001) was less likely among PCC group whereas dialysis and paracentesis rates were similar between groups. PCC utilization increased modestly from 25.3% in 2016 to 28.6% in 2022. **Conclusion:** From 2016 to 2022, PCC utilization among HRS hospitalizations increased slightly but has remained limited. Significant sociodemographic and hospital-level disparities persist. PCC was associated with reduced hospital charges and shorter length of stay, supporting its potential role in improving value-based care in this high-risk population. Strategies to promote equitable and timely access to palliative care in HRS are warranted.

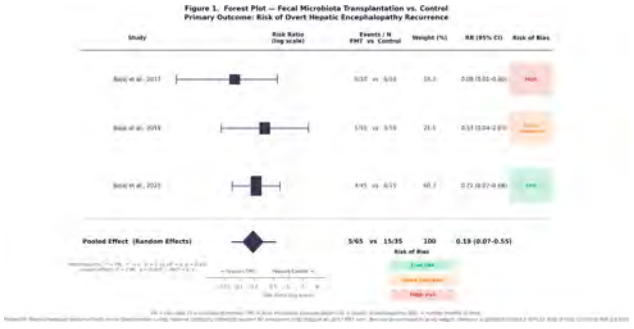
1606 | POST-TIPS URSODEOXYCHOLIC ACID USE AND RISK OF OVERT HEPATIC ENCEPHALOPATHY: A PROPENSITY SCORE–MATCHED REAL-WORLD STUDY

Miao Yi[1] Xiaoze Wang[1] Li Yang[2] Yi Fang[1] Yi Shen[1], [1]West China Hospital, Sichuan University, [2]Sichuan University, West China Hospital

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is an established treatment for complications of portal hypertension in patients with cirrhosis; however, post-TIPS overt hepatic encephalopathy (OHE) remains a major limitation. Ursodeoxycholic acid (UDCA) modulates bile acid metabolism and may exert anti-inflammatory effects, potentially influencing OHE development through metabolic and neuroinflammatory pathways along the gut–brain axis. However, the association between postoepratie UDCA use and post-TIPS OHE remains unclear. This study aimed to evaluate the association between UDCA use and the risk of OHE after TIPS. **Methods:** We retrospectively included patients with cirrhosis undergoing TIPS at a single center from May 2015 to January 2025. Patients were classified by postoperative UDCA use (13–15 mg/kg/day). The primary outcome was OHE within 3 months. Secondary outcomes included OHE at 6 months and 1 year, 1-year rebleeding, HE-related readmission, transplant-free survival, and recurrent OHE. Propensity score matching and multivariable models were used. OHE was analyzed using Fine–Gray competing-risk models with death and liver transplantation as competing events. **Results:** Among 1,025 patients, 111 received UDCA and 914 did not. After matching, 91 UDCA users and 209 non-users were retained with balanced baseline characteristics. UDCA use was associated with a lower 3-month cumulative incidence of OHE (adjusted sHR 0.46, 95% CI 0.23–0.93; P = 0.032). Sensitivity analysis showed consistent results (sHR 0.48, 95% CI 0.25–0.90; P = 0.023). UDCA use showed non-significant trends toward lower OHE at 6 months and 1 year, without significant associations with other secondary outcomes. **Conclusion:** Postoperative UDCA use was associated with reduced short-term OHE risk after TIPS, warranting prospective validation. **Disclosures:** Miao Yi:Nothing to Disclose, Xiaoze Wang:Nothing to Disclose, Li Yang:Nothing to Disclose, Yi Fang:Nothing to Disclose, Yi Shen:Nothing to Disclose.



1608 | FECAL MICROBIOTA TRANSPLANTATION FOR HEPATIC ENCEPHALOPATHY IN CIRRHOSIS: A SYSTEMATIC REVIEW AND META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Rohan Karkra[1] Mahinaz Mohsen[1] Sameer Rao[1] Ethan Shamsian[1] Sai Vendidandi[1] Ahmed Al-Khazraji[1] Zaid Tafesh[1] Paul Gaglio[1], [1]Rutgers New Jersey Medical School

Background: Hepatic Encephalopathy (HE) is a debilitating neuropsychiatric complication of cirrhosis associated with frequent hospitalizations and poor quality of life. Despite standard-of-care therapy with lactulose and rifaximin, a substantial proportion of patients experience recurrent episodes. Fecal Microbiota Transplantation (FMT) has emerged as a microbiome-targeted intervention with mechanistic plausibility, as it modulates the gut-liver-brain axis and may shift the colonic microbiome toward a less encephalopathogenic milieu. We conducted a systematic review and meta-analysis of all published randomized controlled trials (RCTs) evaluating FMT in patients with cirrhosis and HE. **Methods:** We conducted a systematic search of PubMed, Embase, and ClinicalTrials.gov databases through January 2026 to identify all trials evaluating

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

FMT in HE. The primary outcomes analyzed with meta-analysis were HE recurrence within a 6-month follow-up period and FMT-related serious adverse events. Secondary outcomes included hospitalization, cognitive function (Psychometric Hepatic Encephalopathy Score [PHES]), quality of life (Sickness Impact Profile), mortality, and microbiome engraftment. Risk of bias was assessed using the Cochrane RoB 2.0 tool. Pooled Risk Ratios (RRs) were derived using the Mantel-Haenszel random-effects method. This study conformed to PRISMA guidelines. **Results:** We identified 3 RCTs involving 100 patients (86% male; 63.3 ± 8.2 years). Pooled RR for HE recurrence with FMT was approximately 0.19 (95% CI: 0.07–0.55; $p < 0.05$), representing an 81% relative risk reduction. No FMT-related adverse events were reported in the RCT participants. We also identified a non-randomized study ($n = 10$, no control arm) that showed a cognitive benefit (PHES +3.1 points at 4-weeks post-FMT, $p < 0.05$) and documented the sole FMT-related adverse event: a case of ESBL-producing E. coli bacteremia transmitted through FMT capsules. Hospitalization rates, cognitive function, and microbial engraftment consistently favored FMT across all studies ($p < 0.05$). 0 deaths were reported in any patient, except 1 who was transitioned to hospice. FMT increased beneficial, SCFA-producing bacteria and reduced pathobionts, while patients in the placebo group had worsening dysbiosis. Successful donor engraftment was highest with combined oral and enema interventions. To note, all RCTs originated from a single investigator group. **Conclusion:** FMT was consistently efficacious in reducing HE recurrence and hospitalization in patients with cirrhosis on standard therapy, with an 81% relative risk reduction across 3 RCTs. The aggregate safety profile is highly favorable in the RCT setting, though the documented ESBL E. coli bacteremia in one study underscores the need for rigorous donor pathogen screening and careful patient selection. Independent multicenter phase 3 trials are required before guideline adoption.

1609 | COMPARATIVE EFFECTIVENESS OF TERLIPRESSIN VERSUS MIDODRINE/OCTREOTIDE FOR

Razan Aburumman[1] Saqr Alsakarneh[2] Kevin Harris[1] Suraj Suresh[1], [1]Henry Ford Hospital, [2]The Mayo Clinic, Rochester

Background: Hepatorenal syndrome (HRS) is a severe, life-threatening complication of advanced cirrhosis and liver failure. While terlipressin has been approved for treatment of HRS, real-world comparative effectiveness data against standard medical therapy remain limited. **Methods:** We conducted a retrospective cohort study using the TriNetX US Collaborative Network, including 66 healthcare organizations. Adult patients with cirrhosis who were diagnosed with HRS were identified and stratified into two cohorts. The first group included patients who received terlipressin, and the control group included patients who received standard therapy (midodrine, octreotide, and albumin). Patients with a history of HCC or liver transplantation (LT) before the index event were excluded. Outcomes were assessed at 30 and 90 days following the index event. Propensity score matching (1:1) was performed using 29 variables, including demographics, comorbidities, medications, and laboratory values. Primary outcomes included mortality, dialysis requirement, ICU admission, intubation, respiratory failure, pulmonary edema, kidney transplant (KT), and LT. Kaplan-Meier survival analyses were used to compare outcomes between cohorts, with hazard ratios (HRs) and 95% confidence intervals (CIs) reported. **Results:** Before matching, 393 patients received terlipressin and 12,322 received standard therapy. After propensity matching, 380 patients remained in each group for the 30-day analysis and 242 patients per group for the 90-day analysis. At 30-days, terlipressin use was associated with a significantly lower risk of ICU admission (HR 0.734, 95% CI 0.580–0.927; $p = 0.010$) and mortality (HR 0.732, 95% CI 0.573–0.936; $p = 0.012$). There were no significant differences between groups in dialysis (HR 0.919, 95% CI 0.660–1.280; $p = 0.616$), respiratory failure (HR 0.933, 95% CI 0.714–1.219; $p = 0.627$), intubation (HR 0.705, 95% CI 0.465–1.067; $p = 0.097$), or pulmonary edema (HR 1.150, 95% CI 0.799–1.654; $p = 0.445$). However, terlipressin was associated with a significantly higher likelihood of LT within 30 days (HR 2.078, 95% CI 1.201–3.595; $p = 0.007$).At 90 days, there was no significant

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

difference in requiring dialysis (HR 1.062, 95% CI 0.685–1.646; p = 0.788), ICU admission (HR 0.970, 95% CI 0.734–1.282; p = 0.869), mortality (HR 0.853, 95% CI 0.650–1.119; p = 0.247), intubation (HR 0.813, 95% CI 0.519–1.273; p = 0.366), respiratory failure (HR 1.243, 95% CI 0.911–1.697; p = 0.161), pulmonary edema (HR 1.297, 95% CI 0.832–2.022; p = 0.247) or KT. However, terlipressin remained associated with a higher likelihood of LT (HR 2.031, 95% CI 1.151–3.586; p = 0.012). There was also no difference in KT rates between groups (HR 0.945, 95% CI 0.417–2.142; p = 0.893). **Conclusion:** Terlipressin was associated with improved 30-day outcomes. The absence of sustained benefit at 90 days suggests that its primary role may be as a bridge to transplantation.

1610 | THE USE OF MIDODRINE IN LIVER CIRRHOSIS PATIENTS WITH HYPERVOLEMIC HYPONATREMIA: LARGEST SYSTEMATIC REVIEW

Beshoy Yanny[1] Momin Masroor[2] Peter Nguyen[2] Michelle Nguyen[1] Marie Balfour[1] Yao (Michelle) Lan[2] Lora Ibrahim[1] Trinity Michael[1] Kirellos Mikhail[3],
[1]University of California, Irvine, [2]UCI Health, [3]University of California, Los Angeles

Background: Hypervolemic hyponatremia is a challenging complication that occur in patients with hepatic cirrhosis. Hyponatremia is an independent predictor of mortality and is incorporated into the MELD score to better risk stratify cirrhosis severity. Midodrine is an alpha-1 adrenergic agonist and can counteract with splanchnic vasodilation. This will improve hemodynamics associated with RAAS and free water excretion. Our systematic review aims to study the efficacy of midodrine to improve hyponatremia in such patients. **Methods:** Literature review was done using multiple databases, including PubMed and ClinicalTrials.gov through April 2026. Included studies evaluated the administration of midodrine compared to standard of care in adult and pediatric patients with liver cirrhosis and concurrent hypervolemic hyponatremia. The primary efficacy outcomes were the incidence of hyponatremia and mean change in sodium levels. Secondary outcomes included the incidence of acute kidney injury and mean change in serum creatinine from baseline. **Results:** Six randomized controlled trials comprising 340 patients (305 adult patients and 35 pediatric patients) were included. Midodrine significantly reduced the overall incidence of hypervolemic hyponatremia (RR 0.47, 95% CI 0.28-0.78, p = 0.004). While short-term sodium changes were comparable to standard care, subgroup analysis revealed midodrine provided a significant serum sodium increase during medium-to-long-term follow-up (≥ 28 days) with a mean difference of +1.39 mEq/L (95% CI 0.24-2.55, p = 0.018). Furthermore, acute kidney injury (AKI) incidence was significantly lower in the midodrine arm (12.2% vs 23.8%; RR 0.56, 95% CI 0.35-0.90, p = 0.017), although overall mean creatinine reduction was non-significant (-0.06 mg/dL, p = 0.188). **Conclusion:** Treatment with Midodrine as an alpha-1 adrenergic agonist is effective for hypervolemic hyponatremia and AKI in advanced cases of hepatic cirrhosis. Sodium correction is believed to support overall survival and quality of life. Further large-scale, multicenter studies are needed to validate these findings and establish standardized dosing protocols.

Figure 2: Forest plot comparing the mean difference in serum sodium levels between midodrine and control therapies. While the overall pooled effect crosses the line of no effect, subgroup analysis reveals a distinct temporal trend: short-term administration (≤7 days) yields comparable sodium stabilization to standard care, whereas midodrine provides a statistically significant improvement in maintaining higher serum sodium during medium-to-long-term follow-up (≥28 days).

1611 | ENDOTOXIN ACTIVITY PREDICTS FIRST AND FURTHER DECOMPENSATION IN CIRRHOSIS

Akihiko Shibamoto[1] Tadashi Namimsaki[1] Yui Osaki[1] Hitoshi Mori[1] Shinya Sato[1] Norihisa Nishimura[1] Kosuke Kaji[1] Hitoshi Yoshiji[1], [1]Nara Medical University

Background: Endotoxemia contributes to systemic inflammation and disease progression in cirrhosis; however, its association with hepatic decompensation based on the Baveno VII consensus remains unclear. We investigated whether endotoxin activity predicts first and further decompensation in cirrhosis. **Methods:** We retrospectively analyzed 431 patients with compensated cirrhosis evaluated between January 2014 and December 2024. Among 78 patients who developed first decompensation during follow-up, predictors of further decompensation were additionally analyzed. First and further decompensation were defined according to the Baveno VII consensus. Serum endotoxin activity was assessed using the Endotoxin Activity Assay (EAA). Clinical variables including hepatic reserve, renal function, inflammatory markers, and fibrosis-related parameters were evaluated. Cox proportional hazards models were used to identify independent predictors of decompensation. Receiver operating characteristic (ROC) analyses were performed to assess predictive performance, and Kaplan–Meier analyses were used to compare cumulative incidence rates according to EAA stratification. **Results:** The mean age was 69.5 years, and 263 patients (61.0%) were male. Etiologies included HCV (n = 114), HBV (n = 40), ALD (n = 93), MetALD (n = 29), MASH (n = 89), and others (n = 66). During follow-up, 78 patients developed first decompensation, and 49 subsequently developed further decompensation. Multivariate Cox proportional hazards analysis identified low albumin levels and high EAA values as independent predictors of first decompensation. In ROC analysis, EAA showed good predictive performance (AUC 0.752), comparable to albumin (AUC 0.735; p = 0.699). Patients with elevated EAA values demonstrated significantly higher cumulative incidences of both first and further decompensation than those with low EAA values. High EAA values were also independently associated with further decompensation and showed favorable predictive ability (AUC 0.783). These findings suggest that endotoxemia may contribute not only to initial hepatic deterioration but also to progression toward recurrent decompensating events. **Conclusion:** Elevated endotoxin activity was independently associated with both first and further decompensation in cirrhosis. EAA may serve as a useful biomarker for risk stratification based on the Baveno VII framework and may help identify patients at high risk for progressive hepatic decompensation requiring closer monitoring and early therapeutic intervention.

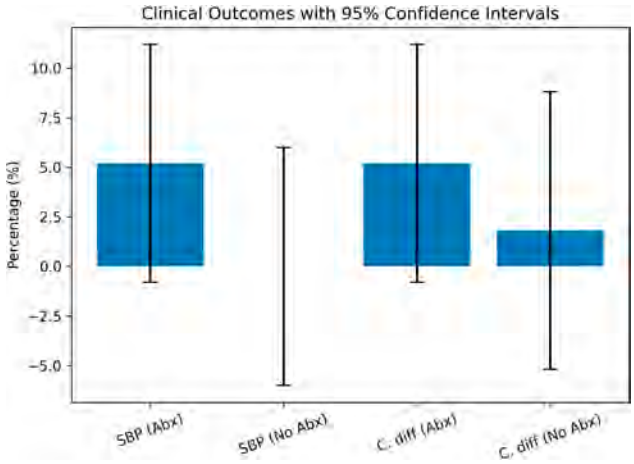
1612 | EVALUATING THE IMPACT OF PRIMARY PROPHYLAXIS FOR SPONTANEOUS BACTERIAL PERITONITIS ON INFECTIOUS AND SAFETY OUTCOMES IN PATIENTS WITH CIRRHOSIS



Alekhya Mannava[1] Gokturk Tepe[2] Katie Zhang[3] Jaime Perez[2] Resham Ramkissoon[2], [1]University Hospitals Cleveland Medical Center, Case Western, [2]University Hospitals Cleveland Medical Center, Case Western Reserve University, [3]Case Western Reserve University School of Medicine

Background: Spontaneous bacterial peritonitis (SBP) is a serious complication of cirrhosis. Although AASLD guidelines recommend primary antibiotic prophylaxis for high-risk patients, supporting evidence remains limited, with concerns regarding C. difficile infection, drug toxicity, and antimicrobial resistance. This study examined prophylaxis eligibility, prescribing patterns, and safety outcomes in hospitalized cirrhotic patients. **Methods:** We conducted a retrospective chart review of 114 adults with cirrhosis evaluated at our tertiary care center over a 10-year period. Demographic, clinical, and laboratory data were collected at the index paracentesis, including renal and liver function markers, MELD-3.0 score, and ascitic fluid studies. Patients were categorized by whether they met AASLD criteria for primary SBP prophylaxis and whether prophylactic antibiotics were prescribed. Outcomes included SBP, C. difficile infection, antimicrobial resistance, and culture results. **Results:** Of 114 patients, 70% met criteria for primary prophylaxis and 51% received antibiotics. Those meeting criteria had more advanced disease, with higher creatinine (1.9 vs. 0.7 mg/dL, p0.001), BUN (29.9 vs. 14.4 mg/dL, p0.001), bilirubin (5.9 vs. 1.4 mg/dL, p0.001), INR (1.7 vs. 1.4, p0.001), MELD-3.0 (24.3 vs. 13.7, p0.001), WBC (9.3 vs. 7.0 $\times 10^3/\mu L$, p = 0.006), and AST (92.1 vs. 43.2 U/L, p0.001).Prophylaxis recipients were younger (59.9 vs. 64.8 years, p = 0.043), had more alcohol-associated liver disease (81.0% vs. 58.9%, p = 0.010), lower sodium (134.3 vs. 136.4 mmol/L, p = 0.031), higher MELD-3.0 (22.5 vs. 19.5, p = 0.046), and lower hemoglobin (9.0 vs. 9.7 g/dL, p = 0.016). C. difficile infection was uncommon (3.5%) with no difference by antibiotic

exposure (5.2% vs. 1.8%; p = 0.619). SBP incidence was low (2.6%), occurring only in antibiotic recipients (5.2% vs. 0%; p = 0.244). Secondary prophylaxis was rare (6.2%) and strongly associated with prior SBP (71.4% vs. 1.9%; p0.001). No antibiotic-resistant or multidrug-resistant organisms were identified. **Conclusion:** Nearly half of patients meeting AASLD criteria for primary SBP prophylaxis did not receive recommended therapy, revealing a substantial guideline adherence gap. Clinical decision-making appeared driven by subjective severity impressions rather than established criteria, contributing to both underuse in high-risk patients and use in lower-risk individuals. These findings identify an actionable opportunity to standardize prophylaxis practices and potentially reduce preventable SBP. Adverse events among antibiotic recipients, including C. difficile and antimicrobial resistance, were rare, suggesting prophylaxis was generally well tolerated, though low event rates limit efficacy conclusions. These findings highlight variability in patient severity and underscore the need for larger studies to define the benefit–risk profile of primary SBP prophylaxis.

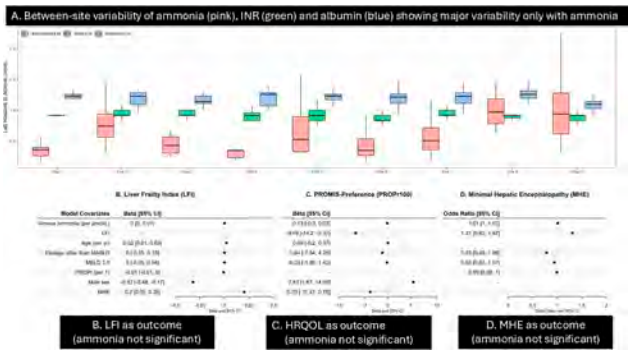
1613 | VARIABILITY AND CLINICAL CORRELATES OF AMMONIA IN COMPENSATED CIRRHOSIS: A MULTICENTER STUDY FROM THE LIVER CIRRHOSIS NETWORK



Jasmohan Bajaj[1] Elliot Tapper[2] David Goldberg[3] Douglas Simonetto[4] Mandana Khalili[5] Srinivasan Dasarathy[6] Elizabeth Verna[7] Arun Sanyal[1] Neehar Parikh[2] Bilal Hameed[8] Vijay Shah[4] Andrew Scheinberg[3] Giuseppe Cullaro[9] Nicole Welch[6] Miranda Gurra[10] Lauren Bonner[10], [1]Virginia Commonwealth University, [2]University of Michigan Medical Center, [3]University of Miami, [4]Mayo Clinic Rochester, [5]University of California, San Francisco, [6]Cleveland Clinic, [7]Columbia University Medical Center, [8]UCSF, [9]Columbia University, [10]Northwestern University

Background: Elevated blood ammonia is implicated in hepatic encephalopathy, frailty, and cognitive impairment in cirrhosis, but ammonia measurement is difficult to standardize across institutions. We characterized between-site variability in ammonia levels and evaluated the association of elevated ammonia levels with frailty, cognitive function [minimal hepatic encephalopathy (MHE) on EncephalApp Stroop], and health-related quality of life (HRQOL) in compensated cirrhosis. Aim: Determine whether ammonia levels predicted cognitive impairment, frailty, or HRQOL. **Methods:** Cross-sectional analysis of a prospective cohort of adults with compensated cirrhosis enrolled at 7 centers (9 clinical sites) of the NIH-supported Liver Cirrhosis Network (LCN). Each sample was tested at the local laboratory for each site. Variations between sites were assessed as levels above the upper limit of normal (ULN) for ammonia and INR, and below the lower limit of normal (LLN) for serum albumin. Outcome measures were: Frailty using Liver Frailty Index (LFI), cognitive function using MHE on Stroop, and health-related quality of life using the PROPr (0–100). Multivariable linear regression evaluated the association of venous ammonia with PROPr and LFI while logistic regression was done for MHE, adjusting for the other two outcome measures and clinical covariates. MHE and ULN ammonia percent were compared. **Results:** Among 334 participants (mean age 61 years, 59% male, 44% with MASLD, mean MELD 3.0 of 9), 56% had MHE. 60 (19%) had an ammonia level ≥ ULN. Ammonia levels (and ULN) varied substantially across the 9 sites, while albumin and INR were relatively consistent (Fig A). 14% with ammonia. Ammonia > ULN proportion was statistically similar in MHE/not (14 vs 22%, p = 0.07). In multivariable models, higher ammonia levels were not independently associated with MHE on Stroop (OR 1.01, 95% CI 1.00-1.03; p = 0.2, Fig B), PROPr (β = −0.13; 95% CI −0.30 to 0.03; p = 0.12, Fig C) or with LFI (β = 0.00; 95% CI 0.00 to 0.01; p = 0.4, Fig D). However, LFI was independently associated with both Stroop time (β = 19; 95% CI 8.3 to 30; p < 0.001) and PROPr (β = −10; 95% CI −15 to −5.8; p < 0.001). **Conclusion:** In a multicenter cohort of patients with compensated cirrhosis, venous ammonia levels varied markedly across institutions while standard liver synthetic markers did not. After multivariable adjustment, higher laboratory values for venous ammonia were not independently associated with MHE, frailty, or health-related quality of life. Ammonia levels do not significantly affect clinical,

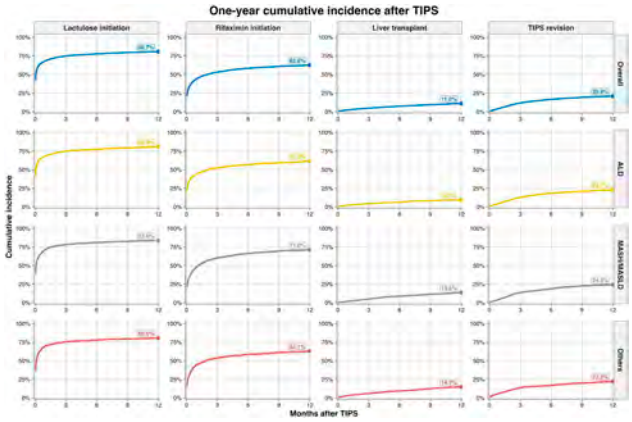
1614 | REAL-WORLD PATTERNS OF RIFAXIMIN PROPHYLAXIS AROUND TIPS: A MULTICENTRE COHORT STUDY OF HEPATIC ENCEPHALOPATHY PREVENTION



Yee Hui Yeo[1] Sheng-Yin Chen[2] Hanyou Loh[3] Peng-Sheng Ting[4] Dian-Jung Chiang[5] Chuanlong Zhu[6] Feng Zhang[7], [1]Cedars Sinai Medical Center, [2]Massachusetts General Hospital and Harvard Medical School, [3]Canton Medical Education Foundation, [4]Tulane University School of Medicine, [5]Cleveland Clinic Foundation, [6]The First Affiliated Hospital with Nanjing Medical University, [7]Affiliated Hospital of Medical School, Nanjing University

Background: Recent professional guideline recommended starting rifaximin prophylaxis from 14 days before elective transhepatic intrahepatic portosystemic shunt (TIPS) through at least 6 months after to prevent post-TIPS hepatic encephalopathy (HE). Due to rifaximin cost and access disparities, real-world uptake of guideline-adherent prophylaxis remains uncertain. We evaluated peri-TIPS HE-directed therapy use and the cumulative incidence of TIPS revision. **Methods:** We performed a retrospective cohort study using the TriNetX US Collaborative Network (66 healthcare organizations) on adults with cirrhosis undergoing TIPS between 1/1/2006 and 3/30/2026. Patients with prior TIPS or liver transplant were excluded. Outcomes included the prescription of lactulose, rifaximin, liver transplant, and TIPS revision. Follow-up extended to 12 months post-TIPS or outcome occurrence. Kaplan-Meier analyses were stratified by etiology. Pre-TIPS medication exposure, including prophylaxis window (-14 to 0 days) and baseline treatment window (-180 to -15 days), was assessed. **Results:** The cohort included 8,839 patients who underwent TIPS (mean age 57.5 ± 11.2 years; 62.5% male). ALD was the most common etiology (N = 2,829, 32%), followed by MASH/MASLD (N = 1,738, 19.7%). Patients with MASH demonstrated the highest proportions of hypertension (70.9%), diabetes (72.5%), and obesity (BMI ≥ 30: 47.5%). Within 14 days before TIPS, lactulose use was observed in 24.8% of patients, while rifaximin use was documented in only 14.3%. The prevalence of lactulose prescription increased to 42% on the first day post-TIPS, while it was 20.8% for rifaximin. Kaplan-Meier analyses demonstrated substantial

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

cumulative incidence of HE-directed treatment after TIPS across all etiologies, and about a fifth of patients across all etiologies went on to require TIPS revision within a year after the procedure. Notably, there were 29.4% and 17.7% using lactulose and rifaximin, respectively, during the -180 to -15 day baseline window, indicating a significant proportion of patients with underlying/treated HE received TIPS. **Conclusion:** In this large real-world cohort, peri-TIPS rifaximin prophylaxis was infrequently used despite evolving guideline recommendations. These findings highlight an implementation gap between evidence-based recommendations and clinical practice, potentially driven by medication cost, access, and subspecialty care disparities.

1616 | INTESTINAL COLONIZATION WITH MULTIDRUG-RESISTANT ORGANISMS IN PATIENTS WITH CIRRHOSIS: PREVALENCE, RISK FACTORS AND CLINICAL SIGNIFICANCE

Krystalia Dimitriou[1] Vasileios Sevastianos[2] Florentia Athanasaki[1] Nektarios Karamanolis[1] Larisa Vasilieva[3] Dimitra Krystallaki[1] Eleni Geladari[2] Helen Sambatakou[1] Georgia Vrioni[4] Alexandra Alexopoulou[1], [1]Hippokration General Hospital, Athens, Greece, [2]Evangelismos General Hospital, Athens, Greece, [3]Department of Gastroenterology, "Alexandra" Hospital, Athens, Greece, [4]Department of Microbiology, Medical School, NKUA, Greece

Background: Bacterial infections (BIs) caused by multidrug-resistant organisms (MDROs) have emerged as a major global healthcare concern. In patients with liver cirrhosis (LC), pathological bacterial translocation of gut-derived bacteria commonly occurs, leading to endogenous BIs such as spontaneous bacterial peritonitis and spontaneous bacteremia. Therefore, intestinal colonization (IC) by MDROs is of clinical importance. The aim of this study was to evaluate the characteristics of patients with LC colonized by MDROs and to investigate the potential role of these colonizing organisms in the development of subsequent endogenous BIs. **Methods:** Rectal swab samples were collected within one hour of presentation. Cultures were performed on chromogenic media, followed by identification of isolated microorganisms using mass spectrometry. Detection of carbapenem-resistant *Enterobacterales* (CRE) was carried out using immunochromatographic methods, while antimicrobial susceptibility testing and minimum inhibitory concentrations were determined. Patients were followed for 6 months after rectal sampling, and all culture-positive BIs were recorded. **Results:** A total of 71 consecutive patients [80.3% male, median age (IQR) 63 (54–77) years, Child-Pugh score 9 (7–10)] were enrolled. The etiology of LC was viral at 52.1%, alcohol-related at 14.1%, and other in 33.8%. IC by MDROs was identified in 40.8% of patients. Among colonized individuals, 72.4% demonstrated polymicrobial IC (≥ 2 bacterial species). Extensively drug-resistant (XDR) were the most frequently isolated (62.1%), followed by multidrug-resistant (MDR) (31%) and pandrug-resistant (PDR) organisms (6.9%). The most isolated bacteria were vancomycin-resistant Enterococcus faecium (VRE) (47%), carbapenem-resistant Enterobacterales (CRE) producing *Klebsiella pneumoniae* carbapenemase (KPC-CRE) (9.8%), and CRE co-producing KPC and New Delhi metallo-β-lactamase (KPC/NDM-CRE) (9.8%).In univariate analysis, recent antibiotic use, rifaximin exposure, history of hepatic encephalopathy, high Child-Pugh score, and recent hospitalization were associated with IC by MDROs. In multivariate analysis, only recent antibiotic exposure remained independently associated with IC by MDROs (OR 6.19, 95% CI 1.44–26.55, $p = 0.014$). During follow-up, a subsequent culture-positive BI was documented in 22 and endogenous BIs accounted for 15 patients. In 10 (45.5%), the isolated pathogen was identical to the colonizing strain. **Conclusion:** Patients with LC demonstrate high rates of IC by MDROs, with XDR representing the predominant resistance phenotype. Recent antibiotic exposure was identified as the only independent risk factor for MDRO colonization. In nearly half of culture-positive BIs, the isolated pathogen matched the IC strain, suggesting a possible association between IC and subsequent endogenous infection.

1617 | NEW SUBMISSIONHIGH VS NORMAL AMMONIA-TO-UREA RATIO AND CLINICAL OUTCOMES IN CIRRHOSIS: A MULTICENTER RETROSPECTIVE COHORT STUDY

Chimezirim Ezeano[1] Moises Garcia[2] Jaimy Villavicencio Kim[3] Siddesh Besur[3], [1]Advocate Health-Aurora Sinai Medical Center, [2]Aurora Health Care, [3]Advocate Health- St Luke's Medical Center

Background: Hyperammonemia contributes to cirrhosis-related complications, yet serum ammonia alone incompletely reflects hepatic nitrogen handling. An elevated ammonia-to-urea (A:U) ratio has been linked to portal hypertension and varices, but its association with clinical outcomes in cirrhosis is not well characterized.We evaluated the association between a high A:U ratio phenotype and major cirrhosis-related decompensation outcomes in a large, multicenter cohort. **Methods:** We conducted a retrospective cohort study using the TriNetX Global Collaborative Network, including adults ($\geq$18 years) with cirrhosis defined by ICD-10 codes K74.x or K70.3. The benchmark for a high A:U ratio was derived from Ouahbi et al., who identified an A:U ratio >1.53 mg/g as predictive of clinically significant portal hypertension, unit harmonization yielded a clinically equivalent cutoff of ammonia/BUN > 1.92. The high A:U cohort was defined by ammonia $\geq$50 µmol/L and BUN $\leq$15 mg/dL, while the normal A:U cohort was defined by ammonia $\leq$49 µmol/L and BUN $\geq$16 mg/dL.Propensity score matching (1:1) balanced baseline characteristics, yielding 12,488 patients per cohort. Outcomes were identified using ICD-10 and CPT codes and included hepatic encephalopathy (HE), portal hypertension, variceal bleeding, spontaneous bacterial peritonitis (SBP), hepatorenal syndrome (HRS), gastrointestinal bleeding, ascites, and transjugular intrahepatic portosystemic shunt (TIPS). Risk differences (RD), risk ratios(RR), odds ratios (OR), Kaplan–Meier analyses with log-rank testing, hazard ratios (HR), and number-of-instances t-tests were performed **Results:** Compared with the normal A:U cohort, the high A:U cohort had higher risk of HE (30.7% vs 16.4%; RD −0.143 [95% CI −0.154 to −0.132], RR 0.535 [0.508–0.563], OR 0.443 [0.415–0.474]; log-rank p<0.001; HR 0.503 [0.475–0.533]), variceal bleeding (13.2% vs 8.4%; RD −0.048 [−0.057 to −0.040], RR 0.635 [0.588–0.687], OR 0.602 [0.552–0.657]; log-rank p<0.001; HR 0.633 [0.583–0.687]), portal hypertension (34.7% vs 26.5%; log-rank p<0.001; HR 0.741 [0.701–0.783]), and TIPS placement (3.0% vs 1.4%; log-rank p<0.001; HR 0.494 [0.413–0.592]). Conversely, the high A:U cohort had lower risk of HRS (4.5% vs 10.9%; RD 0.064 [0.057–0.071], RR 2.410 [2.188–2.656], OR 2.584 [2.329–2.866]; log-rank p<0.001; HR 2.548 [2.305–2.816]) and SBP (5.6% vs 7.6%; RD 0.020 [0.014–0.026]; log-rank p<0.001; HR 1.411 [1.277–1.559]). Overall gastrointestinal bleeding rates were similar between groups (18.6% vs 18.9%; p=0.612). **Conclusion:** High ammonia-to-urea ratio was associated with increased risks of HE, portal hypertension, variceal bleeding, and TIPS placement, but lower rates of HRS and SBP. Impaired hepatic urea synthesis and nitrogen detoxification, rather than hyperammonemia alone, may drive specific decompensation pathways.. This readily available laboratory phenotype may refine prognostication in cirrhosis

1618 | PLATELET COUNT <135/MM^3 PREDICTS SBP RECURRENCE ON SECONDARY SBP PROPHYLAXIS IN A NATIONAL CIRRHOSIS COHORT

Scott Silvey[1] Nilang Patel[1] Jacqueline O'Leary[2] Heather Patton[3] Sofia Jakab[4] Timothy Morgan[5] Shari Rogal[6] Jasmohan Bajaj[7], [1]VCU, [2]UTSW, [3]VA San Diego Healthcare, [4]Yale University, [5]VA Long Beach Healthcare System, [6]University of Pittsburgh, [7]Virginia Commonwealth University

Background: The effectiveness of secondary SBP prophylaxis (SecSBPPr) for preventing SBP recurrence is being questioned. However, the predictors of success with SecSBBPr (i.e. prevention of recurrence) in the current situation are unclear. **Aim** : Determine clinical predictors associated with lower recurrence after SecSBPPr that can maximize effectiveness. **Methods:** We created a cohort of pts with first (index) SBP who had SecSBPPr initiated (continuous ciprofloxacin/Bactrim post-SBP with $\geq$1 additional outpatient refill up to 120 days post-initiation) using the VA Corporate data warehouse (CDW) between 2009-2019. Follow-up was 30 days post-discharge through 2 yrs post-initiation. Those who died, received a liver transplant (LT), or were lost to follow-up were excluded. SBP recurrence: defined as a new episode $\geq$30 days post-index case. Demographics, cirrhosis severity & Charlson comorbidity index (CCI) were collected &

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

compared between with/without recurrence. Death and LT were considered competing events. Time-to-event analyses of cause-specific hazards were performed for SBP recurrence. We separately analyzed death post-SBP recurrence as well. **Results:** Of the 2,539 patients with a first SBP episode started on SecSBPPr, 609 (24.0%) patients developed recurrent SBP, 1,564 (61.6%) died, and 88 (3.5%) received LT. 25% (390) of the deaths occurred after a recurrent SBP episode. Younger age, white race/Hispanic ethnicity, lower CCI, lower WBC and platelets counts, and lactulose usage were significantly associated with SBP recurrence while statin usage was associated with a reduced risk of recurrence (Table 1).Multivariable analysis revealed that only lower platelet counts (HR: 0.78 (0.71-0.87) per-100 units, $p < 0.001$) were independently associated with a higher risk of SBP recurrence. The median platelet count was 101 [66-170] and we found that above a platelet cutoff of 135, the risk of recurrence was 5.9% compared to 18.0% with ≥ 135 ($p = 0.001$) (Fig. 1). Of the entire cohort, 34% had platelet count < 135.In the subgroup of those who died post-recurrence, higher age (HR: 1.03 (1.01-1.04, $p < 0.0001$) and MELD-Na (HR: 1.06 (1.04-1.08, $p < 0.0001$) were associated with a higher risk of mortality. **Conclusion:** Secondary SBP prophylaxis after index SBP in a National VA cohort results in a recurrence rate of 24% over 2 years, which impacts mortality. The prevention of SBP recurrence is most effective with SecSBPPr in patients with platelet counts >135/mm3. Consideration of restriction for SecSBPPr to these individuals could potentially reduce antibiotic resistance and overuse and streamline potential effectiveness.

Table 1	NO RECURRENCE (n=1930)	SBP RECURRENCE (n=609)	p-value

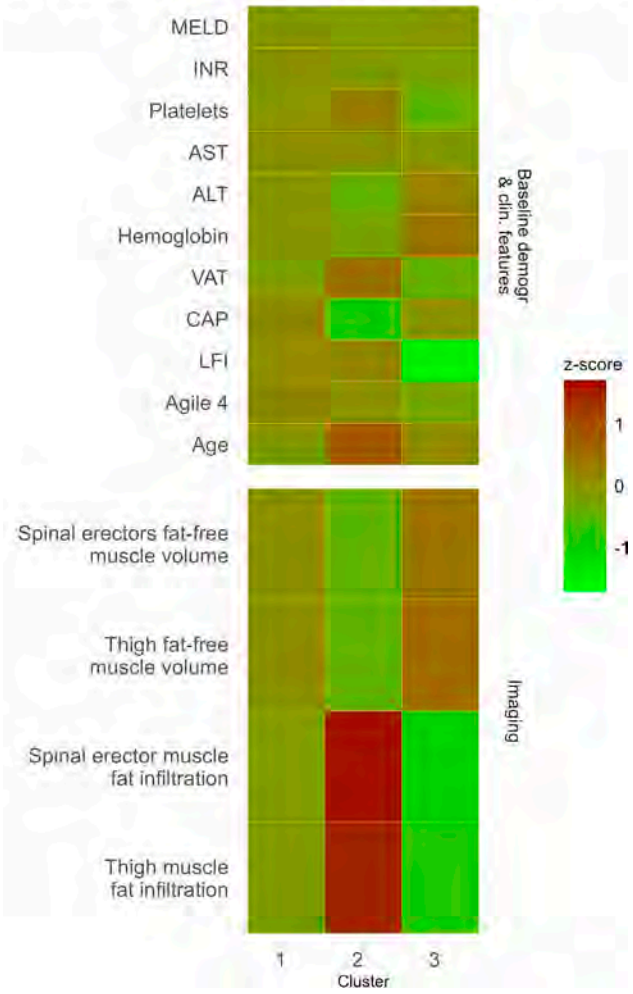
1619 | ADIPOSE AND MUSCLE COMPARTMENT BASED ENDOTYPES REVEAL SEXUAL DIMORPHISM AND DIFFERENTIAL EFFECTS ON FRAILTY INDICES IN CIRRHOSIS DUE TO METABOLIC DYSFUNCTION ASSOCIATED STEATOHEPATITIS (MASH)



Mohammad Siddiqui[1] Manal Abdelmalek[2] Mikael Forsgren[3] Danielle Kirkman[4] Samar Okaily[4] Ekaterina Smirnova[4] Arun Sanyal[4], [1]University of Virginia, [2]Mayo Clinic, [3]AMRA Medical AB, [4]Virginia Commonwealth University

Background: Frailty is linked to poor outcomes in cirrhosis and is associated with adiposity, sarcopenia and myosteatosis which however vary across individuals. It is not known if there are distinct metabo-phenotypes based on these features with differential impact on frailty independent of liver injury, function, fibrosis burden and portal hypertension. **Aims:** To define if there are distinct metabo-phenotypes associated with frailty in those with compensated cirrhosis due to MASH **Methods:** A prospective cohort study of compensated MASH cirrhosis was performed. Metabo-phenotypic parameters included visceral and subcutaneous adipose tissue (VAT, SAT respectively), fat-free muscle volume and muscle fat index and quantified by MRI. Frailty was assessed by the liver frailty index (LFI). Liver and spleen stiffness were measured by elastography (LSM, SSM respectively) as surrogates of fibrosis burden and portal hypertension respectively. K-medoid clustering based on metabo-phenotyping parameters and the distribution of frailty, clinical and laboratory indices evaluated across groups. Regression was used to model independently predictive of frailty. Significance was set at $p < 0.05$. **Results:** 81 persons with compensated cirrhosis, based on biopsy (n = 55) or Agile4 scores (n = 26) were studied. They were predominantly white (90%), female (71%) and over 50 years of age (median 63 yrs). The mean (SD) for the LFI was 3.91 (0.83). Metabo-phenotype clustering identified three clusters with 59, 13 and 9 individuals. Cluster 3 had lower thigh (5.75 ± 1) and spinal erector (8.2 ± 2) muscle fat infiltration compared to clusters 1 (8.2 ± 2 and 14.2 ± 4) and 2 (12.0 ± 3 and 22.9 ± 4) $p < 0.001$. Cluster 3 (vs clusters 1 and 2) also had higher fat-free thigh (mean 12.11 vs 9.78 vs 9.69, $p < 0.02$) and spinal erectors muscle volumes (mean 0.83

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

vs 0.62 vs 0.63, p < 0.02) and lower VAT (5.56 vs 5.72 vs 9.13 l, p < 0.001). Cluster 3 had lower LFI (2.6 ± 0.9) compared to clusters 1 (3.9 ± 0.7) and cluster 2 (4.0 ± 0.6) p < 0.001. Cluster 3 was comprised entirely of males whereas cluster 1 and 2 had 81% and 69% females. Cluster 3 also had higher hemoglobin (14.9 ± 1.6) vs clusters 1 (13.5 ± 1.6) and 2 (12.9 ± 2) p = 0.02). The clusters were otherwise not distinguishable by LSM, SSM or liver function. Regression models identified percent fat ratio and left anterior thigh fat free muscle volume as independent predictors of frailty (adj. R-squared = 0.31). **Conclusion:** Frailty measures vary in compensated MASH cirrhosis and are linked to gender and metabo-phenotypes rather than liver-related parameters.

Figure 1: Heatmap of baseline demographic, clinical, and imaging features (y-axis) for 3 clusters (x-axis). Measures are represented as z-scores with color intensity ranging from green for lower (z=-1.7) to red for high (z=1.7).

1620 | RIFAXIMIN VS. FLUOROQUINOLONE-BASED SECONDARY PROPHYLAXIS FOLLOWING SPONTANEOUS BACTERIAL PERITONITIS IN CIRRHOSIS WITHOUT PRIOR HEPATIC ENCEPHALOPATHY: A PROPENSITY SCORE–MATCHED COHORT ANALYSIS

Jashanveer Johal[1] Brandon Cunha[1] Mahmoud Al-Bataineh[1] Archana Salek[1] Bianca Patel[1] Abdallah Hussein[1] Yecheskel Schneider[1] Jason Hyman[2] simona rossi[1], [1]Virtua Health, [2]Einstein Medical Center, Philadelphia

Background: Norfloxacin and ciprofloxacin represent guideline-standard options for secondary SBP prophylaxis in cirrhosis, but rifaximin is increasingly prescribed off-label given its favorable resistance profile and non-systemic absorption. Prior analyses have been confounded by rifaximin's co-indication for hepatic encephalopathy (HE). We examined outcomes in HE-naive patients to reduce channeling bias and better isolate the prophylactic effect. **Methods:** We conducted a propensity score–matched retrospective cohort study using the TriNetX Global Collaborative Network (191.9 million patients). Cohort 1 comprised cirrhotic patients with ascites and a documented SBP episode who received rifaximin within one year of index SBP, without prior HE or concurrent fluoroquinolone use. Cohort 2 comprised matched patients receiving norfloxacin or ciprofloxacin without rifaximin, also HE-naive. Both cohorts excluded prior HCC, liver transplant, and ESRD. 1:1 PSM yielded 2,587 patients per arm over a 6–120 month follow-up. Outcomes included SBP recurrence, gram-negative sepsis, HRS, C. difficile infection, ESRD progression, transplant listing, and all-cause mortality. **Results:** SBP recurrence was lower in the rifaximin arm on cumulative risk analysis (32.6% vs. 37.5%; RR 0.87; p = 0.0002), though KM analysis was equivalent (HR 1.02; p = 0.81), reflecting competing mortality differences. Gram-negative sepsis was higher in the rifaximin arm on KM analysis (HR 1.44, 95% CI 1.24–1.68; p < 0.001). C. difficile infection was lower with rifaximin (4.3% vs. 5.6%; RR 0.77; p = 0.029). ESRD progression was higher with rifaximin (11.4% vs. 7.3%; HR 2.01; p < 0.001). All-cause mortality was significantly higher in the rifaximin arm (57.6% vs. 41.9%; HR 1.98; p < 0.001), with median survival of 128 vs. 1,391 days. **Conclusion:** In this HE-naive propensity-matched cohort, rifaximin was associated with lower cumulative SBP recurrence and reduced C. difficile incidence, but with higher rates of ESRD progression and all-cause mortality compared to

norfloxacin or ciprofloxacin. The mortality and ESRD differentials more plausibly reflect residual confounding by disease severity than direct drug toxicity. These findings reinforce the need for prospective, severity-stratified trials before rifaximin can be recommended as first-line secondary SBP prophylaxis over standard fluoroquinolone-based regimens.

1621 | UTILITY OF SPLEEN ELASTOGRAPHY IN ADULT PATIENTS WITH FONTAN PHYSIOLOGY: A PILOT STUDY

Edward Cytryn[1] Renata Mazurek[1] Thomas Schiano[2] Ali Zaidi[1] Lauren Grinspan[2], [1]Icahn School of Medicine at Mount Sinai, [2]Recanati/Miller Transplantation Institute at Mount Sinai

Background: Fontan-associated liver disease (FALD) has emerged as a significant long-term complication in the growing population of Fontan patients. It remains a challenge to non-invasively assess disease progression as well as monitor for the development of portal hypertension. Vibration controlled transient elastography (VCTE) is an established method for non-invasive evaluation of liver fibrosis and steatosis. In addition to liver stiffness measurement (LSM), VCTE has also been used to measure spleen stiffness (SSM), however, to our knowledge, no studies have evaluated the utility of measuring SSM with VCTE in Fontan patients. **Methods:** A prospective pilot study of adult patients with Fontan physiology was initiated to evaluate both LSM and SSM using VCTE. Baseline LSM and SSM were measured in 10 patients between March 2024 and November 2025. 6-month and 12-month follow-up measurements were obtained in 9 and 4 patients to date, respectively, with additional follow-up data collection ongoing. Baseline invasive (congenital cardiac catheterization) and non-invasive (MELD-XI) clinical markers were also collected. When applicable, a Pearson's correlation was used to compare SS with MELD-XI. **Results:** Of the 10 patients currently enrolled, 7 are male, median age at start was 35.5 years and median MELD-XI score is 10 (range: 4-17). The underlying congenital heart disease diagnoses represented are tricuspid atresia (n = 4), double outlet right ventricle (n = 3), hypoplastic left heart syndrome (n = 1), hypoplastic right heart syndrome with pulmonary atresia (n = 1), and double inlet left ventricle (n = 1). At baseline (n = 10), the mean hepatic vein pressure was 9 mmHg and mean hepatic wedge pressure was 11 mmHg (Table 1). Mean SSM was 40.7 kPA (SE 3.4) while average LSM was 19.9 kPA (SE 2.6). Mean SSM at 6 months remained higher than mean LSM (n = 9) at 47.3 kPA (SE 6.2) vs. 20.6 kPA (SE 2.9), respectively. Among the 4 patients who have completed 12-month follow-up, mean SSM was 61.3 kPA (SE 10.5) and mean LSM was 21.6 kPA (SE 3.3). No statistically significant correlation was found between baseline SSM and MELD-XI ($r = 0.3732$, $p = 0.29$). **Conclusion:** VCTE is an established modality for non-invasive measurement of liver fibrosis. The clinical utility of SSM measurement using VCTE in Fontan patients is not well established and may become elucidated through a larger cohort. In this pilot study, no clear correlation was noted between SSM and MELD-XI score or hepatic venous pressures. This is limited by small sample size and additional data collection is needed. Given the progressive nature of FALD into more advanced liver disease and cirrhosis, continued investigation into the utility of SSM compared to LSM in these patients is essential.

Table 1. Baseline patient characteristics

Fontan patient characteristics (n = 10)	
Sex	
Female	3
Male	7
Age (years)	35.5
Time from Fontan procedure (years)	32
CHD Diagnosis	
Tricuspid atresia	4
Double outlet right ventricle	3
Hypoplastic left heart syndrome	1
Hypoplastic right heart syndrome with pulmonary atresia	1
Double inlet left ventricle	1
Mean free hepatic vein pressure (mmHg)	9
Mean hepatic venous pressure gradient (mmHg)	2
Mean MELD-XI	10
SSM mean ± SE (kPa)	40.7 ± 3.4
LSM mean ± SE (kPa)	19.9 ± 2.9
SSM/LSM ratio mean ± SE (kPa)	2.5 ± 0.4

CHD = congenital heart disease; SSM = spleen stiffness measurement; LSM = liver stiffness measurement

1622 | ALBUMIN-BILIRUBIN SCORE VERSUS MELD 3.0 FOR PREDICTING 90-DAY MORTALITY AFTER TIPS

John Guieb[1] Giorgio Roccaro[1] Jay Jung[1] Michael Yu[1] Brandon Lei[1] Peter Park[1] Bryan Swilley[1], [1]Emory University School of Medicine

Background: Risk stratification before transjugular intrahepatic portosystemic shunt (TIPS) remains challenging as metabolic dysfunction-associated steatotic liver disease (MASLD) accounts for an increasing proportion of cirrhosis. Patients with MASLD often have chronic kidney disease (CKD) and metabolic comorbidities that may influence creatinine independent of hepatic function. Because MELD incorporates creatinine, it may overestimate procedural risk when elevations are driven primarily by renal factors, especially in elective TIPS candidates. The albumin-bilirubin (ALBI) score, a liver-specific metric derived from albumin and bilirubin, excludes creatinine. We evaluated whether ALBI predicts 90-day post-TIPS mortality and compared its performance with MELD 3.0. **Methods:** We conducted a retrospective cohort study of adults undergoing TIPS at a large academic medical center from 2022 to 2025. The primary outcome was 90-day post-TIPS mortality. The primary predictor was pre-TIPS ALBI score; pre-TIPS MELD 3.0 was the comparator. Groups were compared using Mann-Whitney U testing. Logistic regression estimated odds ratios (ORs), and discrimination was evaluated by area under receiver operating curve (AUC). Paired DeLong testing compared correlated AUCs. Prespecified subgroups included MASLD, ascites indication, MELD >18, elective TIPS, no malignancy, no pre-TIPS hepatic encephalopathy, and ALBI grade. **Results:** Among 260 patients, 28 (10.8%) died within 90 days of TIPS. Pre-TIPS ALBI differed between survivors and non-survivors ($p = 0.018$). Higher ALBI was associated with increased odds of 90-day mortality (OR 1.82 per 1-point increase; 95% CI 1.05-3.16; $p = 0.034$), with modest discrimination (AUC 0.637). MELD 3.0 was more strongly associated with mortality (OR 1.16 per 1-point increase; 95% CI 1.10-1.22; $p < 0.001$) and superior discrimination (AUC 0.814). By DeLong testing, MELD outperformed ALBI (AUC difference 0.177 favoring MELD; 95% CI for ALBI-MELD, -0.295 to -0.058; $p = 0.004$). In a combined model, ALBI was not independently associated with mortality (OR 0.84; 95% CI 0.43-1.64; $p = 0.608$), whereas MELD remained significant (OR 1.17; 95% CI 1.10-1.24; $p < 0.001$). Subgroup analyses did not identify a population in which ALBI outperformed MELD. **Conclusion:** Pre-TIPS ALBI was associated with 90-day mortality on univariable analysis but demonstrated modest discrimination and did not add prognostic value beyond MELD. MELD remained the dominant predictor across analyses and had higher discrimination. Although ALBI did not outperform MELD 3.0, the hypothesis remains relevant given rising CKD prevalence in MASLD, where creatinine-driven MELD elevations may misrepresent hepatic reserve. Larger studies incorporating granular renal function measures and well-defined elective versus emergent TIPS cohorts are needed to clarify whether ALBI offers incremental risk stratification in this setting.

Table 1: Paired DeLong Comparison of ALBI and MELD 3.0 for Prediction of 90-Day Mortality After TIPS

Cohort / Subgroup Analysis	N	90-Day Deaths	ALBI AUC	MELD AUC	AUC Difference, ALBI–MELD	95% CI for ALBI–MELD	DeLong p-value
Overall cohort	260	28	0.637	0.814	-0.177	-0.295 to -0.058	0.004
MASLD cirrhosis etiology	81	5	0.511	0.884	-0.374	-0.726 to -0.021	0.038
Ascites indication for TIPS	108	10	0.493	0.777	-0.283	-0.546 to -0.020	0.035
MELD >18	62	18	0.388	0.701	-0.313	-0.518 to -0.109	0.003
Outpatient/elective TIPS	39	3	0.769	0.852	-0.083	-0.364 to 0.197	0.561
No malignancy	221	22	0.632	0.819	-0.187	-0.317 to -0.057	0.005
No pre-TIPS hepatic encephalopathy	200	19	0.637	0.804	-0.167	-0.317 to -0.017	0.029
ALBI grade 3	72	10	0.640	0.677	-0.037	-0.200 to 0.126	0.655
ALBI grade 1-2	188	18	0.667	0.858	-0.191	-0.343 to -0.040	0.013

Abbreviations: ALBI, albumin-bilirubin; AUC, area under the receiver operating curve; MASLD, metabolic dysfunction-associated steatotic liver disease; MELD, Model for End-Stage Liver Disease; TIPS, transjugular intrahepatic portosystemic shunt.

Table note: AUC difference and 95% CI are reported as ALBI AUC − MELD AUC. Negative values indicate higher discrimination for MELD.

1623 | DO OUTCOMES AFTER TIPS DEPEND ON THE UNDERLYING CIRRHOSIS ETIOLOGY?

Ian Tobal[1] Ricardo David-Espinosa[1] Sameera Shuaibi[1] Patt Panuncillon[1] Daniyaal Kamran[1] Elizabeth Howard[1] Tyler Sandow[2] Juan Gimenez[2] George Therapondos[3], [1]Ochsner Clinic Foundation, [2]Ochsner Department of Interventional Radiology, [3]Ochsner Department of Hepatology and Transplant Hepatology

Background: Transjugular intrahepatic portosystemic shunt (TIPS) is performed in patients who suffer from complications related to portal hypertension, most commonly in cirrhotic patients with refractory ascites or refractory variceal bleeding due to alcohol, viral hepatitis, and metabolic dysfunction-associated steatotic liver disease (MASLD). Data related to TIPS

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

outcomes based on the etiology of cirrhosis are lacking. The underlying cause of cirrhosis is often treated in alcohol-related disease and viral hepatitis but not in MASLD. We hypothesized that post-TIPS survival and the number of further decompensating events may depend on cirrhosis etiology. **Methods:** In this retrospective analysis, we reviewed patients with cirrhosis due to MASLD, alcohol use, viral hepatitis, or other etiologies who underwent TIPS placement at any Ochsner Health facility between 2015-2020, with a follow-up period of 5 years. All patients over 18 years old were included unless they had a history of liver transplant or HCC prior to TIPS. Overall survival and episodes of further decompensating events post procedure were recorded. **Results:** 161 cirrhotic patients (mean age 57.3, 88% male) were included in this analysis. 66 patients had MASLD, 43 had alcohol-related disease, 39 had viral hepatitis, and 13 had cirrhosis from other causes. 83 patients had refractory ascites, 62 had refractory variceal bleeding, 10 had portal vein thrombosis, and 6 had refractory hepatic hydrothorax as their initial TIPS indication. For overall 5-year survival, viral hepatitis served as the reference group (HR = 1). The HR for MASLD was 1.51, 95% CI 0.62–3.68 (p = 0.364). The HR for alcohol-related disease was 1.16, 95% CI 0.48–2.84 (p = 0.743) and 1.96, 95% CI 0.59–6.52 (p = 0.270) for cirrhosis from other causes. The 5-year rate of further decompensating events, defined as episodes of GI bleeding, ascites requiring paracentesis, hepatorenal syndrome, hepatopulmonary syndrome, portal vein thrombosis, and hepatic hydrothorax was 95.5% (95% CI 84.9-100) in patients with MASLD, 63.4% (95% CI 44-83) in those with alcohol-related disease, and 90.6% (95% CI 75.9-100) in those with viral hepatitis. A rate could not be calculated for those who had cirrhosis from other causes. **Conclusion:** Patients with MASLD had a 51% higher adjusted hazard of death after 5-years, but this difference was not statistically significant. Patients with alcohol-related disease had a similar mortality risk to viral hepatitis. No statistically significant differences in survival were observed across etiologies, though the point estimates suggest a higher hazard in the MASLD group. MASLD and viral hepatitis had the highest cumulative rate of further decompensating events at 5 years, with alcohol-related disease having the lowest.

1624 | WHEN ASCITES RECURS: SGLT2 INHIBITORS VERSUS DPP-4 INHIBITORS AND LIVER-RELATED OUTCOMES IN DIABETIC CIRRHOSIS

Chimezirim Ezeano[1] Ifelunwa Osanakpo[2] Sarpong Boateng[3] Ihunanya Kanu[4] Emeka Stanley Obi[5] Guy Loic Nguefang Tchoukeu[6] Cherechi Nwabueze[7] Goodness Joseph[8] David Narvaez-De los Rios[9] Onyinyechukwu Ozumba[10] Samuel Ayedun[11] Madu Chimezie[0] Angel Umahi[0], [1]Advocate Aurora Healthcare, [2]Carle Foundation Hospital, [3]Yale New Haven Health, Bridgeport Hospital, [4]Baptist Memorial Hospital- Golden Triangle, [5]Brookdale University Hospital and Medical Center, [6]Texas Tech University Health Science Center, Permian Basin, [7]John H. Stroger Jr. Hospital of Cook County, [8]Nnamdi Azikiwe University Teaching Hospital, [9]Universidad Icesi, [10]Dept of Internal medicine Cape fear valley North Carolina, [11]Montefiore Medical Center, Bronx NY, [0] University of Lancashire School of medicine and dentistry

Background: Although SGLT2 inhibitors (SGLT2i) have been linked to improved outcomes in type 2 diabetes mellitus (T2DM) and cirrhosis, evidence in established decompensation remains limited. In recurrent ascites, their natriuretic effect is appealing, but renal vulnerability raises concern for acute kidney injury and hepatorenal syndrome. We compared SGLT2i versus DPP-4 inhibitors (DPP4i) in adults with T2DM and procedurally defined recurrent ascites. **Methods:** We performed a retrospective 1:1 propensity score-matched cohort study using the TriNetX Global Collaborative Network (16 healthcare organizations). Adults aged at least 18 years with type 2 diabetes, cirrhosis, ascites, and recurrent abdominal paracentesis were included. Patients with hepatocellular carcinoma, malignant ascites, portal vein thrombosis, peritoneal malignancy, or type 1 diabetes were excluded. After matching, 286 patients remained in each group. The primary outcome was a liver-related composite of hepatic encephalopathy, variceal bleeding, and liver transplant status. Secondary outcomes were acute kidney injury, hepatorenal syndrome, and all-cause mortality. **Results:** Before matching, 593 SGLT2i-treated and 578 DPP4i-treated patients met eligibility criteria; after matching, 286 patients remained per cohort. SGLT2i were associated with lower liver-related event-free

Symbols: ♦, Poster of Distinction; ★, Foundation Award Recipient

© 2026 American Association for the Study of Liver Diseases. Published by Wolters Kluwer Health, LLC. Unauthorized reproduction of this article prohibited.

hazard than DPP4i (18.20% vs 24.90%; RD −0.07, p = 0.11; RR 0.73; OR 0.67; HR 0.63, 95% CI 0.41–0.97; log-rank p = 0.04). Renal and survival outcomes were similar between groups: acute kidney injury occurred in 35.10% vs 37.00% (RD −0.02, p = 0.76; HR 0.88, log-rank p = 0.54), all-cause mortality in 40.00% vs 42.70% (RD −0.03, p = 0.52; HR 0.85, log-rank p = 0.20), and hepatorenal syndrome in 7.30% vs 9.00% (RD −0.02, p = 0.47; HR 0.75, log-rank p = 0.34). **Conclusion:** In this paracentesis-defined recurrent-ascites cohort, SGLT2i were associated with better liver-related event-free survival than DPP4i without higher observed acute kidney injury, hepatorenal syndrome, or mortality. These findings extend prior SGLT2i data into a higher-risk decompensated population and support prospective studies to define patient selection, renal safety, and hepatic benefit.
